creation of knowledge in, about, and for practice, which has significant impact on learners, individual teachers, professional learning communities, schools, and HEIs. While traditional school–HEI partnerships rest on the maintenance of unequal expert–client relationships, reciprocal, collaborative, and equal relationships assume that both parties engage in professional development and contribute to their partner's professional learning. It is important to differentiate between partnerships that are formed as a result of teachers', schools', and universities' needs and vision and are driven by these, and those which are created by governments primarily as a means of implementing and embedding external reform agendas. Examples of both have been provided in this article. The prerequisites for successful, sustainable partnerships are time, knowledge and expertise, mutually respectful relationships, shared goals, collaboration rooted in joint ownership and accountability, strategies to overcome potential challenges, and supportive leadership. **Table 1** presents the key features of three kinds of partnership: those which are externally designed, equal and internally designed, and the possibilities which each holds for change (Day, 2007).

The success of each type of partnership will depend upon factors related to geography (how dispersed the partners are relates to their ability to sustain necessary interaction); mode of learning (how involved teachers are in choice and decision making about inquiry will determine

Table 1 Features and consequences of different partnership models for change

	<i>Externally-designed partnerships</i>	<i>Equal partnerships</i>	<i>Internally designed partnerships</i>
Content	Externally defined	Externally/internally defined	Internally defined
Planning	System and central initiative led	External/internal agencies collaborate	Internal agencies lead
Process	External agency employs, commissions or provides tutors/mentor/coaches/consultants	External and internal agencies identify need and jointly determine and resource the support required	Internal agencies provide or buy in support
Evaluation	External quality assurance and control against externally defined standards	Agreed mix of external quality assurance and internal quality control	Internal quality assurance and control only
Contractual relationship	External agency holds participants accountable for meeting its agenda/targets, i.e., they are regarded as 'sub-contractors' to be audited	All agencies negotiate and agree outcomes (formative and summative), roles and responsibilities, and reciprocal accountabilities.	Self-defined outcomes
Possible consequences	Dependency model Little or no examination of ethical or pedagogical issues or contextual variables	Collegial/interdependency model. Collaborative development/joint ownership/collegial relationships. Sense of trust/ownership/respect. Examination of ethical/pedagogical purposes.	Independency model Sense of exclusive ownership. No necessary examination of pedagogical purposes
	Change likely to be short-term	Change may be likely	Change may or may not be sustained. The dependent variable is the quality of school leadership and culture

Adapted from Day, C. (2007). Collaborative approaches to (continuing to develop effective teachers). In Whitehead, J. (ed.) *Collaborative Approaches to Preparing and Developing Effective Teachers*, pp 22–28. London: Universities Council for the Education of Teachers, Occasional Paper No.16.

their sense of ownership and thus the successful transfer and/or implementation of new attitudes, knowledge, or skills); the nature of communicative decision making (whether they are shared or independent); the leadership and, professional development support (nature, quality, frequency, and relevance); the ability of the system to adapt to new environments (structures, cultures, and knowledge systems); and the dispositions of those who work within HEIs and schools to work together.

There are five tensions within each of the forms of partnership provided in this article and included in the table above, which must be managed, if not resolved, if success is to be achieved and sustained:

1. leadership;
2. accountability;
3. cooperation to collaboration between schools and higher education;
4. sustainability; and
5. change and improvement.

Leadership

Robust partnerships are those that are based on reflection, inquiry, and open discussion (internal scrutiny and critique) of values, principles, and practice and the personal, social, and policy contexts in which these exist. They demand the continuing, sustained engagement and support of all parties. Paradoxically, contribution to knowledge production in internally designed partnerships which result in a sense of ownership and responsibility by all relies on a strong element of joint leadership and control, relational trust and respect, and is especially dependent upon the quality of school leadership. Thus, attempts to replicate traditional hierarchies and power relations built on expertise and status rather than stature and influence are likely to produce adverse effects. If partnerships are to be successful, leadership trust is essential. It is important because members of the partnership will need to be willing to take risks, rely upon each other to gain in individual and collective self-efficacy (a sense of increased competence), exercise honesty and openness, and be emotionally confident in their relationships. The ingredients of partnership learning systems suggest sustained attention by leaders in the building of collective intra and interorganizational trust. Trust is the glue that holds partnerships together.

Accountability

Externally designed partnerships which are created in order to implement externally imposed reform agendas hold participants accountable and audit their progress. The sense of ownership is lacking in this client-expert

relationship, and change of participants' practice, attitudes, values, and beliefs is likely to be short-lived. Equal, collegial partnerships, which are jointly developed and owned by all partners, are more likely to sustain change. Successful partnerships are underpinned by a contractual relationship of ongoing negotiation and agreement of outcomes that address a common agenda, which takes into account the needs of teachers, schools, and universities. In this way, all partners have clearly defined complementary roles and responsibilities, joint ownership of the project and partnership, and an equal investment in ensuring that the aims and objectives are met. They hold themselves jointly responsible and jointly accountable.

Cooperation and Collaboration Between Schools and Higher Education

There is an inherent tension in striving to establish equal partnerships between teachers and university academics. The traditional theory-practice divide between academics and teachers, for example, still exists in many countries and is a major constraint in achieving success. Teachers in schools and universities also inhabit different professional cultures of power and autonomy. There is, for example, no culture of collaboration between staff in universities. The traditions are that individual achievement is rewarded (through research and publications). Collaboration is, then, not easy. The intensification of teachers' work also means they might have little time for working intensively with a mentor or colleague. Sachs (2003) distinguishes between collaboration and cooperation in school-HEI partnerships. Collaboration is based on trust and joint decision making. Cooperation does not have equal partners, and traditionally experts hold the knowledge. Where teachers actively participate as co-researchers, jointly choose the research, its design, and means of development, and are supported in concomitant change processes by tutors from higher education, the inquiry undertaken is more likely, it seems, to support long-term change. Sutherland *et al.* (2005) highlight the need for teacher educators to continue to maintain links in order to enhance their credibility with practicing teachers and preservice teachers, a commitment which will require support from teacher education departments.

Sustainability

Fullan (2001: 7) argues that deep and lasting change in education, of the type that is required for students to cope with the complex demands of a global and knowledge society, is not achieved through implementation of the latest policy, but rather through fundamental change in "the culture of the classrooms, the schools, the districts."

Success of schools–HEI partnerships depends not only on partners' initial commitment to the partnership and common goals and interests but also upon their willingness and capacity to sustain that commitment and the extent to which they receive the moral and practical support of leadership. Lack of time is generally acknowledged as being the greatest challenge for all partners, especially in reform contexts where teachers face increased workloads, diversification of roles, and changing workplace conditions. The termination of external funding to support collaboration can result in projects being discontinued. Turnover of committed personnel may also relegate initiatives to the charge of individuals without the necessary institution-wide support and thus adversely impact on outcomes.

Alongside leadership, ownership of goals, ongoing negotiation of inquiry focus and of roles and responsibilities, and sense of achievement are key elements in the amelioration of such challenges and the sustainability of partnerships.

Change and Improvement

The partnerships identified in this article may be said to provide illustrations designed primarily to combine internal and external pressures for change. However, while it is clear that they embody change at a system level in relation to the promotion of new forms of learning relationships and new ways of producing learning for change and improvement, little research has been conducted into the relationships between systemic (organizationally controlled) and individual (personally empowered) change. Yet the nature of this relationship is one of the key challenges to the growth of partnerships between schools, local authorities (school districts), and universities.

Partnerships represent an important, innovative strand of the change process, focusing as they do upon the promotion of interdependent as opposed to independent learning, and the freeing up of traditionally boundaried roles, responsibilities, and expertise. The danger that they may be used as a form of prescriptive policy implementation, on the evidence here, seems remote. Rather, they seem to create the space for learning which is perceived to be defined by and significant to the participants, locating responsibilities for decisions about change and improvement with those who are closest to teaching and learning in classrooms but ensuring, also, that they are able to consult with and learn from those outside schools who have similar felt responsibilities and moral purposes for the betterment of children and young people.

Conclusion

This article has drawn on HEI–school partnerships established in different policy contexts and educational cultures

that have been judged by research to be successful in order to identify and explore their key contexts, purposes, processes, characteristics, benefits. Even within accounts of these, however, challenges to relationships and sustainability have been identified. These reside in issues of power, culture, time, ownership, and leadership. Partnerships are not easy ways to engage in improving teachers and teaching; they are still a minority endeavor in all countries. However, it would appear that they do represent desirable productive routes for the further development of teacher professionalism, school improvement and enhanced student learning and achievement which go some way toward meeting the twin challenges of education in the twenty-first century of building social cohesion (rather than allowing by default isolation and fragmentation), and enhancing capacities for learning and change (in an increasingly economically unstable society). We conclude that the evidence, so far, is consistent in pointing to their important contribution to raising the quality of teaching and learning in the ever-shifting landscapes of policy and practice.

PREFACE

A preface usually provides a brief introduction to a work, intended to set the stage, provide some background insight, and whet the appetite of the reader. In our case, however, this preface has to address a fundamental question, one that was in our minds at the time we were recruited as Editors-in-Chief for the International Encyclopedia of Education. The question was “Why do we need an Encyclopedia? Its subtext was inspired by the ever-growing, ever-popular Internet. We believe that *this* Encyclopedia is desperately needed and will become a valued resource in education and associated social sciences and arts. The reasons are intellectual and procedural. Anyone with a modicum of knowledge knows that finding and trusting information gleaned from the Internet are two separate actions. The reliance on browsers to help discover references and comments result in resources based on popularity not quality. Pithy titles catch the eye and references rise in the ranks of browser searchers. Related to this is the “editing” in the Internet realm of populist efforts at encyclopedia, references, and other compilations. Once again, after removing offensive material, the accuracy, completeness, lack of bias, and other provenance for entries simply do not exist. Experienced researchers in education can sort through and make intelligent choices. Novices and many journeyman, or practitioners, parents, and policy makers cannot. Contrast how this Encyclopedia was built. Key domains of educational research were identified, and a tentative list of sub-domains or useful applied areas was posited. Then the Editors-in-Chief (apologies for the awkwardness of the term) identified the leading researcher in a particular domain, and with surprisingly little effort, recruited them to participate. They in turn identified the two best researchers in a sub-domain, such as formative assessment or the training of pre-school teachers. The authors of the sections of the Encyclopedia do not represent a collective group of friends and acquaintances, although friendships have been made. Rather they embody a deep and broad scholarly community. The difference from compiled Internet resources is the built-expertise and intellectual engagement of the authors. The summary of the developments and futures in their personal areas of scholarship have been filtered through their years of experience, both as scholars and communicators. Quality, then, is endemic to each piece, developed through this top-down identification of expertise, and made indelible by the bottom-up application of high standards from people leading the sub-domains – the authors, and the domains themselves, the section editors.

On a procedural level, the publishers early committed to the notion that this Encyclopedia would also be an online resource, and access would be available through print, for those with strong bookcases and the persisting love of turning real pages. The Internet version will allow multiple prisms through which the reader may access articles and provide, as it were, an emulation of the Internet in our field, albeit bounded by expertise and high quality.

What must be underscored in the assessment of this effort are the Editors-in-Chief and the publishers’ commitment to find excellence worldwide. We tried very hard to persuade notable scholars from all parts of the world to make contributions. Less than to fulfill the title of “International,” we were on the hunt for perspectives that would enrich the scope and depth of the sections. Our section editors put in enormous time attempting to find the best in the field, wherever they resided. Yet, not everyone is in the volume. Some were overcommitted. Many were not fully confident of their English, and the automated translation software has not yet met standards for technical writing. We believe that such writing and editing tools will make the outreach to an even broader International group of scholars possible in future revisions, or online updates. Furthermore, the birth of the World Educational Research Association (in 2009) will provide a better set of interlocking networks to find and evaluate scholarship from any place on the globe.

Finally, the scope of the effort must be acknowledged: 28 section editors, 926 articles were commissioned, drafted, reviewed, redrafted, edited, and put together in the space of four years. The publishers underwent some internal changes, and alterations in management. We as Editors-in-Chief, changed roles, moved, and also had to keep our own research and development enterprises afloat. Deadlines wobbled; authors dropped from view and had to be replaced.

Yet, at times frustrating as all development is, we find the final product exhilarating. We are enthusiastic not simply because it came into being at all, but because the collective light of the minds that wrote have left a bright resource for the future, one that will impact the way our colleagues understand and experience the educational knowledge, improvement, and impact in the future.

HOW TO USE THE ENCYCLOPEDIA

The International Encyclopedia of Education is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of education and common topics of research by academics in this domain. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students, and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

The contents of the encyclopedia are arranged alphabetically by section, and within sections, alphabetically by article. The Subject Index is located in Volume 8. Some topics are covered in a multitude of articles from differing perspectives, while other topics may have only one entry. We encourage use of the index for access to a subject area, rather than use of the Contents list alone, so that a reader has a full notion of the coverage of that topic.

The articles include cross-references to other related encyclopedia articles, suggested further readings where applicable, and many contain relevant websites for additional information. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The Further Reading sections include recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. These suggested further readings are not intended to provide a full reference listing of all material covered in the context of a given article, but are provided as next steps for a reader looking for additional information.

Scholar-Baller®: Student Athlete Socialization, Motivation and Academic Performance in American Society	<i>C K Harrison, S Bukstein, J Mottley, E Comeaux, J Boyd, C Parks, and D Heikkinen</i>	860
Service-Learning and Diversity as Mediums to Foster Civic and Community Engagement in Undergraduates	<i>L Oseguera</i>	866
Success and Failure in Education and Criminal Justice: Identifying Common Mechanisms	<i>S Ramirez and A Harris</i>	874
The History of Education: Race and Education	<i>J O Jewell</i>	881

VOLUME 2**E****Early Childhood Care and Education Theory**

- Early Childhood Care and Education: The Family, The Market, and The State *S B Kamerman and M J Neuman* 1
- Gender Issues in Early Childhood Education and Care *B Pocock* 11

Early Childhood Education and Care Governance

- Early Childhood Risk, Protection and Abuse Prevention *E Khoo* 17
- Evaluating Early Childhood Education and Care Programs *M Janus and S Brinkman* 25

Early Childhood Education and Care Investment

- Investing in Early Childhood Education and Care: The Health and Wellbeing Case *T Moore and F Oberklaid* 32
- Cost-effective Early Childhood Programs from Preschool to Third Grade *A J Reynolds, J A Temple, and B White* 38
- Early Childhood in Post-Modern Cultures: Thoughts and Some Concerns *P Gammage* 49
- Investing in Early Childhood Education and Care: Some Policy Implications *J Bennett* 55
- Investing in Early Childhood Education and Care: The Economic Case *G Cleveland and M Krashinsky* 63

Early Childhood Education and Care Programs

- Early Care and Education Programs for Infants and Toddlers *B Nyland* 69
- Literacies in Early Childhood: The Preschool Period *M Flear and B Raban* 75
- Participation in Early Childhood Education and Care Programs: Equity, Diversity and Educational Disadvantage *M Vandenbroeck* 81
- Teaching in Early Childhood Centers Instructional Methods and Child Outcomes *I Siraj-Blatchford* 86

Early Childhood Education and Care Provision

- Early Childhood Education and Care in the People's Republic of China *Zeng Xiaodong* 93
- Home-Based and Institutional Early-Childhood Education and Care Services *R Fukkink and H Blok* 98
- Integrated Early Childhood Education and Care Services – Care, Upbringing, Education and Health *S Colley* 104
- Issues of Access and Program Quality *J T Hustedt and W S Barnett* 110
- Kindergarten Transitions and Linkages to Primary School – Readiness Re-conceptualized *A Petriwskyj* 120
- Parent Support in Early Childhood – Approaches and Outcomes *K S Howard, K A Beckmann, and J Brooks-Gunn* 126

Early Childhood Education and Care Research

- Development and Implementation of Early Learning Standards in the United States *C Scott-Little* 132
- Global Status of Early Learning and Development Standards *P R Britto and S L Kagan* 138
- Rethinking Early Childhood Education and Care: Implications for Research and Evaluation *K Thorpe, D Cloney, and C Tayler* 144

Early Childhood Education and Care Theory

- Child Rearing and Early Education: Parents and Professionals: Theoretical and Historical Influences *H Penn* 151

Early Childhood Education and Care Workforce

- Early Childhood Education and Care Professional Profiles in the United Kingdom: Multiagency Teamwork and Transdisciplinary Challenges *A Anning and P Calder* 157
- Early Childhood Education and Care Staff Support: Mentoring and Professional Development in Finland *P Lindberg* 162

Economics of Education

- Education and Health *P Muennig* 169
- Data *M Perez and M Socias* 178
- Empirical Research Methods in the Economics of Education *P J McEwan* 187
- Theoretical Concepts in the Economics of Education *D J Brewer, G C Hentschke, and E R Eide* 193

Economics of Education – Costs and Financing of Schooling

- Cost–Benefit Analysis and Cost–Effectiveness Analysis *C Belfield and H M Levin* 199
- Economic Approaches to Adequacy *J Imazeki* 204
- Economic Approaches to School Efficiency *L L Taylor* 210
- School Finance Reform *T Downes* 216
- School Finance: An Overview *J K Rice, D H Monk, and J Zhang* 222
- The Economics of Tuition and Fees in Higher Education *R G Ehrenberg* 229

Economics of Education – External Benefits of Schooling

- Education and Civic Engagement *T S Dee* 235
- Education and Crime *L Lochner* 239
- Education and Economic Growth *E A Hanushek and L Wößmann* 245
- Parental Socioeconomic Status, Child Health, and Human Capital *J Currie and J Goodman* 253
- The External Benefits of Education *W W McMahon* 260

Economics of Education – Labor Markets, Education and Earnings

- Education and Inequality *J Blanden and S Machin* 272
- Human Capital *E R Eide and M H Showalter* 282
- Race Earnings Differentials *M Carnoy* 288
- Returns to Education in Developed Countries *M Gunderson and P Oreopoulos* 298
- Returns to Education in Developing Countries *H A Patrinos and G Psacharopoulos* 305
- School Quality and Earnings *J R Betts* 313
- Signaling in the Labor Market *M E Page* 321
- The Economics of High School Dropouts *R W Rumberger* 325

Economics of Education – Markets, Incentives and School Choice

- Competition and Student Performance *A A Payne* 331
- Educational Privatization *C Belfield and H M Levin* 337

Student Incentives	<i>E R Eide and M H Showalter</i>	342
The Economic Role of the State in Education	<i>D N Plank and T E Davis</i>	347
The Economics of Catholic Schools	<i>W Sander and D Cohen-Zada</i>	354
The Economics of Charter Schools	<i>R Zimmer and R Buddin</i>	360
The Economics of Parental Choice	<i>R Chakrabarti and J Roy</i>	367
The Economics of School Accountability	<i>D N Figlio and H F Ladd</i>	374
The Efficacy of Educational Vouchers	<i>R Zimmer and E P Bettinger</i>	380
Tiebout Sorting and Competition	<i>T J Nechyba</i>	388

Economics of Education – Production of Schooling

Desegregation, Academic Achievement and Earnings	<i>S Rivkin</i>	394
Education Production Functions: Concepts	<i>D N Harris</i>	402
Education Production Functions: Developed Country Evidence	<i>E A Hanushek</i>	407
Education Production Functions: Evidence from Developing Countries	<i>P Glewwe and S Lambert</i>	412
Family Environment in the Production of Schooling	<i>R Rothstein</i>	423
Neighborhoods and Peers in the Production of Schooling	<i>J Vigdor and J Ludwig</i>	431
Teacher Quality in Education Production	<i>I Pelayo and D J Brewer</i>	438
The Economics of Class Size	<i>D W Schanzenbach</i>	443
The Economics of Early Childhood Interventions	<i>M Nores</i>	450

Economics of Education – Teaching Labor Markets

An Overview of Teacher Labor Markets	<i>H Lankford and J Wyckoff</i>	456
Compensating Differentials in Teacher Labor Markets	<i>J Chambers</i>	465
Economic Approaches to Teacher Recruitment and Retention	<i>S Loeb and J Myung</i>	473
Teacher Incentives	<i>L Santibañez</i>	481
Teacher Supply	<i>P Dolton</i>	489
Teacher Training and Preparation in the United States	<i>M Podgursky, M G Springer, and R Hutton</i>	498
Teachers in Developing Countries	<i>F H Rogers and E Vegas</i>	504
The Economics of Teachers' Unions in the United States	<i>K Strunk</i>	512

Education of Children with Special Needs

Adapted Physical Activity for Students with Special Needs	<i>S R Hodge</i>	519
Assessment Accommodations for Children with Special Needs	<i>R J Kettler and S N Elliott</i>	530
Assistive Technology and Educational Practice	<i>H P Parette and G R Peterson-Karlan</i>	537
Augmentative–Alternative Communication	<i>C Mason and K M Chinn</i>	544
Community Integration and Employment of Youth with Special Needs	<i>B A Ford and A W Daviso III</i>	550
Cooperative Learning for Children with Special Needs	<i>E A Dooley and K R Kossar</i>	555
Co-Teaching	<i>E D Cramer</i>	560
Cultural and Linguistic Diversity and Children with Special Needs	<i>J M Patton, N Day-Vines, and A McSwain</i>	565
Curriculum-Based Assessment and Students with Special Needs	<i>D J O'Shea and J D Katsafanas</i>	571

Diagnosis and Classification	<i>M Sapp</i>	577
Direct Instruction and the Education of Children with Special Needs	<i>T Mehring</i>	584
Disabilities and Gifted Education	<i>V I Daniels and M J McCollin</i>	588
Early Childhood Special Education: Birth to Eight Years Old	<i>T S Lovelace, R Gardner III, J B Axe, and D M Sainato</i>	594
Early Intervention for Students with Special Needs	<i>P A Grant</i>	608
Early Transition of Children with Special Needs	<i>S A Fowler</i>	613
Educating Children Who are Deaf-Blind	<i>J Wood and K M Chinn</i>	621
Educating Children with Deafness and Hearing Impairments	<i>G M Mukuria and C J Eleweke</i>	628
Educating Children with Other Health Impairments (ADHD)	<i>G M Mukuria and F E Obiakor</i>	634
Educating Children with Physical Disabilities	<i>Z P Nkabinde, F E Obiakor, M T Ofor, and D J Smith</i>	640
Educating Children with Specific Learning Disabilities	<i>P A Grant and P B Grant</i>	646
Educating Children with Speech and Language Disorders	<i>S L Green and C D Qualls</i>	654
Educating Students with Autism and Related Disorders	<i>T T Dyches</i>	661
Educating Students with Cognitive Disabilities	<i>J P Bakken</i>	669
Educating Students with Emotional and Behavioral Disorders	<i>S W Smith and G G Taylor</i>	678
Educating Students with Special Needs: An Overview	<i>F E Obiakor, M K Harris, P Harris-Obiakor, and G M Mukuria</i>	688
Educating Students with Traumatic Brain Injury	<i>S Burkhardt and A Rotatori</i>	695
English Language Learners with Special Needs	<i>R Rueda and G Ragusa</i>	701
Functional Behavioral Assessment	<i>J P Bakken</i>	708
History of Special Education	<i>L M Garrick Duhaney and S J Salend</i>	714
Inclusion of Students with Special Needs in General Education Classrooms	<i>M A Prater</i>	721
Instructional Accommodations for Children with Special Needs in Inclusive Settings	<i>A L Yurick, S Musti-Rao, and G Cartledge</i>	727
Interagency Agreements	<i>L A Owens</i>	733
Interdisciplinary Collaboration in Early Childhood	<i>N File</i>	739
Language Development in Children with Special Needs	<i>M S L Stewart</i>	745
Large Scale Assessment and Accountability and Students with Special Needs	<i>M L Thurlow</i>	752
Literacy Instruction for Students with Special Needs	<i>L H Mason</i>	759
Math Instruction for Children with Special Needs	<i>B A Bottge</i>	767
Overrepresentation of Culturally and Linguistically Diverse Students in Special Education	<i>S C Trent</i>	774
Paraprofessionals in Special Education	<i>B Y Ashbaker, S C Dunn, and J Morgan</i>	780
Parent and Family Involvement in the Education of Children with Special Needs	<i>L P Prater</i>	788
Peer Relations and Socialization of Children and Adolescents with Special Needs	<i>L M Bullock, M Wong-Lo, and R A Gable</i>	794
Peer-Tutoring	<i>L J O'Shea and D J O'Shea</i>	802
Postsecondary Participation of Students with Special Needs	<i>R A Stodden and K D Roberts</i>	808
Prereferral Strategies	<i>C G Simpson and J P Bakken</i>	815

Preventing Antisocial Behavior and Delinquency: A Comprehensive School-wide Approach <i>P R Hallam, K R Young, P Caldarella, D G Wall, and L Christensen</i>	820
Programs and Instructional Strategies for Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	829
Related Services for Children with Special Needs <i>S O Obi</i>	834
Risk and Resilience Frameworks in Understanding Special Education <i>W-Y Hsieh and M L Donahue</i>	840
School Dropout Prevention <i>F E Obiakor</i>	845
School-Based Services for Children with Special Needs <i>S O Obi</i>	850
Self-Determination <i>M L Wehmeyer</i>	857
Social Competence <i>L A Owens and S Johnston-Rodriguez</i>	865
The Identification of Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	870
Transition from School to Adult Life <i>M J McCollin and F E Obiakor</i>	876
Visual Impairment <i>W Sapp</i>	880
Workforce Issues in Special Education <i>E Carlson and B Billingsley</i>	886

VOLUME 3

Education of Professionals

An Overview of Accreditation, Certification, and Licensure Processes <i>J J Norcini and M van Zanten</i>	1
Educating America's Military Officers <i>M H Adamshick</i>	7
Education for Architecture in the United States and Canada <i>S Schreiber</i>	13
Education for Medicine <i>M B Anderson</i>	19
Education for the Legal Profession <i>J W Wegner</i>	25
Education of Clergy <i>D O Aleshire</i>	31
Framing Professions Education <i>P S O'Sullivan</i>	37
Issues in Accounting/Business Education <i>W H Gijsselaers and R G Milter</i>	39
Professions – Engineering <i>J Heywood</i>	45
Professions – Health-Related <i>G M Jensen and C B Royeen</i>	51
Professions – Pharmacy <i>D E Beck</i>	58
Teaching for the Complex Practice of Nursing <i>P Benner and M Sutphen</i>	65
Veterinary Education <i>K M Edmondson</i>	71

Education Research Methodology: Quantitative Methods and Research

Abductive Research Methods <i>B D Haig</i>	77
Field Experimentation in Education <i>M A Constan</i>	83
Internal Validity <i>M H Clark and S C Middleton</i>	90
Methods for Approximating Random Assignment <i>B Schneider and S-K McDonald</i>	97
Methods for Approximating Random Assignment: Regression Discontinuity and Propensity Scores <i>L M Scheier</i>	104

Multitrait–Multimethod Designs	<i>M Bong and S Hong</i>	111
Multivariate Longitudinal Data Analysis	<i>H Liu and L Chang</i>	120
Quasi-Experimentation: Two Group Design	<i>E Hong</i>	128
Regression Discontinuity Designs	<i>A Kelava, S Rohrmann, and V Hodapp</i>	134
Sampling	<i>R S Brown</i>	142
Statistical Conclusion Validity	<i>P L Busk</i>	147
Survey Research Methods	<i>A Fink</i>	152

Educational Assessment

An Overview of Educational Assessment	<i>M James</i>	161
Assessment and the Evaluation of Institutional Effectiveness	<i>S M Thomas</i>	172
Assessment in Schools – Dispositions	<i>R D Crick</i>	181
Assessment in Schools Related To Literacy: Reading	<i>K J Topping</i>	189
Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality	<i>M Segers, F Dochy, and D Gijbels</i>	196

Educational Assessment – Assessment Activities

Alternative Assessment	<i>G Stobart and C Gipps</i>	202
Classroom Assessment Tasks and Tests	<i>J Phelan and J Phelan</i>	209
Dynamic Assessment	<i>J G Elliott, E L Grigorenko, and W C M Resing</i>	220
Instructional System Provided Feedback	<i>H F O'Neil, S Chuang, and T Huang</i>	226
Peer and Self-assessment	<i>C Harrison</i>	231
Portfolio Assessment	<i>V Klenowski</i>	236
Records of Achievement: Beyond Traditional Tests	<i>P Broadfoot</i>	243

Educational Assessment – Assessment in Domains

Assessment in Higher Education	<i>D R Sadler</i>	249
Assessment in Schools – Affective Domain	<i>M Ventura, R D Roberts, and M Zeidner</i>	256
Assessment in Schools – Creative Subjects	<i>T E Costantino and L Bresler</i>	262
Assessment in Schools – Learning to Learn	<i>A Hautamäki, J Hautamäki, and S Kupiainen</i>	268
Assessment in Schools – Literacy Writing (Extended)	<i>J M Parr and L Earl</i>	273
Assessment in Schools – Mathematics	<i>M Brown and J Hodgen</i>	279
Assessment in Schools – Oracy	<i>A L Bailey</i>	285
Assessment in Schools – Primary Science	<i>W Harlen</i>	293
Assessment in Schools – Secondary Science	<i>J Shemwell, A Fu, M Figueroa, R Davis, and R Shavelson</i>	300
Assessment in Schools – Technology Education and ICT	<i>A Jones, B Cowie, and J Moreland</i>	311
Assessment in the Early Years	<i>M J Drummond</i>	316
Assessment in the History, Civics and Social Studies Domains	<i>P G Avery</i>	323
Assessment in the Workplace of Performance, Developing Expertise and Competence	<i>A J Brown</i>	330
Assessment in Vocational Education	<i>K Ecclestone</i>	337

Educational Assessment – Concepts and Issues

Assessing Group Work	<i>M Galton</i>	342
Assessment and the Regulation of Learning	<i>L Allal</i>	348
Challenges of Developing and Implementing Formative Assessment Practices in Schools	<i>R Sutton</i>	353
Formative Assessment	<i>P Black</i>	359
Formative Assessment and Instructional Planning	<i>B Marshall</i>	365
Progression and Assessment: Developmental Assessment	<i>M Forster and G Masters</i>	369
Students' Rights in Assessment and Evaluation	<i>J Gardner and B Holmes</i>	378
Summative Assessment by Teachers	<i>R Daugherty</i>	384
The Multiple Purposes of Assessment	<i>P E Newton</i>	392
The Relationship between Assessment and the Organization and Practice of Teaching	<i>L B Resnick, D William, R Apodaca, and E S Rangel</i>	397

Educational Assessment – Enhancing Quality and Use

Assessment Conversations: Reading and Writing Conferences with Students and with Parents	<i>M Barrs</i>	403
Assessment: Pre-service and In-service Teacher Education	<i>A Davies</i>	410
Classroom Assessment in Policy Context (Australia)	<i>J J Cumming</i>	417
Classroom Assessment in Policy Context (England and France)	<i>M Osborn and M Raveaud</i>	425
Classroom Assessment in Policy Context (French Sources)	<i>D Laveault</i>	432
Classroom Assessment in Policy Context (Hong Kong)	<i>D Carless</i>	438
Classroom Assessment in Policy Context (New Zealand)	<i>T J Crooks</i>	443
Classroom Assessment in Policy Context (Sub-Saharan Africa)	<i>S J Howie, L Zimmerman, and K Draper</i>	449
Moderation of Student Work by Teachers	<i>G S Maxwell</i>	457
School Policies and Practices to Support Effective Classroom Assessment for Learning	<i>D Pedder</i>	464
Student Assessment: Policy and Practice in Eastern Europe	<i>G Bethell</i>	472

Educational Assessment – Key Relationships

Assessment Practice in Policy Context: Latin American Countries	<i>F M Rizo</i>	479
Impact of Assessment on Learner Groups (Boys/Girls)	<i>J Elwood</i>	486
Impact of Assessment on Learner Groups (Disabilities)	<i>M Rouse</i>	492
Impact of Assessment on Students' Test Anxiety	<i>P Buchwald and C Schwarzer</i>	498
Impact of Assessments on Classroom Practice	<i>J L Herman</i>	506
Social Practices in School Assessment and their Impact on Learner Identities	<i>A Pollard and A Filer</i>	512

Educational Evaluation – Concepts, Practice, and Future Directions

Educational Evaluation: Concepts, Practice, and Future Directions	<i>Y J Ni</i>	518
---	---------------	-----

Educational Evaluation – Contemporary Themes in Evaluation

Evaluating E-Learning	<i>D D Williams and C R Graham</i>	530
Evaluating Schools as Learning Communities	<i>S M Thomas</i>	539
Evaluation of Adult Education and Training Programs	<i>G McNamara, P Joyce, and J O'Hara</i>	548
Evaluation of Integrated Health Programs in School	<i>T M Franke</i>	555

Formative Assessment in Teacher Education and Teacher Professional Development	<i>H Tillema</i>	563
Informal Education and Evaluation	<i>T Jeffs</i>	572
Methods to Evaluate Technology	<i>W L Bewley</i>	578

Educational Evaluation – Contexts of Educational Evaluation

Cost Analysis in Evaluation Studies	<i>J D Fletcher</i>	585
Cultural Issues that Can Affect the Validity of Educational Evaluations	<i>R P Durán</i>	592
Evaluation and Accountability	<i>E Sato and S N Rabinowitz</i>	600
Evaluation Governance and Planning	<i>R Picciotto</i>	607
Evaluation Use	<i>V G Thomas</i>	614
Moral and Ethical Issues in Evaluation	<i>M Morris</i>	622
The Role of Stakeholders in Educational Evaluation	<i>S Taut and M C Alkin</i>	629

Educational Evaluation – Evaluation Domains

Curriculum Evaluation	<i>T Levin</i>	636
Evaluating Education in Three Policy Eras	<i>M A Peters, R Britez, and S M Weber</i>	645
Evaluation of Mathematics Education Programs	<i>J Cai</i>	653
Evaluation of Science Education Programs	<i>G Berberoğlu</i>	660
Evaluation of Social Studies and Civic Education Programs	<i>S G Grant</i>	667
Evaluation of Teacher Quality and Practice	<i>W Robinson and J Campbell</i>	674
International Evaluations	<i>A Schleicher</i>	681
National Assessment Programs: The Example of the U.S. National Assessment of Educational Progress	<i>M Schneider</i>	690
Principal Evaluation: Concepts, Needs and Realities	<i>N S Glasman and L D Glasman</i>	698
Program Evaluation	<i>C A Christie and L A Fierro</i>	706
School Based Evaluation: Purposes, Protocols and Processes	<i>J MacBeath</i>	713
School Inspection/External School Evaluation	<i>C Chapman and P Earley</i>	719
The International System for Teacher Observation and Feedback: A Theoretical Framework for Developing International Instruments	<i>L Kyriakides, B P M Creemers, C Teddlie, and D Muijs</i>	726

Educational Evaluation – Evaluation Methods

Evaluation Methodology	<i>M Chatterji</i>	735
Evaluation Reporting and Communicating	<i>R T Torres</i>	746
Longitudinal Evaluation Designs	<i>X Ma</i>	757
Meta-evaluation: Purpose, Prescription, and Practice	<i>L A Wingate</i>	765

Educational Evaluation – Purposes and Models of Educational Evaluation

Defining Quality in Evaluation	<i>P Dahler-Larsen</i>	775
Internal and External Evaluation	<i>D Nevo</i>	781
Needs Assessment in Education	<i>J W Altschuld and T L Lepicki</i>	786
The Purpose of Educational Evaluation	<i>S Mathison</i>	792
Understanding Approaches to Evaluation	<i>A J Love</i>	798

VOLUME 4**Educational Measurement**

Ability Testing	<i>P B Tymms</i>	1
Admissions Testing	<i>R Zwick</i>	7
Appropriateness Measurement: Person Fit	<i>R R Meijer and A M Weekers</i>	15
Automated Essay Scoring: Writing Assessment and Instruction	<i>M D Shermis, J Burstein, D Higgins, and K Zechner</i>	20
Classical Test Theory Reliability	<i>M D Miller</i>	27
Criterion-Referenced Measurement	<i>S A Shrock and W C Coscarelli</i>	31
Differential Item Functioning	<i>M D Hidalgo and J Gómez-Benito</i>	36
Educational Measurement: Overview	<i>R L Linn</i>	45
Equating and Scaling	<i>A A von Davier</i>	50
Fairness	<i>C Gipps and G Stobart</i>	56
Generalizability Theory	<i>R L Brennan</i>	61
Impact of Assessment on Classroom Practice	<i>J L Herman</i>	69
Intelligent Systems	<i>V J Shute and D Zapata-Rivera</i>	75
Item Response Theory	<i>W J van der Linden</i>	81
National Assessments	<i>T J Crooks</i>	89
Norm-Referenced Measurement	<i>H D Hoover</i>	95
Progress Monitoring	<i>L S Fuchs and D Fuchs</i>	102
Rasch Models	<i>D Andrich</i>	111
Scoring Rubrics	<i>J A Arter</i>	123
Second Language Assessment	<i>L F Bachman</i>	140
Self Adaptive Testing	<i>J Revuelta</i>	148
Student Test Results in School Accountability	<i>L S Hamilton</i>	153
Test Development	<i>S M Downing</i>	159
Test Translation and Adaptation	<i>A Allalouf and P Hanani</i>	166
Testing Creativity	<i>M A Runco</i>	170
Testing in History	<i>S Wineburg and B Fogo</i>	175
Validity	<i>R L Linn</i>	181
Validity of Achievement Gains on High-Stakes Tests	<i>D Koretz</i>	186
Validity of Educational Indicators	<i>B P M Creemers and L Kyriakides</i>	193

G**Globalization of Universities and Institutions**

Globalization, Universities and Medium of Instruction	<i>J Lo Bianco</i>	201
The Washington Accord on Engineering Curriculum	<i>E Ko</i>	209

H

Higher Education

Higher Education: An Overview	<i>P Scott</i>	217
-------------------------------	----------------	-----

Higher Education – Management, Leadership and Governance

Academic Managers – Heads of Departments/Schools	<i>S Marshall</i>	229
Leading and Managing the University – Presidents and their Senior Management Team	<i>R Middlehurst, T Kennie, and S Woodfield</i>	238
Management of and in Higher Education Institutions	<i>B Sporn</i>	245
Managerialism and Collegialism in Higher Education Institutions	<i>M Shattock</i>	251
Strategic Planning in Higher Education	<i>L Zechlin</i>	256
The Changing Role of University Presidents, Vice-Chancellors and Rectors	<i>M F Green and P D Eckel</i>	264
The Changing Roles of University Governing Boards and Councils	<i>J Fielden</i>	273

Higher Education – Research and Scholarship

Funding of University Research	<i>G Harman</i>	279
Mobility of PhD Students and Scientists	<i>S Avveduto</i>	286
National Science Policy and Universities	<i>M Henkel and U Kogan</i>	294
Research Commercialization	<i>S Slaughter</i>	300
Research Quality Assessment	<i>I McNay</i>	307
The Management of University Research	<i>J Kirkland</i>	316
The Training of New Scientists	<i>R Neumann</i>	322

Higher Education – Society

Academic Freedom	<i>S F Macintyre</i>	328
Access and Equity in Higher Education	<i>G Baldwin and R James</i>	334
Boundaries of Institutional Autonomy and their Impact on Higher Education	<i>V L Meek</i>	341
Diversity of Higher Education	<i>U Teichler</i>	347
Employability of University Graduates and Graduate Outcomes	<i>J Brennan</i>	354
Higher Education and the Knowledge Society	<i>J Välimaa</i>	360
Higher Education and the Labor Market	<i>J Enders</i>	365

L**Leadership and Management**

Leadership and Management Overview	<i>B Mulford</i>	695
------------------------------------	------------------	-----

Leadership and Management – as a Field of Study

Contexts for Leadership at the Beginning of the 21st Century	<i>M Bottery</i>	704
Educational Leadership: Philosophical Issues	<i>C W Evers</i>	710
Ethical/Moral Issues in Educational Leadership	<i>R J Starratt, L Langlois, and P Duignan</i>	717
History of Educational Leadership/Management	<i>R Bates</i>	724
Educational Leadership as a Field of Study: Professional Journals 1994–2006	<i>A R Thomas</i>	731
Research on Educational Leadership – Approaches/Promising Directions	<i>W A Firestone and V M J Robinson</i>	740

Leadership and Management – Leader Preparation

Leaders for Productive Schools	<i>J Murphy, S N Elliott, E B Goldring, and A C Porter</i>	746
New Approaches in Preparing School Leaders	<i>S G Huber</i>	752
Research for Leaders: The National College for School Leadership	<i>G Southworth</i>	762
School Leadership Standards	<i>L Ingvarson</i>	768

Leadership and Management – Leadership Issues

Effective Leadership in Challenging Schools	<i>A Harris</i>	777
Esthetics, Educational Leadership and Management	<i>R Bates</i>	783
Leader Mistreatment of Teachers	<i>J Blase and J Blase</i>	790
Leadership and Gender	<i>J Blackmore</i>	797
Leadership and Student Voice	<i>C Lanskey and J Rudduck</i>	803
Leadership and Urban Education	<i>K A Riley</i>	809
Leadership for Learning	<i>J MacBeath</i>	817
Leadership in Diverse Cultures	<i>A Walker and P K Yu-kwong</i>	824

Leading Diverse Schools	<i>J Ryan</i>	832
Supervision and Personnel Administration	<i>P D Tucker and D G Pounder</i>	839
The Big Challenge: Leadership for Inclusion	<i>M Ainscow and A Sandill</i>	846
The Educational Leader's New Work	<i>P Gronn</i>	852

VOLUME 5

Leadership and Management – Leadership Types

A Distributed Perspective on School Leadership and Management	<i>J P Spillane</i>	1
Leadership: Authentic	<i>P T Begley</i>	7
Leadership: Democratic	<i>J Møller</i>	12
Leadership: Instructional	<i>P Hallinger, K Leithwood, and R H Heck</i>	18
Leadership: Transformative	<i>C M Shields</i>	26
Strategic Leadership	<i>B Davies and B J Davies</i>	34
Teacher Leadership and Organizational Development	<i>A Harris</i>	40
Understanding How Leadership Influences Student Learning	<i>K Leithwood and B Levin</i>	45

Leadership and Management – Politics and Governance

Equity and Educational Effectiveness	<i>P Sammons</i>	51
Leading/Managing Schools in Communities Made Poor	<i>P Thomson</i>	58
Principals Role in Restructuring Schools	<i>G M Crow and K D Peterson</i>	66
School Reform and Restructuring: Self Managing School	<i>B J Caldwell</i>	72
System Leadership	<i>D Hopkins and R Higham</i>	78

Leadership and Management – School and Community

Educational Leadership and Social Capital	<i>J West-Burnham</i>	85
Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy	<i>D Jackson</i>	92
Networks and Communities of Knowledge	<i>T Schuller and H Theisens</i>	100
School Community Relations	<i>R L Crowson and E B Goldring</i>	106
Social Capital, Educational Institutions and Leadership	<i>S Kilpatrick, S Johns, and B Mulford</i>	113

Leadership and Management – School Effectiveness and Improvement

Leadership and Technology	<i>C F Webber</i>	120
Leadership in the Implementation of Innovations	<i>I E Bogotch, T Townsend, and M Acker-Hocevar</i>	128
Leadership: School Improvement	<i>R H Heck and P Hallinger</i>	135
Organizational Learning in Schools	<i>B Mulford and H Silins</i>	143
Professional Learning Community	<i>L Stoll</i>	151
Transformational School Leadership	<i>K Leithwood</i>	158

Learning and Cognition – Issues and Concepts

Attention in Cognition and Early Learning	<i>M Heimann, T Tjus, and K Strid</i>	165
Concept Learning	<i>S J Unsworth and D L Medin</i>	172
Cooperative Learning	<i>R E Slavin</i>	177
Intelligence	<i>R J Sternberg</i>	184
Learning from Multiple Information Sources	<i>H I Strømsø and I Bråten</i>	191
Memory	<i>S Magnussen and T Brennen</i>	197
Metacognition	<i>L Baker</i>	204
Personal Epistemology in Education: Concepts, Issues, and Implications	<i>I Bråten</i>	211
Piaget: Recent Work	<i>L Smith</i>	218
The Adult Development of Cognition and Learning	<i>E A L Stine-Morrow and J M Parisi</i>	225
Vygotsky and Recent Developments	<i>J V Wertsch</i>	231

Learning and Cognition – Issues and Concepts – Focus on Cognition

Cognition and Emotion	<i>F Pons, M de Rosnay, and F Cuisinier</i>	237
Cognition: Overview and Recent Trends	<i>J Wiley and B D Jee</i>	245
Development of Creativity	<i>M A Runco</i>	251
Knowledge Domains and Domain Learning	<i>L Maggioni and P A Alexander</i>	255
Problem Solving and Human Expertise	<i>T J Nokes, C D Schunn, and M T H Chi</i>	265
Problem Solving and Reasoning	<i>R E Mayer</i>	273
Reasoning, Moral and Social	<i>N S Jampol, C B Richardson, and M Killen</i>	279
Remembering as Social Activity	<i>D Middleton</i>	285

Learning and Cognition – Issues, Concepts, Types

Computer-Supported Collaborative Learning: Basic Concepts, Multiple Perspectives, and Emerging Trends	<i>S R Ludvigsen and A I Mørch</i>	290
Learning as Inquiry	<i>S R Goldman, J Radinsky, S Tozer, and D Wink</i>	297
Learning Through Narrative Socialization	<i>A Fasulo</i>	303
Neuroscience Bases of Learning	<i>M H Immordino-Yang and K W Fischer</i>	310
The Neuroscience of Reading	<i>U Goswami</i>	317

Learning and Cognition – Issues, Concepts, Types – Focus on Learning

Learning Strategies	<i>C E Weinstein, J Jung, and T W Acee</i>	323
Learning Through Play	<i>K Aronsson</i>	330
Situated View of Learning	<i>A Collins and J G Greeno</i>	335
The Neuroscience of Aging and Cognition	<i>W J Hoyer and B Bessette-Symons</i>	340

Learning and Cognition – Language, Literacy and Subject-Related

An Overview of Language and Literacy in Educational Settings	<i>V G Aukrust</i>	345
Bilingualism and Learning	<i>L S Verplaetse and E Schmitt</i>	355
Classroom Discourse and Student Learning	<i>L Hemphill</i>	361
Early Writing	<i>B E Hagtvet</i>	367

First Language Acquisition	<i>N B Ratner</i>	375
Foreign Language Learning	<i>C Kinginger</i>	382
Learning Science	<i>J Leach and P Scott</i>	387
Learning to Read	<i>M S Burns and J K Kidd</i>	394
Mathematics Learning	<i>L Verschaffel, B Greer, and E De Corte</i>	401
Music Learning	<i>S Hallam</i>	407
Reading Comprehension: Reading for Learning	<i>C E Snow</i>	413
Second Language Learning	<i>J S Arnfast, J N Jørgensen, and A Holmen</i>	419
Writing: Advanced	<i>R Andrews</i>	426

Learning and Cognition – Other Issues

Gender and Learning	<i>L Yates and J McLeod</i>	432
Parent–Child Relationships in Early Learning	<i>C P Edwards, S M Sheridan, and L L Knoche</i>	438
Peer Interaction and Learning	<i>S Blum-Kulka and S Dvir-Gvirsman</i>	444

Learning and Cognition – Places of Learning

Learning in a Cross-Cultural Perspective	<i>L-F Zhang and R J Sternberg</i>	450
Learning Outside of School	<i>T Nunes</i>	457
Reasoning and Explanatory Talk: Learning in Everyday Settings	<i>D E Beals</i>	464

Learning and Cognition – Theoretical Perspectives – Learning

Apprenticeship Approach to Learning	<i>K Nielsen</i>	469
Connectionism and Learning	<i>T R Shultz</i>	476
Constructivism and Learning	<i>S Sjøberg</i>	485
Cultural–Historical Activity Theory	<i>A Havnes</i>	491
Learning in a Sociocultural Perspective	<i>R Säljö</i>	498
Self-Regulated Learning and Socio-Cognitive Theory	<i>P H Winne and A F Hadwin</i>	503

N

National Systems of Education

Australia	<i>C N Power</i>	510
Austria	<i>M J Gaertner</i>	517

Suriname	<i>H R Ori</i>	826
Taiwan	<i>C-M Lee</i>	834
Tanzania	<i>R Wedgwood</i>	841
Thailand	<i>C Rukspollmuang</i>	847
The Gambia	<i>Y A-M Jobe</i>	858
The Philippines	<i>E A P Valenzuela</i>	865
Uruguay	<i>B Guinovart and C Troncoso</i>	873
USA	<i>B Pusser and M E R Lloyd</i>	888
Zanzibar	<i>I M Hija</i>	896

VOLUME 6**P****Philosophy of Education**

Philosophy of Education: Overview	<i>P Enslin</i>	1
-----------------------------------	-----------------	---

Philosophy of Education – Contemporary Issues

Neoliberalism, the Market and Performativity	<i>M A Peters</i>	11
Parents and Children's Rights	<i>M Clayton</i>	17
Peace Education	<i>I Gur-Ze'ev</i>	22
Philosophy and Educational Research	<i>D Bridges</i>	29
Race, Critical Race Theory and Whiteness	<i>B Applebaum</i>	36
School Choice and the Common School	<i>G Haydon</i>	44

Philosophy of Education – Philosophical Perspective

African Philosophy of Education	<i>K Horsthemke</i>	50
Feminism	<i>L Stone</i>	56
Hermeneutics	<i>C Bingham</i>	63
Islamic Education	<i>Y Waghid</i>	69
Liberalism and Education	<i>W Feinberg</i>	74
Phenomenology and Existentialism	<i>B Levering</i>	80
Pragmatism	<i>B Thayer-Bacon</i>	86
Psychoanalysis and Education	<i>P Smeyers</i>	92
Social and Cultural Capital in Education	<i>M Print</i>	97
The Aims of Education	<i>R Marples</i>	103
The Analytical Tradition	<i>D Carr</i>	108

Philosophy of Education – Philosophical Themes

Adult Learning: Philosophical Issues	<i>D Beckett</i>	114
Autonomy	<i>C A Wringe</i>	121
Bildung	<i>J Masschelein and N Ricken</i>	127
Critical Theory and Pedagogy	<i>M Mason</i>	133
Critical Thinking	<i>H Siegel</i>	141
Environmental Education	<i>M Bonnett</i>	146
Identity	<i>M S Merry</i>	152
Inclusion	<i>R Cigman</i>	158
Justice and Care	<i>M Tjiattas</i>	164
Lifelong Learning	<i>J Halliday</i>	170
Post-Structuralism and Education	<i>M Mason and M Clarke</i>	175
Reason and Rationality	<i>P Hogan</i>	183

Religious and Spiritual Education	<i>J C Conroy and S J McKinney</i>	189
The Capabilities Approach	<i>L Terzi</i>	194

Primary and Secondary Education – Learning and Teaching in School Age Education

Class Size – Arguments and Evidence	<i>P Blatchford and K C Lai</i>	200
Continuing Professional Development of Teachers	<i>P Earley</i>	207
Homeschooling	<i>P Farenga</i>	214
Innovations and Early Intervention in the Teaching of Literacy	<i>R E Slavin</i>	221
Personalized Learning in School Age Education	<i>D Hopkins</i>	227
Perspectives on Schooling in the Middle Years	<i>V J Russell</i>	233
Reform of the School Workforce	<i>H M Gunter and G Forrester</i>	242
Secondary Education in Developing Countries	<i>P Hughes and A Walker</i>	249

Primary and Secondary Education – Social Justice Issues in School Age Education

Community Focused Schools	<i>A Dyson</i>	255
---------------------------	----------------	-----

Primary and Secondary Education – The Effectiveness of School Systems

Reforming the American School System	<i>M Barber</i>	261
School Effectiveness in Developed Societies	<i>D Reynolds</i>	269
School to School Collaboration: Innovation and Improvement	<i>R Higham</i>	274
Studies of School Improvement in Developing Countries	<i>S E Anderson</i>	281
Sustainable Educational Reform	<i>A Hargreaves</i>	289
The Role of the District in Tri Level Reform	<i>M Fullan</i>	295
Whole School Designs for Enhancing Student Achievement	<i>S Stringfield and J Nunnery</i>	303

Q

Qualitative Research

Action Research in Education	<i>E Stringer</i>	311
Classroom Ethnography	<i>F Erickson</i>	320
Computer Assisted Qualitative Data Analysis	<i>C Silver and A Lewins</i>	326
Conversational Analysis	<i>H G Levine</i>	335
Critical Ethnography	<i>D Foley</i>	337
Critical Race Theory	<i>D Gillborn and G Ladson-Billings</i>	341
Critical Theory	<i>J J Ryoo and P McLaren</i>	348
Cultural Studies	<i>R Gaztambide-Fernández and K Cairns</i>	354
Cultural–Historical Activity Theory	<i>Laboratory for Comparative Human Cognition</i>	360
Design Experiments	<i>A Collins</i>	367
Discourse Analysis	<i>P Nikander and S Vehviläinen</i>	373
Document Analysis	<i>T Rapley and K N Jenkins</i>	380
Ethnography	<i>M Hammersley</i>	386

Ethnomethodology in Education Research	<i>D Macbeth</i>	392
Focus Groups	<i>D L Morgan and K Hoffman</i>	401
Grounded Theory	<i>K Charmaz and A Bryant</i>	406
Hermeneutics	<i>J Dyer</i>	413
Interpretive Research	<i>E Rauscher and M E Graue</i>	419
Interviews and Interviewing	<i>A Marvasti</i>	424
Life History	<i>J A Hatch and S K Newsom</i>	430
Narrative Inquiry	<i>D J Clandinin and J Huber</i>	436
Participant Observation	<i>J Schostak</i>	442
Phenomenology	<i>M van Manen and C A Adams</i>	449
Qualitative Case Studies	<i>S B Merriam</i>	456
Qualitative Data Management	<i>C Grbich</i>	463
Semiotics	<i>M Danesi</i>	475
Symbolic Interactionism, Naturalistic Inquiry, and Education	<i>J A Forte</i>	481
The Quality of Evidence in Qualitative Research	<i>S K Biklen</i>	488
Visual Data in Education Research	<i>J Wagner</i>	498

Qualitative Research – Standards of Proof

Validity: Mapping Diverse Perspectives	<i>G B Rossman, S F Rallis, and A M Kuntz</i>	505
--	---	-----

Quantitative and Qualitative Approaches to Research – Integration

Mixed Methods	<i>A Tashakkori and I Newman</i>	514
---------------	----------------------------------	-----

Quantitative Methods and Research Design

External Validity	<i>G E Matt, A Brewer, and M Sklar</i>	521
-------------------	--	-----

R

Role of NGOs in Globalization

NGOs and Globalization of Education	<i>M Ahmed</i>	529
-------------------------------------	----------------	-----

S

Social and Emotional Aspects of Learning

Achievement Goal Theory: Definitions, Correlates, and Unresolved Questions	<i>T Urdan</i>	537
Affect, Mood and Emotions	<i>S Schnall</i>	544
Anxiety	<i>M Zeidner</i>	549
Attribution Theory	<i>B Weiner</i>	558
Children's Friendship	<i>S R Asher and K L McDonald</i>	564
Coping with Stressful Situations: An Important Aspect of Self-Regulation	<i>M Boekaerts</i>	570
Culture in Motivation Research: A Challenging and Enriching Contribution	<i>K Kimmel and S Volet</i>	576
Early Social Development and Schooling	<i>G M van der Aalsvoort</i>	585

Emotion in Educational Contexts	<i>P A Schutz, P D Quijada, S de Vries, and M Lynde</i>	591
Empathy	<i>R Arnold</i>	597
Flow in Education	<i>J A Schmidt</i>	605
Interest	<i>M Ainley</i>	612
Intrinsic and Extrinsic Motivation	<i>C Levesque, K J Copeland, M D Pattie, and E L Deci</i>	618
Motivating Students in Classrooms	<i>J Brophy</i>	624
Motivation Regulation	<i>C A Wolters and S A Mueller</i>	631
Peer Learning in the Classroom	<i>N M Webb</i>	636
Poverty, Effects of on Social and Emotional Development	<i>N Philipsen Hetzner, A D Johnson, and J Brooks-Gunn</i>	643
Seeking Help as an Adaptive Response to Learning Difficulties: Person, Situation, and Developmental Influences	<i>S A Karabenick and R S Newman</i>	653
Self-Concept in Learning: Reciprocal effects model between academic self-concept and academic achievement	<i>H W Marsh and L F Scalas</i>	660
Self-Efficacy Beliefs	<i>D H Schunk and F Pajares</i>	668
Social and Emotional Outcomes of Learning	<i>J Vorhaus</i>	673
Social Aspects of Collaborative Learning	<i>M Arvaja and P Häkkinen</i>	685
Social Development and Schooling	<i>G W Ladd</i>	691
Social Interaction and Learning	<i>K Littleton</i>	698
Social Networks and the Education of Children and Youth	<i>B Schneider, T G Ford, and L Perez-Felkner</i>	705
Sociocultural Issues in Motivation	<i>R A Walker</i>	712
Socioemotional Aspects of Technology-Supported Learning	<i>S Järvelä</i>	718
Volitional Control of Learning	<i>J Husman and L Corno</i>	724
Wellbeing	<i>T Hascher</i>	732

VOLUME 7

Statistics

An Overview of Statistics in Education	<i>S Sinharay</i>	2
Analysis and Interpretation of Multivariate Data	<i>D J Bartholomew</i>	12
Analysis of Covariance	<i>N T Longford</i>	18
Analysis of Extreme Values in Education	<i>J Beirlant, G Dierckx, K Luwel, and P Onghena</i>	25
Analysis of Variance	<i>B M King</i>	32
Bayesian Statistical Analysis	<i>G Kokolakis</i>	37
Bootstrap Method	<i>K Singh and M Xie</i>	46
Canonical Correlation	<i>A Basu and A Mandal</i>	52
Categorical Data Analysis	<i>S E Fienberg and B W Junker</i>	58
Causal Inference	<i>D B Rubin</i>	66
Cluster Analysis: Overview	<i>S Landau and I Chis Ster</i>	72

Cognitive Psychology and Educational Statistics	<i>H S Kim and S Embretson</i>	84
Computational Statistics	<i>J E Gentle</i>	93
Continuous Probability Distributions	<i>S Sinharay</i>	98
Correspondence Analysis	<i>M Greenacre</i>	103
Data Mining	<i>R S J d Baker</i>	112
Decision Theory	<i>M Mendoza and E Gutiérrez-Peña</i>	119
Design of Experiments	<i>C A Albers and T R Kratochwill</i>	125
Discrete Probability Distributions	<i>S Sinharay</i>	132
Discrimination and Classification	<i>R C Neath and M S Johnson</i>	135
Empirical Bayes Methods	<i>E Ip and G Molenberghs</i>	142
Evaluation Research	<i>T Kellaghan</i>	150
Exploratory Data Analysis	<i>A Unwin</i>	156
Factor Analysis: An Overview and Some Contemporary Advances	<i>F A N Alhija</i>	162
Generalized Linear Mixed Models	<i>S Rabe-Hesketh and A Skrondal</i>	171
Generalized Linear Models	<i>J J Faraway</i>	178
Generating Random Numbers	<i>P J Pashley and A Amodeo</i>	184
Goodness-of-Fit Testing	<i>A Maydeu-Olivares and C García-Forero</i>	190
Graphical Models	<i>R G Almond</i>	197
Growth Modeling	<i>I Plewis</i>	203
Hierarchical Linear Models	<i>D Rindskopf</i>	210
Hypothesis Testing and Confidence Intervals	<i>T R Konold and X Fan</i>	216
Instrumental Variables	<i>E P Bettinger</i>	223
Jackknife Methods	<i>S Sinharay</i>	229
Large-sample Statistical Methods	<i>J M Singer and D F Andrade</i>	232
Latent Class Models	<i>J K Vermunt</i>	238
Markov Chain Monte Carlo	<i>A M Johansen</i>	245
Matrix Algebra	<i>H Yanai and H Ishii</i>	253
Measure of Association	<i>G-H Huang</i>	260
Measures of Central Tendency	<i>D Clark-Carter</i>	264
Measures of Dispersion, Skewness and Kurtosis	<i>D Rindskopf and M Shiyko</i>	267
Meta Analysis	<i>J Sánchez-Meca and F Marín-Martínez</i>	274
Missing Data	<i>C A W Glas</i>	283
Model Selection	<i>S J Haberman</i>	289
Monte Carlo Methods	<i>A M Johansen</i>	296
Multidimensional Scaling	<i>Z Zhang and Y Takane</i>	304
Multiple Comparisons	<i>C Lewis</i>	312
Multivariate Analysis of Variance	<i>N T Longford</i>	319
Multivariate Linear Regression	<i>S Ganesh</i>	324
Multivariate Normal Distribution	<i>J Tacq</i>	332

Nonlinear Regression Analysis	<i>H-H Huang, C K Hsiao, and S-Y Huang</i>	339
Nonparametric Statistical Methods	<i>K Sijtsma and W H M Emons</i>	347
Observational Studies	<i>P R Rosenbaum</i>	354
Order Statistics	<i>I Bairamov</i>	360
Point Estimation Methods with Applications to Item Response Theory Models	<i>F Bartolucci and L Scrucca</i>	366
Principal Components Analysis	<i>D J Bartholomew</i>	374
Probability Theory	<i>T Rudas</i>	378
Recursive Partitioning	<i>S Landau and S Barthel</i>	383
Sampling	<i>J Qian</i>	390
Sequential Probability Ratio Test	<i>T J H M Eggen</i>	396
Sequential Testing	<i>H J Vos</i>	401
Signal Detection Theory	<i>H Abdi</i>	407
Small Area Estimation	<i>A Noble</i>	411
Statistical Analysis of Functional Data	<i>F Ferraty, P Sarda, and P Vieu</i>	417
Statistical Inequalities	<i>H M Mahmoud and J L Gastwirth</i>	426
Statistical Paradoxes	<i>Y-K Tu</i>	429
Statistical Power Analysis	<i>L V Hedges and C Rhoads</i>	436
Statistical Significance Versus Effect Size	<i>X Fan and T R Konold</i>	444
Stochastic Processes	<i>F Baudoin</i>	451
Structural Equation Models	<i>S-Y Lee and X-Y Song</i>	453
Survival Data Analysis	<i>A F De Champlain</i>	459
The Normal Distribution and its Applications	<i>J Tacq</i>	467
Time Series Analysis	<i>P J Brockwell</i>	474
Univariate Linear Regression	<i>M L Hazelton</i>	482
Value-Added Models	<i>D F McCaffrey</i>	489

T

Teacher Education – Evaluation in the Teacher Education Program

Accreditation and Standards in Teacher Education	<i>R J Yinger and K L Daniel</i>	495
Determining Long Term Effects of Teacher Education	<i>C N Brouwer</i>	503

Teacher Education – Evaluation of the Prospective Teacher

The Evaluation of Prospective Teachers in Teacher Education	<i>D E H Tigelaar and J van Tartwijk</i>	511

Glossary

Agent – A software program that assists the user in performing some task, taking into account the nature of the user and the situation.

Asynchronous communication technology – Any technology designed to support an exchange of messages with posting and reading occurring at different times; examples include email and blogs.

Avatar – A graphic representation of oneself that a user either creates or chooses to represent his/her identity online; for example in a chat room or multiplayer game.

Clickers – Devices used to register a response as part of a classroom response system.

Immersive environment – A computer-created scene or world that gives the user the sensation of being within the scene rather than being outside of it.

Information and communication technology – A general term encompassing computer hardware and software as well as their application.

Instructional management software – System that manages the gathering, processing, and display of student data from computer-based instruction.

Online learning – Learning that occurs over the Internet.

Open source – A computer program for which the source code is made available for free use and modification by others.

Podcast – Digital media file (either audio or video) distributed over the Internet for download and playback on a mobile device or personal computer.

Recommendation system – Software that uses information about a user, in conjunction with data on the opinions and choices of all users of the system, to identify and present items or products that are likely to interest the user.

Response system – Hardware and software that enable members of a class or audience to respond simultaneously to a question from an instructor or presenter, who receives a tabulation or other representation of the aggregated responses.

Social networking site – A Web site that supports building online communities by having users post a public or semi-public representation of themselves and indicate other users with whom they wish to share information; examples include Facebook, Twitter and MySpace.

Synchronous communication system – Systems in which all users are logged on at the same time; examples include videoconferencing, Internet telephony and instant messaging.

Virtual manipulative – A software representation of a thing or system that the user can interact with.

Advances in information and communication technology (ICT) have enabled its use to support teaching, learning, and assessment both within and outside of schools. The current state of access to ICT within schools and ways in which ICT is used are described below. At the same time, it is noted that the increased use of ICT in schools has not produced the dramatic changes in pedagogy and learning content that some technology proponents had predicted. Formal educational systems impose curriculum standards, high-stakes tests, and criteria for promotion or selection into educational programs at higher grade levels that reinforce continuity in educational approaches. Research on the implementation of ICT in schools and classrooms has found that elements outside the technology – including principal support, teacher training, the design of the learning activity in which ICT is used, and assessment practices – influence the extent to which ICT is used and

its effectiveness as a tool for learning. Thus, those who would like to see ICT transform the nature of education are still waiting for the long-promised radical shift. Reformers can point to current technology trends as potential sources of major change, however. These technology trends include the increasing availability of open-source course content on the Internet; the dramatic rise of collaborative, user-generated content (termed Web 2.0); and the high level of engagement triggered by immersive, multi-user games with complex structures and highly realistic, dynamic graphics.

Spread of Technology Within Schools

Few areas of education have experienced as much change over the last 15 years as the use of ICT to support learning. In 1994, when the prior edition of this encyclopedia was published, the World Wide Web was in its infancy. At that time, only 35% of public schools in the United States had Internet access anywhere in the building and just 3% of instructional classrooms had a computer connected to the Internet. By 2005, in contrast, 94% of instructional rooms had computers with Internet access (Wells and Lewis, 2006). The United States was not alone in making a major investment in technology in schools during this time frame. By 2006, schools in the 22 countries participating in the SITES 2006 international survey had, on average, one computer with Internet access for every seven students (Law *et al.*, 2008).

During the same time period, the cost of computing power dropped dramatically, and smaller, lighter computing devices became available in the form of personal digital assistants, MP3 players, mobile phones, and tablet PCs. Today's iPhone is vastly more powerful than a top-of-the-line 1994 desktop computer.

Further, advances in projection technology have made it feasible to provide bright, lightweight projectors to every classroom. Indeed, many classrooms go beyond projectors to provide an electronic whiteboard on which the teacher can write or draw, interact with computer applications, and access resources on the Internet.

The declining cost of computers and the increase in digital resources for learning have led a number of schools, districts, and countries to launch one-to-one computing initiatives to provide every student with a computer. For example, in 2005 Australia launched a AU\$1.2-billion plan to provide every secondary student in years 9–12 with a computer. At the same time, it must be acknowledged that the playing field with respect to access to ICT that can support learning is still not level. A survey of principals in 56 countries participating in the 2006 PISA assessment of 15-year-olds, for example, found that schools in the 14 countries with the strongest technology infrastructures had an Internet computer for roughly every three or four

students, while the 14 countries with the least technology had an Internet computer for every 25 or more students, and three countries reported no instructional computers with Internet access in their schools.

There is no doubt that technology will continue to become more available to teachers and students. The more difficult challenge has proven to be the design, development, and dissemination of educationally meaningful learning activities supported by technology.

School Uses of Technology for Learning

Technology use within schools has been promoted since the mid-1980s. Early predictions of how personal computers and learning software would transform education, however, have given way to an appreciation of the complexity of technology integration and of educational change. Some critics have argued variously that ICT has had no significant impact on schools (Cuban *et al.*, 2001) or that it has had negative impacts (Healey, 1999). Even so, technology continues to be a part of school instruction, albeit a less common instructional practice than more traditional pedagogies such as teacher lecture or question-and-response cycles.

In a 2005 survey of US teachers, 45% reported requiring their students to use technology once a week or more (Bakia *et al.*, 2008). The most often teacher-reported weekly uses of technology were to practice or review mathematics or reading topics, enrichment activities in mathematics and reading, and taking tests or quizzes online. Student use of technology for their school work does not necessarily occur within school, however. Across the 40 countries with students' participating in the PISA 2006 survey, only 9% of 15-year-olds reported using a computer at school almost every day. Even among countries with the largest number of Internet computers in classrooms, none had as many as a third of its students reporting use of a computer at school on a daily basis. In contrast, 75% or more of students in more than a third of the participating countries reported home use of computers on a daily basis.

Typical Uses

Observers of ICT in schools often contrast uses that seek to make the current system more efficient (e.g., by providing for more practice or feedback in the same amount of time) with those that seek to fundamentally change or transform the nature of teaching and learning (Means *et al.*, 2004). Among the types of applications that most educators would consider enhancements of efficiency are uses of new technologies for transmitting information (such as lectures offered online); skills practice software for reading, mathematics, and second language

learning; and instructional management systems that keep track of the mastery status of every student on a set of skills or content standards. These technology uses can be incorporated into classrooms as they are currently constituted without fundamentally changing the nature of what is taught or interactions between students and teachers. Likewise, many large-scale installations of electronic whiteboards have succeeded only in reproducing existing teaching practice using a new medium. In contrast, technologies that structure and scaffold independent inquiry and design activities on the part of individual students or groups of students and those that are designed to support collaborative knowledge-building activities require changes in the content of learning and in the roles of teachers and students.

While case study research tends to highlight more innovative, transformative uses of technology (some of which will be described below), large-scale surveys provide a more representative picture of what teachers are asking students to do with ICT. In teacher surveys conducted during the first wave of microcomputer use in schools in the mid-1980s, the most commonly reported student uses of technology were as part of computer literacy and programming classes and for drill-and-practice in basic skills (Becker, 1985). Twenty years later, a 2005 national teacher survey in the United States (Bakia *et al.*, 2008) found that teaching technology as a subject was no longer a major emphasis: rather the dominant pattern of school technology use was a combination of general productivity software and continued use for basic skills development. The most frequent uses of technology across grade levels were word processing, Internet research, and reading or mathematics skills practice, with each of these practices occurring once or more a week in the classes of about a third of all teachers. The fourth most common practice – use of software to teach content in a subject other than mathematics or reading – was reported as a weekly occurrence in just 16% of classrooms.

Potential uses of technology within classrooms extend far beyond the typical uses described above. Across a wide range of subject areas, technology has been used to organize and individualize student instruction, provide a motivating, realistic context for learning, give students access to a broad range of resources, and structure learning tasks in ways that reduce the load on memory and stimulate use of analytic strategies and reflection. Some of these uses are described in more detail below.

Subject-Specific Uses of ICT

Reading

Software has been developed to foster emergent literacy in preschool children through word and alphabet games. More broadly, ICT can support creation of an environment that supports young children's literacy skills through the

creation of literacy props such as signs, tickets, and cards that can be used in play-like activities involving literacy skills. In addition, commercial software products aimed at developing phonemic awareness and phonics skills are broadly available. Research on the effectiveness of such products has produced mixed results and suggests that the child's entering skill level, the nature of the non-ICT-based instruction offered, and the phonetic regularity of the child's language may be factors in explaining why some studies find an advantage of software use while others do not.

There is a greater body of supportive research for the use of technology to support struggling readers with the development of greater reading fluency and comprehension. Software can present students with a text to read and provide a digitized spoken presentation of the text synchronized with the child's utterances. When the child has difficulty with a word, these systems typically have mechanisms for helping to analyze the word or presenting it orally so that the child can continue reading. Speech recognition systems are now capable of processing a young reader's spoken word and determining whether or not corrective feedback is in order. Such reading support systems help students acquire needed reading practice, and many students appreciate the patience and privacy of a computer-based system.

Software systems can also support students' vocabulary learning and comprehension through hyperlinks to definitions or illustrations of unfamiliar words or concepts. Some systems provide summaries of main ideas or periodic comprehension checks to help students monitor their level of understanding. Interactive Strategy Training for Active Reading and Thinking (iSTART), for example, is a web-based program that uses animated agents to teach comprehension strategies such as paraphrasing, predicting, and elaboration. Universal Design for Learning (UDL) is an approach in which instructional materials are designed with optional supports so that they can be used effectively by the broadest possible spectrum of learners (Rose and Meyer, 2002), including those with disabilities. These supports include many of the kinds of mechanisms discussed above (text to speech translation, glossaries, prompts for strategic reading strategies) plus an electronic log of the student's work. Research on the application of UDL to learning from science texts has found that having students manipulate electronically presented diagrams of key concepts or having the support of computer agents enhances students' concept learning (Dalton and Strangman, 2006).

Writing

As noted above, the most pervasive use of technology within schools is as a productivity tool, making word processing software the leading educational application. Numerous studies have compared the composition

and editing skills of students with and without access to technology. A 1993 meta-analysis of the early word processing studies (Bangert-Drowns, 1993) found a modest but significant positive effect of word processing on overall writing quality. More recent studies of the effects of giving students a personal laptop have found a positive effect on student writing skills (Kulik, 2003; Penuel, 2006).

Mathematics

Graphing calculators have been the leading technology in mathematics classrooms; most secondary students in the United States and several other countries have access to a graphing calculator. While some critics have warned that the introduction of calculators into mathematics instruction will lead to an inappropriate de-emphasis on calculation skills, mathematics educators recommend that the calculators be used not as a substitute for skill learning but to support students when they are engaged in learning mathematical concepts. Calculators can handle calculations and graph construction, freeing students' cognitive resources to concentrate on solution strategies and understanding concepts. Other software tools supporting students' mathematics problem solving include the Geometer's Sketchpad and Cabri Géomètre, which can be used to support students' exploration and development of geometry proofs, and Tinkerplots and Fathom, which provide tools for organizing, analyzing, and representing data in ways that support understanding of statistics. SimCalc MathWorlds, a research-based tool, similarly provides representations that support students' learning of concepts in Algebra and the transition to Calculus. Advanced calculators incorporate Computer Algebra Systems, which can support students in reasoning about algebra strategically, while allowing the calculator to handle tedious rewriting of symbols. Libraries of virtual manipulatives provide similar capabilities to explore mathematical situations and concepts, but within a narrower focus. Overall, these tools provide support for both calculation and representation of mathematical concepts.

Cognitive tutors represent another advance in the use of ICT in mathematics learning. A cognitive tutor observes the step-by-step process of a students' problem solving and intervenes when the student deviates from an expert solution process. Carnegie Tutors are available for pre-algebra, algebra I and II, geometry, and integrated mathematics. Half a million students in roughly 2600 US schools have used one or more of these tutors.

The commercial market also contains many examples that reflect earlier computer-assisted instruction approaches. These approaches typically present students with tutorials and then offer feedback and hints as students solve problems.

Recent advances in classroom networking are leading to mathematical tools that allow groups of students

to participate in constructing mathematical objects. For example, the commercial TI-Navigator system allows students to simultaneously submit graphs or equations to the teacher and offers the teacher controls to compare and contrast students' work. Research projects have been exploring the potential of collaboration with such specifically mathematical tools.

Second language learning

Technology has played a significant role in many language classrooms since the language labs of the 1960s. While software designed to teach a language and provide practice opportunities remains available and popular in CD-ROM form, the rise of Internet usage within schools has ushered in a new era with a wider range of learning activities in support of second-language learning. In addition to the option of formal language instruction, students can practice and enhance their second language skills by working with original materials such as newspaper articles, blogs, and speeches, developed for the purpose of communication rather than language teaching, available on the Internet in the language they are learning. Opportunities for language classes to interact online with native speakers of the language they are studying have become commonplace. Hybrid language classes, which combine elements of face-to-face instruction and online learning, have become increasingly popular.

Science

Technology tools have become essential to the practice of science, and this change in the nature of the profession has influenced science instruction. Probes and sensors connected to computers, online databases, computer simulations, and models are central to the practice of scientific fields such as physics, biochemistry, and environmental science. Versions with appropriate interfaces and simplifications for education purposes have been developed for many of these, while in other cases students use the same tools as science professionals. In addition to supporting measurement and data storage and analysis, these technology-based tools provide access to phenomena that occur at a size or timescale that would be difficult or impossible for the unaided human to apprehend and, in some cases, involve dangers that make them inappropriate for classroom use. Students can interact with computer-based simulations of viral epidemics, for example, providing a context demonstrating the real-world relevance of science concepts while protecting students from the real world's hazards.

A number of ICT-supported science education programs involve having students interact with scientists working in the field that students are studying. Features such as email, electronic chat, webcasts, and bulletin boards have been used to support student-scientist interactions in programs, including Kids as Global Scientists,

GLOBE, BioKids, Project FeederWatch, and Hands-on Universe. In these programs, students are expected to collect scientific data using scientist-developed protocols and to contribute their findings to a shared database on the World Wide Web. In BioKids, for example, students use personal digital assistants (PDAs) with special software to record the animal life within a study site near their school (Songer, 1996). Because the data are entered into a database shared with other schools, data can be aggregated across schools within the same city, or at a state or regional level. Students can then use BioKids data to address questions about changes in biodiversity over time or in different areas of their state.

Another set of technology-supported tools specific to science learning are systems that build in supports for science inquiry skills. The Knowledge Integration Environment (KIE) and Web-based Inquiry Science Environment (WISE), both developed at the University of California, Berkeley, present students with prompts, reminders, and organizational devices that they use as they explore scientific issues and controversies (Linn, 2006).

Rapidly Growing Uses

Open-source online resources and curriculum materials

One of the biggest transformations wrought by the World Wide Web is the increased availability of the world's cultural, historical, and information resources. The treasures of major museums such as the Louvre and the British Museum are available to anyone with an Internet connection. History students can inspect original documents such as manifests of ships engaging in the slave trade or Leonardo de Vinci's notebooks.

Beyond access to information and artifacts, the Web also offers educational resources organized into units or learning activities and increasingly, entire courses that a school or individual may choose to use. Many educational jurisdictions have organized collections of instructional resources and learning activities keyed to their content standards. The governments of Australia and New Zealand, for example, have collaborated in supporting The Learning Federation, which develops educational content tied to those countries' curricula, and makes it available online to schools at no cost. Curriki is a community web site where educators can post K-12 open-source lesson plans and curriculum materials for review, modification, and use by other teachers. Intended as a global resource, the Curriki site comes in Spanish, French, Hindi, and Bahasa (the native language of Indonesia) as well as English versions. At the tertiary level, the Open Courseware Consortium (OCW) organized by the Massachusetts Institute of Technology (MIT) has made materials from 1800 courses from major universities available online at

no cost. While online collections offer teachers access to impressive resources, teachers often have too little time to search for appropriate resources and too little expertise to assemble a coherent plan of instruction from a library of fragmentary resources.

Online learning and virtual schools

Web-based online learning has been well-established in tertiary education and corporate training since the 1990s. More recently, this use of technology has become a significant part of K-12 education as well. A survey of US school districts commissioned by the Sloan Consortium (Picciano and Seaman, 2007) estimated that 700 000 US public school students were taking online courses in school year 2005–06 – a tripling of K-12 online learners in the 3 years following a National Center for Educational Statistics survey of districts concerning their online course offerings in 2002–03 (Setzer and Louis, 2005). Most of the online courses taken by K-12 public school students at the time of the survey were at the high school level, but the practice now is spreading to lower grades.

In addition to online course offerings through conventional schools, there are also increasing numbers of K-12 school programs that are entirely online. By fall 2007, 28 of the 50 US states had online virtual high school programs (Tucker, 2007). The Florida Virtual School, the first statewide public virtual school in the United States, had 64 000 secondary and middle school students enrolled in online classes in 2008–09.

Online learning has become popular because of its potential for providing more flexible access to content and instruction at any time, from any place. Online learning is often selected with goals such as (1) increasing the availability of learning experiences for learners who cannot or choose not to attend traditional face-to-face offerings, (2) assembling and disseminating instructional content more cost-efficiently, or (3) enabling instructors to handle more students, while maintaining learning outcome quality that is equivalent to that of comparable face-to-face instruction.

Different technology applications are used to support different models of online learning. One class of online learning models uses asynchronous communication tools (e.g., e-mail, threaded discussion boards, and newsgroups) to allow users to contribute at their convenience. Synchronous technologies (e.g., webcasting, chat rooms, and desktop audio/video technology) are used to approximate such face-to-face teaching strategies such as delivering lectures and holding meetings with groups of students. Early online learning applications tended to implement one model or the other, but current online learning applications tend to combine multiple forms of synchronous and asynchronous online, as well as occasional face-to-face, interactions.

Frequent assessment and individualization of learning

Some of the earliest learning software, developed in the 1960s by Patrick Suppes at Stanford University, incorporated the principle of individualizing the material presented to a learner based on that particular learner's state of knowledge. Proponents of mastery learning (an instructional approach organized around specific learning objectives with learning time allowed to vary so that each student works on an objective until he or she has mastered it) quickly appreciated the value of ICT for supporting their instructional approach. While current generations of instructional software are built in new programming languages and have more sophisticated interfaces, much of the mathematics and reading software for elementary and secondary students is a revision of early computer-assisted instruction (CAI) content developed with a mastery learning design. Common software features include reports for teachers showing each student's performance and a summary of the performance of the whole class, organized by curriculum standard or instructional objective.

The increased accountability pressures around mathematics and reading achievement ushered in by the No Child Left Behind Act of 2001 in the United States and similar legislation in other countries has sparked more widespread interest in frequent assessment of students on the content and skill objectives that are part of the accountability system. Even for schools where none of the instruction in reading and mathematics takes place on computer, it has become common for students to take frequent interim or benchmark tests to see where the student is with respect to accountability standards at a point where there is still time to provide extra services or focused instruction on areas of weakness. In many cases, these assessments are provided on computer and scored almost instantaneously. Instructional management software helps teachers and school leaders maintain records and generate reports of interim assessment data. Mislevy and colleagues describe technology's role in supporting the systematic design of assessments and assessment delivery.

Technology is also enabling the development and use of formative assessments. Formative assessments are those that provide feedback to the learner and the instructor that is used to advance learning. Such assessments are most effective when conducted in close proximity to the relevant learning experience and when they have been designed based on research on how people learn the content being assessed. Such assessments reveal both what a student does not understand and why it is not understood. The advantage of technology is in extending the range of situations or tasks that can be presented to the student so that more complex skills and the students' ability to integrate multiple concepts and skills can be assessed. Complex, multi-step problems, data sets, simulations, and models can be incorporated into

technology-based assessments, and not just the student's final answer to the problem but each step taken in addressing the problem can be recorded automatically. Pellegrino describes examples of research-based formative assessments in reading, science, and mathematics. Bennett describes how these same technology capabilities are starting to extend the range of skills addressed by assessments designed for large-scale administration, such as the Keystage 3 ICT Assessment Tasks developed by England's National Assessment Agency and new science assessments being studied for potential incorporation into the National Assessment of Educational Progress (NAEP) in the United States.

Emerging Uses

Technology changes at a much more rapid pace than education, and whenever a new technology emerges, there are those who want to see it applied in schools. Experimentation with mobile phones, podcasts, and social networking sites as educational tools are ongoing. Three major themes in emerging research and development on educational technology are collaborative knowledge building through Web 2.0 applications, immersive environments and games for learning, and interactive classroom communication systems. A common thread among these three themes is increased opportunities for contribution and participation.

Web 2.0

Although without a precise definition, the term Web 2.0 was coined to cover what are considered second-generation Internet sites, distinguished by their dynamic content shaped by multiple users. It includes social networking sites such as MySpace, recommendation systems such as that used by Amazon.com, and community-developed resources such as Wikipedia. Within an education context, Web 2.0 applications engage students in working with others (other students, instructors, or content experts) to explore and build knowledge around concepts or phenomena. The WISE science learning environment described above is an example of a Web 2.0 educational application as is the Knowledge Forum, developed at the Ontario Institute for Studies in Education (Scardamalia and Bereiter, 2006).

The Knowledge Forum software environment is a multimedia database that allows students, teachers, and external mentors to post notes containing information, questions, or interpretations. It was designed to promote knowledge-building discourse – the kind of exchange of information, conjectures, questions, and interpretations one would expect to see in a research laboratory (Scardamalia and Bereiter, 2006). The software provides a set of labels including 'my theory,' 'new information,' 'this theory explains,' and 'this theory does not explain' to scaffold students' efforts to make sense of and build theories about the content of their shared database. The software also

provides ‘views,’ which are alternative organizations of the database contents – for example, categorization of cases on the basis of different features or on the basis of chronology or consistency/inconsistency with a certain theory or school of thought. Knowledge Forum has been used with groups ranging from kindergartners to graduate students and professionals (Scardamalia and Bereiter, 2006) and in a range of countries, including Canada, the United States, Finland, and Hong Kong.

Immersive environments and games

A second technology trend with potential to influence education is the increasing realism and interactivity offered by multi-user virtual environments. While some critics decry the amount of time that young people spend on multi-player online games such as World of Warcraft, others argue that the level of engagement engendered by such games can and should be harnessed for educational purposes (Federation of American Scientists, 2006). A number of so-called serious games have been developed to demonstrate the educational potential of this approach (Barab *et al.*, 2004; Steinkuehler, 2006). River City, for example, is an environment in which students learn middle school science concepts by acting as a character (an avatar) in a simulated eighteenth-century city where the citizens are falling ill at an alarming rate. Students use their knowledge of biology along with the results of tests conducted online with equipment such as virtual microscopes to investigate the mechanisms through which the disease is spreading (air, water, or insects). Students collaborate to write up their research findings as a report to River City’s mayor. River City’s developers believe that the power of such virtual environments lies in their ability to situate student learning in an authentic context while providing scaffolding through system prompts and input from experts that is gradually faded as students acquire stronger inquiry skills.

Interactive classroom communication systems

Another long-standing trend in classroom technology has been increased use of student response systems or clickers. In their simplest form, these devices allow students to simultaneously vote on a multiple-choice question posed by the teacher. The votes can be anonymously collected and displayed as a histogram, indicating the proportion of students that selected each answer. This facility, on its own, has little impact on learning. However, it can support new pedagogical strategies, such as Peer Instruction (Crouch and Mazur, 2001), that increase learning. In Peer Instruction, for example, the instructor uses the feedback to focus student attention on the cognitive contrast between the two most frequent answers to the question. The students are asked to work in pairs to convince each other of the correct answer. This process

of argumentation often results in students’ convergence toward the correct response. In addition, response systems provide feedback to the teacher, who can use this feedback to adjust instruction.

Classroom communications systems now go considerably beyond simple multiple-choice responses. For example, researchers have developed participatory simulations in which all students take the role of an agent in a simulation. Further, using a networked classroom communication system such as the TI-Navigator, students can contribute mathematical expressions, graphs, data sets, and other mathematical objects to a common shared display. In another research prototype, GroupScribbles, students can contribute handwritten notes (like familiar office sticky notes) to a shared group display, enabling many forms of collaborative brainstorming and critique.

Evidence of the Effects of ICT on Teaching and Learning

Parents and teachers report that students’ motivation for learning increases with the use of ICT, and most believe that ICT enhances students’ learning. Rigorous evidence regarding the effects of ICT on objectively measured learning outcomes is harder to come by, however.

Evaluating the effectiveness of technology is complex because there are so many different technologies and even more ways in which technologies can be used. Some have argued for trying to isolate the effects of technology *per se* by providing exactly the same pedagogy and content with and without technology in an experimental design (Clark, 1983). ICT proponents argue that this is a self-defeating strategy, however, because the most important reason to use ICT in instruction is to support kinds of learning that cannot be accomplished without it (making an all-other-things-equal control condition logically impossible).

A recent meta-analysis of controlled studies comparing learning outcomes for online and face-to-face classes, found that students learned more in classes that included online learning activities (Means *et al.*, 2009). The researchers noted, however, that the classes that combined online and face-to-face elements differed from the conventional face-to-face classes not just in terms of the additional instructional medium but also in terms of differing content, instructional strategies, and learning time.

Increasingly, researchers see technology as infrastructural and not itself as an intervention. New computing power, networking, and displays provide the capability to create new instructional activities, but without those new activities, the infrastructure *per se* adds little to teaching and learning. Further, new technology-enabled instructional activities often require additional teacher professional development and new forms of assessment. Hence, a modern perspective emphasizes systems of instruction

which build upon the new infrastructural possibilities offered by ICT.

Systems of instruction include both ICT components and curriculum, teacher training, and other supports. The strongest and best-designed studies have examined such technology-supported systems of instruction in large numbers of classrooms with random assignment of teachers or classes to experimental and control conditions. The effectiveness of the SimCalc MathWorlds software and associated instructional activities and teacher development was evaluated in a randomized controlled trial involving 95 middle school mathematics teachers. Students who used SimCalc attained a better understanding of rate and proportionality than did similar students in control classes.

In contrast, a randomized control trial conducted by the US Department of Education involving 16 different commercial mathematics and reading software applications found no effect of software use on either reading or mathematics learning (Dynarski *et al.*, 2007). A potentially critical feature of the US Department of Education study is that schools and teachers were left to their own devices to determine how they would implement the commercial software; there was no R&D organization helping teachers develop an instructional system to integrate the software with the rest of their instructional program. Moreover, because every school had teachers in both the experimental and the control conditions, a schoolwide program of support for software implementation was not possible.

Effective Implementation of Technology-Supported Learning

A number of large-scale teacher surveys have provided insights into the characteristics of teachers and school environments associated with teacher integration of ICT into instruction. Survey data suggest that teachers who themselves have stronger ICT skills are more likely to have students engage in ICT-supported activities for their classes. The extent to which teachers have their students use ICT is larger also for teachers who have participated in professional development around technology integration and for those whose school leaders promote the use of technology (Zhao *et al.*, 2002). There are also teacher characteristics with no obvious connection to technology use that nevertheless predict the extent of technology integration in a teacher's classroom. Teachers with constructivist or student-centered teaching philosophies have their students use technology more often than do other teachers (O'Dwyer *et al.*, 2005). Teachers who engage in a broader range of professional activities (collaborating with colleagues around instructional issues in their school, participating in professional activities outside the school, and acting as leaders in professional activities) are

significantly more likely than other teachers to have their students use technology weekly or more often (Becker and Riel, 2000). Teacher leaders are particularly likely to have their students use ICT in more sophisticated ways involving knowledge building, problem solving, and collaboration (Riel and Becker, 2008).

Beyond the question of the extent to which ICT is being used in schools and classrooms, there is the broader system-level question of the educational goals its use is addressing. UNESCO (2008) has provided a framework describing different strategies for using ICT to support education reform. The technology literacy strategy aims to harness technology to increase the basic skills of the populace and also to increase students' skill in using ICT, often through taking a specific course taught by a specialized technology teacher. The knowledge deepening strategy seeks to prepare students to use ICT to address complex high-priority problems in the real world, and implementations of this strategy include student use of digital resources and technology tools to address complex problems in a content area (e.g., by exploring a simulation of a watershed in science class). Finally, the knowledge creation strategy involves teaching and using technology in ways that prepare students to become innovators through developing the problem solving, communication, collaboration, and critical thinking skills that are often called twenty-first-century skills.

Law, elsewhere in this encyclopedia, suggests that the skills that teachers need with respect to ICT vary for these different strategies. The technology literacy strategy requires only a few teachers with strong ICT skills to help students acquire technology fluency. The knowledge deepening approach, in contrast, requires all teachers to have not just basic technology competency but also a knowledge of available technology resources in their subject area and an understanding of how these resources can be used to enhance learning in this domain. The knowledge creation strategy requires teachers to be able to move beyond teaching the content conventionally covered in their subject area to develop learning activities that provide the opportunity to learn and refine twenty-first-century skills. Law suggests that execution of this strategy requires a school's staff to be able to use technology to support their communication and collaboration with each other and to manage and analyze student assessment data. Hinostroza, Labbe, and Lopez describe how ICT can be used to support the learning that teachers must do to support such educational reform strategies.

Some researchers have reasoned that acquisition of twenty-first-century skills and the likelihood that these skills will be applied outside of school can be increased through learning experiences that place students in an active role within a collaborative group working with a realistic or situated problem context. By making the context of learning similar to the contexts within which

students will apply their learning (i.e., complex problems that transcend disciplinary boundaries, problem-solving teams with differentiated roles, ICT supports for information finding, reasoning, and communication), educators expect to promote inquiry skills while also making learning activities more motivating and increasing the likelihood that acquired skills and dispositions will transfer to real-world situations.

Use of Technology for Learning Outside of School

As noted above, ICT is becoming increasingly ubiquitous in young peoples' lives and is in fact more common outside of school than inside. Some observers have expressed strong concern about potentially harmful social and physical side effects of excessive technology use, but available empirical research suggests a more balanced view, with some areas of risk and general benefits.

Collins and Halverson suggest that people have many experiences involving searching for and synthesizing information from disparate sources, and using ICT to expand one's cognitive capacity outside of school. Through the Internet, young people engage in communities of individuals with like interests, engage in sophisticated gaming, and acquire new knowledge and skills when they need them (see also Jenkins *et al.*, 2006). Collins and Halverson see the world moving toward a culture of lifelong learning with ICT playing a pivotal role in supporting learning activities, a majority of which will occur outside of brick-and-mortar schools.

It is also possible that in-school and out-of-school learning activities will develop new lines of convergence supported by technology. Signs of this are apparent in the growth in online learning connected to educational institutions. Several universities offering their courses online have reported that the largest single group of online learners consists of regular residential students who prefer the anywhere/anytime quality of the online course to sitting in a lecture hall. In K-12 education, some school districts are offering both classroom-based and online versions of key secondary school courses. In addition to those students opting for the online version from the beginning, there are students taking the classroom-based course who avail themselves of the online learning option for part of the course after becoming ill or needing to travel. Increasingly, students as well as adult learners will expect to be able to access tailored learning resources when and where they want them.

Conclusion

ICT has become increasingly prominent in schools, and many classrooms now have processing power, networking

capabilities, and projected displays that were barely imaginably two decades ago. However, technology is infrastructural and by itself has produced few changes in teaching and learning. Effective use of this new infrastructure depends on systems of instruction that include cognitive tools, pedagogical activities, teacher professional development, and appropriate forms of assessment. Many systems of instruction incorporate the capability of technology to provide increased interactivity and feedback. Further, the most successful systems of instruction have been subject-matter-specific. Reading, mathematics, and science each require specific kinds of software and approaches. The Internet is also making it possible to provide original source content, for example, from museums, directly to the classroom. Emerging approaches to ICT include immersive games, collaborative Web 2.0 applications, and classroom communication systems – all means to increase student participation and collaboration in learning. Still, the evidence that technology improves learning is rather thin. Additional research is needed that tests technology in the context of full instructional systems with adequate implementation support.

Educational Data Modeling

Glossary

Educational modeling language – An educational modeling language is a semantic information model and binding, describing the content and process within a unit of learning from a pedagogical perspective for the purpose of support, reuse, and interoperability.

Indicator – A particular observable, because it has a specific meaning in the pedagogical field. It is calculated or simply built with some observed, and reflects the quality of interaction, activity, and learning with the learning environment. If we consider the indicator with the teacher, it defines what is relevant to observe. For the analyst or the engineer, the indicator is an observable, that is to say an observation mean and a set of observables used in the calculus.

Observable and observed – When we are interested in the observation modeling and the observation analysis, each observational data are defined by a specification of the way of getting before being instantiated by the observation. An observable is a variable which has to be calculated through the use's observation of a learning environment. An observed is an observable calculated. A raw data is a particular observable/observed.

Observational means – Observation modeling consists in defining all analysis techniques, automatic or not, that provide an observable. Observation analyzing consists in applying these techniques on tracks in order to get an observed. Hence, these techniques are called observational means.

Pedagogical scenario – The result of the design process of a learning activity. A scenario is composed of learning objectives, learning activities organization, time line, students' tasks description, and the evaluation modalities and their sequencing.

Raw data – By definition, the nature and format of a track are specific from the learning environment. In order to capitalize, share, and reuse the tracks analysis techniques and tools, one of the objectives of modeling is to represent tracks with a format independent from the learning environment used. Moreover, only a part of data is significant for the use analysis. Observation modeling also focuses on the retrieval and the extraction of relevant data from

tracks. Data of this type are called raw data; they are provided by the transformation of the track after the collection, and they have to be represented with a format independent of a learning environment.

Track – Each user of an interactive system may keep some tracks of its use. When the recording of tracks by the system is deliberate, the data structure generated is a sequence of actions which are temporally ordered. Often, tracks are collected inside a log file. Sometimes, they are preprocessed to be integrated inside a database or to be valid to an XML Schema. Some learning environments use videos, polls, or interviews to collect tracks of use. These tracks are all considered as data collected by a learning environment, without considering the ways of collection.

Introduction

Nowadays, numerous universities and enterprises have made the choice of electronic (e)-learning environments to increase individual or specialized learning. Technology-enhanced learning (TEL) has transformed the activities organization in that domain. Teachers are assisted by instructional designers, developers, and sometimes by usage's analysts. All these people need to communicate and to negotiate together during their activities. Therefore, it is necessary to have means and tools to facilitate this dialog. During the last decade, we observed a lot of work around specification, representation, and modeling. In the field of e-learning, these works fall into two categories which seem to merge actually. The first one concerns the learning activity modeling. The idea is to describe the teacher's pedagogical intentions behind the learning activity in order to play that description inside a learning environment. This description has to support the negotiation between learning actors. It is also interesting for the replay of the activity and for its reengineering. This specification is called a scenario. The scenario is one of the two faces of a same coin of educational data modeling. The second one concerns the observation of the learning session. Teachers or instructional designers are interested in a feedback of that new usage: How the environment is used? What exactly is the scenario played by the learner? Have all resources been used by learners? How do learners have appropriate resources? The environments

offer a lot of generic tracking features. Therefore, we now have a huge amount of data that increases all day long. At the same time, we observed that people on the Web want to share and reuse techniques in order to manage these data. Due to the variety of learning environment, all techniques available are specific to an environment and to the learning scenario when it is defined. However, there are two main problems. First, there is a gap between the observational need and the element really observed and analyzed. We observed that usage analysis is often guided by the technical capabilities of the learning environment instead of being teacher oriented. Next, actually, there is no standard for observation specification, everything is built on demand. However, some proposals are made to try a kind of normalization of what have to be observed, why, and how that can be analyzed. In this article, we present what is educational data modeling and how it is used. We conclude by some perspectives of work in that recent domain.

Educational Data Modeling

Modeling becomes very important in e-learning today. We can consider two main areas: first, the scenarization of the learning activity and, next, the scenarization of the observation of the learning activity.

The Learning Scenario

Dealing with the teaching expertise in order to explicit it for embarking it in technology-enhanced systems is one of the main and original aims of the artificial intelligence and education community. Nowadays, the growing interest for the Web technologies applied to distance education has fostered the emergence of standards as IMS Learning Design (LD) and ADL SCORM with, mainly the reusability and the sharing concerns. Koper (Open University of the Netherlands) proposed to describe pedagogical activities with an educational modeling language (EML). The EML model structures pedagogical activities by units of study, that is to say a lesson, a case study, etc. These objects are organized and linked with specific relationships. EML focuses on the concept of activity and considers a unit of study as a set of activities realized by a set of actors in a specific learning environment. These are three main categories of activities, such as learning activities, tutoring activities, and instrumental activities.

Next to this proposal, various languages were developed: PALO, EML, Learning Design Language (LDL), IMS-LD, etc. If we consider LD, which is the most used and also the most criticized, it has been defined as a standard that is pedagogically neutral, which allows different kinds of learning strategies to be supported. Actually, it has the most advanced specifications and several projects of LD editors or LD players are well advanced. The pedagogical

intention as well as the context of use of a scenario written with LD are therefore described in meta-data or diffused in the scenario itself, without any possibility for making them explicit regarding the neutrality of the expressiveness of the model of the language. From the LD specification designer's viewpoint, any pedagogical scenario can be modeled as a method specifying activities to certain actors and in a certain order. A scenario must at least contain a collection of components and a method. Components can be roles (learners, tutor, etc. that can be split in many subgroups), activities, or static scheduling of activities (activity structures), whereas who (which role) does what (which activity) and at which moment is determined by the method (which, strictly speaking, can be considered as the scenario). A method is made up of one or many plays formed by a series of acts. Different plays will represent alternative scenarios, while acts are subsets of the scenario that allow the activity synchronization for the different roles (all actors involved in an act must have finished it before starting the next one). Moreover, the theater metaphor provided by IMS/LD could seem obvious and not natural for some teachers with specific pedagogical expertise and aims in mind. As a consequence, on the one hand, extensions for LD are proposed for better fitting with specific learning activities, and we can also find some authoring tools and design patterns for helping teachers to model their scenarios with this language. On the other hand, we have other languages which are alternatives to LD, better suited for specific purpose as collaborative learning activities for instance, in the case of LDL.

The Observational Scenario

Currently, most of the e-learning systems need some kind of feedback on the usage in order to improve them. In the specific context of distance learning and teaching, the desynchronization between teachers' two major roles – instructional designer and tutor – brings about a lack of uses feedback. The software development process should explicitly integrate a usage analysis phase, which can provide designers with significant information on their systems' uses for a reengineering purpose. Semantic Web aims at facilitating data management on the Web. It brings languages, standards, and corresponding tools that make the sharing and building of automatic and semiautomatic programs easier. Automatic usage analysis is often made by mathematicians or computer engineers. In order to facilitate the appropriation, comprehension, and the interpretation of results by teachers and instructional designers, who are the main actors of an e-learning system development process, some people consider they should be fully integrated in this analysis phase.

This is the reason why educational data modeling also focuses on the observational needs and the tracks' analysis. The teacher has to define his/her observational needs.

He/she has to be able to describe them with questions such as what he/she wants to observe? When (during the session or after the session)? How the result has to be delivered? Also, why it is interesting to observe that specific point? There is no standard actually to specify observational needs. Some people propose to use specific tools and others consider that it is better to use the EML used for the learning scenario. The specification of observational needs is a process of negotiation between the teacher and the analyst and also between the analyst and the developer. In fact, the analyst has to clearly understand the teacher in order to provide the awaited result. The analyst has also to negotiate with the developer in order to know whether it is possible to collect all the data with the learning environment, and if it is not possible, to analyze the cost of the development.

The description of observational needs is necessary for defining prescribed indicators. Therefore, the indicator has a specific meaning in the pedagogical field. It is calculated or simply built with some, and reflects the quality of interaction, activity, and learning with the learning environment. Concerning indicators, some projects of the European Network of Excellence called Kaleidoscope have studied this object and its use (ICALTS, TRAILS, DPULS, IA, etc.). They focused on the observation in the learning life cycle, and proposed definitions, classifications of observational data, and also information on how to support the designer of a TEL system during the modeling phase.

Indicators are described and built from a set of other data. We present now the typology of the DPULS project. The primary data are not calculated or elaborated with the help of other data or knowledge. They could be recorded before, during, or after the learning session using, for instance, a log file recorded by the system, a video tape of the learner recorded during the session, a questionnaire acquired before or after the session, or the sets of posts in a forum. This kind of data is classified as datum. The data qualify data which are linked to the learning situation and could be involved in the usage analysis. Additional data could be – which may be picked from the learning materials, as the meta-data of a learning object – the formal planned scenario for the pedagogical situation, any information which is directly accessible, etc. Predictive data type refers to the outcomes provided by the learning session actors (learners, tutors, and/or teachers). This kind of data is mainly produced by the learners, intended to be assessed, but it also could be, for instance, a tutor's report on the activity of a learner, or on the use of a resource. The data qualify primary data which are *a priori* by an actor of the learning situation (a learner, teacher, or a tutor) or part of the analysis (output by an analyst, designer, or any learning staff member who is involved or concerned with the analysis). The data calculated are inferred from primary data or other data.

Actually, these are various ways to compute indicators, for instance, Tracks-Based System (SBT)) and Usage Tracking Language (UTL).

Conclusion

Educational Data Modeling is a recent domain. There is no real standard, but there are many proposals that have to be evaluated and used by teachers and actors of a learning situation. The development of learning environment has to integrate the concept of learning scenario specified through an external editor and also the concept of observational scenario in order to provide a feedback on the learning session. This feedback not only facilitates the improvement of the quality of the scenario and the learning situation, but it also allows developers to improve their learning environment. Being aware of the need to model education data offers the capabilities of sharing, reusing learning scenario and indicators. The next step concerns the capitalization of these data and their integration inside the learning environments. The main goals behind this work are the qualification of data for information retrieval and the automation of their use.

Glossary

Assessment system – A computer data system that rapidly organizes and analyzes benchmark assessments.

Calibration – A term first used by Wayman *et al.* (2006) to describe a process for establishing an aligned, common vision for education and how data use will support this vision.

Data – Any piece of information that can help educators know more about student learning. Examples include summative achievement tests, interim or benchmark tests, grades, disciplinary information, and teacher judgment.

Data use – The effective examination of educational data for educational improvement.

Data warehousing system – A computer data system that integrates other data systems, providing complete access to historical data of all types.

Student data system – A computer system that enables teachers and other educators to access, aggregate, and examine student data.

Student information system (SIS) – A computer data system that provides automated management of transactional data such as attendance, grade reports, enrollment, and course scheduling.

describe student data systems as an effective use of education dollars under the American Recovery and Reinvestment Act of 2009. Organizations such as the Data Quality Campaign are supportive of data systems, but also are concerned with examining difficulties in implementing these systems.

Technology is a critical component of any educational data use initiative. Historically, however, educational data have been stored in ways that rendered them inaccessible to most educators; as such, use of educational data frequently involved an unrealistic amount of time and effort (Stringfield *et al.*, 2001). Fortunately, the recent advent of more user-friendly computer systems that deliver appropriate data in a timely fashion (Wayman, 2007; Wayman and Cho, 2008; Wayman *et al.*, 2004) has provided a more robust infrastructure for effective data use.

As the quality of data systems available to educators has improved dramatically, so too have the number and type of computer systems being marketed toward educators increased exponentially (Mieles and Foley, 2005; Wayman, 2007; Wayman *et al.*, 2004). Unfortunately, research about the functions and limitations of these different systems is relatively scarce, leaving educators with little information on which to rely in selecting a student data system. Toward that end, we offer a description of the different types of student data systems available to educators in the United States, an overview of the key features of student data systems, and a discussion of the current and future use of student data systems in educational contexts.

Introduction

In the United States, recent federal and state accountability mandates such as the No Child Left Behind Act (NCLB) have increasingly focused the attention of educators on the collection and reporting of student achievement data. Implicit in these policies is the expectation that educators will use these and other data to make decisions that improve educational practice. Largely as a result of this policy shift, phrases such as data use, data-driven decision making, and data-based decision making are increasingly part of the educator's lexicon. Some districts have exceeded the reporting requirements of NCLB and other policies, using student data systems to perform advanced functions such as predicting student achievement (e.g., Datnow *et al.*, 2007).

About the time that this article goes to press (in late 2009), policies from the Obama administration frequently

Types of Student Data Systems

A burgeoning number of student data systems are available to educators, providing a variety of functions designed to efficiently deliver student data. Because of the varied functions that may be performed, no single system provides access to every function a school or district may want. As such, educators must integrate various types of data systems to find one or more that best suit their needs.

Wayman (2005) outlined three common types of data systems that deliver student data to educators: (1) student information systems (SISs), which provide real-time accounting of daily school functions (e.g., attendance and schedules); (2) assessment systems, which rapidly organize and analyze frequent benchmark assessments;

and (3) data warehousing systems, which provide access to historical data of all types and link disparate databases.

In addition to these primary types of data systems, Wayman (2007) identified instructional management systems (some vendors are starting to use this term to generically describe their system, regardless of the functions it performs), which are not designed specifically for student data, but which incorporate student data as part of a broader service. These systems often offer connections between student data and instructional supports such as curriculum resources, learning standards, intra-staff communication, and home-school linkages. Finally, educators have recently begun asking for educational content linked to data, resulting in an increasing number of systems that serve this purpose.

Although commercial vendors are increasingly looking toward offering solutions that integrate the functions of these various types of data systems, such systems are still relatively inchoate. As such, educators must piece together several individual systems to form one comprehensive data solution. Thus, it is critical for educational personnel to understand the various functions and limitations of the various system types. In the following paragraphs, we describe the functions and limitations of the three main systems described by Wayman (2005).

Student information systems. SISs support a vast array of functions that improve the daily work flow of schools and districts. Such systems provide automated management of previously time-intensive and detailed work such as attendance, grade reports, enrolment, and course scheduling. SISs are also increasingly being used to facilitate communication between home and school, providing parents with a portal to access information regarding their children's academic progress.

SISs, however, are rarely designed to facilitate assessment of student learning, support analysis of assessment data, examine longitudinal data beyond the current year, or investigate multiple variables at once.

Assessment systems. Unlike SISs, assessment systems offer powerful tools for facilitating periodic, systemic assessment of student learning. Often used with commercially provided and researched assessments, these systems offer school personnel the ability to administer, grade, and organize assessments, and use their results to illuminate strengths and deficiencies. Assessment systems also support instructional management, often offering assessments aligned and linked to state standards and curriculum supports.

Because of the volume of data generated, assessment systems generally do not provide access to assessment data over time. Further, assessment systems typically fail to link assessment data to other forms of student data such as SIS data, historical student data, demographic information, and other assessments.

Data warehousing systems. Systems that serve to integrate and offer seamless access to disparate forms of data are

loosely termed in education circles as data warehousing systems. (Many such systems are not data warehouses in the strictest sense of the term, instead integrating a fraction of the data that a true data warehouse might.) At the district level, a data warehouse may contain state assessment data, locally administered assessments, student learning histories, teacher information, and demographic information such as absences, free- and reduced-price lunch status, and special education status. Data warehouses are a powerful tool for analyzing a variety of learning phenomena, placing nearly all available student data at the fingertips of the teacher, administrator, or staff member.

Because of the volume of data stored in data warehouses, such systems are not designed to be dynamic; rather, they require periodic uploading or refreshing of the data. As a result, data warehouses are not used to perform the functions of real-time SISs or timely assessment systems. Instead, these functions are performed via other systems and loaded into the data warehouse.

Key Features of Student Data Systems

Although research on student data systems is a relatively young field, an emerging research base permits insight into the key characteristics of student data systems. Wayman *et al.* (2004) surveyed data systems and identified the features central to an effective student data system. They categorized these features into four general factors: (1) user friendliness, (2) user features, (3) information access, and (4) data quality. These factors provide a convenient framework for discussing the extant research on the important features of data systems.

User friendliness. An important aspect of any software, user friendliness is especially crucial in educational settings, where teachers, administrators, and staff have little time or tolerance for difficult or counter-intuitive solutions. Empirical research has demonstrated that absent efficient technology effective data use is both limited and labor intensive (Stringfield *et al.*, 2001; Supovitz and Klein, 2003; Wayman *et al.*, 2007). Moreover, even in the presence of efficient technology, unfriendly interfaces and frustrating response times may constitute a significant barrier to consistent use (Wayman and Stringfield, 2006). Conversely, user-friendly, efficient technology has been demonstrated to facilitate capacity building for independent data use (Chen *et al.*, 2005; Lachat and Smith, 2005; Wayman and Stringfield, 2006).

User features. User features such as query tools, graphic displays, and remote access are important in promoting effective educational data use. Because different educators at different levels of the educational hierarchy access different information for different purposes, studies have demonstrated the importance of powerful query tools that

allow users to extract data appropriate to their role such as teacher, principal, or district superintendent (Chen *et al.*, 2005; Lachat and Smith, 2005; Wayman and Stringfield, 2006). Chen *et al.* (2005) demonstrated the importance of interesting and relevant graphic interfaces, such as histograms, pie charts, scatter plots, and gauges, in facilitating the inquiry of teachers.

Information access. Information access is crucial to the success of any data system. For instance, because many educators work outside school or office hours, it is critical that they have access to data systems when and where they need them (Wayman and Stringfield, 2006). Besides system availability, information access also implies effective methods of presenting information and the availability of a broad range of relevant data. Contrasting examples of these were shown by Brunner *et al.* (2005). In studying data reports available to educators in New York City, Brunner *et al.* (2005) found that a student data system that produced reports in a comprehensive, easy-to-understand fashion was highly useful to both educators and parents. On the other hand, these reports were not populated with a broad range of dynamic data. Ultimately, their utility became short-lived as user advancement necessitated deeper inquiry than was supported by the reports.

Data quality. A data system is only as good as the data it contains. As such, high-quality, accurate data, and the ability to maintain an accurate, quality database is paramount to any data system. Wayman and Conoly (2006) underscored this point, demonstrating that a system with rich, clean data could be rapidly implemented in a large district. The study also described postimplementation sustainability issues faced by the district regarding the expansion and maintenance of their data. Inputting accurate data is an important consideration, and is often found to be more difficult than initially anticipated (McLeod, 2005; Wayman *et al.*, 2004).

The Use of Data Systems in Educational Contexts

While data systems are a necessary component of effective data use, they are not sufficient. To be successful, a data initiative must also address the context in which the data system is implemented. Prior to the last 3 or 4 years, electronic data systems were not frequently employed in schools, thus limiting research on data use in technology-rich educational contexts (e.g., Chrispeels *et al.*, 2000; Massell, 2001; Supovitz and Klein, 2003). As data systems have become more common, however, a growing corpus of research has examined the use of data systems in educational contexts. This work offers a number of interesting insights and reveals a number of contextual factors that are critical to the effective use of educational data systems.

Calibration and alignment with district vision. An effective data initiative involves the alignment of all district organizational levels and personnel around a systemic vision for data use that addresses how data will be used to support teaching and learning (Datnow *et al.*, 2007; Halverson *et al.*, 2005; Mandinach *et al.*, 2008; Wayman *et al.*, 2007). To ensure that student data systems will be effective in supporting district goals, districts should purchase or construct such systems only after a district-wide vision for data use has been outlined (Wayman and Cho, 2008).

To establish an aligned, common vision for education and how data use will support this vision, educators should engage in a formal process of calibration (Wayman *et al.*, 2006, 2007), which involves a productive dialog around questions such as: What do we mean by teaching and learning? How will teaching be conducted under these definitions? How will we assess student learning so we know it when we see it? How will we react to results? To ensure richer discussions, Wayman *et al.* (2007) recommend that districts conduct a thorough, district-wide evaluation of available data, existing data practices, and support capacities, prior to commencing the calibration process.

Principal leadership. Principals are often cited as key players in the data process and they play an integral role in the health of any data initiative (Copland, 2003; Lachat and Smith, 2005; Wayman and Stringfield, 2006; Young, 2006). For example, Wayman and Stringfield (2006) found that principals were the single most important factor contributing to the success of the schools in their study. Principals of successful schools were heavily invested in the use of data systems at their schools and were often avid users of data systems. In addition to modeling with their own data use, principals demonstrated a variety of innovative methods of support for these systems such as requiring data reports at all conferences, granting time and development to allow teachers to hone their skills at using the system, and meshing different types of systems to meet specific situational needs.

Conversely, research suggests that ineffective data initiatives are often characterized by poor principal leadership (Wayman *et al.*, 2007; Wayman *et al.*, 2009; Young, 2006). For example, Wayman *et al.* (2009) described schools where ineffective use strategies muted the extent to which a perfectly effective data system was implemented. The authors surmised that ineffective principal preparation was a leading cause of these inefficiencies.

Faculty involvement. While principals are the key catalysts for data use, teachers are its key users. Wayman (2005) has suggested that full faculty involvement is critical to the ultimate success of a data initiative with computer systems. However, faculty involvement is often predicated not only on principal leadership but on the fit between the data system and teachers' work as educators (Wayman *et al.*, 2007, 2009). Teachers have been

shown to be enthusiastic about the use of a data system when it meets their needs (Brunner *et al.*, 2005; Chen *et al.*, 2005; Lachat and Smith, 2005; Wayman and Stringfield, 2006), but dismissive when they perceive it to be cumbersome or not useful (Brunner *et al.*, 2005; Wayman and Stringfield, 2006). Thus, while educators are often skeptical of data use and data systems because of concerns that such initiatives will add to their already full workdays (Ingram *et al.*, 2004; Valli and Buese, 2007; Wayman *et al.*, 2009), such skepticism may be mitigated by ensuring that student data systems are integrated with the work of teachers.

Educator collaboration. Researchers often tout the advantages of collaboration in promoting inquiry (Massell, 2001; Murphy, 2002; Young, 2006). In practice, however, fostering collaboration among faculty can be difficult. Collaborating around a data system, whether formally or informally, can often help remedy the situation, bringing focus and a common language to collaborative efforts (Wayman *et al.*, 2006). For example, Wayman and Stringfield (2006) observed formally structured collaboration involving data systems, while Chen *et al.* (2005) and Lachat and Smith (2005) described informal collaboration opportunities that arose around data systems. Further, the collaboration–data relationship is reciprocal: While data systems can support collaboration, collaboration can also ensure the success of data initiatives (Chen *et al.*, 2005; Lachat and Smith, 2005; Wayman, 2005; Wayman *et al.*, 2006; Wayman and Stringfield, 2006).

Other institutional supports. A variety of other institutional supports influence the implementation of data systems, including educator training and development, system access, and time for data use.

Although data systems are powerful tools, their success, like that of any tool, is contingent upon adequate user training, knowledge, and support. Thus, it is important to ensure that educators are data literate and proficient in using their data systems in everyday practice via training that is immediately, specifically, and practically relevant to each educator. Although most commercial vendors offer some sort of training as part of their agreement, districts should provide deeper and ongoing training on the use of the system.

Full access to student data, wherein educators are given personal login information that allows them 24-h access to data and system functions they are legally allowed to access, has been shown to enhance and broaden teacher data use (Chen *et al.*, 2005; Wayman and Stringfield, 2006). Moreover, lack of technological access has been cited as a hindrance to effective data use (Halverson *et al.*, 2005; Supovitz and Klein, 2003). However, some leaders are wary of providing access to data for all educators (Young, 2006), often concentrating access to data on certain ‘go-to’ individuals rather than encouraging educators to access data directly (Lachat and Smith, 2005). Wayman and Cho

(2008) have cautioned against over-reliance on such ‘go-to’ individuals, arguing that data systems are most effective when individual educators can and do access data directly.

Another key support for effective use of data systems is structuring educators’ schedules to allow them time to examine data (e.g., Ingram *et al.*, 2004; Lachat and Smith, 2005; Wayman, 2005; Wayman and Stringfield, 2006). While some researchers have cited the effectiveness of providing large portions of time in periodic intervals (Massell, 2001; Young, 2006), others have emphasized the importance of providing time more frequently. Wayman and Cho (2008) have argued that educators should be permitted and encouraged to use the data system on a daily basis, thus conveying that data use is valued, expected, and supported.

Future Directions

As evidenced by the previous discussion, data systems hold great potential for promoting educator inquiry and fostering educational improvement. Accordingly, most extant research paints a rosy picture of the implementation of these systems. However, these findings must generally be interpreted with caution, as most research has been conducted on schools and districts singled out for their exemplary use of such systems. Thus, although knowledge of data systems and their use has increased dramatically over the past years, additional research on nonexemplary schools is necessary to strengthen the research base and determine whether research findings generalize beyond these exemplary contexts (e.g., see Gallagher *et al.*, 2008; Wayman *et al.*, 2007). Further, the rarity of such exemplary schools suggests that student data systems are still far from ubiquitous facilitators of educational improvement. In the following, we discuss five themes shaping the future of educational data systems: acquisition, interoperability, modularity, triangulation, and future technological advancements.

Acquisition. One key issue involves the acquisition of student data systems. In acquiring a student data system, districts must generally choose whether to buy a commercially available system or build their own. Wayman *et al.* (2004) suggested that most districts are better off buying a commercial system than developing their own, noting the difficulty of building a data system. The authors suggested that commercial vendors bring economy of scale, and that many districts lack the time and local talent to build an efficient, first-rate system. Further, although some districts may view commercial data systems as expensive luxuries, Wayman *et al.* (2004) suggested that districts likely will recupereate these monetary costs in terms of efficiency, time, and regained teaching opportunities.

Regardless of the decision to build or buy, districts should take care to adopt systems specifically tailored to

their needs. To this end, districts can be forward looking by engaging in calibration exercises and other formal needs assessments (Wayman *et al.*, 2007). This enhances equally the request for proposal (RFP) for districts buying systems, as well the system design process for districts developing their own.

Interoperability. Another central issue is data system interoperability. As noted previously, no system provides every function a district would want. As such, educational personnel must piece together independent systems to address all their data needs. Exchange of data among disparate systems, however, is often problematic owing to proprietary specifications and restrictions. Districts may partially mitigate this problem by using a commercially available product, as many vendors have partnerships with other vendors providing different services and have thereby ironed out many data exchange problems. However, districts are at the mercy of whatever partnerships their member has forged.

The Schools Interoperability Framework (SIF) is an example of an organization working to solve these compatibility issues. The SIF is a partnership of vendors, educators, researchers, and other stakeholders that has issued definitions and specifications to govern data exchange. Vendors may elect to become SIF-certified by agreeing to exchange data following these protocols and having their systems pass a complex (and expensive) vetting process. Districts and states are increasingly including SIF-certification as a requirement in their RFPs for data system acquisition.

Modularity. Although there is not yet a single universal student data system, many commercially available and locally developed systems are large and serve many functions. Unfortunately, employing such a system may in practice not be ideal for most districts. Some districts are already hamstrung by their current system because buying data systems is like buying a house – once bought, the owner must stay in it for a while to recoup their investment. Moreover, the bigger the investment, the more it costs to change. Ideally, however, schools and districts could buy or build different modules that could plug and play with other modules. These modules would serve a variety of functions currently available in larger systems. For instance, a district or school might require three or four modules that together would perform the functions of a single student data system. Thus, buying data systems would be more like buying a blender than a house – once bought, the owner can easily and affordably upgrade or discard the module. A promising vision in this regard is offered by Midgley (2006), in advocating for open-source solutions in education.

Triangulation. Student data systems and the work of education (e.g., teaching) are continually evolving together. Technological advancements have the potential to improve teacher practice and decision making, thus opening the door to new policies for supporting teaching and learning.

At the same time, changes in policy and pedagogy change the landscape of demands placed upon data systems. At the crux of this co-evolution of teaching and technology is the issue of how educators triangulate using multiple forms of data.

Currently, much of the attention given to data by educators, commercial vendors, and policymakers has focused on standards-based accountability and its assessments. This is only one layer of data. In fact, the most effective practices involve educators individually and collectively triangulating with multiple forms of data (Datnow *et al.*, 2007; Wayman *et al.*, 2006; Wayman and Stringfield, 2006). Besides accountability-style assessments, other important data elements may include benchmark or interim assessments, classroom assessments, and professional judgment. Given better access to a broader range of appropriate data, educators report increased capacity for understanding and attending to the ‘whole student’ (Lachat and Smith, 2005; Supovitz and Klein, 2003; Wayman and Stringfield, 2006).

Future technological advancements. There are a number of new applications of technology already in place outside of education that we believe hold promise for more effective data systems. First, advancements in technology and assessment are leading to more advanced ways to interpret student learning. In many ways, these technology-mediated assessments break the mold of standardized testing, offering more creative, dynamic approaches to measuring students’ abilities. For instance, Silva (2008) describes one assessment where students are asked to develop remedies for traffic congestion caused by population growth and improvise solutions in light of research reports, budgets, and other documents. Also, Tucker (2009) describes one assessment where students are able to plan and conduct experiments with virtual helium balloons, as well as another assessment where students determine the appropriate trajectory and speed for rescuing an injured skier. These examples are different from current assessments in that: (1) both assessments go beyond looking for right or wrong answers, and (2) technology allows a more thorough, complex evaluation of student skills in ways such as applying algorithms that assess students’ sequences of decisions and actions. Whereas some educators may have previously found it difficult to weave standardized data into practice (Ingram *et al.*, 2004), assessments such as the above suggest that the data provided to educators may soon be more complex and tied to real-world skills.

Second, handheld mobile devices have become almost ubiquitous outside of schools. Outside of education, technology is mobile and comes to the user; within education, educators still go to the technology (e.g., accessing a data system through the PC in their office). Although not yet common, companies are currently marketing applications that allow teachers and principals to access data through

their handhelds while walking around the classroom, moving about the school, and interacting with parents, students, or other educators. In schools, such technologies could change how students might interact with content and each other, as well as how teachers might deliver interventions or process data about their students (Schuler, 2009).

Third, intelligent or push technologies could offer automatic recommendations based upon the data at hand and use profiles. For instance, when a user executes a particular query, the system might respond with a message noting that users who performed this query also performed another type of query, or that users who performed this query accessed a particular resource. These technologies are becoming increasingly capable at tapping into practice-based, tacit knowledge or professional intuition (Alavi and Leidner, 2001; Stenmark, 2000/2001), so it is not far-fetched to imagine data systems one day offering teachers automatic support derived from patterns in student learning, attendance, and other focus areas. That support may range from recommendations about assisting particular students to connecting educators to professional development or other colleagues.

Fourth, technology that helps connect professionals to resources and to each other is important to organizational performance (Alavi and Leidner, 2001; Malone *et al.*, 1987). Technologies can help capture and distribute expertise, and we believe this capacity holds promise for data systems. For instance, video and other multimedia are one way to effectively share best practices, often in ways that are more rich in content and craft knowledge than traditional print media (Thomas *et al.*, 2001). Similarly, social networking sites and wiki-style resources have become a popular way to connect and share information. One could imagine these applied to instructional resources and lessons, thus further pooling district knowledge and distributing that expertise collegially. Concerns about the quality of these resources may be allayed through peer commentary – the capacity to review, rate, and comment about items online has been found to effectively affect other users' attitudes and promote shared norms (Forman *et al.*, 2008).

Conclusion

Data systems provide a critical tool for leveraging student data toward educational improvement. Recent technological advancements have fueled the development of data systems facilitating the organization, access, and querying of large volumes of student data. Without the proper technology, even the most capable and interested educators may find it challenging to use data to facilitate student learning. Such technology, while necessary, is not sufficient to ensure effective data use. Rather, data use initiatives must adapt to the complex context in which

data systems are embedded, through alignment with district vision and via the provision of key institutional supports. Although research regarding the use and utility of student data systems has increased substantially over the past years, additional research is required to better understand how data systems may be used to facilitate improvement. Further, effective and efficient systems are still far from ubiquitous. It is argued that the future of student data systems will be contingent upon the ability of districts to acquire interoperable and modular data systems whose capacity can expand in accordance with technological advances.

Glossary

Access to ICT – Is the availability of ICT or “technology” for use generally within a school or home setting.

ICT – See Information and communication technology.

IEA (International Association for the Evaluation of Educational Achievement) – Is an international organization that coordinates comparative assessments and other research studies.

Information and communication technology (ICT) – Refers to any technology used for access to information or to communicate information. In particular, it encompasses multi-media generation and consumption. ICT is sometimes called “technology” or “educational technology” in the context of education.

PISA (Programme for International Student Assessment) – Is an international assessment coordinated by the OECD, the Organization for Economic Cooperation and Development.

SITES (Second International Technology in Education Study) – Was an international survey of teachers and schools coordinated by the IEA.

TIMSS (Trends in International Mathematics and Science Study) – Is an international assessment program for math and science and is coordinated by the IEA.

Use of ICT – Consists of some occasional or more frequent “hands-on” activity with a hardware or software technology application.

19 and 26 countries, respectively. In 2006, the Organization for Economic Cooperation and Development Programme for International Student Assessment (OECD PISA) included questions on technology for samples of 15-year-olds in 57 countries. These data, combined with results from two other recent international comparative studies, provide a profile of student access to technology for learning worldwide.

Student access to ICT in learning environments became a political issue in the later part of the twentieth century. Many educational policy makers came to believe that ICT augmented and enhanced learning, and investments in ICT infrastructure spread around the globe (Plomp *et al.*, 2009). This encouraged educational researchers to seek evidence regarding the instructional effectiveness of different types of technological applications to learning (cf. Cuban, 2003; Kozma, 2003; Law *et al.*, 2008). Meanwhile most education decision makers supported the acquisition of ICT because of the intuitively compelling argument that ICT provides a means of receiving and creating new knowledge (Anderson, 2008).

Conceptual Aids

Several theoretical traditions aid understanding of the spread of ICT in schools. The oldest relevant theory is the innovation adoption theory championed by Everett Rogers over 50 years ago (Rogers and Rogers, 2003). This popular theory views technology innovation as a sociological process involving successive stages of susceptibility influenced by precipitating factors. Another important theory of adaptation to technology is the technology acceptance model (TAM) that depends upon individuals' perception of its utility and ease of use (Bagozzi, 2007). In organizational and cross-cultural contexts, theories that focus upon resources and organizational decision makers are needed. For example, resource dependence theory assumes that the principal concern of organizations is to control environmental resources (Pfeffer, 1982). Anderson and Magnan (1996) applied the theory to the adoption of school networking, arguing that adoption would occur when a school perceived pressures from stakeholder groups to obtain networked resources.

Two other conceptual approaches offer insight by suggesting how resources and economics are moderated by social processes. Warschauer (2003) detailed how unique

Introduction

Recent international surveys enable us to compare a large number of countries in terms of students, access to computers and the Internet. Not only does this article report these statistics on information and communication technology (increasingly called ICT for short) access, but it also discusses their implications. In 1992 and 1998, international surveys of computer access in schools were conducted under the auspices of the International Association for the Evaluation of Educational Achievement (IEA) in

cultural contexts, especially institutional embeddedness, shape how education responds to new digital technology. Institutional embeddedness encompasses the many ways that cultural contexts, social norms, and organizational processes play a part in determining acquisition of ICT, adequacy of training and support, and effective use of ICT in learning (Warschauer, 2003). Using data from 82 countries, Drori and Jang (2003) found that national sophistication in networking was a function more of international cooperation and scientific growth than of economic development. Lack of well-developed institutional links with other countries account for instances where countries had low penetration of technology despite having the resources to acquire it.

One of the difficulties of research on technology access within education is the confusion over seemingly simple terms like access, availability, use, familiarity, and proficiency. In an attempt to be clear, we define technology access as equivalent to the availability of technology within a school or home setting. There are times when a distinction between access and availability is necessary, such as if one is studying how schools may keep certain students from using technology. Technology use consists of some minimal level of hands-on implementation of a hardware or software technology. No international study has yet conducted an assessment of ICT proficiency, but in this report, we infer that a student or teacher has some minimal level of skill or proficiency if he or she responds in the affirmative to a question about ability to perform a specific ICT-based task, for example, pending an e-mail. It is helpful to keep in mind that educational systems in some countries, especially in Eastern Europe and Asia, have long traditions of giving priority to having students learn to use ICT (acquire technology skills) rather than to using ICT to learn other subjects and skills (such as mathematics or inquiry skills).

Data Sources

Large-scale international studies assessing student competence in various areas of study provide a unique opportunity to gain information about students' access to educational resources. The findings from PISA, Trends in International Mathematics and Science Study (TIMSS), and Second International Technology in Education Study (SITES; SITES, 2006) provide an indication of the extent to which participating students from around the world have access to ICT and the ways in which they and their teachers use technology. These studies provide internationally comparable data based on rigorously designed and implemented samples of well-defined populations.

The PISA is an assessment of reading, mathematics, and science literacy among 15-year-old students, which

was developed by the OECD (OECD, 2007). Fifty-seven countries participated in PISA 2006, which encompassed an in-depth assessment of science and a less detailed assessment of reading and mathematics literacy (OECD, 2007). As part of the PISA 2006 survey, schools in all countries provided information about the computer resources available and 40 countries administered a set of questions to students about their familiarity with and confidence in using ICT (OECD, 2007).

The TIMSS is conducted every 4 years by the International Association for the Evaluation of Educational Achievement (IEA); it examines students' achievement in mathematics and science at grades 4 and 8 (Mullis *et al.*, 2008; Martin *et al.*, 2008). Fifty-nine countries participated in the 2006/7 cycle of TIMSS at either or both of grades 4 and 8: 37 at grade 4 and 50 at grade 8. Teachers provided information about the availability and use of ICT in their teaching, and students provided an indication of their access to, and use of, computers at home and at school.

The SITES was initiated by the IEA to investigate the role of ICT in education. Module 1 (SITES-M1) was a school survey of principals and technology coordinators in 26 countries (Pelgrum and Anderson, 1999). Module 2 (SITES-M2) explored the relationship between ICT and teaching through a set of 174 case studies of innovative pedagogical practices using ICT from 28 countries (Kozma, 2003). SITES 2006 was a survey of grade-8 mathematics and science teachers in 22 countries, as well as the principals and technology coordinators in their schools (Australia completed the survey as a benchmarking country in 2007). It investigated the use of ICT in mathematics and science teaching in schools, the factors associated with the use of ICT, and the relationship of ICT to pedagogical practices.

Access to ICT

ICT in Schools

The PISA 2006 school questionnaire asked principals to provide an indication of both the overall number of computers in the school and the number of computers in the school available for instructional use (OECD, 2007). On the basis of this information, the number of computers available per student can be calculated. **Table 1** contains two ratios, one for the total school computers per student and the other for total school computers available for instruction. (For each ratio, the country mean and the associated 95% confidence interval is shown. The precision of an estimate derived from a sample survey can be represented as a confidence interval (typically the 95% confidence interval) that indicates the range around the population parameter within which a survey estimate would fall on 95% occasions. The confidence interval is 1.96 times the standard error.) The countries are sorted

Average (non-OECD countries)	0.09		0.07		0.08	

^aStatistics computed from PISA database. From OECD (2007).

^bInstructional computers are computers in the school available for instructional use.

^cInternet computers are all computers in the school connected to the Internet or World Wide Web.

^dMeans are average number of computers per student averaged across schools within each country.

^eConfidence intervals indicate the range around the population parameter within which a survey estimate would fall on 95% occasions. The confidence interval is 1.96 times the standard error.

into descending order within the table by each country's total computer ratio, and then the countries are grouped into quartiles.

The rankings (and quartiles) of countries by total and instructional computer ratios are nearly identical. The principal exceptions are Korea and Iceland in that they rank considerably higher on total computers than instructional computers because such a high proportion of their school computers are used for administration. Whereas the average percent of computers used for administration across all countries was 24%, in Korea and Iceland, it was 38% and 30% respectively. These two countries are in the upper quartile for total number of computers, but in the second quartile for instructional computers. They exchange places with Switzerland and Denmark. Otherwise, the quartile assignments remain essentially the same for total computer ratio and instructional computer ratio.

On average across all the participating countries, the total number of computers per student was 0.17, indicating that there are approximately six students to each computer. However, there is a large difference between the countries with the lowest number of students per computer and those with the highest. In **Table 1** the countries have been grouped into four equal-sized groups.

Group 1 contains the countries with the highest level of computer provision in schools. These countries, which have computer to student ratios from 0.25 to 0.38, include Japan, the United States, the United Kingdom, Norway, Australia, Sweden, Austria, Korea, New Zealand, Canada, Iceland, Luxembourg, and Hong Kong. In broad terms, these countries can be thought of as having three or four students per computer.

Group 2 includes countries with the next highest level of computer provision in schools with computer to student ratios from 0.15 to 0.24. It includes countries such as Switzerland, Slovenia, Chinese Taipei, Denmark, Colombia, Belgium, Finland, Hungary, Italy, Netherlands,

Macao-China, Czech Republic, Estonia, and Qatar. In general terms these countries have typically five students per computer.

Group 3 embraces countries with slightly less abundant provision of computer resources in schools. It includes countries such as Poland, Ireland, Mexico, Spain, Israel, Germany, Greece, Portugal, Latvia, Lithuania, Slovak Republic, Uruguay, Croatia, and Turkey. The computer student ratios in these countries range from 0.08 to 0.15 which equates to more than seven students per computer.

Group 4 includes countries with the least abundant provision of computer resources in schools with computer to student ratios of 0.07 or less and on average being equivalent to more than 20 students per computer. This group includes countries such as Bulgaria, Romania, Thailand, Montenegro, Jordan, Chile, Russia, Serbia, Argentina, Indonesia, Tunisia, Brazil, Kyrgyzstan, and Azerbaijan.

Countries also differ according to the percentage of computers that are connected to the Internet, as shown in **Table 1**. Countries such as Colombia, Qatar, and Mexico have high to moderate computer ratios but relatively low ratios of Internet-connected computers. Internet technology evolved several decades after computer technology so we might expect the gap in Internet-connected computers to be greater. Taking the mean Internet computers per student as a percent of the mean computers per student, we find that in 16 countries more than 90% of school computers are connected to the Internet. In an additional 17 countries, between 80 and 90% of computers are connected to the Internet. There are 12 countries where fewer than half the school computers are connected to the Internet.

Perhaps what is most striking in these distributions in **Table 1** is the difference between computers and Internet computers in the bottom quartile of countries. In these 14 developing countries, most have five or more computers per 100 students. However, most of these countries have only 2 or even fewer Internet computers per 100 students.

ICT at Home

The findings of TIMSS 2006/7 also provide an indication of the opportunity students in grade 4 and grade 8 have to access ICT at home. Among grade 4 students, approximately 70% had access to a home computer and 56% had Internet access. For grade 8 students, the figures were almost the same: 70% and 50%. However, access to ICT resources at home varies considerably across the surveyed nations. **Table 2** provides an indication of the percentage of grade 8 students with an Internet connection at home.

There were 12 countries in which more than 80% of grade 8 students reported having an Internet connection at home: Hong Kong SAR, Norway, Sweden, Korea, England, Scotland, Australia, Chinese Taipei, Singapore, the United States, Slovenia, and Israel. There were a further 10 countries in which more than half (but fewer than 80%) of the grade 8 students had an Internet connection at home. In the remaining 26 countries, fewer than half the students had an Internet connection at home.

Using ICT

ICT Use at School

PISA 2006 provides data on the frequency with which 15-year-old students use ICT at school. The data in **Table 3** indicate that ICT use is not routine in the sense of being used every day, even in countries where there is a high level of availability. There are countries that stand out as having a significantly higher percentage of students reporting the daily use of ICT at school than in any other country: New Zealand, Australia, Denmark, Canada, Austria, Norway, and the Netherlands. These countries all have 16% or more students (i.e., one in six) reporting daily ICT use at school.

There is an association between the percentage of students reporting the daily use of ICT and the availability of ICT as reflected in the mean computer to student ratio for each country. The between-country correlation coefficient is 0.37 and would be 0.45 if Japan is not included (Japan has a high mean computer to student ratio but a low percentage of students reporting daily use of ICT). This association suggests that availability is associated with ICT use at school but that the association is far from perfect.

ICT Use at Home

As shown in **Table 3**, the daily use of ICT by 15-year-old students is much higher at home than at school. In every country, the percentage of students using ICT at home every day is greater than the percentage using it at school by a large margin. On average, less than one in ten

association between the percentages of students using ICT on a daily basis at school and at home (the correlation coefficient is 0.21).

Patterns of ICT Use

PISA 2006 provides data on the frequency with which 15-year-old students use various ICT functions. These functions embrace two groups of activities (a structure

supported by an analysis of the relationships among the responses) (OECD, 2007: 342).

The first group of functions is referred to as Internet/entertainment use and is probably close to what is referred to in some literature as social networking. It includes the following items:

- browsing the Internet for information about people, things, or ideas;

- playing games;
- using the Internet to collaborate with a group or team;
- downloading software from the Internet (including games);
- downloading music from the Internet; and
- communicating (e-mail or chat rooms).

The second group of functions is referred to as program/software use and includes the following items:

- writing documents (e.g., with Word or Word Perfect);
- using spreadsheets (e.g., Lotus 123 or MS Excel);
- drawing, painting, or using graphics programs;
- using educational software such as mathematics programs; and
- writing computer programs.

Figure 1 and Table 4 provides an indication of the percentages of 15-year-old students using each of these functions at least once or twice each week. The data are represented as the first quartile, median, and third quartile of the distribution of country percentages. From these data it is evident that the most frequently used functions are concerned with communication (e-mail or chat rooms) or browsing the Internet for information followed by downloading music and playing games.

Of the program/software functions only writing documents and using graphics programs were identified by substantial numbers of students as being used at least weekly.

Learning and ICT

There are two strands to the application of ICT in school education. The first concerns developing the ICT proficiency of students so that they can participate fully in a modern society where ICT plays such an important role in our work and social lives. The second strand refers to the use of ICT to facilitate new approaches to teaching and learning in schools and to more closely align what students do in the classrooms with what they are required to do in real life. In this sense ICT facilitates access to a wider range of information sources, enriches the possibilities of transforming information, and enhances the possibilities for communication and collaboration (Anderson, 2008).

Learning to Use ICT

Findings from PISA 2006 provide an indication of students' perceptions of their ability to carry out various ICT tasks and their confidence in performing these tasks. Students participating in PISA 2006 were asked to indicate, for a number of ICT tasks, how well they could perform that task on a scale from 'I can do this very well by myself,' through to 'I can do this with help from someone' and 'I know what this means but cannot do it' to 'I don't know what this means'. A factor analysis (using an oblique

rotation) of the student response data suggested that most of the tasks formed two groups (and could be used to generate two scales). This reflects a pattern in which students who report being able to do one of the things in a group independently are also likely to be able to do the others in the group.

The first group concerned ICT Internet tasks and comprised the following tasks (listed with the average percent correct):

- searching the Internet for information (86%);
- chatting online (78%);
- writing and sending emails (77%);
- downloading files or programs from the Internet (72%);
- downloading music from the Internet (72%); and
- attaching a file to an email message (66%).

The second group concerned ICT product development tasks and comprised the following tasks (listed with the average percent correct):

- using a word processor (e.g. to write an essay for school) (76%);
- creating a presentation (e.g. using MS PowerPoint) (57%);
- editing digital photographs or other graphic images (54%);
- using a spreadsheet to plot a graph (49%);
- creating a multimedia presentation (with sound, pictures and video) (43%);
- using software to find and get rid of computer viruses (41%);
- constructing a web page (29%); and
- creating a database (e.g. using MS Access) (27%).

In addition, there were two items that did not fit either of these groups: moving files (79%) and copying data to a CD (71%).

Using item response theory (IRT) analyses of student responses to these questions, two scales were constructed by the PISA group: confidence in ICT high-level tasks and confidence in ICT Internet tasks. **Table 5** records the mean scores and associated confidence intervals on these scales for the participating countries.

The mean scores in **Table 5** indicate a considerable difference between countries in terms of student's confidence in using ICT. The range in the country means for confidence in ICT product development tasks is 1.2 logits and in the country means for confidence in ICT Internet tasks, the range is 1.9 logits. The highest means for confidence in ICT product development tasks were recorded for Liechtenstein (but with small numbers of students), Portugal, Australia, Norway, Austria, and Canada. The lowest means on this scale were recorded for Thailand and Japan. The highest means for confidence in ICT Internet tasks were recorded for Korea, the Netherlands, and Canada, with the lowest means on this scale being recorded for Thailand, Jordan, and the Russian Federation.

Further research is needed to investigate the relation between student confidence and measured performance and to probe the antecedents of differences in ICT proficiency.

Using ICT in Teaching Mathematics and Science

SITES 2006 surveyed grade-8 mathematics and science teachers in 23 countries to find out whether they had used ICT in any type of teaching activity during that school year. **Table 6** shows the percentages of mathematics and science teachers who reported having used ICT with their classes. The lowest usage levels were reported by mathematics teachers (18%) and science teachers (16%) in South Africa. At the other end of the spectrum, very high percentages (more than 80%) of science teachers in Australia, Singapore, Hong Kong, and Alberta, and of mathematics teachers in Norway reported using ICT in their grade 8 teaching.

In 14 of the 23 countries, the percentage of teachers reporting ICT-use was significantly higher for science teachers than for mathematics teachers within the same country. In the remaining countries, the difference in ICT use between science and mathematics teachers was not statistically significant. In general, the higher the percentage of science teachers in a country using ICT, the higher the percentage of mathematics teachers using ICT in their grade 8 teaching. Furthermore, among both science and mathematics teachers, and within each country, use of ICT is higher when the teachers themselves are confident users of ICT. This suggests that an important element in the use of ICT is building the expertise of teachers. At present, the two activities where ICT was reported to be used by the highest proportions of teachers were looking up ideas and information and short-task projects. The activity in which ICT was reported to be used by the smallest proportions of both science and mathematics teachers was field study activities. The potential of ICT as a tool for data collection, management, and interpretation is not yet being realized on a wide scale.

Conclusion

A glance at the cross-national comparisons contained in our tables leaves us with the impression that national economic wealth determines school ICT infrastructure and use of technology for learning. While there is some truth to that conclusion, it fails to take into account several critical mediating factors, especially institutional embeddedness (Warschauer, 2003) and complexity of linkages within world networks (Drori and Jang, 2003). Without these social conditions in place, an ICT infrastructure may not be built, and if it is built, it may not be used effectively or even used at all.

^aStatistics computed from PISA database. From OECD (2007).^bScale scores are in logits.

Lack of well-developed institutional links with other countries account for instances where countries, for example, Columbia, had relatively low use of computers in schools, even though the schools had a lot of them. Simply putting ICT into schools does not assure that it will be used. Schools also need commitment from external communities and need to invest in support services and teacher training. Japan is another case in point; they had a lot of school computers, but relatively few students who were able to perform a variety of Internet and ICT tasks. In contrast,

Portugal had few computers but their students were relatively skilled in their ability to use the Internet and ICT.

Merely installing and using ICT in the classroom does not necessarily improve learning. Wenglinsky (1998) correlated computer use in schools with math and science achievement and found that when use included any kind of ICT use, then achievement was actually lower. However, achievement was higher when use was limited to specific applications like advanced simulations. This supports Warschauer's (2003) argument that the contextual meaning

of the learning activity plays the critical role in determining whether ICT use in learning will be successful.

These conclusions do not negate concerns for digital divides in learning. Rather, they clarify how the possession of the technology itself does not produce social gaps; how the technology is defined and integrated with social and institutional elements in schools widens or narrows the gaps between advantaged and disadvantaged groups. Van Dijk (2005) argues that the digital gaps are increasingly becoming more problematic as the knowledge-based economies continue to predominate. Servon (2002) examines attempts to bridge the digital divide in the United States and concludes that access clearly is an incomplete approach. She advocates a community-based approach in which community technology centers partner with schools and other community-building organizations.

While this report encompasses well over 50 countries, we must keep in mind that the world has upwards of 200 more countries and many of them cannot afford to put electricity and books into schools, much less ICT. Most of the poorest nations were not included in these studies, so it is not possible to systematically estimate how many students in the world lack technology access. However, given that roughly half the world's population lives on less than \$2 (US) per day, it is probably safe to speculate that less than half of the world's primary and secondary age

children attend a school in which they can access either a computer or the Internet. In recent years, a global digital divide movement has emerged out of many peoples' concern over digital inequity.

One final conclusion to draw from this analysis is that very little is known about the nature of ICT in education worldwide. The statistics are sketchy and the indicators to assessments of other subject added like after thoughts. SITES 2006 was designed to study learning pedagogy and ICT, but teachers were surveyed in only a handful of countries. Presumably, as more and more learning moves online, the need for raising the priority of conducting solid research on ICT access and learning at all levels will be recognized.

TECHNOLOGY AND LEARNING – AS A SUBJECT OF INSTRUCTION

Conceptions of Technology Literacy and Fluency

O Erstad, University of Oslo, Oslo, Norway

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Appropriation – Becoming part of one's identity as learner.

Cultural ecology of literacy – The practices involved in reading, writing, and exchanging information in online environments, as well as the values associated with such practices – cultural, social, political, and educational.

Digital competence – The confident and critical use of Information Society Technologies for work, leisure and communication. Consisting of knowledge, skills, and attitudes. These competencies are related to logical and critical thinking, to high-level information management skills, and to well developed communication skills. At the most basic level, ICT skills, comprise the use of multimedia technology to retrieve, assess, store, produce, present, and exchange information, and to communicate and participate in networks via the Internet.

Digital divide – Processes of inclusion and exclusion in the information society.

Fluency – The ability to reformulate knowledge, to express oneself creatively and appropriately, and to produce and generate information (rather than simply to comprehend it).

ICT literacy – The ability of individuals to use ICT appropriately to access, manage, integrate, and evaluate information, develop new understandings (create), and communicate with others in order to participate effectively in society.

Literate lives – What it means to be literate in a culture ('bildung'), and democratic participation.

Media/Internet literacy – The ability to access, understand and create communications in a variety of contexts.

Multiple literacies – The many different kinds of literacies needed to access, interpret, criticise, and participate in the emergent new forms of culture and society.

Technological literacies – Social practices in which texts (i.e., meaningful stretches of language) are constructed, transmitted, received, modified, shared (and otherwise engaged), within processes employing codes which are digitized electronically, primarily, through not exclusively, by means of (micro)computers.

Introduction

Change forces related to the advances of information and communication technologies (ICT) have created an increased interest in the social implications of these developments. Sociological descriptions of key processes in our societies today use terms such as the information society (Mattelart, 2003), to indicate the increased availability of information to the population at large, the knowledge society (UNESCO, 2005), to indicate an escalation in the importance of knowledge building (Bereiter, 2002) for all levels of social development, and the network society (Castells, 1996), to denote the way organizations and people work together in new ways due to the use of new technologies. All these point to the importance of knowing about information technology, which raises important questions about literacy and fluency in how we use and relate to such technologies.

The influential report *Being Fluent with Information Technology* (1999) from the National Research Council Committee on Information Technology Literacy (NRC) (commissioned by the National Science Foundation) in the US gives the following explanation of the difference between the terms literacy and fluency:

Generally, computer literacy has acquired a skills connotation, implying competency with a few of today's computer applications, such as word processing and email. Literacy is too modest a goal in the presence of rapid change, because it lacks the necessary staying power. As the technology changes by leaps and bounds, existing skills become

antiquated and there is no migration path to new skills. . . . To adapt to changes in the technology . . . involves learning sufficient foundational material to enable one to acquire new skills independently after one's formal education is complete. This requirement of a deeper understanding than is implied by the rudimentary term computer literacy motivated the committee to adopt fluency as a term connoting a higher level of competency. (NRC, 1999: 2)

As stated in this quote, it is necessary to distinguish between a more skills orientation and a higher level of competency. Other concepts like ICT literacy, digital competence, and digital literacy have later been used to indicate the same advanced use of technology as that which is denoted by fluency in the aforementioned quote, at the same time taking technological developments into consideration.

An Historical Dimension

A distinction is traditionally made between orality and literacy (Ong, 1982), with the latter being defined as reading and writing. In recent years, there has been an interest in how traditional conceptions of literacy change due to new digital technologies. An important point is that technology literacy and fluency changes over time due to sociocultural processes (Scribner and Cole, 1981). The German literary scientist and media theorist Friedrich Kittler has described this as the development of different cultural techniques over time (Kittler, 1990). Similar perspectives are reflected in sociocultural learning theories where learning is related to the use of specific artefacts and tools (Säljö, 1999).

This also points to the relationship between mastery and appropriation (Wertsch, 1998). One might, for example, master the use of the technology without having appropriated it so that it becomes a part of one's identity as a learner. This can easily be the situation when introducing digital technologies in schools without considering the broader social issues of how children and young people use such technologies outside of schools (Buckingham, 2003).

The link between computer technology and literacy in educational practices can be described as moving through three main phases. The first is the mastery phase (1960s to the mid-1980s), with an emphasis on gaining knowledge and skill on how to master the computer and different programming languages. The second is the application phase (mid-1980s to late 1990s) with a more accessible user interface, whereby the computer is perceived as an everyday tool, which can be applied to a wide range of activities in education, work, leisure, and the home. This is accompanied by the production of training materials and the appearance of mass certification schemes focusing on basic levels of ICT

competence. The third is the reflective phase (late 1990s on). Movement to this phase was stimulated by the recognition that ICT could be a vehicle to accomplish student-centered pedagogies. All students need key skills of communication, numeracy, use of ICT, and learning how to learn. In terms of the evolution of computer/ICT literacy, there is an awareness of the need for more critical, evaluative, and reflective approaches to using technology.

An important break in the conceptual understanding of literacy and technology was brought about by what has been called the new literacy studies in the 1970s and 1980s. Several researchers at that time (see, e.g., Scribner and Cole, 1981; Heath, 1983; Street, 1984; Graff, 1987) were critical about the conception of literacy as a neutral set of skills, or what Street (1984) describes as the autonomous model of literacy, which means literacy as a set of neutral skills can be used in different contexts and for different purposes to complete a set of tasks. The new literacy studies expanded this limited notion of literacy to take into account sociocultural influences. The term literacies emerged to signal the different ways people use language and the different systems of representation in social practices. One consequence was that the concept of literacy was opened up to include interaction with different text forms, which need to be studied in different social practices (Barton, 1994). In addition, this trend has been reinforced by studies of how children and youth use different media and media education in schools, where the term media literacy has been used to emphasize the need to teach children about the social and cultural influences of different media in our society (Tyner, 1998; Buckingham, 2003). The term digital literacy builds on these conceptions and is then linked to the development of digital technologies and media forms.

In the mid-1990s an international group of researchers, the New London Group (Cope and Kalantzis, 2000), gathered to make a statement on the research agenda on literacy and technologies. They argued for the use of multiliteracies as an overall term. Their research perspective implies that literacy is a many faceted thing, from Gee's (2003) work on computer games to Kress's (2003) research on multimodal literacy. In a way, this points back to what Freire and Macedo (1987) described as reading the word and the world, implying that literacy is linked to a critical analysis of the social framework in which men exist and it is embedded in social practices that are important for people. It is not only about how we use specific artefacts, but also about the social implications of such artefacts for knowledge production (Wertsch, 1998; Bereiter, 2002) and learning (DiSessa, 2001).

In her book *Literacy for Sustainable Development in the Age of Information* Rassool (1999) presents an overview of different debates on literacy during the last decades. Her point is that research perspective on technology and literacy needs to reconceptualize power structures within the information society, with an emphasis on communicative

competence in relation to democratic citizenship. Digital technologies create new possibilities for how people relate to each other, how knowledge is defined in negotiation between actors, and how it changes our conception of learning environments in which actors make meaning. Empowerment is related to the active use of different tools, which must be based upon the prerequisite that actors have the competence and critical perspective on how to use them for learning.

In the *Handbook of Literacy and Technology* (1998), with the subtitle ‘Transformations in a post-typographic world’, David Reinking *et al.* present several perspectives on how the development of digital technologies changes conceptions of text, of readers and writers, and ultimately of literacy itself. This implies that technology literacy and fluency relate to changes in traditional cultural techniques such as reading and writing, and yet meanwhile opening up new dimensions to what it means to be a competent reader and writer in our culture.

Definitions and Conceptions

What exactly should be included within the conceptual domain of literacy has become increasingly fuzzy, especially among those educators and researchers whose professional interests emanate from that term (Reinking, 1998: xiv). This is, of course, due to the fact that literacy is not a static term but relates to technological innovations, and cultural and political strategies and developments.

In the report *Digital transformations: A framework for ICT literacy* (ETS, 2002), an international group of scholars, initiated by the Educational Testing Service (ETS) in the US, decided to use the concept of ICT literacy instead of other terms such as competency, ability, or fluency used by others. This indicates that concepts, conceptions, and definitions within this field changes over time. It is, however, possible to define two main conceptions of technology literacy and fluency. One is oriented toward skills needed to operate the technology, and the other toward social practices where technology is embedded.

Lankshear and Knobel (2006) describe, on the one hand, the traditional conception of digital literacy as the in thing, implying that it is about relating to the technology itself, as seen in the way Gilster (1997) argues for digital literacy or Potter (2001) for media literacy. The last decade of research has been on trying to map the interrelationship between cognition and the use of technological tools (see, e.g., Lajoie, 2000; Gärdenfors and Johansson, 2005), which builds an understanding of literacy and fluency as a combination between certain technologies and cognitions.

On the other hand, Lankshear and Knobel (2006) argue for a focus on digital literacies as social practices, as technology used in certain social and cultural settings.

To a larger extent than the former, this conception sees literacy and learning as embedded in social practices inside and outside of schools, for example, in the case of young people playing video games (Gee, 2003). Lankshear (1997) proposes a definition of technological literacies in line with this thinking:

Technological literacies may be defined as social practices in which texts (i.e. meaningful stretches of language) are constructed, transmitted, received, modified, shared (and otherwise engaged), within processes employing codes which are digitized electronically, primarily, though not exclusively, by means of (micro)computers Our main interest . . . is with *extant communications and practices of reading, writing, viewing, manipulating, communicating, etc. digital texts*, and their potential integration into critical forms of literate practice. (1997: 141)

This definition is not bound by certain technologies. It proposes to study literacies in practice (what people do with technologies and digital texts), and not as something predescribed, indicating that we need to understand what people are already practicing concerning technological literacies and what the role of education should be in employing such literacies for new knowledge levels.

In her book *Literacy in a Digital World* (1998), Kathleen Tyner studies some of the elements of a modern interpretation of literacy both related to what she terms tool literacies, to indicate the necessary skills to be able to use the technology, and literacies of representations, to describe the knowledge of how to take advantage of the possibilities that different forms of representation give the users, especially the new information and communication technologies. This indicates a similar division between a tool orientation of literacy and a more reflective social process.

Ofcom, the independent regulator and competition authority for the UK communications industries, initiated several reviews on media and Internet literacy defining it as “the ability to access, understand and create communications in a variety of contexts” (Buckingham, 2004: 2). This definition indicates different dimensions of technology literacy and fluency, with basic access as the first and foremost. Understanding includes both comprehension and critique. Moreover, creation includes both interaction with media and creation of media by the public (Livingstone *et al.*, 2004).

On a broader cultural level, Selfe and Hawisher (2004: 5) discuss what they refer to as cultural ecology of literacy, examining how factors such as age, gender, ethnic and racial group, and geographical background interplay with historical, cultural, economic, and political factors to affect a person’s development of technological literacy. Referring to the conflicting views on defining technological literacies, they propose their definition as “the practices involved in reading, writing, and exchanging information in online environments, as well as the values associated with such

practices – cultural, social, political, and educational” (Self and Hawisher, 2004: 5).

Toward Multiple Literacies

Some terms are oriented toward specific areas of people’s use of technology, while other terms are more general, such as media, ICT, and digital. These broader terms can be said to draw upon other terms, which have gained new or increased relevance with the emergence of digital environments. Some even use the alternative term *electracy* (Ulmer, 2003; Erstad, 2003) to indicate a break from literacy and reading and writing toward using electronic media. The following are a few specific terms that seem to be important at present:

- *Information literacy*. This has developed in the US since the late 1980s as a re-focusing of bibliographic instruction in academic libraries. It indicates both the ability to recognize when information is needed and how to locate, evaluate, and use effectively the needed information (see also Bawden, 2001). With the increasing importance of the World Wide Web as a source of information, the idea of information literacy has gained more centrality.
- *Visual literacy*. This has developed out of art criticism and art education, and was initially concerned with both the physiology and psychology of perception, and the way in which artists and designers have used perspective, ratio, light, color, and other techniques of visual communication (Messaris, 1994). Visual images have of course always been a powerful medium for the interpretation of information and the communication of meaning. Yet today, the wealth and complexity of visual imagery is stronger than ever.
- *Multimodal literacy*. Kress argues that in the posttext language is itself being affected by visual forms. “The screen more than the page is now the dominant site of representation and communication in general, so that even in writing, things cannot be left there The screen is the site of the image, and the logic of the image dominates the semiotic organisation of the screen” (Kress, 2003: 65).
- *Communication literacy*. This emphasizes communication as a key element in the educative process. This perspective builds on the increased interest in the collaborative learning as seen in Computer Supported Collaborative Learning (CSCL). Learners must be able to communicate effectively as individuals and work collaboratively in groups.

Some literacy theorists have sought to hold together the many new literacies under some umbrella concepts stressing the plurality of literacies, such as *multiliteracies* (Cope and Kalantzis, 2000, 2009; Snyder, 2002) and

metamedia literacy (Lemke, 1998). According to Kellner (2002: 163), “The term ‘multiple literacies’ points to the many different kinds of literacies needed to access, interpret, criticise, and participate in the emergent new forms of culture and society.” Kress (2003) however argues against the multiplicity of literacies, suggesting that it leads to serious conceptual confusion. He believes that instead of taking this path, it is necessary to develop a new theoretical framework for literacy, which can use a single set of concepts to address the various aspects of literacy. Although Tyner (1998: 63–68) recognizes the need to refer to *multiliteracies*, she feels that the dangers of oversimplification, and of isolation of literacies that are complementary and should therefore be linked, mean that constellations of linked literacies should be clearly identified and the relationships drawn out, and that the broad heading literacy be retained as an overarching concept.

Developing Frameworks

The different definitions and conceptions of technology literacy and fluency have been related to certain frameworks and the development of standards for educational practices. In January 2001, the ETS assembled a panel to develop a workable framework for ICT literacy. The outcome was the report *Digital Transformation. A Framework for ICT Literacy* (ETS, 2002). Building on this document one might, as the Australian authorities have done (Ainley *et al.*, 2006), define ICT literacy as

the ability of individuals to use ICT appropriately to access, manage, integrate and evaluate information, develop new understandings (create), and communicate with others in order to participate effectively in society.

The concepts mentioned are described in **Figure 1**.

All of these terms are oriented toward information handling. They also relate to the issues of problem solving and self-regulation. This consists of more general competencies that are not connected to specific subjects in school or specific contents in subjects. They can be taught and are not only related to what is learned in school settings, but also to situations outside the school.

Similar points are made in the earlier report *Being Fluent with Information Technology* (NRC, 1999). Fluency in Information Technology (FITness) covers three types of knowledge:

1. Contemporary skills: “the ability to use particular (and contemporary) hardware or software resources to accomplish information processing tasks” (NRC, 1999: 18). Naturally these skills will change over time as hardware and software evolve.
2. Foundational concepts: “the basic principles and ideas of computers, networks, and information” (NRC, 1999: 2–3). These include computer structure, information systems,

<i>Item</i>	<i>Description</i>
Access	Knowing about and knowing how to collect and/or retrieve information
Manage	Applying an existing organizational or classification scheme
Integrate	Interpreting and representing information. It involves summarizing, comparing and contrasting
Evaluate	Making judgments about the quality, relevance, usefulness, or efficiency of information
Create	Generating information by adapting, applying, designing, inventing, or authoring information
Communicate	Processing information in a way that highlights main points and process it to others

Figure 1 Key concepts of ICT literacy. Data from Australian Report, written by Ainley *et al.* (2006), but which a Ministry report by MCEETYA.

networks, modeling, algorithmic thinking and programming, and the limitations of IT and its social impact.

3. Intellectual capabilities, which “integrate knowledge specific to information technology with problem domains of personal interest to individuals” (NRC, 1999: 20). These are general thinking skills which might be recognizable in many disciplines, and include sustained reasoning, managing complexity, testing solutions, evaluating information, collaboration, anticipating change, and expecting the unexpected.

The concept of fluency in this connotes the ability to reformulate knowledge, to express oneself creatively and appropriately, and to produce and generate information (rather than simply to comprehend it) (NRC, 1999: 9).

Other frameworks have used digital competence as an overall term. One example is the working group on key competences of the European Commission Education and Training 2010. This program identifies digital competence as one of the eight domains of key competences, defining it as “the confident and critical use of Information Society Technologies for work, leisure and communication” (European Commission, 2004: 14). Information society technologies (IST) are defined as “offering services based on the use of Information and Communication technologies (ICT), the Internet, digital content, electronic media, etc., via, for example, a personal computer, a mobile telephone, an electronic banking machine, an eBook, digital television, etc.” (European Commission, 2004). Digital competence is regarded as consisting of knowledge, skills, and attitudes, as shown in **Figure 2**.

Competence here refers to a combination of skills, knowledge, aptitudes, and attitudes, and the disposition to learn in addition to know how (European Commission, 2004: 3). Several initiatives for such standards are now being developed around the world. They are defined as important tools for teachers in the way they use technologies in their educational practices. It is, however, important

that such standards do not become static tests, but can relate to technological and cultural change processes.

In addition, it is important to stress that technology literacy and fluency is related to situational embedding, that is, the use of technology within life situations. To understand such processes we have to look at different contexts where literacy is practiced and given meaning. This is especially important when relating it to how children and young persons use digital technologies.

Several studies show that young people gain most of their competence in using digital technologies outside the formal institutions of knowledge building (Livingstone, 2002; Buckingham, 2003; Alvermann, 2002). Thus, digital competence among young people today is of direct relevance to discussions about learning in schools, and it seriously confronts earlier conceptions of literacy and learning.

Building on the above discussion, one might see conceptions of technology, literacy, and fluency as three different aspects that are brought together (**Figure 3**).

How we relate to texts is changing due to the fact that new genres and multimodal expressions are developing. New demands are then put on our competencies, fluency, and literacies in using such texts. Furthermore, such processes are framed within certain sociocultural practices where literacies are conceptualized.

Implications

Conceptions of technology literacy and fluency also open up broader implications.

Literate Lives

This refers to issues of what it means to be literate in a culture. It has a philosophical connotation to the German term *bildung*. Related to digital technologies, *bildung* suggests an integrated, holistic approach toward cultural competence.

Framework for key competences in a knowledge-based society				
Domain	Definition of the competence	The competence consists of the following elements of knowledge, skills, and attitudes as appropriate to the context		
		Knowledge	Skills	Attitudes
Digital competence	<p>Digital competence involves the confident and critical use of Information Society Technologies (IST)¹⁸ for work, leisure and communication.</p> <p>These competences are related to logical and critical thinking, to high-level information management skills, and to well developed communication skills.</p> <p>At the most basic level, ICT skills comprise the use of multimedia technology to retrieve, assess, store, produce, present and exchange information, and to communicate and participate in networks via the Internet.</p>	<p>Sound understanding of the nature, role and opportunities of IST in everyday contexts comprises¹⁹:</p> <ul style="list-style-type: none"> Understanding the main computer applications, including word processing, spreadsheets, databases, information storage and management. Awareness of the opportunities given by the use of Internet and communication via electronic media (e-mail, video conferencing, other network tools); and the differences between the real and virtual world. Understanding the potential of IST to support creativity and innovation for personal fulfilment, social inclusion and employability. Basic understanding of the reliability and validity of the information available (accessibility/acceptability) and awareness of the need to respect ethical principles in the interactive use of IST. 	<p>As IST have many and growing applications in everyday life, such as learning and leisure activities, the required skills comprise:</p> <ul style="list-style-type: none"> Ability to search, collect and process (create, organize, distinguish relevant from irrelevant, subjective from objective, real from virtual) electronic information, data and concepts and to use them in a systematic way. Ability to use appropriate aids (presentations, graphs, charts, and maps) to produce, present or understand complex information. Ability to access and search a website and to use Internet based services such as discussion fora and e-mail. Ability to use IST to support critical thinking, creativity and innovation in different contexts at home, leisure, and work. 	<ul style="list-style-type: none"> Propensity to use IST to work autonomously and in teams; critical and reflective attitude in the assessment of available information. Positive attitude and sensitivity to safe and responsible use of the Internet, including privacy issues and cultural differences. Interest in using IST to broaden horizons by taking part in communities and networks for cultural, social and professional purposes.

Figure 2 Digital competence as defined by the EC key competences working group of the Education and Training 2010 Programme. From *Key Competences for Lifelong Learning: A European Reference Framework*. Directorate-General for Education and Culture, p 14. Copyright European Union, 2004.

Figure 3 Three aspects that influence conceptions of technology, literacy, and fluency.

Traditionally conceived in an elitist way as a distinction between the literate and the illiterate, the technological development changes conceptions of what it means to be literate and enlightened in a technological culture.

Literate lives also refer to democracy and participation. In a society where digital technologies are having an impact on all aspects of social life, a question remains about how it might influence democratic processes, and what it means to be an informed citizen (e-citizenship).

These sentiments are echoed by the Declaration of Principles of the World Summit on the Information Society (2003):

Each person should have the opportunity to acquire the necessary skills and knowledge in order to understand, participate actively in, and benefit fully from, the Information Society and the knowledge economy. ... Awareness and literacy in ICTs are an essential foundation in this regard. (WSIS, 2003: §29, 31)

Digital Divide

Another important issue is the growing concern about digital divides in the world and within societies. In several of his texts, Warschauer (2007) has raised questions about inclusion and exclusion in the information society. Who are the winners and losers in this society? In this sense, literacy issues are redefined in relation to the challenges of technology-saturated societies, and furthermore, to the role of education and schooling as social processes of overcoming digital divides.

Curriculum Change

In several countries (e.g., Norway, Finland, Singapore, and New Zealand) technology literacy or digital competence has been written into school curricula as a key competence area. Issues of technology and education have thus moved from curriculum matters of access, implementation, and teacher competence, to issues of knowledge building and literacy when using technology. However, within the research field, there is still a need to specify how technology literacy and fluency may impact learning processes in schools.

Assessment

Another implication is the role of ICT and assessment as a driving force for educational change (McFarlane, 2003).

Without changes in the way we assess students and what we assess, technology literacy and fluency can easily become mere good intentions with little real impact on literacy practices in education. Some efforts have been initiated. For instance, the National Educational Technology Standards in the US have developed an online test for students and teachers to measure ICT literacy, which is based on certain standards and definitions mentioned earlier. According to these standards, all students should have opportunities to demonstrate the following performances: basic operations and concepts; social, ethical, and human issues; technology productivity tools; technology communications tools; technology research tools; technology problem-solving and decision-making tools. Other approaches toward performance assessment using ICT are now being tried out in Australia and Hong Kong (Ainley *et al.*, 2005).

Future Perspectives

Although there are many approaches to literacy, there is now a consensus that literacy is a social phenomenon as well as an individual characteristic. Literacy development is to a large extent linked to economic growth and the development of civic consciousness and political maturity. The literate person lives within the literate society:

Literacy is no longer exclusively understood as an individual transformation, but as a contextual and societal one. Increasingly, reference is made to the importance of rich literate environments – public or private milieus with abundant written documents (e.g. books, magazines and newspapers), visual materials (e.g. signs, posters and handbills), or communication and electronic media. (UNESCO, 2005: 159)

An important driving force today is the processes of convergence. This relates to how technologies merge, how production of content changes, how new text formats are developed, and how the users relate to information as part of communication networks in different ways. All this brings about new challenges for how we conceptualize technology literacy and fluency. As this article shows, the different perspectives reflect the complexity of skills, competencies, and literacies for being a citizen in the twenty-first century.

Issues of literacy and fluency in relation to different technologies also raise some key issues about how our education system is tuned to the challenges of the knowledge society. Conceptions of technology literacy and fluency in a future perspective would then be just as much about knowledge development and the educational framework as about using specific technologies.

Glossary

Effect size – A measure of the strength of the relationship between two variables in a statistical population, or a sample-based estimate of that quantity. The magnitude is often expressed in terms of the difference between two means divided by a standard deviation for the data.

This article describes how technology can be and is being used to support the process of implementing quality assessment, especially formative assessment. First, it considers what is meant by formative assessment, why it is such an important assessment activity, and how technology might support implementation of a range of assessment processes. The discussion includes some of the issues related to the implementation and use of technology-based tools and systems for formative functions. Then it presents examples of technology-based applications, including large-scale, district- or state-level commercial systems that have come into prominence in the last few years as well as small-scale, content- and classroom-based diagnostic systems often derived from cognitive and instructional research. The article concludes with a brief discussion of current opportunities and possibilities for the future.

A Consideration of Definitions, Timescales, Users, and Uses

Wise instructional decision making and differentiated instruction depend on teachers being able to take evidence of what students know and can do, compare it to expected learning outcomes, and create learning opportunities that reflect appropriate next steps for individual students (Donovan and Pellegrino, 2004; NCTM, 1995,

2000; Webb, 1997). Quality classroom-based assessment can support such a process and serve as a critical component of effective teaching, typically leading to enhanced student learning outcomes (Black *et al.*, 2004; Pellegrino, *et al.*, 2001; Shepard, 2000; Stiggins, 2001, 2002). For example, there is now a substantial body of evidence from K-12 classrooms showing that quality formative assessment practices enhance teaching effectiveness and produce student academic achievement gains ranging from 1/2 to a full course grade, reflecting effect sizes of 0.4 to 0.7 or higher (Black and Wiliam, 1998). (Such effect sizes reflect higher performance in conditions with formative assessment relative to control conditions without such assessment. The difference is on the order of 0.4 to 0.7 standard deviations relative to the mean performance of the control conditions.) Similar findings have been obtained in studies conducted within higher education settings (Nyquist, 2003).

Often it is assumed that classroom assessment is synonymous with formative assessment, and that large-scale assessment, such as district-, state-, or national-level tests, is synonymous with summative assessment. In fact, summative and formative functions can be identified for most assessment activities regardless of the level at which they are operating (see, e.g., Pellegrino and Hickey, 2006). As highlighted in influential discussions by Sadler (1989) and Black and Wiliam (1998), assessment is ultimately about feedback. These and many other articles have led to widespread appreciation that assessment is maximally valuable to educators to the extent that it generates useful information for advancing learning and instruction so long as the information is then acted upon. It is the latter feature – the use of assessment to directly improve the outcomes of teaching and learning that makes something formative.

Drawing from the work of Lemke (2000), it is apparent that different assessment practices can be understood as operating at different timescales spanning minutes, days,

weeks, months, and years. Timescale is important because the different competencies that various assessments aim to measure (and therefore the appropriate timing for being impacted by feedback) are timescale specific. What teachers and students say in class constitute verbal exchanges; these exchanges make up the lesson; a sequence of lessons make up the unit; units form a curriculum, and the curricula form an education. Each of these elements operates on a different cycle or timescale: second to second, day to day, month to month, and year to year. All can be potentially impacted by assessment and thus there is a tendency to confuse the timescale of the assessment with the function served – formative or summative. It is how useable the information may be, combined with how the information is used, that defines the function of an assessment as formative or summative. Given that there are formative uses for assessments that operate at different timescales, it must be noted that evidence of the positive impact of formative assessment on student learning outcomes has been most clearly obtained for cases where it is very close and proximal to the timing of instruction (see also Ruiz-Primo *et al.*, 2002). The issue of timescale and proximity to instruction is one that we return to in the sequel when we consider technology-based systems that have been developed commercially for use at school and district levels versus those that are much closer to curricular content and the instructional process.

As indicated above, assessment results allow educators and policymakers to address a variety of questions about how a district, school, program, group, or individual is performing. The goal is to make assessment results available to the right people, in the right form, at the right time so that assessment informs decisions and actions. Before individuals can answer questions, they must have the assessment results to work with. The goal is to collect the results in timely and efficient ways that allow them to answer their most important questions. Finally, it is not enough to answer questions – they must act on those answers. The goal is to help people use assessment results to make decisions about what actions they should take. A technology infrastructure is a collection of tools and processes that help people achieve these goals.

There are a variety of roles that technology might play in this complex process. It is likely that a collection of tools, rather than a single tool, will fulfill these roles. However, information must flow appropriately between tools to support the differing needs of different people. **Table 1** lists some of the roles that technology might play in the assessment process. Part of designing and implementing an assessment system for a school, district, or state is determining the appropriate roles for technology in that system.

Given the range of assessment tasks and data on student performance that are potentially available within the

Table 1 Functions of technology in assisting the assessment process

<i>Collecting</i>	<i>Reporting</i>	<i>Using</i>
Create assessment	Manage assessment data	Identify resources
Administer assessment	Analyze assessment data	Identify possible actions
Collect assessment data	Create reports	Design professional development
Score assessment	Distribute reports	

Source: Reproduced from Table 2.3, p45, in Pellegrino, J. W., & Goldman, S. R. (2007). *Beyond rhetoric: Realities and complexities of integrating assessment into teaching and learning*. In C. Dwyer (Ed). *The future of assessment: Shaping teaching and learning* (pp. 7–52). Mahwah, NJ: Erlbaum.

educational context, it is clear that the processes of collecting, scoring, and interpreting assessment data and then longitudinally tracking student performance are formidable. It is highly unlikely that any teacher, principal, or district or state administrator would be able to be successful in using all the assessment data available to him or her without the support of technology tools to assist in such a process across a variety of assessment levels and timeframes. Thus, an important direction for development and implementation of assessment systems is the design of specific and general technology-based tools that can assist educators in managing the assessment process. Ideally, one would like to have a system with extensive diagnostic assessment capability. That is potentially far off, however, and requires considerable research and development efforts. Even so, some very basic data collection, data entry, and data management tools can be of great assistance to teachers, principals, and others. The design and deployment of even simple technology tools must ultimately rely on a technology infrastructure that connects the classroom to powerful database management and information retrieval systems that operate within and across schools and systems. This is especially true when the classroom assessment data are viewed as part of a coordinated system of assessment data that would potentially include curriculum-embedded assessment information, benchmark assessment data, and state-level test data.

The next section describes two distinct classes of technology-based systems and tools designed to support the formative functions of assessment. The key distinction between them is how close the assessment is to integration with classroom curriculum and instruction – very close and proximal (tied to specific curriculum content) versus distal (tied to state or national standards).

Examples of Technology-Based Assessment Resources and Tools

Systems Driven by Content Standards – Large-Scale, Commercial Products

In the United States the number of summative assessments has been increasing recently with the authorization of No Child Left Behind Act (NCLB) at the federal level. In preparation for statewide exams required under NCLB, school districts are turning to more frequent in-house assessments that can produce data useful for decision making. Schools that effectively collect and utilize data have been shown to improve student achievement. This culture of using data to improve student achievement involves making decisions based on a variety of data such as instructional practice, goal implementation, achievement, and assessment data (Datnow *et al.*, 2007).

Perie *et al.* (in press) discuss the fact that while most assessment systems created commercially are marketed as formative assessment systems, they should properly be classified as interim assessment systems. Typically, these systems are either web- or server-based software with item banks that teachers use to provide periodic checks of student understanding. Those periodic checks can be at any designated time – monthly, tri-monthly, etc. – but rarely provide diagnostic feedback that teachers and students can use to address immediate deficiencies. In reviewing several commercially available assessment systems, we found this to be true with few exceptions.

Often these assessment systems are constructed to include items from the core subject areas and claim to be aligned to state or national standards. Some companies will specify that their items are aligned with the standards of a specific state (such as California) or those of the National Council of Teachers of Mathematics (NCTM, 2000). In either case, school officials need to check alignment claims for themselves and evaluate the assessment items' alignment with their own local standards and purposes. To the extent that assessment systems are aligned with state standards, they have the potential to create a practice summative assessment mirroring the yearly state exam. Most commercial assessment systems are touted as providing diagnostic, formative, and summative assessments, all from the same item bank. The difference in the assessments comes from the timing of the assessments, the frequency, and how the results are used.

A key theme found throughout evaluation of assessment companies' technology products for creating and dealing with assessment data, is the speed and ease of scoring. The process of formative assessment begins when assessment results are available with a very short turnaround time. From a commercial perspective, it seems that it is the turnaround time that qualifies an assessment as formative rather than the data's usefulness in providing feedback to both the teacher and the student. In some cases, the

predictive validity of the assessment also places it within the formative realm, since proficiency on the state NCLB assessments is considered the learning goal. If assessments are given early enough, teachers can use assessment data to diagnose student deficiencies and address them before administration of the state test. District officials like the ability to give an assessment at the beginning of the year for student placement purposes, and in the middle and end of the year for evaluative purposes. Teachers like the automatic scoring, ease of test construction, and reporting aspects.

These technology-based assessment systems rely on speed and an abundance of reporting options, but are mostly tied specifically to state and national standards rather than to an individual school's curriculum. Knowing the standards in which students are having difficulty is just a first step in a process of unpacking what the standards mean, identifying where they are taught within the curriculum, and connecting items with those aspects of the curriculum. As we noted earlier, formative assessment is not effectively assessment for learning if it is not utilized by the classroom teacher immediately to inform instruction and address student deficiencies.

While most assessment systems contain item banks that are aligned to content standards, it is unknown, but highly doubtful, that these item banks are fully developed to the point where an effective assessment can be constructed that can diagnose both what and why a student does not understand. This is the type of actionable information that teachers can use to change their instructional methods and goals so that students can succeed. In order for an assessment to do this, it has to be constructed in such a way that it includes a sufficient set of items with carefully selected distracters related to a single concept to pinpoint student problems and misconceptions. Typically, large-scale standardized assessments contain one to three items related to a target content standard and cannot identify student misconceptions. If the goal is to provide formative assessment, the item banks should be analyzed to verify their capabilities beyond creating small versions of a large scale standardized assessment, as well as their quality.

Table 2 presents a nonexhaustive set of technology-based assessment resources keyed to content standards. Little has been written regarding the use of these systems although some manufacturers have conducted small studies on the effectiveness of the assessments included within their system. These studies involve both the reliability of the assessment and an aspect of validity and are proudly displayed on company websites. Other studies involve the use of assessment in a general sense such as the effect of the frequency of assessments (Bangert-Drowns *et al.*, 1991; Kika *et al.*, 1992; Kling *et al.*, 2005; Martinez and Martinez, 1992). Further investigations are needed, however, in order to understand how best to use these systems, what

may be missing from them, and what a district should look for if purchasing a system.

Small-Scale, Research-Based (diagnostic) Systems

Among the most intriguing applications of technology are those that extend the nature of the problems that can be presented and the knowledge and cognitive processes that can be assessed. By enriching task environments through the use of multimedia, interactivity, and control over the stimulus display, it is possible to assess a much wider array of cognitive competencies than has heretofore been feasible. New capabilities enabled by technology include directly assessing problem-solving skills, making visible sequences of actions taken by learners in solving problems, and modeling and simulating complex reasoning tasks. Technology also makes possible data collection on concept organization and other aspects of students' knowledge structures, as well as representations of their participation in discussions and group projects. A significant contribution of technology has been to the design of systems for implementing sophisticated classroom-based formative assessment practices. Technology-based systems have been developed to support individualized instruction by extracting key features of learners' responses, analyzing patterns of correct and incorrect reasoning, and providing rapid and informative feedback to both student and teacher.

Given what we have noted above about the affordances of technology, it is relatively easy to differentiate the present class of technology-based assessment systems

Table 3 Research-based assessment resources

relative to the large-scale systems discussed in the prior subsection. What unifies these systems as a group and separates them from the systems described above is that they are each based on an underlying analysis or model of learning and performance in the content domain and they typically make use of a range of task and performance formats, and yield more complex and multifaceted forms of data. These systems often explicitly promote or provide formative interventions and very detailed diagnoses of student understanding. The strong cognitive emphasis underlying the design of these systems results in a much deeper assessment, but this depth often occurs at the expense of breadth. That is, these systems are typically not able to assess as much of a content area as the large-scale systems, but they are often richer in diagnostic and instructionally useful information.

Table 3 presents the names of example research-based assessment resources and systems covering the reading, science, and mathematics content domains. This is by no means a comprehensive list of such systems and resources. We have, however, attempted to represent the variety of options that are becoming available. For several of these examples there is a substantial base of published work related to their implementation in classrooms and on their effectiveness in improving student learning and performance (see, e.g., Good *et al.*, 2001; Goodman *et al.*, 2006; Feng and Heffernan, 2005; Kintsch *et al.*, 2000; Minstrell and Kraus, 2005; Ritter *et al.*, 2007; Stevens and Dexter, 2003; Vendliniski and Stevens, 2002).

Summary and Implications

It is an exciting time in the field of assessment for several reasons. First, individuals have realized that there are multiple roles for assessment to play in the educational process and that one of the most valuable roles is the formative function of assisting student learning. Second, cognitive research and theory have provided us with rich models and representations of how students understand many of the key concepts in the curriculum, how they develop knowledge structures, and how to analyze and understand simple and complex aspects of student performance. Third, technology makes it possible for us to present students with a much wider array of tasks and

situations where students can learn and where they can show us what they know and how they know it. Thus, there is an interesting and powerful confluence among theory, research, technology and practice, especially as regards the integration of curriculum, instruction, and assessment.

In numerous areas of the curriculum, information technologies are changing what is taught, when and how it is taught, and what students are expected to be able to do to demonstrate their knowledge and skill. These changes in turn are stimulating people to rethink what is assessed, how that information is obtained, and how it is fed back into the educational process in a productive and timely way. This situation creates opportunities to center curriculum, instruction, and assessment around cognitive principles. With technology, assessment can become richer, more timely, and more seamlessly interwoven with multiple aspects of curriculum and instruction. As discussed earlier, the most useful kinds of assessment for enhancing student learning often support a process of individualized instruction, allow for student interaction, collect rich diagnostic data, and provide timely feedback. The demands and complexity of these types of assessment can be quite substantial, but technology makes them feasible. In diagnostic assessments of individual learning, for example, significant amounts of information must be collected, interpreted, and reported. No individual, whether a classroom teacher or other user of assessment data, could realistically be expected to handle the information flow, analysis demands, and decision-making burdens involved without technological support. Thus, technology removes some of the constraints that previously made high-quality formative assessment difficult or impractical for a classroom teacher. Several examples discussed earlier illustrate how technology can help infuse ongoing formative assessment into the learning process.

Clearly, we are just beginning to see how to harness technology to support the formative and summative functions of assessment. A great deal needs to be learned about the quality and efficacy of systems operating at both the large-scale level and the small-scale level. Not the least of the concerns facing us is integrating assessment tools and practices into the educational system and the practices of teachers. However, we must also take note of the fact that extremely powerful information technologies are becoming as ubiquitous in educational settings as they are in other aspects of people's daily lives. They are almost certain to continue to provoke fundamental changes in learning environments at all levels of the education system. Many of the implications of technology are beyond people's speculative capacity. Little more than 15 years ago, for example, few could have predicted the sweeping effects of the Internet on education and other segments of society. The range of computational devices and their applications is expanding exponentially, fundamentally

changing how people think about communication, connectivity, information systems, educational practices, and the role of technology in society.

Technology for Large-Scale Assessment

R E Bennett, Educational Testing Service, Princeton, NJ, USA

© 2010 Elsevier Ltd. All rights reserved.

This article presents a conceptual framework for understanding the recent evolution of technology for large-scale assessment, gives examples of applications that illustrate that evolution, and identifies issues associated with the use of technology in large-scale assessment. (For purposes of the article, the term, technology, is taken in its narrow sense to refer to computer, network, software, and related capabilities. The term, large-scale assessment, is used to refer to professionally designed tests administered to large numbers of students under standardized conditions for making a variety of educational decisions.) **Table 1** presents a framework adapted from Bennett (1998), which describes three generations of large-scale assessment that differ in the degree to which they capitalize on advances in technology. The first generation is one of infrastructure building in which the hardware, software, and facilities for delivering tests by computer are put into place. Because this is an initial developmental phase, tests of this generation may be more costly than their paper versions. Tests of this generation take relatively limited advantage of technology. They measure traditional skills, use test designs and item formats closely resembling those of paper administration, are given in centers (e.g., commercial or school labs) using stand-alone computers or machines connected via a local area network, are administered as one-time measurement events, and primarily serve institutional (as opposed to individual) needs. Among the few advanced capabilities such tests are likely to offer is adaptive administration, where the measure is dynamically customized to match the skill level of the examinee taking it. (In adaptive testing, the examinee's skill level is re-estimated after each item is administered. The next item to be administered is then chosen based, in part, on that updated skill-level estimate.)

Next-generation tests represent a qualitative change from those of the first generation. Although they continue to serve institutional needs primarily and to be administered in centers, they leverage technology for such item formats as constructed response and for initial forays into the assessment of proficiencies not directly measurable through conventional means (e.g., skill in electronic information search). (A constructed-response item is a question for which the examinee must generate a response instead of selecting it from a short list of options.) Because the infrastructure has been substantially established, next-generation tests also can more effectively use technology to improve efficiency. They may employ technology to generate test items or to score constructed responses

automatically, and utilize the Internet, not only for test delivery, but for other internal processes (e.g., human performance scoring), as well as for customer interaction (e.g., examinee scheduling, score reporting).

The third generation, Generation R, represents reinvention in the sense that the purposes, processes, and results of testing differ in important ways from those of the two previous generations. Through the affordances of technology, Generation R tests are grounded in modern cognitive-scientific research; become more integrated with instruction, sampling performance repeatedly over time; employ complex simulations to better model real-world tasks; permit more natural interaction with computers; allow for the measurement of new skills in more sophisticated ways; and come to serve both institutional and individual needs.

We now turn to a discussion of examples within each of the three generations and of the issues those applications raise. In considering these examples, it should be noted that few fit unambiguously into a single generation because testing programs advance over time in their use of technology and because a program may simultaneously incorporate characteristics of more than one generation.

First-Generation Computer-Based Tests

The first generation of technology-based educational testing is in place to a significant degree for several assessment purposes. These purposes include college course placement, graduate and professional admissions, teacher certification, state accountability, and school achievement monitoring. With the introduction of the College Board's Computerized Placement Tests in 1986 (now ACCUPLACER) and of ACT's COMPASS, college course placement was one of the first purposes served by large-scale computer-based educational assessment. These adaptive tests are given millions of times per year at very low cost because institutional users take full responsibility for scheduling and administration, and because the low-stakes nature of the assessment purpose does not require the frequent creation of new test items.

Computerized testing for teacher certification dates to the early 1990s with the introduction of Praxis I, now the Praxis I: Pre-Professional Skills Assessments (PPST). This nationally administered test is intended for use by colleges and universities to evaluate individuals for entry into US teacher education programs. It is required for

Table 1 Three generations of large-scale educational assessment

Generation	Key characteristics
First-generation computer-based tests (infrastructure building)	<ol style="list-style-type: none"> 1. Primarily serve institutional needs 2. Measure traditional skills and use test designs and item formats closely resembling paper-based tests, with the exception that tests may be given adaptively 3. Administered in dedicated test centers as a one-time measurement 4. Take limited advantage of technology
Next-generation electronic tests (qualitative change and efficiency improvement)	<ol style="list-style-type: none"> 1. Primarily serve institutional needs 2. Use new item formats (including multimedia and constructed response), and may make initial attempts to measure new constructs, to begin to change what is assessed 3. Improve efficiency through automatic item generation, automated scoring, and the use of the Internet for internal processes, as well as for interactions with consumers 4. Administered in dedicated test centers as a one-time measurement
Generation R tests (reinvention)	<ol style="list-style-type: none"> 1. Serve both institutional and individual purposes 2. Integrated with instruction so that performance is sampled repeatedly over time 3. Designed according to cognitive principles 4. Use complex simulations that model real environments and allow more natural interaction with computers 5. Administered at a distance 6. Assess new skills in more sophisticated ways (e.g., through simulation or extended constructed response)

Adapted from Bennett, R. E. (1998). *Reinventing Assessment: Speculations on the Future of Large-Scale Educational Testing*. Princeton, NJ: Policy Information Center, Educational Testing Service.

certification by a majority of US states. The test is administered through dedicated centers, most of which are commercially operated.

At least three major programs use technology delivery for graduate and professional admissions. These programs include the Graduate Record Examinations (GRE) General Test, introduced on computer in 1992, the Graduate Management Admission Test (GMAT), first offered on computer in 1997, and the Test of English as a Foreign Language (TOEFL), introduced electronically in 1998 (A timeline of the history of the MBA and the GMAT, 2004; Kirsch *et al.*, 1998; Schaeffer *et al.*, 1995). Several hundred thousand tests are taken on computer by each of these programs annually, including in US and overseas venues. In their first-generation versions, each of these tests was adaptive (at least in part), and was delivered primarily in dedicated centers via local area networks, with transfer of test items and examinee responses accomplished through specially arranged private data lines.

For state accountability purposes, two programs stand out. Although both programs utilize the Internet for delivery, they are first generation in most other ways. The Virginia e-SOL (Standards of Learning) assessments, initiated in 2001, comprise well over a dozen different tests in English language arts, mathematics, science, and social studies (Department of Education and Virginia Information Technologies Agency, 2005). The tests are administered operationally at the middle- and high-school levels for such high-stakes decisions as promotion and graduation. The

e-SOL assessments were given over 900 000 times in the 2005–06 school year, with the overwhelming majority of the state's high-school students participating (R. Triscari, personal communication, September 5, 2006).

The Oregon Technology Enhanced Student Assessment (TESA) is an adaptive test administered in grades 3–12 in reading, mathematics, science, and social studies. It was administered over 1 million times in the 2004–05 school year (State: Online testing helped raise scores, 2005). Among other things, TESA is employed by the state for federal reporting purposes under the US No Child Left Behind Act.

Finally, for district achievement monitoring, the best example is the Northwest Evaluation Association's Measures of Academic Progress (MAP). This adaptive testing program includes measures in math, reading, language use, and science. The MAP tests are used by more than 2400 US school districts (Measures of Academic Progress, 2006). Because MAP tests are adaptive, they can more accurately measure the achievement of students who are at widely varying skill levels than can a conventional test. Moreover, MAP tests can be administered to the same students more than once a year for purposes of estimating progress.

The examples above illustrate several points. First, computer-based tests are already being administered on a large scale for a variety of educational purposes. In that regard, first-generation computer-based testing is established, even if it is not yet the dominant mechanism for all of those purposes.

A second point is that these first-generation tests are for the most part relatively simple, multiple-choice measures meant to closely resemble the task format of a paper-and-pencil exam. In fact, several of the programs, including Praxis I and the Virginia e-SOL assessments, offer paper forms intended to be comparable to the computerized versions. The most notable distinction from a paper test is in the adaptive nature of delivery and scoring utilized by several of the programs.

A third point is that because they constitute an initial developmental stage, these tests were inevitably expensive. Substantial investments had to be made in the infrastructure for large-scale technology-delivered testing – hardware, software, network capability, physical facilities, methods, and processes had to be purchased or newly created. As a result, in most cases, first-generation tests proved more costly than their paper counterparts (Wainer and Eignor, 2000).

These first-generation tests have helped identify at least two critical issues. One issue relates to infrastructure. For college course placement, teacher licensure, and graduate and professional admissions, the US infrastructure is adequate, especially when testing is offered continuously instead of in a limited number of fixed (and consequently larger) administrations. Outside of the US, the adequacy of the infrastructure varies widely, such that for the internationally offered GRE General Test, paper versions are sometimes the standard. At the school level, adequacy of infrastructure is also a concern. The US National Center for Education Statistics reports that there were 3.8 students for every Internet-connected computer located in public-school instructional rooms in 2005 (Wells and Lewis, 2006), probably enough to support simultaneous testing of grade cohorts. This ratio varied, however, by school size and minority enrollment, suggesting the potential for problems in some locations. Data from the Organization for Economic Cooperation and Development (OECD) suggest that, outside the US, the adequacy of the infrastructure is in general less developed (Schleicher, 2006).

A second critical issue relates to the comparability of scores. One type of comparability concerns the scores from computer versus paper tests. Students may perform differently if they are more comfortable or practiced at taking tests in a particular mode (e.g., in taking writing tests on paper vs. on computer). For tests offered in both modes, or for tests transitioning from paper to computer, it is essential to support claims regarding the comparability of scores empirically.

Such evaluations should, at a minimum, include consideration of the similarity of score distributions across modes and of the similarity of examinee rank orders. With adults, research has generally shown score distributions and rank orders to be highly similar across computer and paper formats for cognitive tests like those used in education (e.g., Gallagher *et al.*, 2000; Mead and Drasgow, 1993).

For school-age students, the existing research base is far less extensive and largely unpublished, so dependable conclusions are difficult to draw. The US National Assessment of Educational Progress (NAEP) has conducted two nationally representative studies, one in mathematics and one in writing, both focused primarily on 8th grade students (Bennett *et al.*, 2008; Horkay *et al.*, 2006). In both cases, the computer and paper tests did not appear to measure the same skills.

Even in those cases where a test is offered only on computer and all students are proficient in taking it that way, infrastructure differences among (and within) schools can affect score comparability and, hence, fairness. For example, under some computer-based test delivery models, questions may display differently from one machine to the next, changing test scores in unwanted ways. Bridgeman, *et al.* (2003) found scores on reading comprehension items taken from the SAT I: Reasoning Test to vary as a function of monitor size and resolution, presumably because of differences in the need to scroll text passages.

Next-Generation Electronic Tests

Next-generation tests are distinguished from first-generation tests by qualitative change achieved through the introduction of new item types, including constructed response, and more generally by attempting to measure new constructs not as easily assessed through conventional means. Further, next-generation tests use technology for efficiency improvement. Qualitative change and efficiency improvement may come about as additions to existing first-generation tests, thereby moving them to the next generation, or alternatively through the introduction of totally new measures.

The first example of a test that has introduced new item types is the new TOEFL, now called TOEFL iBT. The TOEFL iBT includes a speaking section in which the examinee responds via microphone to audio prompts delivered through a headset. Questions ask the examinee to do such things as listen to a short lecture and summarize it; or read a brief passage, listen to a short lecture, and answer a question calling for integration of information from the two sources.

A second example comes from the Indiana Core 40 End-of-Course Assessments, available in selected subjects for middle- and high-school students. These tests were among the first electronic assessments to contain constructed-response item types, a qualitative change from the multiple-choice format that dominates first-generation tests. The English 11 assessment includes short-answer and essay questions for which students type their responses. The algebra assessments include questions that call for the entry of numerals, mathematical expressions, and short-answer text responses.

An initial attempt to measure constructs not directly accessible through conventional means is illustrated by the Educational Testing Service (ETS) iSkills assessment (Educational Testing Service (ETS), 2008). This assessment is intended for students transitioning to college or already enrolled, and targets the ability to use technology as a tool for cognitive purposes. Questions are presented in an applied context and the examinee is asked to use generic versions of such common tools as a word processor, presentation software, e-mail client, web browser, and spreadsheet.

Whereas the infrastructure development needs of first-generation tests often did not allow for cost savings, next-generation tests are applying technology to internal and external processes, including item development, constructed-response scoring, and interaction with customers. An example of a tool employed for operational item development is the Mathematics Test Creation Assistant (Singley and Bennett, 2002). With this tool, the test developer creates an item model, an abstract representation of a question class from which the computer can generate multiple instances. A given model can be tightly structured so as to produce instances that are highly similar in difficulty (Graf *et al.*, 2005), or more loosely formulated to produce instances with a wider range of difficulty. This tool is being used to create questions for the GRE General Test quantitative section, as well as for such state programs as the Virginia Standards of Learning assessments.

Technology is being applied to constructed-response scoring in two distinct ways. Online scoring involves the presentation of an examinee's constructed response to a human judge via computer display. If the test was administered on paper, the scoring vendor must first convert the response to digital form. If the test was administered on computer, no such conversion is needed. Most major testing companies have online scoring systems. In some configurations, human judges are gathered in a central location to conduct scoring. In other configurations, scoring is distributed, with judges working from home or office via the Internet. Online scoring is employed for the constructed-response portions of such tests as the NAEP, Advanced Placement (AP) Program Examinations in Chinese and Japanese, the California High School Exit Exam (CAHSEE), the GRE General Test, Praxis: Professional Assessments for Beginning Teachers, and the TOEFL iBT, including items from the speaking section described above.

In contrast to online scoring, automated scoring entails grading a constructed response entirely by machine. Several such programs exist for scoring essay-length responses, including the Intelligent Essay Assessor (Pearson Knowledge Technologies), Intellimetric (Vantage), Project Essay Grade (PEG) (Measurement, Inc.), and e-rater (ETS). Tests that use automated scoring operationally include the constructed-response portions of the

GMAT, ACT's COMPASS, the College Board's ACCUPLACER, and the Indiana Core 40 examinations in biology, algebra, and English 11. For the GMAT, the machine score is combined with that of a single human rater. For all of the other tests, the machine score is used alone.

Electronic interaction between customers and testing programs is perhaps best illustrated through advances in registration and reporting. Examinees for many educational testing programs may register using the Internet. Such registration is available for the College Board's SAT, the ACT Assessment, and the GMAT, among many others.

In addition to being able to electronically register, score results for many testing programs are also routinely delivered electronically, speeding the process of reporting considerably and making it less costly. For institutional purposes, electronic reporting can also make results more useful. The NAEP Data Explorer is probably the most advanced of such tools, allowing users to generate reports instantaneously with the variables and data representations of their choosing. The resulting reports may involve comparisons of the performance of demographic groups (by gender, race/ethnicity, poverty level, region of the country, school location, school type), or of groups categorized by student factors (e.g., affective disposition), instructional content and practice (e.g., modes of instruction), teacher factors (e.g., credentials and experience), or school factors (e.g., organization). Reports may include tables, graphs, charts, or text.

The examples above illustrate two points. First, these examples illustrate that large-scale testing programs are beginning to use technology broadly. Programs are not just using technology for test delivery and response collection but to improve the efficiency of other internal processes, including item creation and scoring. Further, programs are taking advantage of the Internet as a network to connect more directly with consumers for such purposes as registration and reporting. A second key point is that testing programs are beginning to use technology to change what is being tested through the introduction of constructed-response item types and by considering skill in using the computer as an object of assessment in its own right.

The advances associated with next-generation tests have brought novel issues. One such issue relates to automated scoring. Research suggests that automated essay scoring programs tend to agree with the scores of human judges to about the same degree as two judges agree between themselves (Keith, 2003). Should we care how these computer programs achieve that agreement? For example, should we care what response features are electronically judged and how those features are combined to produce scores? Some companies, claiming proprietary technology, refuse to release enough detail about their scoring mechanisms to permit evaluation of the processes

used. Other companies have released processing details. In such cases, however, it is not always clear that the automated scoring uses response features that account sufficiently for the characteristics of good writing or that combine those features in defensible ways (Bennett, 2006; Ben-Simon and Bennett, 2007). Ben-Simon and Bennett (2007) found that the dominant features used to compute scores automatically were essay length and mechanics, with only minimal weight given to content or organization and development. The concerns raised by such findings are potentially problematic because they may make automated scoring harder to explain, defend, and generalize to new testing purposes and populations.

Generation R (Reinvention)

Among the defining characteristics of Generation R tests are a basis in cognitive principles (as well as content considerations), the use of complex simulation, sampling of student performance repeatedly over time, integration of assessment with instruction, and the measurement of new skills in more sophisticated ways than possible in next-generation tests. Generation R tests produce information that can support summative and also, to a significant degree, formative decisions by repeatedly probing in a theoretically driven manner using instructionally sound tasks. In the Generation R view, more assessment opportunities allow for better tasks and for higher-quality information through aggregation. Although no operational examples exist in large-scale educational assessment, instances are emerging, each with some of the key characteristics.

One example is not an assessment at all but an instructional program that thoroughly integrates assessment. The Cognitive Tutors (Carnegie Learning) present instruction in mathematics designed around adaptive control of thought—rational (ACT-R), an extensive theory of learning, knowledge organization, and human performance (Anderson, 1993). Of particular relevance for Generation R is that the Cognitive Tutors dynamically build a rich representation of a given student's domain knowledge as the student interacts with the tutor by solving problems. The student may interact with the tutor repeatedly over time, updating the tutor's representation of the student's knowledge state and extending that representation to new domain components as problems relevant to those components are encountered. The tutor uses this representation (the student model) to make relatively fine adjustments to the instruction it presents.

A second example illustrates the use of extended, complex, highly contextualized simulations, as well as how such simulations might be employed formatively to measure new skills in sophisticated ways. The Key Stage 3 Information and Communication Technology (ICT) Assessment Tasks are available on demand through what was England's

National Assessment Agency (National Assessment Agency (NAA, 2008), now the Qualifications and Curriculum Development Agency. The purpose of the assessment tasks is to help develop information and communications technology skills and offer students instant feedback on their performance. The assessment tasks call for the integration of skills by requiring the use of multiple ICT tools in concert (e.g., word processor, web browser, and spreadsheet) to solve extended problems, in much the same way such tools are used in real work and academic environments.

Similar to England's Qualifications and Curriculum Development Agency, the US NAEP has been exploring the use of complex simulations for measuring new skills. In the Technology-Rich Environments Study (Bennett *et al.*, 2007), nationally representative student samples were administered measures intended to tap skill in using the computer for problem solving in a science context. Of special note is that the tasks were intended to afford incidental learning opportunities beyond those possible from conventional assessment. One task, shown in **Figure 1**, asked students to use a simulated Internet to find out, and explain why, scientists sometimes use helium gas balloons instead of other mechanisms to explore planetary atmospheric space. A second set of tasks, one of which is shown in **Figure 2**, asked the student to discover through experimentation the relationship between the payload mass that a scientific helium balloon could carry and the altitude to which the balloon could rise in the atmosphere. Performance on these tasks was scored in terms of both the quality of the constructed-response answers and process features (e.g., whether the experiments conducted covered a wide enough range of payload masses to support defensible conclusions about the relationship between mass and altitude). Based on student behavior, scale scores were produced using a psychometric methodology similar to that employed in operational NAEP assessments.

A vision for a system that incorporates many of the characteristics of Generation R has been proposed by Bennett and Gitomer (2009). In their view, first, accountability assessment, formative assessment, and professional support should be grounded in a common conceptual base derived, not only from curriculum objectives, but also from cognitive-scientific research. Second, they envision accountability and formative assessment as comprising primarily extended, integrated tasks worth teaching toward. Finally, they propose that accountability assessment be periodic, instead of a one-time event, and that the results of those periodic measurements be aggregated to form a final accountability result. Periodic assessment allows for at-risk students to be identified while there is still time to take instructional action and for tasks to be more instructionally worthwhile, because there is more time for assessment in the aggregate. Also, the aggregation of results across measurement occasions means that no student, teacher,

(2007). *Problem Solving in Technology-Rich Environments* (NCES 2007-466). Washington, DC: National Center for Education Statistics, US Department of Education.

administrator, or school can suffer significant adverse consequences for one bad performance.

As noted, no operational Generation R tests exist. This situation is the case because many significant

issues remain to be solved. For one, how might cognitive principles be integrated with such content-based domain descriptions as those embodied in state or national curriculum standards? One possibility is to use cognitive

principles to translate the outcomes typically represented by curriculum standards into the processes, strategies, and knowledge structures needed to achieve those outcomes.

A second issue concerns the aggregation of information gathered from repeated samplings over time to produce summary proficiency estimates usable for such consequential decision-making purposes as school evaluation and student promotion. Would a simple average suffice? Should greater weight be given to more recent samplings?

Third, how should performance on complex tasks be scored? Responses to such tasks are, by their very nature, composed of many locally dependent components. For example, a student may misread instructions or make an early mistake that affects his or her responses to all subsequent task components. Similarly, a student with interest in a certain area may by chance encounter a task for which such background knowledge will provide an unfair advantage on all components. Such dependencies can perhaps be accounted for through psychometric modeling or be acceptably dampened through the use of a sufficient number of complex tasks.

Fourth, how might the use of a large-scale assessment comprising complex tasks be made affordable? Complex tasks are costly to produce and to score meaningfully. Affordability will come only through technological advances in the tools for task creation and automated scoring.

Finally, how might teachers and education policy-makers be convinced to spend more time on assessment? Repeated sampling, after all, means a test that is, in the aggregate, potentially longer than the traditional one-time administration. If assessment continues to be regarded as a burdensome activity comprising irrelevant tasks providing little instructionally useful information, no one should want more of it. However, if Generation R assessments can be designed as learning events, can consist of exercises worth teaching toward, and can produce actionable results, the reaction may be different.

Summary

This article has presented a conceptual framework for understanding the recent evolution of technology for large-scale assessment, given examples to illustrate that evolution, and identified issues associated with technology use. The conceptual framework described three generations of tests: (1) infrastructure building, (2) qualitative change and efficiency improvement, and (3) reinvention.

The examples reviewed make clear that a first generation of large-scale, computer-based educational tests is in place, even if such tests are not the dominant mode for all purposes. These first-generation tests essentially duplicate the key characteristics of paper-and-pencil measures, with the most notable distinction being the adaptive

nature of delivery and scoring utilized by several programs. The large-scale administration of first-generation tests for graduate- and professional-school admissions, college placement, teacher certification, state accountability, and school achievement monitoring demonstrates that to a significant degree the required infrastructure exists, though further development is clearly needed in many locations around the world.

The reviewed examples also suggest that next-generation tests are emerging. Such tests are beginning to use technology to change what is being assessed through the introduction of constructed-response item types and by considering skill in using the computer as an object of assessment in its own right. Additionally, next-generation tests are pursuing efficiency improvement by using technology for generating items automatically, scoring constructed responses, and connecting more directly with test consumers.

Although no operational third-generation tests exist, some fundamental characteristics of these envisioned measures have appeared in instructional products and national studies. These characteristics include basing assessment design on cognitive principles, repeated sampling of performance over time, use of complex simulations, and tasks intended to constitute learning events.

Several important issues were noted. Mentioned with respect to first-generation tests was the need to evaluate comparability claims empirically when both paper and electronic versions are offered, variation in the quality of infrastructure for some populations and testing purposes, and the fact that some students may not be able to take tests effectively on computer for reasons of skill or comfort. For next-generation tests, of particular concern was the use of undisclosed processes for automated scoring or of processes that were not designed in keeping with construct considerations. Finally, with respect to the envisioned Generation R, a host of issues was apparent. These issues include integrating cognitive principles with content-based domain descriptions, aggregating information gathered from repeated samplings over time, scoring complex tasks, making large-scale assessment comprising such tasks affordable, and convincing teachers and policy-makers to spend more time on assessment.

Glossary

Adaptive testing – Testing in which tasks are administered based on an examinee's previous responses, in order to improve the efficiency of measurement.

Assessment argument – An explication of the rationale for making inferences about an examinee's knowledge or skill, based on the observation of a sample of performances in an assessment.

Assessment delivery – The processes by which assessment tasks are selected to administer, examinees respond, responses are evaluated, and scores are reported.

Assessment implementation – The processes of constructing the elements of an operational assessment, such as authoring tasks, specifying scoring rubrics, and calibrating the psychometric model.

Classical test theory – A probabilistic model that posits observed test scores to be the sum of a true score and a random measurement error.

Cognitive diagnosis models – The psychometric models that characterize examinees in terms of their proficiencies on multiple aspects of knowledge and skill, that are typically required in combination to carry out complex task performances. These models are used in some applications of diagnostic assessment.

Conceptual assessment framework (CAF) – In the evidence-centered design approach to assessment, the CAF builds specific models for use in a particular assessment, taking into account the specific purposes and requirements of that assessment. The primary models of the CAF are the student model, the task model, and the evidence model.

Constructed response – In contrast to selection tasks such as multiple-choice and true–false, constructed response tasks require an examinee to produce an answer such as an essay, a proof, a diagram, or a performance.

Construct-irrelevant variance – The variance in scores among examinees due to differences in knowledge or skill that are not central to the knowledge and skills that are intended to be

assessed. For example, if it is meant to assess chemistry knowledge with an essay test, skills in composition can influence scores in ways that do not reflect differences in the chemistry knowledge.

Construct-relevant variance – The variance in scores among examinees due to differences in knowledge or skill that are central to the knowledge and skills that are intended to be assessed.

Design pattern – An assessment design pattern systematically provides advice about how to construct tasks, capture performances, and score work in some skill area, such as model-based reasoning or building scientific explanations.

Diagnostic assessment – An assessment that seeks to assess, and report in terms of, multiple specific elements of knowledge or skill required to perform in a specified domain. For example, a cognitive diagnosis analysis of mixed-number subtraction test would report on an examinee's mastery of finding a common denominator, adding fractions with like denominators, converting a mixed number to an improper fraction, etc.

Domain analysis – In the evidence-centered design approach to assessment, domain analysis encompasses the processes of researching and cataloging aspects of the world relevant to an assessment activity. It includes expert–novice studies, cataloging representations, surveying curricular materials, etc.

Domain modeling – In the evidence-centered design approach to assessment, domain modeling encompasses the process of building assessment arguments at a narrative level, in terms of the knowledge or skill to be measured, the kinds of performances required, the features of tasks, and the rationale connecting them.

Evaluative submodel – In the evidence-centered design approach to assessment, the evaluative submodel of the evidence model specifies how examinees' work on the task is scored.

Evidence model – In the evidence-centered design approach to assessment, the evidence model specifies how examinees' performances will be evaluated and combined across tasks. It contains evaluative and statistical submodels.

Instantiation Variables – A class of variables such that the class name itself can be used as if it were the automatic instantiation variable. This provides a mechanism for accessing default instances of the class.

Intelligent tutoring system – A computer system that dynamically adapts learning content to objectives, needs, and preferences of a learner.

Item forms – The frameworks for authoring families of test items, with a common form and slots that are filled in with different content in order to produce distinct items. In common usage, item forms are usually meant for producing relatively simple tasks, such as arithmetic items.

Item models – The frameworks for authoring families of test items, with a common form and slots that are filled in with different content in order to produce distinct items. In common usage, item models are usually meant for producing more complex tasks such as architectural design problems.

Item response theory – A probabilistic model that models observed responses to test items as functions of parameters for examinee characteristics such as ability and item characteristics such as difficulty.

Knowledge representation – A knowledge representation denotes the notation or formalism used to code information. Maps and graphs are examples of widely used knowledge representations. Test specifications and structural equations diagrams are more specialized knowledge representations that are used in test design and analysis.

Layers of assessment – The distinguishable kinds of activities that are carried out in different stages in the design and conduct of assessments. The layers in the evidence-centered design (ECD) assessment framework are domain analysis, domain modeling, CAF, assessment implementation, and assessment delivery.

Objects – In object-oriented computer programming, objects are structures that consist of data, procedures carried out on the data, and messages that can be sent to other objects. In assessment systems, examples of objects are tasks, work products, scoring algorithms, and task design patterns.

Schema – A schema is an organized structure that describes some event or set of relationships at a general level, and has slots that can be filled in to describe particular instances.

Scoring procedures – Scoring procedures are involved in the identification, extraction, summarization, and evaluation of key features of performance in student work. In particular, scoring procedures are used to synthesize nuggets of information in the form of values of observable variables or tasks.

Statistical submodel – In the evidence-centered design approach to assessment, the statistical submodel of the evidence model specifies how scores across tasks are combined to produce scores. This may be a simple total score or a complex algorithm defined through a psychometric model.

Stem – For simple assessment tasks, the stem is the question or prompt to which the examinee responds. In multiple-choice tasks, for example, the stem can be a question, which is followed by a small number of possible answers from which the examinee chooses.

Student model – In the evidence-centered design approach to assessment, the student model contains variables that characterize the knowledge and skills of the examinee.

Task design wizard – A task design wizard is a computer program that guides a task designer through choices, which when made, create an assessment task. A task designer wizard is built around a task model.

Task model – In the evidence-centered design approach to assessment, a task model is a schema that contains descriptions of elements and interactions that define a class of assessment tasks, and variables which, when specified, provide the information needed to implement a specific task.

Task-model variables – In the evidence-centered design approach to assessment, the task model variables indicate systematic ways that tasks following the same task model can differ from one another. Specifying the values of the task-model variables provides the information necessary to implement a specific task.

Web-based adaptive testing – The administration of a test over the Web, where the selection of the next test question to be presented to a student and the decision to end the test are performed dynamically by a computer based on a student profile which is created and updated through interaction with the system. Web delivery enables this efficient testing procedure to be carried out virtually anywhere in the world, and to draw upon the rich array of media and learning environments in creating tasks and valuating performances.

Introduction

Educational assessment involves making inferences about what students know or can do, based on observing what they say, do, or make in a handful of particular circumstances (i.e., assessment tasks). (Task encompasses short self-contained items that comprise familiar educational tests, but performances which may be longer, more, complex, or interactive, such as troubleshooting a computer network or carrying out a scientific investigation. Assessments consisting of tasks such as these also need to be designed and constructed around assessment arguments.) Designing an assessment requires analyzing the domain, building an argument, and creating tasks. These processes require gathering, organizing, and transforming information in a variety of representational forms. At each stage, technology can help organize work, enhance validity, and increase efficiency. This article discusses roles of technology supports for assessment design. It begins by reviewing assessment arguments and layers in the design process.

Arguments, Layers, and Knowledge Representations

An active line of research in assessment is making explicit the assumptions and principles that underlie educational assessment so that tools can be developed to make assessment design both more efficient and more consistent in quality. Examples of such work include Embretson's (1998) cognitive assessment design system and Luecht's (2002) integrated test design, development and delivery. The present article uses the language of a third such framework, Mislevy *et al.* (2003b) evidence-centered design (ECD) approach. ECD is an approach to assessment that uses a principled framework that is applicable to many forms of assessment.

The central ideas in ECD are the assessment argument, layers of assessment, and the role of knowledge representations. Messick (1994: 16) orients assessment designers to the key aspects of an assessment argument by asking, "what complex of knowledge, skills, or other attributes should be assessed. . . Next, what behaviors or performances should reveal those constructs, and what tasks or situations should

elicit those behaviors?" These questions lead to formal specifications in terms of student, evidence, and task models (see **Figure 1**), which will be discussed in detail in the section titled 'Supports for the CAF'.

Design typically begins with a purpose and some ideas about what is important in the domain, and then it moves to the specific materials and processes of an operational assessment. The ECD organizes the design process in terms of the following layers: domain analysis, domain modeling, conceptual assessment framework (CAF), assessment implementation, and assessment delivery (Mislevy and Riconscente, 2006). **Table 1** summarizes these layers in terms of their roles, key entities, and knowledge representations that assist in achieving each layer's purpose. The layering suggests a sequential design process, but cycles of iteration and refinement across layers are the norm.

The fundamental work in assessment design can be viewed as creating, transforming, and using information in the form of knowledge representations within and between such layers.

Supports for Domain Analysis

Domain analysis is the first step in the process of designing and delivering an assessment. It entails gathering information about how people acquire, construct, represent, use, and communicate knowledge within the domain. It lays the foundation for later layers by defining the knowledge, skills, and abilities (KSAs) assessment users want to make inferences about, student behaviors they can base their inferences on, and situations that will elicit those behaviors. This process is relevant to assessments of all kinds, whether formative or summative, large-scale or classroom.

Technology supports can be used in domain analysis to aid in defining and gathering the domain information, then to organize it in ways that will inform or facilitate the design of assessment tasks. One well-studied example of a technology tool that streamlines domain analysis is Shute *et al.* (2000) automated knowledge elicitation tool DNA (for Decompose, Network, Assess). The DNA provides structured, user-friendly web forms to elicit domain experts' input on declarative-, procedural-, and conceptual-knowledge requirements of common tasks in the domain. Other examples include Williams's (2000) Cognitive

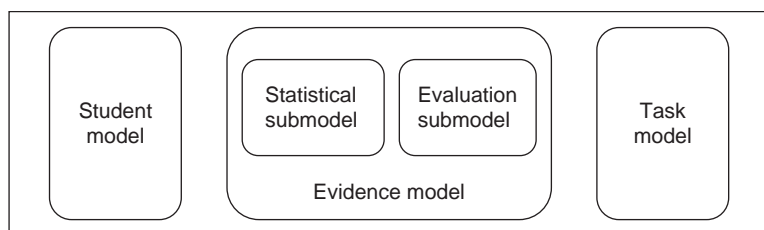

Figure 1 The central models of the conceptual assessment framework.

Table 1 Layers of evidence-centered design for educational assessments

<i>Layer</i>	<i>Role</i>	<i>Key entities</i>	<i>Selected knowledge representations</i>
Domain analysis	Gather substantive information about the domain of interest that has direct implications for assessment: how knowledge is constructed, acquired, used, and communicated.	Domain concepts, terminology, tools, knowledge representations, analyses, situations of use, patterns of interaction.	Content standards, concept maps (e.g., <i>Atlas of Science Literacy</i> , AAAS, 2001); representational forms and symbol systems of domain of interest, such as, algebraic notation, maps, computer interfaces.
Domain modeling	Express assessment argument in narrative form based on information from domain analysis.	Knowledge, skills, and abilities; characteristic and variable task features, potential work products, potential observations.	Assessment argument diagrams, design patterns, content-by-process matrices.
Conceptual assessment framework	Express assessment argument in structures and specifications for tasks and tests, evaluation procedures, measurement models.	Student, evidence, and task models; student model variables, observable variables, and task model variables rubrics; measurement models; test assembly specifications.	Test specifications; algebraic and graphical representations of measurement models; PADI task template; item generation models; generic rubrics; algorithms for automated scoring.
Assessment implementation	Implement assessment, including authoring presentation-ready tasks, scoring guides or automated evaluation procedures, and calibrated measurement models.	Task materials (including all materials, tools, affordances); pilot test data for honing evaluation procedures and fitting measurement models.	Coded algorithms for rendering tasks, interacting with examinees, evaluating work products; tasks as displayed; computer-deliverable representations of materials; American Standard Code for Information Interchange (ASCII) files of item parameters.
Assessment delivery	Coordinate interactions of students and tasks: task- and test-level scoring; reporting.	Tasks as presented; work products as created; scores as evaluated.	Renderings of materials; numerical and graphical summaries for individuals and groups; results files.

PADI, Principled Assessment Designs in Inquiry.

Analysis Tool – Human Computer Interaction (CAT-HCI) software tool for eliciting experts' domain knowledge, and from CHI systems for analyzing and subsequently modeling cognitive tasks (Zachary *et al.*, 2000). More specialized tools can be employed for specific purposes. Technology-based tools can be used to capture information about experts' knowledge that would be difficult to capture with more traditional methods of task analysis. For example, in the domain of satellite-image analysis, eye trackers have been used as part of cognitive task analyses (Kurland *et al.*, 2005).

Supports for Domain Modeling

Domain modeling structures the outcomes of domain analysis in a form that reflects the structure of an assessment argument, in order to ground the more technical student, evidence, and task models that are required in the subsequent, more technical, CAF layer shown in **Figure 1**. One tool for this purpose is design patterns, a concept that originated in architecture (Alexander *et al.*, 1977), and was later adapted in computer science (Gamma *et al.*, 1995). As

defined by Alexander *et al.* (1977), a design pattern provides a “description of a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over” (p. x). Design patterns for assessment compile knowledge about ways to address assessment challenges that recur across domains or within particular domains (Mislevy *et al.*, 2003a). Examples of design patterns include model revision and building a scientific explanation. Each makes explicit the knowledge and skills that the developer wants to measure, the kinds of observations that could provide evidence about the acquisition of the knowledge and skills, and features of task situations that allow the examinee to provide the requisite evidence. Hively *et al.* (1968) proposed a type of design pattern called item forms for assessing behavioral objectives. Item models (e.g., Bejar *et al.*, 2003) and item structures (Embretson, 1998) were developed to incorporate an accounting of task features from the perspective of their cognitive-processing demands.

Technology supports can facilitate the domain-modeling process by helping designers create, search, or tailor design

patterns. In Principled Assessment Designs in Inquiry (PADI), design patterns help designers bridge the educational goals (in the form of standards, learning objectives or knowledge, skills, and abilities) with the technical design specifications that will be realized in an operational assessment.

Embodying a validity argument in an assessment requires more than authoring individual assessment tasks. The assessment designer must judiciously use certain design patterns in ways and in combinations that best support the purpose of the assessment as a whole (see, e.g., Davidson and Lynch (2001), on test specifications). Many considerations, including resources, operational constraints, content representation, and statistical information, impact on which design patterns and how many can be used to produce an optimal design. Optimization tools that have been developed for test assembly (van der Linden, 2005) can be used to sort through competing sets of design patterns that would lead to an assessment satisfying an array of constraints, including the adequacy of coverage of KSAs or educational standards.

Supports for the CAF

The CAF concerns technical specifications for the nuts and bolts of assessments, that is, the materials and processes that embody assessments. The CAF contains the student, evidence, and task models as shown in **Figure 1**. An assessment argument that was laid out in narrative form in the domain-modeling layer is now expressed in terms of specifications for tasks, measurement models, scoring methods, and delivery requirements. Details about task features, measurement model parameters, stimulus material specifications, and the like are expressed in terms of representations and data structures that will guide their implementation and ensure their coordination. Technology supports can be applied with each of the CAF models to facilitate task designers' work. Moreover, knowing the supports that are available at the level of the CAF helps shape the designer's work in domain analysis and domain modeling. The kinds of supports that are available to implement and carry out assessments thus define the universe of assessments that can be conceived.

Student Model

Scores from assessments help synthesize evidence from students' performances, in terms of variables organized around KSAs. These are student-model variables. Each variable corresponds to some aspect of knowledge, skill, ability, proficiency, etc., presumed to drive probabilities of observable response. Psychometric models such as classical test theory, item response theory, and cognitive-diagnosis

models use probability-based methods to ground inferences about students and characterize their precision. Especially in applications requiring multivariate models, designers will find it useful to use technology-based tools to construct modular components of the required student models and assemble them for diagnostic assessment and intelligent tutoring systems, such as van Lehn's Andes physics tutor (Conati *et al.*, 2002). These reusable student-model pieces are combined with the measurement-model pieces described below, allowing assessment designers to create tasks that support detailed feedback without having to create complicated measurement models anew for each task.

Reusability of measurement models is of particular importance for not only tasks requiring multivariate models, but also those with multiple scores, dependencies, or modeled relationships between task features and measurement parameters (Rupp, 2002). The psychometric implications of these relationships usually lie outside the expertise of domain specialists who create assessment tasks. However, assessment task authors can be provided with a library of preconfigured measurement fragments around which to write any number of unique assessment tasks (Almond *et al.*, 2002). When these kinds of supports are available, designers can link task models to student- and evidence-model fragments, so that the designers are not constrained to assessment arguments that simply address overall proficiency in the kinds of tasks that comprise the assessment.

Evidence Model

The evidence model provides a mechanism for connecting observable student behaviors to student-model variables. The evidence model has two components, herein called the evaluative and statistical submodels but referred to elsewhere by other names, including evidence extraction and evidence synthesis (e.g., Williamson *et al.*, 2006).

The evaluative submodel involves extracting the features that are relevant to a given student-model variable from observable behavior (or some work product), and then judging those features in terms of the evidence they provide about the KSAs of interest. In simple situations, this may just be correctness. In tasks where examinees produce more complex performances, this may be efficiency of problem-solving steps, appropriateness of cohesive devices in an essay, or time-on-target in a training exercise. This extraction-and-judgment operation can be performed by machine, by human rater, or by some combination of the two. In the case of a multiple-choice test, the operation is straightforward because the features are represented by the penciled marks on a scannable answer sheet, and judging the correctness of each mark is governed by the match between the mark's position and an answer key. For a constructed response, the rater (human or automated)

must locate relevant features and then judge the quality of each feature. Again, knowing what technologies will be available to support evaluation determines the range of performances a designer will note in domain analysis, and it determines the range of possibilities for capturing and evaluating evidence that will be available for constructing assessment arguments in domain modeling. Williamson *et al.* (2006) provide in-depth discussion of automated methods for evaluating complex performances, from the perspective of ECD.

Various commercially used technology tools exist for feature extraction and judgment. For example, the Online Scoring Network (OSN; Odendahl, 1999) represents a class of tool that displays the student's constructed response (or a digitized image of it) on a computer screen for the human rater to process. Such tools must be able to aid the human rater in extracting and judging features relevant to the assessment argument and avoiding ones tangential to it. For example, OSN allows the rater to highlight and annotate portions of a digitized response as a means of organizing relevant evidence. A compatible kind of technological support for human scoring provides underlying communication and database capabilities that allow scorers at different locations to evaluate work products, and that allow assessment designers to monitor, analyze, and improve raters' performances (Whalen and Bejar, 1998).

Other technology tools are capable both of automatically extracting relevant features from constructed responses and judging their adequacy. Examples of tools for evaluating essay responses include e-rater (Burststein, 2003), the Intelligent Essay Assessor (Landauer *et al.*, 2000), and Project Essay Grade (Page, 2003). The features such tools extract and judge, however, must also be aligned with the ones assessment designers intended as evidence for informing standing on student-model variables (Bennett, 2006).

The statistical submodel is the second component in the evidence model. The statistical submodel provides a mechanism for combining the judged features in a principled manner, in terms of a score or value for one or more student-model variables. Ideally, this synthesis would include an indication of how much evidence should be associated with each resulting score, as provided by item parameters in item response theory models or weights in summed scores. Dependencies among the several features of a complex performance can be difficult to model. However, as with student models, technology supports make it possible to construct appropriate statistical models from pre-constructed modules in computer-based assessment (Rupp, 2002), so that a task designer can build unique assessment tasks, guided conceptually by design patterns, around configurable evidence structures. In this way, technology supports based on an ECD or similar unified assessment framework can improve the designer's work in terms of both conception and implementation.

The statistical submodel may additionally incorporate multiple features of a complex performance, to produce an intermediate item-level score. This is common in automated essay scoring. Regardless of whether the aggregation is within items, across items, or both, the aggregation should be done in a manner that is consistent with the assessment argument. For example, the use by some automated scoring programs of such brute-empirical methods as step-wise regression undermines the assessment argument because the features selected and the weights assigned may diverge from one task and examinee sample to the next, as well as from the judgments of writing experts (Bennett, 2006; Bennett and Ben-Simon, 2006).

Task Model

During domain analysis the assessment designer identifies potential tasks to elicit the relevant student variables. A task model is a more detailed structure that includes information about how the information it elicits is related to other components of the assessment, and it serves as the blueprint for instantiating actual tasks to be presented to the student. Item forms and item models, mentioned as forms of domain modeling, can serve as the basis for task models by augmenting them with task-model variables. A simple example is an item form for two-digit addition without carrying: $ab + cd$, where a , b , c , and d are digits between 0 and 9, and $b+d < 9$. The task-model variables are a , b , c and d . Alternatively, for tasks that call for complex responses, a task template (Riconscente *et al.*, 2005) is a means of reaching the definition of a task model. In either case, a task model is a schema with variables that are needed to make the task model come alive, so to speak.

Figure 2 shows task-model variables in context. The left portion of **Figure 2** shows the flow of information at assessment time. A student is presented a task and then produces a work product such as a written response, a graphical design, a mathematical formula, or a response log. The work product is then analyzed to extract response variables (evidence extraction) and possibly to aggregate them (evidence synthesis). The result is a set of observable variables that characterizes the work product in a manner consistent with the statistical model that updates the student-model variable(s) via a suitable measurement model. **Figure 2** also shows some possible task-model variables. The variable shell refers to a template that contains details about the task as it appears to the student. The content variables indicate key features of stimulus material, domain focus, knowledge requirements, and the like, which can be used to select tasks or assemble them into tests. **Figure 2** assumes that a task model is the basis for producing instances (i.e., particular tasks) and, therefore a subset of the task-model variables are designated as instantiation variables, the values of which are used to create the specific tasks. If automated

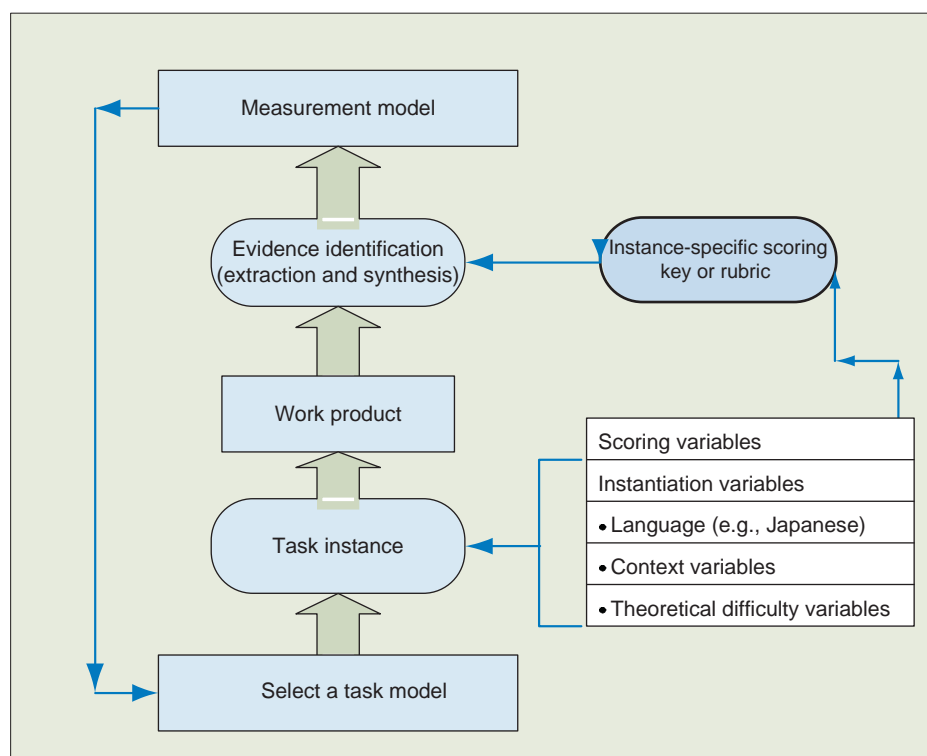

Figure 2 Schematic showing two roles of task-model variables.

scoring is being used, these variables may be also used by the scoring procedure (Braun *et al.*, 2006). Alternatively, if scoring is done by judges, these variables inform the scoring rubric for each specific instance of the task model. **Figure 2** also assumes that the domain analysis and modeling have been sufficiently thorough that a difficulty model is available to estimate or impute the difficulty of specific task-model instances (e.g., Enright and Sheehan, 2002). Finally, **Figure 2** assumes that the language in which a task is rendered is a variable (see Higgins *et al.*, 2005). A relational database can be designed to hold all the information for tasks. The challenge in any particular project is to enable queries that are relevant to assessment design and to display the results in a form amenable to design reasoning, for example, in the form of a task design wizard (e.g., Hamel and Schank, 2006).

Supports for Implementation

Task Authoring Support Tools

Task-authoring tools help developers create tests more efficiently. Many such tools exist, especially for authoring multiple-choice and other selected-response items; banking them so that they can be easily retrieved; and assembling them into tests. Such tools as Questionmark Perception incorporate item templates that facilitate paper as well as on-screen formatting, permitting a full preview of the

layout as the item will appear to the examinee. However, in addition to improving efficiency, task authoring tools ideally should support the assessment argument by channeling the developer toward some types of implementation and away from others. Tools, that in some way incorporate considerations found important in domain analysis can be particularly helpful in this regard.

An instructive example is SourceFinder (Passoneau *et al.*, 2002; Sheehan *et al.*, 2006), which assists test developers with one particular aspect of the item authoring process. SourceFinder searches online repositories (e.g., databases of literary and scientific journals) to help the test developer more quickly locate appropriate passages for graduate admissions-level reading comprehension questions. The tool uses natural-language processing techniques to characterize each text selection in terms of critical features. The critical features were chosen because of their relationship to the assessment argument, in particular, and their potential to influence passage difficulty in construct-relevant and irrelevant ways. For example, level of argumentation features ensure that text selections contain conflict, divergent ideas, uncertainty about outcomes, or other characteristics that can serve as the basis for questions that call upon the targeted verbal reasoning construct. Other features, such as detecting specialized jargon, center on reducing irrelevant variance. Echoing the theme of modularity, SourceFinder allows features to be added or removed as new natural language processing

methods emerge or as the assessment argument changes to accommodate, for example, a different test purpose or population.

Another example of a tool that incorporates considerations found important in domain analysis is the Mathematics Test Creation Assistant (TCA) (Singley and Bennett, 2002). The TCA helps task designers in two ways to make task authoring more efficient and more strongly connected to the research carried out in domain analysis and the argument construction carried out in domain modeling. First, TCA allows the test developer to create item models, abstract descriptions that are more general than specific test items, essentially constrained versions of task models. Working at this more general level of abstraction brings the test developer conceptually closer to the categories that comprise the domain analysis than would be possible by crafting each test question individually. Second task designers can author many instances of tasks from the item models.

Creating individual tasks can further be supported with technology assistance. An example of this type is Katz's (1995) Free-Response Authoring, Delivery, and Scoring System (FRADSS) task-authoring system, which permits test developers to construct computer-based items from objects. Each object brings with it capabilities that enable the item to behave in certain ways (e.g., present an animation), or the examinee to act upon it (e.g., draw a line, shade a portion of a figure, and move figures). The developer can create items from various combinations of objects, interact with them as would the examinee, revise them in real time, assemble a test, and deliver it in pilot form.

Automated Task Generation

Within the framework described above, task generation refers to instantiating an actual assessment task as a function of the variables that comprise the task model. Generation can be fully automated or partially manual depending on the complexity of the stem or stimulus material. In the manual case task specifications are instantiated rather than ready-to-deliver tasks. For example, assessment of architectural expertise by means of design problem solving is an instance requiring task specifications that are then used by subject-matter experts to finalize a task (Bejar, 2002). Skills such as reading comprehension call for a variety of task models, some of which can be instantiated automatically. For example, consider a format that asks the student to summarize a paragraph where difficulty is to a large extent a function of the attributes of the text to be summarized. Automating the instantiations of such a task requires a detailed text model that describes by means of a set of variables the attributes of the text, such as genre, lexical, syntactic, and other relevant textual attributes (Deane *et al.*, 2006). In addition, a statistical

model that predicts the likely difficulty of text supplies parameter values to the evidence model. The predicted difficulty for each potential text can be stored along with the text to facilitate retrieval. Retrieving candidate texts of a given difficulty from a corpus becomes a simple database query (Sheehan *et al.*, 2006).

In domains such as mathematics (e.g., Bejar *et al.*, 2003) or fluid intelligence (Embretson, 1999; Hornke, 2002; Newstead *et al.*, 2006) automated instantiation of task models has reached operational status. Math TCA, mentioned above, has also been used for authoring tasks from task models (see Graf *et al.*, 2005).

Supports for Delivery

Technology-rich delivery environments, such as simulations, are complex and expensive to create and to score. Complexity means that there are many opportunities for assessment designers to inadvertently do a good job measuring unintended KSAs and a bad job measuring the intended ones. The expense associated with creation and scoring means that recovering from bad design decisions will almost certainly be very costly and very possibly infeasible. Thus, the delivery environment should attempt from inception to reinforce the assessment argument by minimizing construct-irrelevant variance and maximizing construct-relevant variance. Information about relevant knowledge and ways to obtain it is best addressed early on, in domain analysis and domain modeling (Luecht, 2002). The System of Intelligent Evaluation using Tests (SIETTE) used in Europe in several projects incorporates this philosophy (Conejo, *et al.*, 2004); in addition to managing web-based adaptive testing SIETTE supports item models and multilingual tests.

The delivery platform used in the National Assessment of Educational Progress (NAEP) technology-rich environments project offers an example of technology support for delivery that addresses considerations from domain analysis and domain modeling (Bennett *et al.*, 2003). In this project, eighth-grade students were asked to use the computer for problem solving in a science context. The task involves conducting simulated experiments to discover the relationship between a set of quantities (the payload mass carried by a helium gas balloon and the altitude to which it can rise in the atmosphere). Student behavior in this environment provides evidence for several student-model variables, including a general problem-solving with technology variable, and two more specific ones, scientific inquiry and computer skills.

To minimize irrelevant variance associated with learning the environment, the tools employed for conducting experiments are explained in a brief tutorial and, also, utilize such common software conventions as dialog boxes and wizards. Further, the tools are organized around

a representation of the experimental process designed to reinforce what students are expected to do substantively (i.e., design experiment, run experiment, interpret results).

Evidence for the student-model variables is gathered from two sources, both of which are intended to contribute to construct-relevant variance. The first key source of evidence is the adequacy and completeness of the written description of the relationship between payload mass and altitude that the student provides. A second source of evidence is how the student uses the tools to arrive at that relationship. Tool use is relevant only because the tools, by design, provide conceptual and data structures to support the assessment argument. For example, the student's use of the design-experiment and run-experiment tools indicates whether the student has executed enough experiments – and covered the range of payload masses sufficiently – to support a defensible conclusion about the relationship between payload mass and altitude. Similarly, his or her use of the interpret-experiment tools indicates whether a table or graph was created that even includes the two variables relevant to solving the problem.

Conclusion

Designing an assessment entails many carefully considered steps, or layers. At each layer, technology supports can aid the thinking and building of the processes and elements that are needed to embody the assessment argument. They can make particular tasks more efficient, as well as open up new possibilities for tasks that were previously too expensive, difficult, or not even considered. However, the focus should not be on technology *per se*, but rather the ways in which it can support the process of designing an assessment so that it fully embodies the assessment argument. Thinking about assessment and technology supports from the perspective of assessment arguments, layers, and knowledge representations provides a method for understanding and evaluating the roles of current technology supports for assessment design not only as it exists today but also as it will evolve in the future.

Introduction

Given the lack of any natural resources, Singapore recognized very early on that its national well-being is dependent on successfully building its human capital. The focus on education, both within the formal educational system as well as adult learning, has a clear link to economic perspective. This emphasis has been reiterated continually, and is likely to remain a key aspect of Singapore's development for the present and foreseeable future (Ng, 2002).

Increasingly, the development of Singapore's human capital needs to be seen in the larger international and globalized context. Singapore's past economic success has depended largely on its ability to provide excellent infrastructure and to establish conditions that attracted multinational corporations (MNCs) to build industrial capacity in the country. While these are likely to remain important for the foreseeable future, the knowledge-based and globalized environment will require the development of human capital that can not only effectively add value to these processes, but also lead in innovation and value creation.

Apart from strengthening local capability and capacity, building a successful education system that can produce top talent for a technology workforce can potentially act as a magnet for internationally mobile talents. It does this in three important ways. First, it provides a strong educational environment for talented children overseas, and this can be a key consideration for relocating to Singapore.

Second, foreigners educated in Singapore will be more likely to form important ties to the country, providing a basis for continual links and contributions to the economy. Third, the diversity injected into the education system through foreign participation in local schools can further strengthen the system by providing a platform for mutual learning and greater interactions among students from diverse backgrounds. These are important to the country, as the ability to attract talent that can contribute to the economic activities of the country is a key contributor to sustained economic growth.

In developing and shaping the education system to build a technology workforce, it is also useful to be conscious of the need to retain talent. Given the nature of the globalized environment, where structures and participation within a flat world (Friedman, 2007) is such that talents can move easily across national boundaries, it is important to maintain strong ties with these mobile talents. Thus, graduates from an education system should ideally be locally anchored and globally relevant. In other words, while the system develops the student holistically and equips him/her with important twenty-first-century skills and disposition, it is equally important to also develop a strong sense of belonging. This is not an easy outcome to achieve.

Singapore's Education and Economic Developments

To appreciate the development of Singapore's education from a largely developing world system to a developed world system in a short span of time, a review of the parallel educational developments, information and communication technology (ICT) plans and economic demands is useful, highlighting the strong link between education and economic imperatives. **Figure 1** places key education,

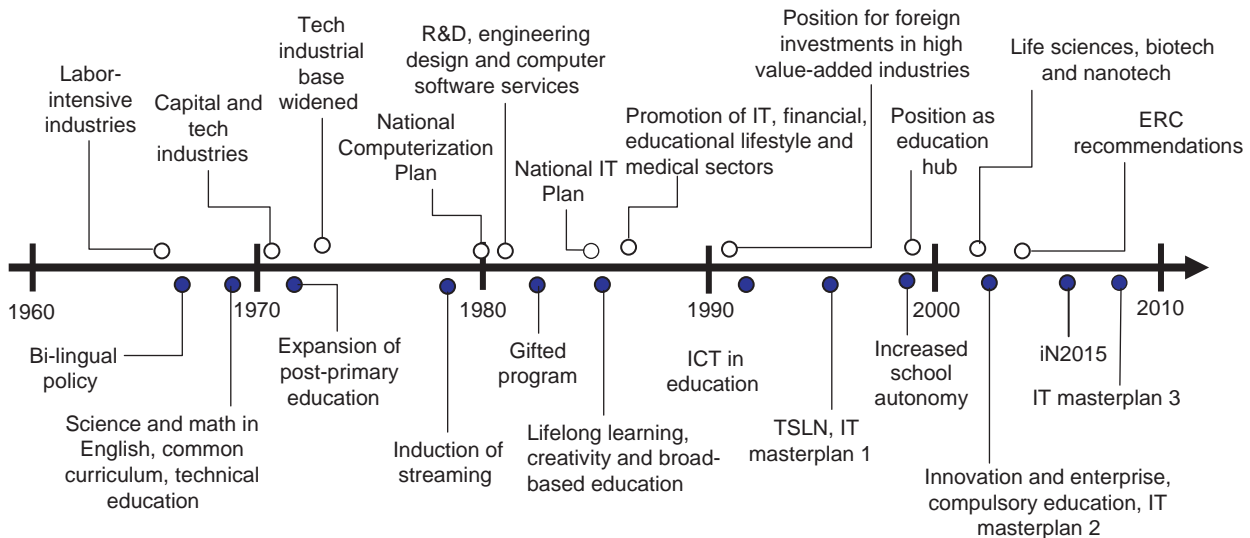

Figure 1 Parallel developments in education, manpower, and economic policies.

ICT, and economic initiatives along a chronological timeline from around the time when Singapore became independent in 1965 to the present. It charts the progress and shift in emphasis in these three arenas and how they interact and move in tandem.

The parallel developments may be broadly grouped into four stages with increasing alignment among educational development, manpower needs, science and technology policies, and global forces as the economy matures.

From early 1960s through to the early 1970s, Singapore, having become independent in 1965, was acutely aware of the need for economic survival. This was a period where there was a high dependency on the transfer of technology from foreign MNCs, and the focus was on exploiting available technologies rather than developing new ones. Although most children had access to primary education during this period, the adult literacy rate was only about 50% (Aldcroft, 2000). These factors prompted a concerted push to enhance the quality of education. To cater to the export-oriented manufacturing, there was a rapid expansion of primary and secondary education aiming to foster national identity and to produce a workforce with the necessary skills. It was also during this period that a bilingual policy was introduced, which gradually shaped up to require each student to learn English and one other official language. (Apart from English, the other three official languages are Chinese, Malay, and Tamil.) A common curriculum was introduced such that mathematics and science subjects were required to be taught in English. These two policies have enabled subsequent generations of Singaporeans to stay connected to the world economy as it grew and evolved; and to keep abreast of technological developments which facilitated their addition to the local capacity as the country gained traction in its economic push.

In the second stage of development, roughly from early 1970s to early/mid-1980s, Singapore oversaw a period of rapid industrialization where local manufacturing capabilities were developed through adapting and innovating acquired practices. The nature of the manufactured products also moved significantly up the value chain, becoming more complex and high-tech. To support such activities, and to lay the infrastructure to attract investment as well as to further develop capabilities, the National Computerization Plan was launched in 1980 to (1) computerize the major functions of every government ministry; (2) develop and facilitate the growth of a local information technology (IT) industry; and (3) develop the necessary IT manpower to meet the future needs of industry. After this plan had established a reasonable foundation, the second plan, entitled National IT Plan, was introduced in 1986 to shift the focus from the public to the private sector, specifically to integrate computing and communications via networking technologies to provide one-stop, fast, and efficient services. This stage of development, spanning about one-and-a-half IT plans, coincided with the consolidation of various education policies to develop greater coherence which served to prepare the workforce to later take advantage of the effects of globalization (Yip and Sim, 1990). For instance, a focus on mathematics and science was reflected in the expansion of higher education in local polytechnics and universities to produce the number of engineers and technicians who can support the buildup of high-tech manufacturing capabilities. The need to maximize the individual's potential led to the introduction of streaming within the education system based largely on academic ability. The gifted program for high-ability students was also established a few years later. The primary aim of these education policies was to provide a differentiated curriculum that can best

match the capability of students. Although these policies attracted a fair amount of discomfort in later years and probably increased the stress level of students, the positive outcome was a significant reduction in student attrition and a sharpened system that could cater better to individual needs.

The third stage, from about mid-1980s to mid-/end-1990s, represented further shift in the balance of industrial focus. This stage was sandwiched between two recessions, one in 1986 and the Asian financial crisis in 1998; and in both cases, it prompted important adjustments to the economic structure which helped the country pull out of these difficult periods relatively intact. Although the economy continued to put in place infrastructure that made it attractive for foreign investments, there was a shift toward high value-added industries and the development of an external economy that could be effectively linked to the domestic economy. Perhaps the most significant development was the realization that the economy cannot just rely on exploiting technologies developed elsewhere and transferring such capabilities to the resident population. While this remained a key aspect of Singapore's industrial engagements, the need for producing new ideas and technologies initiated a concerted phase of large-scale injection of funds for research and development (R&D), especially toward the mid-1990s. The National Science and Technology Board (NSTB) was set up in 1991 to oversee the development and implementation of integrated science and technology policies. This helped drive the first national technology plan which had a strong applied industrial focus. Important parallel structures were set up during this period to attract R&D activities into Singapore. These included the establishment of the Science Park next to the National University of Singapore (NUS) to stimulate R&D activities; and the Institute of Molecular and Cell Biology that signaled an important area of development.

The first ICT master plan for education (MP1) was launched in 1997 to tap the affordances of ICT for teaching and learning. This led to a systemic leveling up of ICT skills for all teachers, as well as putting in place a strong ICT infrastructure for schools. This was in line with the articulated wish to develop "Thinking Schools, Learning Nation" (Goh, 1997) and a culture of continual learning beyond formal education. On the education landscape was also the further provision of vocational and technical training at the secondary and postsecondary levels. Over and above all these, promotion of various identified R&D areas was supported by the encouragement given to students to undertake relevant courses of study at the university level. Greater refinements to the education system were also brought into being during this period, especially the increased porosity between different education tracks, allowing students to have greater flexibility and choice over subjects and academic levels in the different streams.

The fourth stage began from around the late 1990s with an economic plan that emphasized knowledge-based industry and technopreneurship akin to the spirit exemplified by Silicon Valley (Wong, 2001). At this point, the earlier focus on R&D was beginning to bear fruit as spin-offs from R&D institutions and venture capital increased noticeably. However, the increased uncertainties of the world economy prompted the need for constant innovation and the necessary speed to exploit the economic potential of any ensuing products. For this to be the case, it is important to increase the connectivity both within and outside national boundaries to facilitate collaborative and efficient development of ideas. To engage in the latest frontiers in various fields, a number of key research institutes were established, focusing on ICT, chemical and engineering sciences, electronics manufacturing, biomedical, and new media. These efforts were further consolidated through the setting up of the National Research Foundation (NRF) in 2006 to coordinate the research of various institutions situate within a larger national framework, and drive the national R&D agenda (NRF).

In line with these developments and to cultivate a mindset of lifelong learning, the Workforce Development Agency was formed in 2003 with an initial focus on continually upgrading low-skilled or unemployed workers. It also made available some S\$50 m for the training and development of private-sector professional upgrading in science and technology. On the education front, several initiatives were also introduced to lend greater coherence to the concerted effort. These include introducing the Teach Less, Learn More (MOE, 2007) initiative that focused on transforming teaching and learning practices so as to achieve engaged learning. Project work was introduced in grades 11 and 12 as assessable components that would count toward local university admission. These efforts were aimed at creating a more holistic schooling experience for pupils. At the same time, research institutions and centers continued to promote the learning of science and technology. For instance, there was a significant increase in the number of scholarships offered by agencies such as the Agency for Science, Technology and Research (A*STAR). As for teachers, various professional-development support and resources were made available, which included the setting up of a DNA center to cater to teachers teaching life sciences in schools.

Overview of Singapore's Education System

Singapore has largely followed a 6–4–2 structure (i.e., 6 years of primary, 4 years of secondary, and 2 years of preuniversity education) for grades 1–12 until recent years. For a better catering to the diversity in talents, and for providing more time for learning, greater flexibility was

injected into the system to equip it better to meet the diverse needs of the education and economic landscape. One important change was the introduction of integrated programs (IPs) that allow selected students to skip one high-stake national examination at grade 10. (These programs are available for students who have demonstrated sufficiently high academic ability such that they are most likely to gain entry to university education.) The time freed up from exam preparation can then be used by the schools to engage the students in a broader range of pursuits. Two variations of IPs are currently available, one that takes students in at grade 7 through to grade 12; and the other for students from grade 9 to grade 12.

Some degree of streaming into three different tracks is also done at the start of secondary education for a better matching of the capability of the students with the orientation and delivery of the programs. Successful completion of these programs allows students to either move on to preuniversity education or start postsecondary education. On the whole, about 66% of the primary-one cohort of students gain admission into institutes of higher education (~24% gets into universities and ~42% gets into polytechnics) (Ed Stats, 2008).

About 21% of the primary-one cohort, after grade 10, continue their studies in the Institute of Technical Education (ITE). This is a postsecondary institution that offers pre-employment training in various areas of specialization, including courses on automotive, electronics, hairdressing, and printing. It currently has ten campuses which will be consolidated into three regional campuses catering to 21 000 students by 2015.

There are five polytechnics in Singapore to provide vocational and professional preparation for students through its various diploma programs. Examples of these 3-year diploma courses include nursing, engineering, and financial studies. The polytechnics have established very strong links with industries, enabling them to adjust their programs to respond quickly to the changing skills demands. To provide greater options and variety within the education system, polytechnics could also explore providing degree programs in selected areas that are not traditionally provided by the local universities, such as in hospitality studies.

Three government-supported universities, namely, the Nanyang Technological University (NTU), the NUS, and one privately funded university, called the SIM University, cater to the bulk of local university education needs. In April 2006, NTU and NUS were granted autonomous status (SMU already had autonomous status when it was founded in January 2000) as not-for-profit educational corporations. Although the government continues to subsidize the fees of local students studying in the three universities, the autonomous status means that each university can set its own practices and operation guidelines and have control over the courses and programs it offers. They will also have the autonomy to shape their

respective research directions and develop the strategies to meet their goals. For instance, the universities have been able to offer specialized joint programs with other distinguished universities, such as the Massachusetts Institute of Technology (MIT), Stanford University, and Chicago School of Business, usually at the postgraduate level. The privately funded university, the SIM University, caters to adult learners.

In addition to the above universities, there are a number of foreign universities offering undergraduate and postgraduate degrees. They are normally affiliated with a local partner with a variety of delivery models, such as co-teaching between local and overseas academics. Most of the affiliated universities are from Australia, the UK, and the USA and the degrees are awarded by these foreign universities.

From IT Plans to Interactive and Digital Media Engagements

The development of both an enabling infrastructure and a workforce with the mindset and skills to undertake high-complexity jobs are central to Singapore's ability to compete effectively in the global environment. A key set of initiatives spanning almost three decades has provided the backbone for such developments.

In recognizing the importance of using ICT to enhance major aspects of business, educational, and administrative transactions, five national IT plans had been launched and implemented to support the needs of the country as its economy grew. After the completion of the first two national IT plans mentioned earlier in this article, the third, entitled IT200 (NCB, 1992), was started in 1992 to transform Singapore into an intelligent and wired island. This was envisaged to provide the sort of telecommunication infrastructure needed to attract cutting-edge economic activities to the country. It provided Singapore ONE, the first nationwide broadband network (NCB, 1997) to reach most households, all schools, and many public and private institutions. The fourth national IT plan, called Infocomm21, was Singapore's strategic plan for information and communication technologies (Infocomm) in the new economy (Infocomm21, 2000a). The vision of Infocomm21 was to "develop Singapore into a vibrant and dynamic global Infocomm Capital with a thriving and prosperous e-Economy and a pervasive and infocomm-savvy e-Society." To drive this plan, the Infocomm Development Authority (iDA) of Singapore was formed by merging the National Computer Board (NCB) and Telecommunications Authority of Singapore (TAS). In Infocomm21, it was recognized that the active participation of the private sector in taking the lead to come up with projects and enterprises was of crucial importance. As such, the intentions of the Singapore government were to play the facilitator and catalyst roles,

for instance, by reviewing policy or regulatory impediments with a view toward making them, where possible, compatible with a knowledge-based economy. At the same time, there would be concerted efforts to attract new international players onto the infocomm scene of Singapore, and to help local enterprises to regionalize and globalize (Yeo, 2000a, b).

Recognizing the increasing need to have greater coherence across various sectors in Singapore for any future infocomm efforts, the iDA led an effort in 2005 which brought the public, private, and people sectors together to develop a 10-year master plan to realize the potential of infocomm over the next decade. This resulted in the Intelligent Nation 2015 (iN2015) report which was published in June 2006 (IDA, 2006), and provided pointers to the way ahead for infocomm development. It laid out the three key themes of innovation, integration, and internationalization which support the vision of establishing an intelligent nation, a global city, powered by infocomm. This is perhaps the most comprehensive plan to date in terms of coverage and the tight alignment of key sectors, which are: digital media and entertainment; education and learning; financial services; government; healthcare and biomedical sciences; manufacturing and logistics; tourism, hospitality, and retail; infocomm infrastructure; services and technology development; enterprise development for Singapore-based companies; and infocomm manpower development. The report also exemplified the complex and interconnected

nature of the economy, and further emphasized the need to take holistic approaches to develop a technology-enabled workforce.

The environment characterized through the increasing presence and use of interactive and digital media (IDM) calls for the development of twenty-first-century skills, in particular, that of social participatory skills, where each person will need to be able to communicate and actualize effective collaboration. Where the IDM environment interacts with the formal learning sphere, one of the resulting effects would be that the learning outcomes, as desired by traditional instructions, would become uncertain. This is because the learner can easily connect to, and interact with, a host of other learning resources, environments, and information. It will thus be challenging for educators to evolve a system that can cater to the learning needs of learners operating within the IDM arena.

IT in Education Master Plans

The introduction of ICT into teaching and learning is seen to be an important element in developing a spirit of creativity and innovativeness among learners (Thaman, 2002). The integration of ICT into education began in the late 1970s when computers were introduced into the schools to raise the computer literacy of students and to support the teaching of computer science (Wong, 1989). Since then,

Table 1 Goals, programs, and achievements of the first two ICT master plans for education

<i>Goals</i>	<i>Main programs</i>	<i>Key achievements</i>
<i>1st ICT master plan in education (MP1)</i>		
<ul style="list-style-type: none"> ● Enhance linkages between schools and the world around them ● Generate innovative processes in education ● Enhance creative thinking, lifelong learning, and social responsibility ● Promote administration and management excellence in the education system 	<ul style="list-style-type: none"> ● Curriculum and assessment ● Content and learning resources ● Physical and technological infrastructure ● Human resource development 	<ul style="list-style-type: none"> ● All schools have basic IT provisions, including broadband ● Pupils performed well in international IT-based activities ● Preservice teachers received IT skills and pedagogies courses ● In-service teachers acquired basic IT skills and pedagogies ● Resource portal – Edumall
<i>2nd ICT masterplan in education (MP2)</i>		
<ul style="list-style-type: none"> ● Pupils use IT effectively for active learning ● Connections between curriculum, instruction, and assessment are enhanced using IT ● Teachers use IT effectively for professional and personal growth ● Schools have the capacity and capability in using IT for school improvement ● Active research in IT in education ● Infrastructure that supports widespread and effective use of IT 	<ul style="list-style-type: none"> IT in curriculum and assessment ● Professional development ● Capability and capacity building ● Research and development ● Infrastructure and support 	<ul style="list-style-type: none"> ● Established platforms for ICT in education innovation (Future Schools, Lead@ICT schools) ● Baseline ICT standards for pupils ● Pervasive use of ICT for teaching and learning ● Strengthen R&D in ICT in education (Learning Sciences Lab in NIE)

several initiatives and projects were implemented to further enhance the use of ICT in education. Although these were systematic efforts, the advent of the Internet brought about greater possibilities and demanded greater coherence in transforming teaching and learning practices. The first IT master plan (MP1) for education was launched in 1997, followed by the second master plan (MP2) in 2002, and, recently, the third in 2008. The key details of the first two IT master plans for education are summarized in **Table 1**.

The key success of MP1 was its ability to systemically put in place a strong infrastructure to support the use of ICT for teaching and learning for both the schools and institutes of higher learning (IHL). It has also ensured that all teachers were exposed to and being trained on key ICT skills and using ICT for teaching and learning. This laid the foundation upon which MP2 was built. During MP2,

which represented a period for seeding innovations for meaningful ICT use, schools were encouraged to undertake research activities and exploration to develop transformative ICT use in the classroom. These efforts were channeled through structures such as the Future Schools and LEAD@ICT schools initiatives. The third ICT master plan for education (MP3), which was announced in August 2008, will be building on the work of MP1 and MP2.

Looking Ahead: Human Capital Development

Similar to other developed nations, Singapore is facing the challenge of having to undergo a critical transformation of its economy in response to the demands of changing

Table 2 Selected recommendations of the Economic Review Committee (ERC) on enhancing human capital

<i>Empowering the individual</i>	School sector
	<ul style="list-style-type: none"> • Greater customization of learning through allowing secondary school students wider access to subjects beyond respective base stream • Broaden school curriculum at school level • More active and autonomous school governance through building more links with industry • Set up steering committee tasked with promoting successful arts and sports education • Present school info to represent holistic development
	Higher education sector
	<ul style="list-style-type: none"> • Increase university cohort participation rate to 30% in the long term • Expand postgraduate intake to facilitate knowledge creation • All polytechnics and universities to combine certain National Manpower Council (NMC) targets to enable them to respond to changing industry needs
<i>Enhancing the system at corporate level</i>	Lifelong learning through continuing education and training (CET)
	<ul style="list-style-type: none"> • Provide financial incentives to encourage greater participation in CET • Strong performance assessment system to encourage training provider to enhance quality and relevance of training. • Set up Centre for Adult Learning (CAL) to ensure that trainers are trained in adult pedagogy • Create one-stop system of decentralized centers for access to training programs/grants
	A global mindset
	<ul style="list-style-type: none"> • Develop Singapore as education hub • Increase exchange programs for more international exposure for Singapore students • Increase international exposure for teachers • More postings between civil service and offshore public service/private sector • Scale up presence of Singapore international schools
<i>Enriching the environment</i>	Developing human capital management (HCM)
	<ul style="list-style-type: none"> • Provide continuing education and training to equip human resource (HR) managers with business skills • Raise HR capabilities of business enterprises
	Upgrading manpower industry to raise HCM competencies
	<ul style="list-style-type: none"> • Establish center or network of research centers for HCM • Partner professional and trade associations for the training and development of professionals, managers, executives, and technicians
	Enhance worker employability
	Framework to attract, retain, and engage talent
	Mechanism to build collaborations between arts, sciences, and technologies
	Governmental commitment and support for arts, culture, sports, and recreation (ACSR)
	<ul style="list-style-type: none"> • Civil service to take lead to give greater emphasis and recognition to sports and cultural participation and achievements • Encourage public and private partnerships to develop and implement a package of programs to encourage public/private sponsorships
	Increased opportunities and public awareness to participate in ACSR activities

global conditions brought about, to a large extent, by the pace and nature of technological innovations. These changes will impact the job market, with the likely characteristics of an ever-shortening life-span for learned skills. The requirements of the country's human capital will thus have to be constantly reviewed and aligned to changing needs.

In the past, Singapore's growth was largely based on strong infrastructure support and MNC-led industrial development of local capabilities. Moving ahead, it is likely that future growth will depend on the workforce's ability to value-add to these processes in ways that focus on value-creation, innovation, and international cooperation. The economic review subcommittee on enhancing human capital (ERC, 2003) has identified three key areas on which to focus developmental efforts. Selected recommendations are summarized in **Table 2**.

It is clear that in attempting to develop a technological workforce, there is a need to adopt a whole-country approach that represents a concerted, cross-agencies effort. The work of the Economic Review Committee (ERC) was a wide-ranging review taking into consideration the constantly changing demands of the global economy and it attempted to make sufficient sense of it so as to shape up a series of recommendations that aimed to provide the Singapore workforce a cutting edge in competing globally. The focus on human capital is an inevitable consequence of the country's lack of practically any resources. The strong alignment among the parallel development of science and technology, education, economy, and manpower is a testament to a nation's efforts to forge ahead for continuing economic viability.

Public–Private Partnerships for Educational Reform

V Quah, Singapore

C P Lim, Edith Cowan University, Perth, WA, Australia

C Brook, Curtin University of Technology, Perth, WA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

There is growing belief that no single sector can effectively bring together the resources and capability to address or resolve the social and development issues we are facing (Googins and Rochlin, 2000; Tennyson, 2003). Traditionally, a key role of government has been the provision of the infrastructure required to sustain the economic activities of the people they govern. Governments fulfill this role through the collection of various taxes to develop and maintain public infrastructure and services. However, as populations grow, the cost of providing and maintaining these infrastructure and services increases; and, in many instances, the complexities associated with managing large public projects and programs become burdensome. Public–private partnerships (PPPs) – as possible mechanisms for developing and sustaining public infrastructure and services – have created growing interest from governments around the world (Moore, 2005). Such partnerships were identified at the 1992 United Nations Conference on Environment and Development – the Rio Earth Summit – as central to achieving global sustainable development.

Prior to engaging in any exploration of PPP, it is important to establish a common understanding of what is meant by the term. Public is used to refer to any service or infrastructure provided by the state whereas private refers to any endeavors that are associated with the private sector or nonstate sector. This includes both civil not-for-profit organizations and those more commonly associated with profit-related objectives (Latham, 2006). For the latter, they are usually corporations that have the resources and desire to undertake social responsibility. Partnership is used to refer to activities that require shared objectives, responsibilities, decision making, and risk. PPP then focuses on the shared responsibility of both the public and private sectors toward the provision and maintenance of infrastructure and services for the general population.

Despite the growing interest in PPP, there have been few peer-reviewed articles with regard to specific case studies of PPP and how they provide or fail to provide for infrastructure and services for the country. Such case studies are, especially, lacking in the area of education reform. Based on a collective case study of Microsoft's Partners-In-Learning (PiL) initiative, this article aims to first contribute to a better understanding of PPP in the

context of education reform from the perspective of a private sector partner, and then draw guidelines for PPP to bring about education reform.

Under this initiative, Microsoft establishes partnerships with ministries of education, national and local government bodies, and other public and private organizations to empower students and teachers to realize their full potential in learning and teaching, mediated by information and communication technologies (ICTs). The PiL initiative consists of three programs: the Learning Grants program, Fresh Start for donated computers, and School Agreement subscription licensing program. While the implementation of the PiL initiative is relatively recent (since 2003), it has made significant impacts on teaching and learning in schools. The impacts include the curriculum, professional development of school staff, school ICT culture, teacher use of ICT for teaching, and student use of ICT for learning. Although the approaches toward the implementation of the PiL initiative vary among the countries – and their levels of ICT-use in teaching and learning are different – there are many similarities in their experiences of implementation.

Models and Guidelines for PPP

There has been growing interest in PPP with conflicting opinions about their potential benefits and pitfalls. While there have been many successful projects made possible by PPP in the past, several academics caution against the pitfalls and highlight the importance of ensuring value for money of the projects, meeting the intended outcomes of the projects (Grout, 2005), and protecting the interests of the public (Moore, 2005). Despite these words of caution, the Academy for Educational Development (AED) describes PPP as untapped resources and suggests exploitation of such resources. In light of such growing interest in PPP among both the public and private sectors – and the considerable debate of the virtues of PPP – this section examines models and guidelines for PPP that may deliver the desired outcomes.

There are several ways to categorize the guidelines for PPP – those associated with cost–benefit analysis and those associated with project management. For the former, Hart, (2003) posits a mathematical model used to calculate the benefits of PPP versus totally public ownership.

For the latter, the National Association of State Chief Information Officers (NASCIO) suggests a model for project development that explores how projects may operate rather than to measure the benefits (NASCIO, 2006). This model is made up of eight key building blocks for effective PPP that include: (1) commitment from executive leadership; (2) a statutory foundation for partnering; (3) direct public sector involvement; (4) a well-crafted plan; (5) effective communication with stakeholders; (6) the right opportunity; (7) the right partner; and (8) well-defined management processes. These building blocks are consistent with the elements of effective project management outlined by Luca (1994) suggesting that models of effective PPP may resemble frameworks of project management. It has also been suggested that the signing of the memorandums of understanding (MOUs) is an important first step toward a public-private partnership (Inamdar, 2004).

In contrast, Davies and Hentschke, (2006) describe an exploration of two educational PPPs that yield an insightful four-stage model:

1. preconditions for partnerships where preconditions refer to the conditions that are required for the partnership to exist;
2. change dimensions that emerge as a result of partnerships where change dimensions refer to the types of changes that are pursued through the partnership;
3. partnering mechanisms that serve as means or vehicles binding the organizations to each other; and
4. success indicators of the partnerships that are the products and byproducts of the partnership which provide value to the partnering relationship.

Drew, (2004) describes a set of guidelines for projects attempting to bridge the digital divide. It includes the completion of a comprehensive needs analysis, completion of pilot studies, keeping costs down, development of multipurpose projects, and seeking funding assistance.

While each of these models and set of guidelines for PPP provides valuable insight, further exploration is required to ascertain the educational benefits associated with PPP, the conditions required for effective PPP, and the roles and responsibilities of each party in the PPP.

PPP, ICT, and Education

The primary motivation for using ICT in schools is that it supports students in their own constructive thinking, allowing them to transcend their cognitive limitations, and engages them in cognitive operations they may not have been capable of otherwise (Lim, 2007). Although master plans, national policies, and strategies of ICT in education exist in many countries, access to – and use of – ICT in classrooms within some countries and communities

are still very low (Plomp *et al.*, 2003). Such digital divides may widen the gap across communities in the areas of quality of life, competitiveness, and economic development. It is in this context of narrowing the digital gap that many governments – especially those in developing countries – have signed MOUs with private corporations that have the resources and the desire to undertake social responsibility (Mitra, 2003). Dangwal *et al.* (2005) provide an account of how a PPP seeks to bridge this gap and provide educational opportunity to those individuals typically associated with the disadvantaged. In this project, the government of a developing nation establishes a PPP with a private sector technology company to provide technical solutions to support the education of students who were irregular or nonattendees in traditional classrooms. While the paper does not describe the structure, operational procedures or the project management of the PPP, it outlines a project that has clear educational benefit for disadvantaged children.

This single case study provides insight into a PPP that has brought about significant educational advantage for those who are involved, and it also highlights the need for further projects to bridge the digital divide in ways that bring about significant educational reform. At the same time, there have been PPP that harness upon ICT to bring about break-the-mold school reforms. One such PPP is the Co-NECT model of school reform that is funded by New American Schools (NAS) – working together with private and public sector partners. The Co-NECT project emphasizes the development of students' higher-order skills through their work on extended, multidisciplinary projects. To provide a conducive environment for project-based learning, Co-NECT restructures the organization of students by forming them into clusters composed of students across grade levels. Co-NECT also provides professional development for the teachers and works closely with the principals to support the teachers. Although ICT is a pivotal tool in all curriculum areas, the Co-NECT model does not position ICT to be a reform in and of itself. In this model, ICT serves as a hub that holds together several aspects of a school reform effort (Russell and Haney, 1997).

Overview of the PiL Initiative

For about two decades, Microsoft has worked with schools and ministries of education to foster greater understanding of – and access to – ICT tools and training. This work has given the company a unique understanding of the challenges faced in different countries and cultures as they struggle to develop and fund ICT in educational programs. Consistent with the present data and assessments with regard to the growing digital divide within countries and communities, Microsoft has identified the three key issues:

1. *Under-utilized resources.* Although donated computers are economic necessity in many countries and communities, they contribute to accessibility problems due to outdated hardware, compatibility problems, and licensing constraints.
2. *Affordability.* The ultimate measure of ICT affordability is the cost of innovation and access, and the basic cost of ICT relative to *per capita* income.
3. *Know-how.* Teacher training and curriculum deployment are pivotal in addressing the economic, cultural, geographic, and physical barriers to ICT in education.

Microsoft launched the PiL in 2003 – a 5-year global initiative that targeted both developed and developing countries. The implementation of PiL was unique to the participating country and its culture. For developed countries, strategic investments promoted pedagogical advantage by training teachers to become fluent or elegantly confident with ICT in order to move less affluent students from basic to more sophisticated competencies. Developing countries – on the other hand – placed strategic emphasis on achieving significant technical competence among high-performing students as a priority for boosting their economies. Regardless of the strategic focus, government and schools require new partners and new resources for developing more competitive ICT skill-sets and capabilities in their countries.

The initiative comprises of three distinct – yet integrated – programs.

1. *Partners in learning grants.* The program seeks to partner with governments and education leaders to deliver local tools and resources for comprehensive ICT-skills training and curriculum leadership. With the goal of empowering schools and communities to improve student learning through school and teacher leadership, the program intends to deliver support in the form of teacher training and ongoing coaching/mentoring, student and teacher ICT-skills-assessment tools, high-quality courseware for teacher development, access to digital content, student certification and technical support, and research and measurement of success. Funding supports the establishment of local Microsoft Information Technology (IT) Academy Centers through joint partnerships with local community organizations, educational institutions, or local training providers. The Centers provide school leadership training, ICT-skills development and curriculum integration.
2. *Partners in learning fresh start for donated computers program.* The program seeks to remove licensing barriers that prevent primary and secondary schools from utilizing donated computers. It targets at donated machines received by schools (Pentium II or older) that are originally licensed with Windows. These schools can request

a copy of Windows 98 and/or Windows 2000 media from Microsoft. This ensures that schools can leverage their donated personal computers regardless of whether or not proof-of-license was provided with the donation.

3. *Partners in learning school agreement subscription.* This program provides extra support for the neediest schools where their ICT-acquisition budgets are constrained by other pressing and necessary social and economic investments. It attempts to reduce the initial cost of education desktop, reduce the cost of upgrading and maintaining the schools' current installed base and promote an easy-to-administer program for managing software investments over time. An MOU is signed with the national or local government where eligible schools can receive a free upgrade to Windows XP Pro for both new and current installed base PCs and/or to acquire Office XP Pro for both new and current installed base for a low price per license per year.

In 2003, the PiL initiative was initially launched in a mix of developed and developing countries including India, Brazil, China, Russia, Thailand, Canada, the United Kingdom, France, Germany, Taiwan, and Japan. For the following 3 years, the initiative has been rolled out to more countries. Access and affordability are central to the initiative where it facilitates ICT in education and ICT access based on community and country needs and priorities. The following section showcases a range of projects in both developing and developed countries – India, Brazil, and United States. As there is a greater variety of projects under the Learning Grants Program as compared to the other two programs, all the case studies discussed fall under this program.

The Collective Case Study

Case Study One: A Partnership with the Government of Maharashtra in Pre-Service Teacher Education

India is a large country with a population of more than a billion. She has the third largest economy in purchasing power and is the second fastest-growing economy in the world. Hidden beneath all the economic growth, India has been – and is still – battling the challenge of poverty and providing quality education for all. Bringing ICT into schools is one of the major challenges. In places where there is access to ICT infrastructure, the availability of trained teachers is a challenge. Under the Learning Grants Program or *Shiksha* as it is termed in India, Microsoft has partnered with ten state governments to train government schoolteachers in the use of ICT for teaching and learning. Since its launch 3 years ago, over 1 00 000 teachers have been trained and at least 5 million students

have been taught by these teachers. One of the state governments that has been involved in this program is the Government of Maharashtra. The partnership commenced, in 2005, with the setting up of three IT academies in Pune, Nagpur, and Aurangabad to train government schoolteachers.

Pre-service teacher education project in the state of Maharashtra

Equipping new teachers with a set of ICT competencies was a challenge identified by the Government of Maharashtra – there was a large number of pre-service teachers and an absence of ICT being integrated into the curriculum in the pre-service teacher-education program. To address these challenges, it was planned that at least 1 05 000 pre-service teachers and over 1000 teacher educators would be trained under a co-constructed process and system that have been set up by Microsoft, the Government of Maharashtra, and the teacher-education institutions. The focus of the project for teacher educators is on soft skills, such as peer-to-peer coaching and pedagogy strategies of incorporating ICT into lesson plans. As the teacher educators become more competent in the use of ICT in their teaching and learning, they serve as role models for the pre-service teachers in adopting ICT in their own classrooms. Such a process ensures the sustainability of the project; where the project is part of the Maharashtra Government's effort to draw upon the teaching and learning opportunities of ICT as an essential driver in the state educational system.

Expected impacts of pre-service teacher education project

This partnership will not only impact the present pre-service teachers and future teachers involved in the project but it will also sustain and scale-up the project to ensure that future generations of pre-service teachers in Maharashtra will undergo the pre-service teacher-education program with an ICT component. As a result, the pre-service teacher-education program in the state of Maharashtra may be used as a prototype to be customized to other teacher-education institutions in India and the rest of the world. Moreover, this project has the potential of changing the teaching and learning processes of the classrooms in the state of Maharashtra. It provides the pre-service teachers with the opportunities for ICT-mediated learning – and more important – equipped them with a set of competencies to integrate ICT in their lesson plans. With this set of ICT competencies among the new teachers, the pressure on the state government for providing in-service teacher education in ICT is eased.

Case Study Two: A Partnership with the State School Isaac Schraiber in a Reading and Writing Project

The State School Isaac Schraiber is located in an under-developed area of the city of São Paulo in Brazil. The literacy level of the students in the school has been low and the learning engagement of the students needs to be enhanced. The school principal has attended a series of ICT for School Leadership professional development workshops under the Learning Grants Program. With his newly acquired understanding of ICT and authentic learning experiences, he crafted a project on the Revitalization of the Cipoaba Stream. The idea was to empower the students to be actively involved in community issues and – as a result of such participation – engage them in reading and writing.

Reading and writing project in State School Isaac Schraiber

The project commenced, in 2004, and was developed by the principal, together with the staff of the school. It aimed at enhancing reading and writing competencies among the students by situating the learning tasks within the context of initiating the revitalization of the Cipoaba Stream – a stream that was located near the school. ICT was pivotal in the implementation of the project as an information and construction tool. To support the project, Microsoft provided both hardware and software necessary for the implementation of the project. It also provided ICT training for both the teachers and students. Based on the environmental problems created by the Cipoaba Stream, the students – at all levels in the school – researched on the Internet for newspaper articles, news clips, songs, and films concerning the related environmental problems. They debated on different environmental topics in the classrooms and created their own books under the supervision of their Portuguese teachers. Teams of students met in the library once a month to brainstorm and plan for actions to engage the community to address the environmental problems facing it.

Field studies to the stream were planned and carried out by the geography, history, mathematics, and physical education teacher to collect data and promote a better understanding of the Stream and the problems associated to it. Photos were taken during these field trips to make records of the area and create models to represent the stream in the past, present, and future. Window Movie Maker was then used to create movies by the students to raise awareness of the initiative to the community and encourage more proactive actions from all levels of the community.

Impact of the reading and writing project

As a whole-school approach was adopted, the teachers reported a significant enhancement of learning engagement

among the students who were participating in the project. The students were more task oriented during the lessons and were engaged not only in reading and writing, but more important, in digital literacy and ICT competencies. They could, effectively, use digital cameras, manipulate digital pictures, use Window Movie Maker, and represent their understanding through hypermedia narratives. The students were also more involved with social issues and showed deeper understanding about the environment. At the same time, the project managed to promote community actions that included the construction of a collector tube, the creation of an environmental park in the neighborhood, and the re-urbanization of irregular dwellings.

Case Study Three: A Partnership with the School District of Philadelphia in the School of the Future Project

The partnership between Microsoft and the School District of Philadelphia was agreed in 2003 to investigate, determine, and deliver a high school equipped to prepare learners for the twenty-first century. There was a meeting of two goals between the two partners: (1) Microsoft was considering investing in and creating a School of the Future (SOF) resource similar to the Home of the Future; and (2) Philadelphia has not built a new school in the last 40 years and the chief executive officer (CEO) was hired on a platform of capital expansion. In addition, hence, the decision was made by both parties to enter into a partnership to build a high school in Philadelphia.

School of the future project in Philadelphia

The goal of this project was to build and redefine the norm for 9–12 urban education. The result is a sustainable and replicable model that addresses functions of business and administration processes and educational practices. Innovation was achieved in five areas: technical architecture, instruction, community engagement, building design, and business management. The Microsoft project manager led the development of each of these innovations. The innovations developed were categorized into three areas: process, people, and environment. The first step for building the SOF was to create a process that would act as a framework and guide for the project. That framework was a 6i development process: introspection, investigation, inclusion, innovation, implementation, and introspection. Based on this process, a set of strengths – weaknesses – opportunities – threats (SWOT)-analysis tools and resources was developed due to the district's lack of strategic planning competencies. More important, training was provided and professional development resources to guide education planning were developed. At the same time, the partnership leveraged on Microsoft's approach to hiring and the start-up team of the SOF

went through training on behavioral interviewing and the loop to hire the principal and staff for the school.

The next area of innovation is people. The education competencies describe the full range of characteristics necessary to help a school district achieve its organizational goals and vision. They were developed in partnership between Microsoft, Lominger International, and school leaders from around the world. To ensure that the impact of this project extends beyond Philadelphia, numerous capacity-building strategies were in place to reach educational leaders around the world. They included the United States Quarterly SOF Briefings, where about 100 education leaders/teams from around the world participated in a 2-day workshop that introduced them to SOF resources and acquainted them with best practices that they might bring back to their organizations. The other professional development event was the SOF World Summit that brought together education elites to discuss and debate schooling for the future.

The third area is environmental innovations. These included the learning space matrix and the technical architecture design. Schools are constantly trying to identify ways that space can support instruction. Through research of appropriate characteristics of learning spaces, six characteristics have been identified for the spaces in the SOF building. For each space, documentation of how these characteristics have been reflected in the design was created in the form of the Learning Space Matrix. At the same time, utilizing the majority of the Microsoft Product suites, the SOF technical architecture provided a complete Learning Gateway Framework with role-specific access for students, parents, teachers, and administrators.

The SOF is a public high school for grades nine through 12. It is a neighborhood high school with no special admits. It has approximately 750 students and a comprehensive curriculum. Approximately US\$60 million was funded by the School District of Philadelphia while Microsoft contributed primarily human capital and development support.

Expected impact of the school of future project

The expected major impact of the project is to develop a school that will serve as a laboratory and model for the school of the future. In doing so, it aims to be replicable – not only throughout the School District of Philadelphia, but also districts nationwide, both large and small, and possibly internationally as well. It will also serve as a planning model of how the private and public sector work together to reform education and – in the long term – transform neighborhoods. The end result of this partnership will be a state-of-the-art educational institution incorporating the latest technology that will advance students' academic possibilities and be a conduit for career development. Some of the processes used in the setting up of the SOF – such as the hiring of staff process – have been

adopted by the district to hire all new principals. The District has been bombarded with inquiries about this project since its inception. Universities, technology corporations, pharmaceutical companies, and other large and small businesses have expressed their interest in this project. Universities and colleges are primed to assist the District with professional development, best practices, and educational research. The business sectors' resources are limitless and the project can tap on their expertise and insight in management, leadership development, and job training. In short, the SOF will be technology rich and a beacon of educational innovation.

Making Sense of the Case Studies: Guidelines for Effective PPP

Adoption of a Holistic Approach

Despite the investment to bring ICT into the classrooms, little impact has been observed on the roles of students and teachers, curriculum, and mode of assessment (Cuban *et al.*, 2001). Much too often, ICT has been introduced to replace traditional learning and teaching media or traditional method of delivery without any changes to the mode of assessment or the organization of the classroom or the running of the school. The learning media may have changed, but the practices and policies to integrate these new innovations remain constant. If nothing significant changes in the learning environment – save the introduction of ICT – few if any important effects can be expected. Therefore, a holistic approach toward the use of ICT in education needs to be adopted (Lim, 2007).

Based on the overview of the initiative and the case studies, it is clear that a holistic approach toward the use of ICT in education has been adopted by the PiL initiative. Besides providing access to working hardware and affordable software, the initiative worked on providing the facilitating factors for teachers and students to use ICT in teaching and learning. These facilitators included school-leadership and peer-coaching training, professional development of teachers, ICT curriculum for students, ICT competency standards for teachers, assessment of students, and sharing of expertise and experiences with partners. These factors were, often, interdependent. For example – without the school leadership training – professional development of teachers might not bring about a transformation of classroom practices as the teachers lacked a supportive school environment to put into practice their new set of competencies. Therefore, for PPP to be effective, the various parties in the partnership adopt a holistic perspective toward the development and implementation of the project, program, or initiative. However, it should be noted that such an approach will only work if all the partners have a good understanding of the sociocultural contexts of the school district or

classrooms they are working in; that is, a situation and needs analysis of the context that the project or program is situated in is absolutely crucial.

Situation and Needs Analysis

This phase consists of analyzing the teachers and students and their needs, the curriculum and mode of assessment, the resources, the school and educational system and their needs, and the community and its needs. The situation-and-needs-analysis phase was present in the three different programs of the PiL initiative and the three case studies. This was most obvious in the formulation of the initiative where the analysis phase was based on the vast experiences and data that Microsoft has due to its work with the education sector in the last two decades. This phase was also supported by literature review of ICT in educational research studies and data collection and analysis of existing educational practices and policies in the country involved in the initiative. It was with the identification of the three problem areas of under-utilized resources, affordability, and know-how that the three integrated programs of Learning Grants, Fresh Start, and School Agreement are developed. Therefore – for PPP to be effective – the situation and needs-analysis phase is carried out to provide the foundation for the project or program.

Piloting and Scaling-Up

Starting with a small diverse sample allows the consolidation of resources and efforts by the partners. This may serve as a piloting phase where best practices and lessons learnt are documented and barriers and potential problems are addressed. The PiL initiative commenced, in 2003, with a few countries – both developed and developing. The initiatives run in these countries may be likened to pilot testing the various programs in the initiative. The three case studies are also good examples. They serve as research sites where a prototype of the innovation is being developed, implemented, and evaluated. The prototype is not restricted to ICT and ICT-mediated practices, but it includes the conditions in which ICT can be used effectively. With the prototype revised and refined, the next phase is the scaling up of the innovation. Scalability is the ability of the innovation to achieve its expected outcomes as it grows; it depends on the possibility to implement the innovation at diminishing marginal cost where replicating the innovation requires less resources and yet produces similar or better outcomes. It has the additional benefits of accumulating knowledge, experiences, and shared resources (Hart, 2003). Therefore – for PPP to be effective – the piloting of the project or program provides the stepping stones for the scaling up of the innovation.

Ownership by Stakeholders

A common thread that emerges from both the review of contemporary literature referring to PPP and the exploration of the three PiL projects included in this article is the need of shared project ownership. In the context of educational systems, shared ownerships of PPP need to extend beyond the higher-level leadership of both the public and private sector partner to include the multiple stakeholders often associated with educational systems (Googins and Rochlin, 2000). Typically, this would include ownership by key stakeholders from centralized educational systems, education districts, schools, and the school communities. For example, the success of the project in the State School Isaac Schraiber was due to the whole-school approach adopted; it gave the teachers and students ownership of the project by empowering them to make decisions and act upon these decisions. Therefore – for PPP to be effective – the ownership of the project or program is shared among the partners and their major stakeholders.

Accountability and Sustainability

Accountability of schools has, often, been very narrowly defined in many countries where it is being associated to grades that are determined by students' performance on high-stakes tests. Although this may be the most no-fuss and economical approach, accountability works in different ways and at different levels. Based on the case studies, it is clear that accountability based on standardized test scores is different from accountability for providing the learning environment to cultivate social responsibilities, empower students to be autonomous learners, and involve communities in and around the school. In all projects and programs, the partners are accountable to the major stakeholders with respect to the expected outcomes. Although improvement in grades may be a pragmatic outcome for many schools, there is an urgent need to broadly define accountability to reflect the essence of education as the holistic development of a child (Darling-Hammond, 2004). In order to avoid misunderstandings, the partners in the PPP have to negotiate and define the accountability of the project or program to its major stakeholders.

Another important dimension of PPP is the sustainability of the innovation – that is, the ability of the innovation to persist over time. The processes and culture within the school or school district are pertinent to the sustainability of project or program. More often than not, there is a need for the partners to build the processes and shift the culture of the school or district during the intervention phase. It is only then that the innovation is most likely to become a permanent and integral part of the school. At the same time, sustainability encapsulates the spatial milieu as well, and it includes transplanting the innovation into spaces such as networks, virtual spaces, and social movement (Hargreaves, 2002). Therefore – for

PPP to be effective – accountability and sustainability are two issues to be negotiated and addressed among the partners. For the latter, it also involves the sustainability of the partnership.

Conclusion and Future Work on PPP

At present, efforts by many countries – especially developing and emerging nations – in education and educational reforms are progressing very slowly. This is compounded by rapid technological advancement that has resulted in a widening digital divide, and further disadvantaging for children and youths from the lower socioeconomic groups. Governments have been exploring PPP in an attempt to stem the flow of this negative cycle and to optimize the use of available resources. While there is conflicting evidence with regard to the past successes of the PPP approach to provision of public services and infrastructure, there is evidence that – under certain conditions – PPPs are effective.

The PiL initiative and its associated projects and programs that have been examined in this article have demonstrated how PPPs support educational reforms. There was evidence that the partnership with the State School Isaac Schraiber resulted in a significant enhancement of learning engagement among participating students. The partnership with the state of Maharashtra has the potential of changing the teaching and learning processes of classrooms teachers and the partnership with the School District of Philadelphia resulted in a model for the school of the future and served as a catalyst for increased community participation and the mobilization of resources. These case studies provide evidence of the benefits of PPP when a set of conditions is present to support the partnership in achieving its intended outcomes.

The review of the literature has revealed two PPP models – one that focuses on cost-benefit analysis and the other focusing on project management that includes roles and responsibilities. Based on the discussion of the three case studies and the initiative, there are several emerging issues that have commonalities with the two models. These commonalities suggest that the models are not mutually exclusive, but – in some ways – complementary. It suggests that a PPP has an increased likelihood of being effective when certain conditions are met. These conditions include:

- adoption of a holistic approach by the project or initiative;
- situation and needs analysis of the context of implementation;
- piloting and scaling up of project or initiative;
- shared ownership by all stakeholders of the project or initiative; and
- accountability and sustainability of the project or initiative.

The evidence presented in this article suggests that the present interest of public and private sectors in PPP as

a mechanism for educational reform is well founded. However, if these projects are to achieve the intended outcomes, there is a need to further explore the conditions required for successful implementation.

Relating Technology, Education Reform and Economic Development

R B Kozma, SRI International, California, San Francisco, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

The Economic Rationale for Educational ICT

Often policymakers employ an economic rationale in calling for increased technology in schools by claiming that the use of information and communications technologies (ICTs), such as computers, the Internet, and multimedia, will prepare students for the global economy and increase the nation's economic competitiveness. For example, in the 2001–03 technology master plan for Ireland, the minister for education and science claimed that the plan "... is vital to ensure that we acquire important skills needed to secure our future economic wellbeing" (n.d., p. 3). At the launch of Singapore's second ICT master plan, the minister of education claimed it would help students prepare for a more competitive future and a new, innovation-driven economic era (Ministry of Education, Singapore, 2002). In describing its technology-based program of educational reform, the Ministry of Planning and International Cooperation in Jordan (2004) claimed that "... the education sector must be responsive to employment market demands in key industries and develop critical 'Knowledge Economy skills' at all levels of the education system" (p. 1).

However, the logical chain that connects the introduction of computers in schools to resulting economic prosperity is rarely articulated by policymakers. This article examines the relationships among ICT, education, and economic development and explores the potential causal connections between the use of technology and economic development in the context of other corollary changes that may be needed in education if the use of technology is to contribute to economic improvement.

ICT, Education, and Economic Returns

There is some empirical support in economic studies for the policymaker's faith that ICT and education can contribute to economic growth. For example, ICT by itself has been an important contributor to economic growth over the past decade and a half (OECD, 2004a; Jorgenson and Vu, 2005). An increase of 2.5–3.0% in gross domestic product (GDP) during a year is usually considered a good rate of growth in developed countries. From 1995

to 2001, ICT by itself accounted for an increase of about 0.5% in GDP in the Organization for Economic Cooperation and Development (OECD) countries, with particularly strong contributions in the United States, Canada, the Netherlands, and Australia, amounting to about one-fourth of GDP growth (OECD, 2004a). Overall in OECD countries, ICT contributed about 16% of the growth in GDP during the first-half of the 1990s and increased to about 20% during the second-half of the decade.

Economists have also established that education is an important contributor to economic growth in both microeconomic studies – those that look at personal returns on investment – and macroeconomic studies – those that look at public returns on investment, including resulting increases in economic growth. Microeconomic data from 42 countries found that an average rate of return for an additional year of schooling was a 9.7% increase in personal income (Psacharopoulos and Patrinos, 2002). In a macroeconomic study, Barro (2000) found that there was an additional 0.44% growth in a country's per capita GDP for each additional average year of schooling attained, a return on investment of 7%. A review by Sianesi and Van Reenen (2002) found a return of 3–6% and a review by Stevens and Weale (2003) found returns that ranged from 6% to 12%.

Of particular interest is the finding of the Barro (2000) study that the quality of education had a stronger relationship to economic growth than did levels of education attainment; that is, the amount learned was more important than the number of years of schooling. Barro found that on assessments of science and math, national scores that were higher by one standard deviation equated to 1% growth in per capita GDP.

While macroeconomic studies show a positive relationships between ICT and economic development and between education and economic development, there is a lack of research analyzing the different components of the educational system – such as curriculum, assessment, teacher quality, or the use of ICT – in terms of their economic impact. Research of this sort is needed before a strong empirical argument can be made for economic benefits of educational ICT investments. But short of this research, the foundations for such an argument must be built upon economic theory and national case studies in which economic growth has corresponded to the implementation of educational ICT policies and programs.

Sources of Economic Growth

According to macroeconomists (see e.g., Stiglitz and Walsh, 2002; Krugman and Wells, 2006), growth in economic output can occur through one of two mechanisms. First, growth can occur as a result of increased input factors: the economy grows as more equipment is purchased and more workers enter the labor force – what economists call capital accumulation. However, at some point, growth based on capital accumulation is subject to diminishing returns – additional increases in input result in smaller and smaller increases in output. Sustained growth results from an increase in the economic output per worker, that is, an increase in productivity.

Economic theory describes three sources of increased productivity: capital deepening (the use of equipment that is more productive than earlier versions), higher-quality labor (a more knowledgeable workforce that is more productive), and technological innovation – the creation, distribution, and use of new knowledge.

Knowledge has some special qualities that are important to economists. Unlike raw material it can be used multiple times without depreciated value and unlike equipment, it can be used by many people at the same time. Knowledge can also be shared widely at little cost. These facts open up the possibility of a productivity factor with compounding rather than diminishing returns. That is, additional investments in knowledge result in new products that, in turn, facilitate the production of new knowledge that leads to continuous growth. These unique qualities of knowledge serve as the basis of what has come to be called the knowledge economy (Stiglitz, 1999).

Implications of Economic Theory for Education Reform and ICT Use

The three factors that lead to productivity-based growth (capital deepening, higher-quality labor, and new knowledge) serve as the basis for three complementary, somewhat overlapping models that connect education with economic development by:

- increasing the basic skills and technological uptake of the workforce (Birdsall *et al.*, 1995; Lall, 2000) – or the knowledge-acquisition model;
- increasing the quality of the workforce and their ability to use knowledge to add value to economic output (Hanusek and Kimbo, 2000; UNIDO, 2003) – or the knowledge-deepening model; and
- increasing the ability of the workforce to produce new knowledge and innovate (OECD, 2004b; Schliecher, 2006) – or the knowledge-creation model.

These three models have somewhat different implications for changes in each of the components of the educational system: policy goals, curriculum and assessment,

pedagogy, school organization and administration, and teacher professional development, as well as the use of ICT.

Knowledge-Acquisition Model

The policy rationale of this approach is to improve economic productivity by increasing the basic skills of the workforce and its capacity for taking up new technologies, thus enabling the deepening of physical capital. Corollary policy goals might include increased school enrolments, increased technology-literacy skills, and improved reading- and mathematics-literacy skills. The strategy might be implemented through policies such as increasing the level of compulsory schooling, mandatory testing, and school accountability, or the requirement of a larger number of courses in science and mathematics. Countries may also try to support these goals by integrating technology into the traditional educational system and making few changes otherwise (Law *et al.*, 2000; Schofield and Davidson, 2002; Schofield, 2006). Technologies involved in this approach may include the use of computers along with productivity software; drill and practice, tutorial, and web content (Kozma, 2003). Under the knowledge-acquisition model, changes in the curriculum may be limited to adding ICT as a subject or including time in the curricula of other subjects for the incorporation of ICT. The curriculum may otherwise continue to be divided by traditional subject areas and assessments that emphasize basic skills. Changes in pedagogical practice may involve the use of various technologies, tools, and e-content as part of whole-class, group, and individual student activities. Teachers may increase their digital-literacy skills and use technology for classroom presentations, for management tasks, and to acquire additional skills for their own professional development. Pedagogy may otherwise consist of the teacher delivering information that is received by students. Little change in social structure is required by this approach other than, perhaps, the spatial placement of hardware and technology resources in the classroom.

Knowledge-Deepening Model

As they entail more significant changes in the education system, the other two approaches to educational reform may have a more profound effect on economic growth and the standard of living. The policy rationale for the knowledge-deepening approach is to increase the ability of the workforce to add value to the economic output by applying a deep knowledge of school subjects, particularly science and mathematics, to solve complex problems encountered in real-world situations of work and life (Tucker, 1996). The traditional curriculum is bounded by school experience, and the focus is often on factual recall. But knowledge of school subjects may remain inert

and not be applied outside the class or contribute to productivity or innovation. To combat this problem, the knowledge-deepening approach supports economic productivity and social development by enhancing students' understanding of school subjects and making these subjects more relevant to the problems and challenges of the community and the workplace. Rather than the superficial coverage of a large number of topics, the curriculum focuses on a smaller number of key concepts, principles, and procedures and on how these ideas are organized and interconnected within and across subject areas to form complex knowledge systems (Bransford *et al.*, 2000). Classroom activities and projects that collaboratively engage students in the solution of extended, open-ended, real-world problems are an important component of the knowledge-deepening approach (Krajcik and Blumenfeld, 2006). Technology can also play an important role as students use visualizations and simulations to explore, understand, and apply complex knowledge (Edleson and Reiser, 2006; Lehrer and Schauble, 2006). Networking can help teachers and students connect classroom activities and learning to the outside world (Bruckman, 2006; Kozma, 2003). Aided by technology, extended assessments consisting of several parts can parallel the complex tasks that students will encounter in the real world (Pellegrino *et al.*, 2001; Mislevy, *et al.*, 2003; Means, 2006). As this type of learning is more complex, teachers need to understand both their subject area and the processes that students employ, and the problems that they face when they engage in deeper learning of subject matter (Darling-Hammond, 1997; Fishman and Davis, 2006). Teachers should be able to integrate open-ended software tools and subject-specific applications with student-centered teaching methods and collaborative projects in support of students' deep understanding of key concepts and the application of this knowledge to solve complex, real-world problems (Means and Olson, 1995; Means *et al.*, 2001; Schofield, 2006).

Knowledge-Creation Model

The policy rationale for the third approach – knowledge creation – is to build a workforce and citizenry that are continually engaged in and benefit from knowledge creation and innovation. The argument goes that if students are to participate in an economy and society in which the creation, sharing, and use of new knowledge are the basis for sustained development, their educational preparation must go beyond the learning of established knowledge (Bereiter, 2002). Knowledge creation does not conflict with knowledge deepening; rather, it can build on a base of deep understanding of school subjects – not only science and mathematics but also social sciences, humanities, and the creative arts. Beyond the learning of key concepts and principles and their use to solve

complex problems, students engage in the sustained, collaborative process of building on current knowledge to create and share new knowledge and cultural artifacts. Knowledge-creation skills include the ability to use a range of technology tools; to search for, organize, and analyze information; to communicate effectively in a variety of forms; to collaborate with others of diverse skills and backgrounds; and to think critically, innovatively, and creatively (Partnership for the 21st Century, 2003; New Commission on Skills of the American Workforce, 2006). But paramount among the knowledge-creation skills are those that allow students to continue their learning throughout their lifetimes – their ability to set their own goals, determine what they already know, assess their strengths and weaknesses, design a learning plan, stay on task, track their own progress, and build on successes and adjust to failures. These skills will enable students to sustain their own personal development and contribute to that of the economy and society in a constantly changing world. With this approach, teachers design a learning community in the classroom in which students are continuously engaged in building their own and each others' learning skills (Scardmalia and Bereiter, 2006). Teachers and students use a variety of networked devices, digital resources, and electronic environments to create knowledge communities for students and colleagues which support the process of continuous, reflective learning and the development of knowledge creation and critical-thinking skills (Scardmalia and Bereiter, 2006; Stahl *et al.*, 2006). The goal is to transform schools into learning organizations in which all actors are involved in the learning process (Elmore, 2004; Fullan, 2001a, b; Senge *et al.*, 2000) and teachers are master learners who are constantly engaged in educational experimentation and innovation in collaboration with their colleagues and outside experts to produce new knowledge about learning and teaching practice (Bransford *et al.*, 2005; McLaughlin and Talbert, 2001).

Examples of Technology, Education Reform, and Economic Development

Singapore and Finland provide two examples of how economic development, education reform and ICT policies can be connected in mutually supportive ways.

The Case of Singapore

Singapore has demonstrated impressive growth over the past 40 years, due in large part to its economic development policies (Anwar and Zheng, 2004; Blomstrom *et al.*, 2002; Castells and Himanen, 2002; Rajan, 2003). Singapore is an island city state of 4.3 million people in Southeast Asia. While Singapore was considered a poor country in

1960 with a per capita GNP of less than US\$5000 (in real US dollars), its per capita GNP in 2000 was US\$35 000, placing it among the countries with the highest standard of living in the world (Rajan, 2003). The government's initial economic development strategy focused on the development of physical and labor capital, that is, a strategy of growth based on capital accumulation. With a small population and land mass, Singapore had few competitive advantages. The government provided incentives to transnational corporations in targeted industrial clusters – such as consumer electronics – who located production facilities in their country. Singapore could thus tap into global value chains of these industries and with it their imported technology and knowledge. Using this approach, Singapore was able to grow its work force, its physical capital, and its economy; but indigenous companies did not participate in this growth. To sustain growth, the government shifted to productivity-based development approaches.

From the beginning of Singapore's modern history in the mid-1960s, there has been a strong connection between the country's economic development plans and its education plans (Ashton *et al.*, 2002; Brown and Lauder, 2000). Officials from the Ministry of Trade and Industry chair the Economic Development Board, a cross-ministry agency that sets directions for policies in other relevant ministries, including education. Initial plans in the 1960s moved from a low-skill, low-wage economic strategy (i.e., capital accumulation) to one of increased productivity based on universal primary education and an increase in literacy, numeracy, and English-language fluency that would provide the resulting workforce with the skills needed to take up the new technology offered by multinational companies (i.e., capital deepening). The government refined its strategy over time, leveraging initial gains in the economy to move from low value-added to high value-added manufacturing and services that required a better-trained workforce (i.e., high-quality labor). Concurrently, Singapore's education policy required secondary schools to produce higher levels of skills in science, mathematics, and language and tertiary institutions to produce more engineers and scientists. The improved quality of Singapore's education system resulted in top scores among all countries in both mathematics and science in both the fourth and eighth grades in the 2003 Trends in International Mathematics and Science Study (TIMSS), an international assessment of student achievement (Mullis *et al.*, 2004a, b).

In its current form, Singaporean economic policy aims at developing a knowledge-based economy that upgrades existing industrial clusters (such as consumer electronics) and promotes the development of new industrial clusters (such as microelectromechanical systems and nanotechnology) and new exportable services in areas such as healthcare, education, and creative industries. In coordination with this shift, the education ministry has instituted a

number of reforms under the title Learning to Think, Thinking to Learn: Towards Thinking Schools, Learning Nation (Ministry of Education, Singapore, 2000). An important component of this reform is to create a better balance between the acquisition of knowledge, the application of concepts, and the development of individual creativity and enterprise. Thus, Singapore's curriculum has been broadened to include information skills, thinking skills, and creativity, self-management skills, and character development. Cross-discipline project work has been introduced into classrooms and assessments revised to include measurement of students' ability to use information, think creatively, and communicate.

ICT has been an important component of Singapore's educational reform. In 1997, Singapore initiated a 5-year ICT plan, called Master Plan for IT in Education, to incorporate technology into the school system (Mui *et al.*, 2004). This US\$1.2 billion project aimed to create an ICT-enriched school environment for every child. This first master plan focused primarily on installing computers and high-bandwidth Internet in schools and classrooms and training teachers on the use of computers. In 2002, Singapore's education ministry launched its Master Plan 2, in coordination with new reform policies. The new master plan adopted a more systemic, holistic approach in which all the key components of the system – ICT, curriculum, assessment, instruction, professional development, and school culture – were integrated. For example, the curriculum was reduced by 10–30% to allow for the integration of technology into the subject areas and university admission criteria were modified to include the submission of an electronic portfolio of student work, in addition to exam scores.

The Case of Finland

Finland's trajectory was different from that of Singapore, emphasizing knowledge production early on in its development. Finland is a country of 5.2 million people. In 1960, Finland too was relatively poor, at least by European standards. In that year, the per capita GNP was less than US\$7400 (in constant dollars), according to the Center for International Comparisons at the University of Pennsylvania. But by 2000, Finland's per capita GNP was US\$24 000, placing it among the countries with the highest standard of living in the world. Between 1990 and 2000, there was a fundamental structural transformation of Finland's economy, as it moved from a raw materials-based manufacturing economy to one with a high concentration in high-tech products, particularly in the area of telecommunications. In responding to a recession in the early 1990s, the Government of Finland adopted an economic policy that emphasized new knowledge as a productivity factor. Finland instituted a series of policy changes that shifted resources from the subsidization of large but uncompetitive industries to investments in

infrastructure, education, and research and development (Blomstrom *et al.*, 2002; Castells and Himanen, 2002). Both public and private research and development (R&D) investments grew rapidly in the 1990s. Public investments encouraged the development of small and medium enterprises (SMEs), through the establishment of incubators for start ups, and cross-sector, private–public collaborations through research grants for groups of SMEs, large corporations, and universities. Networking among these organizations improved knowledge flows and increased productive interactions.

These policies and programs were coordinated by a common vision of how all sectors of society would benefit from economic growth. In the early 1990s, the Ministry of Finance appointed a broad-based Information Science Advisory Board (2000) to construct a national information society strategy and articulate a vision for what Finland would be like as a country enriched by ICT “. . . in which knowledge and expertise form part of the culture and also the key factor in production” (p. 5). The Finnish Information Society Program emerged from this process.

Education was an important part of Finland’s economic shift toward an information society. The school system in Finland is highly decentralized and decision making is distributed across sectors (Ministry of Education, Finland, 1999, 2004). The ministry conceptualizes learning as an individual and community process of knowledge creation and collective problem solving. Each school writes its own curriculum based on very general guidelines from the National Board of Education and developed through discussions among teachers and parents. As a result, school curricula may be quite diverse across the country. Schools and teachers are given the authority to select teaching materials that correspond to the curriculum. Businesses also work closely with schools through apprenticeships and on-the-job training. Business leaders participate in school decision making.

The quality of Finland’s education system is evidenced by the fact that Finnish students scored second to (and not statistically lower than) students in Hong Kong, among 40 countries participating in the mathematics portion of the Program for International Student Assessment (PISA) (OECD, 2004c). (Singapore did not participate in the recent PISA nor did Finland participate in the recent TIMSS.) The country also scored first among nations on the science and reading portions of this test of 15-year-olds. In addition, Finland scored first in a special assessment of students’ problem-solving skills that measured students’ ability to analyze problem situations, apply knowledge to solve problems, and evaluate, justify, and communicate results (OECD, 2004d). The ministry attributes Finland’s excellent performance on PISA to free, high-quality education across the country, high-quality teachers with a high degree of autonomy, development-oriented assessment that gives students feedback on their

progress, and a socioconstructivist approach to learning that treats students as autonomous learners who are guided to develop their study skills and plan their life careers.

As part of this Finnish Information Society Program, the Ministry of Education developed the Information Strategy for Research and Education (Ministry of Education, Finland, 1999, 2004; Kankaanranta and Linnakyla, 2004). The goals of the education policy are to develop learning-centered instructional approaches, move from once-and-for-all training to lifelong learning, ensure that all students have information skills and that all teachers achieve a high level of professional skills, and build global education and research networks. Government programs have helped schools purchase computers, link them to the Internet, promote the introduction of ICT as a tool for teaching and learning, and conduct in-service training for teachers to reform the pedagogical practices in their schools, especially with regard to collaborative teaching.

Policy Implications

Causal connections cannot be claimed for either of these cases. It cannot be determined whether educational policies resulted in economic growth or economic growth provided the resources that allowed for more-advanced educational policies. Similarly, the co-occurrence of economic growth and use of ICT in schools does not justify conclusions about one of these factors causing the other. Most likely, the relationship is transactional. In their macroeconomic study of developing East Asian countries, Birdsall *et al.* (1995) found a double virtuous cycle between economic and educational policy. That is, better education policies contributed to economic growth, which enabled better policies, more growth, and so on. This finding argues for a more holistic approach to the formulation of policies and programs, one that emphasizes alignment rather than the search for causal mechanisms.

From this perspective, national ICT, education reform, and economic-development policies will have the greatest impact if they are aligned so that they can reinforce each other. This includes alignment between agencies, alignment within agencies, alignment through layers of the government, and alignment between policies and programs. Both Singapore and Finland established cross-ministerial agencies to coordinate their policies and programs within the government. This coordination can result in the high-level integration of policies that are articulated in a common vision for how technology, education, and economic development can benefit the entire society, as was done in both Singapore and Finland. Within this vision, ICT policies can best contribute to educational reform and economic development if these policies are all

aligned and if teacher professional development includes skills and activities that incorporate ICT into classroom practices and connects them to broader education and economic goals.

TECHNOLOGY AND LEARNING – EVALUATING TECHNOLOGY

Examining the Effects of Educational Technology Programs: Challenges and Strategies

M Russell, Boston College, Chestnut Hill, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Access to digital technologies in US schools has increased dramatically over the past 20 years. Today, all US public schools are connected to the Internet. On average, US public schools have one computer for every 3.8 students (Ed Week, 2009). Increasingly, schools, districts, and states are adopting 1:1 computing programs that aim to provide each student and teacher with a mobile computing device. With the recent introduction of mini-laptops that cost less than US\$400 and increased federal expenditures on educational technology, the number of 1:1 programs is likely to increase in the coming years.

In addition to computing devices provided by schools, many students bring their own digital devices to schools. These devices take the forms of MP3 players, cell phones, and devices that bundle multiple functions into a single platform such as iPhones. While schools are struggling to form policies and practices regarding these student-owned devices, there is little doubt that the presence of computer-based technologies has altered the landscape of US public schools over the past 20 years.

Examining the effects that the use of digital technologies has on teaching, learning, and school quality, however, is challenging. This article explores some of the factors that complicate research on the effects of educational technologies and suggests strategies that researchers can employ to acquire more accurate estimates of the effects that digital technologies are having on teaching, learning, and school quality. The factors explored here include: clearly defining goals of technology programs, placing outcomes in the context of implementation, measuring technology use, aligning outcome measures with goals and use, and employing statistical methods that account for the multilevel factors that influence technology use and adjust for intraclass correlations. Each of these issues is examined separately.

Defining Goals

Digital technologies are generally provided to schools in one of three ways. One approach introduces digital technology to help address a specific challenge. For example,

digital science probes attached to a computing device are introduced to help students deepen their understanding of data collection and scientific concepts. As another example, computer-based assessment systems are introduced to help teachers monitor students' acquisition of specific knowledge or skills.

A second way in which digital technologies are introduced in schools is through research conducted by a teacher or an external researcher. Here again, a given digital technology is introduced to address a specific challenge. In these cases, however, the tool has often been newly developed or has not been widely adopted in other schools or classrooms. For this reason, the purpose for introducing the technology is to improve the tool's design to enhance its usability, develop methods for integrating the tool with classroom practices, or collecting preliminary evidence about the tool's effectiveness.

A third approach to introducing digital technologies is large-scale adoption of a hardware device that is capable of running many different applications and can be used to meet a variety of needs. Placing computers in each classroom, acquiring a computer laboratory, and 1:1 laptop programs are all examples of large-scale adoptions.

When digital technologies are introduced to address a specific challenge or as part of a research project, the goals for the use of that technology are usually defined before the technology is delivered. Science probes are introduced to increase student engagement during learning, improve data-collection skills, and improve understanding of specific scientific principles. Computer-based assessment systems are intended to provide teachers with more immediate information to inform instruction and to improve student performance in the areas assessed by the system. When digital technologies are introduced as part of research, researchers have specific questions they are addressing and hypotheses they are testing.

When digital technologies are introduced as part of a large-scale hardware adoption, the goals are often less clearly defined. In contrast to studies that examine the effect that individual software applications have on specific aspects of students' learning (see Goldberg *et al.*, 2003; Kulik, 1994; Sivin-Kachala, 1998; Waxman *et al.*, 2003; for

meta-analyses of nearly 800 studies focusing on specific technology applications), most large-scale technology-adoption programs introduce a digital device to meet a variety of goals. In addition, when implementing large-scale adoption programs, most school districts do not articulate the specific goals for their technology programs prior to launching their adoption programs (Herman, 1994).

Although schools purchase technology to enhance teaching and learning, when hardware is first introduced, schools are often unsure how to use the technology in order to have an impact on teaching and learning. It is not until teachers have had multiple opportunities to work with the new technology that they begin to develop a sense of how to use the technology or how it can have an impact on teaching and learning. As an example, consider the Maine Laptop Program, which provided laptops for every middle school student in the state. When first launched, professional development focused primarily on the mechanics of using laptops, such as logging in, launching programs, creating documents, saving files, etc. It was not until the second and third years of the program that professional-development programs for specific subject areas were introduced and focused on specific instructional uses of the laptops (Silvernail and Buffington, 2009).

The lack of clearly defined goals for large-scale adoption programs challenges researchers and evaluators who aim to examine the effects that newly introduced technology has on teaching, learning, and school quality. To overcome this obstacle, two opposing strategies are available. First, a goals-free approach to program evaluation can be employed (Knott, 1993; Scriven, 1972). In a goals-free approach the effects of a technology program are examined with an open lens that aims to detect and document any changes that affect teachers, students, and school leaders.

A second strategy begins by working closely with program leaders to define program goals and then identify the conditions and actions required to obtain those goals. As part of this process, each intended use of the technology is clearly articulated. For each use, the people impacted by the use are identified and the intended outcomes are defined. Next, the infrastructure, personnel, and training required to support each use are detailed. Finally, a timeline for implementation and expected outcomes is defined. Through this process, a logic model is developed that links each intended outcome with the supports believed to be necessary to achieve the outcomes. Research and evaluation then focus on the articulated logic model to examine the extent to which requisite conditions and actions are put in place, and whether the intended outcomes follow (Russell, 2002).

These two approaches contrast sharply with each other. In the first, the researcher or evaluator acknowledges that the program goals are ill-defined and therefore looks broadly at a program to capture any outcomes (positive or negative) that may emerge. In the second, the researcher or evaluator works closely with program

leaders to clearly define a range of desirable outcomes, develops a logic model that details what is required to reach those outcomes, and then focuses closely on examining the extent to which the supports are put in place and lead to the outcomes.

Considering Implementation

It is important that researchers and evaluators examine the effects that digital technologies have on teaching, learning, and school quality. However, it is equally important to place those outcomes in the context of program implementation (Baker, 1999; Herman, 1994; Russell, 2002). Like all attempts to alter teaching, learning, and school processes, the full effects of a given digital tool will not be realized until teachers, students, and school communities develop comfort, knowledge, and skill with the new tool. Traditionally, developing comfort, knowledge, and skill are aided by professional development and, more recently, by collaborative efforts among teachers to improve practices. In addition to training and time to develop comfort, the use of digital technologies often requires additional support structures. Some of these supports are physical, such as easy access to hardware, reliable networks, server communications, and Internet connections. Other supports have a human element, such as personnel who provide technical support, and leadership that embraces and encourages experimentation with a new technology. The degree to which schools provide these physical and human-support structures varies widely. In turn, this variation influences the degree to which and ways in which teachers adopt and adapt digital technologies (Miranda, 2006). As a result, before outcomes can be attributed to the use of a computer-based tool, it is essential to examine and document the way in which a digital technology has been implemented (Heinecke *et al.*, 1999).

Before examining the outcomes of a technology program, it is important to identify the conditions that must be established before meaningful effects can reasonably occur. Depending on the computer-based tool, these enabling conditions might include: (1) providing access to equipment, software, and other physical infrastructure such as the Internet or servers; (2) professional development; (3) time for teachers to learn how to use the tool; (4) time for teachers to work with other teachers or curriculum technology specialists to develop lessons that incorporate the computer-based tool into instruction; (5) time for students to develop the essential skills to make use of the tool; and (6) sufficient time for teachers to improve these lessons. Unless the conditions believed necessary for successful use of the computer-based tool are established and it is established that the tool is actually being used, it is premature to examine the impact the tool has on the intended outcome.

When examining the impact of a computer-based tool, it is also important to consider the extent to which the tool is readily accessible to students and teachers, and used by a critical mass of students and/or teachers. As an example, in a study that attempted to examine the effect that a program, which placed computers in low-performing schools, had on student learning, the researchers assumed that the installation of computers at a ratio of ten students per computer provided sufficient access to the computer-based tools (Angrist and Lavy, 2001). Moreover, it was assumed that the act of placing computers in the school laboratory would lead to the use of computers by students. As a result of these assumptions, analyses focused on comparing changes in test scores in schools that were provided with the computer labs versus those that were not. The analyses, however, did not consider the extent to which computers were being used to aid learning within specific subject areas in either setting. While the study was interpreted to provide evidence that the use of computers do not improve student learning, in fact the study did not focus on use of computers – only the presence of computers in a computing laboratory.

In addition to placing outcomes in the context of use, it is also important to consider the extent to which students and teachers have easy access to a given digital technology. Recent research provides evidence that the ratio of students to computer-based tools has a large impact on the extent to which the tools are used. Across several studies that compare the amount of use that occurs prior to and following the introduction of 1:1 computing programs, researchers have consistently found sharp increases in use when a given technology is provided for each student (Russell *et al.*, 2003, 2004; Bebell, 2009; Shapley *et al.*, 2008). Much of this research also documents that after technology is available for each student, the teacher's role within the classroom shifts. As an example, one study that focused on the introduction of AlphaSmarts (i.e., portable writing devices) at a 1:1 ratio found that the amount of time teachers spend managing student use of the technology decreased and the amount of time they spend working directly with students on their writing increased (Russell *et al.*, 2003). Given the complex relationship between presence, access, use, and a teacher's role in the classroom, simply establishing that technology is present is not sufficient for measuring how often and in what ways a computer-based tool is used. Moreover, without understanding how and how often a tool is used, it is difficult to assess the impact of that tool on the intended outcome.

Measuring Technology Use

When examining educational technology, it is essential to consider the extent to which and ways in which the tool is used by students and teachers. Given the wide range of

computer-based tools and resources that can be used to support teaching and learning, specific, rather than general, measures of computer use are required. Again, Angrist and Lavy's (2001) study serves as a good example of the challenge posed by measuring computer use. In this study, teachers were presented with the following survey items:

1. Which of the following do you use when teaching?
 - Xeroxed worksheets.
 - Instructional booklet.
 - Games.
 - Computer software or instructional computer programs.
 - TV programs.
 - Other audio-visual materials.
2. For each item, teachers were given the following options:
 - Not at all.
 - Sometimes.
 - Frequently.
 - Almost always.

Each teacher's response to how often they used computer software or instructional computer programs served as the measure of instructional use of computers for mathematics and Hebrew.

It may be reasonable to infer that teachers who report that they frequently use computer software or instructional computer programs employ different instructional practices than do teachers whose response is not at all. However, this general measure does not provide sufficient information about how, when, why, or who is actually using computer-based tools. As a result, a teacher who uses PowerPoint several times a week to present information that otherwise would be presented using an overhead projector will appear to use computer-based tools more than the teacher who has students work for 30 min twice a week on a mathematics tutorial. Similarly, this general measure of computer use makes this second teacher appear the same as a teacher who might also have students use a computer twice a week for 30 min to collect data, create spreadsheets, and produce graphs to explore relationships in data. Finally, a teacher who uses computers daily outside of class to create worksheets or record grades might appear to be the most frequent user of computer-based tools. In other words, simply asking teachers to report the frequency with which they use computers does not provide sufficient information to document how computer-based tools are being used or what impact these uses may have on learning. To answer these research questions, computer-use in the context of a given study must be clearly defined and measured.

When measuring technology use by teachers and students, some researchers have developed several items each of which focuses on a specific use of technology (Bakia *et al.*, 2007; Becker, 1999; Russell *et al.*, 2003). Often, these data are collapsed into a single measure of technology use. This aggregated measure is useful for

providing a general sense of whether or not teachers are using technology for some aspect of their job. However, like the single survey item employed by Angrist and Lavy that focuses on computer use in general, these aggregate measures are inadequate for understanding the extent to which technology is being used by teachers, the purposes of these uses, and the impact these uses may have on learning outcomes.

Instead of aggregating several survey items into one measure that represents the general use of computers, a richer understanding of computer use results when these individual items are used to create multiple measures of computer uses. As an example, Russell *et al.* (2003) used data from several survey items, each of which focused on a specific use of technology, to develop seven separate scales that measure teachers' technology use. These seven scales include:

- teachers' use of technology for class preparation (preparation);
- teachers' professional e-mail use (professional e-mail);
- teachers' use of technology for delivering instruction (delivering instruction);
- teachers' use of technology for accommodation (accommodation);
- teacher-directed student use of technology during class time (student use);
- teacher-directed student use of technology to create products (student products); and
- teachers' use of technology for grading (grading).

Analyses of the seven teacher technology-use scales formed from the items showed that each of the individual scales exhibited widely divergent frequency distributions (Bebell *et al.*, 2004). For example, teachers' use of technology for preparation was negatively skewed while the use of technology for instruction was strongly positively skewed. Like instructional use, the distributions for assigning student products and providing accommodations were positively skewed. Using technology for grading had a weak positive skew while teacher-directed student use was approximately normally distributed. Use of e-mail however, presented a bi-modal distribution, with a large percentage of teachers reporting frequent use and a large portion of the sample reporting no use. In short, the distribution of responses differed greatly across the seven scales. However, when all of the survey items comprising these scales were summed to create a single generic composite measure of technology use, the distribution closely approximated a normal distribution revealing none of the patterns observed in the specific technology-use scales.

When compared to a single generic measure of technology use, multiple measures of specific technology use offer a more nuanced understanding of how teachers are using technology and how these uses vary

among teachers. Studies that have utilized a multifaceted approach to measuring technology use have revealed many interesting patterns that were obscured when only general measures of use were employed (Mathews, 1996; Ravitz *et al.*, 1999; Bebell *et al.*, 2004). For example the analysis of the USEIT teacher data indicated that the frequency of teachers' technology use for instruction and accommodating lessons was unrelated to the frequency with which they asked students to use technology during class time. Similarly teachers' use of technology for grading operated independently of teachers' use of technology for preparation of their lessons (Bebell *et al.*, 2004). Given these and other findings that demonstrate the value of discrete measures of technology use in understanding how teachers are using technology and what effects these uses may have on student learning, it is imperative that research on educational technology abandon single, generic measures of technology use and instead develop nuanced measures that reflect specific, discrete uses of educational technology.

Aligning Outcome Measures

A decade ago, McNabb *et al.* (1999: 4) wrote, "Standardized tests scores have become the accepted measure with which policymakers and the public gauge the benefits of educational investments." Given the requirements of No Child Left Behind Act to test every student in grades 3–8 and at least one grade in high school, the importance of standardized tests as a valued outcome measure remains strong today.

Given the availability of standardized and state-mandated tests, it is cost effective and efficient to employ scores from these tests to assess the effect of a computer-based tool on student learning. This strategy has been used for several studies including that of Angrist and Lavy (2001), who used Israel's national Hebrew and mathematics standardized test, Wenglinsky (1998), who used scores from the National Assessment of Educational Progress (NAEP), O'Dwyer *et al.* (2005, 2008), who used scores from the Massachusetts Comprehensive Assessment System (MCAS), and Shapley *et al.* (2008), who used scores from Texas state tests.

While standardized test scores can be useful for comparing performance or changes in performance across a large sample of students, it is essential to consider whether the domain tested by the standardized or state-mandated test is too broad to represent the type of learning believed to be impacted by the use of a given technology. As an example, the NAEP eighth-grade mathematics test includes items from several subdomains that include number sense, probability and statistics, algebra, and geometry. Many software and instructional uses of technology, however, focus on developing students'

skills in only one or two of these areas. For example, an evaluation of a Massachusetts school district revealed that most third- and fourth-grade teachers in this district used computers as part of their mathematics instruction to help students develop spatial reasoning skills (Russell, 2000). However, on the state's fourth-grade mathematics test, only two of the 39 items related to spatial reasoning. Given that only two items measured the skills that may be impacted by this use of computers, the total state test score did not provide a measure that was sensitive to the potential effects of computer use. While analyses could focus on the subset of items that measure spatial reasoning skills, the small number of items was insufficient to provide a reliable estimate of student achievement in this area.

Rather than employing state test results as an outcome measure, an alternate strategy is to develop custom measures that contain a larger number of items specific to the skills and knowledge believed to be affected by computer use. Although it can be difficult to convince teachers and/or schools to administer an additional test, aligned measures of student learning will result in more reliable scores and will increase the validity of inferences about the impacts of specific computer uses on student learning. When developing custom measures that are aligned with the types of skills and knowledge targeted by a given technology or technology program, it is essential to consider the technical quality, including the reliability and validity, of the data-collection tools.

When collecting measures of student learning, it is also important to consider the method used to administer and collect outcome measures. Several studies conducted over the past decade provide evidence that paper-based measures of student learning underestimate the achievement of students who are accustomed to working with technology. This effect occurs when students are required to produce work using a tool (i.e., paper and pencil) that differs from what they use regularly to produce work for the classroom (Horkay *et al.*, 2006; Russell, 1999; Russell and Haney, 1997; Russell and Plati, 2001, 2002). Through a series of randomized experiments, Russell and his colleagues provide empirical evidence that students who are accustomed to writing with computers in the classroom perform between 0.4 and 1.1 standard deviations higher when they are allowed to use a computer when performing tests that require them to compose written responses (Russell, 1999; Russell and Haney, 1997; Russell and Plati, 2001, 2002). These findings were replicated in a study conducted as part of the 2004 NAEP writing test (Horkay *et al.*, 2006). These results suggest that researchers studying the effects of educational technology are particularly at risk for underestimating the ability of technology-savvy students when they rely on paper-based assessment instruments as their outcome measures.

Together, the poor alignment between the broad domain measured by a standardized test, the specific skills and knowledge targeted by a given computer-based tool, and the mode of administration effect that results with a paper-based test, relying on standardized tests to examine the effects of technology use on student learning can be problematic. When using standardized tests, or any measure of student achievement, it is important that the constructs measured by the instrument are aligned with the constructs developed through students' uses of technology and that the form of the test (e.g., paper- or computer-based) does not add construct-irrelevant variance.

Employing Appropriate Analytic Methods

The use of technology by teachers and students is influenced by many factors. Some of these factors are specific to the individual using a given technology and include characteristics such as prior experience, comfort using technology, grade level, pedagogical beliefs, and subject area (Becker, 1999; O'Dwyer *et al.*, 2004; Ravitz *et al.*, 1999). Other factors reside at higher levels within an educational setting and include factors such as local leadership and vision, funding, local policies, beliefs about teaching and learning, available infrastructure, and support (Culp *et al.*, 2003). Given the interrelationships among factors that are found at different levels of a school system, student, teacher and school use of technology can be conceptualized in terms of a multilevel and hierarchical framework. Individual students use technology within the context of a classroom; teachers operate within a school and are influenced by its technology policies; and schools, in turn are affected by district level decisions regarding the allocation and use of technology. This natural hierarchy necessitates the use of multilevel modeling techniques (Rumberger, 2000) when examining or comparing the effects of a given technology or technology programs across settings.

The simplest multilevel model that can be specified is a two-level model. Individuals within groups are modeled at the first level, and their group membership is modeled at the second level. In the three-level model, the individual is modeled at level one, and their membership of two groups is modeled at levels two and three. For example, students are nested within classrooms and classrooms are nested within schools. Alternatively, teachers are nested within schools, and schools within districts. The sample design employed by any research study dictates the complexity of the multilevel model that can be employed; more complex sample designs allow more levels to be modeled, thus yielding more useful and accurate information about the contexts that affect the outcomes of interest. Failure to account for the nested structure in which a given technology is employed has

the potential to produce inaccurate and misleading conclusions about the effects of a digital technology on teaching, learning, and school quality.

In recent years, several studies have employed multi-level modeling techniques to examine the use and effect of digital technologies in educational settings. To estimate the effect that several factors have on the use of technology by teachers for instructional purposes, Miranda (2006) developed a series of multilevel structural-equation models. To examine the relationship between specific uses of computers by students and performance on mathematics and language arts tests, O'Dwyer *et al.* (2005, 2008) developed a series of hierarchical linear models which revealed that the relationship between computer use and test performance varied depending on the specific use of technology. Shapley *et al.* (2008) also employed hierarchical linear modeling techniques to examine the effect that a 1:1 laptop program had on student performance in several Texas schools. Finally, Silvernail and Buffington's (2009) study of a professional development program that focused on the use of technology for mathematics instruction also employed multi-level modeling techniques to adjust for the influence of classroom-specific factors. Across each of these examples, more sophisticated analytic techniques were required to separate the effects that occur at different levels within a learning environment and to account for correlations that occur within classrooms that result from commonalities among students who work with a given teacher, are placed in a given educational program, and/or live in a similar environment.

Summary

Given the investment that our society is making in educational technologies, it is important that research examine the effect that these technologies are having on teaching, learning, and school quality. When examining these effects, however, it is important to collect nuanced measures of the ways in which the technologies are being used. It is also important to place these uses in the context of program implementation and to employ outcome measures that are aligned with and sensitive to the types of changes that a given use is expected to have. Finally, given the complex structure of educational systems, it is important to employ statistical methods that account for the multiple levels that influence teaching, learning, and school quality, and which adjust for relationships that occur within these levels. By considering each of these issues, research is likely to provide a more accurate and nuanced understanding of the effects that digital technologies are having on teaching, learning, and school quality.

Digital divide – The inequality in access to computers and the Internet.

Introduction

Access to information and communications technology (ICT) is vital in the knowledge economy and information society of the twenty-first century. The last 20 years has seen a great proliferation and diffusion of digital media; yet, there remain large inequities in both access to and use of ICT in the United States and around the world.

This article examines the issue of equity and technology as it relates to access, use, and outcomes, both at home and in schools; it surveys the landscape within the United States as well as internationally, looking at the divide both within and across countries; and it discusses current approaches and efforts to promote more equitable access to and use of ICT.

Equity within the United States

Home Access

Although virtually all American children have access to ICT at school, the digital divide is wider in children's home environments. According to the National Telecommunications and Information Administration (2008b), only 61.7% of American households have some type of Internet access (see **Table 1**). Not surprisingly, the greatest gap is seen between low-socioeconomic status (SES) and high-SES households and between households with high and low educational attainment. Similar disparity is seen across racial groups, with Black and Hispanic children less likely than Whites and Asians to have Internet access at home.

There further exists a disparity in the type of Internet connectivity in different households. In 2008, only 59.5% of households with children had broadband connectivity (National Telecommunications and Information Administration, 2008b), and traditionally disadvantaged groups continued to lag behind even further. For example, from 2007 to 2008 broadband adoption slightly declined among the poor (28–25%; Horrigan, 2008). Finally, there is great differential by SES and ethnic group as to the user–computer ratio in home environments with children in White and Asian families much more likely to have their own computer and children in Black and Hispanic families much more likely to share a single computer among four to five family members (Warschauer and Matuchniak, in press).

Home Use

A recent US study of 800 youth and young adults suggests that home use of the Internet is highly bifurcated, with the large majority using the Internet principally for informal interaction with their friends, and a much smaller minority using the Internet for advanced multimedia production, national and international communication, and self-directed learning (Ito *et al.*, 2008). Prior research suggests that the latter group is disproportionately White and from high-income families, with low-income, African-American, and Latino youth discouraged from such sophisticated usages by lack of up-to-date hardware or software, lack of literacy or computer skills, or lack of social support (Attewell and Winston, 2003). Finally, boys have been shown to play computer games substantially more than girls (Lenhart *et al.*, 2008), leading some to be concerned that girls could have fewer opportunities to develop the technological fluency and advanced skills associated with such play.

Academic Outcomes from Home Use

Children's access to ICTs at home appears to have a positive effect on learning outcomes. An analysis of two

Table 1 Percent of US households with Internet access

	Percent of households with Internet access			Broadband as percent of those with access
	Total with access	Broadband	Dial-up	
Total households	61.7	50.8	10.7	82.3
Family income				
Under US\$5000	31.9	26.7	5.3	83.6
US\$150 000+	95.5	90.3	5.0	94.6
Educational attainment of head of household				
Elementary	18.5	13.1	5.4	70.8
BA+	84.1	74.2	9.7	88.2
Race of head of household				
White	67.0	54.9	11.8	82.0
Black	44.9	36.4	8.4	80.9
Native American	41.5	29.8	11.2	71.9
Asian	75.5	69.1	6.1	91.5
Hispanic	43.4	35.2	8.0	81.1

From National Telecommunications and Information Administration (2008b). *Households Using the Internet in and Outside the Home, by Selected Characteristics: Total, Urban, Rural, Principal City, 2007*.

Figure 1 Number of students per Internet-connected computer in high-minority and low-minority US K-12 Schools, 1999–2005. From Wells, J., Lewis, L., and Greene, B. (2006). *Internet Access in U.S. Public Schools and Classrooms: 1994–2005*. Washington, DC: NCES.

national data sets indicated that, when controlling for income, race, parental education, and other factors, teenagers who have access to home computers are 6–8 percentage points more likely to graduate from high school than teenagers who do not have home computers (Beltran *et al.*, in press). However, this effect is highly differentiated, with high-SES students receiving the greatest academic benefit from home computer access and low-SES and minority students either receiving a small benefit or a negative affect from such access, with the differences

attributed to disparities in social support in the home environment that influence the manner in which children use technology in academically productive or unproductive ways (Attewell and Battle, 1999; Clotfelter *et al.*, 2008).

School Access

Much progress has been made over the last 10–15 years in increasing access to computers and the Internet in US schools. In 2005, 94% of instructional rooms had connectivity (compared to only 3% in 1994), and 97% of those have broadband connections (as compared to only 80% in 2000). Similar gains have been seen over the years with regard to the ratio of students to Internet-accessed computers, which in 2005 was 3.8:1 as compared to 12.1:1 in 1998 (Wells *et al.*, 2006). Gaps in school access to computers by race have narrowed but still exist. According to the most recent national US data, the ratio of students to Internet-connected computers in high-minority schools (schools with 50% or more racial or ethnic minorities) was 4.1:1 as compared to only 3.0:1 in low-minority schools (schools with fewer than 6% minorities; Wells *et al.*, 2006) (Figure 1).

School Use

Some 85% of Whites in grades pre-K to 12 report using a computer at school compared to 80% of Hispanics and 82% of Blacks, suggesting that ICTs have become an integral part of school life. The current disparities that remain are less about whether computers are used and more about how they are used. An analysis of national data showed that White and Asian students were more likely than Black or Hispanic students to use computers for cognitively challenging learning tasks such as simulations, and Black

and Hispanic students were more likely to use computers for less-challenging drill-and-practice tasks (Wenglinsky, 1998). A subsequent study (Becker, 2000) confirmed these differences and showed that similar divides existed among high- and low-SES groups.

Differences in how computers are used between high- and low-SES students appear to be related to greater experience and technological expertise among teachers in high-SES schools (Wenglinsky, 1998; Becker, 2000); differential academic expectations and standards in high-versus low-SES schools (Warschauer, 2000); pressure to focus on basic skills and test scores in low-SES schools (Warschauer *et al.*, 2004); and reluctance to assign technology-based homework to low-SES students who may not have computers at home (Warschauer *et al.*, 2004).

Academic Outcomes from School Use

Disparities in academic outcomes associated with technology use in schools mirror those at home. A review of national data sets indicated that SES is the single strongest factor predicting whether technology use is positively (for high-SES students) or negatively (for low-SES students) associated with changes in test-score outcomes in reading, mathematics, and science (Wenglinsky, 2005). Further analysis in the same study showed that the type of drill-and-practice computer activities most frequently used in low-SES schools contribute to a decrease in reading, math, and science test scores, while the more cognitively challenging simulations and applications predominately used in high-SES schools contribute to higher test scores in those areas.

In summary, though there has been some progress in equalizing physical access to computers and the Internet, especially in school environments, there still remains broad inequality in the United States in terms of how diverse groups use new technology and the academic outcomes associated with such use.

Equity within Other Countries

The United States is not alone in its differential access to ICT; other economically developed and traditionally more egalitarian countries such as the United Kingdom, Australia, Sweden, Denmark, and Japan also exhibit stratification in access to ICT. As one might expect, developing nations too face similar if not greater challenges in providing equal access to ICT to all its citizens. We briefly review issues of technology and equity in a number of countries, drawing on general societal data when specific educational data are not available.

Canada

Although more Canadians are now online than in previous years (in 2007, 73% of Canadians aged 16 or older went online as compared to 68% in 2005), the digital divide between the rich and the poor continues to exist – 91% of those in the top economic quintile reported using the Internet as compared to only 47% of those in the lowest economic quintile. Age and level of education are also important factors in the unequal use of ICTs. Ninety-six percent of young Canadian adults between the ages of 16 and 24 went online in 2007 as compared to 29% of those aged 65 and older. A full 84% of Canadians with some postsecondary education used the Internet in 2007 as compared to 58% of those who had less education (Canadian Internet Use Survey, 2008).

The numbers on school use reveal other divides. Whereas 98% of public schools in Canada had Internet-connected computers, less than 25% of the schools had a majority of their computers running on the most current operating system. This aging effect of the hardware no doubt has an impact on use as more and more computers breakdown or become obsolete (Information and Communication, 2004). In some cases, though, school computers are the only access students have to ICT. Students in rural areas of Canada are less likely to have home computers than students in urban areas, resulting in higher school use (29%) for rural students than for urban students (19%; Digital Divide, 2003).

The significance of these divisions is all the more troubling in the light of a study on the link between ICT use and literacy skills which showed that people who do not have access to computers also have significantly lower literacy skills than computer users (Study, 2005).

European Union

In 2004, on average, 54% of the European Union (EU) households had a computer and 43% had Internet access. These numbers vary quite a bit from country to country, with 50% of the households in countries such as Denmark, Norway, Luxembourg, Germany, and the Netherlands having Internet access and only about 16% of households in countries such as Latvia, Lithuania, Hungary, Bulgaria, Romania, and Turkey having Internet access. These geographical divides appear to be related to urbanization, with thinly populated, rural areas across Europe having low Internet penetration (Demunter, 2005). Some countries stand out for their especially high or especially low ICT penetration levels. Sweden ranks as one of the highest with 73% of households having Internet access of which 40% are connected via broadband connections. Greece ranks at the bottom with only 24% of households having Internet access of which a mere 6.84% are connected via

Table 2 World Internet usage

<i>Region</i>	<i>Percent of population using the Internet in 2008</i>	<i>Usage growth, 2000–08</i>
Africa	5.6%	1100.0%
Asia	17.4%	474.9%
Europe	48.9%	274.3%
Middle East	23.3%	1296.2%
North America	74.4%	132.5%
Latin America/ Caribbean	29.9%	860.9%
Oceania/ Australia	60.4%	172.7%
World total	23.8%	342.2%

From <http://www.internetworldstats.com/stats.htm> (July, 2009).

broadband connections (Supporting Policy Development for eInclusion, 2005).

Looking at the demographics of the population, as expected, there is a significant age gap in ICT use, with 75% of those under the age of 24 being Internet users, but only 11% of those between the ages of 64 and 74 being Internet users. Level of education is also a factor in ICT use. Those who had completed tertiary education were 2.5–3 times more likely to use the Internet than those who had lower-secondary education. A third important factor was the presence of children in the home. Some 70% of all homes with children had computers, whereas only 46% of childless homes had computers (Demunter, 2005).

India

People in less-developed nations face similar, if not worse, inequities. In India, for example, a boom in the information technology industry has created a handful of multi-millionaire entrepreneurs and a small middle class consisting of software engineers and other ICT workers, but it has had virtually no trickle-down effect on the vast majority of the poor and illiterate. The population of India is over one billion, 41.6% of whom live below the international poverty line (Poverty in India, 2006), 42% (adults) of whom are illiterate, and 70% of whom live in villages (Rao, 2005). These numbers alone could account for the tremendous disparities that exist in ICT access and use within India. But in addition to the factors of poverty and illiteracy, there exist other factors that further polarize the population.

The first of these is the divide that exists between those who speak English and those who do not. In 2005, approximately 5% (50 million) of the Indian population spoke English fluently, the remaining 95% thus being effectively shut out from access to the vast majority (60–80%) of the world's websites, which are in English. Another factor contributing to the divide is the global economy and the consequent emergence of a new elite in Indian society – the

digerati. Unlike the older elite whose privileges were based on caste and inherited wealth, the new digerati owe their position of privilege to education, entrepreneurial skills, and staying on the cutting edge of technology. Finally, there is the issue of infrastructure and cost. The main obstacle to effective penetration and diffusion of ICT is the lack of infrastructure such as reliable power supply, teledensity, and Internet connectivity. India struggles in all three areas. Furthermore, as with many developing countries, India is faced with assessing the cost–benefit balance of expanding ICT penetration when hundreds of millions of citizens lack basic education, healthcare, and adequate nutrition (Keniston, 2003).

China

The technology policies of the Chinese government over the last 10 years have favored cities and schools/universities, ignoring other, more rural geographic areas and groups (nonschool populations). As a result, those in the urbanized, densely populated Eastern provinces have a much higher level of Internet access and use (30–40% of the population) than those in the rural, sparsely populated Western provinces (5% of the population; Hung, 2003).

In addition to geography, age and education also impact the digital divide in China as they do in other countries. The young and those with higher levels of education use the Internet the most. Sixty-nine percent of Internet users are under the age of 30, and 70% have either a high school or a tertiary degree (Statistical Survey Report on the Internet Development in China, 2008). Interestingly though, unlike in the United States, Internet use in China is not concentrated in the highest-income demographic. This is because students are the heaviest users of the Internet, and typically students have low or no income. Whereas ICT is still the privilege of a small group of people in China, Internet access and use are growing rapidly every year. By June 2008, the number of Internet users (aged 6 and above) had reached 253 million (approximately 20% of the total population) – up 35 million from late 2007 – making China number one in the world when it comes to number of Internet users (Statistical Survey Report on the Internet Development in China, 2008).

Equity Across Countries

Internet access varies widely from region to region, with the greatest access being observed in North America and the least being observed in Africa (see **Table 2**). Not surprisingly, those regions with the least access to the Internet are growing at the fastest rate.

At the country level, the International Telecommunication Union developed the Information and Communication Technology Opportunity Index (ICT OI) to measure

(and compare) access and usage of ICT in countries across the globe. Based on this index, 183 economies were measured and divided into four categories, high, upper, medium, and low. The data revealed that greater economic development is correlated with high levels of access to and use of ICT and lower economic development is correspondingly correlated to low levels of access to and use of ICT.

Yet, some countries have nevertheless managed to overcome their economic disadvantage and score relatively higher on the index, probably due to their small land areas (as in the case of small-island developing states such as Jamaica) and/or their high population density (as in the case of Singapore), both of which make the diffusion of access to ICT easier. When measured over time, the growth rate across all categories has been generally increasing, and more importantly, the gap appears to be narrowing somewhat between the low ICT opportunity group and all other groups, possibly due to the combined effect of mobile-phone saturation in the higher groups and a corresponding catch-up effect in the low group (Measuring the Information Society, 2007).

Approaches to Increasing Equity

Although the digital divide has narrowed somewhat both within and across countries, efforts to further increase equity in access are ongoing. These initiatives span all areas of need from hardware and connectivity to software and content. Often these efforts have involved or stimulated debate about what types of technology access and support are needed to benefit people who are impoverished or otherwise socially marginalized, with many suggesting that hardware access is insufficient without attention to issues of content, language, literacy, and social support (see e.g., Dimaggio *et al.*, 2004; Warschauer, 2003).

An early effort to improve ICT equity in schools was the US E-Rate program, launched in 1996 to provide low-cost Internet connectivity to schools as well as to promote and expand Internet access in out-of-school community technology centers such as libraries. Similar initiatives in countries such as the United Kingdom, Israel, and Germany have had positive results (Balanskat, 2002).

Another ongoing effort has been through the creation of public access points for computers and the Internet, known in much of the world as telecenters and in the United States as community technology centers. These centers often combine public access to technology with formal or informal instruction and support (see discussion in Warschauer, 2003). In highly impoverished rural areas such as parts of India, more common are individual computer kiosks, with a single computer operated by a local employee who finds the computer-based or online information the client desires (Warschauer, 2003).

To enable a higher degree of computer access throughout the world, a number of groups have tried to develop specialized low-cost computers that meet the needs of the poor. In the first few years of the twenty-first century, a multi-language handheld computer for the Indian market called the Simputer received a lot of attention, but in the end failed to sell more than a few thousand units as it could not compete in cost with the falling prices of mass-market computers (Multi-Language, Handheld Computer Yet to Reach the Masses, 2005).

The most prominent current effort in this direction is the XO computer developed and distributed by the One Laptop Per Child (OLPC) program. OLPC's goal was to develop a low-cost, high-functioning laptop designed to run on innovative freeware that would be used by individual children throughout the developing world. Since OLPC's inception in 2005, about 300 000 XO computers have been deployed worldwide (Kraemer *et al.*, 2009). This number, though sizable, is far below the original goals of OLPC. Controversies associated with the program include its large minimum-order requirements (originally at one million units, and then reset to 100 000 units), its reversal of its original decision to run exclusively on open-source software (with eventual inclusion of a Windows option), its target population of schoolchildren in developing and impoverished countries (with many believing that these countries have higher social and educational priorities than individual laptops for children), and its neglect of attention to local educational environments and to teachers' professional development (see discussion in Kramer *et al.*, 2009). Despite any shortcomings of the OLPC project, it is widely viewed as bringing about important innovations in hardware and software design and in helping spawn a new generation of low-cost laptop computers known as netbooks and smartbooks.

Research suggests that the provision of individual computers will not in and of itself erase educational divides, as schools in high-SES communities find it easier to integrate laptops into instruction than do schools in low-SES communities, due to the students' greater literacy skills, English language ability, and prior experience with computers; the support for educational computing found in students' homes and neighborhoods; and the support structures for educational technologies in the schools (Warschauer, 2006). This has been labeled the Sesame Street Effect (see Attewell and Winston, 2003), referring to a more general phenomenon in which technology-based reforms targeted at low-income populations are often best exploited by higher-income populations that can better leverage their preexisting educational, social, and cultural resources. Some initiatives have thus tried to go beyond hardware or connectivity to provide more suitable open-access educational resources. For example, Massachusetts Institute of Technology's (MIT) Open Courseware project has placed the material from some 1800 undergraduate and graduate courses online that

has been accessed by more than 50 million people (Reiddy, 2008). Beyond these initiatives, it is widely believed that professional development, support systems, and curriculum development are all vital means to make technology access meaningful, and are thus required for lessening any divides. Efforts to make improvements in these areas generally take place at the local or state level.

One organization that seeks to promote and coordinate initiatives internationally is the Global Alliance for ICT and Development (GAID), established in 2006 by the United Nations, Department of Economic and Social Affairs. GAID's four main areas of focus for 2008–10 are access, connectivity, content, and education, reflecting the growing recognition that a broad, multifaceted approach is needed to improve educational and social development with technology.

Conclusion

Over the last 10 years, there have been many shifting challenges to providing equal access to ICT. In the United States and other developed countries, the discussion has moved from inequities in physical access and connectivity to the more nuanced issues of meaningful and purposeful use. In developing countries, the majority of people lack even basic access to computers and the Internet, but extending such access for educational purposes has to be balanced with a range of other social and educational priorities.

Glossary

Affordances or, specifically, learning affordances – The features or characteristics of curriculum and software that are specifically designed to allow for particular types of action.

Asynchronous – A communication style that does not require participants to engage in dialog simultaneously, that is, participants can engage whether or not a participant is present or available at a particular time. Postal communication and e-mail are two examples of asynchronous communication.

Avatar – An object representing the embodiment of the user on a computer, which could be in the form of a three-dimensional model used in computer games, a two-dimensional picture used on Internet forums and other communities, or a textual representation.

Credit recovery – This refers to a student's need to retake courses either failed earlier or not yet attempted but needed to advance to the next grade or to graduate. Credit-recovery courses and programs are, generally, geared toward students at risk of dropping out of school.

Dual credit – The courses taken by secondary students, often at an institution of higher education, that allows a student to earn credit – both toward high school graduation and for credit at colleges and university – often, giving students advanced standing when they enter college. Dual-credit courses that are not offered by an institution of higher education have, typically, gone through an articulation-and-approval process that certifies the course as equivalent in scope and rigor to related college courses.

Learner control – The ability of students to influence the pace and sequencing of their curriculum. For example, they can engage in text in a self-determined order or pause, rewind, or fast-forward video segments.

Synchronous – A Communication style that requires participants to engage in dialog, more or less, at the same time. Face-to-face and telephone-mediated dialogs are two examples of synchronous communication.

Internet-Based Education Defined

Internet-based education is referred to by multiple terms, including online learning, e-learning, cyber learning, and Web-based learning. (Internationally, and particularly in developing countries, the term open schooling is also used. Although open schooling traditionally relies on radio, television, and correspondence technologies, Internet-based resources are increasingly common as Internet access expands around the world.) More recently, the term open educational resources (OER) is being used to represent content, tools, and software that are freely available on the Web for educational purposes (Smith, 2009). These terms are used somewhat interchangeably both within the education community and in the text that follows. As the diversity of terms might suggest, it is important to note that a great variety of administrative practices and requirements, content and instructional strategies, technology requirements, and costs are associated with Internet-based education. Internet-based education is offered by public, private, and nonprofit entities and may operate locally, regionally, nationally, or internationally.

Higher education – and to a lesser extent the corporate training industry – were principal drivers of online learning, starting in the mid-1990s as Internet access began to take hold in many places around the world (Mandinach, 2005). The example of just one university in the US demonstrates the impact that Internet-based educational resources can have internationally. In 2000, the Massachusetts Institute of Technology (MIT) made core content – such as syllabi, reading lists, and video-based lectures – available freely on the Web. Since then, 90 universities and colleges from 14 countries have adopted or adapted MIT's resources for local use (Smith, 2009).

Nearly 4 million students enrolled in at least one online course in the US in the fall of 2007, representing a little over 20% of the total student population in higher education (Allen and Seaman, 2008). There are many examples of online education in higher education around the globe. Universiti Putra Malaysia launched its first entirely online program in December of 1999 with 200 students, and serves other countries in the region – including Cambodia, Myanmar, Mauritius, Singapore, and Sri Lanka. Similarly, Libya, Morocco, Sudan, and Tunisia all cite the development of virtual or open universities in Africa (Farrell and Isaacs, 2007), following the development of virtual and open universities throughout Europe and Asia.

The practice of online learning is more recently being applied to elementary and secondary education – which is the primary focus of this article. Examples of elementary and secondary uses of Internet-based education may include primary-grade students working on beginning reading skills over the Internet, middle-school students collaborating with practicing scientists in the design and conduct of research, and high school dropouts taking courses online to recover credits and qualify for graduation. In addition, entire secondary school programs provided over the Internet are increasingly available – such as the charter and contract schools affiliated with K12 Inc., Connections Academy, and Insight Schools. The format and media of Internet-based approaches range from conventional didactic lectures or textbook-like information delivered over the Web, to Internet-based collaborative role playing in social simulations and highly interactive strategy games.

There are two fundamental types of Internet-based education: one replaces existing face-to-face courses and the other is intended to enhance face-to-face courses. Internet-based education that is designed to replace face-to-face courses is, typically, seen as an evolution of distance education – an instructional arrangement in which a student and teacher are separated by time and space. Correspondence courses were among the earliest forms of distance education, and distance education has continued to adopt the latest communications technologies available. In the case of online learning, the Internet has replaced earlier technologies – such as the postal service, radio or television – to deliver instruction at a distance.

A recent and increasingly common practice in secondary and tertiary education is to use Internet-based resources to enhance face-to-face courses. This style of instruction is referred to as a blended or hybrid approach. Blended courses are, typically, defined as face-to-face courses that include a significant online component. These activities are similar to earlier uses of computer-based instructional materials that pre-date widespread access to the Internet in secondary schools. As computing and graphical properties of computers in schools have advanced, enhanced digital resources that are retrieved via the Internet are increasingly common in traditional classrooms. A related practice is emerging in which online courses incorporate significant face-to-face elements in order to enhance the relationships and learning among teachers and students. Similarly, blended programs allow students to take both online and face-to-face courses within a given degree program. This variety of blended approaches appears to be more common in secondary education than in higher education.

Researchers have begun to suggest online learning classification systems which account for a full range of practices from entirely face to face to entirely online. Blended or hybrid models – such as those described above – are, often, defined as having anywhere from 25% to 80% of instruction

occurring online, depending on the classification system. The term Web-facilitated instruction has also been introduced to describe courses with less intensive use of Web-based technologies within face-to-face courses. Examples of this type of use comprise including Web pages in course readings, e-mail communication between teachers and students, and course-management systems where syllabi and other resources are available online.

Technologies that allow students and teachers to communicate at the same time (e.g., via telephone) are called synchronous, while those that rely on sequential communication over time (e.g., posted letters or e-mail) are called asynchronous. A variety of new instructional features and capabilities (sometimes referred to as affordances) are now possible with the advent of Internet-based instruction – including a blend of synchronous and asynchronous approaches.

The latest developments in online learning include multimedia materials, allowing for simulations, visualizations, and auditory reinforcement of key concepts. Some programs have also begun to incorporate avatars or virtual tutors – which depict animated characters that mimic human facial expressions to communicate emotional support or concern. For example, WiloStar3D allows enrolled students to experience an immersive graphical environment depicting a virtual campus. Students take courses in Internet-based three-dimensional (3D) classrooms. Although the experience for students is clearly two-dimensional, graphics are rendered to give the illusion of a 3D space. Teachers are represented in this space as human-like avatars. Similarly – at the Florida Virtual School (FLVS) – avatars are being introduced specifically to display empathetic emotions to the learner. They provide audio when students click on the avatar picture and also exhibit body movements and facial expressions (Reeves *et al.*, 2007). Some developers have suggested that this humanizes online learning and may increase student motivation, particularly for younger students who have not developed skills sufficiently for working independently. Similarly, online learning can take advantage of a variety of communication methods – such as online chat, e-mail, and audio- and video-conferences.

Prevalence of Internet-Based Education in Secondary Education

Online Learning in North America

Although many countries have Internet-based education programs, the largest online learning programs for secondary school students appear to be in North American countries – with the United States and Canada both having large numbers of secondary students enrolled in a wide variety of online courses and programs (Cavanaugh and Clark, 2007). The United States appears to be

one of the few countries where multiple, national surveys of online educational have been conducted. One study conducted by the US Department of Education looked more generally at distance education, and not at Internet-based education specifically. Based on district-survey responses, it estimated that distance-education enrolments in elementary and secondary schools in the school year 2004–05 were almost 507 000 – up from 328 000 in the school year 2002–03 (Zandberg and Lewis, 2008). Districts reported that the use of the Internet was on the rise, with about 70% of districts reporting student enrolments in technology-based distance education also reporting that at least some of these students took courses online. A more recent study estimated that 1 030 000 K12 students took one or more online or blended courses during the 2007–08 school year (Picciano and Seaman, 2008). However, separate estimates were not provided for online or blended courses. (These estimates should be viewed cautiously since the study obtained a response rate of less than 10%.) Enrolment patterns in the US suggest that most students who participate in formal Internet-based education take one or two courses online while enrolled in traditional face-to-face, full-time programs (Zandberg and Lewis, 2008).

Another way to gauge online learning activity is to track government policies that support Internet-based education. In the United States, 44 states supported sizeable Internet-based learning opportunities for students, in the form of online courses, in 2008 (Watson *et al.*, 2008). Twenty-one of these states supported full-time, online schools – which were typically either state-sanctioned charter schools or districts within a state that offered courses to students beyond their traditional geographical borders. The remaining states provided supplemental online courses for brick-and-mortar schools within the state. One of the best-known state-funded programs is the FLVS, which became the first statewide, public virtual school in the United States in 1997. In 2008–09, FLVS served an estimated 64 000 middle- and high school students (Young *et al.*, 2009). In addition to state-led programs, ~40% of high schools offered technology-based distance-education courses in 2004–05 – the most recent year for which estimates are available.

Many Canadian provinces and local districts also actively support Internet-based education. For example, Ontario – a province that is particularly active in this arena – has identified high-quality online learning as an official strategy for increasing high school-graduation rates. Ontario supported more than 50 online courses during the school year 2008–09, many of them in core subjects – such as language, arts, and mathematics. In addition to offering full courses, Ontario maintains a database with thousands of learning objects that include lesson plans for teachers and other multimedia artifacts for use in classrooms or as instructional supplements.

International K12 Projects of Note

Many other countries are also supporting Internet-based education (Powell and Patrick, 2006), although K12 student participation does not appear as widespread as in North America. Australia has been a long-time leader in the use of distance education – suggesting fertile ground for Internet-based education. Where online learning is an explicit policy to replace face-to-face courses, the priority is placed on serving rural, remote communities. In addition, the Learning Federation is a large-scale, joint effort between Australia and New Zealand to create digital content for schools. Efforts focus on the creation of Internet-based artifacts and learning modules to be used in traditional settings or as supplemental activities for students.

Another example of international adoption of Internet-based education is European SchoolNet – an international partnership of 31 European ministries of education that coordinates and supports a variety of educational projects that rely on the Internet, including efforts to develop common standards and specifications for European countries. Another Schoolnet project – CALIBRATE – has sought to develop a common platform for Internet-based teaching materials that could be searched by teachers across the continent. Among European countries, England is often seen as a leader, particularly through the British Educational Communications and Technology Agency (BECTA) – the government agency responsible for effectively integrating innovative technology applications throughout the educational system.

Singapore – a long-time international leader in the use of technology in K12 education – uses Internet-based resources, primarily, to enhance face-to-face education. For example, several web-portals are in use to teach young children how to speak second languages (Hawthorne and Tan, 2005). Similarly, Internet-based objects are replacing earlier reliance on compact disks-read only memory (CD-ROMs) and packaged software. In addition, approximately 75% of Singapore's schools had subscribed to a learning management system by 2006 (Powell and Patrick, 2006).

Countries not typically associated with high-tech adoption also use the Internet for educational purposes. For example, Iran supports four national schools which offer courses online. Courses are developed by the government and provided at no cost to students.

Common Purposes for Online Learning in K12 Education

The popularity of Internet-based education is premised on its potential to offer access to content and instructional feedback anytime and anywhere that an Internet connection is available. Others suggest that well-designed Internet-based

education may improve student outcomes by increasing the individualization of curricula to match the strengths and interests of students, as well as by expanding the range of resources available. Although no systematic surveys have included detailed questions with regard to the size and purposes of Internet-based education, conventional wisdom suggests that online learning is most valuable to particular types of students and for particular subject areas. Typical applications vary depending on whether Internet-based education is being used to replace face-to-face courses or to enhance face-to-face instruction.

Online Learning as Educational Replacement

Online courses intended to replace face-to-face courses have tended to be promoted for rural areas, for advanced courses, and to allow at-risk students to meet graduation requirements.

In rural areas

Rural areas have been targeted users of online courses and programs, following a tradition of distance education in these areas. Online learning has been promoted for rural areas where qualified teachers may not be available, especially in areas of national shortage such as mathematics and science. Small, rural schools may not have enough interested or prepared students to warrant the costs of offering some specialized or advanced courses in their curriculum. Research has shown that rural schools do not provide extra help and support needed to enter and succeed in higher-level mathematics courses, for example, and high schools in rural communities are less likely to offer advanced placement (AP) coursework than schools in suburban or urban locations. Individuals and small groups of students can join together across disparate locales to participate in a virtual course; qualified instructors can be drawn from the faculty at multiple high schools; and per-student course-costs can be reduced if they are amortized over larger numbers of students.

For advanced courses

Even in suburban and urban areas, online instruction has been promoted for advanced courses, especially for AP courses. High school students, often, take AP courses in order to demonstrate college-readiness or to gain advanced standing as college freshman. The supply of qualified AP teachers has not been able to keep up with the demand, however, with shortages most acute in urban as well as rural areas. There is evidence that advanced courses do, in fact, account for a sizable proportion of online enrolments. One study estimated that 25% of US districts with students enrolled in technology-based distance education had students enrolled in AP courses offered through distance education in 2004–05, and 40% of districts with technology-based distance education had

secondary students enrolled in dual-credit college-level courses offered through distance education. The combined enrolments in AP and dual-credit college-level technology-based distance-education courses accounted for 15% of all technology-based distance-education enrolments in 2004–05.

For at-risk students

Online learning providers are also beginning to identify students in need of remediation as likely beneficiaries of online learning. Nearly 20% of FLVS students are reported to be either at risk or in need of credit recovery – a term used to refer to the need to retake courses previously failed or to accumulate more course credits to meet graduation requirements (Young *et al.*, 2009). In the past, distance education, in general, has been shown to benefit nontraditional students, especially those with daytime responsibilities, since asynchronous learning allows for flexible scheduling. However, poorly performing students are a relatively new focus of online learning providers. Previously, only academically successful secondary students were thought to have the skills and motivation necessary to work independently. However, online learning providers argue that online curriculum that increases individualization and provides specialized support to non-traditional or poorly performing students can keep some students in the education system who would otherwise be lost. (As mentioned above, serving these students is an explicit policy objective of the Ontario government in Canada.)

Online Learning as Educational Enhancement

While the use of the Internet to enhance education takes myriad forms, including course-management systems that serve as electronic repositories as well as activities that encourage cross-cultural communication and exploration, tools and resources for science seem to dominate online enhancement materials at the K12 level. One example is River City – a science-replacement unit focusing on scientific inquiry. River City provides a 20-day curriculum – in which, students spend 14 days in an immersive, online environment and 6 days working on classroom activities. Approximately 7000 students used River City during school year 2005–06. Similarly, Web-based Information Science Education (WISE) consists of replacement modules that help students visualize difficult scientific concepts. The program targets middle- and high school science courses. Bugscope is a third example of an Internet-based supplement for classroom-based instruction. Bugscope provides science courses with access to an electron scanning microscope. Students interact online with scientists who operate the microscope while dissecting an insect. All of these examples suggest that the Internet can provide resources

and experiences that would not, otherwise, be available in the classroom.

Research on the Effectiveness of Internet-Based Education

This section focuses on two common metrics of the effectiveness of online instruction: student retention and learning outcomes. Data provided primarily address research with regard to Internet-based education that is intended as a replacement for traditional, face-to-face instruction, although the text regarding learning outcomes also includes data that address the effectiveness of blended approaches.

Student Retention

Research has documented that retention rates are lower for online courses than for face-to-face courses – sometimes dramatically so. This is true across educational levels and is consistent with the distance-education literature generally. For online college and university undergraduates, studies show that the retention rate can range from 50% to 80%, with online course administrators reporting that the retention rate for online courses is 10–20% lower than that for traditional classroom environments (Herbert, 2006). A survey of state online course-providers in the United States showed a considerable range of reported retention rates among 32 providers. Retention rates for online courses varied from 50% to 99%, with most in the range from 65% to 85%. Reported retention rates for online programs (as opposed to courses) were similar. Respondents reported program retention rates between 60% and 95%, with most programs reporting retention somewhere between 70% and 85% (Watson and Ryan, 2007). Several reasons for the relatively high dropout rate in online courses and programs have been suggested, including difficulty accessing technology, the relative immaturity of students, and competing demands – particularly for nontraditional students who may be working or have increased family responsibilities (Moore *et al.*, 2002).

Student Learning Outcomes

Reviews of the distance-education literature (Cavanaugh, 2001; Moore, 1994; Russell, 1999), generally, suggest that there is no significant difference between learning outcomes for distance and face-to-face education. Usually, the lack of a significant positive difference is viewed negatively in research on educational interventions, but because distance education has its roots in efforts to supply services where face-to-face instruction is not possible, the lack of an effect is viewed positively. However, it

is important to note that the general finding that there is no significant difference between distance and face-to-face models of instruction masks large differences in findings across specific studies. A recent, large-scale meta-analysis found tremendous variability in effect sizes, which ranged from -1.31 to $+1.41$ across 232 studies included in the review (Bernard *et al.*, 2004).

A recent review of research studies, conducted between 1996 and 2007, that focused on the learning effects of Internet-based education specifically (Means *et al.*, 2009) found few experimental or controlled quasi-experimental research studies involving K12 students. Only five studies involving secondary and middle-school subjects and meeting accepted quality standards for rigorous meta-analysis were identified. Each of these studies compared student learning in a blended condition – one that included both face-to-face and Internet-based components – to a face-to-face only condition. These five studies addressed eighth-grade student achievement in social studies, eighth- and ninth-grade Algebra 1, middle-school students in Spanish language courses, and a study of fifth-grade student in science classes in Taiwan. Across the five studies, there were seven independent learning outcomes measured for both blended learning and control students. Results were mixed: Three of the comparisons produced significant effects favoring a blended learning condition, one had a significant negative effect favoring face-to-face instruction, and three contrasts did not attain statistical significance. The results for the larger group of studies involving learners of all ages were less equivocal: students in online learning conditions (either purely online or a blend of online and face-to-face elements) performed not just as well as, but better than, students receiving conventional face-to-face instruction on average.

The same group of studies offers evidence that particular design elements of Internet-based education influence student achievement. Earlier meta-analyses have found an advantage for asynchronous over synchronous communication, with certain practices being more effective in one communication format over the other (Bernard *et al.*, 2004). For example, face-to-face meetings with instructors and telephone contact with an instructor were associated with higher student achievement in the studies of synchronous distance education but not in those of asynchronous distance learning.

There is also some suggestion that the ability of the learner to control learning media is important. Increased learner control suggests that students can influence the pace and sequencing of the curriculum. For example, if a video is included in a Web-based module, systems that allow learner control let students pause, rewind, or skip to particular segments of the video as opposed to needing to passively view an entire presentation from beginning to end. Other methods for engaging active student participation in

learning – including soliciting student reflection and self-monitoring of comprehension – may also contribute to student achievement. On the other hand, practices that promote superficial or relatively passive learning experiences for students do not appear to be associated with improved student achievement (Zhang, 2005).

Summary

Internet-based education is a fast-growing practice in secondary education. Based on the available research, Internet-based education appears to be growing at exponential rates. It continues to evolve in many different ways and represents a tremendous variety of policies, practices, and learning objectives. Internet-based resources may be used to augment an otherwise traditional face-to-face course or an entire course or program of courses may be offered entirely online.

The use of Internet-based education has far outpaced research with regard to its effectiveness – particularly for younger students in elementary and secondary education. The handful of rigorous experimental or quasi-experimental studies that have been conducted suggest that Internet-based learning is usually at least as effective as traditional classroom instruction. It is not uncommon, in fact, for students to learn more when part of their instruction takes place online. The most promising online learning practices seem to involve blending asynchronous and synchronous styles of interaction and incorporate both face-to-face and Internet-based instructional components.

Media Use and School Achievement

K Roe, Katholieke Universiteit Leuven, Leuven, Belgium

Introduction

Does media use have negative effects on literacy and academic achievement? The question is an old one. Concern among educators that media communication is detrimental to the work of the school, in general – and to the development of children's literacy, in particular – can be traced back to at least to concern over popular literature in the mid-nineteenth century. Not surprisingly, then, the question of the nature of the relationship between educational achievement and the mass media is one that has been around since mass communication became a discernible area of study.

Historical Background

In the 1920s, the question was posed by the Payne Fund Studies into the effects of movies on children. The results suggested that movies provide a special learning format that facilitates an unusually high retention of factual material, but that movie fans did worse in their academic work and were less well-behaved and less popular in school than members of the comparison group.

The next major (and rather less objective) treatment came, in 1953, as part of Wertham's broadside attack against comic books. In this instance, the reader does not need to go further than the inside flaps of the cover to learn that comic books are viewed as an invitation to illiteracy and, "harm the development of reading from the lowest level of the most elementary hygiene to the highest level of appreciation of good literature."

On the whole – except in very broad mass versus high culture terms – radio seems curiously to have escaped the odium of critics. Where found, criticism tended to focus on cultural passivity and vulgarization. During the 1950s, however, it was television (TV)'s turn to be examined and, as early as 1951, empirical studies began to appear. Most early research not only failed to find much evidence

for negative effects on school work, some studies actually stressed TV's positive influence, conclusions subsequently reinforced on both sides of the Atlantic. In 1958, one major British study concluded that, on the whole, TV appeared to have no direct effects on school work, nor did it lead to poor concentration, a reduction of interest in school, or a correlation with reading skills. In 1961, an American study reported that watching TV could contribute to a fast start in learning because it helps broaden children's vocabularies, although the advantage gained (over nonviewers) was only temporary.

Although studies reporting negative relationships between TV and scholastic achievement did appear in the 1960s, the general consensus was that there were no simple, direct negative effects – with the result that interest in the topic began to wane. However, as TV became omnipresent in the developed world and cable, satellite and video developments led to a multiplicity of channels and contents, and the subject, once more, became topical. A good deal of the credit for this revival of interest can be attributed to Neil Postman – whose polemical books and articles set up the school as a vital bastion of traditional values against the (alleged) disastrous effects of TV. Although Postman's rhetoric was impressive and his ideas, at times, seductive, only a minority of studies could still be said to have given unqualified support to his position.

The mid-1980s to the mid-1990s witnessed another period of relative neglect – as research attention was diverted elsewhere. However, the last decade has, once again, seen a renewal of interest – undoubtedly, as a result of developments in digital technology. This time, however, the parameters of the discourse have been opened up to include not only specific forms of communication (such as computer games and the Internet), and specific skills (such as reading and writing) but the whole concept of literacy and what being literate in the digital world of the twenty-first century actually means. One consequence of these developments is an increasing tendency to differentiate the concepts of literacy and achievement into

various subdomains such as computer literacy, media literacy, etc. According to some observers, digital developments may be transforming the very way in which we communicate – a process which is moving us inexorably toward an entirely new form of literacy in which authorship and reading online will not involve anything resembling current literacy practices. As a result, it is argued, two ideologies of literacy are now in mortal competition: one encoded in books and traditional pedagogics, the other located in the media, computer games, and the Internet – with the educational system caught in the crossfire. In other words, the traditional praxis of the school – based on hierarchical access to print – is, increasingly, at odds with the more diverse, interactive, and less linear forms made available by digital technologies.

Theoretical Perspectives

Based predominantly on studies of TV and school achievement, four major theoretical perspectives have been identified.

The first is displacement theory – which basically states that TV-viewing takes time away from reading, schoolwork, and other activities beneficial to children's intellectual development. However, the earliest studies in both the United States and Europe failed to find consistent evidence for such an effect. Rather, it appears that other mass media and play activities are TV's main competitors and children who neglect reading because of TV would neglect reading in favor of something else if TV were not available.

The second perspective is information-processing theory which postulates that TV (and by extrapolation other electronic media) influences the way people think. Commonly, while reading is assumed to activate the mind, TV-viewing is assumed to be mentally pacifying. However, there has been little, if any, convincing empirical support for this hypothesis.

The third is short-term gratifications theory. This perspective argues that TV and computer games have radically altered the expectations which children have with regard to learning, most notably in the demand for novel, fast-paced, and constant stimulation – expectations which are antithetical to the slower pace, and deferred gratifications, of school-based education. There is much anecdotal and observational evidence for this hypothesis but it has seldom been tested rigorously.

The fourth, and only positive, perspective is interest-stimulation theory – which hypothesizes that the media can enhance learning by creating and stimulating interests and augmenting knowledge. However, while some early studies indicated that TV might stimulate reading by awakening interests in new subjects, more recently, there is a dearth of empirical support for this assertion.

Research

Although there has never been consistent, conclusive evidence that TV displaces reading and has a negative effect on general school achievement, by the 1980s, a substantial number of studies had reported negative correlations between reading achievement and TV viewing. However, most of these studies were based on cross-sectional data employing bivariate analyses that failed to control for possible mediating variables and were, thus, unable to address the issue of causality. These shortcomings led to more sophisticated research designs, making it possible to analyze different groups of children, different types of media and their contents, and different areas of academic achievement. The results of such research have considerably refined the nature of the relationship by identifying significant mediating factors such as age (TV does not inhibit reading achievement among young children but can do so among teenagers), cognitive development (among same-age younger children, the cognitively more developed watch more TV than the cognitively less developed, whereas the reverse is true among older children and adolescents), and academic achievement (with curvilinear differences between high, average, and low achievers). Socioeconomic status differences, too, influence both media-use frequency and reading achievement.

In an attempt to bring some coherence to these disparate sets of results, some researchers have created large-scale, longitudinal designs employing multivariate analyses. The results show, for example, that TV viewing can be both a positive and a negative influence on achievement – depending on the type of content viewed, the social context of viewing, and the developmental level of the viewers. Other studies have tested the efficacy of the various approaches by comparing negative models (media use leads to lower school-achievement scores), positive models (more use of the print media leads to higher achievement scores), and school models (which postulate that school-based factors, such as motivation and academic self-concept, better explain variations in achievement scores than do external factors such as media use). While some support accrues to all three models, the negative model has been found to be empirically stronger than the positive model, while the strongest and most parsimonious results were provided by the school model. These studies also reaffirmed the importance of age, gender, and socioeconomic status in mediating the postulated relationships.

Conclusions

There is no common agreement as to the definition or empirical operationalization of the concept of literacy which – both historically and in contemporary society – carries a multiplicity of meanings. Mostly, it seems to be

equated with functional literacy – defined, basically, as the ability to read and write, although broader definitions encompass achievement in all academic areas. More recently, concepts such as digital or computer literacy have appeared.

The predominant theoretical perspective informing most research has been – and to some extent still is – a simple negative-effects model, dominated by TV use. Various academic consequences of excessive TV-use have been postulated, for example, poor concentration, reading and writing difficulties, and poor examination results. Attempts to formulate and test alternative theoretical models have been uncommon.

Empirical research in the field has seldom been sustained and systematic. The great majority of studies has been limited, one-off, and cross-sectional in nature and the fact that they have been conducted by researchers from a variety of different disciplines – using a wide array of measurement and analytical methods – has made rigorous comparison of results difficult and hazardous. Moreover, many studies of the relationship between media use and educational achievement have been based secondarily on data collected primarily for other purposes. As a result of the piecemeal nature of the research, it is still extremely difficult to draw firm conclusions from the available evidence. Consequently, there is little consensus among researchers.

The enormous increase in the amount and types of TV now available to children – not to mention the rapid diffusion of other forms of media, such as computers (and their games) and the Internet (with all its diverse applications) – has radically altered the whole research context and has imposed new theoretical and methodological parameters. Moreover, this has infused the issue of whether or not media use retards academic achievement with a new sense of urgency and has accentuated the already serious concern felt by many educators, parents, and policymakers.

Glossary

Bulletin boards – Bulletin boards are online public spaces, where users post messages asynchronously (i.e., not in real time) and there may or not be a time lag between messages, which are available for viewing long after they have been posted. Bulletin boards may be organized around a focal topic, such as college admissions, computer use, health, politics, and religion and interactions involve both the exchange of information, advice, as well as emotional support and encouragement.

(Subrahmanyam and Smahel, In press; Adolescents, Internet, and Development. Springer Publishing.)

Displacement hypothesis – Proposed by Nie and Hillygus, it suggests that time spent on the Internet may displace physical activities or social interactions. (Nie, N. H., & Hillygus, D. S. (2002). Where does Internet time come from? A reconnaissance.

IT&Society, 1, 1–20.)

Eating disorders – According to the National Eating Disorders Association “**Eating disorders are illnesses with a biological basis** modified and influenced by emotional and cultural factors.” They include different subtypes such as anorexia nervosa (self-starvation and excessive weight loss) and bulimia nervosa (cycle of binge eating and self-purging). <http://www.nationaleatingdisorders.org/>.

Effect size – A measure of the strength of the relationship between two variables, or the size of the observed relationship in practical terms.

Generalized physiological arousal – Is a bodily response consisting of changes in breathing, heart rate, and blood pressure. Media-induced arousal lingers after exposure, and may have an energizing effect leading to agitation and restlessness in children's behavior (e.g., while playing or interaction with peers) (Valkenburg, 2004) (Valkenburg, P. M. (2004). *Children's responses to the screen: a media psychological approach*. Lawrence Erlbaum Associates.)

Meta analysis – A statistical analysis of other studies' statistical effects.

Nintendinitis – A specific form of tendonitis where severe pain is experienced in the extensor tendon of the right thumb due to the repeated playing of a video game such as the Nintendo.

Online chat rooms – Online spaces, that are public or private, where users interact with each other in real time; they typically involve multiple users participating in several simultaneous conversations occurring in the chat space (Greenfield & Subrahmanyam, 2003) (Greenfield, P. M., & Subrahmanyam, K. (2003). Online discourse in a teen chatroom: New codes and new modes of coherence in a visual medium. *Journal of Applied Developmental Psychology*, 24, 713–738.)

Photosensitive epilepsy – A condition in which epileptic seizures are triggered by visual stimuli such as flashing or flickering lights.

Self-injury – Where the individual deliberately inflicts harm to himself or herself (e.g., by cutting oneself with a razor blade), but not necessarily with suicidal intent.

Social networking utilities – Allow users to create public or private profiles and form networks of “friends” with whom they can interact publicly (e.g., status updates or wall posts) and privately (e.g., private messages). Users can also post user-generated content (e.g., written notes, photos, and videos), which often elicit comments and result in further interaction. Examples include, www.myspace.com, and www.facebook.com (Subrahmanyam and Smahel, In press; Adolescents, Internet, and Development. Springer Publishing.)

Technology has become ubiquitous in today's society and questions abound as to its role in the lives of children and adolescents. Among youth, commonly used technologies include computers, Internet, and electronic devices such as cellphones, Ipods, and sidekicks. Computers include desktop computers and laptop computers as well as electronic games played on computers, stand alone game systems (e.g., X-box or the Wii), and portable, hand-held game systems (e.g., gameboy, Sony play station portable (PSP)). The Internet includes general purpose websites, websites that allow social networking (e.g., MySpace and Facebook), websites that allow online journaling (e.g., www.livejournal.com), websites that allow sharing of videos and music (e.g., YouTube) as well as a wide variety of applications including chat rooms, e-mail, instant messaging, and bulletin boards. Interestingly, the distinctions between the different technologies is blurring – thus, for

instance, electronic games can be played on game systems as well as via the Internet, and hand-held mobile devices such as the iPhone or Blackberry combine in one hand-held device, a mobile phone, as well music, e-mail, web browsing, maps/global positioning system (GPS) and other capabilities.

Three features mark young people's use of these technologies: First, technologies such as computers and the Internet have become so diffused that most youngsters in the United States today have access to them (Jones and Fox, 2009). Second, youth use these technologies for extensive amounts of time (Lenhart *et al.*, 2005; Roberts *et al.*, 2005). Third, it appears that children are using these technologies at a younger and younger age; for example, in the 2003 Kaiser Report, Zero to Six, 64% of children between 4 and 6 years of age knew how to use a computer mouse to point and click (Rideout *et al.*, 2003). Given these trends, concerns have been raised regarding the impact of digital technologies on children's development. The article examines the impact of technology on children's and adolescents' physical and social health.

Impact of Technology on Physical Health

Research on the impact of technology on physical health has examined two issues. The first issue concerns the physical effects of using technology, such as the risk of injuries and seizures as well as obesity. A second issue concerns the health-related uses of technology – for example, the use of the Internet to obtain information about wellness and illnesses as well as use of technology to deliver treatments and interventions.

Physical Effects of Technology

With regard to the physical effects of technology, research has identified both direct and indirect effects. Direct effects include the risks of seizures, hand injuries, and changes in physiological arousal such as heart rate (Subrahmanyam *et al.*, 2001). Based on an extensive review of the literature, Subrahmanyam *et al.* (2000) report that computer and videogames may trigger epileptic seizures in certain users; such seizures appear most likely among those suffering from photosensitive epilepsy, a condition in which epileptic seizures are triggered by visual stimuli such as flashing or flickering lights. Another effect associated with videogame playing is a form of tendinitis or nintendinitis, "which is a sports injury characterized by severe pain in the extensor tendon of the right thumb as a result of the repeated pressing of buttons during game play" (Subrahmanyam *et al.*, 2001). To guard against both risks, users should read and follow guidelines included with videogames and take the same precautions as those that are recommended to prevent any sort of repetitive injury (e.g., frequent breaks).

A meta-analysis by Anderson and Bushman (2001) suggests that exposure to violent videogames increased physiological arousal. In the studies that were considered in the meta-analysis, physiological arousal was measured using systolic blood pressure, diastolic blood pressure, and heart rate. (The association between videogame play and aggressive and violent behavior is discussed later in this article.)

Research on the indirect physical effects of technology have been framed within the context of the displacement hypothesis, which suggests that because time is a finite quantity, time spent on the Internet comes at the expense of other activities, such as participation in physical activities (e.g., organized sports) (Nie and Hillygus, 2002). These concerns have taken on added urgency in the face of reports that the rate of childhood obesity is increasing, in the US. Based on a comprehensive review of research on this topic, the 2004 Kaiser report concluded that youth who used more media were more obese. Interestingly, the report found that media technology use was not displacing physical activities. For instance, people watching less television were often engaging in other sedentary activities, such as talking on the phone, playing board games, and reading books. Instead, it appeared that the content of media, particularly the food advertising, may play a role in increasing rates of obesity among those with more media exposure. At the same time, online advertising may have potential as a medium for antiobesity campaigns targeting youth.

Technology and Health Information

One important health-related use of technology, particularly computers and the Internet, is that it can be used to obtain information about various health-related issues. Suzuki and Calzo (2004) have suggested that because of the option to remain anonymous online, the Internet is particularly attractive as a source of information about sensitive health-related questions that adolescents may not be comfortable asking an adult (such as a parent or physician) in person. Other advantages that they identified included the Internet's availability 24 h a day, 7 days a week, the option to passively obtain information (by looking at other people's questions and the responses they received), and the ability to get advice and suggestions from more individuals than would be possible from one's circle of face-to-face friends. Based on an analysis of a health-related online bulletin board targeting adolescents, Suzuki and Calzo (2004) reported that health-related concerns and questions were among the more frequently posted question categories. Frequently posted health-related questions concerned sexual health, pregnancy and birth control, body image, and grooming of genital areas. The Internet is also more generally used to access health information by adolescents. In a survey study

of tenth graders, Borzekowski and Rickert (2001) reported that 49% reported using the Internet to access health information. The use of the Internet for health information can be potentially very valuable for segments of society that would otherwise not have access to such information. For instance, in another recent study, Borzekowski *et al.* (2006) found that approximately 53% of 15–18-year-olds living in Accra, Ghana used the Internet to search for health information, and that the Internet was a particularly important information source for youth who were out of school. Some of the topics that were most often searched for by the youth in this study were sexually transmitted diseases, sexual abuse, sexual activities, and diet and nutrition, fitness, and exercise. The Internet thus has tremendous potential to reach disadvantaged youth in the area of health education.

Not only are technologies, such as the Internet, used to obtain general health information, they are also used to obtain and disseminate information about specific diseases and illnesses as well as to receive support from peers who have experienced or are experiencing the same illness. Specific Internet technologies that have been studied include web pages and bulletin boards for illnesses such as cancer, eating disorders, and self-injury.

Kyngas *et al.* (2001) found that for adolescents and young adults (between 16 and 22 years) suffering from a chronic illness such as cancer, searching for information on the Internet was a good coping strategy. Suzuki and Beale (2006) studied the personal web pages created by teens with cancer and found three potentially beneficial functions: self-presentation (e.g., essays and poetry), information dissemination (e.g., lists, charts, and hyperlinks), and interpersonal connection (e.g., guestbook entries). They concluded that such web pages were being used by adolescent cancer sufferers for self-expression, information access, and contact with peers. The access to information that technology affords is particularly important given that access to cancer information in young patients is related to lowered anxiety and depression as well as to less anxiety about treatments (Suzuki and Beale, 2006).

The interpersonal connections with peers that technology makes possible may be particularly valuable for isolated youth (e.g., those living in small towns or rural areas), youth suffering from relatively rare illnesses, as well as youth suffering from illnesses that they may not be comfortable talking about to their peers in person (e.g., AIDS, eating disorders, or self-injury behavior). Online bulletin boards and chat rooms are Internet venues that allow youth to form such connections. Whitlock *et al.* (2006) studied 406 online message boards that specifically targeted self-injurious behaviors (e.g., cutting). The authors of these studies report that the boards were most popular among young females between 14 and 20 years of age, the group also most at risk for such behavior.

Similar results have been found in a study of an electronic support group for those suffering from eating disorders, also common among adolescent females. Winzelberg (1997) analyzed 306 messages that were posted on an eating-disorder electronic support group over a period of 3 months. Analysis suggested that most of the posters were in their teens or early twenties. In terms of message content, the most common message types were self-disclosure, requests for information, and direct provision of emotional support. Interestingly most of the messages were posted between 7 p.m. and 7 a.m., when traditional face-to-face sources of support are typically not available.

Although online forums may provide information and support about eating disorders, online images could also have negative consequences. In an experimental study, female undergraduate students ($M = 18.7$ years) were randomly shown one of three kinds of websites: a proanorexic website, a website of female fashion showing average-sized models, or a home-décor site. Pre- and posttreatment questionnaires suggested that among participants who viewed the proanorexic website there was a decrease in self-esteem, appearance self-efficacy, and perceived attractiveness, as well as an increase in negative affect and perceptions of being overweight (Bardone-Cone and Cass, 2006).

The foregoing review suggests that although the Internet may have many positive benefits in the area of illness and disorders, they may also serve to normalize potentially dangerous behaviors such as self-injury, anorexia, and bulimia. This is an important concern considering that the Internet is now home to innumerable sites that provide detailed information and instructions about several dangerous behaviors that are gaining popularity among adolescents (e.g., sniffing glue or choking oneself).

Technology and Treatment Delivery

Technological resources have also been found useful to deliver interventions and treatments. One recent study assessed the effectiveness of an Internet-based lifestyle-behavior-modification program for overweight African-American adolescent girls who also had one obese biological parent (Williamson *et al.*, 2005). Participants were randomly assigned to either an interactive behavioral program (including Internet counseling) or a health-education program delivered over the Internet. The intervention also included face-to-face sessions for all participants. Although only 50% of the participants completed the 6-month trial, measurements taken at baseline and 6 months later showed that adolescents in the interactive behavioral program and their parents lost more body weight; both parents and adolescents showed lowered dietary fat intake. This study suggests that a more passive Internet health-education program is not as effective as an interactive one.

Another study assessed the effectiveness of a psycho-educational intervention using a videogame called

Re-Mission among adolescents (and young adult) cancer patients. A multisite trial was conducted with 375 cancer patients between 13 and 29 years of age; 197 were randomly assigned to receive the Re-Mission game, and 176 received an alternative videogame (Beale *et al.*, 2006). After playing the game, participants filled out a questionnaire about the acceptability of the game as an intervention and its ability to change patients' knowledge, attitudes, and treatment-related self-care behaviors. The authors report that participants expressed a good level of acceptance of the game and that the game had a moderate level of credibility as an intervention. Not surprisingly, acceptability and credibility ratings were related to the amount of time a patient played the videogame (Beale *et al.*, 2006). Playing the game also increased a patient's quality of life, knowledge about cancer information presented in the game, and ability to manage side effects. Importantly, young people who played the game seemed better able to adhere to treatment regimens as evidenced by higher blood levels of chemotherapy and higher rates of antibiotic utilization (Hope Lab, 2007).

Finally, technology has also been used to enhance the physician-patient relationship and to empower chronically ill youth. Rich (2004) describes the video intervention/prevention assessment (VIA) method, which was designed to give children and adolescents with health problems an opportunity to express themselves through video media. Children with chronic asthma were given video recorders, and asked to explain their illness to their clinicians. Four benefits were found for the participants: first, they felt empowered by their ability to express themselves; second, they were able to teach others about their unique individual experiences fighting diseases that millions are afflicted with; third, they learned about the process of creating videos, as did the researchers who worked with them; and finally, they became more self-aware of the risks they were taking and the paths their illnesses were taking.

For the clinicians, the narratives recorded in these videos provided a picture of the actual psychosocial environments in which the patients lived, as well as some of the patients' innermost thoughts. Sometimes, the videos even demonstrated environmental triggers, without the patients even realizing they were doing so. The videos also chronicled depression and the risky decisions that adolescents made because of the stigma they felt from their asthma. Thus, the clinicians benefited because they were able to see information and points of view that were usually not observable in traditional office visits. The video diaries that were created cast light on some of the challenges the patients faced outside of the doctors' offices, including life at home, at school, and interacting with other health-care practitioners. Although the VIA technology was originally created for young asthma patients, it has been used to explore the experiences of youth suffering

from obesity, sickle-cell disease, cystic fibrosis, human immunodeficiency virus (HIV), and spina bifida.

Technology and Social Development

Research on the role of technology in the social development of children and adolescents has focused on two main sets of questions. The first set of questions focus on the effects of interacting with violent content such as videogames; a related issue concerns how technology may be transforming bullying, victimization, and other aggressive behaviors typical among youth. The second set of questions focuses on the effects of computer-mediated communication (CMC) forms on youths' developing social relationships.

Technology and Aggression

One favorite pastime among youth is that of videogames and a recurring concern in the years since their introduction has been their increasingly violent content. In a study of 607 eighth- and ninth-grade students, it was found that on average, participants spent 9 h a week playing videogames and that males played for significantly longer periods of time than females (13 vs. 5 h a week) (Gentile *et al.* 2004). It appears that there is little parental knowledge and control over youths' use of this medium. Less than half of the respondents (31%) think that their parents understand the videogame ratings put out by the Entertainment Software Ratings Board (ESRB), and only 15% reported that their parents consistently monitor the ratings when purchasing or renting videogames. Of note is the finding that 10% of the participants reported having games, whose content would not be approved by their parents. Importantly, the study found that youth who reported greater exposure to videogame violence were more hostile and reported getting into arguments with teachers more frequently, and were more likely to be involved in physical fights.

A meta-analysis by Anderson (2004) reveals that "playing violent videogames was associated with increases in aggressive behavior, aggressive cognition, aggressive affect, and physiological arousal, and with decreases in helping behavior." The methodologically stronger studies in the meta-analysis yielded stronger effects than did the methodologically weaker studies. The author (Anderson, 2004) found the effect size of violent videogame exposure on aggressive behavior to be 0.28. To put this in perspective, it is larger effect than that of condom use on HIV risk or that of passive workplace smoke exposure on lung cancer. Based on a review of the research, Anderson *et al.* (2003) similarly conclude that experimental studies show that violent videogames cause short-term increases in aggressive thoughts, affect, and behavior as well as

decreases in helping behavior. They report that correlational studies of exposure time and aggressive behavior show a link between repeated exposure to violent videogames and real-life aggression. Finally, their review of longitudinal research showed modest but suggestive evidence of long-term effects of the repeated playing of violent videogames on aggressive and violent behavior.

A second major concern with regard to technology and social health are reports that bullying is migrating from school yards to cell phones, instant messages, and the Internet. A survey done in the UK found that 20% of the 770 respondents (11–19) had reported being bullied through technology – they had received a threat via e-mail, Internet, chatroom, or text message (NCH, 2005). Mobile text messaging was the most commonly reported form of bullying. Bullying in Internet chat rooms and via e-mails was reported by 5% and 4% of the sample, respectively. Cell phone cameras are another for harassment. Ten percent of the respondents in the UK survey reported feeling embarrassed, uncomfortable, or threatened by a picture that somebody took of them using a cell phone camera. Ironically, much of the harassment is being carried out by people known to the victims. Researchers in the US have similarly found that about 9% of youth Internet users have experienced online harassment (Wolak *et al.*, 2006). Forty-seven percent reported being harassed via instant messaging, 13% by e-mails, 11% by chatrooms, and 3% by blogs.

Research on the characteristics of cyber bullies and their victims has found that cyber bullies are more likely to report poor parent–child relationships, substance use, and delinquency (Ybarra and Mitchell, 2004). Victims of harassment were also more likely than other youth to report symptoms of depression (Ybarra and Mitchell, 2004). More research is necessary to understand the relation between depression symptomatology and the likelihood of being bullied.

Technology and Social Relationships

Relations with peers and families are an important part of development and technology has become an important means of connecting with others. The popularity of the communication applications of the Internet among youth has raised many concerns. First, there is concern that because CMC lacks important features, such as gestures and eye contact, it is not as rich as face-to-face communication forms. Second, there is concern that online relationships may involve strangers, who are not part of one's offline life. Consequently, online relationships are hypothesized to represent weak ties, which are characterized as relationships that have superficial and easily broken bonds, infrequent contact, and narrow focus (Kraut *et al.*, 1998). Research on this topic has therefore examined the extent of youths' online interactions with strangers

and the impact of their online interactions on their psychological well-being.

To what extent do youth interact online with friends versus strangers? To some extent this is dependent on the popular technology application at any given time. For instance, when chat rooms were popular, contact with strangers was more likely. With the introduction of instant messaging, this changed and youth seemed to be using this newer technology mostly to connect with offline friends (Boneva *et al.*, 2006). The currently popular social networking sites seem to make possible contact both with friends and strangers. For instance, in one national survey conducted in 2006, 40% of 14–22-year-olds who use social networking sites such as MySpace reported that they had been contacted online by a stranger whom they did not know before (Annenberg Public Policy Center, 2006). A subsequent survey conducted in 2007 found that among youth who use social networking sites, the majority do so to keep in touch with friends whom they see frequently (91%) or to keep in touch with friends whom they see rarely in person (82%) (Lenhart and Madden, 2007).

The limited research that has been conducted on the topic suggests that adolescents' online relationships may not be of the same quality as their offline ones. For instance, in one study of Israeli adolescents, it was found that online friendships were shorter in duration and were not as close as measured by the topics discussed (e.g., less personal topics) and frequency of shared activities (Mesch and Talmud, 2006). Research also suggests that relationships from the online realm move to the offline realm only rarely; of the 256 respondents of a national survey ($N = 1501$), who reported close online relationships, only 41% of them reported that they had met their online friend face to face (Wolak *et al.*, 2002). More research is necessary to explore this question, given social networking utilities that seek to enable users to make new friends.

How are online communication modes impacting youth's existing friendships? In a survey study, 80% of the respondents reported using the Internet to maintain existing friendship networks (Valkenburg and Peter, 2007). Participants who communicated more often on the Internet felt closer to existing friends, but only if they were using the Internet to communicate with friends rather than strangers. Interestingly, participants who felt that online communication was more effective for self-disclosure also reported feeling more close to their offline friends compared to adolescents who did not view online communication as allowing for more intimate self-disclosure compared to offline communication.

A related question is whether youths' use of technologies, such as the Internet, displaces activities important for adolescent social development, such as face-to-face interactions with peers. According to the displacement hypothesis, because time is not infinite, time spent on the Internet displaces other daily activities, in particular

face-to-face social interactions (Nie and Hillygus, 2002). Proponents of this view suggest that not only would Internet use displace adolescents' real interactions with peers and family, it also may be substituting weak ties (with online friends) for strong ones (with offline friends). Research suggests that weak ties typically provide less consequential social support than do more intimate ties (Krackhardt, 1994). Consequently, research has examined whether greater Internet use is associated with weaker social ties as well as lowered well-being (e.g., greater depression).

Early research suggested that greater use of the Internet was associated with declines in adolescents' well-being and with weaker social ties (Kraut *et al.*, 1998). Adolescents' perceptions about the quality of their family relationships was also found to be negatively related to frequency of Internet use (Mesch, 2003). However, more recent studies have not found a link between adolescents' time online and psychological well-being, as indicated by dispositional or daily well-being (Gross *et al.*, 2002) or loneliness (Subrahmanyam and Lin, 2007). Finally, time spent online does not appear to be related to aspects of social networks, such as size of local and distant social circles and amount of face-to-face communication (Kraut *et al.*, 2002).

One reason for this conflicting pattern of findings could be that the measures of Internet time use that have been used in the studies did not distinguish between different kinds of Internet use. For instance, e-mailing and chatting with school friends might contribute to well-being, surfing the web for information about sports, music, or movies might have no impact on well-being, and accessing pornographic materials might actually threaten well-being. One study that distinguished among different types of online activity found that more time spent in chatrooms, online browsing, and games was related to higher levels of social anxiety among older adolescent and young adult males, but not females (Mazalin, and Moore, 2004). This correlational relationship does not resolve the question of whether participants are becoming more depressed because of their chat room use or whether they are drawn to chat rooms in the first place because they are depressed and are looking for support, which may be lacking in their offline life. Further complicating the picture is the finding that for extroverted teens, Internet use appears to be associated with declines in loneliness (Kraut *et al.*, 2002). Although no systematic relation between time use and dispositional loneliness has been found, daily social anxiety and loneliness is related to whether a youth communicates via instant messaging with a stranger on that given day (Gross *et al.*, 2002). Adolescents' perceptions regarding the relationship strength may also be important. Subrahmanyam and Lin (2007) found that for a sample of urban teens, loneliness was not related to the total time spent online, nor to the time spent on

e-mail, but was predicted by participants' gender (male adolescents were more lonely) and perceptions regarding their online relationships. Adolescents who felt that their relationship with online partners was one that they could turn to in times of need also reported feeling more lonely.

Conclusion

Overall, extant research presents a mixed picture of the effect of technology on children and adolescents. In the area of physical health, technology poses slight risks such as nitendinitis or epileptic seizures, and physiological arousal; there also seems to be some link between media use and obesity. Although the latter risk is potentially worrisome, education efforts can help minimize the problem. On the positive side, research suggests that technologies such as the Internet and computer games can be enormously helpful for disseminating information about health and illness as well as for delivering treatments and interventions.

In the area of social development, technology has provided new means for youth to bully and victimize their peers; while such behaviors have always existed among youth, more needs to be done to increase awareness in parents, teachers, and others who work with young people. Violent content in videogames contributes to aggression in youth, and parents are often uninformed concerning the nature of the games that their children play. In the area of interpersonal connections, although online relationships may not be of high quality, research has not found systematic links between time online and well-being. As newer forms of online communication are emerging, more research is necessary to understand the relation between youth's online and offline social worlds.

TECHNOLOGY AND LEARNING – MEETING SPECIAL STUDENTS' NEEDS

Universal Design for Learning

D H Rose and J W Gravel, Center for Applied Special Technology, Wakefield, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Elementary and Secondary Education Act – The Elementary and Secondary Education Act (ESEA) is the main federal law affecting education from kindergarten through high school (from 2001 to 2009 known as No Child Left Behind) (US Department of Education).

The Higher Education Opportunity Act of 2008 – The Higher Education Opportunity Act (Public Law 110-315) (HEOA) was enacted on 14 August 2008, and reauthorizes the Higher Education Act of 1965, as amended (HEA). This latest reauthorization now includes language around Universal Design for Learning (US Department of Education, www.ed.gov).

Universal design – Universal design is an architectural concept that focuses on the design of products, buildings, or environments so they can be used readily by the widest possible range of users.

Universal design for learning (UDL) – UDL is a framework for teaching and learning that often capitalizes on the power and flexibility of modern technologies to address the needs of the broadest possible range of students.

Universal design, although well established in architecture and other domains, is relatively new to education. However, there are signs that the newness is waning. In the recent higher education bill passed by the US Congress (The Higher Education Opportunity Act of 2008), the application of universal design to education – called ‘universal design for learning’ (UDL) – is prominently defined and recommended for colleges and universities. Furthermore, a task force composed of nearly 30 major national educational organizations has been formed to advocate for the inclusion of UDL in upcoming revisions of ESEA.

In spite of this recent increase in exposure and advocacy, most educators do not really know what UDL means, and still others have heard of it but do not know

whether or how it differs from the architectural meaning of universal design. In this article, we hope to clarify what is meant by UDL and especially to provide the evidentiary basis for its principles and a review of its guidelines.

Universal Design and Universal Design for Learning

Universal design focuses on the design of products, buildings, or environments so they can be used readily by the widest possible range of users. Virtually all architects in the US now create buildings that are designed from the outset to reduce or eliminate architectural barriers through designs that consider the needs of diverse people. This practice is now recognized as more cost-effective and equitable than trying to retrofit buildings later or providing customized accommodations to individuals who are unable to navigate poorly designed structures. Universally designed environments are engineered for flexibility and designed to anticipate the need for alternatives, options, and adaptations to meet the challenge of diversity. While originally conceived to meet the needs of individuals with disabilities, universal designs actually make buildings that are more accessible and functional for everyone.

A good example of universal design in action comes from the history of television captioning. When captioning first became available, it was an expensive add-on purchase intended for people with hearing impairments. Building captioning into every television, rather than retrofitting it later, turned out to be a better, and more universal, design. It now benefits not only those with hearing impairments, but also exercisers in health clubs, travelers in airports, individuals working on their language skills, and couples who go to sleep at different times. The key to universal design is building options into initial designs, making better choices available for everyone.

UDL is one part of the overall movement toward universal design. The term UDL emphasizes the special purpose of learning environments – they are not created to provide access to information (that is the role for libraries and the Internet) but instead to foster the changes in knowledge and

skills that we call learning. While providing access to information is often essential to learning, it is not sufficient. Success also requires that the means for learning – the pedagogical goals, methods, materials and assessments of instruction – are also accessible. UDL is the process by which we attempt to ensure that the means for learning, and their results, are equally accessible to all students.

Part One: UDL – The Basic Framework

The framework and guidelines for UDL are not derived from the principles for architecture. Instead, they are based on research and practice from multiple domains within the learning sciences – education, developmental psychology, cognitive science, and cognitive neuroscience. The research in those fields guides both the scope of the pedagogy that UDL addresses (i.e., the critical elements of teaching and learning) and the range of the individuals that UDL addresses (i.e., the critical elements of individual differences).

At its simplest, the scope of UDL is based entirely on three principles:

1. providing multiple means of representation;
2. providing multiple means of action and expression; and
3. providing multiple means of engagement.

These three principles have been chosen because they address three critical features of any teaching and learning environment: the means by which information is presented to the learner, the means by which the learner is required to express what they know, and the means by which students are engaged in learning.

While there are many ways to articulate the fundamentals of teaching and learning, the choice of these three foundational principles stems from their commonality across many aspects of theory and research in the learning sciences. Consider the field of cognitive neuroscience where it is common to think of three broad divisions of the learning brain: (1) the pattern recognition capabilities in the posterior regions of the cortex, (2) the motor and executive capabilities in the frontal regions of the cortex, and (3) the affective or emotional capabilities in the medial regions of the nervous system. While even this division is an oversimplification, it is an articulation that is common and draws historically on Luria's classic work and has been elaborated and modified by many others. It is by design that the three principles of UDL match up well with this framework from neuroscience – addressing in turn the perceptual learning of the posterior cortex, the strategic and motor learning of the anterior cortex, and the affective or emotional learning of the medial and orbital frontal cortex – in order to be systematic in considering learning differences.

Beyond cognitive neuroscience, however, researchers and theorists in other learning sciences have adopted very

similar frameworks to consider the scope of teaching and learning. Among the most prominent, Lev Vygotsky, the preeminent Russian psychologist, and Benjamin Bloom, the American educational theorist, both adopted a similar three-part framework for their foundations.

From the three principles, nine guidelines have been developed that form the primary foundation of UDL. Those guidelines articulate the principles but their main purpose is to guide educators and curriculum developers in using evidence-based means of addressing the wide range of individual differences that any classroom typically experiences. To those guidelines we now turn.

Part Two: The UDL Guidelines and Their Research Base

A critical foundation of the UDL approach is to identify those evidence-based practices which should be included within an overall universal design. Typically, these practices have already proven effective for individual students in the margins, but they are generally not integrated within the one-size-fits-all curriculum of regular education. By taking advantage of the power and flexibility of modern technology, UDL provides a vehicle for delivering these practices to the individual students for whom they are likely to be most effective. But which practices, and for whom?

The UDL Guidelines help in making informed decisions about what practices are optimal. They articulate the specific practices that have been shown to be effective for one or specific types of learning or learners and that should be considered as important options to ensure that students with a full range of abilities and disabilities can access and progress in the general curriculum. The Guidelines assist curriculum developers (these may include teachers, publishers, and others) in designing flexible curricula that reduce barriers to learning and provide robust learning supports to all learners.

Each of the Guidelines, along with the three to four checkpoints associated with each Guideline, are based on the work of hundreds of researchers in many different institutions. A description of the Guidelines (CAST, 2008) and the associated checkpoints is described in the following. For a more detailed description of the UDL Guidelines and for a listing of the full references, the reader is referred to the National Center on UDL website.

Guidelines for Providing Multiple Means of Representation

Guideline 1: Provide options for perception

To be effective in diverse classrooms, curricula must present information in ways that are perceptible to all students. It is impossible to learn information that is imperceptible to

the learner, and difficult when information is presented in formats that require extraordinary effort or assistance. To reduce barriers to learning, therefore, it is important to ensure that key information is equally perceptible to all students by: (1) providing the same information through different sensory modalities (e.g., through vision, or hearing, or touch); (2) providing information in a format that will allow for adjustability by the user (e.g., text that can be enlarged, sounds that can be amplified). Such multiple representations ensure that information is not only accessible to students with particular sensory and perceptual disabilities, but also easier to access for many others. When the same information, for example, is presented in both speech and text, the complementary representations enhance comprehensibility for most students. Checkpoints suggesting specific strategies for providing options for perception are listed as follows:

- options that customize the display of information;
- options that provide alternatives for auditory information; and
- options that provide alternatives for visual information.

Guideline 2: Provide options for language and symbols

Students vary in their facility with different forms of representation – both linguistic and nonlinguistic. Vocabulary that may sharpen and clarify concepts for one student may be opaque and foreign to another. A graph that illustrates the relationship between two variables may be informative to one student and inaccessible or puzzling to another. A picture or image that carries meaning for some students may carry very different meanings for students from differing cultural or familial backgrounds. As a result, inequalities arise when information is presented to all students through a single form of representation. An important instructional strategy is to ensure that alternative representations are provided not only for accessibility, but for clarity and comprehensibility across all students as well. Checkpoints suggesting specific strategies for providing options for language and symbols are listed as follows:

- options that define vocabulary and symbols;
- options that clarify syntax and structure;
- options for decoding text or mathematical notation;
- options that promote cross-linguistic understanding; and
- options that illustrate key concepts nonlinguistically.

Guideline 3: Provide options for comprehension

The purpose of education is not to make information accessible, but to teach students how to transform accessible information into useable knowledge. Decades of cognitive science research have demonstrated that the capability to transform accessible information into useable knowledge

is not a passive process but an active one. Constructing useable knowledge, knowledge that is accessible for future decision making, depends not upon merely perceiving information but upon active information processing skills like selective attending, integrating new information with prior knowledge, strategic categorization, and active memorization. Individuals differ greatly in their skills in information processing and in their access to prior knowledge through which they can assimilate new information. Proper design and presentation of information – the responsibility of any curriculum or instructional methodology – can provide the cognitive ramps that are necessary to ensure that all students have access to knowledge. Checkpoints suggesting specific strategies for providing options for comprehension are listed as follows:

- options that provide or activate background knowledge;
- options that highlight critical features, big ideas, and relationships;
- options that guide information processing; and
- options that support memory and transfer.

Guidelines for Providing Multiple Means of Action and Expression

Guideline 4: Provide options for physical action

A textbook or workbook in a print format provides limited means of navigation or physical interaction (e.g., by turning pages with fingers, handwriting in spaces provided). Many interactive pieces of educational software similarly provide only limited means of navigation or interaction (e.g., via dexterously manipulating a joystick or keyboard). Navigation and interaction in those limited ways will raise barriers for some students – those who are physically disabled, blind, dysgraphic, or who have various kinds of executive function disorders. It is important to provide materials with which all students can interact. Properly designed curricular materials provide a seamless interface with common assistive technologies through which individuals with motor disabilities can navigate and express what they know – to allow navigation or interaction with a single switch, through voice-activated switches, expanded keyboards, and others. Checkpoints suggesting specific strategies for providing options for physical action are listed as follows:

- options in the mode of physical response;
- options in the means of navigation; and
- options for accessing tools and assistive technologies.

Guideline 5: Provide options for expressive skills and fluency

There is no medium of expression that is equally suited for all students or for all kinds of communication. On the contrary, there are media which seem poorly suited for

some kinds of expression, and for some kinds of students. While a student with dyslexia may excel at story telling in conversation, he may falter drastically when telling that same story in writing. Alternative modalities for expression should be provided both to level the playing field among students, and to introduce all students to the full range of media that are important for communication and literacy in our multimedia culture. Additionally, students vary widely in their familiarity and fluency with the conventions of any one medium. Within media, therefore, alternative supports should be available to scaffold and guide students who are at different levels of their apprenticeships in learning to express themselves competently. Checkpoints suggesting specific strategies for providing options for expressive skills and fluency are listed as follows:

- options in the media for communication;
- options in the tools for composition and problem solving; and
- options in the scaffolds for practice and performance.

Guideline 6: Provide options for executive functions

At the highest level of the human capacity to act skillfully are the so-called executive functions. Associated with the prefrontal cortex in the brain, these capabilities allow humans to overcome impulsive, short-term reactions to their environment and instead to set long-term goals, plan effective strategies for reaching those goals, monitor their progress, and modify strategies as needed. Of critical importance to educators is the fact that executive functions have very limited capacity and are especially vulnerable to disability. This is true because executive capacity is sharply reduced when: (1) executive functioning capacity must be devoted to managing lower-level skills and responses which are not automatic or fluent (due to either disability or inexperience) and thus the capacity for higher-level functions is taken and (2) executive capacity itself is reduced due to some sort of higher-level disability or to lack of fluency with executive strategies. The UDL approach typically involves efforts to expand executive capacity in two ways: (1) by scaffolding lower-level skills so that they require less executive processing and (2) by scaffolding higher-level executive skills and strategies so that they are more effective and developed. Previous guidelines have addressed lower-level scaffolding, this guideline addresses ways to provide scaffolding for executive functions themselves. Checkpoints suggesting specific strategies for providing options for executive functions are listed as follows:

- options that guide effective goal-setting;
- options that support planning and strategy development;

- options that facilitate managing information and resources; and
- options that enhance capacity for monitoring progress.

Guidelines for Providing Multiple Means of Engagement

Guideline 7: Provide options for recruiting interest

Information that is not attended to, that does not engage students' cognition, is in fact inaccessible. It is inaccessible both in the moment – relevant information goes unnoticed and unprocessed – and in the future: relevant information is unlikely to be remembered. As a result, teachers devote considerable effort to recruiting student attention and engagement. However, students differ significantly in what attracts their attention and engages their interest. Even the same student will differ over time and circumstance: their interests change as they develop and gain new knowledge and skills, as their biological environments change, and as they differentiate into self-determined adolescents and adults. It is, therefore, important to have alternative ways to recruit student interest; ways that reflect the important inter- and intra-individual differences among those students. Checkpoints suggesting specific strategies for providing options for recruiting interest are listed as follows:

- options that increase individual choice and autonomy;
- options that enhance relevance, value, and authenticity; and
- options that reduce threats and distractions.

Guideline 8: Provide options for sustaining effort and persistence

Many kinds of learning, particularly the learning of skills and strategies, require sustained attention and effort. When motivated to do so, many students can regulate their attention and affect in order to sustain the effort and concentration that such learning will require. However, students differ considerably in their ability to self-regulate in this way. Their differences reflect disparities in their initial motivation, their capacity and skills for self-regulation, their susceptibility to contextual interference, and so forth. A key instructional goal is to build the individual skills in self-regulation and self-determination that will equalize such learning opportunities (see Guideline 9). In the meantime, however, the external environment must provide options that can equalize accessibility by supporting students who differ in initial motivation, self-regulation skills, etc. Checkpoints suggesting specific strategies for providing options for sustaining effort and persistence are listed as follows:

- options that heighten salience of goals and objectives;

- options that vary levels of challenge and support;
- options that foster collaboration and communication; and
- options that increase mastery-oriented feedback.

Guideline 9: Provide options for self-regulation

While it is important to design the extrinsic environment so that it can support motivation and engagement (see Guidelines 7 and 8), it is also important to develop students' intrinsic abilities to regulate their own emotions and motivations. The ability to self-regulate – to strategically modulate one's emotional reactions or states in order to be more effective at coping and engaging with the environment – is a critical aspect of human development. While many individuals develop self-regulatory skills on their own, either by trial and error or by observing successful adults, many others have significant difficulties in developing these skills. Unfortunately, most classrooms do not address these skills explicitly, leaving them as part of the implicit curriculum that is often inaccessible or invisible to many. Furthermore, those classrooms that address self-regulation explicitly generally assume a single model or method for doing so. As in other kinds of learning, considerable individual differences are much more likely than uniformity. A successful approach requires providing sufficient alternatives to support learners with very different aptitudes and prior experience in learning to effectively manage their own engagement and affect. Checkpoints suggesting specific strategies for providing options for self-regulation are listed as follows:

- options that guide personal goal-setting and expectations;
- options that scaffold coping skills and strategies; and
- options that develop self-assessment and reflection.

Part Three: Future Directions and Research

In the sections above, we have provided the basis for the general framework of UDL as well as a summary of the UDL Guidelines. To realize the benefits of UDL, however – to improve actual instruction – UDL must be actualized within a specific lesson or unit. While it will never be possible to evaluate the application of UDL to every lesson, in every content area, in every grade level, and for every type of student, it is important to provide evidence that such applications can be implemented effectively in real classrooms. This kind of research is only in its infancy, but exemplars are emerging.

In the field of literacy, for example, there is a growing body of research demonstrating the effectiveness of digital reading environments that are designed in a manner consistent with UDL. CAST's research in this area began with a study of struggling adolescent readers who were reading

digital texts with embedded supports and scaffolds based on the reciprocal teaching strategies of Palincsar and Brown. That study showed that students in the UDL reading environments outperformed peers in printed texts when they later took standardized comprehension tests. These experimental results have now been replicated or extended with other populations who typically struggle in literacy, including students who are deaf, students with cognitive disabilities, and English language learners. In light of these positive results, the US Department of Education has initiated a large-scale efficacy study with the commercial version of *Thinking Reader* (see below). Much more research of this type is needed.

Finally, it is important to recognize that one critical type of research is completely absent: research on full district-wide implementation of UDL. It is not enough merely to show that the core practices and instructional elements of UDL, or even a specific application of UDL, are evidence based. It is essential also to show that the UDL approach can be applied effectively, and at scale, in full district-wide implementations. This is challenging (and necessary) because adequate implementation of UDL will require more than adoption of new technologies or techniques; it will require comprehensive reform throughout a whole school system. As of today, there are no schools or districts where UDL is thus fully realized.

Is that kind of systemic implementation research likely to happen? Three directions are promising. First, there are a number of schools, districts, and even states that have begun to systematically implement UDL at various levels of comprehensiveness. There is, for example, a state-wide UDL initiative in Michigan where schools are incented to adopt UDL practices in their teaching, purchasing, and policies. Many individual districts or schools throughout the country, such as Cincinnati Public Schools in Ohio and Bartholomew Consolidated School Corporation in Indiana, are doing the same.

Second, publishers have recognized the market potential of instructional materials in UDL-type formats. Tom Snyder Productions of Scholastic has released nine award-winning middle school trade books (e.g., *The Giver*; *Bud, Not Buddy*) in this format, calling them *Thinking Readers*. In early 2009, Pearson produced its core history textbook in a completely digital format with many UDL features. Other publishers are preparing to follow suit.

Third, and most importantly, the US Department of Education recently endorsed a National Instructional Materials Accessibility Standard throughout the United States. This standard – called NIMAS – requires that print instructional materials (e.g., textbooks) must be available in digital formats so that they are more accessible to students of all kinds. This legislation is remarkably revolutionary – the first of its kind to recognize that printed instructional materials are no longer adequate to

serve the full population of students in our schools. The Higher Education Bill of 2008 confirms the importance of UDL in the future of education.

While UDL is still in the very early stages of development, it seems clear that there is considerable progress throughout the various sectors of public and private education. Turning that momentum into systemic evidence-based reform will take a great deal more work. There is much to gain in doing that work.

TECHNOLOGY AND LEARNING – SCHOOL LEADERSHIP FOR TECHNOLOGY INTEGRATION

Technology as a Support for School–Community Connections

K M Culp, Education Development Center, Inc., New York, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The wide range of activities and relationships covered by the terms home–school connections or school–community connections has been articulated elsewhere (Epstein, 2001; Ferguson *et al.*, 2008; Keyes and Gregg, 2001), and include building parental engagement with the educational process, enhancing educational opportunities for students' family members, and stimulating community investment in the school.

Schools need to establish multiple forms of communication and coordination of activities with families and the community in order to achieve these diverse and ambitious goals. They must find ways not only to communicate basic information, such as school calendars, emergency closings, and school policies, but also to coordinate supports and interventions with parents or guardians, to serve particular students in need of assistance. They must locate relevant expertise and resources within the community and build relationships with those individuals and institutions. Moreover, they must invite input and sustain conversation with parents and community members.

Timely and responsive communication is critical to meeting the challenge of creating strong connections between schools and students' homes, and the Internet has opened up new possibilities for organizing the relationship between schooling and the community. This article focuses on how electronic information and communication technologies (ICTs) have been used to help strengthen these connections. It focuses primarily on the period since 1993, when Internet access began to increase rapidly both in schools and in students' homes, and on how technology is supporting day-to-day community building around schools and the business of schooling. It places relatively less emphasis on the use of technology to support sustained learning experiences in the community beyond the school. A wide range of projects and research addresses this domain, and they are closely linked to a larger discussion of technology's role in supporting student learning (Blumenfeld *et al.*, 1991; Boss and Krauss, 2007; McKay and McGrath, 2006).

How Can ICTs Help?

Schools face a particularly challenging set of circumstances as they seek to communicate, coordinate, and partner with students' families and the local community. First and foremost, their relationship with their target audience is indirect; they have relatively few opportunities for direct contact with parents or community members, and must rely on students' backpacks or the local media to carry messages for them. Schools also often need to communicate over considerable geographic distances, and often in multiple languages.

Technology tools can help to address many of the obstacles to direct, engaged communication among educators, parents, and community members:

1. *Location and time.* Schools are often physically isolated buildings that offer limited opportunities for parents to enter and engage in face-to-face communication with educators. Many school schedules allow little to no time for regular communication or activities outside of instructional interactions between teachers and students. This makes engagement with parents, community members, or other community resources challenging to arrange or to sustain. Technology can support asynchronous communication, whether via voicemail or e-mail, and can help teachers make their students' work visible to others when and how they wish to, via websites, video, and digital pictures.
2. *Complex, multiple cultural differences.* As schools serve changing, diverse populations, the perspectives parents and community members bring to their engagement with the school will vary widely and will change over time. Technology allows educators to tailor their messages to individual parents and families, can support the translation of written documents, and can provide parents with access to richer resources that they can use to familiarize themselves with schools.
3. *Scale.* The scale of modern schooling often pits the general – school-wide messages or initiatives – against the specific – the need for detailed review and

discussion of individual students' needs. Technology can relieve this tension by allowing educators to reach large groups of parents quickly and easily via voice-mail, e-mail, or website announcements.

4. *Complexity.* Information about student achievement is increasingly complex, and schools face significant pressure to make that data meaningful to parents and community members. Using data management and visualization tools to support parental engagement with accountability and achievement data is a relatively new area of work, building on lessons teachers are learning as they develop their own capacity to work through and make sense of achievement test data.

Several features of ICTs would appear to be well suited to these challenges. First and foremost, ICT can remove the child as a point of transmission. E-mail messages, information posted to websites, or voicemail sent out from a central office can reach parents or the community at large without relying on the child acting as an intermediary. ICT supports both automation and customization of information, which can help educators carry out repetitive communication tasks more easily, while tailoring information to individual families or updating regularly changing information quickly and easily. Technology can also allow a broader pipeline of information and content to flow between the home and the school, particularly in schools involved in laptop computer initiatives or that use classroom websites extensively to support or document project work.

The Research Base

As Ferguson *et al.* (2008) discuss, the research base on the impact of home-school-community connections in general on student outcomes remains weak. While much descriptive work has been done, few studies have either used systematic analyses to identify the key features of promising practices or policies, or conducted rigorous research to test the connections between those programmatic features or structures and student outcomes. Even less research has looked specifically at the effective use of technology to facilitate home-school-community connections.

One meta-analysis, however, has specifically examined the literature on the use of technology to support school-community connections (Penuel *et al.*, 2002). Penuel and his colleagues report a similar state of affairs to Ferguson *et al.* (2008), explaining that there has been little substantial research done to investigate either the effectiveness of technology-based home-school supports, or the conditions of implementation that might support success, and very little that meets the necessary standards for meta-analysis. However, the authors were able to review a handful of program evaluations, and found consistent, if small, positive relationships. Note that this meta-analysis

includes projects that provided laptop or desktop computers for students to use at home, because these programs' goals included increasing parental involvement in students' schoolwork and building the technology skills of other family members. Specifically, the analysis found that these programs had, on average, a significant impact on parent-school communication. They also found that the programs had some impact on students' writing and mathematics achievement (Penuel, 2006: 41), but raised several caveats about the technical qualities of the studies under review.

Relatively little research on the impact of ICTs on home-school connections has been published since this review, suggesting that these findings are still the most rigorous ones available on the impact of technology-supported home-school connections on student learning or on levels of parental engagement in children's education.

A small body of descriptive research has also explored the implementation of projects intended to use technology to improve home-school connections (Nudell *et al.*, 2005; Poor Children Benefit, 1995). These projects do not demonstrate program impact in a systematic way. Rather, they focus on the differential impact of the socio-economic context of the use of ICTs, and how those contextual factors shape the nature of the home-school connection. These studies are an important reminder that the persistent cultural influences that shape home-school connections can be addressed but not eliminated through the introduction of ICTs intended to improve those connections.

Using Specific Technologies to Facilitate School-Community Communications

Between 1994 and 2005, The proportion of US classrooms with Internet access rose from 3% to 94% (Wells and Lewis, 2006). The ratio of students to Internet-enabled computers in classrooms also dropped during this period, reaching one computer per 3.8 students in 2005 (NCES, 2006). This period saw many research initiatives, grassroots efforts, and commercially developed projects using this new technology to support improved home-school and school-community connections.

This article briefly reviews a number of ways that schools and districts are using technology to support home-school-community connections. It groups those approaches into two main categories: practices that facilitate communication between schools and their communities, and practices designed to support the reorganization and restructuring of schooling.

E-Mail

The rapid growth in the use of e-mail during this period has raised both opportunities and challenges for teachers

and administrators who sought to improve their communications with parents and community members. As home access to the Internet has grown, schools and districts have been able to share information quickly and with a broad audience. School districts now frequently use e-mail blasts to share time-sensitive information such as announcements of emergency closings, or to solicit community support for initiatives such as upcoming budget votes or fundraising activities.

Like doctors, classroom teachers have been slow to fully embrace e-mail as a primary means of communication (Fishman, 2007). Teachers spend their working time almost entirely engaged in face-to-face work with either students or their colleagues. Their work lives have not typically been organized to accommodate daily communication with any larger audience, such as parents or community members.

Parents, in particular, could benefit from and may be eager for more frequent and detailed communication with teachers about their children's activities and progress in school. However, teacher–parent communications have typically been primarily one way (through flyers, notes, and newsletters to parents). Infrequent opportunities for interaction, such as open houses or parent/teacher conferences, are often time constrained, and more frequent communication often depends on parental initiative and scheduling conversations before or after school hours. Of course, there are many exceptions to this pattern, particularly among dedicated teachers and the parents of children facing significant difficulties in school. But on average, substantive exchanges between the teachers and parents of individual children in public schools are few and far between.

E-mail and other forms of electronic communication would appear to open up significant new opportunities for teachers and parents to align their efforts to support individual children's progress through school. However, using e-mail makes teachers more accessible to parents and community members, and an increase in the frequency of communication without any associated increase in the time available for this work. As a group, teachers have been hesitant to embrace new expectations for e-mail use, mostly likely due concerns that their already-overextended time commitments will be further strained, or that parents will expect an unrealistic level of day-to-day input about their children's experiences.

The 2007–2008 administration of the *National Center for Education Statistics* (NCES) Schools and Staffing Survey, a nationally representative survey conducted by the US Department of Education's National Center for Education Statistics, will be asking for the first time about teachers' use of e-mail to communicate with parents, and these findings will provide an important new benchmark for understanding how prevalent this form of communication really is.

While teachers have been slow to integrate regular e-mail communication into their work, the communities surrounding them have found ways to use e-mail to increase community focus on and awareness of school activities. Homegrown e-mail listservs and message boards have been common for years, bringing interested parents in contact with one another to support the dissemination of both formal and informal information and opinions about local schools. Similarly, local membership groups such as parent–teacher organizations, booster clubs, and parents supporting athletic programs all use e-mail lists commonly now to share information. While increased communication and coordination in groups like these may seem unremarkable at this point in the development of consumer communication technologies, a byproduct of these activities is likely an increased self-identification among participants as members of some coherent, meaningful grouping. This kind of secondary impact among active members of online communities is well documented for other kinds of interest groups (Goodsell and Williamson, 2008; Drentea and Moren-Cross, 2005), and is likely to be just as true for the communities of parents and other supporters surrounding specific schools or school districts.

Websites

When web browsers first began to appear in the mid-1990s (Netscape was first released to the public in 1994), teachers who had already been interested in using technology to support instruction quickly identified websites as an important new tool for sharing classroom activities with parents. A small but enthusiastic subset of teachers learned hypertext markup language (HTML), and classroom websites displaying student book reports, drawings, and science projects multiplied rapidly. Teachers hoped that by making student work more broadly visible, they would give their students the experience of sharing their work with a broader audience, and would provide parents with a richer window into the work their students were doing in the classroom.

Schools and districts with motivated technology coordinators also started creating websites, publishing curriculum standards, school calendars, and monthly lunch menus, putting their library catalogs online, and sharing pictures of school events. The Web provided a powerful new opportunity for schools and districts to represent themselves and to share detailed information with their community. A well-designed website allowed a school district to knit together information from the different administrative layers and physical sites that constitute the district to represent a cohesive, interconnected whole – something that previously was only accessible as a tacit body of knowledge shared by those already deeply engaged with the district. A family new to a school district, for example, might gain both concrete information and a

powerful set of messages about the tone, goals, strengths, and focus of a school district by visiting the district website. Such sites also opened schools up to new connections with other districts, schools, and individual classrooms around the country and the world.

By the late 1990s, commercial software publishers had moved into the school and district website business, and they continue to provide schools and districts with packages that can be customized to support a range of web-based activities, including supporting parental engagement in students' learning and in school activities. These tools tend to focus on information delivery, providing schools with tools to help them provide parents with a view of their students' progress, grades or attendance, or information about school or community activities, but rarely support broadly interactive or highly personalized forms of communication or interaction.

Summary

Schools and districts are slowly but steadily integrating ICTs into traditional forms of communication and information sharing between schools and their communities. However, much of the ongoing work of forging these connections continues to involve little use of technology. This may reflect a persistent focus among advocates and educators on face-to-face communication, and bringing community members together for special events and sustained learning opportunities. An implicit goal in this work is maintaining the brick-and-mortar school as a pivotal physical location in the community – a point of interaction, exchange, and mutual support. This leaves ICTs as important but tangential tools, improving communication among stakeholders but not playing a central role in shaping the work that they do together.

Using ICTs to Facilitate a Reorganization of the School–Community Relationship

Some educators, researchers, and software and infrastructure companies are using technologies to develop other approaches to schooling. These approaches involve a much broader reframing of relationships among students, their families and communities, and the experience of schooling. In various ways, they challenge the assumption that the brick-and-mortar school is at the center of the educational equation, and increasingly frame the individual student and his or her family as a consumer, placing their needs and priorities at the center and repositioning the school as a provider of services.

One-to-One Computing

Since the early 1990s there has been a gradual increase in initiatives to provide every student with a laptop

computer. These efforts have ranged in scope from individual grade levels in a single school to entire states. For an overview of the evolution of these initiatives, see Keefe and Zucker (2003). For a detailed review of the research base on one-to-one computing, see Penuel (2006). Rationales for providing students with laptop computers, and specific goals for such programs, have varied widely. Typically, these programs not only focus on the opportunity to make technology use ubiquitous in the school, but also share goals that involve strengthening home–school connections by ensuring that all students have computer access at home, and that technology access is seamless between the home and school. Perhaps the best-known statewide initiative has been the Maine Learning Technology Initiative, which provided all seventh- and eighth-grade students in the state, and their teachers, with laptop computers. Silvernail and Gritter (2007) provide an overview of the program, and discuss evaluation findings that demonstrate an association between use of the laptop computers and improvement in students' writing skills.

An earlier example was the Buddy Project, which provided students with desktop computers at home, was active in Indiana between 1988 and 2000, and placed a particularly strong emphasis on home–school connections. Policymakers who supported the program hoped that providing laptops to students would reengage parents in their students' learning, and encourage the growth of family members' technology skills Lemke and Martin (2004). (The Buddy Project continues in a somewhat different form, with an increased focus on writing skills. See Lemke and Martin (2004) for a detailed discussion of the project.)

One-to-one computing initiatives are also gaining visibility worldwide, as the One Laptop Per Child (OLPC) project initiative and Intel's marketing of the low-cost ClassMatePC bring one-to-one computing to diverse communities in many countries. Research, following implementation of the OLPC project or Intel's laptop computers, may provide a pathway for looking more broadly at what roles portable computers can play when schools and communities are defined very differently than they are in the United States. In a recent example, Urrea's (2008) dissertation looked closely at one-to-one computer use (using the OLPC computers) in a small, rural Costa Rican classroom, and grounded her interpretation in the relevance of the program to strengthening connections between the one-teacher school and the surrounding community.

Sharing Accountability Data

Perhaps the largest shift of all in US K-12 education during the 1990s has been the investments made in large-scale testing to meet the accountability expectations of the

Elementary and Secondary Education Act of 2001, better known as No Child Left Behind (US Department of Education, 2002). In response to a range of expectations – from parents who want evidence of school effectiveness to local business owners anxious to use test scores as an indicator of the quality of local schools and hence of the health of the local community – schools have been seeking ways to make testing data accessible and meaningful to their communities. Given the complex and often time-sensitive nature of testing data, educators have looked to technology solutions to help them summarize, share, and explain multiple kinds of accountability data both internally and with community members.

Tools now being used for these purposes range from homegrown PowerPoint presentations to complex data management systems developed by large testing companies (see, e.g., Pearson Benchmark). Some of these systems include components for sharing grades, attendance data, and other information about individual students with their parents (see, e.g., the Skyward system). Other external vendors have also stepped in to address parents' and community members' interest in performance data from their schools. Organizations, including SchoolMatters and GreatSchools, are building front ends to testing databases and inviting parents and community members to review evidence about schools' performance and often to add their own reviews describing their perceptions of their children's schools. Just for the Kids, a site supported by the National Center for Educational Achievement, takes a more complex approach, not only allowing interested individuals to investigate a particular school's performance, but also providing comparisons to other, similar schools in the state. None of these systems, however, is specifically investing in helping parents to explore and understand their own child's testing data or to put their child's achievement in the context of larger patterns of performance within a school or district.

While these sites are likely to be valuable to parents, they also mark a significant movement away from a key assumption of the home–school–community connection literature – that the school is a community created in large part by the voluntary contributions and efforts of the parents whose children attend it. Instead, these services speak to parents as consumers – individuals seeking out, selecting and purchasing those services they choose to receive. This is markedly different from the traditional goal of treating parents as potential participants in the educational process. Like many other services and products being developed and delivered on the Web, these sites invite parents to seek out particular services that meet their perceived needs and characteristics, which is at odds with the traditional role of the school as a point of common ground where families and educators interact and influence one another over time.

Distance Learning and Virtual Schools

Since the 1960s, schools have used various technologies to provide their students with access to courses they would not otherwise have the opportunity to take (Reiser, 1987). The technologies used to support distance learning have evolved from closed-circuit television systems to video-conferencing to web-based streaming video or text- and audio-driven systems such as Elluminate. A history of the evolution of these technologies is available in Reiser (1987), and a summary of the research base on the effectiveness of distance learning is available in Allen *et al.* (2006). A summary on the effectiveness of web-based learning is available in Means *et al.* (2009).

In the mid-1990s, as schools built their access to the Internet, educators naturally were eager to use this new resource to supplement their traditional course offerings. In the following years, schools and universities, as well as an increasing number of for-profit vendors, have begun to offer districts access to individual courses and soon comprehensive curricula. However, policymakers also began to consider not only how the Internet might support communication between students, teachers, and parents, but also could make possible entirely new approaches to defining where and how students could learn. By 2000, an influential report from the Web-Based Education Commission squarely focused its description of the power of the Internet for learning on the opportunity to address learners as individuals, moving away from the classroom or even the school as an organizing unit and appealing to the notion of anytime, anywhere learning (Web-Based Education Commission, 2000).

As high-speed networks became almost ubiquitous in the early 2000s, web-based schooling began to be a viable, and potentially profitable option. Schools and districts use many different mechanisms for developing or acquiring and delivering online courses, ranging from using entirely locally created efforts to partnering with local universities to purchasing services from large corporations. For-profit vendors, such as The Connections Academy, Edison School Inc., and Insight Schools, play a significant role in delivering online learning opportunities. These vendors provide districts with a comprehensive school program, delivered entirely or almost entirely online, and attended by students who work entirely outside of the traditional school building. The emergence of this industry has also dovetailed with state and federal support for charter schools, a policy mechanism that makes it possible for school districts to buy into for-profit online schools. In the USA, the National Education Technology Plan of 2004 strongly argued in favor of the further development of this model, presenting it as one of the seven top priorities for education technology spending (US Department of Education, 2004: 41). For a more detailed review of the current state of online learning opportunities, see Tucker (2007).

Considering these types of schools from the traditional framework of home–school connections raises challenges. They can be seen as strengthening the connection of individual students to their communities, as they offer an in-between strategy such that a student who might otherwise be home-schooled can still be served through the public education system. Students with significant health challenges can also continue to receive a public education when they are unable to attend school physically. However, on the other hand, when students work entirely from distant locations, traditional notions of the school as a distinct grouping of students that not only intersects with students' home communities but also develops and sustains its own structures and culture, largely fades away.

Summary

Each of the three kinds of efforts described above (one-to-one computing, virtual schools, and school comparison sites) reflects two changes that have occurred well outside of individual schools or districts. First, technology has continued to evolve rapidly, and consumer electronics have continued to drop in price. While homes and schools are mostly on par with one another in terms of basic computer-based Internet access, schools have not kept pace with domestic investments in cell phones and other portable, Internet-enabled devices (Shuler, 2009). As youth and many of their parents move toward an online-all-the-time way of living, enabled by social networking sites, smart phones, and laptop computers, schools have moved far more slowly to adapt to and accommodate these new tools. Consequently, new cultures of communication, consumerism, cultural participation, and community building have emerged and are fostering enormous amounts of youth participation, but have made few inroads into traditional schools.

At the same time, technology and media industries and the federal government have largely moved their investments away from school-based instructional technologies and toward using new technologies to support other organized learning opportunities that appeal directly to parents and bypass the brick-and-mortar school. For example, institutions such as the Discovery Channel and the Public Broadcasting Service (PBS) have invested heavily in developing online educational media that will appeal to children, and providing supports to parents to help them make effective use of the resources. The German publisher Bertelsmann is developing a product called Scoyo that will offer extensive content-rich online educational resources and will be marketed directly to parents and their children for home use. These same organizations do invest in teachers through other efforts, such as PBS' TeacherLine professional development program. However, these initiatives are distinct from one another

and few connections are made that might encourage teachers to make links between their own training and the experiences that their students might be having at home using similar resources.

These evolutionary forces are also reflected in the emergence of School 2.0, a phrase that describes a loose movement of school technologists, researchers, and policymakers who are re-imagining how schooling might function if educators were able to embrace current Web 2.0 notions like personal broadcasting, two-way communication, group construction of knowledge, and intensive social networking. For examples of current discussions of School 2.0, see SRI's School 2.0 eToolkit, the for-profit Eduvo.com and The wiki site school20.wikispaces.com. These conversations echo early discussions about the potentially transformative power of microcomputers in the 1980s (see the archives of the Apple Classroom of Tomorrow project, or an overview of past proceedings of the National Education Computing Conference, both available online). Like those earlier conversations, School 2.0 discussions make connections between the flexibility and transparency provided by Web 2.0 tools and a shared desire to create schools in which student learning is more learner directed, open ended, and happening largely outside of the school walls. While some functioning schools are explicitly focused on School 2.0 concepts (Lehmann, 2007), many educators have little opportunity to institutionalize such core School 2.0 concepts as open campuses, flexible curricula, and ubiquitous access to portable technology. To date, discussions of School 2.0 have not yet really focused on parental engagement or home experiences, even though the visions of schooling they promote would have significant consequences for parents' relationships to the educational process.

Conclusion

Traditional schools are still adapting to the technological innovations of the 1990s. For educators seeking to expand and improve communication between schools and their communities, many aspects of new communication tools are appealing, and will allow them to be more responsive, detailed and timely in their communications than ever before. However, other potential uses of technology to sustain and deepen these relationships remain largely untapped, in part because the tools they would involve are still challenging and new for many schools.

The Penuel *et al.* (2005) review of the literature on technology and school–community connections provides limited but positive evidence that technology can help improve relationships across school boundaries that can make a difference in student's achievement, parents' level of involvement, and student engagement in schools. While

little research is currently underway in this domain, it seems important to look more closely at how schools that are ahead of the curve in adopting more innovative technologies (such as handheld devices or social networking sites) may be using those resources to connect with students' lives outside of the school building, as well as with families and community members. Similarly, advocacy and research organizations in the fields of parental involvement and school–community partnerships need to be encouraged to consider how technology can be used to extend and enhance their work, and to include it as a factor to be examined in their research efforts.

Penuel's findings also suggest some areas for a new line of research focused on the principles of 'School 2.0.' What kinds of information, we need to ask, do parents most need access to when their students are participating in this kind of school experience? When the boundaries of brick and mortar or the 3:45 afternoon bell are no longer in place, what still needs to be shared among educators and parents to support students effectively? At a time when students' facility with technology is being praised and examined extensively, it may also be important to continue to examine how students' and parents' access to technology can best be leveraged to ensure that parents can be full partners in their children's education.

TECHNOLOGY AND LEARNING – SUPPORTS FOR MANAGING INSTRUCTION

Classroom Uses of Technology to Manage Instruction

W R Penuel, Center for Technology in Learning, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Instructional-management systems –

Technologies that support teachers to develop lesson plans, track student progress on assessments, and record students' instructional experiences.

Student-information systems – Systems that enable tracking and reporting of student attendance, grades, course enrolment, test scores, and other data. Access to data from student information systems varies, depending on the data source. Teachers and parents often have access to some but not all data in the system.

Student-response systems – Technologies that rely on handheld devices for student input to answer questions posed by teachers. The systems also allow teachers to display student responses in the aggregate with a projection device, to facilitate awareness of the class distribution of responses.

Introduction

Managing instruction encompasses the range of ways in which educators plan, coordinate, and evaluate how students interact with curricular materials, the teacher, and each other. As students' interactions can never be fully determined ahead of time and are – even within the same classroom – quite varied depending on students' interests and abilities, managing instruction requires continuous monitoring and adjustment. For this reason, management of instruction requires strategies and can be enhanced with tools that support ongoing cycles of planning, enacting, and evaluating instruction.

Within education, instructional management takes place at different levels and different timescales. Policy-makers at the state level manage instruction typically by setting standards and monitoring progress through annual accountability testing. Districts and schools provide teachers with textbooks and curricula for use in planning and

coordinating instruction, and most invest in teacher professional development to support use of these instructional materials. To evaluate instruction, districts and schools typically rely on annual assessment data in the aggregate, but increasingly they also examine disaggregated data for individuals and groups and use benchmark tests administered at multiple points during the year to gauge students' progress while there is still time to take corrective action. For their part, teachers manage instruction by adapting materials and activities they have been given by their school or district, implementing mandated testing systems, and engaging in a range of formal and informal classroom-assessment activities.

Technology exists to support individual teachers in managing instruction for students over both the long and short term. Student-information systems (SIS) support long-term management of instruction; they are technologies that support sharing and reporting of basic data on schedules, test results, and background information on students among teachers, administrators, and parents in a school. Over the medium term, instructional-management systems (IMS) can support teachers in developing lesson plans, tracking student progress on assessments, and recording students' instructional experiences over the course of the school year (Archibald, 2001). Another class of technologies supports teachers in coordinating and evaluating instruction as it takes place, allowing teachers to adjust instruction on the basis of up-to-date information about what students know and can do.

This article focuses on two classes of technologies that have been developed to help coordinate students, the teacher, and the curricular content as teachers manage instruction in their classrooms. These two classes are distinct from SIS in that the primary users of the system are students and teachers, rather than administrators and parents. They are distinct from IMS in that they enable different forms of teaching and interaction with content, and they are intended to provide teachers and students alike with real-time data on the effectiveness of instruction. The article provides a review of the features of these classes of technology and the research evidence related to their effects on teaching and learning. The concluding

section focuses on future directions of technology development and research on these classes of technology designed to help teachers manage instruction.

Student-Response Systems

Student-response systems are a relatively mature class of technologies in use for more than 20 years in elementary, secondary, and higher education. These technologies enable teachers to collect and display student responses to teacher questions and to use this information to evaluate student understanding and the effectiveness of their instruction. Indirectly, the technology also supports teachers in their role as managers of instruction by facilitating more active forms of student participation in class, especially in the midst of whole-class instruction.

Features of Student-Response Systems

The core features and required set ups for student-response systems are relatively few. Student-response systems are comprised of a single teacher computer, a projection system for the teacher, a handheld response device for each student, and software that uses infrared frequencies to transmit information from the student devices to the teacher laptop. In some systems, the handhelds are wirelessly connected to a classroom network or the Internet so that the teacher and student devices can be linked without cumbersome cables.

A primary function of the software on the teacher's computer is to input teacher questions. Most systems support primarily selected-response (multiple-choice) types of questions, but a few now support open-ended or textual responses. Teachers can enter a question ahead of time and display it for students, and they can also pose questions without having to enter them as text into the software. For purposes of planning instruction, teachers can consult banks of questions that instructors at the postsecondary level have found useful for testing students' conceptual understanding or for sparking discussion (see, Mazur, 1997, for examples in physics).

Classroom-communication-system software also tracks student responses as they come in and, with the aid of a projection device, displays the student responses for all to see. The tracking includes a real-time display of whether each handheld device has responded to a particular question. A teacher can register each handheld to a particular user and record those users' responses to questions in an electronic grade book that persists beyond an individual classroom session. When ready, the teacher can display the student responses, and a key feature here is that the default mode of display is to show the percentage or number of students who have given a particular response without associating individual responses with a student's name. The result is that the display is an anonymous display of

results, but each student can judge how many other students gave the same answer that they did. In addition, the display does not necessarily show the right answer, so the teacher can stop and re-teach or ask students to explain their answers before she or he decides to identify the correct answer and give an explanation.

It is possible to support the basic functions of student-response systems without technology, by giving students placards with answer choices that only their teachers can see (Judson and Sawada, 2002; Randolph, 2007). But there are some advantages of student-response systems over placards. For example, the response systems allow teachers to keep records of student responses for later review with little added effort required of the teacher. In addition, response-system technology allows the cycle of question and answer to take place in a very short period of time. It provides students and teachers with more rapid feedback on progress without slowing down the pace of teaching (Roschelle *et al.*, 2004).

Teaching with Student-Response Systems

Instructors have put forth models for how best to teach with student-response systems, and researchers have studied teaching practices that help teachers effectively manage instruction.

Models for teaching with student-response systems

There have been at least two models developed for promoting interactive discussion in conjunction with response-system technologies, peer instruction (Mazur, 1997) and the assessing-to-learn model (Dufresne and Gerace, 2004). Both models include time for discussion, but they emphasize to different degrees the role of individual contributions, peer discussion, and class-wide discussion.

Peer instruction is a model for teaching with student-response systems that Eric Mazur at Harvard University developed for use in his introductory physics class. In peer instruction, lecture periods are broken into a series of 10–15-min periods, and each period focuses on a particular concept. At the end of each period, the instructor asks students to answer three or so questions that require the students to demonstrate their qualitative understanding of the concepts. Students have 1 minute to think and then record their answers using the system, as well as to record their level of confidence in their answers. After recording their answers, students turn to a peer to discuss and explain the reasoning behind their answer. Then, after 1 or 2 more minutes, the instructor asks students to record a revised answer and to judge their confidence in their new answer. If the teacher is satisfied that the students have grasped the concept (based on the percentage of correct answers the

second time around coupled with high levels of confidence), then she or he can move on. If not, the instructor can repeat the cycle with a new question on the same subject.

In assessing to learn, as with peer instruction, teaching with student-response systems is organized around specific items. The items in assessing to learn are intended to help teachers diagnose student difficulties, and the answer choices include both correct answers and common misconceptions. The assessing-to-learn model emphasizes whole-group discussion rather than peer discussion. After the system tabulates responses, the teacher displays the distribution to the class as a whole, in order to ensure that all students know how others in the class have responded. Then, the teacher asks a volunteer to explain his or her answer until each different answer choice has been represented. Class discussion ensues, in which the teacher facilitates discussion so as to elicit students' thinking on the topic before offering a correct answer and explanation for the question.

Research on teaching with student-response systems

Much of the research on teaching with student-response systems confirms the importance of presenting good conceptual questions to students, as encouraged in peer instruction and assessing to learn. To stimulate discussion, for example, researchers have suggested that questions that yield divergent student responses are more effective than those that are easy or that lead all students to a single incorrect answer (Wit, 2003). For teachers using response systems to assess student learning, it appears that questions that elicit students' preconceptions and that help teachers adapt their teaching to the needs of students are most effective (Draper and Brown, 2004; Wit, 2003). The timing of questions further shapes the nature of the information that an instructor gains about student understanding. Questions posed after a lecture or explanation can be used to check understanding (Dufresne *et al.*, 1996a). By contrast, posing questions before a lecture tends to elicit preconceptions in ways that can be used to shape instruction (Dufresne *et al.*, 1996a). Structuring opportunities for peer or whole-class discussion also appears to be a critical aspect of promoting greater classroom interaction with response systems (Dufresne and Gerace, 1994; Judson and Sawada, 2002). Researchers have observed that discussion prompts students to engage in alternative ways of thinking about a concept or problem (Dufresne *et al.*, 1996a) and aids in developing deeper student understanding of the meaning of concepts (Judson and Sawada, 2002). Explaining one's reasoning to a peer has the potential to transform students' misconceptions (Judson and Sawada, 2002). Response systems facilitate discussion by providing an anchor (aggregate responses on a shared display) and set of artifacts to which students can refer in the process of building knowledge (Truong *et al.*, 2002).

Researchers acknowledge that difficulties are often encountered when response systems are introduced to classes. Many teachers find it difficult to adjust their teaching style to incorporate interactive engagement into their lectures (Dufresne *et al.*, 1996a). Further, not all subject matters lend themselves well to the kinds of factual and conceptual questions that response systems are designed to accommodate. Research with response systems has focused primarily on the domains of physics, engineering, and computer science, domains in which the ability to learn target or correct answers to conceptual questions is critical (Draper and Brown, 2004). In other disciplines, teachers have found it useful to use student-response systems to pose different kinds of questions to students, about topics such as their perceived interest or boredom in class or their perspectives on some social or historical issue (Anderson *et al.*, 2003; DiGiano *et al.*, 2003; Piazza, 2002; Sung *et al.*, 2004).

One of the key limitations of this class of technologies is the limited support for posing open-ended questions. Scholars who have developed newer technology systems have tended to criticize student-response systems as limited by their emphasis on social comparisons in data – that is, comparisons of how many students got a particular answer correct – rather than on the subject matter itself (Penuel *et al.*, 2004). Some companies marketing student-response systems have developed capabilities for different kinds of student input, in order to address the need for greater variety in question types (Robinson, 2002).

Effects of Student Response Systems

Some of the best empirical evidence concerning the effectiveness of the classroom networks in improving student-learning comes from university-level physics instruction. A number of studies have found that there is an association between students' understanding of introductory physics concepts and use of peer instruction (Fagen *et al.*, 2002; Mazur, 1997). When teachers use interactive engagement methods similar to peer-instruction methods, students in these teachers' classes make higher gains on both the force-concept inventory and the Halloun-Hestenes mechanics diagnostic test than students in comparison classrooms (Hake, 1998; Sokoloff and Thornton, 1997). In neither of these sets of studies, however, is the specific contribution of technology to students' conceptual gains explored. A study of students in engineering classes has similar results and limitations: students made conceptual gains, but the specific contribution of technology cannot be inferred due to limitations in the experimental design (Roselli and Brophy, 2002).

Several studies have also reported that the use of classroom networks helped improve student engagement and participation in class (Boyle and Nicol, 2002; Burnstein and

Lederman 2001; Crouch and Mazur, 2001; Cue, 1998; Dufresne *et al.*, 1996a; Fagen *et al.*, 2002; Kaput and Hegedus, 2002; Poulis *et al.*, 1998; Truong *et al.*, 2002; Webking, 1998; Woods and Chiu, 2003). In some studies, higher attendance has also been reported as an indicator of increased student interest and enjoyment of the class (Duncan, 2005; Ganger and Jackson, 2003; Wit, 2003). The explanation of these findings may come from a changed perception among students that it is important that they participate actively in the class. For example, students often report that seeing their own response in a group display makes them feel more accountable (Davis, 2003; Draper and Brown, 2004). The fact that all students pick an answer – even when they are uncertain about it – that then becomes part of an aggregated display stimulates students to think about the teachers' questions (Dufresne *et al.*, 1996a; Nicol and Boyle, 2003).

The assessment functions of classroom networks appear to enhance both teachers' and students' awareness of the students' level of understanding of the subject matter being taught. Researchers report that classroom networks help students assess their own understanding (Draper and Brown, 2004; Piazza, 2002). At the same time, the systems help teachers identify areas where individual students may need additional instruction or where the entire class may benefit from more and different encounters with the subject matter (Draper and Brown, 2004). In these accounts, researchers again point to the role of the shared display as critical. The display helps students know where they are in relationship to others (Dufresne *et al.*, 1996b). If they see that others are having difficulty, they may have the confidence to ask for help or for clarification when they do not understand something (Anderson *et al.*, 2003; Dufresne *et al.*, 1996a).

Classroom-Network Technologies

Newer technologies – often called classroom-network technology – provide an expanded set of capabilities for supporting classroom interactions. These newer systems provide expanded options for linking students together with the teacher to support group interaction as well as the generation of data on student thinking. Classroom-network technologies have in common with student-response systems a shared display of student responses, around which students and teachers can focus attention and activity (Penuel *et al.*, 2004). As with student-response systems, classroom-network technologies provide students and teachers with a representation of student thinking, which both provides feedback on student understanding in class and anchors discussion. This newer class of technologies, however, is distinct from student-response systems in its features and in the ways in which teachers and students interact with

technology. As the technology is more recent, however, there is less research on its effectiveness.

Key Features of Classroom Network Technologies

What distinguishes more sophisticated classroom-network technologies from student-response systems are the inputs supported and the ability to allow specific instructional content to structure the activity. Student-response systems largely limit teachers to posing multiple-choice or other closed-ended questions of students in classrooms. Newer classroom-network technology enables students to input a variety of answers to teacher tasks, including open text and graphical images. In addition, this classroom-network technology also supports the teaching of specific concepts by allowing students to identify themselves as, for example, mathematical objects in a Cartesian plane (Kaput and Hegedus, 2002). In this and other examples, technology is not content independent, as with student-response systems; rather, the technology helps structure students' interaction with content in ways that help make difficult concepts visible and more concrete to students.

The components of classroom-network technology include software for teachers and students to use, a teacher computer, student devices, and a projection device. The software capabilities differ, depending upon the subject matter. For example, in a mathematics classroom where students are studying linear functions, the software supports students being able to project a point of their own choosing particular x, y coordinates onto a Cartesian graph displayed using a graphing calculator. By contrast, in a science classroom, students studying how the coordination of traffic lights influences congestion on city streets might use that same calculator to control a particular traffic light. The display runs a simulation showing the effects of their action, and students can change their own timing of their traffic light to examine its impact on congestion (Wilensky and Stroup, 2000).

The above two examples illustrate the potential of a commonly used student-input device within contemporary classroom-networks: graphing calculators. Such calculators allow students not only to carry out computations of complex mathematics but also to input text. Thus, the calculators have all the functionality of student-response systems, plus they are devices that can be used to teach specific algebraic and geometric concepts.

Classroom-network applications of the kind now being developed have uses that cannot be replicated easily without the use of technology. No analog to individual students projecting themselves as points on a graph that displays the aggregate results of points on a single line exists that can be quickly implemented in a classroom. Similarly, there is no easy way without technology for students to develop and test simulations of traffic in order

to understand how local interactions (traffic lights turning red or green) can lead to complex aggregate patterns of behavior such as traffic. As such, new classroom-network technology offers a potentially transformative approach to managing instruction, especially in mathematics and science classrooms where they have been most widely used to date.

Teaching with Classroom Networks

Teaching with classroom-networks provides for distinctive roles for students that teachers must be prepared to support if they are to expect students to benefit from interacting with curriculum content using networks. In particular, advanced network technologies foster active participation in class by positioning students as agents in class-wide activity. In participatory simulations, for example, students do not manipulate a system or process from outside but from within it (Colella, 2000). In these simulations, each person's agreement to participate in a collaborative, class-wide effort at experimentation is critical to enable the class to construct a model of the system being simulated (Wilensky and Stroup, 1999). The system structure and students' roles in it thus exert a pressure to participate which can be amplified by social processes in which students attempt to coordinate each others' activities (Andrews *et al.*, 2003).

The specific subject matter plays a much more central role in enabling and constraining certain kinds of classroom activity with advanced network technology. The classroom display, rather than representing a distribution of students' answers to a question, might represent a Cartesian plane. Each student can manipulate his or her point in this plane with a handheld device such as a graphing calculator (Kaput and Hegedus, 2002). Researchers argue that the fact that the shared display represents a mathematical space is critical because it provides a way for students to develop an embodied, personalized viewpoint on mathematical concepts (Hegedus and Kaput, 2004). Moreover, as more work is represented publicly, researchers argue that learning can increasingly occur in the social space to complement the individual device-interaction space (Ganger and Jackson, 2003).

Within the subject-matter space, students do not have to be guided only toward correct answers. Advanced networks can support a pedagogy that emphasizes the role of generative, space-creating play in fostering learning (Stroup *et al.*, 2002). For the play to be effective, it cannot be not an unstructured exploration of the subject matter, but it must be bound by rules that designers have implemented or that the students themselves have agreed to in class (Stroup *et al.*, 2002). Especially when students are allowed to construct the rules for play, they are able to test different conjectures and hypotheses and potentially come to a deeper understanding of concepts (Wilensky and Stroup, 2000).

Effects of Classroom Networks

To date, little research has been conducted on the effects of classroom networks. However, there is some preliminary evidence that participatory simulations that rely on network technology can be effective in promoting student learning (Hegedus, 2003; Lonsdale *et al.*, 2004; Wilensky and Stroup, 2000). For example, one study examined what students learned when they engaged in a participatory simulation focused on developing an understanding of how climate change might affect the water cycle. Students used mobile phones and a floor display that showed a map of the water cycle. This study found that students in the participatory simulation learned more about the underlying rules of the system than did students who participated in a control condition in which students participated in a workshop on the water cycle (Lonsdale *et al.*, 2004).

Future Directions for Research and Development

Both student-response systems and new classroom-network technology represent attempts to provide teachers with tools to manage and fine-tune their instruction as it is unfolding in the classrooms. Although these systems are less common than conventional IMS (which teachers use for planning in advance of starting the next unit of instruction) student-response systems and classroom networks represent an important line of research and development. This line of research and development foregrounds the teacher as a thinker and decision maker tasked with solving complex problems on the spot. As our understanding of teachers as instructional decision makers and managers deepens, the knowledge of technology requirements for supporting teachers in this role is likely to increase.

One area of possible future development would extend the current capabilities of both student-response systems and classroom networks. In particular, both might be integrated into classroom management and SIS. Such an integration would provide a richer picture of student achievement and documentation of students' instructional experiences to stakeholders in the educational system. Other possible extensions include the use of handheld technology to support pairing and grouping of individuals who are most likely to be able to learn from one another or to succeed in a particular task. The assignment could be based on data available through the system on general abilities, or it could be based upon data particular to the subject at hand. Finally, more research and development into the kinds of displays and feedback that are readily interpretable by teachers as they work and also after class can extend the utility of systems for evaluating instruction and planning for future lessons.

It is important that research aimed at evaluating the effects of currently available technologies is implemented

in parallel with new technologies. Already, researchers at the Physics Education Research Group at the University of Massachusetts are engaged in a study of the effectiveness of the assess-to-learn model. Their research will examine the effectiveness of teacher professional-development activities designed to prepare instructors to use the approach in their classrooms. In addition, researchers at the Ohio State University are currently engaged in a large-scale randomized control trial to study the impact of using graphing calculators in networked classrooms to teach middle-school mathematics. Many more such studies are needed to examine the professional-development requirements, critical-instructional practices, and outcomes of technologies for managing instruction.

Glossary

Animation – Visual, usually computer-based display of an object or a more abstract scenario either in the form of a dynamic realistic picture or a dynamic logical picture (graph), which changes its structure during the course of time. Animations can be used to display change, but also to focus the observer's attention to specific details of an object or scenario.

Cognitive flexibility hypothesis – The assumption that criss-crossing through a complex network-like hyper-medium will result in a complex mental network in the mind of the learner that allows higher cognitive flexibility.

Coherence principle – Assumption that the multimedia principle, the contiguity principles and the modality principle apply only if the text and picture information can be integrated into a coherent whole.

Comment information – Information within a sentence or paragraph that conveys information about the topic of the sentence or paragraph.

Comprehensibility approach – A pragmatic approach to text designs, which assumes that four factors are important to enhance text comprehension: Linguistic simplicity, structure and organization, conciseness, and affective or motivational stimuli.

General redundancy principle – Assumption that if a text or a picture is fully intelligible without further information, students learn better from only the text or only the picture than from the text combined with the picture.

Gestalt Laws – Rules of the perceptual organization of stimuli, usually applied on visual perception, as studied by the school of Gestalt Psychology. The gestalt laws prescribe, which elements are grouped together into one gestalt. Examples of Gestalt laws are the law of proximity, the law of similarity, the law of good continuation, the law of conciseness, and the law of common fate.

Hypermedia – An electronic medium, which allows computer-based (and usually web-based) access to specific information via a network-like structure, often referred to as information space.

Linear text – Traditional form of written text, which is expected to be read in a linear fashion, sentence by sentence and paragraph by paragraph, according to the inherent sequence of the text.

Logical pictures (graphs) – Visualizations of relations that cannot be perceived in the real world (such as the increase of birth-rates) through a graphical object such as a line graph, bar chart, etc.

Mental models – A (hypothetical) form of mental representation that consists of internal objects, which hold a structural or functional analogy to the represented external object.

Modality principle – Assumption that students learn better from pictures with auditory text than from pictures with visual text.

Multimedia – In the technical sense: the combination of multiple technical media. In the representational sense: the combination of different forms of representation such as text and pictures. In the modality sense: the use of multiple sensory

modalities for conveying information such as the auditory and the visual modality.

Multimedia principle – Assumption that students learn better from text with pictures than from text alone.

New Media – General term for various kinds of digital, usually computer based electronic media.

Non-linear text – Printed text with a flexible access structure due to graphical layout or electronic hypertext, which is expected to be read in a pre-determined linear fashion (i.e. sentence by sentence) only within paragraphs, whereas the paragraphs are not expected to be read in a specific pre-determined linear sequence.

Propositional representations – A (hypothetical) form of mental representation that consists of complex internal symbols (so-called propositions) which describe the represented content in a kind of mental language.

Realistic pictures – Pictures of objects or scenarios, which resemble the depicted object or scenario.

Semantic memory – Memory system that includes (usually general) world knowledge, based on information from others or on one's experiences.

Spatial contiguity principle – Assumption that learning from text and picture is enhanced, when both sources of information are presented contiguous to each other in space.

Specific redundancy principle – Assumption that students learn better from pictures with (only) auditory text than from pictures with auditory and visual text.

Temporal contiguity principle – Assumption that learning from text and picture is enhanced, when both sources of information are presented contiguous to each other in time.

Topic information – Information within a sentence or paragraph that indicates what the sentence or paragraph is about.

Working memory – Memory system for cognitive processing of information, which is currently in the focus of attention. According to the theoretical model of Baddeley, working memory consists of a central executive and (at least) two slave-systems: the phonological loop and the visuo-spatial sketchpad. Recently, an episodic buffer has been added as a further subsystem.

New media allow flexible combinations of different forms of representation, such as text and static or animated pictures, with different sensory modalities, such as the visual modality when – for example, written text and pictures are to be presented – and the auditory modality when – for example, spoken text and sounds are to be presented. The combination of different forms of representation is commonly referred to as multimedia (Mayer, 2001, 2005). As new media are based on computer (i.e., information processing) technology, they also allow a high degree of interactivity and can provide users with quick access to a multiplicity of information. A set of text paragraphs interconnected via a nonlinear, network-like access structure is usually referred to as a hypertext. When not only text paragraphs, but also pictures or sounds are presented via this kind of nonlinear access structure, a hypertext turns into a hypermedium.

A common assumption in the field of instructional design is that multimedia and hypermedia allow better adaptation of instruction to the needs and preferences of learners. Furthermore, new media are often assumed to increase motivation in learners, thus increasing their investment of cognitive effort and resulting in better learning. The history of media in education reveals, however, that a new medium *per se* has never improved learning (Cuban, 1986). Learning with new media can only be successful to the extent that it takes into account the functioning of the human cognitive system.

Text in Multimedia Learning Environments

Texts – irrespective of whether they are written or spoken – are sequences of verbal information that guide an individual's cognitive processing toward the construction of a coherent knowledge structure with regard to the topic described in the text (Kintsch, 1998). Most cognitive psychologists agree that, when reading or listening to a text, a learner constructs multiple forms of mental representations: a mental representation of the text surface, a propositional representation of the text's semantic content, and a mental model of the content described in the text (Graesser *et al.*, 1997). These mental representations are constructed via an interplay of data-driven bottom-up processes and concept-driven top-down processes.

Whereas reading a written text and listening to a spoken text are not very different with regard to higher cognitive processes – including the construction of a propositional representation and a mental model – they are different with regard to lower-order cognitive processing. Written text usually provides a relatively stable form of information, allowing the reader to go back if a previous phrase has not been understood. Reading a written text enables more self-directed processing on

Promises of Learning with New Media

The term new media is used as a synonym for the use of computer technology to transmit and deliver information.

a micro-level than does listening to a spoken text. When listening to a text, information that has not been processed during presentation cannot be processed later because of the transient nature of the information carrier – acoustic sound waves. In multimedia environments, technical features for going back within an audio file do allow repeated presentation, but selecting specific passages to review is not as easy with audio files as it is in written text.

Linear and Nonlinear Text

In traditional printed text, information is presented in a linear order. In hypertext – on the other hand – relatively short text segments are connected via specific links (so-called hyperlinks) that create a network-like access structure and allow presentation of information in a nonlinear manner. Hyperlinks can help avoid redundancy by linking to the same passage from other different passages, whereas conventional linear text would require repetition of the corresponding passage.

It has often been assumed that hypertext (and – as an extension, hypermedia) would result in more effective and more efficient learning than traditional text because the highly flexible access to information in hypertext allows more freedom in learning. The network-like structure of information presentation was also conjectured to be especially appropriate for learning because it would correspond to the associative, network-like knowledge structures in semantic memory. This so-called cognitive plausibility hypothesis was abandoned because a closer analysis revealed that hypertexts still require sequential reading and cognitive processing and, therefore, cannot directly implement network-like knowledge structures.

In contrast to the simple cognitive plausibility hypothesis, the cognitive flexibility hypothesis assumes that the crisscrossing of learners through the network-like structure of hypertext-information spaces allows the processing of the same information in different contexts depending on the previously read passages and, thus, increases cognitive flexibility. However, the assumption that a network-like information representation would foster knowledge construction in long-term memory has not been confirmed empirically, raising the question of whether hypertext should be considered an information-access device rather than a learning device (Rouet and Levonen, 1996).

Designing Text

Designing written or spoken text for multimedia learning environments is, essentially, complex problem solving that involves the satisfaction of multiple constraints. Text design needs to take into account the instructional objectives, the learners' prior knowledge and cognitive skills, and the limitations of the human cognitive system in syntactic and semantic processing of language. A pragmatic approach to

the design of text has been suggested by Langer *et al.* (1974) in their comprehensibility approach. This approach specifies four key elements of text quality: linguistic simplicity, structure and organization, conciseness, and stimulation.

Linguistic simplicity

Sentences of a text should be relatively short and include simple phrases. If possible, familiar, concrete, vivid words should be used. For texts in multimedia learning environments, linguistic simplicity is especially important for texts in multimedia learning environments because learners read texts on the screen more slowly and get tired more quickly than when reading texts on paper.

Structure and organization

Texts should be well structured internally with regard to their content. They should refer to a global topic, and their internal structure should be made obvious by an appropriate external organization – including headlines, different fonts, shaded text boxes, and so on. Graphical overviews and classification schemata are especially important in fostering learning from hypertext.

Conciseness

Texts should focus on essential information and avoid prolixity or redundant information, without increasing semantic density *too much*. A medium degree of conciseness is considered better than maximum conciseness for comprehension. Hypertexts allow avoiding unnecessary redundancy by interlinking text elements.

Additional stimulation

A text should stimulate readers through the use of vivid formulations and by presenting people and examples from real life. This kind of additional stimulation is assumed to motivate individuals and prolong their process of learning.

Because of the limited capacity of working memory, only a restricted amount of information is available for cognitive processing at any one moment. Accordingly, a learner has to know, at every moment of reading or listening, the specific topic that the text is about in order to activate the corresponding prior knowledge. Whenever the topic changes, the change has to be signaled clearly to the learner *to allow him or her the necessary focus tracking*. The necessary signals for shifting the focus of attention can be transmitted through the topic information within the corresponding sentences or text segments.

In every sentence or text segment, two information components can be differentiated: the topic information and the comment information – the topic information indicates what the text is about; the comment information is the specific information about the topic. Readers or listeners identify the topic information in each sentence (Fletcher, 1984) and try to match it with the previous topic. If the match is positive, the previous topic is still valid.

If the match is negative, a mental search process is triggered in order to find (or create) the new specific topic within the learner's mental representation. The topic information has to contain enough information to allow the learner to identify the new topic, meaning that the various search parameters should allow easy topic identification.

A further guideline for text design is thematic continuity. If a topic has been introduced, it should not be unnecessarily interrupted, because when the topic is picked up again, the reader has to reactivate what he or she has learned so far about the topic, and will usually not reactivate all the previous information. Accordingly, what the individual has in mind during the process of reading will be less rich or less elaborated when topic continuity is low than when topic continuity is high (Schnotz, 1993).

Pictures in Multimedia Learning Environments

Multimedia learning environments use static or dynamic pictures (animation) in conjunction with text as additional sources of information. In contrast to texts, pictures possess structural characteristics in common with what they represent. From a cognitive point of view, pictures can illustrate, organize, explain, and improve memory. However, pictures are, also used sometimes, for primarily decorative purposes. From a purely cognitive point of view, decorative pictures can be considered seductive details because they require some working-memory resources without contributing to deeper understanding of the subject matter (Harp and Mayer, 1998). However, the widespread use of pictures for decorative purposes suggests that these pictures increase the attractiveness of the learning material and therefore pictures may have a motivational function (*cf.* Fisch, 2004).

Kinds of Pictures

Pictures can be subdivided into two main categories: realistic pictures and logical pictures (i.e., graphs). Realistic

pictures are surfaces, which can be looked at to create (nearly) the same perception as looking at the corresponding real object. Realistic pictures reveal (to some degree) similarity with what they represent; they represent height by height, width by width, color by color, etc. The degree of realism can differ. Photographs and realistic drawings show a high degree of realism, whereas simplified drawings and illustrations contain less detail, and schematic pictures present only the most essential elements of the depicted object (see **Figure 1**). Whereas realistic pictures have similarity with the content that they depict, graphs possess only an abstract structural commonality with what they represent. For example, a bar graph can represent nonspatial features such as birth rates, import quotas, and so on by spatial features such as the length of bars. In other words, represented features and representing features may be different from each other. Both realistic pictures and logical pictures can further be subdivided into static and dynamic ones according to their temporal stability.

Dynamic pictures (also referred to as animations) are, often, assumed to result in better learning – when the content being portrayed is itself dynamic. A meta-analysis by Höffler and Leutner (2007) found an average superiority of animations in terms of learning compared to static displays, especially if human movements were involved. However, whether and under which conditions animations will lead to better learning outcomes is still under debate (Lowe and Schnotz, 2008) because, on the one hand, animations provide more information (i.e., information about processes), but on the other they, animations provide information that is transient in nature. If learners have to compare different states within an animation, they have to hold previously seen pictures in working memory over a longer period, which can lead to cognitive overload of the working memory. Although learning with movies and animations is quite popular, these media are also, from a motivational point of view, not necessarily the best choice for learning, because viewing movies is usually considered easy and hence may trigger less learner effort than does reading a text, which is considered more difficult (Salomon, 1984). There is a risk that learners do not elaborate mentally the content of animated pictures with

Figure 1 Degrees of realism of a picture.

the same effort that they elaborate the mental model they derive when reading a text.

Understanding Pictures

Pictures provide a relatively direct way to construct mental models, because the external and the internal representation are both analogous in nature. The process of understanding a picture includes both visual perception and higher-order cognitive processing. The basic processes of visual perception are largely pre-attentive. These processes are primarily bottom-up, include automated visual routines, and run in parallel. In order to not only perceive but also understand a picture, higher-order cognitive processes, which are attentive in nature, are required. The learner must read features of the perceptual representation and interpret them semantically in order to understand what the picture represents. These semantic processes are run serially and include both data-driven, bottom-up and concept-driven, top-down components. Accordingly, they are strongly affected by both the learner's prior knowledge and his/her goal orientation.

In contrast to reading text, which suggests a specific linear sequence of cognitive processing, reading pictures provides high degrees of freedom with respect to the sequencing of pictorial information during cognitive processing. However, there are different ways to influence the learner's processing order. For example, certain parts of a picture can be highlighted by increasing their visual contrast to the background or by labeling. Directive signs – such as arrows, frames, or drawn magnifiers – can be used to emphasize certain areas within the picture. Furthermore, processing order can be influenced by numbering pictorial elements. Finally, there are cultural habits – such as reading from the left to the right in the Western world – that can also influence the processing of pictures.

A high degree of realism is not necessarily beneficial for picture comprehension. Instead, the degree of realism should be adapted to the level of the learners' prior knowledge. Dwyer (1978) demonstrated that novices learn better from schematic pictures with limited detail rather than from highly realistic pictures.

Understanding graphs differs from understanding realistic pictures because graphs do not have perceptual similarity to what they represent, which implies that the learner cannot use perceptual schemata based on everyday experience. Sub-semantic pre-attentive processing includes discrimination, identification, and grouping of graphical components, such as points, lines, and surfaces, according to the so-called Gestalt laws. This kind of processing results in the perception of specific graphical configurations. Semantic interpretation of these configurations requires that the individual knows the underlying representational conventions – that is, has acquired a corresponding graphic schema (Pinker, 1990), which allows him or her to map the

graphical configuration onto a corresponding mental model of the learning content. Understanding graphs requires cultural skills, which have to be learned. Empirical findings suggest that experts and learners with higher domain-specific prior knowledge are better at detecting global visual patterns and create more elaborate and more hierarchically structured knowledge structures from these patterns, whereas learners with lower prior knowledge are more bound to local search processes.

Designing Pictures

Pictures should be designed in such a way that their elements can be easily detected and identified. Essentially, this means that the design should take the so-called Gestalt laws into account. According to the Law of Proximity, spatially adjacent elements are more likely to be associated with each other than are distant elements. According to the Law of Similarity, elements with a similar appearance (in terms of form, color, orientation, texture, etc.) are more likely to be associated than are nonsimilar elements. According to the Law of Closure (or the Law of 'Good Gestalt'), visual information is organized as simply as possible, resulting in simple, concise forms. According to the Law of Good Continuation, two crossing lines will be kept separated by the implicit assumption that the crossing lines proceed continuously at the crossing point. Finally, the Law of Common Fate assumes that different lines with the same course are grouped into one unit.

Graphs should be designed in a way that supports the message to be conveyed as clearly as possible. This requires consideration of syntactic, semantic, and pragmatic constraints. Syntactic constraints refer to the relation between pictorial elements. For example, elements that form a set should be grouped together by using the same color, the same form, the same texture, or by using a common frame. Semantic constraints refer to the relationship between the graph and the represented subject matter. Different visual attributes differ in their usefulness for different representational purposes. For example, quantities are usually represented by the size of graphical elements (such as the lengths of bars), whereas different qualities are represented by different colors, textures, or graphical forms. Pragmatic constraints refer to the specific communicative purpose of the graph. Learners should not be tempted to draw incorrect inferences because of interrupted scales, exaggerated size differences stemming from simultaneous variation of multiple attributes (such as length, width, and depth), or due to the use of multiple axes in a graph that suggests a comparison of trends when no such comparisons can be made. Generally, the number of visual attributes that are used to convey information should not be higher than the number of represented attributes.

Learners often assume that one short look is enough to understand a graph. Graphs and diagrams should, therefore, be designed in a way that counteracts this tendency toward superficial processing. Relevant elements can be emphasized by frames, by the magnifying-glass technique, or by directive signs such as arrows, which guide the learner's attention toward key elements. For specific communicative purposes, specific forms of graphs, have been developed, such as pie graphs, bar graphs, line graphs, and scatter plots. As these forms of graphs are frequently used, readers are more likely to possess the corresponding graphic schemata required for understanding these graphs than the schemata needed to comprehend other forms of visualization (Pinker, 1990).

Learning with Multimedia

Theoretical Models of Learning from Multimedia

Numerous studies have found that students learn better from text combined with pictures than from text alone. Whereas early research focused on the mnemonic function of pictures combined with narrative text, recent studies also deal with the explanatory function of pictures. Mayer and his colleagues have found that students understand technical devices or natural phenomena better when they learn from text and pictures. This so-called multimedia effect seems to be especially strong when learners have low domain-specific knowledge (Mayer, 2001; Mayer and Moreno, 1998). In other cases, however, adding pictures to a text has been shown to have detrimental effects on learning (Sweller *et al.*, 1998). So, the question arises as to when multimedia learning is more successful than learning from a single medium, and why it is more successful under those circumstances.

Dual coding theory

The advantage of combining texts with pictures was often explained through Paivio's dual coding theory (DCT). According to this theory, the human cognitive system entails two separate – but related – subsystems: a verbal and an imagery system. Both systems can interact, but can also be activated independently, and both have a limited capacity. Usually, verbal information is processed only in the verbal subsystem, whereas pictorial information is processed in both systems. As the two subsystems are interconnected, cross-referential connections between the representation of a subject matter in the verbal system and a representation of the same subject matter in the imagery system can be established. The overall memory representation is, therefore, more elaborated, which is assumed to be the basis for the positive text–pictures effects.

Cognitive theory of multimedia learning

Building on the DCT, Mayer (2001) developed a cognitive theory of multimedia learning (CTML). This theory

assumes that the human cognitive system includes verbal and pictorial (image) subsystems. Accordingly, individuals can use different representational formats to internally encode and store knowledge. Furthermore, the theory draws on the ideas of Baddeley (1986) about human working memory. Baddeley hypothesizes that humans' working memory is characterized by a rather limited capacity and high decay rates. It includes a central executive and two slave systems: the phonological loop and the visual sketchpad. Similarly, Mayer assumes that there are two sensory subsystems in working memory: a phonological system and a visual system. His first basic assumption with regard to multimedia learning merges the notion of dual coding and the notion of two sensory subsystems. Humans are supposed to process information in their working memory through two channels: an auditory–verbal channel and a visual–pictorial channel. Mayer's second basic assumption is that these two channels have a limited capacity to convey and process information. His third basic assumption is that humans are active sense-makers: They engage in active cognitive processing to construct coherent knowledge structures from both the available external information and their prior knowledge.

According to Mayer's theory, verbal selection processes synthesize a so-called propositional text base, and verbal organization processes lead to a text-based mental model. Similarly, pictorial selection processes synthesize a picture base, and pictorial organization processes lead to a picture-based mental model. Integration processes constitute referential relations between the text-based and picture-based mental models (see **Figure 2**).

Integrated model of text and picture comprehension

The parallelism of the text and picture processing assumed in Mayer's model can be questioned on the grounds that texts and pictures use completely different representation principles. Schnotz (2005) has developed an integrated model of text and picture comprehension (IMTPC), which is depicted schematically in **Figure 3**. This model incorporates the following assumptions: Text and picture comprehension take place in a cognitive architecture that includes a working memory of limited capacity, modality-specific sensory registers as information-input systems, and a long-term memory. Verbal information (i.e., information from written or spoken texts) and pictorial information (i.e., information from visual pictures and from nonverbal auditory sounds) are transmitted to working memory through the visual channel and the auditory channel, respectively. Further information processing in working memory takes place in two representational channels: the verbal channel and the pictorial channel. Information from written or spoken text is processed in the verbal channel. Information from visual pictures or from sounds is processed in the pictorial channel. The channels have

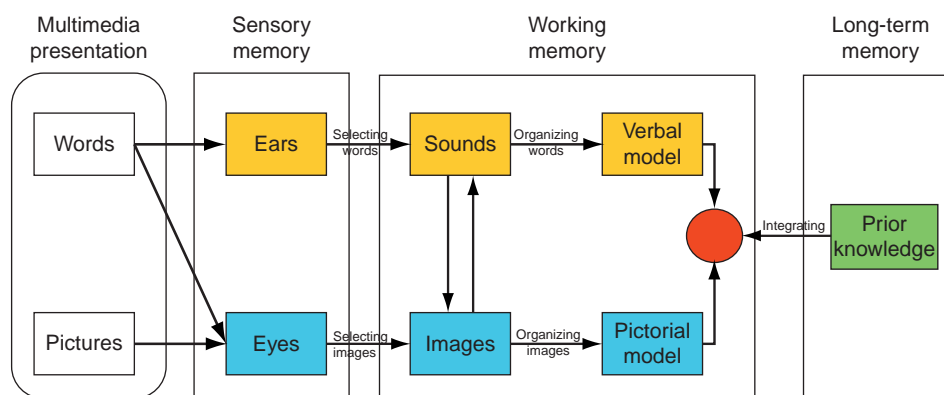

Figure 2 Cognitive Theory of Multimedia learning. From Mayer, R. E. (ed.) (2005). *The Cambridge Handbook of Multimedia Learning*. Cambridge: Cambridge University Press. S. 37.

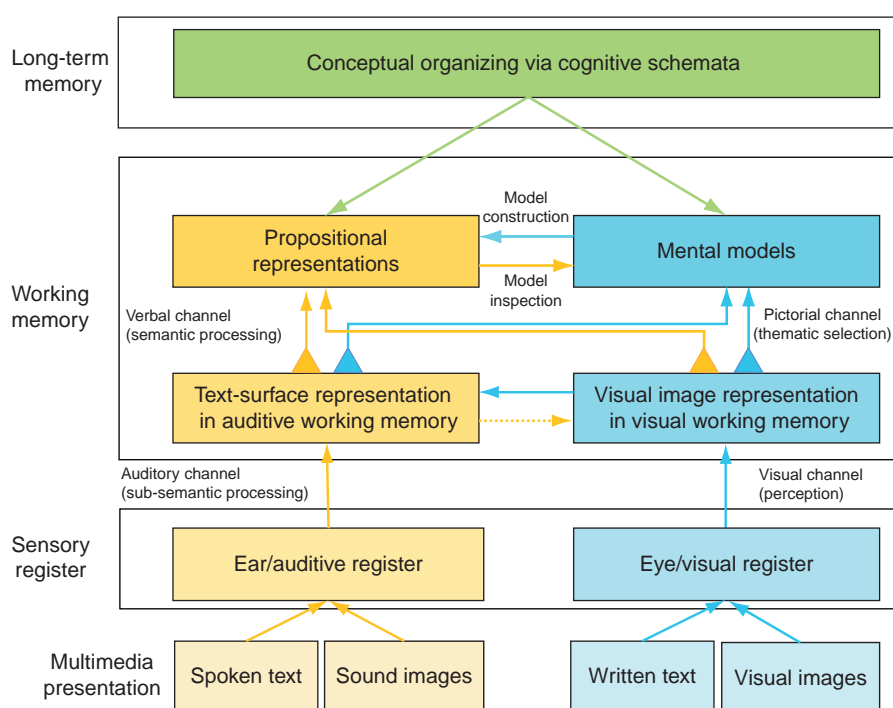

Figure 3 Integrative model of text and picture comprehension. From Schnotz, W. (2005). An integrated model of text and picture comprehension. In Mayer, R. E. (ed.) *Cambridge Handbook of Multimedia Learning*, pp. 49–69. Cambridge: Cambridge University Press.

limited capacity to process and store information. Text and picture comprehension are active processes of coherence formation. In comprehension, individuals engage in building coherent knowledge structures from the available external verbal and pictorial information, and from their prior knowledge.

The CTML and the IMTPC differ in terms of structure as well as in terms of some predictions. With regard to structure, the CTML merges sensory aspects and representational aspects by assuming an auditory–verbal channel and a visual–pictorial channel. The IMTPC, on the contrary, keeps sensory aspects and representational

aspects distinct: the sensory channels are assumed to feed information into working memory, whereas the representational channels (verbal and pictorial) are supposed to process information within working memory. Whereas the CTML assumes the construction of two mental models (a verbal and a pictorial one) in comprehension and learning, the IMTPC assumes that only one mental model is constructed. Whereas the CTML predicts that students generally learn better from text and pictures than from text alone, the IMTPC predicts that adding pictures is not always beneficial, and can also be harmful for learning: First, learners may use the pictures instead of

the text and, therefore, process the text only superficially, resulting in lower learning than when using text alone (Schnotz and Bannert, 2003). Second, learners with sufficient prior knowledge may be able to construct a mental model without pictorial support; they would only waste time and effort when learning from text and pictures rather than from text alone (Sweller *et al.*, 1998). Third, because processing of information in the pictorial channel is assumed to include procedures of structure mapping between picture and mental model, a picture with a non-appropriate structure for the task at hand may interfere with the construction of an appropriately structured mental model, resulting in lower learning performance (Schnotz and Bannert, 2003).

Research Findings

The two models agree that the main reason for the learning-enhancing function of multimedia compared to single media is that multimedia can support integrative processing of verbal and pictorial information in working memory. Integrative processing requires both verbal and pictorial information to be held simultaneously in working memory. Because the capacity of working memory is limited, and decay rates are high, students learn better from words and pictures than from words alone when verbal and pictorial information are simultaneously available in working memory. From this fundamental condition of integrative processing, various principles for the design of multimedia can be derived.

Coherence and contiguity

Students learn better from words and pictures than from words alone if the words and pictures are semantically related to each other (the coherence condition) and if they are presented closely together in space or in time (the contiguity condition). Text and pictures can only contribute to a joint mental model construction if corresponding text information and picture information are simultaneously available in working memory. Because information decays quickly from working memory, this requires the combined presentation of words and pictures as far as possible, then fulfilling the contiguity condition. If a picture is combined with a spoken text, simultaneous availability of related pictorial and verbal information in working memory is enhanced by the simultaneous presentation of the picture and the semantically related part of the text (i.e., temporal contiguity). If a picture is combined with written text, all information has to enter working memory through the visual channel. Since only one kind of information can be processed through the visual channel at a time, the eye has to switch between pictures and words. This so-called split of visual attention implies that unproductive visual search processes from the picture to

the text, and vice versa, have to take place. If pictures and related written words are presented closely to each other (i.e., spatial contiguity), visual search processes are reduced. In short, high spatial contiguity of pictures and written words enhances the simultaneous availability of pictorial and verbal information in working memory.

Modality

Various studies have shown that students learn better when pictures are presented with spoken text instead of written text (Mayer, 2001; Mayer and Moreno, 1998). If a picture is combined with written text, information processing has to be highly selective: The eye has to focus either on the picture or on the text and, thus, information from only one source can be conveyed at a specific moment. Because all visual information has to be processed through the visual channel, which has a limited capacity to convey information, the overall information input into working memory within a limited amount of time is lower than in the case where both the visual and the auditory channel are being used. Thus, split of attention, which is essentially the use of one information channel for different sources of information, results in a reduced amount of information that is put into working memory within a specific amount of time. The negative effects of split attention on learning are especially pronounced when animated pictures are used instead of static pictures because of the fleeting nature of animations (Mayer, 2001). The modality effect results from differences in the amount of information that is processed through sensory channels as well as from differences in the amount of working memory capacity that is involved in further cognitive processing (Mayer and Moreno, 1998).

Redundancy

Contrary to the DCT and the CTML, which assume that adding pictures to texts always leads to better learning because two codes in memory are better than one, the integrated model predicts that the combination of texts and pictures can also have detrimental effects under specific conditions. One of the detrimental effects is called the redundancy effect (Sweller *et al.*, 1998). If learners have high prior knowledge, they frequently do not need text as well as pictures as information sources because one source provides all the required information. In this case, adding a picture to a written text or adding a written text to a picture means adding unneeded information. Although only one of the two information sources is needed, the eye wanders between both of them resulting in a split of attention. Thus, the learner loses time and expends mental effort searching for redundant information. The integrated model predicts that learners with higher expertise will perform better with only one information source (i.e., text or picture) while those with lower expertise will perform better with

two information sources (i.e., text and pictures). This prediction is in line with various research findings (cf. Mayer, 2001; Sweller *et al.*, 1998) and is also referred to as the expertise reversal effect (Kalyuga *et al.*, 2000).

Designing Multimedia

From the empirical findings presented above, the following principles for designing multimedia learning environments can be derived:

- *Multimedia principle.* Use text combined with content-related pictures when learners have low prior knowledge, but sufficient cognitive abilities to process both the text and the pictures.
- *Spatial contiguity principle.* If written text is used, present it in close spatial proximity to the picture.
- *Temporal contiguity principle.* If spoken text is used, present it in close temporal proximity to the picture.
- *Modality principle.* If animation is used, use spoken text instead of written text.
- *Specific redundancy principle.* Do not add written text that duplicates spoken text combined with pictures.
- *General redundancy principle.* Do not combine text and pictures if learners have sufficient prior knowledge and cognitive ability to construct a mental model also from one source of information.
- *Coherence principle.* Do not use extraneous words and pictures. Do not add unnecessary sound or music.

Whereas Universal Design for Learning (Rose and Meyer, 2006) generally suggests presenting, multiple representation to give learners various ways of acquiring information and knowledge, empirical research on multimedia learning suggests that this may be a two-edged sword, because too many sources of information presented at the same time can overwhelm the learner's cognitive capacity. In any case, designers of instructional material should resist the temptation to add irrelevant bells and whistles to multimedia learning environments. Simply speaking, less can be more.

Outlook

Understanding multiple external representations – such as text, static or animated pictures, and graphs – requires processing the different sources of information in an integrative manner. Combined usage of text, pictures, and graphs in multimedia learning environments allows better learning for individuals with low domain-specific prior knowledge – those who are not yet able to construct multiple mental representations from a single external source of information. However, the combined usage of text, pictures, and graphs requires skills of mapping information from one external representation to another external representation. These skills include not only simple

verbal literacy in terms of reading written text, but also skill in reading information from pictures and graphs, which can be referred to as visual or pictorial literacy.

Successful teaching and learning with multiple external representations requires more than following simple rules of thumb in a mechanical way. Rather, it requires scaffolds for orientation based on empirical research, and simultaneous and systematic consideration of multiple constraints. In this way, the design of multimedia learning environments can go beyond pure intuition and make instructional materials look good, through the manipulation of surface variables. Instead, the design of multimedia learning environments should take the functioning of the human cognitive system into account.

Glossary

Decoding – Methods used to decipher the printed work.

Digitized speech – Artificial speech compiled from recordings of human speech.

Hypertext – Electronic text that is linked to other chunks of text.

Multimedia – The integration of multiple forms of media, such as graphs, illustrations, photographs.

Phonemic awareness – The ability to isolate and attend to individual sounds.

Reading in Light of Technology

In addition to providing alternative ways of supporting the acquisition and development of traditional print-literacy skills, technology changes the nature of text and reading. Indeed, technology has expanded the notion of text to include a broad array of media objects, including: digitized multimedia (e.g., video, sound, graphics, text, and photographs) that are presented in a linear structure, and hypertext and hypermedia, which are constructed in parallel or hyper-based structures.

While the literacy community rejects the notion that any texts, no matter what their structure, ever have predetermined meaning since the reader is always making connections – reading in and reading between the lines (Purves, 1999) – it is certainly the case that hypertexts make the role of the reader more salient in co-authoring the text, since the reader determines the paths taken and ignored, and can reorder, change, augment, and delete paths that may have initially been forged or proposed by the creator of the hypertext. This characteristic offers new challenges and opportunities to readers, and changes the vista of reading research. However, research on these aspects of reading and technology is emergent; hence, in this article, we focus principally on research that has been conducted regarding the use of technology to support the development of print-literacy knowledge and skills, and to provide compensatory and remedial support for students who require additional assistance to learn to read and to use reading to advance their learning.

We have organized the article around areas of reading instruction deemed crucial by the National Research Council Committee on Preventing Reading Difficulty in Young Children (Snow *et al.*, 1998) and the Report of the National Reading Panel on Teaching Children to Read (National Institute of Child Health and Human Development, 2000). Those key areas are: alphabets (phonemic awareness and phonics), fluency, and comprehension (vocabulary and comprehension strategy) instruction. There is also a discussion of some applications of technology to encourage early reading and writing-related behaviors, or emergent literacy skills, which lay a foundation for conventional literacy. In the final section, we identify research efforts that are underway to exploit the additional affordances of new technologies.

Emergent Literacy

Very young children engage in reading and writing-related activities during cooperative and dramatic play in environments rich in print materials. They discover the symbols – numbers, letters, and icons – used to think about and express ideas; they use symbols to create their own messages in conventional and unconventional ways (Roskos and Neuman, 2001). Computers can support preschoolers' emergent literacy by contributing to dramatic play, offering practice in conventional literacy skills, and enabling children to explore their world and communicate their discoveries, (McGee and Richgels, 2006).

Preschoolers can explore their world via the World Wide Web. Computer use prompts children to collaborate and share their literacy knowledge (Labbo and Ash, 1998). They can communicate messages of songs, celebrations, classroom mascots, seasonal artwork, fall leaves of local trees, information about their pets, and photos of their communities with peers around the world. With computers, teachers and students can easily produce literacy props such as menus, tickets, maps, signs, and shopping catalogs for dramatic play. Inclusion of these props in play centers increases literacy-related play and the opportunity to develop literacy skills (Labbo and Ash, 1998). Alphabet-game software provides practice in the conventional literacy skill of letter-sound association. CD-ROM talking books with animation and sound effects support literacy development by improving children's understanding of stories, sustaining their attention with minimal adult scaffolding, and developing word-reading skills

(but only in those with some grounding in sound–symbol correspondence). Children at risk of school failure have been shown to produce more complex retellings and learn more new words and sentence structures from multimedia storybooks than from storybooks with static pictures (Bus *et al.*, 2006).

The utility of computers in preschool classrooms is constrained by technical limitations: the average preschool classroom computer is 10 years old, limiting the functions it can perform. Software is not yet capable of listening to children to take their dictation or provide corrective feedback on verbal responses (McGee and Richgels, 2006). In addition, there are attitudinal limitations: preschool teachers may not recognize the importance of information and communication technologies (ICT), may be reluctant or inadequately supported to integrate technology meaningfully into the curriculum, or may devalue computer competencies that children bring from home (Turbill and Murray, 2006).

Phonemic Awareness and Phonics

Mastery of phonics and phonemic awareness is prerequisite to developing the fluent word recognition of skilled reading (National Institute of Child Health and Human Development, 2000). Phonemic awareness is the ability to isolate and attend to the individual sounds, or phonemes, of spoken words. Phonemic awareness is necessary to develop an understanding of phonics, the system of letter–sound relationships needed to put spoken words into writing. Direct instruction in phonics and phonemic awareness includes tasks such as: matching sounds to letters, counting sounds in words, identifying beginning, middle, and ending sounds in words, rhyming, segmenting (cat → c-a-t), blending (b-a-t → bat), and manipulating (stop without s' → top) sounds to read and spell real words and pseudowords.

An abundance of commercially available beginning-reading software uses colorful, animated graphics to deliver potentially tedious drills in an entertaining format so that students will expend sufficient time and attention on phonemic awareness and phonics tasks (Burns *et al.*, 1999). Ideally, this software should reflect best practices in phonics and phonemic teaching such as progressing from blending individual phonemes to blending onsets and rimes, and from applying skills with single syllables to using multisyllable words (McKenna, 2002). Software can gate these progressions, ensuring that students demonstrate mastery of each skill in a carefully structured sequence. Software can provide spoken models and corrective feedback. Thus some tasks formerly performed by a teacher may be delegated to a computer, allowing students to work at their own pace, independently.

While generally effective and fun, computer-assisted phonics instruction may not be necessary or cost effective for typically achieving readers who often make comparable

gains in response to systematic phonics and phonemic-awareness instruction with and without computer support (Blok *et al.*, 2002; Dynarski, *et al.*, 2007; Macaruso *et al.*, 2006; Olson and Wise, 2006). There is some evidence that speakers of English may benefit more from computer-assisted instruction in beginning-reading skills than speakers of languages (e.g., Dutch) in which letters and sounds have more predictable relationships than they do in English (Bus *et al.*, 2006).

Direct, computer-assisted instruction in phonics and phonemic awareness has proven to be more effective than such instruction without supplementary computer support, for certain readers. Computer-assisted instruction is particularly effective in improving phoneme awareness, and phonologic decoding, in at-risk and poor readers, who need intensive, extended practice (Barker and Torgesen, 1995; Blok *et al.*, 2002; Macaruso *et al.*, 2006; Mitchell and Fox, 2001; Olson and Wise, 2006; Wise *et al.*, 1999). In some studies, practice in phonemic-awareness tasks also led to improved word identification (MacArthur *et al.*, 2001). Struggling readers, in the second grade and younger, benefit more than older struggling readers, who may improve in phonics and phonemic awareness without significant improvement in word recognition (Olson and Wise, 2006). Software programs that target phonemic awareness, but do not engage the participant in reading words, have not proven effective in improving word reading. Examples of such programs are those that target auditory temporal and speech processing, or perception of the order of a sequence of rapidly presented speech sounds or tones, and articulatory awareness, or attention to the movements of the mouth associated with each speech sound (Olson and Wise, 2006).

Fluency

Once readers have sufficient phonic and phonemic awareness to decode some words, they must practice their decoding skills through wide reading to build a repertoire of automatically recognized words (Kuhn and Stahl, 2006). Fluent reading is characterized by quick, accurate, and automatic word recognition and meaning-laden prosody (rate, phrasing, pitch, and inflection of speech) that facilitate comprehension. An example of computer-assisted support for fluent reading is talking books that offer (1) digitized speech with synchronized highlighting allowing the reader to follow along as the computer reads aloud and (2) prompts for word identification, either phonological word analysis (part-word prompts) or speech feedback (whole-word prompts) that the reader can request when confronted with difficult words. Talking books offer guided, independent reading opportunities that allow the reader to reduce the amount of computer-provided support as reading skill improves (McKenna, 1998).

For struggling readers, digitized speech provides opportunities for repeated readings with an expert, a practice

shown to improve reading fluency for print texts (National Institute of Child Health and Human Development, 2000). Again, a time-intensive task typically guided by an adult is shifted to the computer, allowing readers who need intensive practice to do so independently. Struggling readers who are older or adverse to monitoring and correction by others may find the computer to be a more amenable practice partner (Anderson and Speck, 2001).

There is evidence that extended exposure to computer-provided narration, accompanied by highlighted text, focuses readers on print and improves word reading, though benefits accrue only to those who have some beginning-reading skills. Struggling readers of any age or grade usually need some concepts of print, knowledge of letter-sound relationships, a basic level of phonemic awareness, and at least a small repertoire of sight words before digitized speech accompanying text will produce gains in word recognition and, sometimes indirectly, phonemic awareness (Bus *et al.*, 2006; Das-Smaal *et al.*, 1996; Heimann *et al.*, 1995; Higgins and Raskind, 2000; Olson and Wise, 2006; Raskind and Higgins, 1999).

Audio prompts for phonological analysis of difficult words include supplying: phonemes one at a time until the reader has enough of the word to identify it, breaking words into syllables or onset and rime (ring → r-ing), and phonic analogies (if h-at is hat, then fl-at must be ...). These prompts may reinforce phonologic decoding skills, but they also draw the reader away from the text enough to disrupt comprehension (McKenna, 1998).

Readers can also request speech feedback, that is, to have selected, difficult words read aloud. In general, reading with speech feedback has a positive impact on speed and accuracy of oral reading for struggling, school-aged readers (Dawson *et al.*, 2000; Moseley and Hartas, 1993; Van Daal and Reitsma, 1993; Van Daal and van der Leij, 1992). Simply supplying difficult words by means of digitized speech, rather than eliciting through hints or analogies, may be a better form of speech feedback for struggling readers since it does not require reader prerequisites (e.g., sight words or knowledge of print conventions) (McKenna, 1998). It does, however, require that the reader self-monitor and adopt strategies for accessing speech feedback. Some struggling readers require considerable training in monitoring their own reading before they request speech feedback when their reading is in error (McKenna, 1998).

Several promising technologies are currently in development. Speech-recognition software shows the potential to facilitate fluent reading and, thus, comprehension, without either the reader asking for assistance or an adult monitoring. A speech-recognition system can listen to a student read aloud and supply troublesome words when a student struggles (Adams, 2006). Text-to-speech-translation software reads aloud any text that can be loaded or scanned into the computer. This software offers

readers access to an array of reading materials, including content from the World Wide Web, thus maintaining reader interest when it might begin to flag in the face of frustration.

Vocabulary

When beginning readers decode, they translate words from an unfamiliar form in print to a familiar form in speech. Soon, though, readers encounter words whose printed and spoken forms are both unfamiliar. To ensure comprehension of text, reading instruction often includes vocabulary instruction, including computer-assisted instruction, to develop word meanings (National Reading Panel, 2000). Research shows that computer-assisted instruction can be more effective than traditional methods of direct vocabulary instruction (NRP, 2000). Productive applications of technology are those which address key components of vocabulary instruction including: multiple, varied encounters with target words, opportunities to use target words in novel contexts, and information about how knowledge of a word can be developed (Nagy and Scott, 2000).

Electronic texts can offer multiple, varied encounters to develop knowledge of important words through hypertext links – to glossary, simpler substitutions, examples of the word used in a sentence, additional background information, and explanations – and multimedia illustrations and graphics enhanced with animation, interactive features, narration, and sound effects. Readers learn words best when hypertext-linked information and animation features are not simply called up, but mediated, that is, extended through actions such as questioning, clarifying, or making inferences (Blachowicz and Beyersdorfer, 2006). Mediation opportunities, typically found in discussion with adults or peers, can be built into electronic texts as prompts to apply word knowledge, thus making the reader more independent. Multimedia CD-ROM storybooks have been used successfully to enhance word awareness and word knowledge in second-language learners, readers who have a particular need to acquire many new words in a short period of time. It is important that these animations be congruent with the text (Bus *et al.*, 2006).

Comprehension and Learning from Text

Comprehension is broadly conceived as an active process in which readers simultaneously extract and construct meaning as they interact with written language (Rand Reading Study Group, 2002). Hence, in addition to quick, accurate word recognition and broad, deep word knowledge, readers must also bring, or seek, additional resources to support making sense of text. This activity entails the use of cognitive processes of selecting, organizing, connecting, and evaluating what is being read. Strategies include making predictions while reading, drawing inferences,

self-questioning, paraphrasing, and using text features, including the structure of text, to support meaning making.

There are at least three ways in which technology is thought to have the potential to support text comprehension. The first is through supporting decoding so that readers have ready access to the ideas in text. The second is by offering multiple representations of information (e.g., prose, graphics, and animations), and the third is by using technology to teach students to be more strategic in their reading of text.

The use of text-to-speech (TTS) and digitized speech technologies is thought to facilitate comprehension by bypassing decoding problems so that students can focus on constructing meaning from the text. Indeed, many studies have shown that reading with speech feedback positively affects comprehension (Elbro *et al.*, 1996; Elkind *et al.*, 1993; Lundberg and Oloffson, 1993; Montali and Lewandowski, 1996). However, only one study (Elbro *et al.*, 1996) has found improvement that transferred to reading traditional text without TTS support. This particular study provided grade 2–6 Scandinavian students who had reading and language disabilities with uniquely interactive TTS support for 20 min a day for 40 days. When students clicked on a word, the word was presented broken into visual and auditory segments, and students were required to generate their own pronunciation before hearing the whole word. The interactive nature of the TTS support and the extended time for which students were offered TTS support may have enhanced the effectiveness of the treatment. Another factor that may affect the effectiveness of TTS support is the learner's age. Lundberg and Oloffson (1993) suggest that older students' comprehension may benefit more from TTS support because they read more difficult texts with a higher percentage of complex and multisyllabic words. Another possible explanation is that older students may be able to make better decisions about targeting words for TTS support. It should be noted that several studies have reported that TTS does not affect comprehension (Farmer *et al.*, 1992; Leong, 1995; Wise and Olson, 1995; Wise *et al.*, 1998, 2000). Possible explanations for this lack of influence are that students with learning disabilities do not access supports, even when warranted, and that the effect of TTS may vary by reading ability and type of reading difficulty. It is also possible that the effect of TTS may be mediated by the larger instructional context.

While TTS allows for basic access to text, struggling readers often face additional problems such as a lack of background knowledge or a lack of strategic reading skills that prevent them from learning from text. A few studies have developed hypertexts including various types of representation supports, such as an online glossary, background material, or a summary of main ideas, that are designed to help readers understand content (Boone and Higgins, 1993; Higgins *et al.*, 1996; Leong, 1995; MacArthur and Haynes,

1995; Moore-Hart, 1995). With the exception of Leong's (1995) study, which found no effects for TTS, for TTS with explanations of difficult words, for TTS with explanations and with reading awareness prompts, or for TTS with simplified passages, these studies tend to demonstrate that the hypertexts improve comprehension for struggling readers of varying ages.

Multimedia applications can provide enhanced access to ideas through visual and verbal representations. Pictures, drawings, diagrams, graphs, tables, and video clips (static, animated, or interactive) complement written words. Dual-coding theory states that simultaneously processing both verbal and visual representations of an idea, that is, dually coding the information, will make the information more memorable (Kamil *et al.*, 2000). Multimedia electronic text facilitates comprehension in young readers (Bus *et al.*, 2006), typically achieving and struggling elementary readers (Kinzer and Risko, 1998), and high school (Webb, 2005) and college students (Ainsworth and VanLabeke, 2004). However, the technological capacity to produce multimedia is currently well in advance of research to establish how characteristics of the reader, cognitive demands of the content, and the multimedia features of text should be aligned to produce an optimum learning environment for a particular reader (Hegarty, 2004).

A burgeoning area of inquiry is the use of technology to teach readers to be more strategic in their reading of text. Illustrative is the design and study of Interactive Strategy Training for Active Reading and Thinking (iSTART) (McNamara *et al.*, 2004), a Web-based tutoring program that uses animated agents to teach reading strategies to young, adolescent (grades 8–12), and college-aged students. The program is derived from research on self-explanation reading training (SERT) and teaches metacognitive reading strategies in the context of self-explanation. Specifically, users of iSTART are taught to engage in comprehension monitoring, paraphrasing, predicting, elaborating, and bridging (tying the current sentence with material covered previously in the text) as means of enhancing learning from text. When students are first introduced to the software, an agent (an animated electronic one-on-one trainer) provides self-explanations while the learner watches; but as the learner progresses through the modules, he or she creates self-explanations that are evaluated by the agent. Research to date suggests that the program is most beneficial for students with the least knowledge about the domain at hand, as well as for students who are less strategic in their approach to text. Furthermore, protocol analyses indicated that iSTART improved the quality of students' self-explanations that, in turn, were reflected in improved comprehension scores.

A program of research conducted by Dalton and her colleagues at the Center for Applied Special Technologies has been designed to investigate the use of

technology to enact universal design for learning (UDL), (Rose and Meyer, 2002), an approach through which the needs and interests of the broadest spectrum of learners is considered from the outset. In addition to providing such supports as TTS and online glossaries, students working in this environment have technology supports for being strategic in their reading. As they work their way through the text, they are periodically prompted to stop and apply a strategy. They enter their response in writing or audio-record it and save their response to an electronic work log that can be viewed at any time by the student and teacher. The program offers five levels of support that move students from high support to low support to independent application of the strategies, ending with an open-ended response option that can be used for any purpose (e.g., making a journal entry). Furthermore, the level of support is adjusted to meet the demands of particular strategies. For example, more support is provided for summarization than for predicting (Dalton *et al.*, 2002).

Dalton and Palincsar and their colleagues have explored the use of digital environments to support students' learning of challenging science concepts. In their reading-to-learn research (Dalton *et al.*, 2006), typically achieving and struggling fifth graders readers interacted with one of three versions of digital texts, all of which presented the same prose and graphics. The static version offered TTS and embedded vocabulary support. The interactive diagram version, which contained the same supports as the static version, also offered a prose/diagram-interaction feature (PDI) that would animate the graphic that corresponded with information presented in the prose; furthermore, students in this condition were directed to use a diagram-manipulation (DM) feature to explore ideas that were presented in the prose. The third version was enhanced with the addition of two animated pedagogical agents, who provided procedural and conceptual support. Students in the static group demonstrated significantly less growth in science vocabulary and concept learning than students in either of the interactive conditions. Students in the interactive conditions significantly outperformed their counterparts in the static condition, with struggling readers in both conditions making gains comparable to their typically achieving peers. There was no advantage to the addition of agents in this environment.

Reading on the Internet

The Internet has assumed an increasingly important role in contemporary life, with nearly 75% of all US households reporting that they had Internet access in 2004 (Nielsen/NETRatings, 2004), 93% of US classrooms reported to have at least one computer linked to the Internet (Kleiner and Lewis, 2003). In 2003, the ratio of students to instructional computers with Internet access in

public schools was 4.4 to 1, a decrease from 12.1 to 1 in 1998 (National Center for Education Statistics, 2005).

Literacy researchers argue that the open networked nature of the Internet requires that readers not only construct meaning from text, deploying the kinds of strategies described above, but also that readers must be sufficiently flexible and purposeful in their reading to make thoughtful, efficient, and effective use of the hyperlinks, graphics, and icons that are integral to accessing information in Internet contexts (Leu *et al.*, 2004; Spiro, 2004). The research in this area is lean, but points to the challenges that school-aged students experience when conducting inquiry on the Internet (Lyons *et al.*, 1997) and trying to use information that has been located there (Wallace *et al.*, 2000). Using case study and verbal-protocol analysis methodologies, Coiro and Dobler (2007) investigated how skilled sixth-grade readers searched a number of multilayered websites carrying out an array of activities (e.g., looking for answers to both literal and inferential questions). Their findings illustrated the broad array of processes their participants engaged in, including conventional strategies, such as goal setting, predicting, comprehension monitoring, and evaluation of relevancy, in addition to novel and more complex reading processes such as drawing upon prior content knowledge in hand with knowledge of website structures and Web-based search engines.

Theory Development Regarding Reading in Relationship to Technology

The preponderance of theory development informing our understanding of text comprehension has been conducted with traditional print text. There have been numerous and vivid attempts to capture the differences between traditional (print) text, multimedia, and electronic media and the implications of these differences for defining and studying literacy, broadly writ. Typically, while print literacy is described as linear, ordered, sequential, hierarchical, and logical, hypertext is characterized as fluid, spatial, decentered, bottom up, and playful (Burbulus, 2001; Ryan, 1999).

Reflecting these differences in text, there is a lively discussion in the literacy community about the need for expanded definitions of literacy and new theories that place ICTs at their center. Leu *et al.* (2004) argue that for the past 500 years, literacy has emerged from a variety of social contexts but has primarily been shaped by the book and printing press. But today, both the social context and technologies are rapidly changing; ICTs and the Internet are in the process of becoming the central technologies of literacy. Such a change demands new theory that acknowledges the changing nature of literacy as a function of technology, the multiple literacies called for, and enabled by new technologies, and the new forms of

strategic knowledge necessary for engaging in new literacies. Fruitful theoretical stances that seem well-matched to ICTs include: social semiotic theory (Lemke, 1998), cognitive flexibility theory (Spiro *et al.*, 1991), cultural theory (Cope and Kalantzis, 2000), and social and linguistic theory (Chandler-Olcott and Mahar, 2003). The next generation's encyclopedia entry on reading and technology is likely to reveal the fruits of applying these theoretical perspectives to the study of reading.

Summary

Burgeoning research and development in the area of technology has dramatically affected the landscape of opportunities for the teaching and learning of print literacy. Technology has been used to support learners in the areas of emergent literacy, phonemic awareness and phonics, fluency, vocabulary, and comprehension. While the utility of computers in preschool is constrained by availability, software has been used to support emergent readers' engagement with rich print materials. Software programs that support young learners' mastery of phonics and fluency development have demonstrated effectiveness, largely due to the need for extensive practice and extended exposure in these areas. Vocabulary development is also aided by the multiple varied encounters to important words that electronic texts can offer. Technology has been used to support reading comprehension in at least three ways: supporting decoding, offering multiple representations of texts, and teaching students to be more strategic in their reading of text. The Internet has provided learners with a new medium for developing literacy skills. Limited research in this area has shown that readers must be particularly flexible and purposeful when accessing information via the Internet.

Technological Supports for Acquiring Twenty-First-Century Skills

C Dede, Harvard Graduate School of Education, Cambridge, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Augmented reality – A simulated experience created by interweaving real and digital people, places, and objects.

Avatar – The digital representative of a participant in a virtual world.

Complex communication – The ability to help others master complicated concepts through providing a variety of explanations and examples.

Data mining – The techniques used to find and interpret interesting patterns in very large data sets.

Digital literacy – The types of fluent use of tools, applications, and media to accomplish complex tasks.

Expert decision making – The ability to solve difficult problems for which all standard methods of problem solving fail.

Immersive media – The emerging media, such as multi-user virtual environments and augmented realities, in which the user has the sensation of being present in a digitally created world.

Multi-user virtual environment (MUVE) – A virtual world containing the avatars of users, computer-based agents, and digital artifacts.

Situated learning – Learning through apprenticeships and mentoring on authentic, real-world tasks.

Skills Needed for Twenty-First-Century Work and Citizenship

The twenty-first century seems quite different from the twentieth in the capabilities people that need for work, citizenship, and self-actualization. In response, society's educational systems must transform their objectives, curricula, pedagogies, and assessments to help all students attain the sophisticated outcomes requisite for a prosperous, attractive lifestyle based on effective contributions in work and citizenship. This article describes an innovative strategy by which new pedagogies based on emerging immersive media can aid all students in attaining sophisticated twenty-first-century skills and knowledge.

Thus far, the twenty-first century has seen a dramatic shift in the economic model for industrialized countries

(Dede *et al.*, 2005). Systems of economic development based on geography, trade rules, and tariffs; slow dissemination of scientific and technological discoveries; and long cycles of product life have given way to global trade, rapid product innovation, the lowering of trade barriers, rapid dissemination of scientific and technological discovery, and quick global deployment and movement of capital and the means of production (Chang, 2003). In the early twenty-first century, income and wealth come from applying technology and novel ideas to create new products and processes. Adding value to products and processes is the key to growing jobs and incomes in this new economic environment (Aubert and Reiffers, 2004).

Numerous reports on the global, knowledge-based economy and the flat world document that tomorrow's workers must be prepared to shift jobs and careers more frequently, to be flexible and adaptable in acquiring job skills, and to integrate and focus a changing mix of job-derived and education-based knowledge on business processes and problems (Card and Dinardo, 2002; Business-Higher Education Forum, 2005; National Academy of Science, 2006; American Association of Colleges and Universities, 2007). As the global economy continues to evolve, predictions are that workers will change jobs seven or eight times during their work life. The worker of the twenty-first century must have science and mathematics skills, creativity, fluency in information and communication technologies (ICT), and the ability to solve complex problems (Friedman, 2005); these are also important capabilities for citizenship at the local, national, and global level.

Further, the types of work done by people, as opposed to the kinds of labor done by machines, are continually shifting as computers and telecommunications expand their capabilities to accomplish human tasks. Economists Levy and Murnane (2004) have documented a very important aspect of what constitutes twenty-first-century understandings and performances:

Declining portions of the labor force are engaged in jobs that consist primarily of routine cognitive work and routine manual labor – the types of tasks that are easiest to program computers to do. Growing proportions of the nation's labor force are engaged in jobs that emphasize expert thinking or complex communication – tasks that computers cannot do. (pp. 53–54)

These economists go on to explain that “expert thinking [involves] effective pattern matching based on detailed

knowledge; and metacognition, the set of skills used by the stumped expert to decide when to give up on one strategy and what to try next” (Levy and Murnane, 2004: 75). What a skilled auto-mechanic does when all diagnostic systems show normal functioning, but the car is still malperforming is expert decision making – inventing new problem-solving heuristics when all standard strategies have failed. “Complex communication requires the exchange of vast amounts of verbal and nonverbal information. The information flow is constantly adjusted as the communication evolves unpredictably” (Levy and Murnane, 2004: 94). A skilled teacher is an expert in complex communication, able to improvise answers and facilitate dialog in the unpredictable, chaotic flow of classroom discussion.

Twenty-first-century education needs to prepare students for a world in which almost all types of routine cognitive tasks are done by computers and in which expert thinking and complex communications are the core intellectual capabilities by which people attain prosperity and economic security individually, as a region, and as a nation. These higher-order performances are based on fundamental knowledge about how to do simpler types of work, so the shift needed is not to remove the learning of routine cognitive skills (such as basic arithmetic operations) from the curriculum. Rather, the fundamental change involves deemphasizing fluency in simple procedures as an end-goal of preparation for work and life (e.g., counting bills as a bank teller), and instead using these routine skills as a substrate for mastering complex mental performances valued in the future workplace, such as advising clients about global investment strategies tailored to their individual situations.

Thus, a crucial challenge for education in all countries is to align curriculum and learning to new economic and governance models based both on a global, knowledge-based workplace and on emerging world-level problems such as human-induced climate change (Friedman, 2008). To accomplish this, we must transform children’s learning processes in and out of school and engage student interest in gaining twenty-first-century skills and knowledge for work, citizenship, and a satisfying lifestyle.

Organizing Twenty-First-Century Skills into a Curricular Framework

A variety of groups have developed frameworks that describe the twentieth-century skills that students should master as part of their education. Space does not permit summarizing and comparing all these descriptions. Such litanies of twenty-first-century skills often lack clarity about why a skill is twenty-first-century, as opposed to knowledge that has been generically useful at any point in history. Determining what constitutes a twenty-first-century skill requires stipulating the metrics by which one judges whether a human performance is truly significant in

its projected importance to attaining an attractive, prosperous job and lifestyle – and also is sufficiently different from twenty-first-century skills to merit inclusion. Assessing the degree to which the capability is valuable in work, and citizenship is key to these metrics, as is distinguishing in kind between perennial and contextual performances.

For example, collaboration is a perennial capability, always valued as a trait in workplaces across the centuries; as such, the basic value of this interpersonal performance is not intrinsically special to our emerging economic context. However, the degree of importance for collaborative capacity is growing in an era where work is increasingly done by teams of people with complementary expertise and roles, as opposed to individuals doing manual operations on an assembly line. Thus, even though perennial in nature, collaboration is worthy of inclusion as a twenty-first-century performance because, for the context in which today’s students will function as adults, the importance of cooperative interpersonal capabilities is substantially higher than in the prior industrial era.

In contrast, the ability to rapidly filter huge amounts of incoming data, extracting information valuable for decision making, is a contextual capability. Due to the prevalence of ICT, for the first time in human history people are inundated by enormous amounts of data that they must access, manage, integrate, and evaluate. The ability to separate signal from noise in a potentially overwhelming flood of incoming data is a twenty-first-century performance not in degree but in kind – because this is novel in history as a valuable capability. This distinction is important because, unlike perennial capabilities, new types of human performances are typically not part of the legacy curriculum inherited from twentieth-century educational systems.

Some frameworks for twenty-first-century skills discuss new literacies based on the evolution of ICT (Dede, 2008). For example, Jenkins *et al.* (2006) delineate a set of novel literacies based on new media (**Table 1**).

This list illustrates how twenty-first-century skills, such as collaboration and information filtering, are linked to the capabilities of emerging interactive media.

Dede *et al.* (2005: 5) describes the types of learning strengths, styles, and preferences of what he calls neomillennial students. These students are defined not by the timeframe of their birth but by the way they like to learn – through use of immersive collaborative media, such as multiplayer online games or virtual environments like Second Life:

- fluency in multiple media, valuing each for the types of communication, activities, experiences, and expressions it empowers;
- learning based on collectively seeking, sieving, and synthesizing experiences, rather than individually locating and absorbing information from some single best source;

Table 1 Selected new literacies delineated by Jenkins *et al.* (2006)

Play	The capacity to experiment with one's surroundings as a form of problem solving
Performance	The ability to adopt alternative identities for the purpose of improvisation and discovery
Simulation	The ability to interpret and construct dynamic models of real-world processes
Appropriation	The ability to meaningfully sample and remix media content
Multitasking	The ability to scan one's environment and shift focus as needed to salient details
Distributed cognition	The ability to interact meaningfully with tools that expand mental capacities
Collective intelligence	The ability to pool knowledge and compare notes with others toward a common goal
Judgment	The ability to evaluate the reliability and credibility of different information sources
Transmedia navigation	The ability to follow the flow of stories and information across multiple modalities
Networking	The ability to search for, synthesize, and disseminate information
Negotiation	The ability to travel across diverse communities, discerning and respecting multiple perspectives, and grasping and following alternative norms

From Jenkins, H., Clinton, K., Purushotma, R., Robinson, A. J., and Weigel, M. (2006). *Confronting the Challenges of Participatory Culture: Media Education for the 21st Century*. Chicago, IL: The MacArthur Foundation, with permission from Henry Jenkins.

- active learning based on experience (real and simulated) that includes frequent opportunities for reflection;
- expression through nonlinear, associational webs of representations rather than linear stories (e.g., authoring a simulation and a web page to express understanding, rather than a paper); and
- co-design of learning experiences personalized to individual needs and preferences.

As discussed later, using immersive collaborative simulations in classroom settings offers a powerful method to nurture twenty-first-century skills.

Leu *et al.* (2007) describe four characteristics of the new literacies generated by ICT. First, emerging ICT tools, applications, media, and environments require novel skills, strategies, and dispositions for their effective use. Second, new literacies are central to full economic, civic, and personal participation in a globalized society. Third, new literacies constantly evolve as their defining ICT continuously are renewed through innovation. Fourth, new literacies are multiple, multimodal, and multifaceted.

Leu's third point raises important issues about stability: How durable are twenty-first-century performances in their applicability to work, citizenship, and self-actualization? How quickly will additional, important twenty-first-century understandings and behaviors emerge as ICT continue to evolve? Certainly, tools, applications, media,

and environments are changing rapidly, with no end in sight. Typically, despite predictions of paperless offices or the end of the book, this evolution involves adding additional literacies and understandings rather than new performances displacing previously useful behaviors. Examining predictions about the future of ICT helps to illuminate what these additional literacies may be and what knowledge and skills may become less useful over time.

Overall, the skills advocated by various groups as twenty-first century are sophisticated cognitive, affective, and psychosocial performances generally manifested through fluent use of digital tools and media. In the twenty-first century, people frequently use ICT to accomplish objectives never before attainable (e.g., remote collaboration via groupware among a team scattered across the globe). How can we not only prepare today's students for the new jobs generated by these capabilities, but also build their capacity to hold novel careers that will emerge a decade or two from now based on future breakthroughs in ICT and other fields?

An Innovative Strategy for Teaching Illustrative Twenty-First-Century Skills

The remainder of this article describes how innovative, technology-aided pedagogies can help students learn sophisticated cognitive, affective, and psychosocial performances important for twenty-first-century work and citizenship. A cluster of twenty-first-century skills neglected in most current curricula is collective problem resolution via mediated interaction. In twenty-first-century work, knowledge is grounded in a setting and distributed across a community, rather than abstract and isolated within individuals (OECD, 2004). Problem finding (the front end of the inquiry process: making observations and inferences, developing hypotheses, and conducting experiments to test alternative interpretations of the situation) is crucial to reaching a point where the work team can do problem solving. Individual and collective metacognitive strategies for making meaning out of complexity (such as making judgments about the value of alternative problem formulations) are vital.

Each person involved in this interrelated suite of twenty-first-century skills has strong strategies both in effective pattern matching based on detailed knowledge and in judging when to give up on a particular problem-solving strategy and instead try another approach. Individuals on the work team are adept at manipulating sophisticated ICT applications and representations utilized within the complementary perspectives they bring to bear (e.g., using a spreadsheet to examine financial hypotheticals). They also are skilled in expressing core insights from their knowledge to others who have different backgrounds and experiences. Richly interactive

complex communication among team members is not limited to face-to-face dialog, but frequently relies on mediated interaction across distance in which the team co-constructs and negotiates shared interpretive understandings and a problem-resolution strategy.

For example, a school district might task a team of teachers, school administrators, parents, and local business executives to develop a plan for improving students' educational outcomes in mathematics. Potential factors leading to subpar educational performance include individual differences in native language, gender, culture, and socioeconomic status; teachers' experience and preparation in mathematical content, subject-specific pedagogy, classroom management, and student engagement; state and district policies related to educational reform, the curricular materials used in mathematics, and the capacity of the technology infrastructure at local schools, among others. Under these circumstances, individual and collective skills in problem finding, inquiry, metacognition, collaboration, expert decision making, complex communication, and use of ICT tools, communicative media, and representations are vital to the team's success.

In classroom settings, sophisticated ICT capable of supporting the teaching of such collective problem resolution via mediated interaction are now emerging. This is important because, until this point in history, schools have lacked the capacity to inculcate twenty-first-century skills and knowledge best learned through participation in real-world communities of practice. Reports such as the National Research Council's *How People Learn* cite situated theories of learning (mentoring and apprenticeships in communities of authentic, real-world practice) as powerful in life, but very difficult to achieve in school settings. Emerging interactive media now have the capability to redress this deficit, a vital advance in teaching many twenty-first-century skills.

Emerging Media for Situated, Immersive, and Collaborative Simulation

Three complementary technological interfaces are currently shaping how people learn, with multiple implications for K-12 education:

- The familiar world-to-the-desktop interface provides access to distributed knowledge and expertise across space and time through networked media. This interface provides the models for learning that now underlie most tools, applications, and media in K-12 education.
- Emerging multi-user virtual environment (MUVE) interfaces offer students an engaging Alice-in-Wonderland experience in which their digital emissaries in a graphical virtual context actively engage in experiences with the avatars of other participants and with computerized agents. Researchers are exploring

the affordances of such models for learning in K-12 education (Dede, 2009).

- Augmented reality (AR) interfaces enable ubiquitous computing models. Students carrying mobile wireless devices through real-world contexts engage with virtual information superimposed on physical landscapes (such as a tree describing its botanical characteristics or an historic photograph offering a contrast with the present scene). This type of mediated immersion infuses digital resources throughout the real world, augmenting students' experiences and interactions. Scholars are starting to study how these models for learning aid students' engagement and understanding (Klopfer, 2008).

MUVEs empower creating digital contexts inaccessible in the real world, while AR enables the infusion of virtual contexts within physical locations. For reasons of space, only the MUVE interface is used as an example of immersive collaborative simulation to teach twenty-first-century skills.

In a MUVE, knowledge is grounded in a setting and distributed across a community, rather than isolated within individuals. Contrary to conventional K-12 instruction where knowledge is decontextualized and explicit, in MUVEs, the learning is situated and tacit; problem finding is central to problem solving. This parallels the nature of twenty-first-century work, as well as the learning styles and strengths of today's digital-age students.

The Power of Situated Learning for Inculcating Twenty-First-Century Performances

Situated learning requires authentic contexts, activities, and assessment coupled with guidance from expert modeling, mentoring, and legitimate peripheral participation. As an example of legitimate peripheral participation, graduate students work within the laboratories of expert researchers, who model the practice of scholarship. These students interact with experts in research as well as with other members of the research team who understand the complex processes of scholarship to varying degrees. While in these laboratories, students gradually move from novice researchers to more advanced roles, with the skills and expectations for them evolving. Potentially quite powerful, situated learning is infrequently used for classroom instruction because classrooms are by design isolated from the real world in order to encourage reflection and to provide custodial care. However, immersive interfaces can draw on the power of situated learning even in school settings by enabling collaborative simulations with problems and contexts similar to the real world.

Situated learning is important in part because of the crucial issue of transfer. Transfer is defined as the application of knowledge learned in one situation to

another situation and is demonstrated if instruction on a learning task leads to improved performance on a transfer task, typically a skilled performance in a real-world setting. One of the major criticisms of instruction today is the low rate of transfer generated by conventional instruction. Even students who excel in schooling or training settings often are unable to apply what they have learned to similar real-world contexts. Situated learning addresses this challenge by making the setting in which learning takes place similar to the real-world context for performance in work or personal life. Learning in well-designed digital contexts can lead to the replication in the real world of behaviors successful in simulated environments (Schwartz *et al.*, 2005).

Moreover, the evolution of an individual's or group's identity is an important type of learning for which simulated experiences in immersive interfaces are well suited. Reflecting on and refining an individual identity is often a significant issue for students of all ages (Colwell, 2007), and learning to evolve group and organizational identity is a crucial skill in enabling innovation and in adapting to shifting contexts (Engeström and Middleton, 1996). The social sciences see both the self and the organization as often fragmented, with complementary parts, rather than centralized and unitary (Sternberg and Zhang, 2001). Identity play through trying on various representations of the self and the group in virtual environments provides a means for different sides of a person or team to find common ground and the opportunity for synthesis and evolution, vital for the affective and psychosocial aspects of learning twenty-first-century skills.

Immersion is important in this process of identity exploration because virtual identity is potentially unconstrained by physical attributes such as gender, race, and disabilities, even though individuals often infuse these attributes into their avatars (Everett and Watkins, 2008; Pitaru, 2008). Virtual environments based on games and simulations illustrate how participants take advantage of fluidity in the identities they present. Simulations in virtual environments and augmented realities increase the value of these explorations by providing realistic feedback on how the real world responds to various patterns of individual and group behavior.

But what is so special about the situated learning now enabled in classrooms by emerging media? After all, outside of school contexts, students have opportunities for situated learning without using technology. One attribute that makes mediated immersion different and powerful is the ability to access information resources and psychosocial community distributed across distance and time, broadening and deepening experience. A second important attribute is the ability to create interactions and activities in mediated experience not possible in the real world, such as teleporting within a virtual environment, enabling a distant person to see a real-time image of

your local environment, or interacting with a (simulated) chemical spill in a busy public setting. Both of these attributes are actualized in immersive interfaces.

Learning Twenty-First-Century Skills in the River City MUVE

With funding from the National Science Foundation, for almost a decade, the author's research team has used design-based research methods to study an educational MUVE called River City. In the River City MUVE, a participant takes on the identity of an avatar, a virtual personal in the world, and communicates with other participants' avatars via text chat and virtual gestures. In this graphical virtual context (Figure 1), participants also interact with digital artifacts, such as viewing pictures or manipulating tools (e.g., an online microscope), as well as with computer-based agents (Figure 2).

The River City curriculum is a middle school science unit designed around national content standards and assessments in biology, ecology, epidemiology, and scientific inquiry. Students work in teams of three to collaboratively solve the problem of why the residents of River City are falling ill. Students travel back in time – into a series of virtual worlds – to the period in history when scientists were just discovering bacteria.

The curriculum is historically accurate and contains pictures from the Smithsonian Institute that help to portray accurately what the time period was like. The River City virtual world is an industrial eighteenth-century city with a river running through it (see Figure 3). Different forms of terrain influence water runoff in the various neighborhoods (wealthy area, middle-class area, and tenements). Digital artifacts include audio clues of sick residents coughing or mosquitoes buzzing, as well as images from that period in history (Figure 4).

Engaging in inquiry also involves students learning how to collect data and test their hypotheses and use the tools of scientists, such as an online microscope. For example, in River City, students can use the virtual microscope to

Figure 1 Aerial view of River City.

take water samples from one of the water-sampling stations in the city (Figures 5 and 6).

Students use twenty-first-century knowledge and skills to identify a problem and then develop and test a hypothesis based on one of the three disease strands infecting the city (i.e., insect-borne, air-borne, and water-borne). After testing

their hypotheses, students analyze their data and then write up their research in the form of a report to the mayor of River City. The report, based on the concept of a lab report, describes their experiment, research findings, conclusions, and recommendations for how the mayor can stop the spread of illness in River City.

These reports constitute representations of students' inquiry learning. From a technical standpoint, MUVEs are unique in their ability to keep minutely detailed records of the moment-by-moment movements, actions, and utterances of each participant in the environment. With the data-tracking system, we are able to collect, store, and retrieve information on the activities of each student as s/he explores the MUVE. These data form the basis of a personal MUVE history of each student that follows him or her from session to session, in the form of extensive log files – a feature impossible to replicate in a classroom-based experience. The level of detail in these records is extensive: the logs indicate exactly where students went, with whom they communicated, what they said in these interactions, what virtual artifacts they activated, and how long each of these activities took. Using data-mining techniques on these detailed event logs provides a powerful lens by which we can study individual students' use of twenty-first-century skills in this learning environment and document gains in students' engagement, learning, and self-efficacy.

Conclusion

This extended example illustrates how situated, immersive, collaborative simulations based on MUEs can support twenty-first-century understandings and performances, such as collective problem resolution via mediated interaction, while in classroom settings. Other immersive interfaces, such as AR, can accomplish similar engagement and learning. Over time, these interfaces are becoming increasingly prevalent (Dede, 2009), and research is revealing how best to actualize their potential for learning and teaching.

A huge challenge confronts efforts to implement new technologies such as those as described in this article: What do we deemphasize in current instruction and assessment to make room for twenty-first-century understandings? The curriculum is crowded with low-level facts and recipe-like procedures (e.g., In what year did Columbus discover America? What are the seven steps of historical inquiry?), as opposed to nuanced understandings and performances. (i.e., what confluence of technological, economic, and political forces led to the age of exploration around the end of the fifteenth century? By what process of interpreting historical data did you reach this conclusion?)

Downgrading the importance of some material in the current curriculum is much harder than adding content

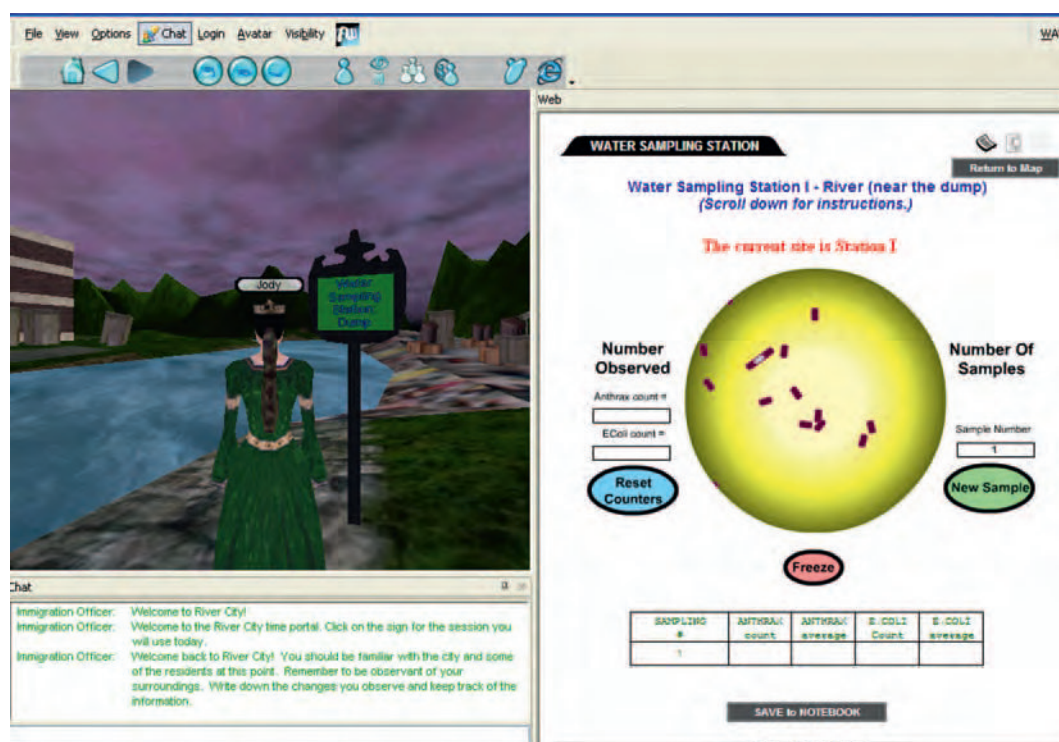

Figure 5 Taking a water sample with the virtual microscope.

Figure 6 Close-up of microscope. Students click 'Freeze' and count the number of *E. coli* and anthrax in the water.

and skills because omission requires unlearning on the part of adults. A major challenge in professional development is helping teachers, policymakers, and local communities unlearn the beliefs, values, assumptions, and cultures underlying schools' standard-operating practices, such as 45-min class periods that allow insufficient time for all but superficial forms of active learning by students. Altering deeply ingrained and strongly reinforced rituals of schooling takes more than the superficial interchanges typical in make-and-take professional development or school board meetings. Intellectual, emotional, and social support is essential for unlearning and for transformational relearning that can lead to deeper behavioral changes to create next-generation educational practices. Educators, business executives, politicians, and the general public have much to unlearn if twenty-first-century understandings are to assume a central place in schooling.

Technology Supports for Acquiring Inquiry Skills

T de Jong, University of Twente, Enschede, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The idea of inquiry, or scientific discovery, as a learning approach has a long history (Bruner, 1961; Dewey, 1938) and has frequently been promoted as an educational reform. Learning theorists and psychologists such as Piaget and Papert have endorsed the idea of inquiry learning where learners draw on their own experiences and prior knowledge to discover what needs to be learned. Leading organizations have acknowledged inquiry as an important aspect of schooling. For example, in 1989, the American Association for the Advancement of Science (AAAS) stated that: "In learning science, students need time for exploring, for making observations, for taking wrong turns, for testing ideas, for doing things over again; time for building things, calibrating instruments, collecting things, constructing physical and mathematical models for testing ideas; time for learning whatever mathematics, technology, and science they may need to deal with the questions at hand; time for asking around, reading, and arguing; time for wrestling with unfamiliar and counterintuitive ideas and for coming to see the advantage in thinking in a different way" (American Association for the Advancement of Science, 1989). This has led to inquiry becoming an explicit part of the curriculum for many nations, including the United States (National Research Council, 1996).

Inquiry learning has a number of potential learning outcomes. First, inquiry learning can be used to learn about a domain, for example, physics, that is the subject of the inquiry process. Learning a domain through inquiry has been studied extensively (see e.g., de Jong, 2006a; de Jong and van Joolingen, 1998; Linn *et al.*, 2006). Second, engagement in the inquiry process means that inquiry or scientific thinking skills can be acquired (White and Frederiksen, 2005). Third, through inquiry, students can acquire positive attitudes toward the domain or toward science in general (Cognition and Technology Group at Vanderbilt, 1992).

In this article, the focus is on acquiring inquiry skills. As a further focus technological environments are used (i.e., computer simulations) as the contexts for learning. The article starts with an overview of inquiry learning processes. Next, a short overview of technological environments suited for inquiry learning is presented. Then, scaffolds that can be incorporated in these technology-based environments to support acquisition of inquiry skills are described. Finally, a short research agenda is discussed.

The Inquiry Process

Scientific literacy is an important goal in many curricula. While there is not one agreed-upon definition of scientific literacy, it embraces aspects such as, for example, understanding the nature of science, as well as ideas of how the scientific process works (Millar, 2006). Inquiry is the central process of scientific advancement. The National Research Council (NRC), in 1996, defined inquiry as:

Inquiry is a multifaceted activity that involves making observations; posing questions; examining books and other sources of information to see what is already known; planning investigations; reviewing what is already known in light of experimental evidence; using tools to gather, analyze, and interpret data; proposing answers, explanations, and predictions; and communicating the results. Inquiry requires identification of assumptions, use of critical and logical thinking, and consideration of alternative explanations. (National Research Council, 1996)

This description lists a large set of processes that constitute inquiry learning. De Jong (2006b) presented a number of processes that encompass the many facets of inquiry as formulated by the NRC: orientation, hypothesis generation, experimentation (experiment design, prediction, data interpretation), drawing a conclusion, and making an evaluation. Similar processes constitute the inquiry cycle specified by others. White and Frederiksen (2005), for example, distinguish development of a research question, generation of hypotheses, investigation design, analyzing data, model creation, and evaluation. Besides these transformative processes, inquiry also requires regulative processes such as planning and monitoring (de Jong and van Joolingen, 1998). Zimmerman (2007), for example, points to the importance of record keeping as an activity within inquiry learning. Inquiry skills can be seen as a distinct skill set, apart from general metacognitive skills (Veenman *et al.* 2002). In their study of the economics of an intelligent tutoring system, Smithtown *et al.* (1990) concluded that general intelligence is certainly a component of discovery learning, but that specific scientific behaviors account for considerably more variance (p. 71). Schunn and Anderson (1999) showed that discovery skills are distinct from general reasoning ability and that they can be learned and transferred from one research area to another.

What Constitutes Skillful Inquiry?

Possessing adequate inquiry skills means knowing the overall structure of the inquiry process and its constituent processes and also knowing how to execute these processes. In an earlier work, de Jong and van Joolingen (1998) outlined a number of difficulties that students have with inquiry processes; several of these were also recently identified in an overview of inquiry in children (Zimmerman, 2007).

Hypothesis generation is probably one of the most central processes in inquiry learning. Shute and Glaser (1990) found that learners with hypothesis-driven behavior have better learning outcomes. De Jong and Van Joolingen (1998) described several difficulties learners generally encounter in hypothesis generation. These difficulties have two aspects. First, learners may have problems simply with forming hypotheses (Njoo and de Jong, 1993), which may result in conducting experiments that are not guided by a hypothesis. Second, they may be unable to adapt their hypotheses on the basis of experimental evidence (Chinn and Brewer, 2001; Klahr and Dunbar, 1988; Kuhn *et al.*, 1995). Difficulties with coordinating hypotheses and experimental data may be more pronounced for children than they are for adults (Kuhn *et al.*, 1988; Wilhelm *et al.*, 2005).

Experiment design is another crucial aspect in inquiry learning. The most-valued experimental strategy is the so-called vary-one-thing-at-a-time (VOTAT) or control-of-variables (CVS) strategy (Chen and Klahr, 1999). Learners using this strategy focus on the effects of one variable. The alternative of holding one variable constant and varying all other variables leads to confounded experiments. Though there is considerable inter- and also intra-individual variation in the use of strategies (Schauble, 1996), there is evidence that designing proper experiments is a trainable skill (Kuhn *et al.*, 2000) and that there is age-related and experience-related development in the use of controlled experiments (Zimmerman, 2007).

A third important aspect of skillful inquiry is the ability to regulate the learning process. This concerns processes such as planning and monitoring. In inquiry-learning environments, which have by nature a relatively open character, a multitude of routes is open to students, stressing the importance of an overall plan of where to go. Since results from inquiry do not organize themselves, careful monitoring of the learning process is also necessary. Research has shown that active regulation leads to higher learning gains (Azevedo *et al.*, 2004). Surprisingly, however, students do not seem very active in regulating their inquiry process (Manlove and Lazonder, 2004).

A number of studies have identified characteristic differences between successful and unsuccessful students. Lavoie and Good (1988) studied the cognitive processes of 14 high school students learning about water pollution with a simulation. One of the comparisons they made

concerned the cognitive processes of good and poor predictors (students received a prediction test after the simulation). The main differences were that compared to poor predictors, good predictors used more abstract reasoning (e.g., introducing qualitative scales for variables), worked in a more systematic way (e.g., changing only one variable at a time, more often returning variables to baseline conditions, and more frequently looking for worst and best conditions), made notes during the exploration, were able to find more complex relations (bidirectional and ratio relations), and showed a high interest and motivation (e.g., by persisting to complete the learning sequence). Thus, it seems that successful predictors conduct more informative experiments (e.g., by controlling extraneous variation, changing one variable at a time, and returning variables to baseline conditions) and are better able to interpret the data (e.g., inferring regularities in the data, finding more complex relations). In a similar vein, Schauble *et al.* (1991) compared the discovery behavior of learners who were successful in learning with a simulation on electricity with those who were unsuccessful. They found that both groups of students were equally active in the simulation but that good learners performed better in: "... the class of evidence generation (controlling extraneous variation), evidence interpretation (generating and evaluating alternative hypotheses, inferring regularities in the data, producing sufficient evidence to support a hypothesis), data management (systematic data recording), and planning (developing plans that are goal oriented rather than procedure oriented)" (p. 223). Klahr *et al.* (1993) observed the discovery behavior of learners in the Big Trak environment. They identified a number of successful heuristics for hypothesis generation and experiment design, such as designing simple experiments to enable monitoring, designing experiments that give characteristic results, focusing on a single dimension of a hypothesis, and exploiting surprising results.

Traditional environments for inquiry learning include practicum and laboratory experiences (see Minstrell and Kraus, 2005, for a series of examples), but today there are opportunities to use technology-based learning environments that are specifically geared toward inquiry learning and that may also contain specific scaffolds for inquiry-learning processes.

Technology-Enhanced Inquiry-Learning Environments

Technological environments that are specifically suitable for inquiry learning include simulations, games, and adventures, remote labs, data sets, and hypermedia environments. All these environments are based on the fact that the knowledge that needs to be acquired is not presented explicitly to learners but must be inferred from the environment.

Students, for example, have to infer the relations between variables by manipulating them and observing their behavior; this relation is not explicitly given in the environment. An exception to this might be hypermedia environments (e.g., WISE; see Linn *et al.*, 2004b) where information often is partly offered in a more direct way. In all the other environments, students must make inferences themselves to see the information that is in the environment.

A basic form of inquiry learning is the situation in which learners perform experiments by manipulating values of variables and observe outcomes of their experiments. This type of inquiry can take place in physical laboratories, such as the wooden ramp in the work of Klahr and Nigam (2004) or in technology-enhanced learning (TEL) environments. TEL environments may mimic the real laboratory (van Joolingen *et al.*, 2005) or provide learners with virtual environments based on simulations (Blake and Scanlon, 2007; de Jong and van Joolingen, 1998), or, in exceptional cases, include a combination of real and virtual offerings (Zacharia, 2007). The advantages of TEL environments are that they provide students with a safe environment in which experimentation can be done (and redone) quite effortlessly. In addition, technology enables the inclusion of scaffolds for students (see later). In studies, where a comparison between physical and virtual learning environments are made, there is an advantage for students in virtual environments on the acquisition of conceptual knowledge (Zacharia and de Jong, in preparation).

Zimmerman (2007: 217) lists several studies that show that just performing inquiry tasks leads to more skillful execution of inquiry processes. It is, however, now clear that effective learning is only realized through a scaffolded or supported inquiry process (Mayer, 2004). These effects have principally been found for domain knowledge, but effects on inquiry skills are also reported (Linn *et al.*, 2006).

Inquiry Scaffolds and the Acquisition of Inquiry Skills

Technology-enhanced inquiry environments provide the opportunity to include cognitive scaffolds in the software. Overviews of such scaffolds appeared in de Jong and van Joolingen (1998), Quintana *et al.* (2004), Linn *et al.* (2004a), and de Jong (2006b). This section explores which technological scaffolds are available for pivotal inquiry processes.

Hypothesis generation is one of the central processes in inquiry learning, but it also seems to be the most difficult one to support. Many learning environments provide students with assignments or at least issues that need investigation (de Jong, 2006b). This seems a straightforward and effective strategy since research has shown the benefits of providing students with readymade

hypotheses (Njoo and de Jong, 1993). The Inquiry Island environment (e.g., White and Frederiksen, 2005) includes a specific advisor (called Ingrid Inventor) who helps students brainstorm new ideas. The process of creating hypotheses can be supported by giving students a so-called hypothesis scratchpad – a tool that helps students to create testable hypotheses (Shute and Glaser, 1990; van Joolingen and de Jong, 2003). Basically, a hypothesis scratchpad provides students with elements of hypotheses (variables, relations, and conditions) that they can combine to form a testable hypothesis. So far, however, studies have been unable to demonstrate advantages of the use of hypothesis scratchpads (see e.g., Gijlers and de Jong, 2005).

Scaffolding the design of experiments is frequently done by providing students with experimentation hints. These hints are often heuristics for performing experiments (Veermans *et al.*, 2006). The most well known of these heuristics is the CVS or the VOTAT strategy (Klahr, 2005; Klahr and Nigam, 2004; Kuhn, 2005; Kuhn and Dean, 2005). Veermans *et al.* (2006) present a longer list of other heuristics, such as simplified values, design experiments that give characteristic results, and use of extreme values. Kuhn and Dean (2005) found that simply suggesting that students focus on one variable resulted in this behavior even when the hints were no longer present. In addition, students following this strategy were also better in drawing inferences from experimental data. Hulshof and de Jong (2006), however, found an effect of this type of hint only on domain knowledge and not on inquiry skills. Teachers can also give direct instruction on how to design experiments. Klahr and Nigam (2004) found that students who received an explanation of the CVS strategy along with examples of good and poor experiments were more successful in acquiring CVS skills than were students who received no instruction. Keselman (2003) found that a group of students who saw models of how to manipulate variables and make predictions improved most on domain knowledge and experiment design skills. Beishuizen *et al.* (2003) also found that training sixth graders on designing CVS experiments and inferencing skills gave students an advantage in finding interaction effects.

Planning of activities is supported at a higher level by presenting an overview of the inquiry cycle (Manlove *et al.*, 2007; White *et al.*, 2002). Manlove *et al.* (2007) found that students who were supported this way wrote better lab reports but constructed poorer models than students who did not receive this guidance. White *et al.* (2002) report better use of notebook facilities indicating understanding of inquiry by students working with Inquiry Island. White and Frederiksen (2005) report that students who learned with Inquiry Island showed higher gains on an inquiry test than students who received traditional instruction. At a more fine-grained level of planning, students can receive assignments that give

them short-term goals for action. For monitoring, students can be offered software scaffolds that help them save and reorganize experiments (van Joolingen and de Jong, 2003).

Conclusions and Research Issues

Research into inquiry skills reflects the complex nature of the topic. Inquiry as such is a comprehensive set of activities, and studies differ in the aspects of inquiry under investigation. In addition, the subjects' age levels, domains involved, and measuring techniques differ widely across studies. Finally, definitions of key terms such as discovery learning and direct instruction are certainly not unequivocal (Zimmerman, 2007). Despite this, some general conclusions can be drawn.

Most studies of inquiry learning have focused on the acquisition of domain knowledge. Studies that assessed the acquisition of inquiry skills concentrated mainly on experiment design. Combining an inquiry task with direct hints or instruction on how to perform informative experiments is clearly an effective approach for improving students' experiment-design skills. Several scaffolding methods that give students overall inquiry templates to work with exist for the support of regulative (planning and monitoring) skills. Following these inquiry templates leads to better inquiry skills. On the other hand, not many tools are available for the hypothesis-generation aspect of inquiry, and the effectiveness of existing tools is not established.

One development that the field would profit from would be a more widely accepted way of measuring inquiry skills. Currently, this ranges from performing a short inquiry cycle (White and Frederiksen, 2005), experimenting in a domain-free specifically designed experimentation environment (Hulshof *et al.*, 2005), creating the design of an experiment (Klahr and Nigam, 2004), and evaluating existing experiment plans (Keselman, 2003) to general and domain-specific tests containing various types of questions (Linn *et al.*, 2006). The character of the inquiry test may well partially influence the experimental outcomes.

Two research developments seem promising for a more flexible and full scaffolding of the inquiry process. One is more adaptive scaffolding where scaffolds depend on the actual experimentation behavior of students. One of the first attempts toward this goal can be found in Veermans *et al.* (2006). The second direction is collaborative inquiry where collaborating learners help to scaffold and advance each other's inquiry skills (Gijlers and de Jong, 2009).

Technology Supports for Acquiring Mathematics

M J Nathan, University of Wisconsin-Madison, Madison, WI, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Technology has become essential to the practice of mathematics. Technology allows some areas of mathematics to flourish, such as the close relationships between fractal geometry with computer graphics, and statistics with computer programs (Ben-Zvi and Garfield, 2004; Frame and Mandelbrot, 2002). Technology also plays a special role in the learning of mathematics. Technology supports for mathematics education largely reflect the form and shifts of underlying theories of learning and intellectual behavior. Information processing (IP) theory and theories of cognitive skill acquisition and concept learning have been dominant influences in mathematics education for the last half century, and these are presented in the first section titled 'Skills and concept learning.' While these traditional cognitive perspectives on knowledge and learning continue to play a significant role in governing the types of technological resources for mathematics education (as well as shaping curriculum, instruction, and assessment practices more broadly), increasingly, designs of educational technology are being influenced by emerging theories of learning and practice. The second section titled 'Mathematical discovery' focuses on technologies that support learning by discovery. In the third section titled 'Collaborative problem solving,' collaborative learning technologies are presented that often draw on situated, social, and cultural perspectives of learning and constructivist views of knowledge. The fourth section titled 'Embodied cognition' reviews some of the newest technologies in craft and fabrication, inspired by emerging views of embodied cognition. Some systems appear in multiple places within this simple taxonomy. In the final section titled 'Challenges facing technology supports for acquiring mathematics,' some of the persistent challenges facing technologies for mathematical learning are discussed.

Skills and Concept Learning

There is a rich history of tools specifically designed for mathematics instruction, including formal systems of manipulatives such as Dienes' blocks, pattern boards, and Cuisenaire rods. Manipulatives are concrete objects that are designed to help students learn math concepts by representing the quantities, operations, and relations between quantities without requiring that the learner

use or comprehend the written (i.e., formal) representations of the same concepts (Uttal, 2003).

Generally, the use of math manipulatives as educational aids is predicated on a view of learning as the acquisition of skills and abstractions (Chao *et al.*, 2000). The mental tool view frames learning as the acquisition of skills and symbolic structures that parallel the physical states and actions of the objects. Learning from this perspective typically favors highly structured and consistent practice to enable the acquisition and speedup of procedures, which may eventually become automated. In the abstraction view, math learning is facilitated through generalization across a range of varied experiences that all model a common concept. This form of learned behavior tends to exhibit slower and more deliberate responses that are highly accurate, along with more frequent use of rudimentary strategies. Even with these trade-offs in mind, the research literature does not consistently show an advantage for manipulatives for math learning among primary grade students (e.g., Hiebert, 1989; Sowell, 1989; Uttal *et al.*, 1997).

Computer-based manipulatives and other instructional tools have emerged to capture the concrete qualities of materials along with the added control and flexibility of digital media. One of the earliest and most influential was Logo, which can be regarded as the forerunner of computers as microworlds, and objects-to-think-with. In a somewhat parallel fashion, graphing calculators emerged as hand-held tools for math activity and math instruction. These early forms also spawned computer algebra systems and more free-form modeling tools, such as Geometric Supposer and Geometer's Sketchpad.

Hand-Held Graphing Calculators

The first graphing calculator was introduced by Casio in 1985. However, graphing calculators exhibited a much greater influence on classroom learning in the early 1990s, with contributions from Hewlett-Packard and Texas Instruments (TI). The TI-82 (released 1993) and the ubiquitous TI-83 (1996; see **Figure 1**) transformed secondary and tertiary math education by putting into students' hands an affordable, portable, and accessible device that allowed them to analyze, program, and visualize mathematical procedures and structures. By the year 2000, over 80% of high-school mathematics teachers in the US who were surveyed, reported using hand-held graphing calculators in their classrooms (Hudson *et al.*, 2002).

Figure 1 Classroom teacher and students using the TI-83-Plus hand-held graphing calculator by Texas Instruments. Photo courtesy of Texas Instruments Education Technology.

Hand-held graphing technology has the potential to change the nature of mathematics instruction and learning, as well as alter the very content of the mathematics that gets taught in schools (Waits and Demana, 1994, 2000). However, reviews of US textbooks exhibit a fairly simplistic use of the technology (Burrill, 2004; Senk *et al.*, unpublished).

Internationally (in studies of Great Britain, Sweden, France, Australia, New Zealand, South Africa, Israel, Netherlands, and the United States), hand-held graphing-technology use generally facilitates learners' concept development and its use is predictive of higher performance gains and measures of problem-solving skills. Those who use graphing calculators show a better understanding of functions, applied problem solving in algebra, and interpreting graphs (Burrill *et al.*, 2002).

Studies suggest that the increased conceptual learning that accompanies use of graphing calculators does not come at the expense of building facility in procedural skills (Burrill, 2004). Frequent use of graphing calculators tends to accompany more graph use and greater flexibility with representations, solution strategies, and reasoning with real data. More broadly, classrooms with graphing calculator use tend to foster a more constructivist climate, with more conjecturing, more frequent use of multiple solutions, and higher levels of discourse than those classrooms with infrequent calculator use. Using graphing technology for nonroutine activities, such as mathematical discovery and complex problem solving, tends to support increased conceptual understanding and higher achievement, while use of technology for routine calculations does not (Dugdale *et al.*, 2004).

Computer Algebra Systems

The next major breakthrough was the incorporation of computer algebra systems (CASs) into calculators. The CASs allow users to perform mathematical operations on

symbolic expressions in support of problem solving, generalization, and reasoning about functions. The CAS made its way into hand-held calculators in the late 1980s with the HP-28, but it was when both Casio (the FX2.0, released in 1996) and TI released new models (the TI-92, released in 1995, and the TI-89 in 1998) that the technology became more affordable and more prevalent among high-school and then middle-school classes.

The promise is that CAS allows learners and teachers to focus on conceptual aspects of expressions and functions (Heid, 1988; Pierce and Stacey, 2007) rather than getting caught up with the mechanics of symbol manipulation, a benefit that may help low-performing students, in particular (Kuzler, 2000). The research does support this view, generally, though, as with other forms of calculators and technology, more generally, these influences are mediated by the types of lessons and instructional approaches. Scholars have shown that calculus students within conceptually oriented classrooms who used CAS demonstrated more conceptual knowledge than those who had skills-oriented lessons (Heid, 1988; Palmiter, 1991). CAS implemented in conjunction with other standards-based practices such as sense making and group discussions also supports college students' understanding and reasoning with symbolic expressions (Keller and Russell, 1997).

Geometric Supposer

In addition to support for skills in computation and symbol manipulation, there are powerful tools such as Geometric Supposer for supporting skills and concept development in geometric reasoning. Geometric Supposer is designed to support exploration and discovery of properties of Euclidean (plane) geometry by providing primitive operations for drawing, analyzing, measuring, and manipulating diagrams. Generalization across cases (induction) is supported by repeating operations on arbitrary exemplars, an experience which may assist students in formulating deductive proof. Geometric Supposer is one of the clearest examples of a system that instantiates many of the ideals of the constructivist philosophy of mathematics education because it allows direct access and construction to otherwise abstract objects, procedures, and concepts.

Although students typically struggle with using geometric diagrams, year-long use of Geometric Supposer has resulted in improvements with diagrams and students' understanding of the objects to which they refer, as well as the variety of ways that diagrams can be viewed and described (Yerushalmy and Chazan, 1990).

Cognitively-Based Tutoring

Some of the most exciting and well-researched technology-based systems come from the class of intelligent tutoring

systems (ITSs). Drawing from cognitive science, artificial intelligence (AI), and expert systems, ITSs typically institute an expert module that contains, usually in rule-based form, knowledge of the skills involved in successful problem-solving behavior, and previously identified bugs, or common errors, in the rules of learners. In the ITS instructional model, the learner engages in problem solving while the expert module tracks learner behavior. Erroneous steps, recognized through pattern matching by the rule-based expert module, are usually met with immediate feedback, in keeping with the theory of the acquisition of cognitive skill. The expert module can also provide context-specific hints, or help, and offer an expert-level solution to the problem (Anderson, 1988).

While there are many ITSs, those derived from Anderson's (1996) ACT theory – the Cognitive Tutors – are of particular interest because of their strong theoretical and empirical support, and because the essential architecture has proven so resilient over time and across a range of mathematical domains and age groups. Cognitive Tutors (Figure 2) provide differentiated instruction in pre-algebra, algebra I and II, geometry, and integrated mathematics to 500 000 students in around 2600 US middle schools and high

schools. Current systems incorporate classroom curricula (often 3 days per week), technology-based instruction and practice (2 days per week), and teacher professional development. Students engage in explanation-based reasoning, as well as goal-directed problem solving.

A number of empirical studies have established the effectiveness of this approach (see Ritter *et al.*, 2007, for a review). For example, Algebra I students in Pittsburgh, PA and Milwaukee, WI, who used the tutor showed superior gains from their peers overall, particularly on performance-based tests of problem solving and uses of multiple representations (Koedinger *et al.*, 1997).

Mathematical Discovery

As educational researchers more fully embraced expanded and alternative views of knowledge and learning such as constructivism (e.g., Cobb *et al.*, 1992) and situated cognition (e.g., Brown *et al.*, 1989), these have been reflected in the designs of educational technologies. New technologies were designed to be student centered, to draw directly from students' own knowledge of mathematical and physical

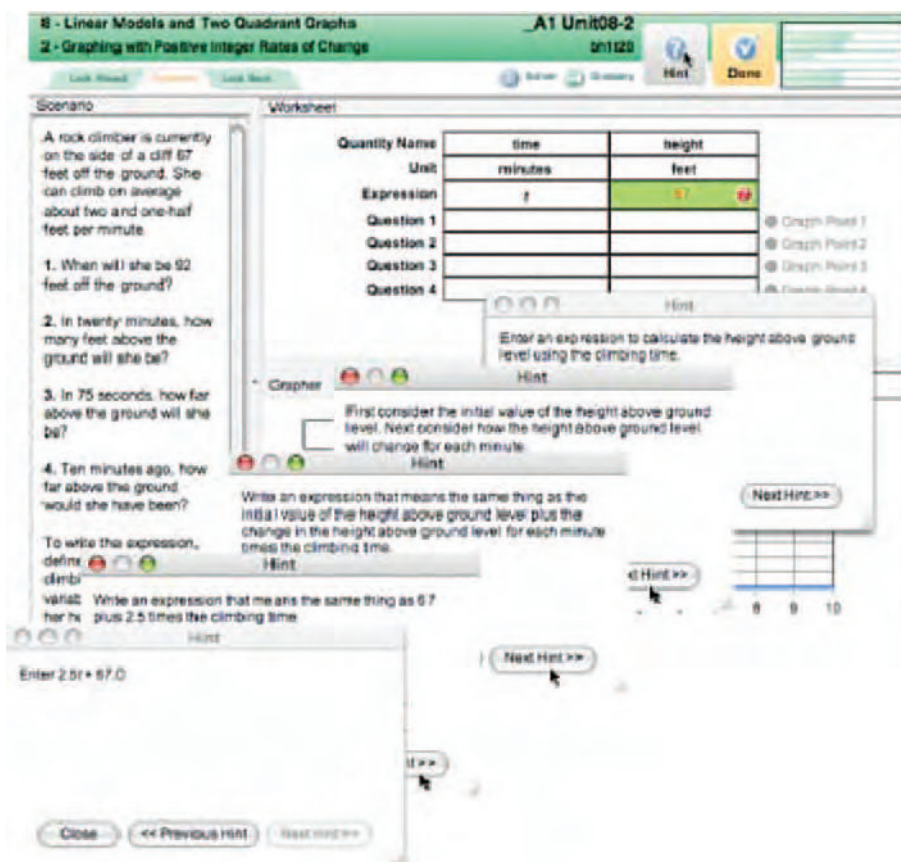

Figure 2 A series of hints, followed by direct instruction provided to a student using the Algebra Cognitive Tutor developed by Carnegie Learning, Inc. Adapted from Koedinger, K. R. and Aleven, V. (in press). Exploring the assistance dilemma in experiments with Cognitive Tutors. *Educational Psychology Review*.

phenomena, and to put more responsibility of discovering and articulating connections between representations and across representation, math concepts, and procedures. Technologies that emphasize the interconnections among representations and the distributed nature of knowledge as it exists between the student and the technology also lead to different types of activities and they reconceptualize the aims of math education as one of learner-centered making meaning.

Logo

Logo (Papert, 1980) is both a computer programming language and a microworld, a designed learning environment to promote mathematical reasoning and problem-solving skills through an innovative process of directing the actions of a mathematical creature called the Logo turtle. The turtle can move forward or backward, stop, and rotate to the left or right, and raise and lower its pen in response to programmed commands. Although the original turtle was a physical robot that ran along the floor or paper, in later versions it was replaced by a graphical turtle on a computer screen.

The Logo environment offers a way for the child to externalize mathematical ideas and procedures and project them onto the actions and properties of the turtle and the Logo programming language (Eisenberg, 2003). Yet, it also becomes an object-to-think-with (Resnick *et al.*, 1996) and has been used to conceptualize many areas of mathematics, including modern algebra and group theory, computer science, cybernetics, as well as Euclidean and non-Euclidean geometry (Abelson and diSessa, 1981).

Logo has long been a tool for doing mathematics and mathematics instruction, and there is a large collection of empirical studies investigating its impact on mathematics learning, teaching, and discovery. For example, fourth graders familiar with Logo programming were better able to apply what they learned and elaborate on their procedural interpretations of geometry concepts than those taught from an inquiry-based approach (Lehrer *et al.*, 1989). In other studies, Logo improved students' use of geometric models in other areas of mathematics, generalization and abstraction of geometric operations, and improved complex reasoning along with more general cognitive skills (Battista and Clements, 1991; Clements and Battista, 1991, 1992; Lehrer and Littlefield, 1993).

As is the case with educational technology, more generally, the effects of Logo have as much to do with the teaching and the engagement of the students, as the technology itself (Kozma, 1991, 1994; though also see Clark, 1983, 1994).

The essential ideas conveyed in Papert's (1980) original work, *Mindstorms*, inspired a broad range of technological designs for learning and instruction, including: StarLogo, which uses concepts of parallel computation to introduce participants to the computational and cognitive aspects of

modeling complex, dynamic systems (e.g., Colella *et al.*, 1999); and the NetLogo Project (reviewed below) at Northwestern University and The University of Texas at Austin (Wilensky, 1999; Wilensky and Stroup, 1999), which supports distributed computing.

Function Probe

Function Probe (Confrey and Mahoney, 1991, 1996) was an early and highly influential technology design for math education to come under the constructivist paradigm. Function Probe integrated a user-friendly calculator with tabular, graphical, and symbolic representations of phenomena to promote the active construction of mathematical understanding for high-school algebra, trigonometry and functions, and high school and college pre-calculus, as well as integrated math and science instruction. Data could be entered in by students or imported using external sensors. Operations on one representation were reflected as changes in other, linked representations, thus promoting representational fluency (Nathan *et al.*, 2002). The system follows one of Kaput's (1989) observations, that mathematical meaning making is actually built upon the ability to translate within and among various representations, and that fundamentally, meaning is based on a "relational semantics" between "linking representations" including internal mental representations and physical systems as well as tables, symbols, and graphs (p. 168). Function Probe also provided a modeling environment that allowed students to articulate and explore their own conceptions of mathematical and physical events as a means toward advanced understanding (Confrey and Doerr, 1994).

ANIMATE

The ANIMATE system presented another alternative to cognitive skill acquisition and the intelligent tutoring system paradigm. It was presented as an unintelligent tutoring system to emphasize that the program contained no expert module and made no attempts at modeling or tracing the knowledge states of the student (Nathan, 1990). Instead, ANIMATE assumed knowledge was distributed among the interactions between the student and the system.

The focus of ANIMATE was on student discovery of quantitative representations for modeling and solving algebra story problems involving systems of equations, including those for distance-rate time (e.g., collision and overtake) problems, combined work, and compound interest. In ANIMATE, a student constructed the algebraic equations that drove an animation of the referent story problem situation (e.g., planes flying at different rates and leaving at different times). Because of the direct causal link between the formal expressions of the algebraic solution (the mathematical symbols and structures to be learned) and the animation (the situation-based meaning

of the mathematical expressions), animated actions that were inconsistent with the student's mental model of the story situation suggested errors in the proposed solution representations, the nature of which were highly constrained by the type of misbehavior. This interlinking of students' thinking and the control of the system is illustrated conceptually in **Figure 3**. Students first proposed and then iteratively debugged their algebraic representations and tested them until an acceptable situation was depicted in the animation. Neither the student nor the system could solve the problems and make meaningful connections on their own. In this way, the intelligence was not localized solely in the computer program or in the learner, but rather from the intelligent interactions needed to bring the mathematics and animation in line with the student's mental model of the story problem.

Students who used ANIMATE learned to reason explicitly about the situations described in typical word problems, and performed better on paper-and-pencil transfer tasks. The ANIMATE users also tended to spontaneously correct their own algebraic errors during problem solving in far greater frequency than control subjects (Nathan *et al.*, 1992; Nathan, 1998).

Dynamic Geometry Systems

Dynamic Geometry computer software such as Geometer's Sketchpad (Finzer and Jackiw, 1998) and Cabri Géomètre (Laborde, 2000), along with Geometric

Supposer mentioned above, offer alternatives to conventional proof-based explorations of geometry by supporting direct manipulation, tracing, and visual forms of thinking without the prior stage of re-representing the intended actions into natural or formal languages.

Classroom observations of Cabri use show that junior high school students in Japan using Cabri are more inclined to explore the propositions and theorems directly through construction and manipulation than under the traditional curriculum, they better visualize the geometric claims, and develop a better sense of what is to be proved (Namura, 1999).

While experimental results are scarce, studies do show that systems such as Cabri and Sketchpad help to promote the proper classroom environment, activities, and forms of interactions that foster deductive reasoning among students (Jones, 2000).

Dynamic Statistics Packages

Several recent dynamic systems allow students to delve into data analysis activities and statistical forms of reasoning without formal knowledge of probability and statistics or the conventions of Cartesian graphs. Data-oriented statistics instruction has moved into mainstream education where it is recognized as a critical methodological tool for reasoning about data with variability, engaging in scientific reasoning, making judgments and evaluating claims, and being an informed citizen. This

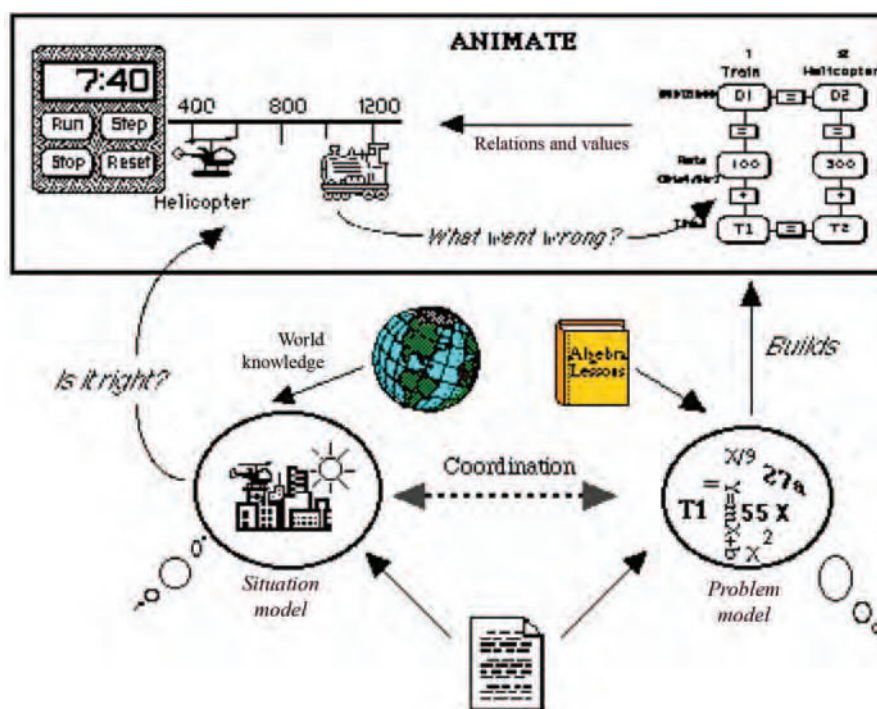

Figure 3 The conceptual underpinnings of learning to model story problems with the ANIMATE system.

reflects the growing appreciation of the need to understand and promote statistical literacy and reasoning more broadly (Ben-Zvi and Garfield, 2004; Cobb, 1993; Rumsey, 2002).

TinkerPlots (Konold, 2002) lets students approach data analysis questions conceptually and in a constructivist manner by providing functionality for organizing and representing data graphically and for progressively constructing and deconstructing graphs in order to develop a more grounded interpretation of the meanings intended by the representations. It also provides several visual methods for displaying variability and co-variation between variables, important ideas for analysis and modeling that are often difficult for students to grasp (Konold and Pollatsek, 2002). In a similar way, Fathom (Erickson, 2000; Finzer and Erickson, 1998) supports discovery of patterns through visually rich exploratory data analysis.

While no formal tests of the effectiveness of these systems compared to other methods have been reported, the approaches they offer are consistent with many of the recent prescriptions for mathematics education offered within current learning theory and standards-based educational reform.

Collaborative Problem Solving

Anchored Instruction uses extended collaborative groups and digital technology to present complex, real-life scenarios – often presented in extended, interactive videos – to situate problems and their solutions in meaningful contexts. The rich and engaging narratives serve as the anchors and give the ensuing mathematical problem-solving activities a meaningful connection to the world. Anchored instruction has been used for a variety of age groups, ability levels, and cultures.

The Adventures of Jasper Woodbury

In math education, the pioneering work on anchored instruction was implemented in *The Adventures of Jasper Woodbury* (CTGV, 1992, 1997). Jasper was developed by the Cognition and Technology Group at Vanderbilt University as a series of 12 open-ended, videodisk-based problem-solving activities that often took groups of elementary-, middle- and high school students several days or more to formulate extended solutions to the series' challenges. Generally, solutions required groups of students to make multiple passes through the information, a variety of plans and computational procedures, and clarifying assumptions. As one might expect, the rich contexts, problem-solving sessions, and clarifying assumptions resulted in complex solutions, no two of which were identical.

Experimental evaluations showed that students using the Jasper program exhibited comparable performance

levels on basic mathematical concepts as matched controls, but superior performance on more complex single- and multistep word problems and multistep planning tasks (CTGV, 1992).

Teaching Enhanced Anchored Mathematics

Enhanced Anchored Mathematics is a form of anchored instruction that situates problems in authentic and meaningful contexts specifically to advance the problem-solving skills of low-achieving and special-education students, adolescents with emotional disabilities, and even re-incarcerated adults (Bottge *et al.*, 2003, 2007; Bottge and Watson, 2002). The anchored activities tie in many of the aspects of traditional industrial arts.

In *Fraction of the Cost* (Bottge *et al.*, 2002; see **Figure 4**), for example, students collaborate to build a life-size skateboard ramp with wood. Problems and information needed to solve the problems, along with irrelevant information, are naturally embedded in the narrative context. Students must use a variety of planning, budgeting, construction, and computational skills. Later, students face transfer problems such as building a working hovercraft.

In empirical research, classroom observers witnessed high and sustained levels of engagement among students of all math abilities, including those with a history of frequent off-task behaviors as they participated in multi-step mathematical reasoning, planning, and problem solving (Bottge *et al.*, 2002, 2003, 2007).

Networked Devices and Participatory Simulations

As technology has progressed to enable networked and distributed interactions, designers have used technology to facilitate students' roles in socially active, life-sized, computational simulations of dynamic systems. Many applications built in earlier decades have recently been reconfigured for networked, interactive uses. Hand-held graphing calculators, discussed earlier in the context of concept learning and skill acquisition, now also serve as one of the central means by which students access distributed networks. Technicians at TI, principally the Classnet Team, are largely responsible for one of the most widely used networking systems, the HubNet hardware, which serves as the central computer architecture through which distributed information is processed and aggregated. Networked systems used by the NetLogo Project at Northwestern University, The University of Texas at Austin, and the SimCalc Project at SRI and the University of Massachusetts at Dartmouth all draw on the TI graphing calculator platform.

Participatory simulations are among the most innovative of these new systems. They provide an individual, first-person perspective from inside the system itself, and

Courtesy of Bottge.

of its emergent behaviors (Colella *et al.*, 1998; Resnick and Wilensky, 1998). The emergent behavior of the system at a macroscopic level and its relation to individual participant's microscopic actions can then become the object of collective discussion and analysis. For example, NetLogo is a programmable modeling environment for simulating complex systems dynamics that occur naturally in biological and social phenomena, such as traffic gridlock and flocking behavior. HubNet allows NetLogo to run participatory simulations in the classroom, where a whole class can enact the behavior of a system even while each student controls only a small part of the system from a networked computer or TI graphing calculator. Thus, participatory simulation activities support new forms of classroom interactions that explore and model complex mathematics typical of biological and social phenomena.

SimCalc

The SimCalc Project (Roschelle and Kaput, 1996; Hegedus, 2005) uses hand-held computer technology to democratize access to the mathematics of change and variation, including ideas underlying calculus (Kaput, 1994, 1997). The MathWorlds software, along with the hand-held technology supports computation, but also can represent mathematical ideas in ways that are important for conceptual understanding.

As with earlier tools, such as Function Probe and ANIMATE, the original versions of MathWorlds allows students to primarily control the motions of animated characters by constructing and modifying mathematical functions represented in graphical, tabular, or algebraic forms. Students can build up their understanding of the mathematics by seeing how changes in formalisms lead to changes in the corresponding animation. As an important

extension from earlier dynamic systems that support proportional and linear functions, students are also asked to model stories that correspond to piecewise linear functions of familiar situations that represent different phases of action (such as resting).

As SimCalc has matured, its capabilities to support classroom connectivity have become more central (Kaput and Hegedus, 2002). SimCalc leverages the revolutionary aspects of wireless networked technology in several ways. It allows teachers or students to collect and display student responses, and thereby support large-scale forms of classroom interaction. As a mobile form of technology, SimCalc flexibly supports new kinds of social and participatory structures than were previously possible with tethered systems and those that require students to gather around a single monitor and keyboard (**Figure 5**). At the core of this connectivity is the use of hub technology that rapidly and wirelessly communicates to the teacher's computer.

SimCalc has been shown to be effective in randomized control-group studies at the middle-school and high-school levels. In a multiyear study of middle-school classrooms in Texas, SimCalc use led to statistically significant gains each year (Roschelle *et al.*, 2008). Detailed analyses showed that SimCalc students exhibited their gains on the most advanced math concepts, while showing no concomitant loss on basic material.

Serious Games

Games have been a long-running source of inspiration for mathematics activities and instruction, and gaming technology stepped easily into this practice as personal computers came on the scene and advances were made in interactivity (e.g., *How the West was Won*; Burton and

Figure 5 A teacher oversees students working with Simcalc.

Brown, 1979) and computer graphics (*Green Globes*; Dugdale, 1982). With the advent and popularity of video games, we have seen emergence of a variety of studies showing learning gains in mathematical reasoning from video game playing (e.g., Okagaki and Frensch, 1994; Subrahmanyam and Greenfield, 1994; Wenglinisky, 1998). While important, these are often unconscious and indirect effects of learning rather than the intended purpose behind the game design.

Some educational scholars have argued that education has much to learn from video game design (Gee, 2003/2007; Shaffer, 2007; Squire, 2006). Serious games exploit many of the compelling attributes of video games that have stoked their popularity. These are advanced computer-based environments with sophisticated graphics and sound that engage the learner/player with a compelling narrative about the video environment and support self-motivated progress, but are specifically designed to support learning rather than entertainment.

While a few, early serious game systems exist (e.g., *Quest Atlantis*, *Civilization III*, *The Triple A Game Show*, *Revolution*, and *Mad City Mystery*) it is still early to point to a body of research literature showing consistent learning gains in mathematics from this approach. Still, for many reasons, both theoretical and pedagogical, this is a promising and rapidly evolving area of study (Barab *et al.*, 2005; Squire and Jenkins, 2003).

Embodied Cognition

One of the traditional criticisms of educational computing is that it distances students from physical, hands-on activities and experiences, and perpetuates a view of the math learner as a disembodied information processor. Within the embodied cognition view (e.g., Barsalou, 2008; Glenberg, 1997; Lakoff and Nuñez, 2001), however, technology should allow people's thoughts and actions to mediate the relationship between real-world phenomena and formal representations.

CamMotion (Boyd and Rubin, 1996) fosters this relationship by providing users ways to extract and analyze data directly from digitized video of objects and events. HyperGami (Eisenberg and Eisenberg, 1998, 1999; Eisenberg and Nishioka 1997) lets students create customized 3-D polyhedral forms on the computer screen that are printed as flat, colorful patterns, but that fold to become tangible models, such as penguins.

Recent advances in new and powerful output devices permit students to design (on the computer) and then print objects in sturdy materials such as wood, acrylic, foam core, wax, and plaster. Advances in materials science and developments in plastics, liquid crystals, and optical fibers also invite new ways of using the hands and body to engage in mathematics, and in so doing, recast the very notion of educational technology (Eisenberg *et al.*, 2005).

This greatly expands the range of mathematical objects and techniques available to students. For example, laser printing can be used to make sliceforms that can be slotted together to form mathematical objects in 3-D that are both educational and esthetic (**Figure 6(a)**). The approach can be used to support proof by construction. It can also be used on fabric, where mathematical patterns can inspire fashion. Laser printing is also instrumental to the MachineShop program (Blauvelt and Eisenberg, 2001, 2006), which directs a laser-cutting device to make toothed gears, cams, and levers from wood based on custom-designed mathematical functions that can then be assembled to make devices, including toys and models of dynamic systems (see **Figure 6(b)** and **6(c)**).

These approaches to tangible mathematics – and there are many more to be reviewed – recall a time when mathematics and art were closer than they are today for many students. Mathematically inspired crafts also encourage a culture of display (Eisenberg *et al.*, 2005). Thus, mathematical craftwork takes the idea of grounding the meaning of mathematics one large step forward, by inviting students to personalize mathematics and enrich our immediate surroundings with beautiful and interesting mathematical entities that we design and construct. Combined with the aims that focus on developing students' spatial reasoning and conceptual and procedural advancement, this is a valuable reminder of what math education can become.

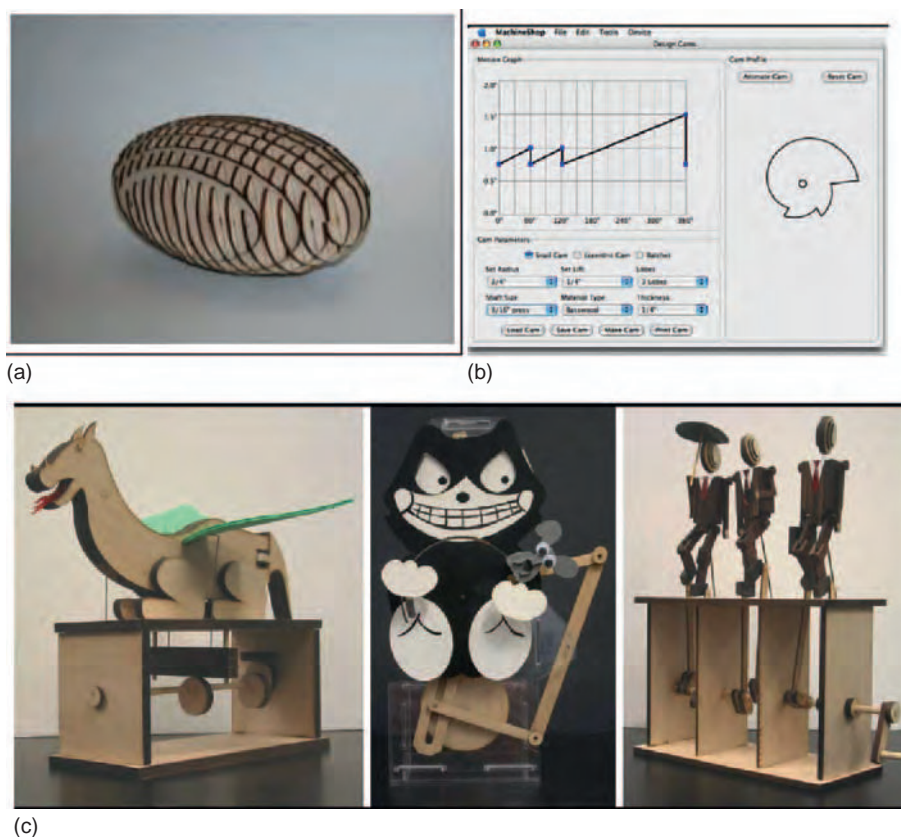

Figure 6 (a) A sliceform ellipsoid constructed from a set of slotted wooden pieces. (b) A custom-designed cam from MachineShop. (c) Some mechanical automata designed and built by students. Challenges Facing Technology Supports for Acquiring Mathematics

New views of learning and behavior are contributing to new forms of technology as the interactions between technological tools and tool users are reconceptualized. While *Jasper Woodbury* series, Cognitive Tutors, and SimCalc are notable exceptions, the empirical research base for many of the technological innovations reviewed is still thin. Most evaluations could benefit from qualitative investigations that document implementation fidelity and the learning process alongside more conventional quantitative studies of assessment performance.

Technology enacts a ratchet effect (Tomasello, 1999) on mathematics education, with intellectual advancements supporting the democratization of mathematics for all learners (Kaput, 1994). Yet new technologies introduce new costs to education. First is the cost of the technologies themselves, as well as adequate technical support. Second, new technology calls for new forms of teacher support that must be ongoing and systemic to the educational institutions and it must provide direct connections between the technology and the mathematical

content that it is designed to support. To adequately meet the potentials these new opportunities afford, teachers need additional training. Third, the new technologies present entirely new areas of mathematics (e.g., dynamic systems and inferential statistics) and are shifting prior topics into earlier grade levels (e.g., algebra and calculus). Finally, assessments of student learning, as well as the curriculum and professional standards will need to be revised to keep pace, or fall seriously out of date.

Glossary

Community of practice – A group of people participating together to carry out different activities, such as garage bands, ham-radio operators, recovering alcoholics, and research scientists.

Long-tail learning – Learners pursuit of unusual topics of interest to them, such as quasars, Chinese history, Japanese animé, cuneiform writing, or Viking ships.

Introduction

All around us, people are learning with the aid of new technologies: children are playing complex video games, workers are taking online courses to obtain an advanced degree, students are taking courses at commercial learning centers, and adults are consulting *Wikipedia*. New technologies create learning opportunities that challenge traditional schools and colleges. These new learning niches enable people, of all ages, to pursue learning on their own terms. People around the world are taking their education out of the school and into homes, libraries, Internet cafes, and workplaces – where they can decide what they want to learn, when they want to learn, and how they want to learn.

This article describes the emergence of such alternative venues for learning and their implications for schools. It suggests that the seeds of a new education system are forming in the rapid growth of new learning alternatives such as home schooling, learning centers, workplace learning, and distance education. These new learning venues foster self-directed learning for people of all ages. Based upon current trends, this article suggests that public schools will not disappear, but that their dominant role in education will diminish considerably.

New Niches for Learning

The seeds of a new education system can be seen all around us. Many of these seeds will affect the learning of children, but many others will affect people of all ages – as learning becomes a lifelong enterprise. The face of

education is changing rapidly, and it remains to be seen exactly what forms education will take over the next decades.

Home Schooling

Technological advances have fueled the development of home schooling, although they did not give rise to the movement. Internet curriculum materials help organize learning content, leaving parents and others to play the role of facilitators. Virtual schools – such as Florida Virtual Schools – provide some of the administrative and curricular structures to support home schooling through distance education (American Youth Policy Forum, 2002). Most K-12 schools have managed to keep technology at the periphery of their teaching, confined largely to courses such as keyboarding, tech prep, and computer programming (Cuban, 2001). It appears that technology fits much more comfortably into the home environment than into the school environment.

Parents of home-schooled children may, in fact, be more helpful than teachers in a context where the content of what students are learning is embodied in computer and video-based materials. Teachers view themselves as experts – whose role is to convey their knowledge to students. In contrast, parents do not think of themselves as experts and hence take on the role of a coach more naturally (Stevens, 2001). The role of coach puts more responsibility for learning onto the student. The parents are available to help the student figure things out and to encourage the students to work hard, but they usually do not take on the role of explaining everything to the learners. Hence, figuring things out for themselves becomes a major job for home-schooled kids.

Workplace Learning

In recent times, both the military and corporations have been building simulations around popular online video games, using the tools that have been developed for creating these games. The military, in particular, has used game design as a path for recruiting and training a generation that grew up on video games. Companies have also picked up on the potential of games for training. Canon, for example, has developed a simulation where technicians must repair simulated copier machines that have different faults inserted in them. In one Cisco game,

players must put together a computer network on Mars. The companies have found the games are more effective than traditional methods for teaching critical skills.

One can imagine a day when most of the training that workers get for their jobs bypasses traditional educational institutions and takes place in online environments. Sales people might practice their skills with simulations of recalcitrant customers. Doctors might practice their skills trying to diagnose unusual cases. Future travel agents might be challenged to develop cost-effective trip plans using the Web. In fact, almost any job-related skill can be taught by practicing the skill, and computer simulations can create immersive environments where the target skills are necessary for solving engaging problems. It is likely that future workers will have to spend much of their time learning – as workplaces keep introducing new processes, techniques, and equipment. Workers may spend their whole lives learning in order to survive in a changing workplace.

Distance Education

Distance education has been around a long time. Correspondence courses have reached thousands of students over the past century. However, the Internet is pushing new kinds of interactive distance education at both the K-12 and collegiate levels. The University of Phoenix, for example, is famous for having tens of thousands of online students all over the country (Maeroff, 2003). Leading universities – including Stanford, Harvard, Massachusetts Institute of Technology (MIT), and Carnegie-Mellon offer a variety of courses to distant locations. The model of the Open University in the United Kingdom has spread across the globe. In addition, over 24 states have developed virtual high schools to provide courses that are not offered in their own schools to students (Tucker, 2007). Distance education has already spread widely, and it will inevitably keep growing in the coming decades.

As busy people realize they need more education, they increasingly opt to take distance-education courses. Often, people find that – to advance in their careers – they need another degree, and distance education courses provide the easiest means to obtain that degree. Although distance education has a head start in adult education, the recent development of virtual K-12 schools challenges brick-and-mortar public schools by providing affordable alternatives.

Learning Centers

Learning centers – whether nonprofit or for-profit – are spreading widely. They usually offer classes, as well as provide access to technology. They are oriented to providing specific knowledge and skills which the users

want to obtain. Such learning centers are likely to proliferate in the coming years.

Privately owned learning centers are growing to fill gaps in the existing education system. These are currently most common as preparation for taking national tests – such as the Scholastic Aptitude Test (SAT) and American College Testing (ACT) – and to provide tutoring for children who are having problems in school. Learning centers are also beginning to develop for adult education. Princeton Review, Sylvan, Thompson, and Kaplan are only some of the companies that provide learning centers. Some of these companies are setting up centers in towns and cities where people can go to prepare for various types of tests or to get specialized teaching in some area of weakness. As they develop, learning centers are likely to employ more and more network-based education and to spread as a way to obtain specific knowledge and credentials.

Learning centers are also making an impact on career education. In the 1990s, the US Department of Education launched an initiative to support nonprofit community technology centers to serve communities where access to computers and other technologies is very limited. The community technology-center network now has over 1000 centers in many different locales – such as housing projects, storefronts, community organizations, and libraries. Most users come to learn job skills and take classes at the centers, as well as to use the Internet facilities. Many acquire improved English-language skills, get tutoring and homework help, or participate in general educational development (GED) and other adult education programs. They also use computers to get information from the Internet, send and receive e-mail, set-up Web pages, and carry out their own self-directed projects.

Computer Simulations

The advent of home computers has led to a proliferation of learning software – some on compact disks-read-only memory (CD-ROMs) and some on the Web. Among the most famous of these are the Sim series – developed by Maxis: SimCity, the Sims, SimLife, SimEarth, SimAnt, and so on. In SimCity, the player is put in charge of developing and running a city – as a kind of dictator. Depending on the user's decisions, the city and its people may thrive or may deteriorate. People who spend time playing the game are learning some of the tradeoffs involved in the dynamics of a city. SimLife, similarly, teaches the ecology of systems, SimEarth – the dynamics of geology – and SimAnt, the behavior of an ant colony. The Sims games allow people to design a human character to represent them and see how the character's actions play out in a simulated world. It is one of the most popular games on the market, at present. The Sim series are engaging games that teach a variety of subjects, but how much children learn from playing such

games depends on how much they think with regard to the ideas and issues the simulations embody.

An understanding of video games as learning environments is becoming increasingly important as gaming culture rivals schooling for the attention of children and adolescents across the world. Gee (2003) argues that the compelling nature of video game participation is, in part, due to the underlying social, cognitive, and developmental learning principles around which successful games are built. The implication of Gee's perspective is that games and gaming can be a source for inspiration in building more effective learning environments.

Given this popularity and the compelling nature of game-play, software designers should be able to draw on games and the principles of game design to build more compelling learning environments. In the best-selling game *Civilization*, for example, players have the opportunity to relive the development of global social and economic history. Players must plan, choose to negotiate or fight, acquire and allocate resources, and make decisions to advance their civilization. Taken together, these activities point toward how students can integrate theories and practices from across the curriculum in playing a compelling historical simulation. Squire (2004) notes how games such as *Civilization* can provide students – who typically are not engaged deeply in learning history – with an opportunity to replay history. Students can investigate, for example, what would have happened if Africans – rather than Europeans – had colonized the Americas, and can begin to understand what theories of social change look like in action, rather than in books.

Trends, at present, suggest that there will be a steady accumulation of learning software both for children and adults. For a generation that has grown up with sophisticated game simulations, learning with technologies is likely to come more easily. Gaming may help players learn a variety of leadership skills, such as resource allocation, negotiating with friends and adversaries, manipulating situations and environments, actively pursuing their goals, and recovering from failures. As Brown and Thomas (2006) have suggested, the gamers of today may become the leaders of tomorrow.

Technical Certifications

In recent years, a host of companies – such as Microsoft, Cisco, and Novell, as well as technical societies such as the Institute of Electrical and Electronics Engineers (IEEE) Computer Society – have started to offer online learning and examinations that certify the mastery of technical skill in computer-related occupations. The Cisco Networking Academy, for example, provides a comprehensive training program for network administration. The Cisco Academy is based on a tight linkage of curriculum, learning-by-doing, and assessment activities that are

coordinated in a learning environment that blends Web-based and classroom learning. Cisco Academy partners with schools to train their teachers to prepare students for the Cisco exams. They have trained over 400 000 students in 150 countries with a curriculum translated into nine languages. Certification programs such as these have, in turn, led to a number of training programs in commercial colleges and community colleges and on the Web to prepare students for the certification exams. These certification programs provide an alternative to technical degree programs for students – who may otherwise struggle with the academic focus of high school and colleges.

In the long run, these certification programs are a threat to the monopoly held by schools and colleges. Because the technical certifications they provide are more specific than a degree or diploma, they are, in fact, more meaningful to potential employers. They specify precisely what skills a student has acquired in a way that a high school diploma or a college degree cannot do. Furthermore, because the certifications are so specific, it is possible to tailor any educational program directed toward them much more carefully. In fact, the companies and technical societies that are developing certification programs have, in many cases, developed very clear specifications as to what and how courses should be taught to prepare people to take the certification exams.

Internet Cafes

All over the world, Internet cafes are springing up where people can go and log on to the Web for a small fee. These cafes are the libraries of the future. They particularly attract young people who spend hours on the Web – engaging in conversations and games, reading about what is happening in the world, learning how to program, or exploring different sites that relate to their interests.

More and more of the world's accumulated knowledge is spreading to the Web. Hence – with access to the Web in many locations – people can begin to educate themselves. This is the role that public libraries played in the past. As people all over the world see the necessity of an education to prosper in a technological society, they are likely to start teaching themselves through the resources of the Web. Inexpensive access to the Web through cafes provides the whole world with access to knowledge, new social arrangements, and new ways of thinking with regard to learning. Alternatively, of course, it also provides an avenue for wasting an enormous amount of time.

Fostering Self-Directed Learning

The Web gives children and adults the ability to pursue topics they are particularly interested in and feel passionate about – including topics such as quasars, Chinese

history, Japanese *animé*, cuneiform writing, Viking ships, and casino games – to name just a few. These are topics that learners never encounter in school unless they pursue them later in college. Nor are learners likely to find people among their acquaintances who share their interests and would study the topics together with them. Such exotic topics remained as lone pursuits for most people until the Web came along.

Virtual communities make it possible to bring together people, from all over the world, with common passions. Their communication can take place over electronic mail and in computer news groups, social networking sites, or Multi-User Virtual Environments (MUEs), such as Moose Crossing (Bruckman, 2002). In these different computer-based environments, people of different ages are gathering around topics that they are passionate about. This enables them to learn about their passion much more deeply than they can on their own. Often, people cannot find others locally who share their passions, but the reach of the Internet allows them to go beyond their local community to find like-minded communities.

Barron (2006) provides a good example of how students can become self-directed learners through exploring their interests on the Web. She finds that they use a number of different strategies for learning on their own. For example, they may learn from friends or mentors, take courses in school, observe the work of others in online communities such as Xanga, or study the products that others exhibit on different websites. Learning to be a self-directed learner by participating in a variety of learning contexts will help more students to develop the skills necessary to choose learning contexts well.

The phrase “The Long Tail” was first coined by Anderson (2004) in an October *Wired* magazine article to describe how modern culture is increasingly shifting away from a focus on mainstream products at the head of the demand curve and toward a huge number of niches in the tail (as exemplified by Amazon or Netflix – that sell a large number of unique items in relatively small quantities). The Web enables long-tail learning in a variety of ways by supporting participation culture among the members of communities interested in idiosyncratic topics. Novices can lurk in these communities to pick up the issues, techniques, and jargon that sustain the communities. When learners develop expertise, they can display their work or their thoughts to the community and get feedback from the community to guide their further development. Finished products may, later, be posted on YouTube or Epinions – where the world might see their work.

Another way the Web enables long-tail learning derives from the plethora of information available on the Web. When learners go into most libraries, they are likely to find a limited amount of information on any topic; the information they find is very likely out of date for most topics, and there is rarely documentation on the

techniques of the community of practice (Wenger, 1998) around the topic are using. Based on the fact that the Web is both constantly evolving and actively filling up all the long tails of knowledge concerning every conceivable topic, it can support long-tail learning in a way not even the largest library in the world could. In addition, the Web can provide expert audit trails, active simulations, and tutorials on topics that support learning well beyond what learners can glean from books.

Conclusion

The changes that are occurring in education are neither all good nor all bad. There are many benefits to the kinds of education that technology affords – such as the ability of learners to pursue deeply topics of interest to them and to take responsibility for their own education. However, at the same time, some of the effects of technology on education are problematic. In particular, the new technologies can undermine both Thomas Jefferson’s vision of educating citizens who can make sensible public policy decisions, and Horace Mann’s vision of a society where everyone can succeed by obtaining a good education. Increasing the ability to personalize educational opportunities provides a natural advantage to those who can afford the services. Citizenship and equity may be undermined by the fragmentation and commercialization afforded by the technological revolution. There are clear dangers as well as great possibilities when people take learning into their own hands.

When taken together, the cumulative effects of these innovations is to extend learning throughout life and over many venues. With time, these pieces might come to comprise the fragments of a new system of education in which schools are pushed to the peripheral role in learning that they once occupied prior to the industrial revolution. However, these elements supporting technology-based learning outside of school have developed independent of one another. They do not, in any sense, form a coherent system of education. That is where the need for visionaries is most apparent. It will take a new group of energetic visionaries, to once again do the kind of work that Horace Mann and his colleagues did – that is, to figure out how to build an equitable and coherent system from these emergent technological pieces.

Eventually, when people and politicians become worried about what kids are learning or what adults do not know, their automatic reaction may not be “How can we improve the schools?” Instead, they may ask, “How can we develop games to teach mechanical engineering?”, “How can we make new technology resources available to more people?”, or “What kinds of tools can support people to seek out information on their own?” These are all questions that push the envelop for improving education out of the

schools and into new venues. The link between schooling and learning forces our conversation into institutional responses – we do not, yet, know how to ask wider questions when we think about improving education (Collins and Halverson, 2009).

The new view of education is structured around the idea of lifelong learning. Lifelong learning requires moving away from schooling institutions that structure individual learning. Instead, learners need to act as consumers of a wide variety of learning experiences. Learners will need to develop the skills to judge the quality of learning venues and to develop the kinds of social networks that provide guidance and advice.

The recent explosion of social networking points to how technologies can replicate the support and guidance functions of schools. For example, user groups and community sites exist for every known disease and disorder, and doctors across the country know their diagnoses are checked by an increasingly informed patient population. These kinds of social networks are blossoming around topics of particular interest to different groups of people – topics such as poetry, chemistry, digital graphics, and fantasy sports. The networks draw people across all ages from very different backgrounds, some quite expert and others virtual novices. Some learn by lurking in the background and others by asking questions. Groups in the network may jointly investigate topics of interest or argue about issues they think important. The successful sites, however, share the characteristic of providing useful information to guide the interests of users.

If schools cannot change fast enough to keep pace with advances in learning technologies, learning will leave schooling behind. With inexpensive computers, young people in Thailand and Brazil can have access to the same resources for learning that people in the developed world now have. Many may choose to take advantage of these resources to escape from poverty. In some ways, they will be a new kind of twenty-first-century immigrant – instead of moving to a new country, they will use information networks to transform their thinking. They will be able to find like-minded souls to share ideas in cyberspace. This new approach to learning that is developing among people around the world will be highly interactive, very personalized, and give the learner much more control over their own learning.

TECHNOLOGY AND LEARNING – SUPPORTS FOR STUDENT COLLABORATION

Knowledge Communities in the Classroom

J D Slotta and H Najafi, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Fostering community of learners (FCL) – An educational model advanced by Ann Brown and Joseph Campione, from the University of California, Berkeley. In FCL classrooms, students work collaboratively to investigate research questions, exchange expertise, and develop a deep understanding of curriculum topics.

Intentional learning – A form of learning that is a characteristic of a knowledge-building environment. Students actively define their own cognitive objectives and pursue them through activities of their own design.

Jigsaw – A curriculum structure defined by Elliot Aronson and his students at the University of Texas and the University of California, and employed as a pedagogical structure within numerous educational methods, including the FCL method of Ann Brown and Joseph Campione.

Knowledge base – The aggregated ideas, resources, or semantic connections that result from collaborative learning structures. A common feature of knowledge-community approaches is that students work together, adding knowledge elements to their shared knowledge base.

Knowledge building – An educational model advanced by Marlene Scardamalia and Carl Bereiter, from the University of Toronto. In knowledge-building classrooms, students collaboratively identify their own cognitive goals and advance them through intentional learning. The goal of knowledge building is the improvement of ideas.

Knowledge community – A collection of individuals who share a common learning goal or activity focus. The community typically shares common practices or goals, and employs characteristic media.

Research cycle – A central pedagogical structure to the FCL model, the research cycle includes three stages: students engage in research activities, share their findings with the whole class to create collective

expertise, and use the knowledge that they have acquired to complete a final project.

Scaffold – The notion of scaffolding was introduced by David Wood, Jerome Bruner, and Gail Ross to describe explicit supports provided by teachers or instructional materials that enable learners to achieve intellectual results that would otherwise fall beyond their capacity.

Scaffolded inquiry – The term scaffolded inquiry now refers generally to any method where students are guided through activities and interactions by instructional materials and technology environments.

Web 2.0 – A term coined by Tim O'Reilly and other pioneers of the Internet to refer to a new generation of Internet-based applications that were functionally distinct from those of the previous era. Whereas earlier web applications emphasized individual production and mass consumption (i.e., of a web page), Web 2.0 emphasizes mass production and mass consumption. Interactivity and social networking are typical of Web 2.0 resources (e.g., <http://Facebook.com>), as well as the aggregation of large collections of resources contributed by millions of users (e.g., <http://Flickr.com>, <http://youtube.com>).

Wiki – This refers to a web page or website where the contents can be contributed and edited by many visitors. First developed by Ward Cunningham in 1994 and referred to as the WikiWikiWeb, wikis are now commonly used by businesses, scholars, and social networks around the world. <http://Wikipedia.com> is perhaps the best-known example.

Now more than ever, schools must prepare students as lifelong learners in a society where change is the only constant. New issues, new opportunities, and an increasingly complex range of messages and materials will greet them at every turn. As the demands of the workplace and everyday life become ever more diverse, students must embrace this complexity. Recently, scholars have suggested that we are becoming a knowledge society where

citizens rely increasingly on processes of knowledge creation and advancement over those of labor or industry (Scardamalia, 2002; Hargreaves, 2003; Tapscott, 2008). To serve this vision, our educational systems must shift their focus from one of preparing students for the workforce (i.e., with relevant background knowledge and skills) to preparing them to think critically, develop ideas and arguments, evaluate their own progress, and collaborate constructively with peers.

Of course, researchers have long argued for an emphasis on such an autonomous agency for students (e.g., Dewey, 1938/1997; Driver, 1985; Bruner, 1993; Bransford *et al.*, 1999; Linn and Hsi, 2000). Indeed, two relevant research traditions that are reviewed in other articles elsewhere in the encyclopedia are those of guided discovery and scaffolded inquiry. Here, we focus on a highly regarded body of scholarship that is concerned with fostering knowledge communities within classrooms (Brown and Campione, 1994; Scardamalia and Bereiter, 1999; Bielaczyc and Collins, 2005). Broadly cast, this approach involves giving students a much higher level of agency and responsibility for developing their own questions, exchanging and critiquing ideas with peers, and even evaluating their own progress. Teachers become members of the classroom knowledge community, and participate as knowledgeable mentors. The students in a knowledge community typically create a knowledge base of commonly held resources that are negotiated and continuously revised through their activities conducted in the classroom, at home, or on the playground. Often, this knowledge is situated in a technology-mediated environment that scaffolds students as they add new ideas to the knowledge base, revise materials, or synthesize the contents into new organizations, designs, or arguments (Stahl, 2000; Hoadley and Pea, 2002; Bielaczyc and Collins, 2005).

Young people today are frequently immersed in technology environments that are deeply social and linked to a variety of knowledge media. Facebook, for example, is a social-networking environment that emphasizes networks of friends, but allows for rapid propagation and evolution of ideas about political candidates, music, movies, and philosophical concepts. The notion of the blogosphere, once a fanciful, futuristic term, is now deeply set in the landscape of all media, political organizations, and public institutions. Word gets out about any new idea, as a variety of social networks allow the most popular or resonant ideas to quickly emerge and become interconnected.

There is considerable and justified excitement about the new forms of aggregated information and interaction that characterize the Web 2.0. For example, Wikipedia is a continuously expanding and self-adjusting body of knowledge that literally emerges from the combined contributions of millions of knowledgeable individuals. By virtue of the sheer number of visitors and their shared value for keeping information current and accurate, these

pages are becoming an authoritative reference. In recent years, an array of socially oriented applications has drawn upon patterns of use and semantic metadata to provide new functionality. For example, Amazon.com has made stunning use of recommender systems to suggest books to readers based on their own past preferences as well as the patterns of selections made by millions of other users. The new technology architecture of Web 2.0, which emphasizes the use of semantic metadata and social networks, provides a means for such emergent functionality. After more than a decade of experience with the Internet, we are beginning to think about repositories not as collections of static objects to be searched through, but as dynamic spaces that support the creation, organization, and access of knowledge.

The tremendous intellectual energy and social capital of the Web 2.0 has enhanced the relevance of educational research that has, for several decades now, emphasized the importance of knowledge communities. The spirit of knowledge sharing, collaboration, and knowledge construction that is evoked by these technologies could promote a surge of activity by researchers as well as practitioners in classrooms and online environments. We review some of the principal ideas, models, and projects that have been offered by researchers of knowledge communities. We discuss cross-cutting elements and comment on the challenges involved in implementing these approaches. We close with a suggestion for hybrid models that integrate the core ideas of knowledge communities with those of more conventional inquiry-oriented instruction, relying on scaffolding technologies to help teachers and students gradually develop the practices of a knowledge community.

The Knowledge-Community Approach

While educational researchers have advanced different conceptualizations of knowledge communities, they share at least three elements. First, within a knowledge community, members with diverse expertise collectively and intentionally develop and advance a shared knowledge base (Bielaczyc and Collins, 1999). Second, community members develop metaknowledge about the processes underlying learning and knowledge creation (Garrison *et al.*, 2000; Brown and Campione, 1994). Third, knowledge communities foster a form of discourse that allows for idea sharing, critique, and improvement. Of special interest to this review are the conceptual frameworks of fostering communities of learners (FCL) and knowledge building (KB), which have been widely recognized and researched in K–12 classrooms.

FCL was implemented in urban elementary schools to promote critical thinking and reflective practice rooted in deep content knowledge within a purposeful scientific learning community (Brown and Campione, 1996; Brown, 1997). Introduced in the late 1980s and developed through

a series of design-based research studies (Brown, 1992), FLC emphasized a research cycle with three stages: students engage in research activities, share their findings with the whole class to create collective expertise, and finally use the knowledge that they have acquired to complete a final project.

KB also engages students in identifying questions and developing a cumulative understanding (Scardamalia and Bereiter, 2008). In this approach, individuals' ideas are added to the public domain of the knowledge community and undergo the scrutiny of all members, who share the responsibility of advancing their collective knowledge. A supportive social context is required to allow all students to work as a knowledge community, identifying conceptually important ideas and improving them through constructive review (Scardamalia, 2000). A clear distinction is made between learning, an internal personal process, and knowledge building, an intentional effort to advance public knowledge (Scardamalia and Bereiter, 2006).

We synthesize FCL and KB according to an overarching perspective of knowledge communities, focusing on three cross-cutting dimensions: distribution of cognitive responsibility, a shared community knowledge base, and scaffolding frameworks and technologies.

Distribution of Cognitive Responsibility

Traditional forms of instruction, such as lectures, are not conducive to helping students integrate knowledge for deep understanding of concepts (Brown, 1997; Slotta and Linn, 2009). In a knowledge-community approach, students become involved in articulating their own learning goals and planning the learning activities. Members of a knowledge community are not only responsible for the quality of their individual learning, but are also held accountable to communicate with other community members to scrutinize the quality of collective knowledge (Bielaczyc and Collins, 1999).

Students in FCL classrooms are acknowledged for what they know and are involved in identifying their learning needs, setting goals, and locating necessary resources to achieve those goals. Thus they develop a metacognitive awareness that requires establishing an environment to promote learners' cognitive responsibility (Brown, 1992; Brown and Campione, 1994; Campione *et al.*, 1995). Metacognition and reflection serve to increase students' awareness of how they learn and thereby enable self-reflection, critical inquiry, and flexible application of knowledge in novel situations (Brown, 1992). The responsibility for developing metacognitive knowledge applies to the classroom community as a whole, with individual students sharing responsibility for monitoring and correcting their peers (Brown and Campione, 1994). As the community depends on the quality of its common

knowledge base, students will hold themselves accountable for developing a coherent understanding of the topic assigned to them (Brown and Campione 1994).

Although FCL advocates increased cognitive agency on the part of students, it emphasizes a balance between the accountability of teachers and students. Teachers are not expected to know the answers to all questions; rather, they should become inquiry role models who are competent in identifying problem areas and can effectively locate and utilize sources of knowledge and expertise (Brown, 1992; Brown and Campione, 1994; Brown, 1997). Further, they should distinguish among the situations where the students need help to avoid misconceptions, when they are ready to undertake more advanced topics, or where they should be left on their own (Brown, 1992; Brown and Campione, 1994). Without the support, monitoring, and feedback from teachers, students could develop misconceptions about the topic of inquiry or fail to progress in their understandings.

In KB classrooms, the students also assume responsibility for defining their own learning goals, conducting inquiry to pursue solutions, developing their knowledge as a classroom community and monitoring their own progress (Scardamalia, 2000; Scardamalia and Bereiter, 1999, 2006). They identify relevant problems that will expand their knowledge, develop solutions to those problems, share their understandings with others in the form of knowledge objects and finally attend to inconsistencies in the shared ideas (Scardamalia, 2000, 2002; Scardamalia and Bereiter, 2006).

A higher level of cognitive agency for students differentiates KB from FCL (Scardamalia, 2002; Scardamalia and Bereiter, 2008). FCL takes a rather hierarchical approach to cognitive responsibility. In contrast, KB distributes the cognitive responsibility equally among all members of the community. This collective responsibility takes the form of an ongoing negotiation for each student between personally held ideas and those that are external to them (Scardamalia, 2000). Although teachers may have less control in directing classroom discussions, they are actively developing their own understanding of discussed concepts and also improving their knowledge of processes underlying students' understanding (Scardamalia and Bereiter, 1999).

Shared Community-Knowledge Base

A knowledge-community approach encourages students to pursue their personal interests in the context of shared classroom interests. Knowledge sources are no longer limited to the teacher and curriculum materials, but include knowledge artifacts identified or created by the students (Bielaczyc and Collins, 1999).

Students in FCL classrooms collaboratively build a shared knowledge base that is characterized by integrated and transferable knowledge as opposed to declarative facts (Brown, 1992). During benchmark lessons, carefully selected curricular themes are frequently reintroduced to the students as generative ideas that constitute the foundation of community knowledge base, on which students elaborate during the FCL research cycle (Brown and Campione, 1994; Brown, 1992, 1997). Generative ideas are broad enough to be divided into subtopics that students address during research cycles (Shulman and Sherin, 2004; Sherin *et al.*, 2004). Students and teachers together develop a deep understanding of disciplinary topics, which requires communication channels and collaborative structures for sharing and improving a collective knowledge base.

In FCL classrooms, students formulate research questions about their chosen topics, informed by the seeded ideas, and then refer to selected references to thematically categorize their questions, which are divided into subunits. Students then select a subunit to research, thereby increasing their personal agency in learning. To avoid misconceived ideas or unproductive inquiry efforts, the teacher and, partly, the students should monitor the progress of their community's knowledge development. Structured collaborative activities intentionally distribute expertise among students, requiring them to negotiate their individual knowledge within collaborative groups and organize their new understandings in a common community knowledge base (Brown and Campione, 1994; Brown, 1997). Thus, each member of the learning community is knowledgeable in certain areas, or is achieving expertise through cognitive apprenticeship (c.f., Collins *et al.*, 1989).

In KB classrooms, students take the initiative in solving shared knowledge-building problems that motivate a persistent inquiry geared toward idea improvement. Non-knowledge-building questions test current understandings and can be answered either explicitly or implicitly through available print, digital, or human resources (Scardamalia and Bereiter, 1999; Bereiter and Scardamalia, 2000). Knowledge-building questions, in contrast, engage students in proposing solutions at the level of underlying principles, such as gravity, rather than concrete cases, such as why objects fall (Bereiter and Scardamalia, 2000, 2003). The two kinds of questions can be distinguished by the degree of finality required in responding to them.

Students learn to develop their own theories in response to problems that emerge during ongoing inquiry. These theories become objects of students' inquiry and are subject to continuous improvement, similar to the process of scientific researchers (Scardamalia and Bereiter, 1999, 2006; Bereiter and Scardamalia, 2000). Bringing problems of understanding to the center of inquiry requires abandoning the more familiar topic-centered structure of

classroom where curricular themes dictate the topic of discussions at a given time during the school year.

The community knowledge base in KB is public, requiring all students to share their ideas for critique by peers, comparison with other ideas in the knowledge base, and integration into the shared knowledge (Scardamalia, 2000, 2002). Students' contributions to the community knowledge base will survive and be further built on only if they are deemed important to the community (Scardamalia, 2000). Upon presenting a new idea, students should deliberately negotiate the significance of their contribution by citing its connection to the dominant discourse of the community (Scardamalia and Bereiter, 1999; Scardamalia, 2000). The instructor's attention shifts from engaging students in activities that ultimately showcase their understandings to activities that focus on idea improvement as the goal of classroom discourse (Bereiter and Scardamalia, 2003). Thus any artifact produced during such activities should carry the potential to be improved by others. Moreover, unlike FCL, where ideas are only shared with the whole class at certain intervals, students in KB classes have access to all ideas at all times.

In general, the shared knowledge base should promote diversity of ideas and facilitate access to those ideas in order to encourage the growth of community knowledge (Scardamalia, 2002; Brown and Campione, 1994). Authoritative sources, in the form of print and digital resources or expert opinions, are included, as long as they are treated with a critical stance and not as ultimate truth (Scardamalia, 2002; Bereiter and Scardamalia, 2003; Collins *et al.*, 2004). FCL and KB differ to some extent in where they place the responsibility to assess the congruency of the community knowledge base with that of scientific discourse. In KB, this responsibility is delegated to students, where it is seen as an opportunity for students to practice idea improvement and take corrective action (Scardamalia and Bereiter, 1999; Scardamalia, 2002). In contrast, FCL requires teachers to identify and address misconceptions to prevent an incorrect concept from prevailing within the community discourse.

Pedagogical and Technological Scaffolds

To help teachers and students achieve the nuanced flow of ideas, activities, and the discourse within a knowledge-community approach, researchers often introduce specific forms of guidance, constraints, or scaffolds. These include scripts that delineate the groups that students should form, their goals, and what materials they will access. They can also take the form of technologies that guide students' knowledge-building processes or discourse.

As most of the research was conducted before the arrival of the Web, the scaffolding employed by FCL takes the form of carefully specified collaborative and

pedagogical structures. These structures familiarize students with knowledge sharing and knowledge construction, help them understand what is expected, and guide their transition from one activity to another (Campione *et al.*, 1995). The following structures have served to balance collective and individual learning within the FCL classroom:

- *Reciprocal teaching.* Students work in pairs or small groups to interpret materials or work on a problem, summarizing assigned sections of the text, asking questions about the text, clarifying misconceptions, and predicting how the text would continue (Lehrer and Schauble, 2006). Reciprocal teaching promotes comprehension, cognitive monitoring, and complex reasoning (Brown, 1992; Brown and Campione, 1994).
- *Jigsaw groups.* Students are assigned to a research group that is a subtopic of the overall theme. Although every student in the group is ultimately responsible for learning the whole subtopic, they work independently within their research group, investigating their own questions and engaging in reciprocal teaching with other members of their group. Then new groups are created that include one student from each of the subtopic groups. The new group then works together on some consequential task that is seen as a product of the overall cycle (Brown and Campione, 1994).
- *Cross talk.* Students share their progress across groups and sometimes with the whole class to exchange feedback on their research and, if necessary, modify their investigation approaches. Cross talk often takes place alongside jigsaw groups.

Technological scaffolds designed for FCL were limited, although computers were used from the outset to produce materials. In later phases of the research, the Web was added as a searchable resource, as well as e-mail communications where students consulted with content-knowledge experts (Brown, 1997). These communications served two purposes: to broaden the knowledge pool of the community beyond spatial and temporal limitations of classroom, and to provide students with the opportunity to observe scientific discourse and ways of thinking.

In KB, technology plays an essential role, serving as a repository of ideas as well as a tool for collaborative knowledge construction (Scardamalia and Bereiter, 1999). The development of the technological environment, known as the knowledge forum (KF) – known earlier as the computer-supported intentional learning environment (CSILE,) progressed side by side with development of the KB theory (Scardamalia and Bereiter, 2006). KF presents a visualization of the KB discourse in the form of notes that students create within the environment. In contrast with other electronic discussion forums, where posts are stored chronologically with older post buried

under newer ones, KF represents the notes spatially, with those that have been of greatest interest (e.g., with most links) placed nearer to the center of the screen, no matter when they were created. Teachers benefit from such a visualization (Scardamalia and Bereiter, 1999) by gaining insight into the ideas that students have been most focused upon, allowing them to tailor their feedback to students.

Through the use of shared community knowledge, KB makes the knowledge within the community public so that all members can participate in idea improvement. In KB, idea improvement happens when every member of the community takes actions, such as searching, commenting, synthesizing, critiquing, or modifying, on publicly shared notes (Scardamalia, 2002; Scardamalia and Bereiter, 2006). Through these actions, the whole community takes on the ownership of the ideas and become responsible for the quality of their progress. KF facilitates students' participation in a progressive discourse by providing scaffolds that help clarify the underlying cognitive processes of the composed notes (Scardamalia, 2002).

While FCL employs carefully designed collaborative structures as a scaffold for the exchange of ideas among students, KB uses the technology environment to scaffold continuous collaboration for improving the state of common knowledge (Scardamalia and Bereiter, 2008). Organization and the structure of collaborative groups are less important as long as the students identify opportunities when they can contribute to idea improvement (Bereiter and Scardamalia, 2003). Although not necessarily designed to support small-group collaboration, KF makes the content of small-groups' discourse available to the whole class so that the ideas remain public. In this way, the transition between small-group and whole-class discussions will take place more smoothly.

Challenges for Researchers

We have reviewed two research programs – FCL and KB – within a single overarching category that we refer to as the knowledge-community approach. While the research in FCL and KB may emphasize somewhat different pedagogical processes and epistemological frameworks, both are dedicated to the vision of a classroom where students collaborate in developing ideas, and rely on the contributions of their peers as a primary resource for learning. Both projects require a deep epistemological commitment from students and teachers that is consistent with autonomous lifelong learning, resulting in radical departure from conventional forms of classroom instruction.

While the ideas outlined above offer a compelling vision of knowledge communities in the classroom, and have been acclaimed within research reviews (e.g., Bransford *et al.*, 2000), a number of challenges have restricted the

capability of educational researchers to investigate this approach. Any researcher who wished to investigate using such a model would have to begin by establishing a relationship with a teacher who was willing to embrace the required epistemological commitments and radically revise his or her classroom methods. The researcher would have to work with the teacher for a substantial period of time, perhaps years, as they developed the pedagogical knowledge required to succeed with a knowledge-community approach. Finding such a teacher who is willing to overhaul his or her curriculum and teaching methods would be a daunting challenge, particularly at the secondary level where content expectations are high and high-stakes assessments are often mandated. Still, in order to investigate a knowledge-community model, or make any progress on the theory or methods, a researcher would need first to establish a suitable classroom ecology.

Moreover, the knowledge-community approach is extremely difficult for teachers to implement in advanced topics like secondary science, due to challenging conceptual domains and heavy content expectations. KB, for instance, discourages topic-centered discussions in favor of inquiry problems, and has been successful at the elementary level (Bereiter *et al.*, 1997; Zhang *et al.*, 2009). But with so many required topics in most secondary courses, teachers are not likely to have the freedom to pursue such an unstructured approach. Scardamalia (2002) suggests that it would likely require at least half the school year to establish a knowledge community within a teacher's classroom. Even with such a community running smoothly, it would be quite challenging to help students achieve a deep understanding of some advanced conceptual domains like those in secondary science courses. In one of the very few published studies of KB for secondary science, Van Aalst and Chan (2007) employed a hybrid approach where students in the course (physical geography) received some direct (i.e., conventional) instruction and then held online discussions using KF. The authors of this study acknowledged that they only addressed a portion of the KB principles, and therefore did not technically follow the KB method.

The difficulty of engaging in such research, while understandable, has made it difficult for the field as a whole to adopt the core ideas and contribute new theoretical ideas or practicable models (Slotta and Peters, 2008). Very few replications of the FCL approach have been published, for example, and even fewer theoretical extensions or adaptations. Yet, if there is to be progress in the learning sciences, it is vital that our powerful ideas and theoretical constructs are accessible to researchers in order to support replication and extension of those ideas. The few published studies conducted on FCL-inspired classrooms report challenges with regard to instructional design and implementation (e.g., Sherin *et al.*, 2004). Concerns have also been raised that any new designs could fall

short of the theoretical goals, simply imitating the technological and pedagogical scaffolds and ignoring the important underlying epistemologies (Whitcomb, 2004).

Given the challenges and potential pitfalls, it is important to consider how we can support researchers who are interested in pursuing the knowledge-community approach. What are some of the design principles for establishing a valid knowledge community? How can a new research approach be connected, theoretically, to the work of FCL or KB? Some guidance is provided by Scardamalia (2002), who advances the notion of collective cognitive responsibility, articulating 12 core ideas that are determinants of a learning community. While these clear theoretical descriptors are of value, there remains a need for a more practical set of guidelines or design principles and a wider theoretical space in which new approaches and technology environments could be situated (Lehrer and Schauble, 2006). One important contribution of this nature is provided by Bielaczyc (2006), who offers a framework for defining a social infrastructure, including specific design considerations and examples for each dimension of the framework.

Knowledge Communities for Twenty-First-Century Classrooms

The recent emergence of social networking and knowledge construction technologies, together with new philosophical movements that espouse a twenty-first-century knowledge society (Hargreaves, 2003; Tapscott, 2008) has raised awareness and interest in the knowledge community approach. There is a growing level of excitement about a general shift, in society, away from an industrial-era view of knowledge as commodity (i.e., that is required for the performance of some task) to one of an engaging, collaborative process that transcends specific disciplines (Hargreaves, 2003; Gilbert, 2005). Many authors and researchers argue that the workplace of the twenty-first century is becoming one of dynamic collaboration and real-time learning, requiring an educational system that emphasizes the development of critical thinking, problem solving, collaboration, and creative application of knowledge resources (Bruer, 1993; Scardamalia, 2002; Sawyer, 2007). This characterization of a new knowledge age is due in no small measure to the emergence of the Internet as an ubiquitous phenomenon in the lives of citizens – particularly students (Tapscott, 1998, 2008).

In recent years, the Web itself has become transformed with new genres of knowledge-oriented media that present exciting opportunities for education. Indeed, scholars have begun exploring how Web 2.0 can be used productively for educational purposes (Ullrich *et al.*, 2008; Greenhow *et al.*, in press). Wikis, for example, provide a technology scaffold that enables students to

collaboratively construct knowledge resources. Bryant *et al.* (2005) demonstrated that students involved in a wiki authoring task shift their learning focus from one of personal contribution to one of concern for the shared artifact. Students can also socially tag their wiki entries, resulting in folksonomies that make them accessible to a wider audience, which can encourage more thoughtful and conscientious contributions (Wheeler, *et al.*, 2008). It is evident that such technologies are well suited to scaffolding knowledge communities in the classroom. In particular, the powerful new mechanisms of social networking and data mining (i.e., of semantic metadata) could enable new ways of implementing knowledge bases, connecting students with ideas, and allowing knowledge to grow dynamically within the community (Slotta, in press).

A promising direction for future research would be the application of Web 2.0 technologies to scaffold the complex and emergent processes within a knowledge-community approach (Slotta and Peters, 2008). While KB does employ a technology environment for its community knowledge base, this technology does not digitally interconnect the resource materials with the student-generated ideas, nor does it employ semantic metadata to connect students with peers or reveal emerging themes within the knowledge base. In FCL, the elaborate patterns of jigsaw and cross talk provide a powerful means of ensuring that the knowledge and expertise of the community is distributed, and yet they were orchestrated with no help from scaffolding technologies. Thus, one means of making the knowledge-community approach more accessible to researchers would be to create a new generation of scaffolding technologies that are designed to support the distributed cognitive responsibility, the shared knowledge base, and the pedagogical patterns.

It will be important for researchers who are new to this domain to read carefully from the literature cited above. Establishing a knowledge community within the classroom involves changing the learning practices of all students and teachers, as well as their epistemological perspectives. This cannot be achieved simply by adding a wiki or a blog to a classroom. On the other hand, there is a very wide range of pedagogical applications that satisfy the three dimensions defined above – much wider than the specific terrain prescribed by FCL and KB – which could allow for new models to be investigated. Our own research group, for example, has begun developing a new model called knowledge community and inquiry (KCI) that makes the three dimensions above more accessible to secondary science teachers (Slotta and Peters, 2008; Peters and Slotta, in press).

Glossary

Asynchronous – Occurring at different times.

Embedded assessment – Assessment integrated into everyday instructional activities.

Multimedia – Involving several media, for example, video clips, images and text.

Multimodal – Involving several modes, for example, visual, auditory and kinesthetic.

Professional development – Opportunities for training and learning for in-service teachers.

Stereoscopic – Three-dimensional image generated by simultaneously looking at two two-dimensional images.

Titration – Volumetric analysis in which a solution of known concentration is used to determine the unknown concentration of a second solution.

Technology, in the broadest sense, is the application of systematic or scientific knowledge for practical purposes. This article considers only computer-based technological tools for science learning. Technology has the potential to transform science education, by supporting collaborative, inquiry-oriented learning. Technology can increase the range of permissible phenomena to study, enable and promote greater social communication and interaction, provide multimodal and dynamic representations, structure and support student investigations, and support effective instruction and assessment. Technology can also help school science become more authentic – that is, more like the practice of scientists – and can facilitate the learning of science outside of the school setting, thus supporting lifelong learning. Policy reports have proposed that educational technology can provide an unusually high return on investment both in

economic and social terms (e.g., President's Council of Advisors on Science and Technology, 1997). In combination with professional development to support teachers, and innovative curriculum materials developed around clearly defined learning goals, technology may support improvements in student outcomes.

Educational technology can be classified into two categories: amplifiers and transformers (Rubin, 1996). Technology supports for science learning are not neutral, but dependent on the learning theory underlying their design. For instance, a behaviorist, learning-to-mastery paradigm may lead to learning technology that emphasizes memorization and the transmission of knowledge from teacher to student. By increasing the amount of practice with basic mathematical facts, the Math Blaster video game acts as an amplifier. The use of multimedia presentations and handouts for students can amplify the amount of material that can be covered as compared to a traditional class using a blackboard. A constructivist paradigm may, instead, lead to learning technology that engages the user in actively constructing knowledge. Constructivism values students' direct and tool-mediated interaction with their physical and social environment – reflectively building upon their prior knowledge – through the use of engaging and contextualized activities. The tenets of this learning theory are consistent with inquiry-oriented science teaching, in which students pose significant questions, design and conduct experiments to collaboratively address these questions, and communicate their findings. The use of technology in a constructivist manner is more likely to be transformative, and may result in higher student learning gains, even when using the same type of technology (e.g., personal response systems, see Judson and Sawada, 2002).

There are several general categories of educational technology use in science learning that are consistent with constructivism (see Table 1). As with any taxonomy,

Table 1 Some categories of technology use that support constructivist, inquiry-oriented science teaching and learning

<i>Category</i>	<i>Description</i>	<i>Examples</i>
<i>Real-time data acquisition and graphing</i>	Probes for pH, temperature, voltage, pressure, dissolved oxygen level, motion, etc., that connect to a computer, graphing calculator, or handheld device	Vernier probes for use with TI 83 plus calculator-based laboratory; Pasco PASPORT and Xplorer handheld probes
<i>Simulations</i>	Computer-generated versions of real-world objects and phenomena that often allow the user to control settings.	Virtual frog dissection kit (http://froggy.lbl.gov/virtual/); chemical kinetics simulation (http://www.chem.uci.edu/undergrad/applets/sim/simulation.htm); Molecular Workbench (http://workbench.concord.org/)
<i>Virtual communities, social networking sites, and collaborative websites</i>	Websites that support blogging, chat, and posting of user-created materials	http://www.classroom20.com/ ; Project FeederWatch http://www.birds.cornell.edu/pfw/ ; CASES (cases.soe.umich.edu); wikipages; http://teachertube.com/
<i>Virtual laboratories</i>	Internet environment allows students to design and carry out experiments	http://www.chem.ox.ac.uk/vrchemistry , http://learn.arc.nasa.gov/vlab/features.html
<i>Remote access to instruments</i>	Students interact with and manipulate instruments that are not available at their school, over the Internet	University of North Carolina atomic force microscope used by rural and suburban high schools in North Carolina (Jones et al., 2003); weather data (Songer, 1996; Edelson et al., 1999)
<i>Modeling software and microworlds</i>	Computer-programming language or software allowing users to create a world	Logo programming languages; Model-It
<i>In-class interaction technology</i>	Devices that enhance social interaction in the classroom	Interactive whiteboards; student-response systems (aka clickers)
<i>Inquiry-structuring software and sites</i>	Software or websites that help teachers and learners plan and manage long, complex investigations	WISE wise.berkeley.edu ; IdeaKeeper http://biologica.concord.org/
<i>Learning environments</i>	Web-based environments integrating curriculum, multimedia, simulations, support for learners, embedded assessment, etc.	WISE wise.berkeley.edu ; BioLogica http://biologica.concord.org/

these categories are conceptually useful but not absolute. Several types of technology can support each aspect of constructivist, inquiry-oriented science learning and teaching, as described below.

Technology Can Promote Interaction with the Physical Environment

Phenomena

Many scientific phenomena are too dangerous or too expensive to include in science classes at the primary or secondary level. Technology can make these phenomena accessible for students through online simulations, virtual laboratories, or remote access to tools and sensors such as atomic force microscopes or telescopes. Simulations are computer-generated versions of real-world objects and phenomena that often allow the user to control settings. Simulations focus on one aspect of reality and portray it so that it is easier to grasp. For instance, the Molecular Workbench simulations explicitly show charges on particles that facilitate student understanding of the role of forces and interactions in self-assembly. Technology can render visible phenomena that are too small or too fast to observe, such as chemical reactions or a gas at the

molecular level. Many such simulations are available online (see **Table 1**) or featured in companion compact disks (CDs) packaged with textbooks. Likewise, simulations can model phenomena that are too large to observe all at once, such as global weather patterns. Events that occur very slowly, like geological processes, can also be modeled using technology. Simulations can help overcome ethical obstacles, such as those involved in the dissection of live animals.

Technology can also increase the range of actual phenomena that students can experience. The use of video and Internet allows high school teachers to incorporate dangerous chemical reactions into their classroom (see virtual laboratories in **Table 1**). Another way of incorporating phenomena that are too dangerous or expensive for primary or secondary education is through the remote access to sophisticated scientific tools. In one such experience, high school students were able to examine viruses through remote access to an atomic force microscope at the University of North Carolina at Chapel Hill, which provided visual and tactile feedback in real time (Jones et al., 2003). In the Kids as Global Scientists and WorldWatcher curricula, students interacted with actual global and local weather data collected by remote sensors, via software that represented the data in an easy-to-understand format

(e.g., Songer, 1996; Edelson *et al.*, 1999). Thus, the use of technology in education can increase the range of available phenomena with which students can interact.

Supporting Student Investigations

A recent National Research Council (NRC; Singer *et al.*, 2006) report states that laboratory experiences are a fundamental part of science education. Laboratory experiences that involve direct interaction with the physical world or with real data can help students understand the relationship between research and theories, and learn about science as both process and content (Singer *et al.*, 2006). The College Board also supports actual laboratory experiences, offering only conditional authorization for Advanced Placement programs that use virtual laboratories. The use of standalone, computer- or calculator-based data-acquisition tools or probeware simplifies the collection of measurements of pH, gas pressure, dissolved oxygen level, temperature, and other variables. Probeware can help students investigate questions that they otherwise could not address; for instance, collecting data points separated by very short time intervals, or simultaneously collecting data on several variables. Variables, such as dissolved oxygen content or pH, that are traditionally measured using titrations or comparison to standards can more easily be studied experimentally by young students using probeware. Ultrasonic motion-detectors, or rangers, let students generate their own distance, velocity, and acceleration graphs by walking toward or away from a wall, allowing them to study the relationship between these variables without the use of calculus; motion-detectors also open the possibility for experiential, kinesthetic learning experiences that are engaging to many students. The NRC report recommends that laboratory experiences go beyond making observations and collecting and analyzing data, to include posing questions, designing experiments, creating explanatory models, and communicating findings (Singer *et al.*, 2006). Several of these aspects can also be supported by technology, as described below.

Dynamic Representations

Simulations can demonstrate the dynamic nature of processes much more effectively than can static images in books. Technology can make abstract processes concrete through effective visual and multimedia representations. SimCalc is a tool for the learning of the mathematics of change and variation that allows even elementary school students to begin to explore and understand elements of calculus in the context of motion (Roschelle *et al.*, 2000). Dynamically linked multiple representations such as velocity graphs, position graphs, and animations can help learners make connections in building conceptual understanding, when used appropriately (see Ainsworth, 2008).

Simulations for chemical equilibria can graphically represent the forward and reverse reactions that occur at equal rates, combating the common student alternate conception that no process takes place at equilibrium. The simulations can generate accompanying charts displaying the values of variables, helping the learner link between the atomic-molecular and macroscopic levels (see, e.g., Nakhleh and Postek, 2008).

Constructing Models and Representations

While simulations allow the user to manipulate settings, modeling software and programming languages permit the user even greater latitude to model the phenomenon of their choice. The Logo family of constructionist programming languages enables computer environments in which the learner actually builds computer representations of a system of interest (see, e.g., Resnick, 1994). The user determines the rules governing the behavior of one or many agents. Software such as Star Logo enables students to model emergent phenomena such as birds' flocking behavior or traffic jams by defining the rules governing the behavior of a large number of agents. Modeling software such as Model-It (Jackson *et al.*, 2000) allows the user to input variables along with the functional relationships between variables, in order to build – from the ground up – a model of a system such as a river ecosystem. By viewing output graphs, students can explore the behavior of an entire system, and the effects of changing one or more variables.

Technology Can Promote Interaction with the Social Environment

Technology can also facilitate social interactions. In the last decades, science has been envisioned as a socially mediated process (e.g., Kuhn, 1962; Latour and Woolgar, 1986). Similarly, current conceptions of science learning stress the role of communities and social interaction (e.g., Bransford *et al.*, 1999). Innovative curriculum programs such as Kids as Global Scientists and BioKIDS (Songer, 1996; Songer, 2006) have included student–scientist communications via e-mail, student–student collaborations across even widely distant locations, and asynchronous communications using bulletin boards. The anonymity afforded by electronic communications can empower participants who otherwise might not engage in discussions. Other programs – such as Project FeederWatch – use the data from amateur bird-watchers all over the USA to track populations and migrations, and can be incorporated into the science curriculum. Such uses of technology enable the compilation of large-scale databases that allow students to track processes that would otherwise not be possible, while supporting increased collaboration.

While some uses of computer technology can be isolating, experiences involving visualization, modeling, and simulation can provide opportunities for interaction among students and teachers. Technological tools such as interactive whiteboards – which are systems that combine a projector and a large, touch-sensitive screen to display and facilitate manipulation of a computer screen – can enhance classroom interactions. Interactive whiteboards allow teachers to instantly add notes to a presentation, or record students' ideas, and then save them in a digital format. Web pages that support collaborative creation and editing, such as Wiki pages, can also increase social interaction. Wiki pages can pool the expertise of many individuals without the need for face-to-face interaction, allowing for asynchronous and long-term collaborations. Both the process and the product of building a Wiki page can support science learning. Student-response systems, in which students use an infrared remote control or clicker to register a response (e.g., to a multiple-choice question), allow for real-time formative assessment that teachers can use to modify instruction. These systems can also facilitate social interaction even in large college lecture halls, if the instructor encourages small-group discussions about the question. Some computer-based environments for science learning specifically encourage and rely on small-group interaction (e.g., ChemSense – Michalchik *et al.*, 2008).

Many of the above applications depend on student access to a laptop or desktop computer; however, the use of portable, handheld devices such as MP3 players, personal digital assistants (PDAs), and probeware allows for autonomous learning and can increase motivation, collaboration, and communication. One example is the use of handheld PDAs in the BioKIDS curriculum to help students collect biodiversity data in their schoolyards, which were then aggregated over a classroom, a school, or a state. Another example is the use of standalone or calculator-based handheld probeware for data collection in the lab or in the field.

Technology Can Support Reflective Construction of Knowledge

Reducing the Load on Working Memory

The effective use of educational technology can support learning by structuring tasks for students. Humans have a limited working-memory capacity, and technology can help overcome this limitation in several ways. By focusing only on relevant aspects, simulations can simplify a complex natural phenomenon. Multimodal simulations that employ both visual and phonological channels (e.g., text and images alongside narration) can reduce working memory load (Mayer, 2001). In addition, technology can be used to handle routine tasks, such as graphing or simple forms of data

analysis, in order to allow students to concentrate on the relevant concept. This offloading must be used judiciously, however, as it can keep students from learning graphing and analysis processes that are basic to science.

Computer technology can be used also to speed up student workflows and provide immediate feedback. For instance, the use of computer- or calculator-based probeware in the laboratory allows for instantaneous, real-time graphing of data, thus reducing students' need to coordinate the lab experience itself with subsequent data analysis conducted over a long period of time. By allowing students to concentrate on the construction of meaning rather than on recording data in their notes, interactive whiteboards that allow teachers to save and post or reproduce class notes can also reduce the load on working memory. Printouts of computer-based presentations can help students concentrate on taking their notes, to help them make sense of class, rather than on copying the information being delivered.

Managing Time and Complexity

Software tools can help structure a complex task and support planning. Science-learning environments like the Web-based Inquiry Science Environment (WISE) (Williams and Linn, 2002) and software such as Idea Keeper (Quintana *et al.*, 2005) provide structure for students during complex investigations through the use of checklists, prompts and reminders, graphical organizers, and other means of tracking progress. Progress can also be tracked by digital portfolios. Restricting the problem space or simplifying the phenomenon of interest can focus the efforts of students. On the other hand, software tools can problematize student learning – making it more complex but also more productive – by focusing students' attention on unresolved aspects of the investigation or requesting rationales for decisions (Reiser, 2004); for instance, by prompting users to analyze whether parts of the arguments they have constructed are evidence or claims, and whether the evidence supports or disconfirms the claim.

Supporting Teachers

Research has found that quality of instruction is a major determinant of student outcomes (e.g., Wright *et al.*, 1997). Technology can support teachers so that they can help students learn better. Science-learning environments can have embedded formative assessments that teachers can access immediately in order to gauge the effectiveness of their instruction and modify their plans accordingly; student-response systems – used frequently in undergraduate science classes – can achieve the same end. Teachers can search for laboratory lesson plans and safety

data on information-access environments such as the Internet or digital encyclopedias.

Online professional development opportunities for teachers have also been employed, to improve their pedagogical capacity as well as science-content knowledge. CASES (Davis *et al.*, 2004) is an online system for elementary science teachers that includes a unit-plan library, resource library, and descriptions of how to teach, modify, and adapt lesson plans. Virtual communities and social networking sites allow teachers and educators to share ideas, hold discussions, post materials such as videos and lesson plans, and easily search for specific resources that they need.

Technology Can Support Contextualization

Authenticity

The Kids as Global Scientists and World Watcher curricular projects access the actual data of professional scientists, using the Internet and custom software. Other uses of technology involve students in generating genuine scientific data, as in the Project FeederWatch, BioKIDS, and Global Learning and Observations to Benefit the Environment (GLOBE) projects. Remote access to sophisticated tools such as telescopes and microscopes allows students to use the instruments of practicing scientists. All of these factors increase the relevance and authenticity of science learning for students, in comparison to traditional instruction based on books and simple, often decontextualized laboratory experiments. The use of computers, simulations, communications technology, and the Internet is pervasive in professional science; when students learn to use these technologies, they are learning to use some of the tools of scientists. Students can use the Web to locate information, collect data, analyze and display it, and communicate their findings and understanding using technology that is similar to that in use by scientists.

Relevance to Everyday Life

These uses of technology have opened up the possibility of addressing topics that are relevant to students but that were previously too difficult. For instance, the ideas of calculus that were previously taught to talented high school students and undergraduates using complex mathematical notation are now being introduced to much younger children in an intuitive and graphic manner (Roschelle *et al.*, 2000). The behavior of traffic jams is easy to study and comprehend in a computerized environment, but difficult otherwise; this phenomenon is of interest to any city-dweller. Technology has also been

used to support studying the school grounds as an ecosystem (BioKIDS) or a local stream (using Model-It) – also topics of relevance for students.

Technology Supports Increased Access to Information

The explosion of the information available on the Internet is impacting education in multiple ways. The Internet facilitates teachers' searches for factual information (through both general sites like Wikipedia and more targeted sites such as those of National Aeronautics and Space Administration (NASA), Public Broadcasting Service (PBS), or science magazines online) and for educational activities, research, and ideas (e.g., the ERIC database and teacher virtual communities). The Internet lets students access textbook-publishers' companion websites featuring tutorials, practice problems, interactive or stereoscopic figures, simulations, and even the electronic versions of textbooks. Course websites may include podcasts of lectures, notes or multimedia presentations, online quizzes, and links to useful websites. Databases and online journals increase the pace of scientific progress and of science learning by allowing quick and convenient access to journals and papers, along with earlier access to papers published on the Web and posted on the journal website in advance of publication in hard copy.

Integration of Features Can Transform Education

While many of the features mentioned above amplify existing characteristics of science teaching without technology, taken together they can be transformative. Learning environments that combine innovative curriculum and effective use of technology can be qualitatively different from curricula that do not incorporate technology, allowing real-time and asynchronous collaborations among students, teachers, and scientists, focused on otherwise inaccessible phenomena. For instance, the WISE learning environments support students in collecting, synthesizing, and analyzing information from a variety of authentic sources and simulations, to address engaging questions such as, "Does light go on forever?" WISE activities also build students' argumentation and communication abilities. Other modules use multimedia and simulations to address complex questions, with planning support in the form of checklists, prompts, graphic organizers, and so on. Such inquiry-oriented instructional activities are consistent with constructivist learning theory and can lead to deeper, more flexible understanding. Technology affords immediate feedback and multiple opportunities to make students' thinking visible, enabling science teaching that is more responsive to students' needs.

Pitfalls and Challenges to Implementation of Technology

Some challenges to the implementation of technology in the science classroom are general: for example, technology is expensive, requires maintenance and technical support, teachers may need professional development in order to use technology effectively, and so on. Some pitfalls are specific to the use of technology in the science classroom. For instance, simulations that portray relationships between variables as smooth curves may misrepresent the nature of empirical work in science in a way that a laboratory experiment would not. Science teachers may struggle to simultaneously learn to use the technology and learn to teach in inquiry-oriented ways. The opportunity costs of adopting technology for science education must also be considered. Funding for technology may be in competition with funding for laboratory supplies, and time spent on computers may be time not spent in the laboratory or other important activities.

The Role of Technology in Increasing Equity in Education

The costs that a school district incurs in adopting technology are a challenge to equity. Lower-income areas in the United States tend to have poorly funded schools, with smaller percentages of certified teachers teaching in a subject that they are trained to teach, and lower budgets for technology. On the other hand, once in place, technology may offer underprivileged students opportunities that are currently unavailable to them. Small, underfunded, or rural school districts may benefit from online courses in topics that enrich their curriculum at a lower cost than offering the course themselves. Videoconferencing, likewise, can support collaborations or enable access to experts.

Adaptive technology for disabled students can help their access to education, in general. This article has been written at an ergo pod: an accessibility workstation with dictation software, image magnification, screen reader for the visually impaired, adjustable-height work surface, etc. There has been some development of software and equipment specifically for visually impaired students to carry out laboratory chemistry experiments, for instance, colorimeters with an auditory output to help in titrations.

Emerging Applications and Future Directions

The Web 2.0 generation of Internet sites that allow users to create, post, and share content (e.g., YouTube, Facebook,

and Second Life) may affect science learning in interesting ways. Teacher communities allow for discussions, sharing of resources, and collaborative projects. Games such as Spore are not explicitly meant for the education market but embody the principles of evolution and genetics. Recent research at the University of Wisconsin at Madison has found that role-playing games such as World of Warcraft require and build problem-solving skills that may transfer to the science classroom (Steinkuehler and Duncan, 2008). Increasingly powerful and portable smart phones with digital cameras, probes, and Internet connectivity may enable students to pursue science topics in which they are interested outside of the school setting in ways we cannot imagine at present. Cognitive tutors – which track student knowledge and the knowledge space in delivering highly individualized instruction – are currently restricted to well-defined topics such as mathematics or computer programming, and do not, at present, support the contextualized and open-ended exploration typical of inquiry-oriented science teaching. However, the possibilities of individualized instruction delivered via future generations of cognitive tutors that can address more complex domains are tantalizing. Customizing instruction and assessment for groups of students with particular needs (English language learners, the visually impaired, and so on) is another possible future direction for technology in science education.

Large-Scale and Systemic Impact

The scaling up and sustainability of promising educational innovations are an important challenge to the field of science education. The Internet offers a platform that increases access to and the longevity of learning environments. Ongoing projects to digitize books will increase the number of sources of information available to learners, but will also transform the experience of finding information in books, with features such as keyword searching in a single book or across entire databases. As technology allows learners to have access to tools and information independent of their physical location, life-long and self-directed learning will become more feasible. Finally, one can foresee feedback cycles that lead to further leveraging of technology to support science learning. As students routinely use Web 2.0 applications such as YouTube and Facebook, and virtual environments such as Second Life, they construct novel digital literacies. These technological abilities may support the development of future technologies to support science learning in ways as yet unforeseen.

Technology Supports for Second Language Learning

D Nunan, University of Hong Kong, Hong Kong, SAR, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

Glossary

e-learning – Learning through Internet-based instruction rather than in face-to-face instruction.

Foreign language learner – An individual who is learning a language which is not the medium of communication in the country where the learner resides, for example, an individual learning Chinese in the United Kingdom would be said to be learning Chinese as a foreign language.

Globalization – The interlinking of economies and markets and the spread of corporations worldwide.

Internet – An international network linking computers worldwide for the purposes of exchanging electronic messages and documents.

Learning management tool – The use of technology for managing the learning process rather than transmitting content.

Second language learner – An individual who is learning a language other than their first language in a country where the language being learned is widely used for communication, for example, a first language speaker of Punjabi learning English in Canada would be said to be learning English as a second language.

Technology – The application of scientific and technical systems for practical purposes.

World Wide Web – An information system that allows documents to be linked together through the Internet.

Technology has supported second-language pedagogy for many years. In the 1960s and 1970s, language laboratories provided drill-based practice to support audiolingualism – the dominant instructional approach of the day (Richards and Rodgers, 1986). In the 1980s, videotapes became increasingly common, and computers made their first appearance in the second-language classroom (Higgins and Johns, 1984). However, it was in the 1990s, with the explosion in Internet use and the emergence of the World Wide Web, that technology became ubiquitous (Warschauer, 1999; Beatty, 2003).

The first part of this article examines the roles played by technology in second-language learning, focusing in particular on technology as a provider of content, as a learning management tool and as a communication tool. We then examine models of classroom organization, and

suggest that technology has forced us to redefine our concept of the classroom. The final major section of the article enumerates seven areas of second-language pedagogy where technology is demonstrably superior to face-to-face instruction.

The Impetus for Increased Technology Use in Second-Language Classrooms

Technology has become so pervasive that it is not longer appropriate to see it as playing a supporting role to face-to-face instruction. A major stimulus for the rise of technology in second-language classrooms has been the explosion in the demand for language training. This demand is principally, but not exclusively, for English and is a byproduct of globalization. In a recent survey of more than 25 000 employees of global corporations, the percentage of respondents who said that English was either critical or important for success in their current positions increased each quarter over an 18-month period. **Figure 1** shows the growth in the perceived importance and use of English over the period from June 2003 to December 2004. During this time, those who reported that English was critical for their jobs rose from just over 50% to 80%. The percentage of global corporation employees who used English daily in their jobs rose from 35% to 60% (**Figure 2**).

The vast majority of those surveyed reported that their English-language proficiency was insufficient for them to be successful in their current jobs (only 9% said their English-language proficiency was sufficient to do their current jobs). Under these circumstances, the explosion in the demand for English instruction is quite understandable. This demand overwhelmed traditional face-to-face providers, and many workplace human resource managers looked to technology, particularly the Internet, to provide English-language instruction. Private corporations, such as Global English, are meeting a demand that is simply beyond the reach of conventional second-language classrooms.

Roles of Technology in Second-Language Classrooms

The three major roles played by technology in classrooms are as a carrier of content and an instructional tool, as a learning management tool, and as a communication tool.

Figure 1 Percentage of respondents who report that English is critical for their job. From Nunan, D. (2005). The evolution of technology and the value of online English language learning, p. 5, *White Paper*, Global English Corporation, San Francisco, CA, USA.

Figure 2 Percentage of respondents who use English daily in their jobs. From Nunan, D. (2005). The evolution of technology and the value of online English language learning, p. 5, *White Paper*, Global English Corporation, San Francisco, CA, USA.

In second-language learning, the dominant role for technology is as a provider of content and as an instructional tool. When the computer presents learners with listening and reading input, and information on pronunciation, vocabulary, and grammar, it is acting as a carrier of content. This content can be specially written for pedagogical purposes, or it can be authentic material that exists on the Web. Web-search activities are becoming increasingly popular in language instruction, and provide foreign-language learners, as opposed to second-language learners, with opportunities to learn through interacting with authentic texts. Such texts were originally created for the purposes of communication, not to teach English (Nunan, 1999). When the computer provides opportunities for learners to practice a language by doing spoken and written drills, completing comprehension questions, carrying out grammar exercises, and so on, it is acting as an instructional tool.

The second major role for technology in classrooms is as a learning management tool. This role is becoming increasingly significant in second-language pedagogy, particularly with the spread of proprietary software, such as Blackboard and Moodle. These learning management software packages enable teachers to carry out many learning management tasks more efficiently and effectively than more traditional face-to-face methods. For example, a good learning management system can:

- administer and collate needs analysis data from students;
- allow teachers to post course information, handouts, and other materials for student to download;
- enable students to submit assignments, and teachers to grade and return assignments, electronically;
- document student achievement and archive learner portfolios containing samples of spoken and written language;
- administer, analyze, collate, and store the results of classroom quizzes;
- administer, collate, and present student evaluations of teachers.

The third major role for technology in language learning is as a communication tool. One of the greatest frustrations for learners attempting to acquire another language in a foreign-rather than second-language context is finding opportunities to activate their language by interacting with other people in that language. One of the greatest benefits of technology is that it can bridge distance and time, enabling learners to interact with native speakers and other learners who are living, working, and learning in a wide range of cultural contexts in different parts of the world. At present, the most common technology-based means of communicating for purposes of language learning are e-mail and text chat, although voice chat and webcam are becoming increasingly common.

The Technology-Supported Second-Language Classroom

As Internet resources began to supplement and, in some cases, replace traditional face-to-face instruction, teachers and instructional designers debated the merits of the virtual classroom (Nunan, 2005). Initially, there was considerable skepticism toward the notion that someone could learn a language through the Internet. Such arguments are rarely heard these days. The issue is no longer whether to use technology, but rather how technology can support classroom instruction, and the extent to which it can replace conventional second-language classrooms. Studies in online second-language learning suggest that this approach has a number of benefits – specifically, online language learning, as it

- promotes a deep rather than surface approach to learning (Biggs and Telfer 1993);
- stimulates active, constructivist learning rather than straight knowledge transfer (Weasenforth *et al.*, 2002);
- fosters students' awareness of discourse-related aspects of communication (Davis and Thiede, 2000); and
- allows students to share perspectives and experiences, to establish relationships, and to seek assistance (Chong, 1998).

Before examining models of classroom organization, a word on terminology is in order. Classrooms are traditionally seen as places in which teachers and learners are gathered together for instructional purposes. "The L2 classroom can be defined as the gathering, for a given period of time, of two or more persons (one of whom generally assumes the role of instructor) for the purposes of language learning" (van Lier, 1988: 47). However, with the development of distance learning, and, in particular, the use of technology, the gathering together may happen in a virtual classroom rather than a physical space.

The ease with which the computer can bring people together across time and space is forcing a redefinition of the classroom. Through the computer, the gathering together for language learning no longer requires the individuals to inhabit the same physical space. The following vignettes illustrate some of the changes wrought by technology and some of the ways in which technology has redefined the second-language classroom.

A teacher educator in Auckland, New Zealand, conducts a graduate class on second-language acquisition through a text chat site with students in Tokyo, Japan; San Diego, California; Bangkok, Thailand; and Buenos Aires, Argentina.

A student in Toronto, Canada, who was unable to make his Spanish class, is able to review a transcript of the lesson which is posted on to the Web several hours after the conclusion of the class.

A secondary school teacher in Hong Kong posts all her assignments and class handouts onto the class website. Students either work with these online as needed or download those that they want in hard copy.

Using voice chat, English as a Foreign Language (EFL) students in China, Korea, and Japan take part in a conversation class with a teacher based in Bogota, Columbia.

A school in Osaka has its students complete an online placement test which automatically assesses and places students into instructional groupings in a fraction of the time it used to take using a pencil-and-paper test.

In a keynote paper, which explored the impact of technology on second-language pedagogy, Legutke commented on the ways in which changes wrought by technology have forced a redefinition of the foreign-language classroom. He notes that "These changes challenge our self-concept as foreign language teachers, because, much

more than in the past, we are now called upon to redefine our roles as educators, since we need to mediate between the world of the classroom and the world of natural language acquisition" (Legutke, 2000: 1).

Several models of classroom organization have been proposed for technology-supported classrooms. All of them involve some form of integration of traditional face-to-face classroom activity and virtual classrooms. Such combinations are referred to as blended or hybrid learning in the online learning literature. Several models have been proposed for blended learning:

- *Model 1: The traditional classroom is supplemented and supported by technology.* In this model, classroom content is delivered in the traditional face-to-face manner, but instruction is supplemented by technology. This supplementation can take the form of additional content or support for the management of learning. The teacher decides what is to be taught, how it is to be taught, and how it is to be assessed, and technology plays a secondary role.
- *Model 2: Technology delivers the content and is supported by web-based live instruction.* In this model, instructional content is delivered through technology, and is supplemented and supported by a teacher. This is the model that is followed by commercial enterprises such as English Town and Global English. For example, Global English consists of a comprehensive ten-level suite of courses which are accompanied by a wide range of additional resources such as online needs analysis instruments, grammar and vocabulary enrichment, and an online magazine. Self-paced learning is supported by a talk-with-the-teacher feature. This feature enables students to interact with a teacher and other learners in a virtual classroom through text and voice chat.
- *Model 3: Technology delivers the content and is supported by supplemental face-to-face instruction.* This model is similar to model 2, except that the live support is provided in traditional face-to-face classrooms rather than through the Internet.
- *Model 4: The fully integrated classroom.* In the fully integrated classroom, technology and live instruction work side by side. Teachers do what they do best, such as facilitating interaction in the target language, while technology does what it does best. (The final section of this article describes seven things that technology does better than teacher-led instruction.)

These models demonstrate that the early dichotomy between face-to-face instruction and virtual, technology-mediated instruction was overly simplistic. At the time that this article was written, the overwhelming consensus among second-language instructors was that some form of blended learning was the preferred option in most pedagogical situations.

Research into Technology and Language learning

A rapidly growing body of research is beginning to provide insights into the ways in which technology is having an impact on, and changing the nature of, second-language instruction. Initially, instructors rather naively wanted to know whether the virtual classroom was more effective than the face-to-face classroom. The question is naive because, as noted in the preceding section, it is not an either-or issue. Technology and teachers each have a unique contribution to make to the learning process. The question is also naive because it is almost impossible to control and assess the relative contributions made by technology and face-to-face instruction. It also represents a return to the old method of comparing studies (is method X superior to method Y?) that proved to be futile over 30 years ago (Scherer and Wertheimer, 1964).

Contemporary research into technology and language learning can be quite sophisticated in terms of the questions and issues it addresses and the range of methods that it employs. This can be seen by looking at the list of contents from recent issues of the top journal in the field, *Language Learning and Technology*. Here, for example, is the contents list from the most recent issue of that journal:

- e-learning and the development of intercultural competence
- ESL students' computer mediated communication practices
- L1 and L2 glosses: their effects on incidental vocabulary learning
- Noticing and text-based chat. (*Language Learning and Technology*, 10(3), September 2006.)

Questions currently preoccupying second-language researchers concerning the impact of technology on second-language pedagogy include:

- What similarities and differences are there between the discourse of online chat and face-to-face classroom interaction?
- What affective factors are at play in technology-supported classrooms?
- What aspects of pedagogy are best delivered through technology and what aspects are best delivered through teacher-led instruction?
- What is the reaction of language learners to technology-enhanced instruction?

The discourse of technology-supported communication has been a particular focus of research in second-language classrooms. This is not surprising, given that language is both the medium and the content of instruction in second-language classrooms. In one of the studies reported in the latest issue of *Language Learning and*

Technology ('Noticing and text-based chat'), it was found that online chat was more effective than face-to-face conversations in prompting learners to notice their own linguistic mistakes (Lai and Zhao, 2006).

In another study into the discourse features of online English as a Second Language (ESL) classes, the researchers drew the following comparisons and contrasts with face-to-face classes:

1. All the pedagogical functions identified in face-to-face classroom interaction are evident in synchronous teacher-hosted chat.
2. Choosing the appropriate responding move is crucial, both to pedagogy and the ongoing interaction.
3. The responding move enables the teacher to build a pedagogical interaction.
4. The multilayering of discourse in chat is even more complex than in face-to-face interaction.
5. Text chat may have pedagogical advantages over voice chat. For example, learners will have a visual record of the interaction. This will provide them with more time to process the message.

Benefits of Technology

There are areas where teacher-led instruction has benefits that clearly outweigh those offered by virtual instruction. These include the ability to organize, monitor, and facilitate interactive learning in small groups of learners, the ability to diagnose and deal with specific learning difficulties (although in some aspects of learning technology is catching up fast), and the ability to offer emotional support and encouragement. The importance of this last benefit should not be underestimated. The attrition rate in virtual classrooms is much higher than that in face-to-face classrooms, and it may be the positive presence of the teacher, along with the support and pressure of peers, that helps to maintain much higher attendance rates in face-to-face classrooms.

Conversely, there are areas where technology offers clear advantages over teacher-led instruction. This section comments on six of these:

- individualized study plans;
- anywhere/anytime instruction;
- patient tutoring;
- a private space to make mistakes;
- immediate, individualized feedback; and
- detailed records of achievement.

Individualized Study Plans

While there is room for some flexibility in face-to-face classrooms, in most, instruction is pitched at the middle ground. Syllabus content as well as course goals and

objectives have to be tailored to the majority, and individual needs and wants, both in terms of learning outcomes and preferred learning pathways, can rarely be satisfactorily catered to.

Technology, however, can facilitate the development of individualized study plans. In courses which are 100% virtual, each learner can have a program tailored to his or her needs, and each learner in the program can thus follow his or her own unique program. In blended classrooms consisting of a mix of teacher-led and virtual instruction, a degree of individualization can also be achieved.

At the beginning of the learning process, a series of menu-driven choices can lead the learner through questionnaires and prompts that elicit a set of terminal learning objectives. Learners can select their own preferred learning styles and strategies, and the program can recommend tasks and activities based on these choices. Learners can also indicate the level of proficiency gain they would like to achieve by a certain date. Given their current level of proficiency, the system can suggest the approximate number of hours that the student will need to study in order to achieve the goals. If the system is linked to an online bank of materials, it can also assemble a tailored set of learning resources for each individual learner.

In online courses, where the content is tagged with lexical, grammatical, and functional information, the software can also perform an important diagnostic function. As students work through the materials, the program can identify those aspects of the linguistic system where students are weak, and can suggest adjustments to the study plan to provide additional remedial practice in these areas.

Anywhere/Anytime Instruction

Unlike conventional classrooms, where the time and place of instruction are established in advance, electronic (e)-learning allows students to engage in learning at the time and place of their choosing. This is possibly the most obvious benefit of e-learning, although it is also a possible disadvantage. Having a set time to attend a teacher-led class provides a learner with a routine that is missing from the virtual classroom. The daily pressures of work and personal life can push the time that was set aside for e-learning to the back of the learner's daily agenda. This is likely one reason for the higher levels of attrition from virtual as opposed to face-to-face courses.

Patient Tutoring

As it is a skill rather than a body of knowledge to be mastered, acquisition of a second language requires time and extensive repetition. It is rarely feasible for adequate

repetition to be provided in conventional classrooms. A natural tendency in a classroom with more than one student is for the teacher to move on when a majority of students demonstrate a skill, leaving the slower learner behind. The technology-driven classroom, however, has infinite patience, and learners can spend as long as they feel they need on a particular exercise or task.

A Private Space to Make Mistakes

Technology enables learners to study in their own private space. Here, they are free to make mistakes in private. They need not be subjected to the embarrassment and even personal humiliation of making mistakes in front of classmates. The fear of making mistakes in public is partly personal and partly cultural (see Ellis, 2009). Many learners are unconcerned at making mistakes in public. Others, however, are paralyzed with fear and embarrassment at the prospect of making mistakes. This attitude to making mistakes in public appears to be a personality factor that is linked to learning style preferences (Willing, 1994).

This is particularly important for Asian learners for whom making mistakes in front of others is a major deterrent to language learning (Biggs and Telfer, 1987).

Immediate, Individualized Feedback

Providing feedback to learners on how successfully they completed a particular task or exercise is a fundamental aspect of the instructional process. In second-language pedagogy, considerable research has been conducted into the dynamics of this process. Researchers have looked at what aspects of a learner's performance should be evaluated by the teacher, when it should be evaluated, and the form that feedback to the learner should take (Chaudron, 1988).

Extensive research in both content classrooms and language classrooms indicates that the timing of the feedback is critical. The closer the feedback is to the actual performance, the more powerful is its impact on subsequent performance as well as learner motivation (Dorneyi, 2001).

In regular classroom instruction, the ability of the teacher to provide individualized feedback is severely constrained. Apart from the occasional asides to particular students during group activities, it is impossible to provide instant feedback to all the students in the class. The best that the teacher can do is to monitor student activity during the lesson, and provide feedback on the most common errors.

Online instructional programs, on the other hand, can provide instant feedback. As soon as the learner has completed a grammar exercise or comprehension task and

submitted his or her responses, the program can provide feedback on how well he or she has done. Most programs can not only tell students which answers are correct and which wrong, but also provide qualitative information on why particular responses are incorrect.

Of course, there are constraints on the types of learner performance that can be evaluated without the intervention of a human being. Questions and tasks that have a clear right or wrong answer are easier for technology to handle than ones in which more than one response is acceptable. Giving feedback on receptive skills (listening and reading) is easier than giving feedback on the productive skills of speaking or writing. At the time that this article was written, considerable time, effort, and money were being spent on developing tools for assessing students' productive language (de Jong and Bernstein, 2001). In terms of speaking, one of the more successful efforts has been the commercial program known as Phonepass (de Jong and Bernstein, 2001). Using speech-recognition technology, this program administers a test of speaking ability on the telephone, and provides assessment takers with a language-proficiency rating. Efforts are currently underway to assess learners' writing skills.

These programs are achieving impressive results. Phonepass assessments correlate highly with standardized proficiency tests such as Test of English for International Communication (TOEIC) and Test of English as a Foreign Language (TOEFL; Bernstein *et al.*, 2000). However, there is considerable resistance from consumers, who are skeptical at the notion that a computer can furnish valid and reliable assessments of second-language speaking and writing (McLure, K. Global English Corporation, Personal Communication).

Detailed Records of Achievement

Allied to the preceding point is the fact that e-learning programs can assemble and provide detailed records of achievement on individual learners. This is especially helpful in a corporate setting where an administrator may be tracking thousands of learners. Global English has a particularly sophisticated set of reports on learners. Corporate administrators can track the progress and status for every user, no matter how large the program, so that they can see the impact that the program is having on individual performance.

Summary

This article began by outlining the three main roles of technology in the second-language classroom: as a

provider of content and instruction, as a learning management tool, and as a communication device. It then described how technology is helping to fill a demand for language instruction that has far outstripped the capacity of the conventional classroom, and outlined four instructional models of the technology-enhanced classroom. The final section of article examined six key aspects of pedagogy where technology offers benefits over conventional teacher-led classroom instruction.

Glossary

Information and communication technology (ICT) – The term often used interchangeably with information technology (IT) in the literature on technology in education.

Information technology – It is also used interchangeably in the literature on technology in education with the term ICT and refers both to computer hardware and software as well as networking infrastructure to enable the user to connect to the Internet via the computer hardware.

Teacher learning is crucial to the process and outcome of integrating information technology (IT) in the learning and teaching process in schools. Studies of information and communication technology (ICT) implementation in schools have often found teachers' lack of IT knowledge and skills to be a major obstacle (e.g., Pelgrum and Anderson, 1999). A recent comparative study of pedagogy and ICT use in schools in 22 countries and educational systems found teachers' self-perceived technical and pedagogical ICT competence to be positive, significant predictors for teachers' ICT adoption in their own teaching practice (Law and Chow, 2008). In particular, pedagogical ICT competence, which is the teachers' ability to make appropriate selection and use of ICT tools in different curriculum contexts for different pedagogical purposes, is the most crucial determinant of actual ICT use in instruction.

The core skills and knowledge that teachers need to have differ depending on the perceived purpose and anticipated impact of technology integration in the curriculum. Efforts to integrate ICT in the teaching and

learning process to achieve some general or specific educational goals, rather than as an object of study as in early computer programming classes, started around the early 1980s (e.g., Becker, 1985). Since then, there have been major shifts in the rationale put forward for the role of ICT in the curriculum, both in the academic literature and in educational policy documents around the world, moving from a focus on improving students' learning in the school curriculum to the reforming/transformational role of ICT (Means, 2000; Pelgrum and Law, 2003).

Teacher Learning to Realize the Enabling Potential of ICT in Education

One of the earliest published ICT-related standards for teachers was established in the UK (DES, 1989) for pre-service teachers, which exemplified the kind of knowledge and skills expected of teachers in order that they will be able to select and make appropriate use of IT to promote learning. The standard included competence to make use of technology as a personal productivity tool, such as using a wordprocessor for writing and a spreadsheet for exploring the consequences of different scenarios given a set of mathematical relationships, as well as the ability to critically review and select software and IT devices suitable for the subject matter and student profile concerned, plan, and execute schemes of work that incorporate the use of such resources. This has evolved later into a detailed curriculum for the use of ICT in teaching specific subjects. Standards with this focus can operate within curriculum frameworks that have been developed without specific considerations or demands about what technology may bring to the teaching and learning situation, that is, these are standards for enabling uses of technology to improve students' learning effectiveness.

Related competence includes the knowledge of when, when not, and how to use ICT in different classroom settings, and how to make use of ICT in assessment. The kind of knowledge and the associated skills required of teachers is conceptualized by Mishra and Koehler (2006) within a technological pedagogical content knowledge (TPCK) framework. This framework builds on Shulman's (1987) notion of pedagogical content knowledge as knowledge about how to teach specific concepts within a curriculum. Shulman asserts that a competent teacher possesses not only pedagogical knowledge (general teaching strategies) and content knowledge (knowledge of the subject area), but also pedagogical content knowledge. Mishra and Koehler extend this notion to the appropriate instructional use of technology, arguing that teachers not only need technical knowledge, but also technological content knowledge (i.e., knowledge about how technology and content are reciprocally related to each other, e.g., the use of simulations and modeling tools will allow learners to explore the interrelationships between different entities in a system such as species in an ecological environment without requiring an understanding of calculus (Mellar *et al.*, 1994)), technological pedagogical knowledge (i.e., knowledge of the existence, components, and capabilities of various technologies for use in teaching and learning settings and pedagogical considerations for their selection, e.g., whether e-mail, a discussion forum, or a wiki would be an appropriate means for supporting student collaboration in a specific context), and TPCK (i.e., knowledge of the dynamic, transactional relationship between these three knowledge components to support pedagogical decisions, e.g., a teacher may decide to select a particular concept mapping tool for students to share and discuss ideas about a particular topic which is known to be prone to misconceptions and difficulties for most students, and the choice of the tool is made on the basis of its functionality and ease of use by students).

Many European countries, such as the Scandinavian and East European countries, have adopted the European computer-driving license, a computer-skills-certification program adopted by many professions, as a core part of a teachers' ICT competence for technology integration in their teaching practices. The license comprises seven modules which can be studied and tested in any order: concepts of IT, using the computer and managing files, wordprocessing, spreadsheets, databases, presentations, and information and communication (Internet and e-mail). Some countries have included additional requirements related to pedagogical use of ICT. In the late 1990s, Denmark formalized such requirements into a pedagogical ICT driving license for the integration of ICTs in education. More recently, a European pedagogical ICT license (EPICT) has been established by a consortium of EPICT organizations, involving countries like Greece, Italy, Hungary, Australia, Ireland, Austria, Iceland, Uganda, and UK

for continuous professional development of teachers in the pedagogical integration of information, media, and ICT in education. A teacher needs to complete eight modules (four compulsory and four optional) to qualify for the license within a developmental framework, starting with three compulsory modules on finding information on the web, text and the writing process, and electronic communication and collaboration, followed by a selection of four optional modules among 12 (choices include digital images, spreadsheets, presentations and interactivity, publishing on the web, databases, simulations and models, ICT and learning strategies, reading and ICT, games and ICT, etc.), and finishing with a compulsory module on ICT and school development. The EPICT program emphasizes the blending of pedagogical knowledge of ICT-skills integration with ICT-skills training, and adopts a collaborative and problem-based approach to learning and team-based assessment.

Teacher Learning to Foster Students' Information-Literacy Skills

The advent of personal computers and hence the widespread availability of computers to the general public has brought about significant changes in society at large. Toffler's (1981) argument that the third wave in human history, an information revolution, is already occurring, bringing the world into a new era, the information age, has been widely accepted for at least two decades. Kuhlthau (1987) put forward the concept of information literacy as encompassing library skills and computer literacy, integrating resources and skills into subject-based inquiries across the curriculum, with the school library/media center as the key place for this integration.

With the increasing recognition of the need for schools to prepare students for life in an information society, the definition of what constitutes information literacy has also expanded. The national educational technology standards for students (ISTE, 1998) developed in the US by the International Society for Technology in Education (ISTE) is an example of a comprehensive framework that embodies the use of technology as productivity, communication, research, problem-solving, and decision-making tools as well as an understanding of the social, ethical, and human issues related to technology. On the basis of this set of standards, ISTE (2000) published a corresponding set of teacher standards and performance indicators in order that they would be able to foster the development of information literacy in their students. These standards were designed to be incorporated into subject-matter teaching and hence incorporate some of the technical and pedagogical competences described in the previous section. However, these standards emphasize the ability to use technology to locate, evaluate, and collect information, process data and report results, and to facilitate

higher-order and complex-thinking skills such as problem solving, critical thinking, decision making, and knowledge construction. They also require teachers to be able to use technology in the development of strategies to solve real-world problems and in connecting with peers and experts for collaboration and interaction.

This focus on information literacy skills as a key rationale for integration of ICT in learning and teaching is also evident in education-policy documents in many parts of the world, even if not all of them have developed specific ICT-related teacher education standards. The UNESCO (2002a,b) framework for ICT in teacher education also takes the development of students' ICT literacy skills as the goal for IT integration in the curriculum. The framework comprises four groups of ICT-related competencies: pedagogy, collaboration and networking, social issues, and technical issues. Pedagogy-related competencies are essentially the knowledge and skills necessary for appropriate and effective use of ICT to support teaching and learning in the subject matter concerned. Teachers also need to have adequate understanding of the social issues such as intellectual property and health related to ICT use in the society and be able to guide students on such matters. The other two competencies concern expectations of teachers as members of a professional community. They are expected to be able to make effective use of the communication capability of technology to organize and provide learning opportunities for students outside of the classroom walls as well as new professional-development opportunities for themselves. The technical-issues component relates to whether a teacher is adequately prepared to undertake self-directed learning as a lifelong learner to meet the challenges posed by continuing technological advances.

An important feature of the UNESCO (2002a,b) framework is that it conceptualizes ICT development in schools into four stages of maturity and provides an adaptive guideline for a different implementation approach, depending on the school's specific stage of development. The framework incorporates four stages: emerging, applying, infusing, and transforming uses of technology. At a very preliminary stage, an emerging approach could be adopted whereby a school provides ICT courses to students, taught by individual teachers who have the technical competence. At a later stage, the applying approach can be adopted when the curriculum focus is on providing opportunities for students to apply their ICT skills in some specified learning contexts. The training focus at this stage is still on those teaching the ICT curriculum to ensure that students will have the requisite ICT skills to undertake the designed learning tasks. The school advances to the stage when an infusing approach can be adopted when all teachers share the vision of bringing about new learning opportunities to students through ICT integration. The professional development focus at this stage is on technical

and pedagogical ICT skills in the relevant subject areas as well as on collaborative, cross-curricular uses of ICT. A school reaches the most advanced stage of development according to this framework when the school is ready for and committed to making use of ICT to realize visions for the school of tomorrow; hence the use of ICT in the curriculum is characterized as a transforming approach for this stage. Here, the curriculum emphasis is on providing differentiated and individualized learning opportunities for students, and on learners taking responsibility for their own learning and contributing to solving real-world problems. When the school is ready for a transforming approach to ICT integration, the teacher has to be a lifelong learner to be able to innovate and to contribute to leading the school into a learning community. The framework envisions professional development at this stage as a self-managed, continuous, and critically reflective process.

Teacher Learning to Prepare Students for the Twenty-First Century

The information revolution coupled with an increasing rate of globalization has led to deep changes in many aspects of the social and economic realities in disparate corners of the world. There are many publications describing how the economic order of the world is changing from one heavily reliant on natural resources and industrial production to one based on knowledge (e.g., Drucker, 1993). While different terms such as postindustrial economy, digital economy, service economy, and postcapitalist economy have been used to describe the changing landscape in economic development, knowledge economy is the term that is gaining popularity as it highlights the importance of knowledge as the engine of economic growth and development. Over the last several decades, there is an emergence of businesses that engage in knowledge-intensive activities, exploiting IT to create wealth from knowledge (Chichilnisky, 1998; Schwartz *et al.*, 1999). In this new order, the economic well-being of a country is largely dependent on the level of competence that its people have in accessing, using, managing, and creating knowledge. Hence, the importance of the quality of educational outcomes to national well-being is at the highest in human history, as is evidenced by the main educational reforms and IT in education master plans that have been launched in many different countries around the world (Pelgrum and Law, 2003). In particular, there have been projects that focus on identifying the kind of knowledge and skills needed for functioning effectively in the twenty-first century (e.g., CERI, 2006; European Commission, 2007), with an important focus on preparation for employment. For example, the Partnership for 21st Century Skills (2007), an advocacy organization formed from more than 30 organizations comprising

multinational businesses and professional/educational bodies, put forward a framework for twenty-first century skills for US K-12 student schools that include three sets of skills beyond the core subjects and cross-curricular themes to include: life and career skills; learning and innovation skills; and information, media, and technology skills.

It is within this broader policy context that UNESCO undertook the ICT Competency Standards for Teachers (ICT-CST) project to take further the 2002 curriculum and program guidelines for ICT in teacher education described in the previous section (UNESCO, 2008a). The project is based on the premise that in any nation or community, education plays a central function in promoting personal and societal well-being for sustainable development. The new set of competency standards is constructed around three approaches to ICT integration for educational change on the basis of three factors leading to human-capacity-based growth that have been identified by economists: capital deepening, higher-quality labor, and technological innovation. The technology-literacy approach focuses on increasing the technological uptake of students and citizens by incorporating technology skills in the curriculum, a goal suitable for a capital-deepening economy. The knowledge-deepening approach focuses on building up a high-performance workforce by developing the ability of students and citizens to solve complex, real-world problems by applying the knowledge they have learned. The knowledge-creation approach aims to produce a workforce that can innovate, produce, and benefit from new knowledge for a knowledge economy. The UNESCO (2008b) policy framework provides a set of standards for six aspects of ICT use and teacher professional development for each of these three approaches: policy and vision; curriculum and assessment, pedagogy, ICT, organization and administration; and teacher professional development. The ICT-CST framework and standards was designed to help countries to align their teacher-education program with national-development goals by allowing them to adopt an approach appropriate to their country's current stage of development within the context of the broader developmental trajectory.

Irrespective of the approach to ICT integration adopted, the ICT-CST framework expects that curriculum adaptations and changes may need to be made in order to fulfill the requisite educational goals. For the technology-literacy approach, the curriculum will need to include basic technological literacy skills and the integration of relevant ICT skills into different parts of the curriculum as appropriate. The requisite teacher competencies include technical and pedagogical competence for ICT integration in subject teaching and assessment as well as using ICT for managing classroom data and for supporting their own professional development. The knowledge-deepening approach requires that the curriculum

has emphases on depth of understanding and application of understanding to real-world problems. Teacher competence for undertaking this approach includes the ability to design and implement learning activities that promote deep understanding and application of key concepts to solve complex, real-world problems that make use of open-ended as well as subject-specific tools using student-centered methods and collaborative projects. Teachers should be able to use ICT to monitor students' learning progress as individuals and in groups, use communication and networking technology to support student collaboration, seek help and advice from experts, set up professional collaboration and for their own professional development.

The knowledge-creation approach requires that the curriculum go beyond a focus on knowledge of school subjects to include knowledge creation as an important twenty-first century skill. While achieving this goal entails that students undertake various forms of learning to meet their identified learning needs, knowledge creation (sometimes called knowledge building) is not the same as learning. Learning scientists working in the area of knowledge building generally believe that it has to take place in a social, collaborative process of inquiry. Scardamalia and Bereiter (2003), for example, argue that knowledge building is not the same as guided discovery or other forms of project-based learning where the inquiry is just a form of learning activity for learners to acquire a predefined set of content goals. In contrast, knowledge building has a goal of creating or modifying public knowledge and requires a group of people working intentionally to extend the frontier of knowledge as the community perceives it. The availability and use of a digital environment that supports the interactions among members of the community as they engage in evolving cycles of idea improvement and deepening levels of understanding is an important part of the knowledge-building process.

The most significant goal of the knowledge creation approach is to develop students into lifelong learners, who are capable of determining their own learning goals and plans, identifying learning needs and monitoring progress as they work together in a community of learners. Under this approach, the school becomes a learning organization in which everyone, students and teachers, is involved in learning and knowledge building. To be able to guide students in knowledge creation, the teacher has to model the knowledge-building process by working alongside the students as a co-learner as well as by engaging in a professional community to build knowledge about this new model of schooling. The professional competence required of the teacher in such contexts cannot be developed through conventional learning contexts but has to be nurtured in a setting in which teachers collaborate as a community to undertake curriculum and pedagogical innovations in their own practices (Scardamalia and Bereiter, 2005; Looi *et al.*, 2008).

The shifting emphasis toward transforming schools into learning organizations to prepare students for the twenty-first century as the context of developing a teacher-competence framework and standards for ICT integration is happening in many parts of the world. ISTE (2007) has revised its national education technology standards for students to have a much stronger focus on developing students' ability to make appropriate and effective use of technology in tasks that require twenty-first-century skills, such as creativity and innovation, communication and collaboration, research and information fluency, critical thinking, problem solving and decision making, as well as understanding of issues related to digital citizenship. Competence in technology operations and concepts is a necessary substrate but just a small part of the expected repertoire of competence. A related set of technology standards and performance indicators for teachers was released by ISTE in mid-2008 (ISTE, 2008).

Changes in teacher-competence standards need to be coupled with implementation mechanisms for their realization, which appears to be lagging behind in practice. Within the US, many states have used the ISTE technology standards as the basis for their technology standards for teachers. Few states, however, actually assess teachers' skills in technology integration in any manner other than requiring completion of a course on technology and instruction. Anderson and Plomp (2008) also report, based on results from a survey about national contexts of education and ICT-related education policies from 22 education systems, that most of the surveyed systems do not have any ICT-specific requirements for teacher certification, and none report any requirement related to subject teaching with ICT.

Teacher Learning Beyond Knowledge – ICT Integration as a Lever for Innovation and Transformation

It is clear from the preceding discussion that the knowledge and skills required of the teacher differ depending on the goals and approaches adopted for ICT integration. Even the lowest level of integration – adopting the use of ICT as a tool in the accomplishment of learning tasks in the curriculum – would require some adjustments in curriculum-task designs. In more advanced models of ICT integration, technology is perceived as a lever for curriculum and pedagogical innovation and for institutional transformation. The role of a teacher changes completely as he/she moves from using technology to enhance students' learning effectiveness to setting up and orchestrating communities of learners that make pervasive use of technology. The various research and development projects reviewed earlier identify long lists of teacher competencies that require the mastery of

identifiable knowledge and skills. However, teacher professional development for ICT integration designed to bring about transformative changes in education need to go beyond the development of knowledge and skills for it to be successful.

Webb and Cox (2004), in their review of research on pedagogies associated with the use of ICT in primary and secondary schools, found that the benefits from ICT integration in teaching and learning depend on how the teacher selects and organizes ICT resources and how these are integrated into the learning activities. The teacher's pedagogical approach, and hence the pedagogical reasoning adopted, are crucial determinants of the learning outcomes from ICT integration. There is evidence that teachers need to undertake more complex pedagogical reasoning in their planning and teaching in order to incorporate knowledge of technology affordances with subject-based teaching objectives. Webb and Cox also show that teachers' pedagogical reasoning is strongly influenced by their beliefs about the value of ICT for learning and the nature of successful learning environments.

Kozma (2003) reports on a comparative study of innovative pedagogical practices using technology conducted in 26 countries and education systems. The study found evidence of changing forms of activities as well as changing roles of the teacher and the learner in the 174 case studies collected. Teacher professional development was identified as an essential condition for an innovation to be sustainable beyond the span of a year, and in many of those cases, teachers were provided not only with traditional forms of training but also with collaborative, problem-oriented types of activities such as peer-study groups that allowed teachers to learn and develop new technical and pedagogical skills in the context of the innovation. Building on further analysis of the cases collected in this study, Law (2008) argues that ICT plays a disruptive role in pedagogical innovations as its use is not to sustain but to change existing processes and relationships. A teacher who integrates such uses of technology is in effect an agent of change, one who leverages ICT as a disruptive force. To support educational transformation, teachers need to develop the metacognitive ability as an autonomous learner to identify and tackle problems that arise in the innovation process, the sociometacognitive capacity to work in collaboration with peers (and experts) in a professional community to institute changes at the classroom level and beyond, and the socioemotional capacity to engage in change, take risks, and foster trust. All these functions require courage and motivation. Professional development designed for educational change and innovation needs to foster the development of an epistemological belief aligned with socially grounded, constructivist theories of learning (Oakes, 2002; Law, 2008). Failures to attend to these aspects of teacher learning will undermine efforts

to institute innovation and transformation through the use of technology.

Technology in Preservice Teacher Education

N Davis, University of Canterbury, Christchurch, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In the context of our twenty-first-century information society, it is not surprising to find that outcomes relating to information and communication technologies (ICTs) are required for programs preparing tomorrow's teachers. Indeed, the United Nations Educational, Scientific and Cultural Organization (UNESCO) recognizes that teacher training has an important role and recommendations from the world summit on the information society acknowledged that training teachers to use ICTs in education is a critical success factor (UNESCO, 2007).

It is important to appreciate that ICTs, often known simply as technology in the US, is incorporated into preservice teacher education for three main purposes: (1) preparing teachers to use ICTs in educationally effective ways; (2) preparing K-12 teachers to teach ICT-related content; and (3) applying ICTs to serve teacher education. In essence technology is a cross-curricular theme, a content area, and a tool that can be applied to learning and teaching, which includes the use of telecommunications to improve access to education.

Preparing Teachers to Use Technology

This section describes approaches to technology in preservice teacher education, which has developed since its introduction in 1980s in the US and the UK. In Europe, the terms used have been information technology, or ICTs, in initial teacher training. Technology in preservice teacher education expanded from an emphasis on competence with computers to the application of technology to enhance learning, teaching, and professional development. Where the majority of students entering preservice teacher education have grown up with technology, educators have the advantage of assuming basic skills and knowledge and have developed benchmarks or standards for ICTs in teacher education. The goal is similar in other countries but more challenging due to the lack of resources, including basic skills and knowledge about information technology systems. Comprehensive guidance is provided in the planning guide on ICTs and teacher training produced by UNESCO (2002; see online appendices) and UNESCO is in the process of developing ICTs competency standards for teachers (2007).

Standards that have been widely adopted include the International Society of Technology in Education's detailed US national educational technology standards for students,

teachers, and educational administrators (ISTE NETS). The original NETS were organized in six categories (Strudler and Wetzler, 1999). ISTE (2008) revised them into five standards for NETS-T that are also used by preservice programs:

1. Facilitate and inspire student learning and creativity;
2. Design and develop digital-age learning experiences and assessments;
3. Model digital-age working and learning;
4. Promote and model digital citizenship and responsibility; and
5. Engage in professional growth and leadership.

A similar comprehensive set of competencies that had been developed in 1998 in England and Wales was relaxed in 2002 and replaced with extensive non-statutory guidance (Selinger and Austin, 2003). Perhaps most useful here are the seven benchmarks of good practice identified by Kirschner and Davis (2003: 131) in the quick scan study of best practice across Europe, North America, and Australia. All of the 26 programs selected as displaying good practice had the first four benchmarks, and the experts agreed that those programs modeled twenty-first-century constructivist thinking and pedagogy:

- become a competent personal user of ICTs (100%);
- competently make use of ICTs as a tool for teaching (95%);
- competently make use of ICTs as a mind tool (100%);
- master a range of educational paradigms which make use of ICTs (100%);
- master a range of assessment paradigms which make use of ICTs (81%);
- understand the policy dimension of the use of ICTs for teaching/learning (71%); and
- other (often social) aspects of ICTs use in education (91%).

Effective teaching of technology in preservice teacher education recognizes that technology, pedagogic, and content knowledge are all involved, including combinations of all three separately and together. In essence, this concept of technology content pedagogic knowledge (TPCK) builds on the work of Schulman, who clarified the interdependence of content and pedagogic knowledge, and added the domain of technology knowledge. The American Association of Colleges for Teacher Education (AACTE, 2007) *Handbook of TCPK* provides a primer for many content areas including English, Mathematics, and Science.

The major strategies used to incorporate ICTs in pre-service teacher-education programs are: a stand-alone technology course, resource-based learning including mini-workshops, infusion of technology into methods and foundation courses, application during field experience including mentoring, plus combinations of these strategies. Best practice uses a combination of all of these and applies technology to enhance teacher education while also modeling practice for K-12 schools (Kay, 2006; Kirschner and Davis, 2003). As described in section entitled ‘The preparation of teachers to teach ICT’, technology is also offered as a specialist and/or subspecialist area in some programs and is a strong component of preservice programs for business studies teachers.

The first and most widely adopted strategy is the stand-alone technology course. In a national survey of 88 preservice programs in the US (selected because they were part of the national Homes group “committed to making programs of teacher preparation more rigorous and connected to liberal arts education, research on learning and teaching, and wise practice in schools”), 39 of the 53 respondents reported offering a specific introductory course for the preservice program and 36 of them used a three-credit lecture and lab format (mandatory for all students in 27 of the programs). Although a stand-alone course may teach a wide range of basic computer skills, Hargrave and Hsu noted significantly more emphasis was placed on integrating instructional technologies into the curriculum than ICTs use for teacher productivity or personal use. Kay (2006) also noted a range of more innovative approaches that he categorized into content-based, project-based, or process-based use of ICTs. The advantages of a stand-alone course are the provision of a foundation by specialist instructors and improvement of students’ self-efficacy, but the learning of technology skills in isolation is likely to limit later adoption, including application of ICTs in the K-12 classroom. Moursund and Bielefeldt’s (1999) large-scale survey of US programs revealed that a single required technology course did not adequately prepare graduates to use technology in their teaching and Strudler and Wetzel (1999) noted that exemplary programs retained the stand-alone course in addition to the integration of technology within the teacher-education program.

A complementary or alternative strategy is to integrate the use of technology across the program of teacher education. The main advantage is the opportunity for preservice teachers to learn with computers, not about them, in ways that permit meaningful authentic problem solving, and this approach has also been successful in improving confidence and technology skills. Challenges comprise adequate access to resources, including hardware, and limited time and expertise of faculty and supporting staff. The AACTE *Handbook of TPCK* describes technology in content-specific method courses where

teacher educators choose applications, to enhance preservice teachers’ learning, that are powerful because they are transferable to K-12 classrooms. Occasionally, the integration of technology is promoted with other important aspects to stimulate educational renewal. McShay’s (2005) model of double infusion for both technology and multicultural education within preservice programs is notable in this context.

The third strategy, field based, strongly supports standards and benchmarks discussed earlier because it actively supports ICT-based lessons by preservice teachers in K-12 schools, but it remains challenging to adequately prepare and equip students and their cooperating teachers for teaching with ICTs. It has been difficult to place students in K-12 technology-rich classrooms and therefore, innovative programs have worked on the simultaneous renewal of preservice teacher education and K-12 schools in which they place students. One successful strategy has been to provide additional preparation for students so that they become technology mentors for their cooperating K-12 teachers (or faculty) in a way that complements the teacher’s mentoring of the preservice student in K-12 classroom practices. When faculty model transferable practice for student teachers with appropriate technology, such as an interactive white board and mathematical modeling software that are also accessible in the K-12 classroom, it has been possible to provide evidence of the impact of technology in preservice education on the learning of K-12 students. Unfortunately, such tight coupling of resources and practice in both the university and K-12 school is extremely difficult to achieve. Perhaps more examples will be forthcoming in a project that is preparing millennial teachers with practice in schools designed for twenty-first-century learning promoted by the National Commission on Teaching and America’s Future.

The Preparation of Teachers to Teach ICTs

Preservice preparation for teaching of ICTs and the coordination of technology in K-12 schools is an option in some programs in most countries. While the preparation of teachers to teach technology as their major area is not common in the US, ICTs are a discipline in the UK national curriculum, but note that the term technology can be confusing in the UK due to its use for the discipline of design and technology. Many national curricula in Europe include ICTs and it is increasing as an examined subject in Africa and Asia because countries that aim to develop economically have recognized the need to train such teachers. For example, Rwanda has included technology as an optional subject within its national curriculum and the first batch of teachers of computing for Rwandan secondary schools graduated in 2007.

In addition, a minor specialization in technology is available in some preservice programs to prepare elementary and secondary teachers for a future role as a leader of cross-curricular ICTs in K-12 education. Examples of programs with technology minors include Iowa State University in the US (Davis, 2003) and the University of Oulu in Finland (Neimi, 2003). It is useful to note that many programs expect students to make up for gaps in their knowledge and skills with technology through independent learning, which is often problem based. This is successful when accompanied by development of learning resource centers rich in technology and a supportive community, and such centers provide relevant internship opportunities for students in a technology minor.

Technology as a Tool or Medium in Education

This section focuses on application of ICTs to address common challenges in preservice teacher education. Three examples are briefly described: digital images, electronic portfolios, and distance education including telementoring.

Digital images, both still and moving, have a range of applications in preservice teacher education. Video case studies of K-12 practice are deployed successfully in most programs using a constructivist or process-oriented learning approaches to examine teaching in K-12 classrooms. For example, Reading Classroom Explorer is a web-based software environment housing exemplary video clips of literacy in elementary classrooms accompanied by a complementary notepad, database search engine, additional resources, and online discussions (Ferdig *et al.*, 2002). Images of classrooms can also be captured in a virtual reality format so as to permit students to explore a range of classroom layouts. Preservice teachers can also develop their practice by capturing digital images or video of their own teaching. Digital stories with still or moving images, sound, and narration have been used successfully to support reflective practice in many disciplines including mathematics and social studies. The use of presentation software with digital images is a practice that transfers well between preservice teacher education and K-12 classrooms, and thus supports simultaneous renewal in education.

The reflective documentation of professional practice and knowledge in an electronic portfolio is the second example of the application of technology to serve teacher education. As described earlier, most programs of preservice teacher education are assessed in part by a comprehensive set of standards or competencies, including those for ICTs itself. In practice, this requires documentation of assessed evidence for each student and for the program as a whole. A portfolio of evidence from teaching practice and university course work accompanied by reflection on how the artifacts cover the standards is often adopted

during preservice programs and it can provide a foundation for the teacher's career. An electronic format may be used to facilitate the process that moves from a learning portfolio, to an assessment portfolio, and then an employment portfolio to support career progression. Some more-comprehensive software applications also permit multiple portfolios to be used for advising and program evaluation. However, electronic portfolios are a complex innovation that requires a cluster of innovations involving technology, faculty, staff, course, program, and organizational development. At times, the multiple evolving purposes of an electronic portfolio can cause stress on students and faculty where these purposes are in conflict (Strudler and Wetzler, 2005).

ICT are also used to increase access within preservice teacher education, as well as distance education. Telephone, e-mail, and/or videoconference are used by many programs to increase input from the field by providing access to distant guest speakers and virtual visits to K-12 classrooms. Team teaching of complementary classes of preservice and in-service teachers permits mutual benefits such as preservice teachers' development of resources for schools accompanied by feedback from in-service teachers in training. Probably, the most effective collaborations include contrasting cultures, such as inner-city schools linked with a rural preservice program or an international collaboration. Communication technologies, in combination with mentoring by teacher educators, are also valuable in improving the quality of reflection by preservice teachers in K-12 schools. E-mail has been used extensively and online discussion groups with peers have also been found to provide effective support when carefully integrated within the contexts. Such integration includes the development of a community of practice, in which preservice student teachers are legitimate members (Kirschner *et al.*, 2003; Laferriere *et al.*, 2004).

Distance education for preservice teacher education has used technology as the main mode for delivery of a few programs in several countries. The first distance education preservice program for primary and secondary teachers was provided by the UK Open University. Concerns relating to quality of such programs have been addressed by quality-assurance bodies, including the National Council for Accreditation of Teacher Education (NCATE) accreditation of Western Governors University's program in the US. This form of preservice program requires strong collaboration between organizations including K-12 schools with a team to design the program that includes instructors, advisors, designers, and producers who use technology to prepare and publish materials as well as to deliver courses. The scale of this mode of preparation is increasing. For example, in China, the Beijing Foreign Language University has developed a program to prepare thousands of teachers of English each year. Finally, the rapid increase of K-12 students' distance education, particularly in the US, brings with it

an additional mode of education for which preservice teachers must be prepared (Davis and Ferdig, 2009).

Issues in Technology and Preservice Teacher Education

This final section reviews four issues in technology and teacher education: faculty and organizational development and related national initiatives, equitable access to technology and teacher education, and the challenge of researching this field. Faculty and organizational development have been and will remain a major challenge worldwide because technology and education continue to evolve. ICTs are best viewed as clusters of innovation that are adopted and/or rejected by individuals and organizations in stages. For example, as described earlier, best practice in the preparation of preservice teachers to use an interactive whiteboard in a high school classroom includes adoption of new hardware, software, and procedures in the preservice program by faculty with the support of staff and administrators, along with similar adoption in the school where preservice teachers practice. Goodlad (1994) described the link between the development of colleges and K-12 schools as simultaneous renewal to emphasize that one could not come before the other; both must develop together. The adoption of each cluster of innovation takes place in stages and the speed of adoption is related to the concerns of each organization and individual with related development of TCPK and resources (Davis, 2008). In the eclectic range of strategies used to promote effective practice with technology in preservice teacher education, technology mentoring is one of the most successful strategies because it takes individual faculty concerns as a starting point and provides one-on-one support from a student who also gains knowledge of educational practice (Thompson *et al.*, 2007).

The adoption of technology in preservice teacher education has been promoted through national and international projects starting with the project, Integrating new technologies in initial teacher training (INTENT) in the UK in 1992 (Somekh and Davis, 1997), which was followed by preparing tomorrow's teachers to use technology (PT3) in the US. In some other countries, the development of preservice programs has occurred alongside in-service initiatives. For example, the Enlaces initiative in Chile and other South American countries included the majority of preservice institutions (see Hepp *et al.*, 2004) and the telelearning project spanning Canada, which created telelearning communities of practice, included development of preservice teacher education (Laferriere *et al.*, 2004). Finally, the multinational company Intel has worked with educational authorities in many countries and regions to adapt their Intel Teach to the future ICTs teacher-training program and materials to serve national and regional contexts.

Issues of equity related to culture and gender that are common in education and society remain prevalent in preservice teacher education. For example, women and minority students are more likely to enter programs with few technology skills due to lack of access (Bowser-Brown, 2004). Therefore, care is required to provide equitable participation including targeting these populations early. For example, the US PT3 initiative included capacity-building grants for this reason.

The final issue that concludes this article is the challenge of researching ICTs in preservice teacher education. A comprehensive review of research into technology in teacher education by Willis *et al.* (1999) called for multiparadigmatic approaches and it has been answered with research into the current status, descriptions of innovation, instructional design and component studies, and studies that have identified bias of technology. Kay's (2006) review of research concluded that more rigorous and comprehensive research is required into key technology strategies. Additional research in regions beyond the US and Europe is recommended plus a more ecological perspective, which recognizes that ICTs in education requires continuing development of the ecologies of the school, classroom, and of teacher education (Davis, 2008). In addition, there are calls to produce evidence of the impact of technology in preservice teacher education on K-12 student achievement. A longitudinal study of exemplary programs in the US started in 2005 but the findings are likely to be problematic because ICTs change depending on where learning takes place and with whom. Despite that, it is likely that ICTs in preservice teacher education will continue to expand because of the permeation of ICTs in society in the twenty-first century and related links with economic prosperity.

Glossary

Learning communities – The conception of teachers' learning and developing within a broader context of community, institution, polity, and profession.

Situated cognition – The theory that suggests that knowledge is situated – being, in part, a product of the activity, context, and culture in which it is developed and used.

Introduction

From a general perspective, many authors claim that teachers are key for the successful implementation of innovations in schools (Barber and Mourshed, 2007), particularly when it deals with the introduction of digital technology in teaching and learning (OECD, 2001; Pelgrum and Law, 2003; Wood, 2002). Calls for teachers to innovate and change their practice entail implicit or explicit demands on teachers. Teachers are expected to prepare their pupils for the Knowledge Society, which requires the ability to create knowledge, apply knowledge to unfamiliar problems, and communicate it effectively to others. To prepare their students for such a society, teachers are called upon to emphasize higher-order thinking skills and metacognition (thinking about thinking), by using constructivist approaches to learning and understanding, cooperative learning strategies, a wide range of assessment techniques, and computer-based and other information technologies that enable pupils to access information independently (Hargreaves, 2003).

Extensive teacher learning is required to respond to such demands. Most teachers were taught the old traditional paradigms of teaching and learning (teacher centered, knowledge reproduction, etc.) in which technology resources, if used at all, helped to reach traditional goals (e.g., to deliver traditional curriculum but in a more effective way) (Lankshear and Knobel, 2003). At present, new paradigms give new opportunities to use technology resources for teaching and learning never seen before.

This article presents an overview of the potential roles of technology resources for teacher learning, particularly focusing on in-service teachers. Against this backdrop, this article addresses the following questions:

1. What are teachers' learning needs?
2. What factors and processes are related to teachers' learning and innovation?
3. What type of information and communication technologies can help these processes?

To address the first question, a review of different theories describing teachers' knowledge and expertise is presented. This section seeks to characterize the types of learning domains that need to be considered. In relation to the second question, a review of the literature describes innovation processes and how teachers can not only learn something new, but also transfer what they have learned to their practice. Finally, to address the last question, approaches for relating particular technology resources to innovation processes are presented.

Teachers' Learning Needs

The body of knowledge that teachers traditionally share has been analyzed from at least four perspectives:

Kinds of Knowledge (or Know-What)

There are many studies that attempt to classify and describe teachers' knowledge as a set of domains of expertise and their intersections (see, e.g., Grossman, 1995; Leach and Moon, 2000; Mishra and Koehler, 2006; Shulman, 1986). Broadly speaking, they propose the following domains:

- (1) Knowledge of subject matter, content knowledge, or subject knowledge.
- (2) Knowledge of general pedagogy or pedagogical knowledge and broad understanding of classroom management and organization.
- (3) Pedagogical content knowledge, that is, ways of representing specific subject knowledge appropriately for learners.
- (4) Knowledge of curriculum, that is, grasp of the materials, resources and tools of the trade.
- (5) Knowledge of learners and their characteristics.
- (6) Knowledge of educational contexts or school knowledge, ranging from groupings, classrooms, schools, education authorities, and national policies to wider communities and cultures.
- (7) Knowledge of educational aims, purposes, and values.

Nature of Knowledge (or What-Knowledge)

Some authors classify teachers' knowledge as formal (university-based knowledge about education) and informal knowledge (developed largely through experience) (Page, 2001). This perspective is similar to Hammond's cognitive continuum theory (Hammond, 1980), which defines analytic and intuitive thinking as poles of a continuum, arguing that most thinking is neither purely intuitive nor purely analytical. This concept is similar to the one described by Olson (1992) as "folkways of teaching," which emphasize the tacit dimension of practice and the process of change. In a similar vein, Schön's theories about reflection-on-action (Schön, 1983), while criticizing the technical, rational models for describing professional expertise, propose to search for "an epistemology of practice implicit in the artistic, intuitive process which some practitioners do bring to situations of uncertainty, instability, uniqueness and value conflict" (Schön, 1983: 49). Further, some classroom-based research indicates that both planning and classroom interaction are responsive, compositional, and situated (i.e., contextualized) (Yinger and Hendriks-Lee, 1995).

Level of Knowledge (or Know-How)

This perspective is based on a different way of describing teachers' knowledge that looks at the process of expertise development or skill acquisition based on the development of "knowing how" rather than "knowing what" (Dreyfus and Dreyfus, 1986). In these models, the pathway to competence is characterized mainly by the ability to recognize features of practical situations and to differentiate among them, to carry out routine procedures under pressure, and to plan ahead. For example, Berliner (1995) describes five levels of expertise that were defined by Dreyfus and Dreyfus (1986): (1) novice, (2) advanced beginner, (3) competent, (4) proficient, and (5) expert. Each level is characterized according to the way that teachers plan their teaching, their behavior in the classroom, and their actions while facing critical situations. In general terms, these authors argue that the way to progress through these levels of expertise can be summarized as improving the management of the classroom and developing strategies to plan the

lessons. In doing this, they implicitly characterize teachers' knowledge as corresponding to classroom management and lesson planning.

Knowledge in Practice (or How-To)

Finally, the fourth perspective – knowledge in practice – is based on analysis of routines and actions in the classroom. For example, Evertson (1995) describes the research about classroom rules and routines that teachers follow while teaching. She defines rules as general norms for expected behaviors and routines as procedures for accomplishing particular classroom tasks (how-to). In particular, she describes the results of a study by Leinhardt *et al.* (1986) that defines routines as systems of exchange that are set up to accomplish tasks, describing three types of routines:

- (1) Management routines, that include housekeeping, discipline maintenance, and people-moving tasks.
- (2) Support routines, that is, specific behaviors and actions necessary for a learning–teaching exchange to take place, for example, "how to pass in papers."
- (3) Exchange routines, that is, the interactive behaviors that permit the teaching–learning exchanges to occur. They govern the language contacts between teachers and students – for example, routines for choral responses.

These routines imply that teachers need to be knowledgeable about these dimensions of their actions.

This short review demonstrates that there is a significant amount of research in the area of teacher knowledge. Summarizing, it is possible to classify the different approaches as trying to characterize teachers' knowledge from the perspective of its kind, nature, level, and practice. **Table 1** presents these different approaches.

In general terms, it would be difficult to contend that only one of these taxonomies of teachers' knowledge is complete enough to characterize what teachers know or need to learn. Hence, the combination of them appears to be more useful to characterize it, also revealing its complexity. In fact, as Mishra and Koehler (2006) argue, apart from looking at each of these types of knowledge in isolation, there is a need to research and understand the type of knowledge resulting from their intersections.

Table 1 Taxonomy of teachers' knowledge taxonomies

<i>Kind (know-what)</i>	<i>Nature (what knowledge)</i>	<i>Level (know-how)</i>	<i>Practice (how-to)</i>
Content	Formal vs. Informal	Novice	Management routines
Pedagogical content	Intuitive vs. analytical	Advanced beginner	Support routines
Curriculum		Competent	Exchange routines
Pedagogy		Proficient	
Learners		Expert	
Educational contexts			
Educational aims, purposes, and values			

Factors and Processes Related to Teachers' Learning and Innovation

Management of change and innovation in schools have been areas of debate for a while, and although in this article we will not engage in the broad discussion, we will draw on this body of knowledge to discuss the factors and processes related to teachers' learning. In particular, we can transfer conclusions drawn by authors with regard to conditions for innovation in education (Scardamalia and Bereiter, 2006) to teachers' learning. There are two key conditions simplifying the arguments: one related to mastering the innovation in the Classroom and the other regarding to sharing it with Colleagues.

Mastering the Innovation in the Classroom and Sharing it with Colleagues

Huberman (1992) describes innovation as a process of grafting the new on to the old, and he comments that every "old" is a distinctive, local context with its own history and configuration (Fullan, 1992; Huberman, 1992). Olson (1988) also defines the process of change not as substituting one practice for another, but rather as subjecting existing practices to challenges posed by another well-conceived practice. Both definitions have an evolutionary approach to change, rather than a revolutionary one. They suppose that the new should be somehow grounded in the old. These arguments can be easily transferred to teachers', learning domain, implying that their learning will be facilitated if the learning process considers their previous knowledge, experiences, and current context.

The Importance of Understanding Teachers and Teachers' Self-Understanding

Fullan and Stiegelbauer (1991) argue that the subjective world – the phenomenology – of the role of incumbents needs to be understood as a necessary precondition for engaging in any change effort with them. These arguments suggest a situated perspective of teachers' professional development similar to the concept of situated cognition described by Brown *et al.* (1989), and aligned with the concept of learning communities, described by Shulman and Shulman (2004), that present a frame for conceptualizing teacher learning and development within communities and contexts. This implies that the professional development is, in part, shaped by, and becomes a product of, the activity, context, and culture in which it is developed and applied.

From a different perspective, the study called Second Information Technology in Education Study: Module 2 (SITES M2) (IEA, 2000) describes a framework for innovation. The study, conducted during 1999–2003, consisted of a series of qualitative studies which identified and described innovative pedagogical practices that used

technology (Kozma, 2003). The study report describes three levels of factors affecting the innovation process:

- (1) Macro-level or system factors, such as cultural norms, social context, educational policy, curriculum standards, etc.
- (2) Meso-level or school factors, such as the Information and Communication Technologies (ICT) infrastructure available, ICT integration plans, school leadership, innovation history, parents, etc.
- (3) Micro-level or individual factors, which, for teachers, include factors such as pedagogical practice, innovation history, educational background, experience with technology, etc.; and, for pupils, include experience with technology, social and cultural background, etc.

In addition, the conceptual framework describes how these factors relate to the characteristics of innovation, namely its complexity, practicality, clarity, relevance, and need. These characteristics of an innovation can be considered to be the expected characteristics of a course for teachers.

A different – yet complementary – perspective on the innovation process focuses on the individual and his/her practice. Arguments supporting this view are given by Fullan (1993), who says that "systems do not change themselves, people change them." Fullan and Stiegelbauer (1991) assert that "educational change depends on what teachers do and think – it's as simple and as complex as that" (p. 117). From this perspective, some authors discuss the factors and conditions necessary for a teacher to innovate. For example, Shulman and Shulman (2004) – based on the idea of developing a community of learners – claim that, in order to innovate, teachers need six key characteristics:

- (1) Vision: readiness to pursue a vision of classrooms or schools that constitutes, for example, communities of learning.
- (2) Motivation: willingness to expend the energy and persistence to sustain such teaching.
- (3) Understanding: understanding the concepts and principles needed for such teaching.
- (4) Practice: ability to engage in the complex forms of pedagogical and organizational practice needed to transform their visions, motives, and understandings into a functioning, pragmatic reality.
- (5) Reflection: capability to learn from their own and others' experiences through active reflection in and on their actions and their consequences.
- (6) Community: capability and experience in working as members of a functioning learning community and/or of forming such communities in the settings where they work (Shulman and Shulman, 2004: 259).

Another perspective for innovation is based on activity theory, which considers activities as collective, systemic

formation that has a complex mediational structure based on instruments, subjects, rules, community, division of labor, and objects (Engeström, 1994). In this framework, innovation occurs as the interplay among these elements. Finally, other theories of teacher innovation and change are provided by Zhao and Frank (2003) who propose an ecological perspective on the introduction of ICT in schools. In this perspective, they characterize schools as ecosystems in which teachers are immersed and defines the introduction of new ways of using ICT as an invasion of an exotic species into the ecosystem. Using this metaphor, they analyse the innovation in schools using similar rules as the ones used to describe the response of ecosystems to invasions of exotic species.

From a general perspective, many authors have related the concepts of ICT and innovation, basically considering ICT as an instrument that helps to bring about change and innovation in schools and/or teachers' practices. In this vein, authors have defined different roles of ICT in helping the innovation process:

- Trojan Horse: the computer is used as an aid to innovate in the teaching strategy (Olson, 2000).
- Catalyst: technology helps to accelerate the process of innovation (Hawkrige *et al.*, 1990; McDonald and Ingvarson, 1997).
- Lever: technology serves as a tool that is applied purposefully to a task of value (Venezky, 2002).

In summary, considering the variety of theories with regard to teachers' innovation, it is possible to argue that this is still an arena of debate and that there is still much to be researched before being able to more precisely define the characteristics of a teaching innovation that ensures its successful adoption and implementation.

Roles of Technology for Teachers' Learning and Innovation

Although there is "very little fundamental research that investigates how teachers might learn with digital technologies" (Fisher *et al.*, 2006: 2), there is a wide range of ways in which digital technologies (computers, Internet, personal digital assistants (PDAs), mobile phones, etc.) can be used. In particular, Fisher *et al.* (2006) propose to "describe the affordances of digital technologies as 'clusters' of purposeful activity in teacher learning" (p. 21), and to classify the activities and possible roles of technology. Table 2 presents their framework.

Based on this classification and drawing on some of the categories described in the previous sections, Table 3 relates teachers' knowledge to innovation characteristics and the role of technology.

Categories presented in this table provide examples of the roles ICT can play in supporting teachers' learning

Table 2 Clusters of activities with digital technology

Clusters	Examples of activities
Knowledge building	<ul style="list-style-type: none"> • adapting and developing ideas • modeling • representing understanding in multimodal and dynamic ways
Distributed cognition	<ul style="list-style-type: none"> • accessing resources • finding things out • writing, composing, and presenting with mediating artifacts and tools
Community and communication	<ul style="list-style-type: none"> • exchanging and sharing communication • extending the context of activity • extending the participating community at local and global levels
Engagement	<ul style="list-style-type: none"> • exploring and playing • acknowledging risk and uncertainty • working with different dimensions of interactivity • responding to immediacy

From Fisher, T., Higgins, C., and Loveless, A. M. (2006). *Teachers Learning with Digital Technologies: A Review of Research and Projects* (No. 14). Bristol: Futurelab, p 20.

process, considering the particular type of knowledge to be taught and relating these processes to specific innovation characteristics. With regard to the examples of ICT tools, it could be argued that many of them could be categorized as helping to develop several of the types of knowledge or innovation processes listed in the table. Indeed, since these technologies were not necessarily designed using a framework such as the one presented here, the classification responds to its potential to contribute to develop each type of knowledge or to support each innovation process.

In order to further investigate the potential adaptation of these technologies, a methodology such as technology mapping (Angeli and Valanides, 2009) could be used. They present it as a methodology for guiding teacher thinking about the ill-defined problem of designing technology-enhanced learning that can help to recognize and define the roles of ICT in developing different types of Technological Pedagogical Content Knowledge (TPCK). Based on the concept of TPCK (Mishra and Koehler, 2006), the method basically defines a structured process to relate software affordances, content representations, their pedagogical uses, and the different types of knowledge.

Conclusion

In the previous sections, we presented an overview of different theories that describe teachers' knowledge, the main trends with regard to educational innovation and

Table 3 Relation between teachers' knowledge, innovation characteristics, and ICT

<i>Types of knowledge</i>	<i>Innovation characteristics</i>	<i>Role of ICT</i>	<i>Example of ICT tools</i>
<i>Kind: know-what.</i> Examples: content, pedagogical content, curriculum pedagogy, learners, educational contexts, educational aims, purposes and values.	This type of knowledge can be associated with the need of understanding the concepts and principles needed for teaching.	Supporting knowledge building, in particular, adapting and developing ideas and modelling and representing understanding in multimodal and dynamic ways.	Encyclopedias, productivity tools (word processor, presentation, etc.), digital content resources, concept mapping software, learning objects, etc.
<i>Nature: what-knowledge</i> Examples: Formal vs. Informal, Intuitive vs. analytical.	This type of knowledge can be associated with the capacity of learning from their own and others' experiences through active reflection in and on their actions and their consequences.	Supporting distributed cognition, that is, accessing resources, finding things out, writing, and composing and presenting with mediating artifacts and tools.	Wikis, blogs, social bookmarking services (e.g., del.icio.us), podcast, simulation, and modeling software, etc.
<i>Level: know-how</i> Examples: Novice, Advanced beginner, Competent, Proficient, Expert.	This type of knowledge can be associated with the one developed through working as members of functioning learning communities and/or of forming such communities in the settings where they work.	Supporting building community and communication, which is, exchanging and sharing communication, extending the context of activity and extending the participating community at local and global levels.	Virtual learning communities (e.g., Tapped In, Teachscape), social networks (e.g., Facebook), immediate response systems (e.g., Twitter), podcast, video, and image sites (e.g., YouTube, Flickr), learning management systems, etc.
<i>Practice: how- to</i> Examples: Management routines, Support routines, Exchange routines.	This type of knowledge can be associated with teachers' practice, being able to engage in the complex forms of pedagogical and organizational practice needed to transform their visions, motives, and understandings into a functioning, pragmatic reality.	Supporting engagement that means, exploring and playing, acknowledging risk and uncertainty, working with different dimensions of interactivity and responding to immediacy.	Personal learning environment (PLE), Virtual Learning Environments (VLE), virtual worlds (e.g., Second life).

proposals concerning the role of ICT in teachers' learning and innovation.

Based on this evidence, we can conclude that – although there are many theories that describe teachers' knowledge – there is still a need to research and understand the type of knowledge resulting from their intersections before being able to more precisely identify teachers' learning needs and, once identified, to define the particular role that ICT will play in supporting the learning process.

With regard to the factors that facilitate teachers' learning and innovation, different frameworks defining characteristics of successful innovation processes have been demonstrated in this article; however, there is very little evidence to show that a particular set of characteristics can ensure that an innovation process will be successfully adopted and implemented (i.e., its predictive potential). In this context, although technology, acting as a lever, could facilitate different types (or stages) of processes, the consequences of these processes cannot be predicted with certainty.

Therefore, we conclude that although technology is available to support different types of learning processes that can be aimed at developing different types of knowledge, if learning needs are not yet clear and the characteristics of the learning and innovation process are not definitive, the particular role of ICT will remain uncertain, since ICT is only a tool that should be purposefully used to support and enhance teachers' learning processes.

The Economics of Vocational Education and Training

An Overview of Vocational Education and Training

T Karmel, National Centre for Vocational Education Research (NCVER), Adelaide, SA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Vocational education and training is aimed at imparting skills for the labor market, at a subprofessional level. It is the most diverse education sector, delivered in both the classroom and the workplace, and organized in a variety of ways internationally. A cornerstone is the apprenticeship – combining formal education with on-the-job experience – but it is also delivered in schools and tertiary educational institutions. The institutional arrangements of vocational education are complex (with industry playing an important role), its approach to teaching and learning is distinctive (and contested), and expectations by the community demanding, with it being seen as the education sector best positioned to deal with social disadvantage.

The vocational education and training (VET) sector is the least understood and most poorly defined education sector. Whereas early childhood education, primary and secondary schooling, and university education convey immediately to the reader a particular set of content and institutions, this is not the case for vocational education and training. An obvious symptom of this lack of clarity is the multitude of terms used to describe the concept. UNESCO tends to use technical and vocational education and training (TVET), in the United Kingdom people talk about further education, in Australia it has been called technical and further education (TAFE), and vocational and technical education (VTE) although the common term has been vocational education and training.

A second manifestation of the lack of clarity is that its institutional setting is varied. In some countries it is

associated with the latter years of secondary schooling, while in others it tends to be post-school. It can be taught in classrooms but can also occur in the workplace or a combination of the two. It can be at a relatively elementary level or at an advanced level. A further confusion is that much of what is taught at the university level is vocational in nature – what can be more vocational than medicine, for example.

Before going any further, we must make some attempt to define VET. While it is tempting to describe it as being what VET providers do, this is not very helpful. Our definition is that VET refers to education and training that is vocational in nature – that is, with the intent of being useful in the workforce – and is at a subprofessional level. While this is a workable definition it does not do full justice to what VET systems actually do. In particular, VET systems can provide considerable amounts of general education as a preparation for higher levels of education (such as an entry pathway to university education); they address issues of equity in many countries (VET offering second-chance education); and they can be involved in promoting innovation in industry. However, the core of VET is subprofessional vocational education.

In this article, we focus on a range of dimensions of VET that are important to its understanding. Each of these is quite distinctive compared to either school education or higher education. While the survey for this article is relatively self-contained it draws very heavily

on other articles in this encyclopedia that were commissioned under the vocational education and training banner. For convenience, these articles are referenced the first time they are relevant.

For ease of organization we discuss VET under three headings: teaching and learning, the VET system, and VET in context. We end with some comments about current issues and trends.

Teaching and Learning

Teaching and learning is of course a very broad topic. We can think about what is taught or learned, how it is taught or learned, where teaching and learning takes place, and so on.

In terms of what is taught or learned, the competency model has been the centerpiece of VET reform in many countries, for example Scotland, England and Wales, Canada, the United States, Mexico, many South American countries, Australia, New Zealand, Sweden, France, Kuwait, Indonesia, Korea, and Thailand. While the approach has many variants the essence is that the content of courses is based on occupational competency standards. Assessment is in terms of outcomes achieved (competent or not competent) by students or skills demonstrated and, in most cases, not graded. Another feature of this approach is that the competencies are developed by a wide range of interested parties and not left to educationalists. There is input from industry, unions, and bureaucrats as well.

This approach has attracted quite strident criticism from educators who argue that:

- industry needs carry too much weight at the expense of the needs of the students;
- the approach attempts to control teachers' work through national curriculum and assessment; and
- education – even vocational education – should be less instrumental and also include values related to justice, aesthetics, civics, life skills and so on.

These criticisms can be answered by those who advocate the competency approach; it all depends on how VET is constructed. For example, incorporating key competencies can be included in VET to support Dewey's concept of education through rather than specifically for occupations.

Putting aside the tension between those who favor a liberal education and those who are more instrumental, the emphasis on competencies can also be criticized by those who believe that VET is about equipping individuals for the labor market. They argue that narrow technical skills do not equip students for future change in the labor market and therefore generic skills need to be given considerable prominence. In fact, in many countries generic skills have been emphasized upon. One such

example is the Australian Employability Skills Framework as adopted in 2002 which lists the pertinent skills as communication, teamwork, problem-solving, planning and organizing, self-management, and learning skills. It also lists desirable attributes including loyalty, commitment, honesty and integrity, and even a sense of humor. The issue then is how can such skills and attributes be included in VET courses. Should they be integrated within courses containing technical competencies or taught separately? Or should these skills and developments be developed in the workplace rather than in an educational context? Another concern is how can these skills be assessed and recorded.

Back to the concept of competency. Part of the debate around the concept revolves around the lack of clarity of the concept. A commonsense approach is to define competence as the successful performance of a set of tasks; therefore, competency standards are the description of those tasks. But this confuses the tasks and the capacity to perform them. The task view implies that we can have a relatively objective checklist of tasks and omit higher-level competencies such as planning or reacting to contingencies. Another approach views competence in terms of desirable attributes. The trouble with this is that many attributes (e.g., problem-solving) are highly context-dependent. A third approach, labeled as integrated, views competence in terms of knowledge, abilities, skills, and attitudes in the context of a set of realistic occupational tasks. This approach centers on key tasks but emphasizes the attributes (cognitive skills, interpersonal skills, fine motor skills, etc.) which are required for the competent performance of the tasks identified.

A movement that has run parallel to the competency approach is modularization. Modules can be thought of as a group of competencies and can be built into whole qualifications. The argument in favor of modular structures is that they can be more rapidly updated because they are smaller than complete courses. They also provide flexibility for individuals in terms of building their skills. However, the push for modularization has tended to come from the political actors than from educationalists, who have criticized the approach as resulting in fragmented learning, mechanical and instrumental teaching, overassessment and excessive administrative burden for teachers. In trying to assess the validity of the claims for or criticisms of modularization, understanding depends on one key point: the relationship between the qualification as a whole and modules as elements of this whole. Thus there is tension between the idea of modules as being freestanding and being valuable only in the context of the wider structure of the qualification. Naturally, approaches differ. In some countries (e.g., England) the curriculum design process usually starts from the whole, whereas starting from the module is more common in other countries (e.g., in the American system).

While the concept is not straightforward it does appear that modularization remains high on the educational agenda internationally. In some cases, the emphasis has moved to internationally recognized modules, reflecting a trend to an international integration of various aspects of education.

It also needs to be remembered that VET is different from other forms of education and its delivery is not restricted to the classroom. Much of the VET occurs in a workplace setting or on the job. The driving force is the competitive needs of a business. Two shifts in the nature of work have made training in the workplace more important: the movement towards knowledge work and the shortened lifespan of job content. Managers must attend to the skills of employees as well as the management of physical and financial resources.

Learning in the workplace can take a number of forms. It can be planned or unplanned, and formal, nonformal, or informal. Planned and unplanned are self-explanatory, but the distinctions between formal, nonformal, and informal are less obvious. A distinction is drawn between

- formal learning: a program of learning recognized by a qualification or certificate,
- nonformal learning: a program of learning but not usually evaluated, and
- informal learning: learning resulting from daily activities.

There are also a number of modes of instruction that are widely used such as class-room presentation (occurring at a workplace), computer-based training, and distance training. Instruction can also be undertaken by trainers or by experienced employees training novices.

Most structured workplace training occurs in larger organizations. A long-standing policy issue centers on the needs of small businesses which tend to invest relatively little in training. Small businesses provide mostly job-specific training that is directly related to operational needs. Training tends to be reactive originating from immediate needs or, as is often the case, crises. Provision tends to reflect managerial styles and most owners/managers of small firms favor an informal management style. While most owners/managers claim a positive attitude to training, provision is low. In considering the factors affecting provision the most important are directly relevant factors such as market positioning, economic conditions, and availability of relevant training. There is also a whole range of secondary factors such as the cost of training, time constraints, lack of cover for employees who are training, dearth of in-house trainers, and absence of interest in training by employees.

Workplace training by definition has an employer or business perspective. Considerable work has also looked at teaching and learning in VET from a student perspective. There has been much theorizing about how individuals learn, and there are at least 71 models of learning

styles. Much of the research of learning styles in relation to VET has been carried out in Australia and the research suggests that, in general, VET learners are inclined to:

- be more visual than verbal (watching rather than reading or listening),
- prefer to learn by doing and practice, and
- prefer learning in groups and have clear guidance.

Naturally there is variation between different groups. For example, female students tend to be more verbal than males, while trade apprentices prefer a more hands-on approach compared to students in health and community services and business. Of course, the style preferred may not be the most effective.

One particular approach is that of personalized learning. This approach is centered on the needs, aptitudes, and interests of individual learners and has gained popularity in the last 10 years or so in a number of countries including the United Kingdom, the United States of America, Australia, and New Zealand. It should not be confused with sitting alone or self-paced learning. The distinctive features of the approach include:

- teachers' focus on individual students rather than an amorphous group of learners;
- the need for learners to become problem-solvers rather than passive recipients of training;
- assessment that includes analyzing goals, aspirations, and aptitudes at the beginning as well as achievement at the end of the program; and
- information and communications technology seen as key enabler.

We conclude our discussion of teaching and learning with a brief reference to two issues that have received much attention from policy-makers: the recognition of prior learning and noncompletion. Both are related to the efficiency of teaching and learning.

Recognition of prior learning (RPL) – also known as assessment of prior experiential learning and prior learning assessment – has been concentrated in Anglophone countries which tend to separate their initial VET from their secondary schooling, although it is now being widely pushed within the European union. The objective of RPL is to recognize learning that has taken place outside a formal education course. It is seen as a powerful instrument which motivates nonengaged learners, enables existing knowledge and skills to be formally recognized and therefore rewarded, and reduces the cost of training by eliminating time spent on further training. While the public rhetoric has been strident the realization has been a little disappointing with relatively small numbers of students taking advantage of it. This can be attributed to two factors. First, it appears that students often prefer to engage in whole courses of study or training. Second, the assessment of RPL can be expensive with providers

having difficulty relating the unaccredited learning of individuals to the learning outcomes of formal courses.

Completion rates have become key performance indicators for many VET systems. While a completion rate seems to be a sensible indicator of efficiency, noncompletion in VET does not always equate to failure. While a student may not have completed a course he or she may have obtained valuable skills, and the notion of completion itself is problematic when students can return to study shortly after withdrawing from a course. Nevertheless, noncompletion remains a serious problem in many countries, with the Organization for Economic Cooperation and Development reporting considerable variation with rates ranging from 35% in Greece and 42% in New Zealand to 85% in Belgium (OECD, 2007, Table A3.6). Rates vary by course and the personal characteristics of students.

The main reasons for noncompletion can be divided into two groups. The first is institutional factors such as quality of teaching, support for students, flexibility, and monitoring. The second revolves around the student: family background, financial position, intentions, previous educational experience, work situation, motivation, and so on.

A variety of strategies have been mooted to reduce noncompletion. Financial constraints can be addressed by student loan schemes (including income-contingent loans), vouchers, fee subsidies, and paid education leave. The dispositional factors of students whose previous education experience has not been satisfactory can be addressed by ensuring that the education and training is different from what they have experienced in the past. Other strategies tend to stress on a high level of pastoral care and institutional strategies such as the development of curriculum appropriate for intended students, target-setting with formative assessment and improvements to teaching.

The VET System

One thing that is very distinctive about VET is that it is structurally different, at least in many countries, from the school and university sectors. The long-standing apprenticeship model underpins VET in most Anglophone and European countries; this model is unique to VET. Thus, we begin with a discussion of apprenticeships. This is followed by a discussion of two planks that underpin VET systems – qualifications and quality assurance. We then focus on the teaching workforce and, finally, finance.

Apprenticeships date back to medieval Europe when young people went to live in their masters' houses to learn a trade. The essential components of a modern-day apprenticeship are:

- a training regime approved by governments,
- a combination of on- and off-the-job training,

- employers taking responsibility for the development of the apprentice, and
- the award of a qualification or license that enables the occupation to be practiced independently.

This model is not universal with trade training being undertaken in an institutional setting totally in some countries. It should also be noted that occupational licensing appears to be an important element. That is, the trades with the most successful apprenticeship system are often those that are regulated; the apprenticeship is a device for occupational restriction.

The traditional apprenticeship model was based on a model in which the apprentice and the master shared the cost. Under this model apprentices accept low wages in compensation for the costs incurred by the employer in providing the training. This model assumes that the apprenticeship is an indenture. However, this model has broken down with sanctions for breaking an indenture disappearing and apprentices requiring reasonable wages in order to attract them to the apprenticeship. Given that employers in theory will not pay for general training, then it seems that governments have to subsidize apprenticeship to avoid an underprovision of training (although a number of studies have shown that some employers have a strong commitment to apprenticeships despite the economic cost).

The traditional apprenticeship operated in the trades (e.g., plumbing, electrical, carpentry, cookery, and hair-dressing), although in the dual system (which we discuss ahead) it also operates in service occupations. In recent years, as the service sector has become more important, apprenticeship-like models – known as traineeships – have been introduced in a wider range of occupations in a number of countries, notably the United Kingdom and Australia and, to a lesser extent, the United States of America.

The model is facing a number of challenges though. First, it has difficulty coping with economic downturns because employers are less likely to take on an apprentice in a downturn. Structural change is also an issue with the trades declining in importance in developed economies. While it is possible to extend the model to new occupations this is not always appropriate. Many of the new occupations tend to be unregulated and so the model does not fit as comfortably as it does more traditional occupations.

The dual system refers to a specific model of VET that incorporates the apprenticeship model. The dual model uses alternating learning arrangements through partnerships between schools and companies, and is specifically used to describe arrangements in Germany, Switzerland, Austria, Denmark, and the Netherlands. The apprenticeship systems of other countries such as the United Kingdom and Australia have similar features but are not given the dual epithet.

Germany is seen as having the archetypical dual model. Here, the dual system functions as the major nonacademic route for school-leavers and recruits about 60% of 16–19-year-olds, resulting in the German labor market having a very small proportion of unskilled workers. Dual apprenticeships exist in nearly all branches of the economy including the professions and parts of the civil service. The fundamental characteristics of the dual system show that:

- It is a socially accepted pathway into employment. Training is workplace-led and practical. Skill requirements are occupation-based, not task-based.
- The state is involved with the quality of occupational standards as well as legal conditions. The German training culture means that the notion of apprenticeship is set apart from normal work.
- In addition to the government, other social groups have major influence. Public, private, and semiprivate institutions use long-established modes of cooperation, with employers and unions taking the initiative to modernize training regulations.

While not all countries have apprenticeships, virtually all VET systems have qualifications and quality assurance processes. Qualifications can be *ad hoc* or part of a formal framework and in recent years a number of governments have been using qualification framework as a driver of educational reform. The context is that governments have seen qualifications reform as a way to improve flexibility, widen participation, and enhance mobility. The reforms emphasize portability, allowing people to move between qualifications, and transparency, by making explicit what learners have to do to become qualified. Qualifications are seen as motivators for learners but are also very useful instruments for governments which want the VET systems to be more accountable.

Two approaches can be seen. The first is an outcomes approach which incorporates definitions of qualifications, sets of descriptors, and a precise specification of outcomes. This approach has been criticized as invariably leading to overspecification and the trivializing of learning. The second is an institutional approach in which qualifications are not treated as separate instruments of reform but are embedded in the wider education and training system. This approach has been criticized for being slow to adapt to new demands and impeding movement between education sectors. The conclusion, or at least one conclusion, is that qualification systems have a relatively modest role in reform. Successful qualifications are dependent upon establishing communities of trust and these take time to form.

Quality assurance practices vary from one country to another but are an integral part of any system. Quality assurance needs to address three key risk areas. The first is associated with the specification of knowledge and skills the

learner is required to acquire. The second is the risk associated with the training provider. The third relates to the extent to which a VET system meets its wider purpose – meeting the needs of the locality or country.

The first risk is typically managed through the development of systems that provide for expert input. Examples are the Sector Skills Councils in the United Kingdom, Industry Skills Councils in Australia, and Standards Generating Bodies in South Africa. The challenge is to ensure that standards encapsulate all the knowledge and skills relevant to the occupation in question and to ensure that the standards are specified with sufficient clarity to ensure assessors can make reliable judgments. One issue with such systems is the time taken to develop and keep the standards up to date. If there is a trend in respect of such systems, it is a move towards more differentiated, outcome-focused models that can allow both high quality and poor performance to be addressed.

The second risk, relating to providers, can be broken down to a number of elements:

- risks associated with the assessment process;
- resources risk – does the provider have appropriate premises, equipment, and staff; and
- funding risk when public funds are being used – the provider needs to manage the training in accordance with the terms of the funding.

Different countries take different approaches to mitigating the risks. In Australia, for example, quality assurance is largely front-end loaded with an emphasis on approving and auditing providers. By contrast, in the United Kingdom more emphasis is placed on both internal and external inspection.

The third risk in whether the VET system meets its purpose, is typically mitigated through the development of national and regional skill strategies. The aim of such strategies is to provide direction to the VET system, especially with relation to the use of public money. Approaches can be demand-driven, with students or businesses determining what courses are provided, or supply-driven with governments setting national targets. Neither approach guarantees success because of the imperfect information and the impossibility of anticipating the future needs of the labor market.

An important element of any VET system is its workforce. As with many other elements, the process used to train the teachers is quite different from those used in schools and higher education, at least in many countries. Some of the differences in the way VET teachers are trained can be traced to historical influences, with vocational education associated with education for work as distinct from education for culture. The education for work aspect has placed emphasis on occupational experience and many VET teachers (or practitioners) have a background largely through occupational experience rather

than an initial teaching qualification (the craftsman-turned-teacher as distinct from the professional VET teacher). It would seem obvious that a teacher who has never been an electrician, for example, would have no credibility in teaching students to become electricians. On the other hand, proficiency in an occupation may be a necessary condition to being a good teacher but it is not sufficient, given the pressures on teachers to understand new methods of teaching and learning, deal with diverse populations, get on top of new technology, and so on. VET teachers can also be seen as change agents because successful reform can only happen if teachers embed the reforms in their daily work.

Internationally, the professional VET teacher is common in many European countries while the craftsman-turned-teacher is more common in the United Kingdom and Australia, for example. In the United States of America the former is common for the trades/industrial arts while the latter tends to be the model in other vocational areas.

A widespread phenomenon is the use of part-time or casual teachers. This practice is often driven by budgetary pressures and can have negative effects if such teachers are treated as second class and not provided with suitable professional training. On the other hand, such teachers can be very valuable by bringing valuable occupation experience to the classroom. The age distribution of VET teachers is also an issue in many countries, with the VET teacher population being considerably older than other teacher groups. The reason for this is the reliance on teachers with many years of preteaching occupational work experience.

Professional development continues to be a challenge. Elements include support for new teachers (particularly important as a retention strategy), mentoring, opportunities to return to workplace settings to refresh occupational skills, and the development of communities of practice. Professional development is important not only to improve teaching but also to upgrade the status accorded to VET teachers – low status compared to other teachers has been a perennial issue. This is against a background in which VET teachers require a need for a more complex knowledge base than school or university teachers, working in a field that lies between specialist theory and specialist work.

We end our coverage of the VET system with a discussion of finance issues. Training finance has two purposes: it funds the national training system and also has a role in achieving many of the broader goals of national training policy. In conventional training markets there are two components. The private sector training is market-driven, nonsubsidized, and competitive. Firms provide training to their workers and payment is made through initial fees or below-productivity-level wages. Individuals enroll in fee-paying preemployment courses. In most countries there is a parallel public training system, often dominating the supply of structured formal training. Public sector is

predominantly funded by government, and fees, if any, are nominal. Areas covered by public training leave little incentive for private training providers to develop courses. Because of the difficulty of aligning public budgets with outcome measures there is little incentive for the public training sector to align training courses with the needs of the labor market. The very low fees also mean that students are less inclined to see their training as investment in skills from which they expect a return in the labor market. Public training provision remains essentially supply-driven, and this framework has become inadequate to meet skill development needs. Voucher schemes, although largely still experimental, are intended to build an open market and shift providers away from a supply-driven system. Contract financing of government programs is also intended to open the training market to private providers.

We see a trend away from the traditional method of training finance in many countries. Increasing pressures on government budgets have led to a search for alternative sources of funds. At the same time governments have become more interventionist in the training markets in order to counteract the tendency for underprovision of training (because of the presence of market imperfections including externalities – the benefits of skills spilling over to others – and imperfect information).

A number of alternative sources of funding have been pursued: earmarked training taxes or levies, cost-sharing with the beneficiaries (i.e., raising fee levels), additional institutional income through the commercial sale of training services, and an expansion in private training. Various constraints have held back the latter including financial constraints, rigid fee policies, excessive regulation, and information gaps. In addition, enterprise training can be encouraged through levy–grant schemes (incentives to encourage firms to invest in training), direct public subsidy, and through the creation of a training fund.

VET in Context

Arguably, the VET sector has a more complex relationship with society than other educational sectors. This is because it has a multiplicity of roles. It is seen as an agent of social change because in many cases it provides a second chance for disadvantaged groups and a way of integrating such groups into the mainstream labor market. It is also seen, for example, as facilitating the school-to-work transition and a way of spreading innovation and good practice within industry. Indeed, on occasions it seems that VET is being asked to solve all the problems of the world.

In terms of VET's social role, many groups can be identified as being a focus of VET policy including people with a disability, indigenous people, immigrants,

displaced workers, prisoners, older people, and women. In each case the motivation is the same: to provide skills that enable the individuals to lead better and more productive lives. We discuss each of these groups briefly.

People with a Disability

Distinctions are commonly made between intellectual disabilities, learning disabilities, and physical disabilities. For training providers, the primary consideration is the extent to which the disability impinges on the ability to complete a program of study successfully. Apart from the direct effect of a disability on the ability to undertake training, many disabilities can have an effect on the ability to get to training and to participate in work placements (and subsequent capacity to obtain employment). While there has been much support for people with a disability in many VET systems, one matter of concern is that recruitment decisions by employers are made outside the VET systems, and therefore study success does not automatically lead to labor market success.

Support for students with a disability ranges from quite modest to very high levels (e.g., note-takers and sign language interpreters). Funding is typically allocated to students or providers. There is also debate between those who wish to integrate the support for students with a disability within normal training provision and those who think support should be left to experts. A complication is that some students with a disability take longer than their peers to complete their study and funding models often have difficulty accommodating this. There can also be undesirable feedback loops; a provider providing good services to students with a disability will attract more such students, thus exacerbating funding difficulties. One factor that is pointed to in improving support for students with a disability is staff development.

Indigenous People

Definitions of indigenous are contested but a working definition used by the United Nations is along the following lines:

- priority in time, with respect to the occupation of a specific territory;
- the voluntary perpetuation of cultural distinctiveness;
- self-identification; and
- an experience of subjugation, marginalization, dispossession, exclusion, or discrimination.

It is estimated that there are between 300 and 500 million indigenous people worldwide.

For many indigenous people poor schooling means that VET is not only about vocational or technical training but also a means to understanding and engaging with

the outside world. As an education sector, it is arguably the most relevant to capacity development. It is seen as a road to employment and poverty alleviation.

As noted earlier in this article, VET can be delivered in many ways including relatively informal settings. This has the advantage of flexibility but can also lead to fragmented and uncoordinated delivery. Challenges for building effective VET programs are many. Often many indigenous people live in remote and isolated communities where employment options are few and there is low access to even basic levels of education, housing, communication, and health. This means that such people can be locked into being particularly disadvantaged, and this identification with disadvantage can flow over into those living in urban areas. Language and the attitude of many indigenous people who are suspicious of Western education are further challenges.

Key strategies for advancing indigenous engagement with VET include recognition of the indigenous culture, partnership and consultation, blending vocational education with more general education and life skills, using VET to support indigenous knowledge, ensuring that the VET delivered is up-to-standard, reducing barriers to access (e.g., provision of childcare), and time-flexible delivery (not cutting across agricultural seasons and ceremonial cycles, for example).

Immigrants

A central issue in migration policy is the integration of immigrants into the labor market. One reason for immigrants doing poorly in the labor market is their lack of skills relevant to the receiving society. Part of the reason for this is that they often lack qualifications (or the credentials are not recognized) and low-qualified individuals tend in any case to have lowest training participation rates. Similarly, the nature of their employment (e.g., many will be in casual employment) is not conducive to receiving training. Immigrants might also invest less in education and training because of actual or perceived discrimination by employers (which would reduce the financial return to training). Similarly, employers might invest less in the training of immigrants if they believe that they might return to their home country. Cross-country studies suggest that in most countries the native-born undertake more education and training, but this pattern is not universal. However, it needs to be noted that some training, particularly language training, is targeted at immigrants. There is surprisingly little research on the pay-off to VET for immigrants. Israeli research suggests that there is a payoff in Israel, while German research suggests that Turkish vocational school graduates are less able to find appropriate jobs when labor market conditions are poor. Australian data show that strong rates of participation in VET have

not been sufficient to deliver corresponding rates of employment for some immigrant groups.

Displaced Workers

Displaced workers are obvious candidates for VET. It is clearly sensible to provide displaced workers with skills that are in more demand in the labor market; thus they are often targeted with special assistance programs. Evaluations of a number of programs show mixed results. For example, evaluation studies of the Trade Adjustment Assistance program in the United States show moderate gains in the short term and weak gains in the longer term.

One of the challenges in evaluating programs is to ensure that they are scientific, in the sense of making use of experiments or quasi-experiments that provide valid comparison groups. Nonscientific evaluations tend to overestimate the positive effects. However, overall, scientific evaluations have found that there are some improvements in employment prospects and, in some cases, income, particularly in Europe. Of course, clearly the nature of the training must be important and it is likely that the amount of training will have an impact (a week of training is a very different prospect to a year's). Also retraining programs are often evaluated against simpler and cheaper job search assistance programs and costs are rarely taken into account.

Prisoners

Prisoners are typically a very disadvantaged group, with low levels of prior education and often a history of substance abuse. VET has the potential to be of assistance to this group, with the hope that the acquisition of skills will enable an easier integration back into society and lower levels of recidivism. Certainly, VET has the potential in providing marketable skills, although basic literacy and numeracy are probably more important for those with particularly low levels of basic education. There are two broad models of prisoner education. In Nordic countries, prisoners are seen to have rights, one of which is access to education. Another model, prevalent in North America, United Kingdom, and Australia, takes a risk-needs approach in which education and training are seen as a way of reducing reoffending through programs targeting factors such as antisocial attitudes and substance abuse as well as providing skills that would help employment prospects.

Older People

The learning needs of older people have received much attention in many countries, especially in Europe. The motivation comes from two angles. First, the aging population and economic displacement make it important to

increase the proportion of older people who are active in the labor market. Second, learning in later life is seen to have a wide range of positive social effects including life satisfaction, self-esteem, and willingness to take responsibility and increased involvement in community activities. Thus many international institutions emphasize the importance of lifelong learning.

However, participation rates in education and training tend to decline with age. This pattern is consistent to some extent with the argument that front-ended education has a greater payoff; there is a longer period to reap the rewards of greater skills. This argument holds from both employee's and employer's points of view. Another factor is that there are factors other than employer attitudes that reduce training for older workers who often consider themselves unsuited to new learning and lack confidence. Some have negative attitudes to learning and have a disability or health problems. Cost can also be a barrier. More educated workers tend to get more training and this acts against those older workers who are relatively low-skilled. In terms of designing programs for older workers much can be done to take into account older people's needs: a more personal touch, shorter courses, more nonaccredited courses, flexible provision, a consideration of preferred learning styles, a consideration of gender issues, and so on.

Women

Women, as a group, have been the subject of VET policy in both developed and developing countries against a background of occupational segregation and low status. The proportion of women undertaking VET has increased, but this is mostly due to a widening of the occupational coverage of VET rather than success in attracting women into nontraditional occupations. Women have found VET – particularly its provision of courses in general education, business, community services, retail, and hospitality – a useful springboard for re-entry into the labor market. Occupational segregation seems to be very resilient despite attempts to use VET as a change agent.

Moving on, VET is seen as a lever in the wider society in a number of respects. The starting point here is the human capital paradigm in which education is seen as an investment in the skills of individuals which provides a return in terms of more stable employment and higher earnings. The issue of primary interest is which forms of education and training provide the best payoff rather than any argument over the general benefits of education and training. In the allocation of scarce resources VET needs to compete with early childhood education, school education, and higher education. The research suggests that policy needs to ensure that a lot of investment occurs in early life because cognitive skills are less malleable later

in life. By contrast, noncognitive skills can be enhanced into adulthood and this is generally the period targeted by VET. An emphasis on early education does not address the skills deficit of the current generation of adults. Fixing the problem of unskilled adults is hard and costly and it does appear that in a lot of countries the policies being adopted are based more on faith than sound evidence.

We need to go well beyond a simple notion that the role of VET is to provide skills that are valued in the workplace.

First, VET can be a force for innovation. In looking at the role of VET in innovation it is first useful to look at the process of innovation. Innovation today has a lot to do with worker involvement, the idea of sequential innovation – from concept design to refinement and manufacturing – involving many actors. In addition, the distinction between radical and incremental innovation seems to be breaking down, and hence the role of practical knowledge and experience is increasing. Thus it is argued that experience is a very important source of innovation, with new concepts of production giving workers a role as a reflective practitioner meeting the demands of fussy consumers. The question then arises ‘What form of VET trains workers best as innovators?’ It is argued that it is the dual systems and apprenticeship systems that provide the highest level of useful practical experience when compared to institution-based systems. Even a three-year apprenticeship provides limited practical experiences, but this is a much better starting point for augmenting the experience-based than school-based training. Of course, creating innovators does not end there. VET systems need to go beyond simple goals such as employability. They need to aim for graduates who can shape their work: they will need attributes such as expertise in the subject field, virtuosity of performance, social responsibility, and the ability to be reflective. Finally, VET must balance theory and practice; apprenticeship-based systems need to emphasize theory to complement the abundant practice, and school-based systems must provide access to work practice and relate it to theory. This is indeed a challenge.

VET is seen as being an aid to school-to-work transition in an environment which is becoming increasingly difficult. VET has been assigned a number of roles. It has been called on to provide programs to keep students longer at school, and is seen as providing practical skills and work experience to make school-leavers more employable. The apprenticeship path is an obvious success, with its combination of training and work experience. The fact that apprentices have jobs while they train gives them a headstart, particularly if their employer is inclined to keep them on after the apprenticeship is completed. However, despite widespread support for upper secondary VET programs, results are variable. It is not clear if they result in higher school retention. Australian evidence points to a positive impact on postschool employment

(Anlezark *et al.*, 2006, for example). Training provided by labor market programs is more ambiguous in its impact, and questions the effectiveness and efficiency of VET in supporting young people experiencing difficulties with the school-to-work transition.

VET has also been called on to promote the cause of sustainability. It is argued that the key to sustainable development is integrating VET into approaches to development that balance economic and social progress, address cultural difference, and respect ecological values and limits. VET needs to be imbued with values of environmental sustainability, economic sustainability (to supplant the notion of productivities), and social sustainability. Such a push is a challenge since VET is more commonly seen as training for growth or skills for work rather than a vehicle for promoting a broader general education for personal autonomy, citizenship, and sustainability, as advocated by the authors.

Almost all the discussion to date has implicitly assumed that VET is operating in developed or at least stable countries. Protracted conflict leads to widespread destruction of already fragile education and training systems. Young people take up arms instead of learning employment skills. Even when conflicts are over, problems remain. Infrastructure is destroyed, gainful employment is scarce, and often skills available do not suit the job opportunities that do exist. A clean slate provides a window of opportunity, but success in building a VET system depends on political stability and the level of international investment available for reconstruction. New systems tend to address the needs of the formal sector, which invariably is very small, and ignore the development of skills in the informal sector where the majority of people work.

The majority of this article has displayed VET in a positive light although challenges abound. However, there are some issues that need airing. The first is VET’s lower status relative to higher education, primarily because of its association with occupations that have lower status than the professional occupations to which university graduates aspire. Parity of esteem has been an education and training policy goal in many countries, especially in the European Union. The status of VET teachers is also an issue, as has already been noted. Suggestions for raising the status of VET include having education systems that are flexible (e.g., double qualifications and good pathways from VET to higher education) and employing VET to modernize teaching through situation- and work-based learning theories rather than a reliance on academic models. It must be noted that citizens value their career and occupation choices against their aspirations and therefore high status for VET will only come from it being of a high quality and meeting aspirations, not by government decree.

A related policy area is the role of career guidance. Career guidance is seen to be more than advice on

initial training and employment; it is now seen in the context of lifelong learning (lifelong guidance) and is given a wider ambit to cover many aspects of an individual's life (lifewide guidance). Career guidance has traditionally been the purview of educational institutions but now is becoming more common in a number of countries (e.g., Denmark, Ireland, and the United Kingdom) in a workplace setting where it has an emphasis on recurrent VET.

VET is also often called on to solve labor shortages that are often a product of labor market imperfections rather than inadequacies of the training system. While it is easy to blame the training system for shortages, there is a range of factors that need to be considered, notably the slowness of wages to adjust (in a flexible labor market there would be no such thing as a shortage), slowness in adjustment of supply (e.g., length of training, lack of interest by students, employers reluctant to hire qualified but inexperienced workers), and inadequate labor market information to firms, individuals, and education planners.

Concluding Comments

There can be no doubt that VET is an important education sector, and many governments have been giving it increased attention. While general education is very important, and there is no stopping the rise of higher education, there is a widespread view that VET is particularly important because of its focus on skills needed for the workforce. It is also important because it, more than the other education sectors, plays the preeminent role in addressing the disadvantaged.

However, it faces many challenges. The first is, despite much public rhetoric, it has low status relative to higher education. This is unlikely to change while managers and professionals occupy jobs that are better paid and more prestigious than tradespersons, technicians, and para-professionals. It is also unlikely to change unless the education courses leading to professional jobs change to incorporate VET. And this is possible by basing such courses on a sophisticated implementation of competences and contextualizing theory to a much greater extent than is the common practice.

A second challenge is that the direction of structural change does not favor those occupations which VET has traditionally served. Reich (1991) categorizes workers into routine producers, in-person service providers, and symbolic analysts – those who simplify reality into abstract images that can be played with and then transformed back into reality. VET tends to be targeted at the first two of these categories but it is the third, which is largely made up of professionals, that is growing the most rapidly, at least in developed countries. The relative decline of

agriculture and manufacturing, and the growth of services is part of this trend.

VET is also being squeezed by ever-increasing educational levels. We see para-professional groups aspiring to become professionals, and an obvious mechanism to effect this is to move the training from VET to higher education. Thus the VET sector may need to expand the qualifications that it covers or risk being left with a decreasing market share.

The pace of technological change also threatens the underlying orientation of VET. If technology is changing rapidly, then the skills required must also change. But, in general, the possession of general analytic skills makes it easier to update skills compared to the possession of only technical skills. VET tends to focus on the latter rather than the former. Maybe it is time to increase the amount of general education embedded in VET courses, otherwise VET-trained workers will find themselves at a disadvantage in a changing workforce.

VET also risks being assigned a task that is too ambitious. It can be asked to do too much. The skill shortages in the labor market – VET should remedy this. Disadvantaged groups struggle in the labor market – VET is the sector to address this. The economy needs to be more sustainable – let's call on the VET sector to solve this. While education and training are vital for a productive workforce, it needs to be remembered that many skills are learnt on the job and not from formal training and there are many imperfections and distortions in the economy which impinge on the productivity of the workforce. VET is a vital element of creating a skilled workforce and a just society but it is only one element.

Thus VET faces many challenges. To prosper it will need to continually reinvent itself in order to bend itself to changing occupational structures, technology, educational trends, and social conditions.

Acknowledgments

The author is happy to acknowledge that little of this essay is original and makes very liberal use of the material in the individual articles in the encyclopedia. That said, all mistakes and infelicities are mine.

Informal and Non-Formal Learning in Vocational Education and Training

F Beddie and S Halliday-Wynes, National Centre for Vocational Education Research, Adelaide, SA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Is watching *The Simpsons* a form of learning? Where does entertainment end and learning begin? Is watching television informal or incidental learning or just relaxing? Does the answer depend on the viewer's intention or on a change in their knowledge about the world? Can labeling an activity as education detract from the benefits of learning, which seems more like fun? Do these distinctions matter?

These questions highlight the complexities faced by educators, employers, and regulators when deciding how to define different forms of learning. Although the idea of informal adult education has been around since at least the 1950s, when the American educator Malcolm Knowles used this category of learning in his attempt to develop a coherent and comprehensive theory of adult learning, it is only more recently that we have seen a preoccupation with the learning that happens outside of the formal education system. This has come about in tandem with an emphasis on learning as an activity no longer confined to the early school-based phases of one's life; but as one which is lifelong and lifewide. We have become ageless learners, moving through various phases of life, being motivated to learn in different ways to obtain new understanding, skills, and attributes (see **Figure 1**).

Informal learning and nonformal learning are the primary foci of this article. We give an overview of how formal, nonformal, and informal learning can contribute to people's lives in various parts of the world and in a variety of work settings. We consider how informal and nonformal learning influence the lives of people in a variety of diverse geographical areas including, the muddy soccer fields of England, the markets of West Africa, and the forests of northeast Thailand. We look at the role of learning in workplaces and reflect on what the increasing focus on informal learning means for vocational education and training (VET) systems. We conclude with some questions about the extent to which less formal sorts of learning should be defined.

Definitions

Educators and trainers are being asked to respond to fast-moving global economic, social, and technological developments; changing labor markets; and constantly evolving skills sets and new types of work and workplaces. Recognizing these challenges, the Organization for Economic Cooperation and Development (OECD) has embarked on

a project to examine the recognition of formal, nonformal, and informal learning. In doing so, it offers some definitions. These are a starting point for a discussion about the forms of learning that education and training systems around the world must embrace or, at least, recognize:

Formal learning: learning through a program of instruction in an educational institution, adult training centre or in the workplace, which is generally recognised in a qualification or a certificate.

Non-formal learning: learning through a program but it is not usually evaluated and does not lead to certification.

Informal learning: learning resulting from daily work-related, family, or leisure activities. (OECD, 2005: 5)

Another way of thinking about these forms of learning is to consider the extent to which they are structured and whether they lead to a credential: a student who enrolls in a computing course, which results in a qualification, has been involved in formal learning. An employee, who attends a day's training to learn a new software application being used in their workplace, is engaged in nonformal learning. And the manager who asks his assistant how to change the look of a PowerPoint presentation has acquired a new skill through informal learning.

These descriptions are not definitive. Indeed, grasping the nature and outcomes of learning, regardless of format, is a matter of debate among researchers, educators, and assessors. According to the Australian Bureau of Statistics (ABS), informal learning constitutes unstructured and noninstitutionalized learning (ABS, 2007) and is more likely than not the product of incidental learning in the exploration of everyday experience (Conlon, 2003). The ABS, along with other collection agencies such as the OECD and *StatsCanada*, has decided, at least for the purpose of measuring learning, it is essential to put some parameters around notions of informality. In its first survey of adult learning, published in December 2007, the ABS posed the following caveat: "Activities may occur on a self-directed basis, but are excluded from scope if there is no specific intention to learn."

While some researchers have questioned this idea of intention (e.g., Baran *et al.*, 2000; Billett, 2001), it does assist in discussing definitional boundaries when these become necessary, for example, for purposes of assessment.

The definitional task is further complicated by the wide-ranging methods of informal learning, which include: reading

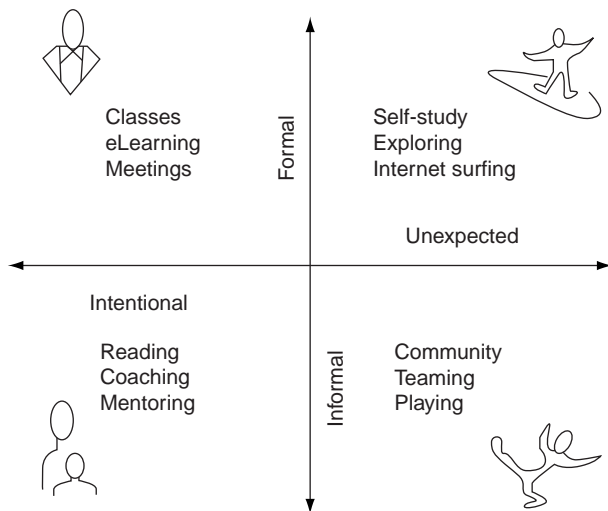

Figure 1 Ageless learners.

journals or articles, participating in workplace mentoring schemes, learning through casual conversation, engaging in on-the-job training, and learning through trial and error. There can be good reasons for people wanting to acquire skills and build on knowledge in these informal ways. Often it will be more efficient – in terms of both time and money – than enrolling in a formal course. For others, education, training, and assessment are terms that conjure up negative memories of school. For them, an informal approach may be more productive, precisely because there are no tests or accreditation processes to encounter.

On the other hand, many adults prefer the discipline and social interaction of the classroom. In terms of vocational training, however, off-the-job training courses may not provide all the necessary content and context for employees, and will be most valuable when reinforced by nonformal and informal learning in the workplace.

In 2007 an OECD policy brief noted that if lifelong learning was to be of value to individuals, member countries would have to reconsider what they meant by the term qualifications. It declared that:

For many, “qualifications” refer to a piece of paper proving someone has successfully completed a specific course of study. But the “qualifications” of use in lifelong learning may be much broader – skills and techniques for performing your job on a day-to-day basis learned from a colleague or workplace mentor, for example. If you stay in the same job, your employer is aware of these added skills, but in a world where jobs are no longer for life, the individual needs a way to communicate this added knowledge to new employers – and they need a way to evaluate these skills. Even paper qualifications tend to lose much, if not all, of their value when someone wants to go and work outside the sector or country that provided the certificate in the first place. (OECD, 2007: 3)

The OECD goes on to argue that the recognition of informal learning is central to creating portable qualifications. If workers learn how to operate a particular machine or software from a more experienced colleague, they may not acquire a formal qualification but have acquired a specific work skill. According to the OECD, recognizing these skills is a cost-effective measure that avoids the need for formal study and ensures that the skills learned are relevant to job requirements. However, the recognition processes are not cost-neutral. They usually involve considerable time in evidence gathering, especially for those with little printed documentation to demonstrate their learning, and a skills assessment, which can be expensive if it involves visits to the workplace (Cameron, 2004). Moreover, recognition is not always necessary, with employers often prepared to recognize specific experience without requiring a formal credential.

Such recognition would also result in a more accurate picture of the extent of adult learning today. Conner (2002) estimates that informal learning accounts for over 75% of the learning taking place in the workplace, although much of that activity is not recorded in official accounts of vocational training. Richardson (2004: 5) suggests that on-the-job training (informal learning) is “the most commonly experienced form of skills development provided by employers.” She goes on to argue that we should pay careful attention to how skills learned informally on the job affect wages and career paths. This type of skills development also needs to be taken into account when measuring the contribution made by employers to workforce training.

Informal learning, according to Livingstone (2000), “is like an iceberg mostly invisible at the surface and immense in its mostly submerged aspects.” Livingstone used this image when discussing the relationship between work and learning, including the knowledge needed not only for paid work, but for volunteering, household- and general-interest activities (Livingstone, 2000: 19), all of which contribute to a person’s vocational skills sets. Becket and Hager (2002) argue that in comparison to formal learning, informal learning is not only more organic but more widespread and effective. But how do we grasp hold of this diffuse and submerged mass of learning? When is it appropriate to do so? (See **Case Study 1** and **Figure 2**.)

Informal Learning across the Globe

That governments around the world are grappling with the difficult task of measuring the extent of informal learning is indicative of its role in helping vocational systems, employers, and individuals cope with contemporary workforce trends such as: greater demand for skilled labor in many industrialized countries; the increasing mobility of workers within and across borders; the growing interest in the

workplace as a learning environment and acknowledgment of the importance of on-the-job learning in skill formation; and the goal of ensuring education for all, including second-chance learners. In the context of equitable development, informal learning should not be identified as just a hook to bring people to more formal avenues of learning and work; it should be recognized as a positive and reliable learning experience in its own right. This is particularly the case in developing countries, where universal formal schooling is not the reality, and where informal learning is sometimes the only option for an individual or a community to gain knowledge and skills (see **Case Study 2**).

The knowledge economy is now placing greater emphasis on creative or more lateral thinking. This presents a challenge to countries that, in the post-World-War-II era, adopted an emphasis on rigid educational

outcomes in order to hasten economic development. These countries are now finding that there is a risk of losing creative ability and are therefore reconsidering the best way to encourage learning. In Singapore, for example, the last decade has seen a shift from an efficiency-driven education system to one where the emphasis is on encouraging ability, encapsulated in the slogan “Thinking Schools, Learning Nation.” Here, the premise is that Singapore’s future depends on the capacity of its people to learn continuously through their lives (Boon and Gopinathan, 2006: 40).

Others, particularly in the developing world, are looking at how informal learning can be used to engage more of their populations. King (1982), whose studies looked at amongst others, Yemen and Senegal, has suggested that in the absence of formal training, skills are often acquired through familial relationships and participation in petty production. For example, someone selling goods in the marketplace becomes numerate by learning from their peers and from experience. This does not, however, detract from the importance of focussing on formal education in basic literacy and numeracy which, King suggests, can increase the gains offered by informal training.

The United Nations Educational, Scientific and Cultural Organization (UNESCO) claims that informal and

Case Study 1 Canada

Guo (2006) estimates that overall Canadians spend longer in informal learning activities than they do enrolled in formal courses. Guo was looking at the impact of this learning on volunteers who were Chinese migrants to Canada. Guo conducted this study through personal interviews and questionnaires, and investigated amongst other themes, motivation and benefits of volunteering. He found that this informal learning assisted individuals to acquire the necessary skills and factual knowledge to adapt to their new home, and also helped increase self-confidence, build networks (both personal and professional), and promote a sense of ownership and connection to their new community. Guo saw that this learning was passed on to family members and neighbours, creating a ripple effect. This suggests that informal and non-formal learning not only has impact that we cannot see (Livingstone’s iceberg) but also has influence across the community.

Gou, S. (2006) Mapping the iceberg of informal learning: Exploring the experience of Chinese volunteers in Vancouver. *Conference Paper, 2006 National Conference On-line Proceedings*, York University, Toronto, ON, May 1006.

Case Study 2 Korea

Traditional Korean pedagogy marries education with wisdom, self-improvement, maturity, and a lifelong appreciation of learning. This holistic approach embraces the concepts of informal and non-formal learning but appears to be in danger of being lost in the development of contemporary Korean emphasis on examined and controlled learning environments.

Pak, M. S. (1997). *Two Wheels for Lifelong Learning in Korea: Credit Banking & Multimedia Technology*. CEDEFOP Discussion Paper.

Figure 2 Informal learning by Jay Cross.

nonformal education is a necessary avenue to attain “learning for all” (UNESCO, 2007: 4). This suggests the need to ensure that we understand how informal learning can be harnessed to maximum effect. A research project in Thailand undertook this task and uncovered a process of unstructured learning acquired by active community participation, experience, and practice, which had far-reaching and positive effects on the standard of living of a whole village (see **Case Study 3**) (Thacheen and Lauzon, 2006).

Learning in the Contemporary Workplace

Informal learning is a constant in the contemporary workplace. Such learning takes place as a result of practice and experience and usually goes unrecognized as anything more than getting on with the job. Often there is no need to recognize these processes, which work well as a means of developing expertise and judgment. There are, however, times when it is important to identify informal learning. It may be, for example, that such learning is resulting in bad work practices and needs to be undone, often by instituting formal training. In other instances, the regulatory environment might require certification of skills. And sometimes workers will want to document their skills in order to seek promotion, higher wages, or to move jobs. This requires the individual to articulate what knowledge and abilities he has gained from that experience. Such a process can involve formal assessment, although for many professionals and para-professionals this is the familiar process of compiling and updating curriculum vitae.

Just as in the developing world, where basic literacy and numeracy are a vital foundation skill, accredited training, informal and nonformal courses are important elements in workplace learning. The 1997 and 2001 British Skills Surveys, by Nordman and Hayward (2006) found that workers require both formal and informal training, with the type of learning often dependent on the complexity of the skills required to do the job. Such findings illustrate the value to employers, employees, and trainers of understanding how workplace learning is best conducted.

This is not, however, a simple matter of categorization of the learning. The UK Learning and Skills Research Centre has argued it may be more beneficial to conceive formality and informality as attributes present in all circumstances of learning, with these elements emphasized (or not) according to the context and the learner (Colley *et al.*, 2003: 9). For example, it can be more effective, when trying to bring disengaged learners back to formal training, for vocational trainers and adult educators to decide not to make the pathway to a qualification an explicit goal; but rather to encourage the learner to undertake the course of study at their own pace and without fear of assessment, which might be taking place surreptitiously and which might well include the recognition of existing skills (see **Case Study 4**) (Parker, 2006).

Much discussion about enterprise learning has focused on the apparent lack of training occurring in small- and medium-sized organizations. A study by Ashton *et al.* (2005: 6) suggests this deficit may have been exaggerated by a focus on the formal training courses typically commissioned by larger organizations. The authors argue that if attention is paid to skill formation rather than to the training of individuals, a different picture emerges, one

Case Study 3 Thailand

The people of Bann Na Isarn, in north-eastern Thailand, have improved their quality of life by learning about how to manage the natural environment and achieve a balance between forestry and rice farming. By following the example of a head man in a neighboring area, one member of the Bann Na Isarn community (Liam) persuaded his fellow villagers to drop their dependence on cash crops, which brought in little money and often resulted in the village going hungry, and to concentrate on community sustainability and cooperation.

Liam started by planting a range of new plants and trees that were not only useful for food, but could be used as building materials and for medicinal purposes. Despite initial community resistance, Liam persuaded others to become involved in this practice of agroforestry.

The success in Bann Na Isarn lay in having a meaningful context for the learning and in embedding cooperation. It was reliant on skills and knowledge being passed on by community elders and across generations, as well as on a conscious effort to share practices and techniques through conversations and demonstrations.

Case Study 4 England

According to Andrew Parker (2006) from the University of Warwick, formal learning is often only a small component of the whole learning experience and imparting knowledge by tangential means is often just as important and effective. This view is borne out of a 2005 study into the experiences of young men participating in an occupational apprenticeship of professional football. Parker suggests that this apprenticeship model provides an example of situated learning, which takes account of the specific, male characteristics of the learners by embracing physical fitness, discipline, and loyalty to teammates and the club, including regulations and procedures. The learning can also be characterized by negative masculine behavior including perpetuating sexist and racist attitudes and entering into abusive dialogs. Nevertheless, the apprentices acquire knowledge through formal means (football skills, game tactics, etc.), and informal interaction, including locker-room banter and peer-group pressure. This combination leads to the boys acquiring not only some certificates in sports-related subjects but also a degree of work-readiness that they may not have achieved outside the particular discipline imposed by the football club.

that includes both informal and formal learning as part of the transfer and acquisition of the knowledge and skills required for performance in the workplace. Many small-business owners and managers are likely to learn informally or incidentally, for example, through discussions with suppliers, customers, trade meetings and other business activities, rather than by attending training courses. Other learning takes place by solving problems with colleagues, observing and working with more experienced colleagues, informal chats, moving between jobs, and participating in team-based activities. The authors suggest that in larger firms much of this informal learning becomes more structured, either through explicit coaching and mentoring programs or specialized training activities (Ashton *et al.*, 2005: 22).

Mentoring is, however, more likely than not to be an informal activity. Indeed, as we see a trend toward the deliberate integration of learning and work, the employee is expected to learn from everyday work activities and through guidance from other workers. In this situation, colleagues become mentors and managers must assume the responsibility for creating a workplace that is conducive to learning.

Trainers, too, have to adapt to this sort of learning environment and to become familiar with the factors that contribute to effective workplace learning. Chappell and Hawke (2005: 21) group these into four categories: the work environment, the context and objectives of the business, the nature of social interaction in the workplace and with external contacts, and managerial attitudes to learning.

The Learner's Perspective

Another important aspect in the consideration of how to define learning is the learner's own perspective. Many people, including employees and their managers equate learning with formal courses – activities which take place in a classroom or in a training center, and which are often associated with certification. As Ashton *et al.* (2005: 31) point out, this experience of learning as synonymous with formal courses is one that echoes the experience of policy-makers and academics. This further complicates the task of devising comprehensive recognition systems and selling the message that sometimes subliminal learning is a better option, for example, when encouraging reluctant learners or when the learning needs to be immediate. In those instances where there is a case for engaging in a recognition process, the policy settings and funding regimes need to be well established. Otherwise informal learning may not be seen as a credible alternative to formal training. For this reason, many OECD countries are exploring how best to recognize informal learning. And in the case of the European Commission, there is a concerted effort in vocational education and training domain to develop a set of common

principles for the validation of nonformal and informal learning. The European Qualifications Framework has adopted an unambiguous focus on outcomes, achieved by whatever means of learning. It is also explicit that the attainment of a qualification can be achieved through a combination of knowledge, skill, and wider personal or professional competence.

Teaching and Assessment

To implement such policies demands flexible teaching and sophisticated assessment practices, whose focus is less on the definitions of types of learning and more on the results of the learning and the capacity for effective action (Smith and Blake, 2005). This approach applies particularly to adults who already have experiences to build on and preferences for the way in which they learn. Some will want to engage in more self-directed learning rather than be guided by a teacher. Others will prefer a hands-on approach rather than learning through listening and reading.

Vocational trainers have to adapt their teaching to the diverse needs of the ageless learner. They must adapt or embrace learner-centric approaches, more traditional knowledge transfer, as well as consider how to facilitate effective workplace learning. They have many avenues open to them, including formal classroom instruction, group discussion, information and communications technology (ICT)-assisted learning, and workplace interactions. In most cases it will be a combination of these that will reap the best results. Assessors, too, have to meet the increasing demand for the recognition of skills and knowledge gained outside the formal education system (i.e., on the job or in the community). This type of assessment may be for accountability purposes or to determine a student's level of performance but can double as a tool to shape the teaching and learning process. This dual role reflects the reality that adults today must be able continuously to adapt to changing circumstances and therefore need to be able to learn new things all the time.

Measuring or assessing informal learning outcomes can pose significant problems. Informal learning is often *ad hoc*. Clarke (2004), who has looked at these issues, notes that because of the difficulties the focus of assessment shifts from measuring outcomes to assessing learning conditions or the opportunities for informal learning to take place. This diversion can mean that a significant issue is overlooked: the recognition of the quality of the learning taking place. It is important that we know people are gaining the right knowledge and are applying it in a safe and effective way. Attention to quality is imperative also if less formal modes of learning are to gain widespread acceptance from employers and assessors. That is why the European Union, in particular through Cedefop, the European agency for the promotion of vocational education

and training (VET), is developing a set of trusted principles for the validation of nonformal and informal learning. In 2007, Cedefop carried out a project on recognizing this learning among VET teachers and trainers. It found it was possible to make informal learning visible and to evaluate it, especially by adopting a portfolio approach. Technology is lending a hand here, allowing learners to demonstrate the richness of their experience, in pictures and film as well as the written word (see **Case Study 5**) (Cotterill, 2007).

Conclusion

This examination of formal and informal learning makes it clear that informal learning is beneficial, but the extent of that benefit is often determined by people's prior educational experience. Those with a sound foundation of formal schooling are likely to gain valuable insights and experience through informal learning on the job and in other extracurricular activities (reading, netsurfing, etc.). Moreover, they are probably more able to articulate such

learning and receive recognition for it, either through gaining promotion, formal qualifications, or receiving credentials. On the other hand, people with little primary education, whose literacy and numeracy may be limited, or whose confidence in their ability to learn in an educational setting has been dented, can find it difficult to articulate the life experience and skills they possess in a way that facilitates a pathway back to training. For them less formal approaches to skills development can be a more effective pathway back to education and training or to building sustainable jobs. This is the experience of much successful community learning, particularly in places where formal training options are limited.

The legitimate attempt to establish boundaries to assist in recognizing informal learning does, however, pose a conundrum: by making it explicit do we change the nature of this learning? And does it consequently lose some of its value? This is one of many questions that the discussion of the nature of learning stimulates. In this article we have put the case not only for the benefits that can accrue from informal learning but also from according it due recognition in those circumstances where this is advantageous to learners, educators, and employers.

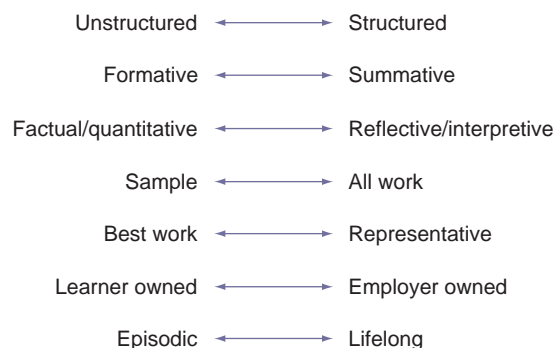

We do so in the hope that this will in turn contribute to a greater impetus to ensuring that all adults are able to engage in the learning they need to live well in the twenty-first century. That may mean being able to watch *The Simpsons* with an easy conscience, having recognized that we all need to keep on learning many things in many ways and knowing we have developed the capacity to sift the learning from the humor.

Case Study 5 Eportfolios: A definition

Simon Cotterill, Senior Research Associate, University of Newcastle upon Tyne, sees the ePortfolio as

a purposeful collection of information and digital artefacts that demonstrates... learning outcomes, skills or competencies. The process of producing an ePortfolio (writing, typing, recording etc.) usually requires the synthesis of ideas, reflection on achievements, self-awareness and forward planning; with the potential for educational, developmental or other benefits. Specific types of ePortfolios can be defined in part by their purpose (such as presentation, application, reflection, assessment and personal development planning), pedagogic design, level of structure (intrinsic or extrinsic), duration (episodic or life-long) and other factors.

Cotterill goes on to explain that within this definition there are many different dimensions, which he presents as follows:

School-Based Vocational Education and Training

B Knight, National Centre for Vocational Education Research, Adelaide, SA, Australia

R Sweet, University of Melbourne, Melbourne, VIC, Australia

© 2010 Elsevier Ltd. All rights reserved.

Setting the Scene and Defining the Scope

One of the major goals of schooling in practically every country is equipping young people with the knowledge and skills that they need for employment. Vocational education and training (VET) undertaken as part of secondary schooling or its equivalent is one of the major strategies that country education systems use to promote this goal. In many situations, it complements the skills, experience, and work ethics that young people gain from part-time, vacation, or voluntary work. However, the institutional arrangements for school-based VET, the form that it takes, the relationship to other parts of the curriculum, and the stage at which it occurs in a young person's education, all vary considerably among countries and even within countries.

The common thread that allows us to present an overview of school-based VET is that, unlike employment-based apprentices who are legally employees, the participants are students. They may have reached the postcompulsory stage of schooling or still be in the compulsory stage if one is mandated. It should be noted that for some disadvantaged groups and people with limiting disabilities, schooling that includes school-based VET can extend well into their adult years; the relevance of VET to these groups is discussed elsewhere in the encyclopedia.

In many countries, a school-based VET program is a coherent, complete course that leads to a recognized, full qualification, typically at the International Standard Classification of Education (ISCED) level 3 or its equivalent. However, many systems allow school students to undertake single vocational subjects, short courses, or modules as part of a general-education program. Additionally, countries such as Scotland and Australia are trying to use vocational education as a way of broadening the upper-secondary general education-curriculum, increasing participation in VET outside of vocational education institutions, and raising engagement with learning in postcompulsory education. By contrast, countries such as Sweden have intentionally taken an integrated view of general and vocational education in both the higher education and 3-year postcompulsory-schooling sectors and have sought to reduce the distinction between practical and theoretical studies (Cully *et al.*, 2009).

The focus of the discussion that follows is school-based VET as part of the broader set of entry-level education and training arrangements for young people. In the next two sections, we consider two dimensions of school-based

VET: the institutional arrangements that exist and the models that are found in education and training systems around the world. However, there is substantial overlap between these two dimensions. Additionally, much of the information and research evidence about school-based VET is embedded in more general treatments of upper-secondary education, with the two often not treated separately. We note also that the country examples given are just that and are far from complete.

Institutional Arrangements

The considerable international variation in institutional arrangements for providing VET to young people who are still legally students (rather than employees), including the inevitable variation in terminology, makes it necessary to take a broad view of the term school. From around grade 7 onward, countries have a variety of institutions – secondary schools, middle schools, *lycées* (in francophone countries), colleges, education or preparation centers, special-education centers, technical or vocational institutes, etc. – whose functions include providing school-based VET. We use the term school as a matter of convenience to encompass all of these institutions.

This means that for students, school-based VET may be provided through a number of different institutional possibilities, which we classify in four broad groups and illustrate with examples from a few countries:

1. Students attend the same institution for both their general education and VET, as in Finland, Sweden, and Brazil (where some schools offer professional – that is, vocational – training in agriculture starting in the early years of secondary school), and India, where some lower-level apprenticeships start at the beginning of secondary school. Included in this category are centers that provide both general education and school-based VET to young people with special needs, such as those in detention or with a serious long-term disability.

This common-institution arrangement has obvious limitations when the school-based VET requires access to equipment and resources that the institution does not have. Some countries overcome this by establishing special schools that provide both general education and school-based VET to prepare young people for a specific industry or occupation. Examples include defense and civil-service preparation centers in some

countries for students selected at a young age and schools run by state-owned business enterprises such as the national electricity authority in China.

2. The learning that a young person undertakes at school is supplemented by work observation, work experience, or structured learning activities in an actual workplace. In some systems (e.g., France and Australia), structured workplace learning may also be formally accredited and assessed. Many countries use workplace learning of some form to provide VET to school students. Sweden provides an example of a country where employers have shown a strong social commitment to this mode of school-based VET: their motivation may include wanting the opportunity to identify possible future employees in a system that has dispensed with apprenticeships.
3. Students attend one institution for their general education and another for their school-based VET, as in Australia when students do their school-based VET at a technical and further education (TAFE) institute concurrently with their general education at an ordinary secondary school. Such arrangements can give students access to much more appropriate teaching and learning resources for their VET studies but may also increase the total cost and cause considerable logistical difficulties. The arrangements can particularly be complicated in countries that allow young people who are still in school to start an indentured apprenticeship or traineeship that includes paid employment as part of the training program.
4. Students leave the institution at which they started their general education and attend one that provides both VET and general education, either explicitly or embedded within VET studies (this is discussed later under the section 'The nature of the curriculum'). Examples of institutions that offer this option include community colleges in Canada and USA, further education and training (FET) colleges in South Africa, *lycées professionnels* in France, the *collèges d'enseignement général et professionnel* in Quebec, and the *Technikum*, *Kolledz* and *Uchilisbe* in Russia.

From the institutional arrangements for school-based VET, we also observe that many countries have a variety of institutions that deliver school-based VET programs. Examples are secondary schools and further education colleges in the United Kingdom, and secondary schools and TAFE institutes in Australia. In Denmark, school-based VET is provided, among others, by commercial colleges, technical colleges, agricultural schools, and social and healthcare (SOSU) schools, all of which cohabit the school-based VET landscape.

Models of School-Based VET

Some dimensions that can be used to classify or describe school-based VET programs are presented below.

The Nature of the Curriculum

In general, a curriculum covers the goals or objectives of the program, what is to be learnt (the content), how it is taught (pedagogical aspects), how it is assessed, and what standards are applied. In reality, there is also a *de facto* curriculum, which is how it all operates in practice. The curricula for schooling generally cover a number of broad areas, including personal and social development, generic academic or vocational skills, and more specific academic or vocational knowledge and skills. The balance between these broad areas has been the subject of considerable debate for many decades, particularly between the proponents of a broad and balanced liberal education and those that favor a more instrumental view of education. In some contexts, curriculum content that focuses on culture, religion, or behavioral norms may also be included.

For school-based VET, the aspect that is particularly relevant is the extent to which the curriculum focuses only upon vocational content compared to that of general education, cultural studies, personal development, and the like.

At one extreme, there are countries where the curriculum has been imported from a wider VET system that is employer-led and is built around the competency standards developed for particular occupations or industries. This model is found particularly in Anglo-Saxon countries and is arguably too narrow and fragmented for young people who are still in schooling. Australia provides an instructive example. Young people who study full-time at a TAFE institute experience a curriculum that is almost completely vocational with very little general education or personal-development material. The institutional dimension is a factor here, as young people who do their school-based VET in a secondary school setting experience a somewhat broader curriculum. The difference arises because the philosophy and management of the school system are directed by government education ministries whereas TAFE institutes are part of Australia's public VET system, which adopts a largely instrumental approach to vocational learning.

At the other extreme, there are cases such as school-based VET programs in Sweden, Italy, and Japan where about half of the content is general education, personal development, or cultural studies (including sport, and religious studies in the Italian case), and Norway's where about a third is general. This more balanced approach is also found in the curriculum for school-based VET programs developed by the national ministry of education in China. In Norway, the aims cover a person's moral outlook, creative abilities, work understanding and skills, general education, understanding and cooperation in a democratic society, and ecological understanding, and they apply to all primary, secondary, vocational, and adult education (Royal Ministry of Education, Research and Church Affairs, 1997). In Singapore, the Institute of Technical Education

(ITE) is a major public provider of school-based VET and about 15% of the content of the courses is life skills; the curriculum is designed to ensure that the young person's general education continues and is integrated with the more specifically vocational aspects of the courses (its slogan, 'hands-on, minds-on, hearts-on,' reflects this; (Law, 2008).

The Role of Workplace Experience and Learning

We have noted that the learning a young person undertakes at school may be supplemented by work observation, work experience, or structured learning activities in an actual workplace. As with most aspects of school-based VET, this varies among countries.

On the one hand, there are countries such as Hungary (Kis *et al.*, 2008), Japan, and Korea (OECD, 2007a) in which there is almost no workplace contact and where workshop practice and simulations are heavily relied upon. Some countries also use this approach for entry-level training of apprentices. In China and India, for example, the whole or perhaps the first year or two of the apprenticeship program is spent in institution-based training using equipment and facilities that are part of the institution's infrastructure.

At the other extreme are Sweden's upper-secondary programs and the *baccalauréat professionnel* in France where the equivalent of a day a week in the workplace is required in all programs. This is regarded as curriculum time and formally assessed, with resources in place to make this possible.

Between these extremes are systems in which some accredited vocational subjects have a workplace learning requirement, sometimes very structured. Meeting the curriculum requirement for the work placement may be as simple as being there for the required time or it may involve a more demanding formal assessment of the prescribed learning outcomes. Where there is some form of assessment, this may be undertaken by an employer's representative, an assessor from the institution where the young person is enrolled, or even an external assessment authority.

Another instructive example is the social and healthcare schools in Denmark in which a workplace rotation model is used to give young people broad skills within a range of entry-level health and social occupations (OECD, 1998). This has some parallels with the model that occurs in Australia when group-training arrangements are applied to school-based apprentices, with apprentices shared among a group of employers for the on-the-job component of training.

The Level and Focus of School-Based VET Programs

Whether school-based VET programs are segmented by level is another important dimension. The level can also

determine whether students are streamed according to their ability into these programs, either formally or *de facto*; this aspect is closely related to the issues discussed elsewhere in the encyclopedia.

The Nordic countries, and South Korea and Japan to a large extent, provide typical examples of upper-secondary school-based VET programs that are not segmented by level. In Japan, the content is relatively nonspecific, and in the initial years of the programs, in Norway and Sweden, the content is quite broadly built around a family of occupations to encourage occupational exploration. Such approaches are much more difficult if the vocational content is tightly focused upon specific occupations, industries, or levels.

Elsewhere, most school-based VET programs appear to concentrate on a relatively tightly defined occupational or industry area. Moreover, it is common to treat vocational (lower level, generally with a focus on manual trade occupations) and technical (higher level, generally with a focus upon technician-level occupations) programs separately. Austria, Belgium, the Czech Republic, France, and Hungary are all examples of systems where school-based VET programs are segmented by level. School-based VET programs in India also span a wide range of levels, partly as a consequence of the wide range of occupations covered by crafts and apprenticeships in that country (DGET, 2007, 2008).

Country systems which allow several school-based VET models to coexist are better placed to overcome a narrow focus on levels and occupations if government policies allow this. In Australia, the curriculum frameworks could accommodate school-based VET programs at a range of levels, but in practice, the majority are at the relatively low certificate-II level if the student is still attending secondary school or certificate III (the level of apprenticeships in most traditional trades) if the student is undertaking school-based VET at a TAFE institute. A range of political factors accounts for this, plus *de facto* streaming by ability.

Articulation with Tertiary Education Programs

The extent to which school-based VET programs link to courses in tertiary education, particularly higher education, has a significant effect on the VET programs that are available to school students and on take-up rates. Using performance in vocational content as the full or partial basis of admission to higher education is uncommon in the Organization for Economic Cooperation and Development (OECD) countries, as the conceptual and intellectual level of the curriculum is not regarded as sufficient. Some exceptions can be found, usually where there is rigorous, quality-assured, and graded assessment of the VET program or where VET and higher education programs have been designed with articulation in mind (as in some dual-sector

VET/higher education institutions in Canada and Australia). In Singapore, the school-based VET programs at the ITE are at national certificate or higher national certificate level, but there are well-defined pathways to diploma- and even degree-level programs for learners with an acceptable grade-point average.

Strengthening pathways between vocational education (both apprenticeship and school based) and tertiary education has been a common theme in most countries for well over a decade. In the case of school-based VET programs, a number of models can be observed. One of the earliest in Europe is the so-called double-qualifying program found in Austria and Hungary, where young people leave school with both a qualification for work and a qualification for entry into higher education. The programs are normally longer than the standard upper-secondary VET program (4–5 years rather than 3), focus upon higher-level technician occupations, and base the case for entry to in higher education upon the demanding level of the vocational content of the entire program rather than, as in other models, upon performance in general-education subjects that form only part of the school-based program.

In Sweden, there has long been a general provision for all graduates of any upper-secondary school-based VET program to be eligible in principle for higher education entry if they meet specified standards, and in some cases, if they complete supplementary work. However, the decision is based only upon their performance in the general-education subjects within the school-based program. The same type of arrangement can be found in Norway's upper-secondary programs, although there, an arrangement exists to provide supplementary instruction in general subjects. Alternatively, young people can transfer from the vocational to the general track midway through their program. In Finland, 1999 legislation gives all graduates of 3-year upper-secondary vocational programs an entitlement to enter all forms of higher education.

In other countries, pathways between upper-secondary school-based VET programs and higher education are minimal. Where pathways do exist, an issue is whether the pathway is to all forms of higher education, as in Sweden and Norway, or is generally to institutions other than universities, such as the *Fachhochschulen* in Austria and Switzerland.

A related issue is the case of countries such as Canada in which school-based vocational preparation is largely deferred until tertiary education, in this case through the short-cycle programs in community colleges (OECD, 2004), or countries where a substantial number of such programs are found in 2-year institutions as well as in upper-secondary schools: South Korea and China are prime examples. Even though the main focus of this article is on programs that are classified as ISCED 3, these school-based VET programs located within tertiary education deserve mention as they seem to be little different from equivalent programs that

are located in upper-secondary education in other countries. The recent OECD review of tertiary education in China (Gallagher *et al.*, 2009) estimated that somewhere between a fifth and a half of all participation in tertiary education was in fact vocational education at upper-secondary level. The position in South Korea appears to be very similar; in recent years, a seemingly wholesale transfer of programs from upper secondary to tertiary level has occurred. Examples include 4-year degree-level courses in hairdressing, and a 2-year associate-degree program in fields such as party planning.

The Relative Weight of School-Based VET in the Initial Vocational-Preparation System

There are two variables that matter here. The first is the overall size of a country's initial vocational-preparation system; the second is whether the initial vocational-education system consists mostly of apprenticeship programs, a mix of apprenticeship and school-based programs, or mostly school-based programs. In **Table 1**, we endeavor to classify the 30 OECD countries using these two dimensions.

The mixed-model countries such as Norway, Turkey, Austria, and Denmark are particularly revealing. In some cases, there seem to be clear distinctions between the types and levels of qualifications linked to the school-based and apprenticeship programs. For example, in Austria, commercial, clerical, and retail programs are largely delivered using school-based programs; in Denmark, the SOSU schools have a clear separation from the apprenticeship system; and most of Norway's school-based programs are in areas in which apprenticeship does not usually operate. In Turkey, the distinction between apprenticeship and school-based programs does not seem to be very clear in terms of the occupational areas, with much of the difference being a function of the level of education of entrants. In many other Middle Eastern countries with a mixed-mode system, the distinction appears largely in terms of the level of the qualification, with school-based programs generally at a higher level than the work-based programs (Sweet, 2009).

There are also differences between countries in the extent to which school-based initial vocational preparation is growing or declining. **Table 2** shows trends over the 1998–2006 period in the proportion of upper-secondary enrolments in vocational programs for those OECD countries whose vocational preparation system is largely school based.

These programs are fairly stable in size in most countries, but growing in Finland, in Sweden, and in Spain:

- in Finland this is probably because of the new pathway that has been opened up between upper-secondary vocational education and tertiary education.
- in Sweden, the likely cause is the creation in the late 1990s of *kvalificerad yrkesutbildning* (KY), a new type of

short-cycle tertiary/postsecondary education program outside of the universities, which as in Finland, has helped to open up new pathways between upper-secondary vocational education and tertiary study.

On the other hand the rates are declining in Hungary, South Korea, and in Poland:

- in the case of Hungary and Poland, the rates were kept artificially high during the communist period, and the loosening of central controls over decisions about resource allocation between different types of schools, combined with high social demand for and recent expansion of higher education, seems to be the explanation.
- in South Korea, the story is much the same, with a loosening of controls over the expansion of higher education institutions, particularly in the private sector, great emphasis on higher education, and a transfer of

many upper-secondary level courses to higher education (not only 2-year programs but also to 4-year institutions) accounting for the changes.

In most of the above examples, both growth and decline, the relationship between tertiary education and upper-secondary vocational education seems to be behind the trend, rather than the changing demand for the skills and qualifications produced by upper-secondary vocational education.

Outcomes and Purposes

The discussion of outcomes from school-based VET programs is closely related to their purposes. In essence, there are two sets of arguments: those about economic

Figure 1 The size of upper-secondary school-based vocational pathways and young people's labor-market competitiveness. From OECD labor force database and *Education at a Glance*, 2007.

purposes and outcomes; and arguments related to participation, pedagogy, and engagement with learning.

Evidence on the economic or skills-based outcomes and purposes of school-based programs are closely linked to the literature on labor market and economic returns from different types of postcompulsory pathways. The impact of pathways is linked to the quality of the students who enter them as well as the labor-market returns of the relevant occupations. Ryan's (1998) paper on apprenticeship returns suggests that there is not much basis for favoring apprenticeship over full-time vocational schooling, although there are some country-specific exceptions. Grubb's (1997) work on sub-baccalaureate returns to vocational education in the USA shows that returns are highly specific to the occupational field. Raffe (2003, 2008) makes similar comments in his work on pathways.

For a number of countries whose upper-secondary vocational pathways are largely school-based, **Figures 1** and **2** show the relationship between the scale of vocational enrollments and two measures of school-to-work transition outcomes: the youth-to-adult unemployment ratio as an indicator of youth's relative labor-market competitiveness; and the number of years expected to be spent inactive (either unemployed or not in the labor market) between the ages of 15 and 29 as an indicator of the smoothness of labor-market insertion. In neither case is there any significant relationship to the scale of upper-secondary vocational programs, suggesting that arguments based upon economic or labor-market purposes need to be treated with some caution as a justification for expanding such programs.

Other arguments about outcomes and benefits focus on the role of school-based VET in raising participation, pedagogy, and engagement with learning. The OECD (2007b) uses such arguments to support the case for VET in schools programs in Scotland. In brief, more active and applied teaching and learning styles are seen as ways to keep young people engaged in education and to build better foundations for lifelong learning. The emphasis upon these sorts of issues seems to be somewhat different in countries such as Scotland and Australia which are trying to raise upper-secondary participation and completion within traditional schooling.

Australia provides possibilities for a case study based on recent experience because the school-based VET options available within the senior secondary certificate were expanded significantly about a decade ago and there has been a significant level of take-up (Polesel, 2001). However, there is little evidence that it has improved retention rates to the end of secondary school and the evidence for improved labor-market outcomes for young people is patchy. School-based apprenticeships were introduced at much the same time, although the take-up has not been great; again, the evidence for positive benefits is patchy (Knight, 2008).

Access and Equity

Evidence for the effect, if any, that school-based VET has on access and equity for young people is difficult to

Figure 2 The size of upper-secondary school-based vocational pathways and the smoothness of young people's labor-market insertion. From OECD *Education at a Glance* 2007.

extract from the more general literature on the relationship between access and equity and upper-secondary pathways. As with the question of outcomes, it is hard to disentangle this from issues of the differential inputs to and economic returns from the different pathways. It is only in very specific situations, such as a special school or training center established to cater to a particular disadvantaged group, that a clear link can be observed. Even in these situations, there is little information publicly available about the benefits that might flow from the arrangement apart from the fact that a school-based VET option is available, which is certainly not the case in all countries.

What is clear is that in all countries in which this type of data has been gathered, those young people who enter (school-based) upper-secondary vocational pathways have on average a lower socioeconomic level and lower achievement levels than those who enter general tracks. The OECD's Program for International Student Assessment (PISA) data (OECD, 2008) make this abundantly clear, even if they are confined to 15-year-olds. Furthermore, it clearly shows that where countries segment these vocational-education programs by level, lower-level programs on average attract more of those from lower socioeconomic backgrounds and more with lower-level achievement scores than do the higher-level programs. European research (Müller and Shavit, 1998; Smyth *et al.*, 2001; Müller *et al.*, 2002) leads to the same conclusion.

Less clear are the conclusions about access and equity that should be drawn from this evidence of streaming by socioeconomic status and ability. For example, Müller and

Shavit (1998) point out that this type of tracking can reduce the risk of dropping out of education among such groups. Similarly, in the United States, empirical evidence strongly favors the view that the disproportionate representation of those from lower socioeconomic status backgrounds in community colleges is more likely to be associated with an opening up of educational opportunities with a decrease in the numbers going to university (OECD, 2004). A similar argument is presented by Polesel about upper-secondary vocational education programs in Italy.

Introduction

The dominant paradigm in the economics of education is Human Capital Theory, which suggests that education and training are investments that make individuals genuinely more productive. Individuals who are more productive will, according to this theory, also have higher earnings and be more employable. The private economic return to investing in education or training, that is, the gain to the individuals, can therefore be measured by the net gain in lifetime earnings accruing as a result of their investment in education or training.

Policy-makers around the world tend to accept unquestioningly the premise that investment in education and training is a good thing, with most committed to investment in human capital, including Vocational Education and Training (VET), as a means of securing higher economic growth and national prosperity as well as achieving equity goals (see Wößmann, 2008). However, some economists have argued that individuals who are more able and productive also tend to invest in more education (Spence, 1973; Arrow, 1973). In other words, education does not necessarily make you more productive it simply acts as an expensive sorting device, to enable employers to identify more able individuals. Wolf (2002) claims that the policy emphasis on education and skills as the main driver of economic growth overstates the importance of human capital investments and that a major function of education is as a sorting device and to some extent a social discriminator. In making policy about education and training, it is clearly important to understand these potential economic returns to education and training to the individual, firms, and the wider economy. However we must also recognize that separating out the genuine impact of education on productivity and earnings from its role as a sorting device is very difficult.

Understanding the economic value of education and training, as measured by gains in wages, is important but not in itself enough to inform policy about the optimal type of education and training system. As recent papers such as Carneiro and Heckman (2003), Cunha and Heckman (2009), and Carneiro (2009) argue, it is also crucial that we understand the technology of skill formation over the life cycle. For effective policy formation, we need to know how different types of people can effectively acquire skills at different stages of the life cycle as well as

the economic returns to those skills once acquired. This is particularly important in the area of VET, since international evidence suggests that the economic returns to some VET are low.

Finally, even if one accepts that education and training genuinely do enhance individuals' productivity in the labor market, it is not clear that focusing on earnings is enough. First, it is not clear that wages always accurately reflect individuals' productivity levels, as suggested by economic theory. This is clearly not the case in the public sector, as the wages of nurses and teachers, for example, are state determined (although influenced by prevailing private sector wages). Of course, education is also far more than an economic investment and yields a myriad of noneconomic benefits for the individual. These benefits may be in the form of reduced crime, better parenting skills, and/or better health outcomes. Noneconomic benefits from education are not considered in conventional rates of return analyses. However, looking at these potential wider benefits of education and training is also crucial for sound policy development – particularly in the area of VET.

In the next section, we look at the economic literature on how skills are formed and the implications this has for VET policy. In the subsequent section, we look at the international evidence on the returns to VET. In the last section, we conclude.

The Technology of Skill Formation and Its Implication for VET

The system of vocational education and training and enrolment rates in VET differs markedly by country. This has already been documented elsewhere in this encyclopedia.

But how effective is VET in raising the skill levels of individuals, how does this vary by country, and what are the implications for policy? We argue that in order to look at this question properly from an economic perspective, VET has to be seen as part of a whole lifecycle process of skill formation which starts in the womb and ends in the grave.

The extent to which VET and other education and training raises individuals' skill levels can be measured by estimating the economic return to such qualifications and skills. The work on skills formation shows that these economic returns to skills investment are higher in early

childhood and decline over the life cycle. From an analysis of both theory and evidence, Carneiro and Heckman (2003) argue that, at the current levels of investment, rates of returns to investment in human capital are declining over the life cycle (**Figure 1** taken from Heckman, 2008).

Numerous studies suggest that there should be strong investments in early childhood, both because the sensitive periods for acquiring several capabilities occur early in life, and also because successful learning early in life is the foundation for successful learning later in life (Carneiro and Heckman, 2003; Cunha and Heckman, 2009; Carneiro, 2009; Meghir and Palme, 2005).

However, this literature also argues that it is not enough to just invest in skill formation (both cognitive and noncognitive) in early life. These investments also need to be followed up by further investment in skills, or there is a strong risk that individuals' will not fulfill their potential. This is particularly so for individuals from poorer socioeconomic backgrounds who not only tend to start with lower levels of investment but then also have access to poorer quality schools and thus experience less subsequent investment.

The stock of human capital available to a young adult as he or she enters the labor market and beyond is therefore a function of the history of skill investments that took place up to that moment. This function is much more complex than just the sum of all the investments up to that point, because the timing of investments over the life course is not irrelevant for the final result. One key point emerging from this literature is that if the degree of complementarity between early and late investments is very strong, then it may be very costly or impossible to remediate the lack of early investments.

Second, this body of literature looks at the plasticity of learning (i.e., the ease with which a person's skills can change and develop) and the critical periods for learning. There is increasing evidence that there are sensitive periods of learning, which imply that if the proper investment is not done at the right time (during the sensitive period), then learning opportunities may be permanently lost. This literature suggests that it is very hard to build on cognitive skills if they have not been acquired in the first 10 or so years of life. On the other hand, the same evidence base suggests there is much more scope for enhancing noncognitive skills into adulthood. So there are critical periods of learning. In case they are missed, one does not get another chance.

These two issues have strong implications for the effectiveness of VET provision. Different VET systems will provide a different mix of cognitive and noncognitive skills and VET specialization will occur at different ages in different countries (some countries select children into VET at an early age). In general, the extent to which VET provision can build on prior investments will be critical to the economic value of VET. Any policy initiative in the VET area needs to take this into account this dynamic complementarity of skill investment as well as the plasticity of skill acquisition.

A competing model would say that investments in skill are substitutes over time, and therefore their timing is irrelevant, so all that matters is the sum of all investments one receives during one's life. If that were the case, then education and training could take place at any point over the life course and still prove effective in boosting the skills and earnings of individuals, even those who left initial education with very little in the

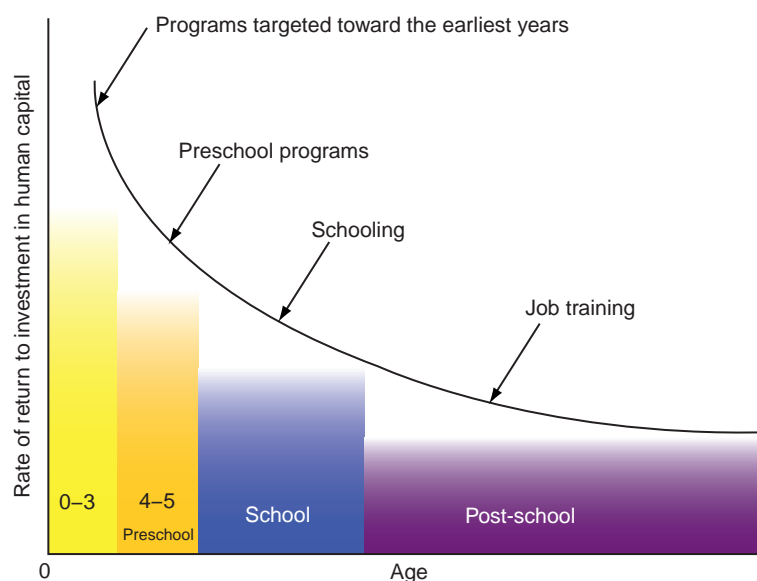

Figure 1 Returns to investment in human capital over the life cycle. Source: Heckman (2008).

way of skill. Our reading of the evidence is that this is not the case and that later investments that are not built on strong initial investments are likely to prove ineffective. Certainly, firms believe this to be so. It is also well known that more educated workers are more likely to be selected for (or select themselves for) company training, suggesting that firm investments in VET are targeted at individuals with higher levels of initial human capital (Blundell *et al.* (1996) for the UK and Carneiro and Heckman (2003) for the USA).

This dynamic complementarity not only means that the returns to later investment in skill are highest for those with strong early investments, but it also means that the returns to early investments in skill will increase with follow-up investments later in life. This is discussed more in the next section – but is important to bear in mind when looking at the rates of return to VET.

Dynamic complementarity is also a potential explanation as to why borrowing constraints in late adolescence play only such a small role in college attendance relative to factors such as family background and ability (Carneiro and Heckman, 2002), and why, as we will see in the next section, the returns to basic skills programs, that is, programs that attempt to improve individuals literacy and numeracy skills (see Torgeson *et al.* (2004) for a summary) and public job training programs, are generally too low across the world, as shown here (e.g., Lalonde, 1995; Cohn and Addison, 1998; Heckman *et al.*, 1999; Carneiro and Heckman, 2003; Dearden *et al.*, 2004; Abramovsky *et al.*, 2005).

International Evidence on the Returns to VET

The wage returns to general education have consistently been found to be strong and significant worldwide. It is widely agreed that the economic return from an extra year of formal full-time education is around 8–10% or even higher for some individuals (see, e.g., the review by Card (1999)).

In investigations that examine the returns to qualifications – rather than years of education – again most studies find significant economic returns. However, it does matter what type of qualification one acquires. In many countries, the wage returns to academic qualifications are significantly higher than the returns to vocational qualifications, government training programs, and adult basic skills training (see, e.g., Blundell *et al.*, 2005; Dearden *et al.*, 2002; Dickerson, 2005; Carneiro and Heckman, 2003).

What are the returns to VET? Why are the returns to some forms of VET so much lower than those for general education? Why do policymakers and governments around the world still invest significant amounts of money in government-sponsored VET programs when the returns are not high?

To address these questions, we start by looking at the international evidence on the returns to basic skills programs, vocational education, government training initiatives, and work-based training and then discuss the rationale for large state-sponsored VET programs.

Basic Skills Training

The value of cognitive skills in the labor market is high in most labor markets, and some studies suggest that there has been an increase in the return to cognitive skill over time, particularly in the USA and the UK (see Tyler (2004a) for an overview; Howell and Wolff, 1991; Murnane *et al.*, 1995, 2000; Bowles *et al.*, 2001). The value of basic skills is also high in some countries, although the evidence base is more limited (see Grinyer (2005) for a summary). In countries such as the USA, Northern Ireland, and the UK, the rate of return to basic literacy and numeracy is substantial (Denny *et al.*, 2003; McIntosh and Vignoles, 2001; Bynner *et al.*, 2001; De Coulon *et al.*, 2007; Tyler, 2004a). However, the returns to basic literacy and numeracy are not high in all countries. In particular, in countries where the supply of basic skills is relatively large compared to demand (e.g., Germany), the rate of return to such skills is much lower (Denny *et al.*, 2003).

Although basic skills have high value in the labor market, it is not the case that the returns to basic skills programs are substantial. Again the evidence base is somewhat limited. A recent international survey by Torgeson *et al.* (2004) suggests first that there is limited robust evidence on the impact of basic skills training. Second, those basic skill interventions that were robustly evaluated (e.g., by Random Control Trial) did not show systematically positive effects. Other UK evidence is consistent with this view: a study using rich cohort data to determine the economic return to basic skills courses and improvements in basic skill in adulthood found limited effects, for example (Dearden *et al.*, 2001). Given that most interventions tend to be small scale and in adulthood, this is perhaps unsurprising. As we discussed in the previous section, later human capital investments need to build on prior investments in the early years, particularly for cognitive skill development. Thus, trying to train illiterate adults is going to be challenging.

This evidence on the effectiveness of basic skills training, or lack thereof, contrasts sharply with the evidence on early interventions that have been found to be successful in improving cognitive skills and basic literacy and numeracy. For example, in the UK context, the *Sure Start* preschool intervention and a primary school intervention called *The Literacy Hour* have been found to be effective in improving children's cognitive and noncognitive skills (NESS, 2008; Machin and McNally, 2004). In the USA, preschool interventions, such as *The Perry Pre-School* random trial which provided 2 years of preschool support for

poor black children in the USA, have had a significant positive impact on children's skills (Nores *et al.*, 2005; Heckman *et al.*, 2008). Thus, it is certainly not the case that one cannot improve individuals' literacy skills, rather that interventions late in adulthood are more difficult.

Vocational Education at the End of Compulsory Schooling

The vocational options available to students at the end of post-compulsory schooling vary hugely across different countries. Some countries specialize in VET options early in middle secondary school (e.g., Germany), while others essentially force students to follow a largely academic curriculum until much later (e.g., the USA). Some countries have been shifting the balance over time, introducing vocational qualifications in secondary schooling that have notional parity with their academic equivalencies (e.g., the UK). Just as the provision of vocational education varies hugely by country, so does the economic value of VET as well. Again, differences in the value of vocational training are linked to the dynamic complementarity argument and the extent to which efficiency and equity considerations are complements, substitutes, or unrelated.

In countries where there are well-developed vocational education systems in schools and well-established apprenticeships systems, returns to vocational education are high (e.g., Steedman, 1993; Acemoglu, 2001; Acemoglu and Pischke, 1999) (or indeed where there is a competitive market for apprentices (e.g., Heckman, 2000). This is not, however, universally the case. In Australia, for example, the returns to VET are positive but vary by qualification level and mode of study (Ryan, 2002).

In countries where there is a less-developed vocational system, the proliferation of vocational qualifications both in the schooling system and beyond has weakened the signal of what the vocational education is providing and returns are less (Wößmann, 2008; Machin and Vignoles, 2005). This is exemplified by the UK experience where vocational specialization generally occurs at the end of compulsory schooling (this is changing somewhat with the introduction of vocationally oriented curricula at 14). Since the 1970s in the UK, there has been a proliferation of vocational qualifications and a dramatic shift away from apprenticeships (the current UK government has tried to reinvigorate the apprenticeship system with some success). Many newer vocational qualifications (e.g., National Vocational Qualifications) have little economic value. Jenkins *et al.* (2007) found, in line with much previous research (Dearden *et al.*, 2004), negative average wage returns to these low-level vocational qualifications and specifically NVQ Level 2 (NVQ2 – supposedly equivalent to the age 16 qualifications acquired in England, namely General Certificates of Secondary Education or GCSEs). Similarly, in the US context, the returns to academic

education are higher (see Kane and Rouse, 1995; Card, 1999). The returns to community college, which tends to be vocationally oriented, are still positive (Kane and Rouse, 1995). However, for those who drop out of high school prior to graduation, the route to obtaining later higher school certification (GED) has been found to have only limited economic returns, and in some cases negative returns (Heckman *et al.*, 2000; Murnane and Willett, 2004; Tyler, 2004b).

Thus, the institutional arrangements for VET provision in the secondary schooling phase and beyond heavily determine the likely outcomes for students who do not proceed down the academic route.

Government Sponsored Adult Training

Public sector job training programs that attempt to provide skills to a population of very low-skilled adults have almost universally been unsuccessful, but despite this such programs remain on many countries' agenda – largely because of equity considerations. Again this comes back to the dynamic-complementarities argument. Such job programs are largely targeted at low-skilled unemployed individuals, and these people accumulated little human capital earlier in their life and therefore they lack strong foundations on which public training can then build on. As a result, they are not able to learn much from the training that is offered to them.

A job program entitled Train to Gain in the UK is classic example of this problem. This program provides subsidized work-related training for low-skilled workers with the subsidy going to firms to encourage them to train. It was introduced on a pilot basis and was fully evaluated in 2003 and 2004. The evaluation suggested only small insignificant effects from the program on the incidence of training being undertaken by firms (Abramovsky *et al.*, 2005). Furthermore, they found that majority of firms undertaking this training would have done so in the absence of the program, that is, the deadweight loss was considerable. Additionally, the training provided in this program at best leads to qualifications which have been found to have extremely low or even nil wage returns. Specifically, the training was designed to lead to lower-level and newer vocational qualifications that have little labor market value (Dearden *et al.*, 2004b; Dickerson, 2005; McIntosh, 2004). Thus, this particular program had the twin challenge of being aimed at adults and also being designed to lead to qualifications that historically have had low labor market value.

Public training programs are not, however, ineffective purely because they are largely targeted at adults. Youth training programs, aimed at unemployed young adults, have been similarly ineffective (e.g., see Fougere (2000) for an analysis of French youth training and Friedlander *et al.* (1997)). Again this may be partially due the modest

amount of training being provided and its low quality. However, it is also the case that such programs are aimed at young adults who lack a good human capital base. They tend to have nil or few qualifications and low levels of cognitive skill. Building on such a weak foundation is undoubtedly more difficult.

Employer-Provided Work-Related Training

There is clear evidence that work-related training, provided by or at least purchased by firms, yields strong positive economic returns across a range of different countries (Almeida and Carneiro, 2009; Bassanini *et al.*, 2005; Blundell *et al.*, 1999; Groot, 1999; Leuven, 2005). This stands in contrast to the evidence on public training programs which have been found to be generally ineffective (Wößmann, 2008). There is also a large body of evidence that convincingly shows that more educated workers receive higher levels of on-and-off-the-job firm-provided training. Furthermore, firms train those who earn the highest returns to VET (Vignoles *et al.*, 2004). Thus, once again we see that there are dynamic complementarities in the VET system and as discussed earlier, firms are more likely to invest in individuals who already have higher levels of skill.

Wider Benefits of VET

Perhaps focusing on just economic returns misses an important part of story (Wößmann, 2008). VET could improve the noncognitive skills of low-skilled adults which will in turn have an impact on the early cognitive and noncognitive skills of their children and as a consequence their lifetime skill acquisition. Alternatively, it might be that training that is not typically valued or supported by government (e.g., that does not provide qualifications or is directly work related) may affect noncognitive skills of adults that will in turn have an impact on the cognitive and noncognitive skills of their children which may have long-term benefits that are typically not evaluated or measured. These potential intergenerational benefits of VET are much more difficult to measure and have not as yet been proven to be important. In fact, some evidence from Australia suggest that while degree and higher-level VET qualifications were associated with better health outcomes, lower-level VET qualifications were not (Stanwick *et al.*, 2006). Only time, and proper long-term evaluations of such qualifications and programs, will tell.

Implications and Conclusions

The economics of VET is complicated and more research, more inventive policy development, and more

rigorous evaluation of VET policies needed worldwide. It is important that these studies not only focus on the economic returns to VET but on the whole process of skill formation. It is clear that policy needs to ensure that lots of investments in skills occur in early life – but this is too late for many adults with low levels of skills. Several current solutions to adults' skills problems are clearly not working and more rigorous testing and evaluation of more innovative policies is what is needed – and these need to take into account the fact that skills beget skills. Furthermore, given the evidence that cognitive skills are potentially less malleable later in life, it may be that adult interventions need to pay closer attention to the development of individuals' noncognitive skill. Focusing on possible intergenerational transmissions of skills may also be important.

The arguments put forth in this article suggest that there should be strong investments in early childhood, both because the sensitive periods for acquiring several capabilities occur early in life, and because successful learning early in life is the foundation for successful learning later in life. These investments also need to be followed up, or there is a strong risk that they will not fulfill their potential. However, this does not address the skills deficit for the current generation of adults in a number of countries in the world. As argued by Wößmann (2008), when policymakers are making decisions about government educational programs, they not only consider economic efficiency (high returns) but also equity (equality of opportunity). He argues that for some educational investments, particularly early investments, efficiency and equity considerations are strong complements – what is good from an efficiency point of view also is good from an equity point of view. However, for other educational investments, in particular, some VET programs, government policymaking often involves a tradeoff between efficiency and equity arguments. This creates a further complexity in the economics of VET.

Fixing the problem of unskilled unqualified adults is certainly hard and costly and at the moment in several countries the solutions being adopted are based on an act of faith rather than sound evidence. We argue that effective, or at least informed, policy involves understanding more fully the nature of dynamic complementarities in the acquisition of skills over the life cycle and a better understanding of the differential sensitive periods in the accumulation of cognitive and noncognitive skills. This is a promising research agenda in which people are starting to make inroads (see Cunha *et al.*, 2008) and this area of research is highly likely to guide education policy, including VET policy in years to come. A more explicit understanding of the tradeoff, or otherwise, between efficiency and equity considerations in government policymaking is also needed. Current research tells us that adult learning builds on learning in adolescence: while equity considerations may

dictate that we need to invest in adults now, only by balancing this with good-quality early investment will we improve outcomes in the future.

Introduction

This article is concerned with older people and vocational education and training (VET). It considers how issues of age and work have received considerable recent attention in many countries, particularly those of Europe, and the reasons for this. Issues covered include lifelong learning, the need for retraining following economic displacement, and pressure to prolong working life as populations age. The article is particularly concerned with the incidence of age barriers in accessing education and training and efforts to overcome them. It begins by considering the importance of participation in learning for older people. Following this, it considers evidence on the extent of participation in European countries, where the issue of extending working lives is currently strongly promoted, before going on to consider factors associated with participation. It then considers the state of policymaking and looks at what is known about overcoming age barriers before offering concluding comments.

The Importance of Social Participation for Active Aging

The World Health Organization (2002) in its Active Ageing Policy Framework defines active aging as “the process of optimizing opportunities for health, participation and security in order to enhance quality of life as people age.” WHO views opportunities for education and lifelong learning as key factors in the social environment that

enhances health, participation, and security: “Loneliness, social isolation, illiteracy and a lack of education. . . greatly increase older people’s risks for disabilities and early death.”

Participation in learning brings major benefits for individuals. The Institute of Employment Studies published a report titled *Learning in Later Life: Motivation and Impact* (2000), key findings of which were as follows:

- 80% of learners reported a positive impact of learning on at least one of the following areas: enjoyment of life, self-confidence, feelings about self, satisfaction areas of life, and coping ability;
- 42% reported an improvement in their ability to stand up and be heard and their willingness to take responsibility;
- 28% reported increased involvement in social, community, and voluntary activities as a result of participation in learning;
- 58% reported that learning improved their enjoyment of life;
- 56% reported an improvement in self-confidence; and
- 36% said that learning had helped them cope better with everyday life.

WHO offers a number of key policy proposals, including the following:

- make basic education available to all across the life course;
- enable the full participation of older people by providing policies and programs in education and training that support lifelong learning; and

- provide older people with opportunities to develop new skills, particularly in areas such as information technologies and new agricultural techniques.

According to Auer and Fortuny (2000), lifelong learning will play a critical role in addressing issues associated with the aging of populations. First, it can help the adjustment of workers' skills and competences to labor-market demand. Second, it can help improve the attachment of older people to the labor market. Third, it can help to overcome productivity declines which may occur with aging.

International institutions emphasize the importance of lifelong learning. For instance, the International Labour Organization (ILO) points to the need for governments to develop policies aimed at avoiding the premature exclusion of older workers from the labor market and stresses the point that workers are less likely to face redundancy in later life if they have benefited from access to lifelong learning opportunities. Lifelong learning is also high on the agenda of the European Commission. The commission communication *Towards a Europe of Knowledge* (1997) places lifelong learning at the center of an integrated approach to future policy action. It stresses the need to promote on a lifelong basis creativity, flexibility, adaptability, the ability to learn to learn and to solve problems which are the conditions we must meet in order to avoid the now-rapid obsolescence of skills. Similarly, at the meeting of the Organization of Economic Cooperation and Development (OECD)'s Education Committee at Ministerial Level: *Making Lifelong Learning a Reality for All* (1996), education ministers emphasized the importance of lifetime learning to deal with the employability of the aging population and agreed on implementation strategies. Additionally, the European Union (EU)'s taskforce on employment led by Wim Kok called for member states to take three key measures to meet European targets:

1. incentives for workers to retire later and for employers to employ older workers;
2. promote access to training for all regardless of age and to develop lifelong learning strategies; and
3. to improve the quality of work to provide attractive, safe, and adaptable work environments throughout the working life.

However, Auer and Fortuny (2000) argue that a shift toward lifelong learning will be a gradual process. Many issues, such as financing remain unanswered. Meanwhile, there is still the imperative need to help the stock of older workers to adapt during the transition. In their view, well-targeted training programs and other labor-market policies can help address specific current labor-market problems of older workers. However, they add that both stock (the current problems facing older workers) and flow (to commence a policy of lifelong learning

for younger-age cohorts) policies must be pursued concurrently.

Levels of Participation in Education and Training by Age

Older people are often considerably less likely than younger ones to participate in training and learning activities. Training tends to be front-loaded but there are important differences between countries. Thus, among the Nordic countries, training appears to be largely age neutral. By contrast, elsewhere, there is a steep decline in the incidence of training by age (OECD, undated).

Table 1 presents figures on job training undertaken in the last 12 months obtained from analysis of the European Working Conditions Survey of 2005. This shows that workers aged 50 or over are generally less likely to receive

Table 1 Incidence of training by age and country for selected European countries (%)

Country	Age group	Under 50	%	50 or older	%
Austria		298	37.1	60	31.1

From European Working Conditions Survey 2005 (author's own analysis).

training than other age-groups, although there are notable exceptions: Finland, Latvia, and Sweden. Notable is the wide variation between countries, with Finland and Sweden having incidences of around 50% for both younger and older workers, with larger countries such as France, Germany, and Italy falling far short of this.

In considering the place of VET in the lives of older people, it is helpful to consider how they fare compared to younger people on specific programs. There is clear evidence older people can benefit from interventions. For instance, in the United Kingdom, Work Based Learning for Adults (WBLA) is a voluntary program which aims to:

- help unemployed people move into sustainable employment;
- help long-term unemployed people to gain skills in areas where there are recognized skill shortages
- enable long-term unemployed people to make a successful transition to self-employment.

In the program, basic employability training is available for people who need extra help before they start job-related training. Those aged 25 or over and have been out of work for 6 months or more and claiming unemployment benefits or another qualifying benefit are eligible.

Findings of a study which aimed to investigate the use and experience of WBLA by people aged over 50 and the factors associated with participation, achievement, and successful provision was published in 2001 (DfEE, 2001). The results were as follows:

- In 1999, people aged 50 and over were underrepresented on WBLA compared to their share of all long-term unemployed people.
- WBLA leavers aged 50 or over were almost as likely as those aged 25–49 to achieve a qualification: 37% of the former compared to 38% of the latter in 1999–2000
- Fewer older leavers found employment: 36% compared to 41% in 1999–2000.

Much of this difference may be explained by the higher proportions of longer-term unemployed and of basic-employability trainees among those aged 50 or over. Fewer trainees of these types in both age groups got jobs. But trainees aged 50 or over who had been unemployed for 3 years or more and nonbasic-employability trainees who had been unemployed for less than 6 months were less likely to get jobs than their younger counterparts. Ageism on the part of employers may have been responsible for this.

Most older trainees interviewed were pleased with their training provision and felt it was meeting their needs in terms of quality of teaching, learning style, and resources. Follow-up survey results showed that about eight out of ten of leavers rated WBLA as useful and helpful in increasing their confidence and in improving their skills/learning new

skills. Leavers aged 50 plus were slightly more satisfied than those aged 25–49 with these aspects.

A more recent evaluation of WBLA undertaken by the Policy Studies Institute and the National Centre for Social Research (2003) and based on survey data shows that short job-focused training (SJFT) accelerated entry to full-time employment. Participation increased prospects of being employed about 5 months after enrolling. The size of this effect was in the region of 5–7 percentage points. However, it was shortlived and no impact was evident by the 10-month mark. However, there did appear to be a sustained effect for clients aged 50 years or over.

More generally, it has been known for a long time that training primarily goes to the most qualified. Research into individual-initiated vocational training among middle-aged workers indicates that it is primarily those with skills already who participate. Those with lower levels of education, who arguably have most to gain, are least likely to self-initiate learning activities (Elman and O'Rand, 2002; Jamieson *et al.*, 1998). Although qualification level is the predominant factor in access to continuing training, age appears to aggravate the situation. Decreasing participation in training with age begins even earlier for those at the bottom of the job ladder. Thus, while a large proportion of managers continue to participate in training after 50 years of age, operatives see their rate of access to training drop significantly around the age of 40. A British Chartered Institute of Personnel and Development survey: *Who Trains at Work*, in 2003, found a significant gap between the training haves and the have-nots with people in lower-grade jobs, those with lower educational achievements, older workers, and part-time workers least likely to be trained by their employer.

However, it is important to note evidence which demonstrates that older people are not disinterested in learning. The UK's National Adult Learning Survey (NALS) found that 67% and 47% of those in the 50–59 and 60–69 age groups respectively were learners. On the other hand, NALS found that 21% of the 50–55 age group and 30% of the 60–69 age group indicated that they were not interested in learning (higher percentages than for any other age group), and the numbers stating that they were too old to learn increased by decade: aged 40–49 (12%), 50–59 (22%), and 60–69-year-olds (30%).

Factors Associated with Participation in Learning Activities

It has been suggested that low levels of training among older workers largely result from a lack of availability (Trinder, 1992). Research would seem to bear this out, providing evidence that the key factor constraining training activities is a lack of opportunities provided by employers rather than disinterest among older workers (Taylor and Urwin, 2001).

This contrasts with the often-expressed view of employers in surveys that training is open to all, and suggests that age discrimination in training often goes unrecognized. Given that the realization of lifelong learning is a major pillar of policymakers' strategies for tackling the economic issues presented by population aging (Auer and Fortuny, 2000: 29), this represents a significant hurdle.

Other research suggests that nevertheless, there may be factors in addition to employer behavior which reduce older workers' training activity. A study of manufacturing workers in a motor-vehicle-manufacturing company (Warr and Birdi, 1998) explored employee-development activities outside formal training. Among the mainly male (95%) workforce questioned:

- older workers were substantially less likely to participate;
- education level, learning motivation, and learning confidence, as well as lower age were found to be predictive of participation;
- support from managers, co-workers, and nonwork sources were positively correlated with activity, while time constraints were found to have a negative association;
- controlling for other factors, age was found to have a negative impact on activity.

Research suggests that older workers often consider themselves unsuited to new learning and lack confidence in such situations. Consideration needs to be given to overcoming such feelings and to the design of programs of training with older people's needs in mind, something that is considered later in this article.

Commentary on Public Policy

In Europe, it is apparent that despite plenty of rhetoric surrounding the social participation of older people in recent years, policymakers are only just beginning to turn their attention from youth education, to education and learning across the life course. In some countries, this is barely the case. In others, rather more has been achieved. According to Withnall (2000) analysis of major policy reports relevant to the development of lifelong learning reveals that strong priority has been given to VET, despite general rhetoric about the noneconomic, personal, and social benefits of lifelong learning generally. She also notes that vague statements concerning the perceived outcomes of policies such as an assured improvement in society and personal fulfillment also tend to permeate recent European policy statements concerned with the promotion of lifelong learning. She adds that while the UK government has acknowledged the need to break down barriers to older people playing a full part in its vision of a learning society, its proposals to date for development and the packages of support available to

adult learners suggest that people who are post work are not genuinely part of the vision. Older people continue to be marginalized in educational policy circles in Europe at a time when later life is primarily characterized as a social problem.

With a new emphasis on extending working lives, policymakers are paying attention to issues of learning for older workers. For instance, in Britain, a potential step forward has come in the form of the Government's Skills Strategy, launched in April 2004, which sets out policies affecting adult learners, including older workers. These include:

- free learning for any adult who does not already have a good foundation of skills necessary for employment;
- opportunities for adults to gain qualifications in technician and higher craft and trade skills;
- a weekly payment for adult learners in priority groups to support them in studying full-time courses in further education;
- removing an age bar on the government's modern apprenticeship scheme so that people over the age of 25 can learn skilled trades; and
- reforming adult information, advice, and guidance services to help adults into learning and ensure that individuals can find out what to learn, where to learn, and what their entitlements are.

On the other hand, policy and practice are apparently at odds in Britain. There is still often an apparent emphasis on younger people, in particular, preparing them for working life. For instance, the British Learning and Skills Council published a consultation document entitled *Funding Adult Learning* in 2003. This set out some potential options and related funding issues for colleges and providers which were being considered. The document argues that the current system is not reaching many of the low skilled and is not leading to a sufficient improvement overall in skills levels. One option, it suggested, would be to focus on adults up to, for example, the age of 30 (19–30 years old), in terms of support. It is stated that:

we recognise that any age cut-off is an artificial mechanism for delimiting support, we do not believe that there are currently sufficient funds in the system to fund fully all adults to achieve a full level 3 qualification. The age limit in this instance would enable young adults who had not completed their initial education to be supported for a longer period. In addition, it would provide an opportunity for those young adults to progress into higher education.

Elsewhere, in France an intersectoral agreement on skills and learning was signed by the social partners in September 2003. Key components are as follows:

- Employees with 20 years experience, and those over the age of 45, regardless of experience, are eligible for a

skills audit after being in post for 12 months, and will be given prioritized access to recognition of their work experience (*Validation des acquis de l'expérience*, (VAE)).

- All employees with 2 years service will be eligible for a career-guidance interview carried out within their company.
- A training passport (passport formation) will be drawn up and updated by the employee. This will set out the skills and knowledge they have acquired.
- An individual 20-h per year training entitlement (*droit individuel à la formation*, (DIF)) is available without age limit. All employees with more than 12 months service are accorded one 20-h credit per year which can be rolled over for 6 years. Employees who lose their jobs will be able to utilize the monetary value of their unused credit to either fund a skills audit, VAE, or a training program.

In Italy, education and lifelong learning have been little developed until recently, with most effort going into equipping younger people with skills. The greatest financial support for lifelong training and employee development at the company level comes from the institution of a training fund under Law No. 236/93, which, from 2003, stipulates that training should be targeted at older workers (45–64 years of age) (OECD, 2004a). In 1999, the Italian government approved the integrated long-term plan on training, education, and research guidelines. As far as lifelong training is concerned, the government has aimed to quadruple the current number of individuals involved in lifelong training activities.

Finally, in the case of Spain, the OECD (2004b) has argued that, despite recent reforms, it lacks a central authoritative body responsible for coordinating adult learning. This is despite evidence, noted above, that it performs poorly compared to other European member states. One could, therefore, conclude then that in Europe, the picture is quite fragmented although the issue of supporting the learning of older people is at least generally on the policy agenda.

Achieving Better Outcomes for Older People

If there is still a gulf between the aspirations and rhetoric of policy makers and the experiences of older people, this is not due to a lack of understanding of how to make training and learning age inclusive. Evans (2002) argues that public policy concerning how to increase and widen participation of mature learners and realize lifelong learning contains many contradictions and paradoxes. He states that the “real harvest of future learners are mature people and yet this obvious and manifest fact is constantly subjected to short-term and often eye catching

headlines, but results in uncertainty in how providers and indeed the potential learners are to be supported on a long term secure basis.” Continuous change to the support mechanisms creates confusion in the potential learner’s mind and changing priorities constantly leads to inevitable initiative overload for providers. Added to this is the front-loading of funding for education.

Recent reviews concerning what works for those aged over 50 and issues for policymakers and providers has been carried out by different bodies (Carlton and Soulsby, 1999, cited in the website of National Institute of Continuing Adult Education; DfEE, 2001; Evans, 2002; Moss and Arrowsmith, 2003; South London Learning Partnership Adult and Community Learning Workshop: The Learning Needs of Older Learners 2003). These are summarized below.

Factors related to job placement and training for older workers:

- Although a range of back-to-work help is available to nonworking older people, and programs are often open to both the economically active and inactive, current take up is mostly among the former, reflecting their greater contact with those able to refer them to programs.
- Having advisers of a similar age to older clients can help overcome barriers and increase rapport.
- For some, experiencing age-specific training makes them feel more comfortable and allows for relevant issues to be addressed, but mixed-age training can help develop a flexible attitude and broaden outlook.
- Clients would welcome in-work support to ensure retention and advancement, particularly at transitional points in their employment.
- Advisers perceive a lack of opportunity (or resources) to refer older clients to specialist providers to address the specific issues they face.
- Both clients and advisers feel that insufficient action has been undertaken to confront and overturn employer age discrimination.
- Older clients need guidance in finding work in a new occupation.
- Skills training before moving into a job is desirable.
- Older people appreciate being consulted about their learning needs.
- Drawing on older peoples’ life experiences and maturity is a useful way of attracting them to learning opportunities.
- Particular barriers include:
 1. lack of and inaccessibility of information;
 2. high cost of courses and loss of earnings for learners;
 3. disabilities and health problems;
 4. inappropriate location and timing of courses;
 5. lack of confidence among older people;

6. negative attitudes toward education, linked to previous experiences and socioeconomic group;
7. gender and cultural issues for both males and females; and
8. availability of transport, mobility problems, and travel costs.

Training provision:

- skills for providers
- lack of recognition and acknowledgment of changing demography in terms of funding and learning needs;
- more effective, specialized training for teachers, trainers, and advisers addressing institutional ageism, low expectations of older learners and assumptions about what older people want to learn;
- use of appropriate teaching strategies and on-course support;
- more collaboration, networking, and sharing of good practice among providers and agencies.
- Communication:
 - more effective and targeted dissemination of information;
 - a comprehensive, centralized source of all relevant information for older learners;
 - more specific targeting of potential older learners;
 - comprehensive and effective guidance systems must be established;
 - establish learning satellites or one-stop shops where people can go for advice on learning opportunities open to them;
 - better use of jargon-free language for induction and course delivery; and
 - more effective targeting of older males.
- Programme design:
 - a more personal touch in recruiting and inducting older learners;
 - better integration of programs;
 - embed older learners' provision in the mainstream;
 - availability of shorter, more focused courses;
 - more nonaccredited courses, work-based and community-based learning opportunities, and social enterprise projects;
 - short work trials for a client group, many of whom may not have worked for a considerable time;
 - offer one-off taster sessions on a noncommitment basis to build confidence and stimulate interest;
 - fewer vocational accredited activities, although for some, accreditation will be relevant and those not desiring a qualification should not be penalized;
 - ensure that ongoing quality evaluation is built into all learning provision;
 - exploration of strategies for improving inclusiveness and widening participation;
 - offer provision which is flexible and tailor-made;

acknowledge that learning is only one aspect of a learning activity;

break away from traditional learning methods and settings and expectations that the learner will come to the learning;

recognize that ethnic minority learners and those who work with them may require additional support;

address physical issues (e.g., hearing and sight problems) faced by older learners;

confidence building activities for older learners, including memory skills;

active creation of a culture of learning and training for older people;

consideration of preferred learning styles;

older tutors, especially male, to act as positive role models;

recognition of gender differences in terms of learning goals and social dimensions of learning;

opportunities for single gender courses and also specifically for older and disabled learners;

providers must develop effective support services for learners on an ongoing and continuous basis;

Individualized and skilled support from a personal adviser and access to specialist provision;

multifunctional use of public premises for one-stop coordinated adult services.

Public policy:

- existing learning provision should be mapped to ensure that it builds on what exists already;
- official bodies should consider how they can make more effective use of the media, both to stimulate interest in learning and to raise awareness;
- the domestic and financial circumstances of learners must be recognized;
- effective and appropriate initial assessment systems must be developed for potential learners followed up with programs of support;
- resources need to be sufficient to respond appropriately to the additional demands made by mature learners; and
- need for more effective partnerships between providers and other agencies.

Concluding Comments

There are marked disparities on the incidence of VET by age. A range of factors are associated with participation among older people. Age is one, but the evidence demonstrates that a better approach would be multifaceted. A need to tackle the issue is acknowledged by European policymakers and international bodies but to date the policy response has been fragmented. There is much

activity in some countries, in others there is little. It is also the case that even among the more active countries, overt institutional barriers to older people's participation remain, although these are being challenged in some cases. At a time when the issue of age and work is the subject of intense interest from public policymakers promoting learning and training remains a major challenge.

Career Guidance in Vocational Education and Training and in the Workplace

P Plant, Danish University of Education, København, Denmark

VET and Guidance as Policy Areas

Both vocational education and training (VET) and guidance are high on the policy agenda. The European Union (EU), for example, has set a course for the development of VET: the Copenhagen process for enhancing cooperation regarding VET included four priority areas: (1) European dimension of VET, (2) transparency and guidance, (3) recognition of competences and qualifications, and (4) quality assurance and development. The Copenhagen Declaration mentioned the overall objectives: “to make the EU the most competitive and dynamic knowledge-based economy in the world, capable of sustaining economic growth with more and better jobs and greater social cohesion by 2010” (EU/Commission of the European Communities, 2002). Further, the Copenhagen Declaration reads: “The development of high quality vocational education and training is a crucial and integral part of this strategy notably in terms of promoting social inclusion, cohesion, mobility, employability and competitiveness.”

Further, the pivotal concepts are as follows: dynamic knowledge-based economy; economic growth; social cohesion; social inclusion; and mobility, employability and competitiveness.

Thus, VET is embedded in these policy goals and in the aims of bridging economic and social goals. The same is true in relation to lifelong guidance policies. In 2004, the EU ministers adopted a resolution on lifelong guidance. It describes guidance as a range of activities which enable

citizens of any age and at any point in their lives to identify their capacities, competences and interests, to make educational, training and occupational decisions and to manage their individual life paths in learning, work and other settings in which these capacities and competences are learned and/or used. . . . Guidance provision within the education and training system, and especially in schools or at school level, has an essential role to play in ensuring that individuals' educational and career decisions are firmly based, and in assisting them to develop effective self-management of their learning and career paths. It is also a key instrument for education and training institutions to improve the quality and provision of learning. . . . Guidance throughout life contributes to the achievement of the European Union goals of economic development, labour market efficiency and occupational

and geographical mobility by enhancing the efficiency of investment in education and vocational training, lifelong learning and human capital and workforce development. (EU/Commission of the European Communities, 2004)

Clearly, guidance is seen as an instrument in enhancing lifelong learning, economic development, and social inclusion, all at the same time. This is no an easy task. Policymakers at all levels strive to deal with and to create a balance between these goals. Both the European Training Foundation (ETF) and CEDEFOP, the European Centre for the Development of Vocational Training have issued tools in the form of booklets to facilitate this policymaking process (OECD, 2004a; CEDEFOP, 2005).

A Rationale

An OECD (2002: 121–126) study of human capital development analyzed the role of career guidance in relation to lifelong learning, and active labor market and welfare-to-work strategies. It claimed that in OECD countries, about 40% of the variation in individual earnings is explicable through primary factors, particularly prior educational attainment, literacy levels, and work experience, combined with secondary factors of gender, language background, and parental education. Thus, some of the remaining 60% might be accounted for by motivation and other personal characteristics, including the concept of human meta-capital – that is, people's ability to manage and develop their own human capital – which would include the role of guidance.

Amundson (2003) argues that an individual's engagement with guidance, if it is to make a difference in terms of motivation for lifelong learning, should be personalized through a process that facilitates constructive reflection. This holistic concept of guidance has three dimensions: length, width, and depth. The first dimension implies the need for guidance to take place over a life span, including adulthood and the third age: lifelong guidance. The second dimension considers the wide range of issues that must be addressed in guidance, including personal and social issues, along with career-related ones: life wide guidance. The third dimension concerns the depth of the guidance activities: life deep guidance. How close, how intimate should guidance be? Such an approach has the potential to encourage VET and learning of all types

by individual workers, thereby enhancing their skills as well as promoting their self-confidence and self-esteem.

Such arguments place guidance center-stage although, as Killeen (1996: 84–85) demonstrates, since guidance is often part of a broader package of assistance available for individuals, it is difficult to distinguish learning outcomes arising from guidance from those that are economic. Structural factors explain why there is a greater need for guidance throughout the working lives of adults, including recurrent VET. Fundamental changes in patterns of employment across Western Europe have arisen from a shift from manufacturing to services. A major consequence of this changing pattern has been unemployment and underemployment, distributed unequally across regions, gender, and ethnic groups, that has resulted in social exclusion. One of the aspects of such exclusion is a persistent learning divide. The learning rich with higher levels of qualifications and income are more likely to return to education and benefit from it throughout their working lives. In contrast, the learning poor, who tend to participate the least, work in manual occupations or are unemployed, having left school with few or no qualifications. It is important to note, however, that learning does not need to be formal (EU/Commission of the European Communities, 2001) and, as Colley *et al.* (2002) argue, the boundaries between formal and other learning can be blurred. This also applies to guidance.

Individual employees are increasingly expected to be responsible for managing their own learning and lifelong VET and development throughout their working lives in the context of an economy characterized by increasingly flexible, risky, and uncertain forms of employment (Harrison, 1998: 235). This is where proactive guidance in the workplace comes in: it reaches out to those who would benefit from guidance, but would not approach conventional guidance settings. Access to guidance, physically and mentally, is crucial here (Clayton and McGill, 2000), in order to break the classical issue of the Gospel according to St. Matthew (25:29): “For unto every one that hath shall be given, and he shall have abundance: but from him that hath not, even that which he hath shall be taken away.”

Definitions

Vocational education and training (VET). It can be defined as an activity which prepares learners for careers that are traditionally nonacademic and directly related to a specific trade, occupation, or vocation (http://en.wikipedia.org/wiki/Vocational_education). This definition puts the emphasis on the VET entry points. This article, by contrast, highlights the lifelong and recurrent aspects of VET and guidance.

Career guidance. This, in turn, can be defined in terms of unfolding the width of guidance activities (Ford, 2004).

Signposting. Ensuring that people have accurate information about helping agencies and the guidance services they provide, and are therefore able to select and access the sources of assistance most suited to their requirements.

Informing. Providing information in a range of formats about opportunities available, without any discussion of the relative merits of options for particular individuals.

Advising. Helping individuals and groups to interpret information and choose the most appropriate options.

Counseling. Working with individuals to help them discover, clarify, assess, and understand their own experience, and to explore alternatives and their possible implementation.

Mentoring. Offering individuals and groups appropriate client-focused support to help them overcome personal barriers and realize their potential. Key factors in mentoring include: the skills, personality, and value systems of the mentor; and her/his ability to act as a role model, enter the client's frame of reference, work holistically, and respect the individual's autonomy and independence.

Assessing. Helping individuals, by formal and informal means, to obtain a structured understanding of their personal, educational, and vocational development, in order to enable them to make informed judgments about the appropriateness of particular opportunities.

Teaching. Providing a planned and systematic progression of learner-centered experiences to enable learners to acquire knowledge, skills, and competences related to making personal, educational and career decisions and transitions, and career management.

Sampling. Providing work experience, work trials, learning tasters, and other experiences that enable individuals to gain first-hand experience of opportunities in order to assist and clarify their decisions.

Enabling. Supporting individuals and groups in dealing with organizations providing or influencing employment and learning opportunities.

Advocating. Negotiating directly with organizations on behalf of individuals or groups for whom there may be additional barriers to access.

Following up. Keeping in touch with individuals after main guidance interventions to establish: whether further guidance is required; what forms of guidance and support may be appropriate; and subsequent progress. Follow-up may include the incorporation of tracking procedures where these are considered desirable.

Networking. Establishing specific links with a range of individuals and organizations to support and enhance guidance provision. These links may be formal or informal, but will include regular contact for information exchange, referral, and feedback, and other joint activities such as staff development, monitoring and review, and outreach work.

Feeding back. Gathering and collating information on the unmet needs of individuals and groups (including designated target groups), and encouraging providers of

opportunities to respond by adapting or developing their provision.

Managing. Managing guidance activities into a coherent program, ensuring it is sustainable within its institutional or organizational setting, coordinating and developing its human and physical resources, evaluating its effectiveness, and promoting its services and interests.

Innovating/systems change. Supporting developments and changes in organizational and guidance practice, in order to improve the quality and organization of provision.

Standard Format?

Clearly, from this list it is evident that guidance is so much more than a face-to-face interview: guidance in VET, in particular, includes assessing, mentoring, and sometimes, advocacy, and so on, as depicted in the examples below. However, the standard format of guidance looks like this: two people sit and talk in an office. This is the convention – also in many parts of VET. Yet, some scholars challenge this convention (Amundson, 1998): It is surprising how often guidance closes itself in, where it could open up and reach out to those who actually need guidance. This implies that guidance would have to move out of the closet and out of the office, and enter into new arenas. VET, with its firm links to work, has many options to break away from the conventional mold: learning and guidance are often blended in situated learning (Lave and Wenger, 1991) and in other arenas than the guidance office. Evidently, much VET guidance takes place in educational institutions such as technical schools and colleges, ranging from Australia (VET guidance targeted at indigenous students) to Iceland (guidance to prevent educational dropout). Such approaches are now largely mainstream guidance activities and will not be covered further in this article as they are well known. What is new and interesting is the recognition that much guidance actually takes place outside and alongside formalized institutional realms. In these cases, guidance takes more informal shapes. Workplaces are such arenas to which we will now turn.

In the Workplace

A number of approaches in VET-related guidance in the actual workplace are linked to the concept of mentoring. Mentor, as we recall from the Greek myth, was a friend of Odysseus. When Odysseus left for the Trojan War, he placed Mentor in charge of his son, Telemachus. Thus, the modern use of the word mentor denotes a trusted friend, counsellor, or teacher, usually a more experienced person. In mentoring programs, newcomers are paired with more experienced people in order to obtain good

examples and advice as they advance. Some such approaches are of a general nature, but most have a particular target group in mind such as women or migrant VET students. In these cases, the driving concept is that guidance needs to get out of the offices and into the places where most people spend their working days: in the workplace. This is a proactive approach which includes peer guidance, mentors, shop stewards, and the involvement of the social partners: both employers and trade unions need to benefit from guidance activities, if they are to take place on the shop floor or even on night shifts.

Workplace Guidance in Practice

In many cases, guidance is a remedial activity targeting the unemployed (OECD, 2004b: 24), yet some initiatives involve a more proactive and sometimes outreach-oriented approach (Watt, 1998). One of these is VET-guidance in the actual workplace, taking place at times when workers might require it, within working hours, night shifts included. This approach has been developed in the UK, Denmark, and in Iceland, inspired by Danish initiatives, where the social partners have initiated schemes of workplace guidance in order to improve access to learning and further educational guidance among employees. The following paragraphs draw upon examples from Plant (2006).

Danish trade unions have played an important role in developing voluntary and local initiatives (Villadsen, 1998). These include individual guidance for trade union members on education and training options; targeted information to members on educational and training issues; and group guidance activities. Several trade unions have adopted one or all of these activities. The Danish Confederation of Trade Unions has prepared a tool-box as part of a project known as The Developing Workplace, DUA (Det Udviklende Arbejde, i.e., enriching work). This includes pamphlets on attitudes and barriers toward participation in training and education, intended for discussion groups among workers.

Kvindeligt Arbejderforbund (KAD) has also developed initiatives in peer guidance, similar to those in the UK. KAD was a trade union for women only (now merged with others), mainly for those with few formal qualifications and low pay in different industries and in the service sector. Their attitudes toward participation in continuing VET are mostly utilitarian so that guidance is mainly linked to periods of unemployment (e.g., guidance on unemployment benefit rules and regulations). Trade unions offer personal, social, economic, educational, and vocational guidance to those members requesting it. Although convenient for unemployed members, it was less so for women in hourly paid employment that found it difficult to travel to a KAD office to seek guidance within working hours. KAD therefore attempted several approaches to guidance

activities in order to overcome some of these barriers by reaching out to its members in their workplaces. Some members, known as Spearheads (Spydspidser), attempted peer-guidance activities after being briefed upon the concept of guidance. After a while, this approach failed due to the lack of knowledge of the range of educational and funding options among the Spearheads. Thus, a higher degree of professionalism was necessary for peer-based activities to succeed. KAD then established guidance corners (Vejledningshjørner) in the canteen or resting areas of several major and medium-sized companies. Slightly different guidance corner models are in operation, depending on the initiators (RUE, 2001). A case study from Western Denmark illuminates the main features of this type of initiative (see **Case study 1**).

Jensen (2002: 12), in depicting guidance corners, highlighted the advantages of a broad and impartial approach to workplace guidance. Plant (2004) made a similar point in a report which looked into an EU-funded guidance project in a major company, which was downsizing and moving premises and changing production methods, all at the same time: VET in action. In this case, guidance played a pivotal role in facilitating all these simultaneous changes, making use of both professional guidance staff and a highly engaged trade union representative in the factory. Much of the drive in this guidance project came from the factory floor: a bottom-up approach. This approach, if taken to its limits, may include the users in actually co-designing guidance offers and policies in collaboration with guidance professionals and policymakers (Plant, 2006).

The Witch

In one Icelandic case, a particular method was used, which highlighted the importance of the guidance methods used in the workplace: in this case, metaphors helped the workers to understand and express how they felt about their present work situation and what they might do to change it (see **Case study 2**).

Guidance within Employee Development Schemes

A contrasting top-down approach to workplace guidance initiated by employers was found in terms of the guidance elements of an employee development scheme in a Scottish university, known as Learning Works. Under the scheme, manual, technical, ancillary, clerical, and secretarial staff – all placed on the lower points of the University's pay scale – may apply for an annual learning allowance of £150. A system of site coordinators across 25 different locations in the university exists, and these volunteers, usually previous beneficiaries of the scheme, encourage fellow workers to consider taking up its benefits by

Case study 1: the development of guidance corners

The guidance corner concept is simple: a trade union representative offers person-to-person guidance in a corner of a workplace assembly room, using pamphlets about education or training with a portable computer containing guidance and information programs. This provides members with information on adult education options plus opportunities for discussion, questions, and reflection on their current situation. Initially, such visits were conducted by KAD every 2 weeks in an open consultation mode, with a permanent exhibition of current training and education available, including rules on the funding for educational leave. This, however, did not meet the actual needs of the female membership. First, they did not take pamphlets offered on training or education to any significant degree. Second, few women in work actually requested guidance spontaneously since they did not see how this might benefit them. The concept of guidance, no doubt, was somewhat blurred, and, in their minds, mostly aimed at unemployed people. Third, working in self-governing groups, as is the case in the high-tech company of Bang and Olufsen, puts economic pressure on all members of the group. This limits their willingness to visit the guidance corner since leaving work for guidance would penalize the whole group.

Visits to guidance corners are now conducted every 6 weeks and take place by appointment during working hours, including day or night shifts. In some enterprises, guidance corners are now established permanently, while others are more *ad hoc* and mobile. KAD sees this type of activity as a mainstream member service and part of a long-term strategy to upgrade its members' skills through formal, informal, and nonformal education and training. An important part of this strategy is proactive guidance of an outreach nature that promotes the concept of lifelong learning in workplaces. Interestingly, KAD does not restrict the availability of these guidance corner services to its female membership. Consequently, in practice, some men also benefit from a guidance service that is primarily aimed at women.

Adapted from: Plant and Turner (2005).

offering some initial advice and information. Thus, on a peer basis, they provide a signposting role similar to that of the learning representatives in the UK or the guidance corners in Denmark. In addition, Learning Works employs a part-time learning adviser, who is a qualified career guidance officer with experience of working with adults, to provide impartial guidance to anyone considering taking up a learning allowance (Plant and Turner, 2005).

Conclusion

In Denmark, Iceland, and the UK, accessible guidance in the workplace is an increasingly significant aspect of promoting lifelong VET and learning to develop the skills of those who have not recently participated in education or training: this is recurrent VET. The examples featured here illustrate contrasting approaches to workplace guidance that have been successfully pioneered in the three countries. Employee development schemes in the UK have

Case study 2: Metaphors in guidance

"What is your feeling towards the job in general?" The young worker said he felt frustration toward his work environment because it was disorganized and messy.

Next he was asked to define or judge the environment, to give it a name as if it was a person. He responded: "A witch that does not listen to reason."

"What is your request toward this witch or environment; what would you ask it in order for it to improve things and make them more positive?"

"That she widens the horizon", was his answer.

He was now asked to try to put himself in the shoes of the witch representing his work:

"What is the feeling the witch has towards you?"

"She is feeling wary."

"How does the witch describe you?"

"That I am careless."

"What does it ask of you?"

"That I put order to things in my working environment."

Here we have an individual complaining about his working environment. To help him clarify his attitude he is asked him to judge his environment and to express his wish toward it. He sees himself as passive, a victim. There is no change or improvement of the situation. He may turn the music louder to compensate for his annoyance about his disorderly workplace, but to no avail. A step towards change is taken when he moves his point of view, imagining how the work perceives him and what its request is toward him.

This method brought to light the fact that unskilled workers in Iceland see vocational counseling as something that could be useful for them. Low-paid workers could, in many cases, use advice and support to solve their work-related problems. There is conflict and harassment in many workplaces that need solving. There are also conflicts and grievances regarding the work itself and the working environment and facilities. Often people experience themselves as stuck and not making use of their abilities; they feel that the work contradicts their values, that it does not correspond to their interests and does not give them fulfillment or satisfaction. For such individuals, work is far from fulfilling, they look at work as a necessary evil, as they are just 'doing time' in their workplace, as they cease to live when they enter the workplace and begin a passive existence, without initiative and meaning.

Adapted from <http://www.gla.ac.uk/wg/pilotise.htm>

made professional guidance about learning opportunities more easily available, particularly in larger workplaces. The Icelandic example points to the importance of varied and innovative methods used in guidance. In general, the attitude of the interviewees was sincere, positive, cooperative, and open. The most apparent weakness of the method regarding the group in question was their difficulty to express themselves, about their own experience, interests, abilities, and how they value their work.

The Danish examples of peer guidance and guidance corners also have both strengths and weaknesses. The strengths include the issue of ownership and commitment reported by Plant (1995) in the Danish Eurocounsel studies in which several examples of peer guidance models were

depicted, including an innovative mix of self-governing career development groups of unemployed people and the Public Employment Service (AF).

On the other hand, bringing guidance and information on VET to the workplace creates problems of access. Flexibility in arrangements over location and timing is necessary to allow easier access to guidance for those whose working and domestic arrangements might otherwise create barriers. Guidance must be offered to potential learners in their actual workplace, rather than somewhere else, however central. Breaks at work are often too short to facilitate any in-depth guidance or allow information gathering on a self-help basis to take place. However, those who do not regard themselves as potential learners due to their prior educational history are least likely to seek guidance. This applies particularly to unskilled or manual employees.

Lifelong learning, guidance and counseling, VET, and employment are continuously intersecting cycles and systems in the lives of European citizens. Information and guidance have an essential role to play in facilitating access, progression, and transitions between these cycles and systems over an individual's lifetime (OECD, 2003). A comparative European study by Clayton *et al.* (1999: 31–33) suggests that there is considerable variation in support from policymakers at all levels for guidance to promote lifelong learning. But it is not enough to have a strategy: power issues lie embedded in the introduction of such outreach guidance provision in the workplace – who is to decide whether this sort of activity is feasible or desirable in the workplace? It might well be seen as a disturbance, and moreover, a nuisance which may well inspire workers to leave their present workplace in favor of better offers which were previously unknown to them. The examples in this article, drawing on examples of bottom-up initiatives, suggests that such power issues may hamper workplace VET-guidance, which needs the active cooperation of education providers, employers, trade unions, and guidance bodies, and which has the potential to make lifelong learning a reality if it is complemented by the resources and legal frameworks necessary to sustain it.

Displaced Workers, Unemployed and Vocational Education and Training

B Kriechel, ROA – Maastricht University, Maastricht, The Netherlands; IZA, Bonn, Germany

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Workers with education that predestine them to occupations predominantly in declining industries are under severe pressure. There is a higher incidence of job loss in those industries, as the decline usually goes along with plant closures and firm failures. Workers cannot easily change employment out of the industry as they are bound to lose the industry-specific human capital or experience, which is usually only rewarded within the industry.

Particularly in the context of occupations that are linked closely to specific vocational education, occupational mobility is likely to be low. Vocational education is often geared to a specific occupation, teaching specific skills that are not easily transferable. It puts workers with the wrong education at risk of losing their employment. This combined with the additional difficulty of lower reemployment chances given that their education predestines them for occupations in declining industries. The choice is to change occupations, implying the loss of the occupation-specific training and experience, or to try to find employment in a declining sector.

One option is to increase the employability of workers by broadening their skills beyond the occupation-specific requirement to enable them to switch to more general positions. Another option, which is usually only taken after job loss, is to retrain displaced workers such that they can take up different occupations. Many countries offer some sort of training either to specific groups of unemployed workers, for instance, displaced workers, or generally retraining programs to all unemployed.

In this article, we concentrate on the retraining of displaced workers. The preemptive broadening of skills to increase once employability as well as to increase a worker's employment opportunities is not discussed in this context.

In the following, we first discuss the differences between unemployed workers and displaced workers. Next, the different retraining strategies that can be used to aid unemployed workers are discussed. Then we go into programs that countries offer to aid specifically displaced worker, or, in some cases, to general training programs. It will not be possible to completely cover all programs or countries; rather, we have tried to give an overview of approaches from geographically different countries, and to discuss what is known about the effectiveness of these programs.

Displaced Worker

There are considerable differences in the definition of displaced worker. The definitions vary from general layoffs (including firing for cause) to large-scale layoffs due to plant closure or reorganization only. The definition is important, especially in the context of government policies specifically aimed at displaced workers. If displaced workers are to be compensated or aided, they need to be defined properly. In addition, scientific research on displaced workers should also use at least closely related definitions of displaced workers.

Before a special survey was introduced, the Displaced Worker Supplement (DWS) to the US Current Population Survey (CPS), displaced workers were often identified as those workers being fired or unemployed in declining industries, local labor markets, or occupations. This is, however, quite a broad category. With the introduction of the DWS, the questioning used to identify displaced workers in the survey, became a focal point of a definition. According to the DWS, a worker is considered displaced if he/she filled in that he/she lost his/her job due to "a plant closing, an employer going out of business, a layoff without recall, or some similar reason." Most economists use definitions that are very close to the above wording, even if they are not using the DWS.

Displaced workers differ from unemployed workers. These workers are not unemployed for cause, or due to their own actions, but rather as a result of a plant closure or large-scale downsizing. The crucial difference between the groups is that the displaced workers undergo no selection, that is, there is no negative selection of the least-productive workers into the layoff procedure.

The group of unemployed contains a mixture of workers: those who are laid off for cause and those who became unemployed for external reasons. Thus, on average, the productivity of the pool of workers should be lower than that of a comparable group of displaced workers. This is the result of the firm selecting the least-productive workers to be laid off first. It can be shown that displaced workers will do better, in terms of wages earned after their unemployment, than unemployed workers who were not displaced.

Causes of Worker Displacement

There are several reasons that can lead to plant closures and large-scale layoffs. They can be due to new production

technologies, increased foreign competition, changes in taste, and managerial errors. The first two causes can also be seen as external causes of displacement. They are the result of common technological progress, rendering some activities superfluous. Mechanization is one of the examples for the production process that leads to displacement of workers.

The cause of displacement, either through foreign competition or technological progress, actually benefits society as a whole. For example, free trade benefits all members of society, as they can buy more products more cheaply than those that are domestically produced. Opening of trade adversely affects not only import-competing companies, but also workers employed in these firms that directly compete with the foreign firms. Often, a whole range of products will be predominantly imported, rendering many workers unemployed in the present occupations. It is therefore of no surprise that society as a whole tries to redistribute some of the gain it achieves to those who are at a loss due to free trade. Similar arguments can be made for technological progress.

Losses of Displaced Workers

Displacement implies a significant burden on a worker. First of all, workers will have to find new employment, which implies that they have search costs and invest time. During the search process, they will depend on unemployment benefits or severance payments from their former employer. If they find new employment, they are often stripped of rights or protections due to seniority offering them benefits over newcomers. Empirical research has consistently shown that higher-educated workers as well as younger workers have shorter search time. However, these direct costs are, according to research into the effects of displacement, only a minor part of the displacement losses: wage drops for weekly earnings are reported to be around 10–20% on average.

In the long run, these losses can even be greater. First of all, the wage drop is not temporary – average earnings remain consistently lower compared to workers who were not displaced. In the evaluation of long-term earning development of displaced workers, negative income effects could be found even after more than a decade. Many displaced workers are not able to find long-lasting jobs. This makes them prone to dismissal in economic downturns (Eliason and Storrie, 2006).

Explanations of Wage Loss

How can the wage losses be explained? Displaced workers can often be found in companies or industries that pay above the average wage. These wage premiums can have different reasons: they can be attributed to investments in human capital, a reward for staying longer with the firm,

which is also known as deferred-compensation schemes, or it might reflect higher compensation for achieving higher hierarchical positions within a company. Displaced workers with higher-than-average labor-market pay will, after being displaced, fall back to lower wages.

Most of the economic displacement literature concentrates its attention on the human capital explanation, as there is strong empirical evidence for its importance. If the wage premium is due to an investment in human capital, it is important to understand how this is productive for the worker in a specific firm. The literature distinguishes between specific human capital and general human capital. General human capital increases the productivity of a worker in all firms and sectors, whereas specific human capital can be described as knowledge or skills that are specific for a certain firm, occupation, or industry. Wage losses that are incurred have therefore been explained by the loss of firm-specific human capital, and for those changing industries, in addition to the loss of industry-specific human capital. On average, industry switchers incur higher losses than workers who can remain within the same industry.

An alternative explanation is a wage premium that workers earn from working in high-wage industries or occupations, which can be explained by compensating wage differentials. Compensating wage differentials assumes that these wage differentials are the result of preferences of workers. Occupations or industries which are not preferred, because they are, for example, dangerous or unhealthy, warrant a higher wage. A good example is miners, who are often well paid for their work. However, it is dangerous and unhealthy work; the higher wage can be explained by these differences. If workers move from high-wage industries, which involve discomfort, to low-wage industries after displacement, it might simply involve a move to a more agreeable occupation, with lower pay.

The internal labor market with hierarchical positions can offer a further explanation for pay differences. If within a firm or sector, a worker's career can bring him/her across several hierarchical positions, it will increase not only the wage spread, but also the average pay that can be expected. If a worker moves away from such a firm with a hierarchical structure, and if he/she comes from a higher hierarchical position, he/she will have to receive a position that is at par with his/her old hierarchical position. There are firms in which higher positions are filled from within. It is therefore difficult for a worker to be able to recoup a position at the same level of his/her former hierarchical standing. Empirical research shows that higher hierarchical positions increase the chance of lower search time, hence less unemployment, along with lower wage losses. Higher hierarchical position can be seen as a form of general human capital, that is, general management skills, which can be transferred to

new employment, thus diminishing wage losses (Kriechele and Pfann, 2005).

Another important aspect is that of the local labor market. Many workers who are displaced are reluctant to relocate their families to other regions. Therefore, the local labor market and the job opportunities within the local labor market will influence the opportunities that a displaced worker faces. A part of the decline in wages is due to a decline in the local labor market of the occupation a displaced worker held. Workers who restrict themselves to the regional labor market diminish the chances of finding employment at the same level and remuneration as before displacement.

Assisting Displaced Workers

The best way to aid displaced workers is by helping them cope with the job loss and moving on to new employment. Avoiding the job loss and supporting the displacing company just keeps inefficient jobs in place. It is better to move the workers to new, more productive employment opportunities and careers. The problem is, however, that many times the loss of jobs is the result of a structural shift in the employment structure of a region or country. This means that the current employment is no longer viable in the long run. A good example is coal mining in Europe. A combination of technological change, replacing coal by other energy sources, and international trade importing coal from countries in which the extraction was cheaper, made the occupation of coal miner redundant in many European countries. The occupation was often linked to a set of vocational training degrees that allowed a worker to pick up the occupation of a miner. However, once the mines were closed many of the skills were no longer needed.

Retraining is then one of the most feasible options, whose goal is to prepare the displaced workers for a new career in a different sector and occupation. Sometimes a part of the skills can be used in the new occupations; sometimes retraining means shifting the set of needed skills completely.

Retraining can be led by two forces. One is to include the existing set of skills, and try to retrain for occupations that are similar, but are not struck by the downturn; or, and that is the case in many government-sponsored retraining programs aiding unemployed, the training is predominantly demand led, offering retraining to occupations for which there is short supply, either now or in the future.

Assistance programs that offer assistance in job search or retraining to other occupations specifically to displaced workers have a long tradition in the United States. In Europe, the whole focus is on the unemployed. Given the generous welfare system, retraining is seen in Europe

as a way to move unemployed workers out of a costly welfare system into productive occupations. Here, the discussion of the assistance programs is confined to the retraining programs, either devoted to displaced workers or to unemployed workers facing unemployment because of structural change.

Assistance Programs in the United States

The assistance to displaced workers can be traced back to the Manpower Development Training Act of 1962 for those displaced from work due to technology, and the Trade Adjustment Assistance (TAA) Act which targeted workers displaced through import competition. In 1974, the trade act established the current TAA program to assist workers employed by a firm that reorganizes due to increased imports or shifts in production to foreign countries. The related Alternative Trade Adjustment Assistance (ATAA) program does not provide any training, as it is devoted to older workers who are allowed to find alternative employment at lower wage while receiving a wage subsidy from the program fund. The main TAA program, however, entails allowances for job search and relocation, as well as training assistance. The training can be classroom, on the job, or customized to the needs of specific employers. The program offers compensation for the training as well as income support for the duration of the training. Many evaluation studies that are made about these programs show mixed results. Moderate gains can only be found for the short-term (Leigh, 1990; Bloom, 1990). In a longer-term evaluation, only weak evidence can be found that the training programs aimed at the displaced workers support the labor-market situation (Decker and Corson, 1995).

Assistance Programs in Countries of the European Union

Assistance programs in the countries of the European Union (EU) are usually devoted to all unemployed workers. Almost all countries have some provision for retraining unemployed workers. Here, only Austria, France, Germany, Spain, and Sweden are mentioned. The programs mentioned have experienced some form of scientific evaluation.

Austria

Training program is one of the many active labor-market programs in Austria. The aim of such a training program is a qualification enhancement of the participants. Vocational training courses result in degrees that are equivalent to apprenticeship degrees. Next to the vocational training, there is also skill training to enhance, for example, language or computer skills. While scientific evaluation is rare, a cohort study of training participants finds a

positive effect of program participation of a cohort of workers on their employment stability (Zweimüller and Winter-Ebmer, 1996). In an extensive case study of a special training scheme of a large-scale downsizing in the steel industry, a special program of retraining was also evaluated (Winter-Ebmer, 2006). The scheme consisted of a combination of retraining and placement assistance, and resulted in considerable wage gains and improved employment prospects. One should be careful about the generalization of the results of this specific case.

France

France introduced specific legislation to aid displaced workers in 1987. In the *Convention de conversion*, employers are obliged to offer displaced workers retraining schemes. While the participation is voluntary for workers, they are offered to all workers with a tenure of 2 years or more, and who are 57 years or younger. Following an assessment of the worker's skills, job-search assistance is given and extra training is offered.

Germany

Germany has a long tradition of active labor-market policies. Training is one of the most important measures. The workers who are supported by the programs are unemployed as well as those who are threatened by unemployment and reentrants. Through the federal employment agencies, participants can get support to vocational training courses leading to a first professional degree. In addition, further vocational training and retraining programs are offered if deemed useful by the caseworker of the federal employment agency. Since the reforms of 2005 training vouchers that enable competition between training providers are given to eligible participants. Recent evaluations studies, using administrative data, suggest that training has positive effects on the employment probabilities and a positive effect on earnings. These evaluation studies examined the retraining of East-German workers. Both short-term training (lasting up to 6 months) and long-term training were evaluated (Lechner *et al.*, 2007).

Spain

Training schemes in Spain usually combine training with practical work experience. In an evaluation study for one region using a control group to compare the results, training programs were shown to increase the employment chances of the participants. However, average earnings were not improved compared to the unemployed who did not take part in the training program.

Sweden

In Sweden, retraining of unemployed workers is not generally devoted to displaced workers. Rather they

fall under the general labor-market training programs (AMU-Arbetsmarknads utbildning) for all unemployed workers. The objective of the program is to improve job seekers' chances of finding a job. Within the AMU there is a vocational training component, which can take place in educational organizations, universities, and companies. The use of AMU is widespread, and it existed for several decades in Sweden. One of the evaluation studies could show that training participants had a significant higher chance of leaving unemployment if vocational training is followed (Richardson and van den Berg, 2001).

Evaluation of Training Programs

In the evaluation of the assistance programs, it is important to distinguish how an evaluation is made. Most programs involve some form of evaluation. However, not all include a rigorous scientific evaluation. A distinction could be made between evaluation using experiments and quasi-experiments. Scientific evaluation always implies that the success of an assistance program is evaluated using some form of comparison group. In the experimental setup, the workers are divided at random in two groups: one receives assistance, the treatment group, and the other does not receive a treatment, or a simple placebo-type treatment, the control group. In the quasi-experimental setup, a control group is constructed using external factors that influence the participation in training without affecting the variables of interest. One typical example is administrative rules that, for example, allow workers into programs based on age. Comparing workers that just are allowed into the program and those that are just not eligible allows for a comparison of similar groups.

The importance of rigorous scientific evaluations can be seen when one compares the results of informal evaluations that in most cases report positive effects of the program on employment chances and income, with programs that have scientific evaluations. Scientific evaluations in many cases report only small effects on employment chances and on income, if they find any effects at all. Particularly important in this context is to look at the scientific evaluations that have been done for several cases of firm or plant closures in the United States. While the evaluation at the end of each program concluded increased employment chances and positive effects on post-displacement income, the scientific evaluation using quasi-experimental approaches could find no effect on income, and only negligible effect on employment chances. In this light, the retraining programs proved to be ineffective, at least not more effective than simpler job-search assistance programs. These job-search assistance programs tend to be much cheaper than the more elaborate retraining programs. Based on studies that had both a scientific and nonscientific evaluation, one can

thus conclude that nonscientific evaluation studies tend to overestimate the (positive) impact of their programs.

The studies evaluated above reflect only the development over the shorter term. A longer-term scientific evaluation of retraining programs in eastern Germany did find positive effects. In the program, no distinction is made between unemployed and displaced workers. The program information is matched to large-scale administrative data sets to construct control groups. In the evaluation, one can distinguish between participation in short- and long-term training, which are respectively shorter or longer than 6 months – those that enhance the skills within the own profession, and those that use retraining leading to a different vocational degree than the one held by the trainee. In the short-term, the evaluation shows negative effects on earnings and employment prospects. However, in the longer run, about a decade after the training, employment prospects and earnings are increased.

However, especially given the specific circumstances in eastern Germany, it is unclear whether the positive results would also be found in different settings and in other countries. It is crucial to consider careful and scientific evaluation studies to evaluate training programs for displaced workers. Preferably, evaluations should be continued to evaluate long-term effects. Administrative data that have become available in several countries would allow to construct both a control group and a (quasi-)experimentally determined treatment group.

Overall, scientific evaluation of retraining programs has shown that there are some improvements in employment prospects and, in some cases, in income as well. This is especially true for the programs in Europe. Some of the effects can only be found if the evaluations consider longer time frames. However, most evaluations do not take the cost of programs into account. While retraining programs are often evaluated against simpler and cheaper job-search assistance programs, they are not compared in terms of costs and benefits.

Glossary

Blue-collar occupations – Pertain to the following occupational groups: skilled agricultural and fishery workers; craft and related trades workers; plant and machine operators and assemblers; elementary manual occupations.

Generalized on-the-job training – Training that equips its participants with general skills, for example, literacy, arithmetic, general cognitive skills, basic cultural, and communication abilities. Such skills can be perfectly transferable between occupations.

Specific on-the-job training – Training that delivers occupation specific skills, that is, skills which are more instrumental to particular functional tasks, for example, accounting, computer programming, and mastery of specific crafts, tools, or machinery. The transferability of specific skills is more limited.

White collar occupations – Pertain to the following occupational groups: legislators, senior officials and managers; professionals; technicians and associate professionals; clerks; service workers, shop and market sales workers.

Introduction

The integration of immigrants into the labor market is one of the central issues of migration research. It largely determines the economic impact of immigrants on the receiving country, as well as the social integration of immigrants and their offspring. Whether immigrants soon become economically integrated or whether long-term ethnic inequality emerges has serious consequences for both the immigrants and the receiving society. Research has shown that immigrants' economic difficulties, for example, higher risks of unemployment and their overrepresentation in the lower ranks of the occupational hierarchy, are to some degree explained by their lack of human capital resources relevant for the receiving society.

First, due to the differences in the level of educational opportunity in various countries, in particular, disparities between Western industrialized countries (as host societies) and Third World countries (as sending societies),

immigrants, and above all those coming from the Third World, bring with them on average lower educational qualifications than is the case among the native-born population. In this regard, the issue of immigrant self-selection should also be mentioned. Normally, people voluntarily emigrating from a particular country are not a random sample drawn from the population, but rather a select group. Economic immigrants, according to Chiswick (1978), represent the more ambitious, motivated, risk-taking, and able individuals of source countries. This self-selection argument has, however, been theoretically and empirically challenged by Borjas (1987, 1990, 1994), who has suggested that immigrants' selectivity in both observed and unobserved traits is not always positive, but rather depends upon the relative returns on skills in source and destination countries. Second, some aspects of human capital, particularly language skills and cultural knowledge, are country specific, that is, they are more relevant and productive in some societal contexts than in others (Borjas, 1994; Esser, 1999). Migration makes these aspects less relevant and leads to a certain devaluation of human capital (Chiswick, 1978, 1991; Friedberg, 2000). With the passage of time in the host country, differences in human capital between the native-born population and immigrants should narrow as immigrants learn the host country language, gain knowledge about the functioning of the host country's labor market, and acquire local education and training (Chiswick, 1978). The third point to be mentioned here is that the trend toward assimilation might be disrupted by immigrants' lack of investment in the human capital specific to the host country, including host country language.

Individual Determinants of Investment in Vocational Education and Training

Why might immigrants be investing less in the host country education and training despite the fact that their economic performance is positively affected by host country language acquisition (Chiswick and Miller, 1995, 2002) and by schooling and training obtained in the host country (Borjas, 1994; Friedberg, 2000)? One of the reasons for immigrants' noninvestment is that they often lack human capital or that their sending country's educational credentials are not recognized in the host country.

Further, it is a well-established finding that low-qualified individuals – irrespective of their migration status – have the lowest training participation rates (OECD, 2003; Booth, 1991; Brunello, 2001). Those who are already more educated, be it natives or immigrants, participate in employment that requires high skills and therefore have higher chances to reinforce their training (OECD, 1999; Arulampalam *et al.*, 2004). This pattern holds for all Organization for Economic Co-Operation and Development (OECD) countries, with particularly pronounced exclusion of low-skilled workers from training opportunities in Canada, Norway, Portugal, Spain, Switzerland, and the United Kingdom.

Apart from lower qualification levels, immigrants' possibly lower rates of education and training might be related to their less favorable employment situation. It has been stressed that training incidence depends on whether people work or not, what sector of the employment and the enterprise they work in, their occupation, and the nature of their employment contract (e.g., fixed term or permanent) (OECD, 2003; Arulampalam *et al.*, 2004). In almost all OECD countries, training participation rates are the highest for workers in white-collar high-skilled occupations, those that require higher education attainment levels. Within blue-collar occupations, adult training participation rates are higher for high-skilled than low-skilled jobs. This is true for all OECD countries with the exception for Portugal and Spain. Furthermore, workers in the service sector jobs have higher training probabilities than workers in other sectors. Finally, it appears that the incidence of training decreases with the size of the enterprise.

In almost all Western receiving societies, immigrants are overrepresented in the so-called secondary labor market (Piore, 1971, 1979; Doeringer and Piore, 1971), that is, jobs characterized by low wages, irregular working hours, bad working conditions, and little prospect of mobility. It is shown above that secondary market workers have reduced access to generalized or specific on-the-job training. Thus, immigrants appear unable to considerably, if at all, improve their human capital (Flanagan, 1973; Cain, 1976; Wallace and Kalleberg, 1981). Instead, they become even further de-skilled and unsuited to work in better, primary sector jobs (Taubman and Wachter, 1986).

All the above-mentioned arguments suggest that once one appropriately controls for individual human capital resources as well as employment characteristics, takes into account additional immigrant-specific determinants of investment decisions (e.g., language proficiency), one should not encounter a residual effect of migration status on the probability of acquiring host country education and training. Sometimes, however, this residual effect exists and could be attributed, at least to some degree, to the reluctance on part of immigrants (as well as employers, see below) to invest in their education and training in

the host country. Often, immigrants consider their stay in the host country as temporary, and, reasonably, refuse to make investments that are not certain to pay off, or they are disinterested in further training due to expected lower or absent returns to this quite costly activity (Bonacich, 1972; Heath and Ridge, 1983; Chiswick, 2000; Dustmann, 2000; Duleep and Regets, 1999).

The underinvestment argument can be formally modeled as follows (see Esser, 1993):

$$EU(\text{inv}) = U(\text{squ}) \quad [1a]$$

$$EU(\text{inv}) = pU(\text{inv}) + (1 - p)U(\text{squ}) - C \quad [1b]$$

where *inv* and *inv* are two immediate options faced by an individual, the first meaning the engagement in a risky investing activity, while the second means the waiving of an active investment. *EU* is an expected utility for each of the options. *U(squ)* denotes the (securely) expected gain by keeping the *status quo* without any investment, and *U(inv)* the expected gain for a successful investment. The (subjective) probability of success is *p*, while *C* denotes the (certain) investment costs. Investment occurs when

$$U(\text{inv}) - U(\text{squ}) > C/p \quad [2]$$

The term on the left-hand side stands for the investment motive, the one on the right stands for the investment risk. When *p* decreases, the transition threshold increases disproportionately, and if it approaches zero, then even extremely high incentives for investment have no effect.

Such a model implies three consequences with respect to the investment motives of immigrants. First, immigrants would presumably have higher costs, *C*, as they often lack specific knowledge about the functioning of the educational and training system in the host country and are possibly deficient with regard to social networks needed to gain missing information (Lundberg and Startz, 1998). Furthermore, they might simply have fewer financial resources to fund training or to sustain themselves while on training (Cain, 1976). Second, immigrants may have larger fears of rejection (expecting discrimination) in the application to undertake education and training activities, resulting in a lower subjective probability, *p*. Third, and probably most important with regard to recent or precarious immigrants, their investment utility may be lower due to their often temporary orientation. In the model outlined above, this would result in a lower value for *U(inv)* as the time horizon for the benefits from training activities to be realized is reduced. Even for permanent immigrants *U(inv)* might be lower as the pay-off to education and training might be reduced due to a belief in or in fact actual employer discrimination. This means that immigrants might invest less in further education and training than comparable natives.

It is important to note that employers anticipating immigrants' temporary presence, might also be hesitant

to invest in education or offer on-the-job training for their immigrant employees, since such investments might be lost if immigrants return to their home countries (Offe and Hinrichs, 1977). The employers' decision making could also be modeled as described above and is affected by employment characteristics, such as industry, occupation, and the size of the enterprise.

VET Participation among Immigrants: Empirical Evidence

Most of the empirical research on immigrants' post-migration investment in education and training is conducted by economists who underscore investment in formal education with less, if any, attention paid to the vocational or on-the-job training. Another body of literature deals with host country language acquisition (see Esser, 2006). Studies cited below examine individual determinants of educational investments among immigrants in a single host country with particular focus on pre-migration characteristics (i.e., national origin and pre-migration schooling), conditions at the time of migration (i.e., age at migration, migration motive, and unemployment level) and conditions after migration (i.e., host country language proficiency, and length of stay; see Chiswick and Miller (1994) for the framework).

Thus, using the 1976 Survey of Income and Education (SIE) Borjas (1982) analyzed post-migration years of schooling of male immigrants of Hispanic origin in the United States. Hashmi Khan (1997) replicated Borjas' results complementing the SIE data with the 1980 US Census of population and extending the analyses to various immigrant groups in the US. Another novelty of her study was to expand the set of explanatory variables to measure the cost and quality of US schooling, student status, and citizenship. Along with the dependent variable, current school enrollment was also analyzed together with years of schooling after migration.

For Australia, Chiswick and Miller (1994) examined the acquisition of post-migration qualifications, including the number of years of schooling and the type of education, and their impact on immigrants' labor market performance. A more recent study for Australia by Cobb-Clark *et al.* (2005) utilized longitudinal data to examine school enrollment within the first 4 years after arrival. Furthermore, the role of the partner's education on individual investment decisions is explored in this study. In Europe, empirical research on post-migration educational investments is extremely rare. A single known study is Van Tubergen and van de Werfhorst's (2006) analysis of the determinants of educational participation and attainment in the Netherlands.

All the above-cited studies report similar results for the migration-related characteristics, age at migration,

and length of stay. Age at migration has a negative effect on post-migration investments in education (Hashmi Khan, 1997; Chiswick and Miller, 1994), with the effect being curvilinear, that is, stronger for those who immigrated at a younger age. (Van Tubergen and van de Werfhorst (2006) find a negative linear effect for the Netherlands.) It indeed appears more attractive for younger people to invest in host country education than to those who arrived at an older age because the time horizon to enjoy the benefits of this education is larger. At the same time, the cost of educational investments is lower as younger people are more efficient in learning.

Studies also find that post-migration schooling depends (nonlinearly) on the length of stay in the host country (Cobb-Clark *et al.*, 2005; Hashmi Khan, 1997; Chiswick and Miller, 1994; Van Tubergen and van de Werfhorst, 2006). Immigrants who have been longer in the receiving country have made more investments in education, and this effect is particularly pronounced for the first few years after migration.

The studies report somewhat contradictory results for migration motive and origin groups. Borjas (1982) and Hashmi Khan (1997) put forward the evidence that refugees (approximated by immigrant origin, i.e., immigrants from China, Cuba, and Vietnam) are more likely to invest in post-migration education than non-refugees. Identifying refugees by category of admission instead of country of origin, Chiswick and Miller (1994) find that refugees are slightly less likely to invest in post-migration education. Furthermore, whereas Hashmi Khan (1997) and Cobb-Clark *et al.* (2005) find that non-English origin groups are more likely to invest in education after migration than immigrants more similar to the host country; Chiswick and Miller (1994) do not find differences by language origin. Van Tubergen and van de Werfhorst (2006), on the other hand, report more difficulties for Mediterranean immigrants (Turks and Moroccans) to participate in the Dutch school system than for immigrants from the former Dutch colonies (Suriname and the Dutch Antilles), equipped with the Dutch language upon arrival.

The studies also differ in their conclusions on the relationship between pre- and post-migration investments in training. Borjas (1982) and Hashmi Khan (1997) report a strong negative effect of the number of years of education acquired before arrival and the number of years of schooling in the United States. Chiswick and Miller (1994: 171) criticize this finding, pointing to a possible spurious result of measurement error due to an indirect measure for the years of post-migration schooling. (Hashmi Khan (1997) and Borjas (1982) calculated post-immigration schooling as total education minus pre-immigration schooling, assuming that individuals attend school continuously from age 6.) Measuring post-migration investments in education directly shows that those with an

educational qualification prior to immigration were more likely to obtain one after immigration. Evidence for such a complementary relationship between education obtained in the sending country and qualifications gained in the host country is also found in the studies of Cobb-Clark et al. (2005) and Van Tubergen and van de Werfhorst (2006).

Unfortunately, empirical research has until now failed to produce a systematic cross-national analysis of VET participation among immigrants, despite the fact that some data sources have been collected recently, at least for Europe. Some figures presented below use the information available from the European Union (EU) Labor Force Survey (LFS) 2003 *ad hoc* module on life long learning (LLL) and show the percentage of native-born, immigrants from EU-15, and immigrants from non-EU countries with and without the citizenship of the host country. A significant advantage of the figures below (over the research summarized above) is the possibility to distinguish between various types of VET: (1) formal, that is, acquired in a regular education system; (2) informal (participation in courses, seminars, conferences, etc. outside the regular education system) job related (e.g., on-the-job training); and (3) informal training attained mainly due to personal and social reasons.

Before going in further detail on the type of training, **Figure 1** shows an overall VET participation rate in EU countries for various population groups in the 12 months preceding the survey. Similar to the OECD (2003) findings, countries with higher VET participation rates are Nordic countries and in these countries, both natives and immigrants profit from the variety of training programs. In Southern European countries, on the other hand, VET participation is very low, which also influences immigrants' VET participation rates. As a rule, non-EU immigrants have lower

participation rates than the charter population, except for Denmark, the UK, Ireland, and the Netherlands. In Sweden, Austria, France, Spain, and Portugal naturalized non-EU immigrants (presumably, immigrants with more pronounced permanent orientation) have higher VET rates than those without citizenship of the host country. Finally, in many countries (Finland, Austria, the Netherlands, Portugal, and Greece) immigrants from other EU-15 countries have even higher VET participation than the native-born.

Figure 2 presents participation rates among immigrants and natives in regular education. We observe quite a similar hierarchy of countries as earlier: higher participation in formal education in Nordic countries, the UK and Ireland and lower in continental and Southern European. Overall, it is evident that in the majority of countries, except for Spain, Luxembourg, Austria, France, and Greece, non-EU immigrants (with and without host-country citizenship) are overrepresented among students. Additionally, the rates of participation in formal education for EU-15 immigrants are higher in Finland, the Netherlands, the UK, and Portugal. It is possible to conclude that many immigrants arrive in European countries in order to study.

Immigrants, particularly from outside EU-15, are also overrepresented among those enrolled in VET outside the regular education system for personal and social reasons, which might also include language courses (see **Figure 3**). Their rates of participation are particularly high in Nordic countries and the UK.

Unfortunately, non-EU immigrants are largely underrepresented among the participants in work-related VET in all European countries, which is evident from **Figure 4**. A situation of naturalized non-EU immigrants is somewhat more favorable in this regard: they seem to

Figure 1 Proportion of individuals, aged 25–64, enrolled in any type of VET in the last 12 months ES – Spain; FI – Finland; IE – Ireland; FR – France; SE – Sweden; GR – Greece; UK – the United Kingdom; BE – Belgium; DK – Denmark; PT – Portugal; NL – the Netherlands; AT – Austria; LU – Luxembourg; DE – Germany. From EULFS LLL 2003, own calculations.

Figure 2 Proportion of individuals, aged 25–64, enrolled in regular education (as student or an apprentice) in the last 12 months. From EULFS LLL 2003, own calculations.

Figure 3 Proportion of individuals, aged 25–64, enrolled in VET outside the regular education due to personal or social reasons in the last 12 months. From EULFS LLL 2003, own calculations.

Figure 4 Proportion of individuals, aged 25–64, enrolled in job-related VET outside the regular education in the last 12 months. From EULFS LLL 2003, own calculations.

participate in work-related training more often than their non-naturalized counterparts.

The question arises then, as to whether we can account for the lower levels of work-related VET participation among non-EU immigrants once we control for individual human capital characteristics and for their employment status. A series of logistic regression has been estimated for each country for employed individuals and the results are shown in **Figure 5**. The bars pertain to the log odds of VET participation for non-EU immigrants relative to the group of native-born (the reference category). Log odds below 0 signify that non-EU immigrants have lower propensity for VET participation, other things being equal, and this is true for all EU countries. Since the countries are sorted by the gross effect of work-related VET participation for immigrants outside the EU (a black bar), one could notice quite a similar pattern to the one observed above. The gap between immigrants and the native-born in work-related training is higher in Southern European countries (except for Portugal) and lower in Nordic countries, the UK, and Ireland. Observed cross-national variation in the VET participations rates among immigrants might be related to the institutional characteristics of the analyzed countries with regard to their migration policies and settlement orientations of immigrants, functioning of the educational and training systems as well as the character of their labor markets. Availability of the special migrant-targeting training programs might also serve as an explanation (see the next section).

Controlling for the sociodemographic and human capital characteristics (age, gender, and education) and accounting for the timing of migration (i.e., migrated before and after 1993; a white bar), the gap between natives and immigrants diminishes in Germany, Austria,

France, and the Netherlands (the effect is no longer statistically significant for the latter two). The variable for migration cohort was significant only for Germany and Denmark, signifying higher training participation for immigrants with residence in the host country longer than 10 years.) For the remaining countries, we observe an increase in immigrants' disadvantage with regard to training participation, which signifies that immigrants get less training than comparable (with regard to age, gender, and education) with the native-born. Employment characteristics appear to be a strong predictor for the lack of training among non-EU immigrants, so that the gap between natives and immigrants is further explained in Greece, Spain, Belgium, Finland, Germany, France, Luxembourg, and Denmark (shown by a gray bar). The opposite trend, that is, an increase in the unexplained affect of the immigrant status, is observed in the UK and Ireland. All in all, in most of the countries, the lower propensity for work-related training among non-EU immigrants with socio-economic and employment characteristics similar to those of the native-born remains unexplained. Whether this is due to the factors unaccounted for in the model (e.g., language knowledge or difference in motivation) or due to the reluctance to invest from the side of employers or employees, it needs to be explored in future research.

VET Targeting Immigrants: Qualitative Evidence

It has been shown above that countries differ both with regard to the overall training participation rates as well as the propensity of immigrants to receive VET. Qualitative

Figure 5 Log odds of enrollment in job-related VET outside the regular education in the last 12 months for employed non-EU immigrants, aged 25–64. The dotted line pertains to the effects that are not statistically significant. From EULFS LLL 2003, own calculations.

studies, some of which are referred to below, give some flavor of VET participation among immigrants but, unfortunately, fail to provide any systematic account for cross-national variation in immigrant training participation.

It is constantly stressed that the lack of the host-country language skills is one of the most important obstacles immigrants face in the new country. Given the difficulties faced by immigrants in successful labor market integration, most OECD countries recently reinforced their integration systems, notably to improve the language skills of newcomers (e.g., France, Germany, and Norway) (OECD, 2003, 2006). Sweden has a strong Swedish for immigrants (Sfi) program, while Denmark also pursues a program of Danish as second language for adult foreigners. The Finnish Broadcasting Company, (YLE), provides Finnish for both Finns and foreigners. In Spain, recent immigration inflows have caused an increase in public and NGO provision of Spanish language and cultural courses. Some countries insist that immigrants participate in classes aimed at improving their integration prospects, for example, in the so-called assimilation and integration training in the Netherlands as a precondition to family reunification and for receipt of social benefits (OECD, 2004).

Historically, in many countries training for newcomers includes not only teaching them the language, but also introducing them to important legal and cultural aspects of the new society or showing them how to operate in the labor market (Wrench, 1998). Some examples include training directed specifically at the needs of a particular organization, where restructuring has affected the existing immigrant workforce. Examples of the firms are ElectroCoat-Genk (Belgium) that provided assistance and training to unemployed miners in the region, which had been in recession since the closure of the local coal training mines. In Austria (iR3 Video International), training was also introduced because insufficient knowledge of the German language in immigrant workers became a potential problem when production began to be restructured. It became no longer sufficient for a production worker to be passively able to understand instructions; instead she/he had to communicate actively within the team, which became the main aim of the course.

Many migrants in the Australian workforce are working below their level of competency due to the fact that their qualifications from the country of origin are not recognized in Australia or because, having been in inappropriate jobs, they have not developed a set of skills that would enable them to become qualified. The lack of recognition of prior learning and inflexibility of learning also contribute to a negative and non-participative view of education and training for migrants (Chandraratna, 1999). In both Canada and New Zealand, the lack of skill recognition was a barrier to gainful employment, though it was not immediately clear, whether recognition of experience

or qualifications was more important. A source of assistance for skilled migrants in this country is the Adult Migrant English Program (AMEP). In Western Australia, its Migrant Pathways Program targeted migrants and refugees with skills in aged care, nursing, engineering, and information technology and provided them with skills recognition and fast-tracked certificate level courses with English language support (The Parliament of the Commonwealth of Australia 2004). CARC (2004) documented some dissatisfaction with programs for English as a second language and the preference of ethnic communities for vocational programs that incorporated English language support. For members of migrant groups, the main purpose of training was to obtain employment and further training is rarely considered once a job has been found. In terms of VET, enrollments and completion were seen to increase if a clear employment pathway was provided, language support was given, cultural issues were addressed, culturally aware teachers were provided, credit for prior learning was given and there was inclusion of work experience programs (Miralles, 2004; Chandraratna, 1999).

VET Pay-Offs

Another body of research deals with the returns to VET and shows that there is a significant and positive relationship between education and training participation and wages (Booth, 1991; Brunello, 2001). Explanations for this are multiple but the issue of causality (i.e., whether training leads to higher wages and not the other way around) has not been yet sufficiently resolved (OECD, 1999). First, it is clear that high-skilled occupations which offer higher training incidence also offer higher wages. Second, people with higher wages are less constrained to purchase training if needed. There are also pieces of evidence for the causal effect of training on wages (e.g., for the UK, Arulampalam and Booth, 1998; for the US, Loewenstein and Spletzer, 1997; Veum, 1995) which pertain to all populations without differentiating individuals by their migration status.

With regard to returns to VET for immigrants, research is also led mainly by economists and much of the empirical evidence stems from Israel, a country with a large immigrant population. Thus, Cohen and Eckstein (2002) analyzing male immigrants from the former Soviet Union arriving in Israel in the 1990s, report a 0.85% growth in wages due to the availability of training in the third year after migration, and 1.4% in the fifth year. They suggest that the effect of training on observed employment and wages is a dynamic phenomenon that takes many years to be realized. Similarly, Cohen-Goldner and Eckstein (2004) confirm these results also for women, in addition pointing to the fact that training is highly valuable for all immigrants but more so for older

and less skilled workers who get the opportunity to search for better jobs. Training, however, seems to have no impact on wages in blue-collar jobs, but has high value for white-collar employment. The above-mentioned studies do not compare immigrants to the native-born population, so it remains unclear whether the two population groups differ with regard to returns to VET.

The study by Seibert (2005) explores whether completion of vocational training in the form of apprenticeship in Germany mitigates disadvantages faced by youth with immigrant backgrounds while entering employment. Results of the occupational registry data from the Employment Study of the Federal Institute for Employment Research (IAB) show that young immigrants holding vocational qualification, with a single exception of Turks, reach similar labor market positions as natives. Turkish men are less able to find appropriate jobs or to enter the labor market in the occupation trained in comparison with Germans, and this is particularly true when labor market conditions are severe. In times of good labor market conditions, Turkish vocational school graduates seem to have similar chances to find appropriate employment.

Evidence from the 2002 Student Outcomes Survey shows that in Australia high rates of participation in VET and successful program completion have not been sufficient to deliver corresponding rates of employment outcomes for some immigrant groups. VET graduates born in non-English speaking countries were more likely to be unemployed than Australia-born graduates or those who arrived from other English-speaking countries. Representing 18% of VET graduates, these youths were only 12.3% among the gainfully employed (Volkoff, 2004). At the same time, those able to find employment were more likely to hold part-time jobs and more likely to have taken longer than Australia-born graduates to find one.

Conclusions

Even though the lack of human capital relevant to the receiving countries has frequently been shown by theoreticians as one of the most serious obstacles to immigrants' labor market integration, empirical evidence concerning educational enrollment and even more so VET participation among immigrants and their children has been scarce until now. Existing studies, largely from the USA and Australia, report underrepresentation of these population groups among students or apprentices and attempt to explain this situation. In Europe, the topic of immigrant education and training has been largely neglected and up until now explored only by Dutch scholars. Even fewer studies (and existing studies tend to deliver unequivocal results) deal with the rate of returns on VET participation among immigrants, compared to countries' charter population. Thus, it is fair to conclude that open questions

remain both with respect to reasons for immigrants' underinvestment into country-specific education and training, their returns to these investments, as well as to the cross-national differences in this regard.

Indigenous People and Vocational Education and Training

Indigenous People in the World

Any discussion of Indigenous people and vocational education and training (sometimes referred to as technical and vocational training) must begin with definitions. Though Indigenous might seem a common sense term, it is in fact controversial in the international context. Some countries deny the existence of Indigenous peoples because to acknowledge them would be to open up difficult issues of what defines a nation; instead, they refer to tribal peoples or ethnic minorities. In contrast, some Indigenous groups strongly assert their aboriginal status and refer to themselves as first nations, or by their tribal or language names, claiming or at least implying some measure of sovereignty. Clearly, the official recognition of these groups has political and economic implications that some Indigenous peoples are keen to press and some governments are anxious to avoid. Consequently, a precise definition of Indigenous is somewhat problematic. Still, a working definition of Indigenous is important for understanding the complexities of how Indigenous people engage with programs and policies related to vocational education and training (VET).

A set of characteristics or features of Indigenous peoples underpins United Nations and many other international organizations' and agencies' definitions of Indigenous peoples and they provide a useful framework for a definition:

- priority in time, with respect to the occupation and use of a specific territory;
- the voluntary perpetuation of cultural distinctiveness, which may include the aspects of language, social organization, religion and spiritual values, modes of production, laws, and institutions;
- self-identification, as well as recognition by other groups, or by state authorities, as a distinct collectivity; and
- an experience of subjugation, marginalization, dispossession, exclusion, or discrimination, whether or not these conditions persist (Daes, 1996).

Even with a relatively clear definition, counting the number of Indigenous people in the world is difficult. Not only are government definitions problematic, but Indigenous people themselves also sometimes disagree about who is Indigenous. In some countries, Indigenous groups define membership according to their own criteria, for example, by historical listing on a tribal roll or by blood quantum. Further adding to these difficulties is the fact that many countries with Indigenous populations are developing countries with administrative systems that struggle to locate

and accurately count citizens who live in remote or isolated regions as many Indigenous groups do.

Box 1 The Sámi

The Indigenous people of northern Europe (Norway, Sweden, Finland, and the Kola peninsula of Russia) are known as the Sámi (Saami, Sami, Same). Originally the Sámi were reindeer herders living in the sparsely settled remote north. Sámi language and culture were oppressed by various governments and over time many Sámi hid or denied their identity and language. Consequently, accurate population estimates are difficult though some suggest a population of no more than about 100 000 today (with only about 35 000 language speakers). Most of the Sámi people in Finland live in the far north of the country in an area referred to as the Sámi homeland. Established in 1977, the educational center of the Sámi region provides basic vocational education in various fields, using Finnish and Sámi as languages of instruction. As members of the European Union, Sweden and Finland have received adult education funding that promotes, among other things, a range of Sámi vocational interests including: Sámi handicraft and reindeer husbandry, Sámi film education, and Sámi language reading and writing.

From Lund, S. (2000). *Adult Education and Indigenous Peoples in Norway*. Hamburg: UNESCO Institute for Education; and Ruoppila, S. (2006). *Finland: 'Feeding in' and 'Feeding out', and Integrating Immigrants and Ethnic Minorities. Study of National Policies*, European Commission, DG Employment, Social Affairs and Equal Opportunities.

Given the difficulties, it is only possible to estimate, and the current best estimates of the size of the world's Indigenous population range between 300 and 500 million, comprising over 5000 language and cultural groups spread across more than 70 countries (United Nations Permanent Forum on Indigenous Issues). Most of these people are in Asia and to a lesser extent in Africa and Latin America. It is also important to note that in all these regions, and even in highly industrialized countries like Canada, the United States, and Australia, Indigenous people are typically among the most poor and disadvantaged in their home countries, often with relatively lower levels of education, employment, and health. These demographic features are important for understanding the challenges of providing VET to Indigenous populations.

VET and Socioeconomic Development

In the most simple terms, VET can be defined as education for the world of work. Yet, it is more than this. Indeed,

VET involves manual and technical training – invariably with an aim toward developing skills and knowledge for practical application in various livelihoods – but it also may include integral elements of general education such as literacy and numeracy and basic life skills. In many parts of the world, Indigenous people have had little or no access to basic education and where they have attended school, it has often been only through the primary level. Consequently, VET for Indigenous people in most cases is not only about technical or vocational training, but it is also a means to new insights, knowledge, and understanding about the outside world and the key to participation in the wider society.

Although there is obviously great variation among the circumstances of Indigenous peoples of the world, VET is for many a critically important means of socioeconomic development. As a sector in education, it is arguably the most relevant to capacity development on both the individual and national levels. It is typically flexible, and in terms of delivery and content, can be modified and adapted to varying needs and academic backgrounds of students. In countries with robust and growing economies, or those where economic growth is stagnant or slow, VET is often the means by which Indigenous people gain access to employment and its associated benefits. In many developing countries, especially those where poverty is widespread, VET is often explicitly conceived of as one of the most important avenues to poverty alleviation among Indigenous peoples.

Models of VET Delivery to Indigenous Peoples

VET delivery varies greatly and differs significantly from general education where delivery is typically through a state or other school and later through a tertiary or higher education system. While some countries do fold VET into schooling at the secondary level, it is more commonly offered outside the general-education system. The delivery structure is highly variable. Formal programs might involve specialized technical and vocational colleges or polytechnics, enterprise or industry-based training, training provided or subsidized by nongovernmental organizations (NGOs) or church-based organizations, private providers paid by government, industry, and sometimes through formal on-the-job apprenticeship programs. In many countries and in some circumstances, the provision of VET is relatively informal, and thus more akin to adult education and lifelong learning programs. Such variability has some advantages in terms of flexibility but can also result in fragmented and uncoordinated delivery. For Indigenous people – especially those in remote regions far from educational services in capital or regional centers – the flexible delivery of VET is often critical.

Box 2 First Nations Technical Institute, Canada

The First Nations Technical Institute (FNTI) is an Indigenous owned and controlled postsecondary institute located on Tyendinaga Mohawk Territory in eastern Canada. The Institute was created in 1985 and serves 300 postsecondary students and adult learners from across Canada who may study from a range of courses. The philosophy and approach of the institute emphasizes holistic, culturally based learning. One area of study is Indigenous community health through which students explore Indigenous knowledge and philosophies as they relate to human health and the natural environment. The program is rooted in Indigenous knowledge and exposes First Nations health professionals to cultural teachings which broaden their understanding about health, healthcare, and environmental and human health issues facing First Nations communities.

Challenges for Building Effective VET Programs for Indigenous Peoples

Universal rights to education for Indigenous people are prominent in the United Nations Declaration on the Rights of Indigenous People, adopted in November 2007, and vocational education receives specific emphasis. The declaration states that Indigenous individuals, particularly children, have the right to all levels and forms of education of the state without discrimination (Article 14). Further, the other articles of the declaration refer to the important role that education plays in empowerment (Article 17.2) and promote vocational training and re-training as one of the means to social and economic improvements (Article 21.1). The reality, however, is that realizing these rights is, for most Indigenous people, still a distant promise. The United Nations' Special Rapporteur wrote that “education for Indigenous peoples would seem to be the ‘ugly duckling’ of national education programmes and in general to be assigned low priority and inadequate budgets at the national level” (Stavenhagen, 2005: 16).

Yet, even where governments have the political will to put the UN Declaration into practice, it is a complex challenge. There are enormous variations in the geographic, political, and socioeconomic conditions in which the world's Indigenous peoples live and no single solution to serve their needs. While there certainly are unique challenges for some specific groups, for example, in countries where the existence of Indigenous people is denied, there are also a range of common and interrelated challenges that deserve attention.

Often, as a function of history, many Indigenous peoples live in remote and isolated communities, with limited infrastructure, far from urban or regional centers where mainstream services are provided. This has several implications. Employment options are often few, given the distance from the labor markets. Service provision is sometimes poor, again simply because of the disadvantage of distance, and

Indigenous people may have less access to even basic levels of education, housing, communication, health, and other social services considered essential in the developed world. The result for many is not just a geographic marginalization, but – and this is true for Indigenous people who live in developed countries in urban settings as well – also a political and socioeconomic marginalization that locks Indigenous people into a role as the most economically, politically, and socially disadvantaged citizens within their home countries.

Consequently, many Indigenous face precarious social and economic circumstances that affect their ability to access resources and participate fully in the social and economic development of their countries. Compounding this is the deeply rooted discrimination and racism that many Indigenous people face in their interaction with the dominant society. This marginalized position also correlates with not just higher levels of unemployment and lower levels of education, but also higher levels of alcohol and other substance abuse, social and family dysfunction, increased rates of suicide (particularly among the young), and generally high levels of morbidity and mortality.

In most countries, education is delivered in the official language of the state. There are obvious political reasons why this should be so. For example, a government may promote a single language in order to consolidate a national identity. But there are also quite reasonable economic considerations. Policy and curriculum documents and teaching materials in multiple languages increase costs. In developing countries, which is where most of the world's Indigenous peoples reside, the cost of education is a significant issue that imposes real constraints. Given that Indigenous people by definition speak minority languages, finding qualified bilingual teachers for VET instruction is often difficult; similarly, developing curriculum and instructional materials in those languages is, in most cases, prohibitively expensive. Consequently, it is often the case that either only Indigenous people who are literate in the national language can effectively engage with the VET materials or the materials must be locally adapted so they can be used with individuals who are illiterate in the national language or literate in the local Indigenous language. Further, education in the nonofficial language is likely to limit access to mainstream labor markets, so even where nonofficial materials are available, the economic payoff at the national level may not be adequate to justify the investment.

Another challenge in the provision of VET relates to the potentially negative perceptions of or deep suspicions about education and training many Indigenous peoples hold. Many Indigenous people feel a strong ambivalence to Western education, of which VET is a part. On the one hand, it is universally cast as the single best tool for empowerment and poverty alleviation – education and training provides skills for employability and engagement

with the national economy. Yet, on the other hand, many perceive education as a continuation of colonialism or forced assimilation; in many countries, education was the method of civilizing Indigenous people, diluting their language, undermining their traditional livelihoods, and destabilizing their culture.

Box 3 Safety in the learning environment

Research into factors that facilitated successful vocational education and training among Māori people in New Zealand identified safety in the learning environment as one of the most important.

The “learning environment” refers to the total physical and philosophical ethos of the organisation. It includes the spaces for formal and informal learning as well as sites of learning that extend beyond the traditional classroom setting. While each of the providers interviewed emphasised certain values that underpin their organisation, a paramount goal of all of the providers was “to provide a place of safety” for their learners. “Safety” refers to the physical and psychological elements of well-being, such as pastoral care and cultural safety. (Skill New Zealand-Pūkenga Aotearoa 2001)

In both developed and developing countries, student and institutional funding and support for VET is a major challenge. In many countries, vocational education sits awkwardly outside mainstream primary and secondary education and tertiary studies. Typically, there is a school sector to provide general education to children and a tertiary sector for adults. Vocational education, however, is often far less distinct as a sector with myriad providers and delivery is often uncoordinated, fragmented, and of variable quality. VET delivery may come directly from government, or from NGOs, industry, employers, private providers, local communities, religious institutions, and more. An answer to the question of who is responsible for funding and supporting the VET needs of Indigenous people can vary not only from country to country but from region to region or community to community.

All these challenges make planning for and evaluation of vocational education and training for Indigenous people extremely difficult. To develop policies and programs for the delivery of VET to Indigenous people, data on a wide range of important variables need to be collected. For example, local needs, student readiness, student performance, enrollments, completions, staffing, and facilities are but a few. In addition, for these data to be of value, they need to be accurate and reliable and collected in a systematic fashion. In a developed country with established administrative data systems, this is a challenge; in a developing country where administrative systems are incomplete or nonexistent, the tasks of planning and monitoring the delivery of VET to Indigenous people is exponentially more difficult.

Key Strategies for Advancing Indigenous Engagement with VET

Increasing numbers of countries are articulating commitments to enhance the vocational and life skills of their Indigenous citizens and there are many examples of success. Still, there would be little value in attempting to provide a list of best practice in the provision of VET to Indigenous peoples around the world. The field of VET shifts and changes with new innovations and emphases, governments come in and out of power and reorganize, abolish, or reinvent policies, departments, and institutions, and the political relationships between Indigenous people and their home nations move in and out of the national and international spotlight. Yet, there are some clear strategies that have been implemented in various countries that have resulted in tangible advances for Indigenous peoples:

1. *Recognition of Indigenous culture.* The most fundamental factor in successful VET for Indigenous peoples is recognition by the national (and regional and local) government that Indigenous people have unique histories, traditions, and cultures and that a one-size-fits-all approach to training rarely works. Increasingly, Indigenous people are asking for VET that takes into account Indigenous knowledge systems and intellectual property and incorporates culturally appropriate modes of delivery and instruction.
2. *Partnerships and consultation.* Extending the point above, it is clear that many countries attain gains in participation and outcomes when programs are built in partnership with Indigenous people. That might involve a government- or industry-sponsored Indigenous consultative body at the national level and/or regional or local discussions about what local people feel they want and need in terms of VET. In some countries, Indigenous-controlled VET institutions have been successful, particularly among students who would not otherwise engage in mainstream education. Participatory, bottom-up development of VET enables the delivery of training that reflects local interests and needs and greatly increases the quality of training outcomes. It also appears to be the most effective means of overcoming the ambivalence many Indigenous people feel about education.
3. *Blending vocational education with more general education and life skills.* While employment is almost invariably the desired outcome of VET, for Indigenous people in very remote areas, where labor markets are limited or nonexistent, that will not always be possible. In many countries, VET takes a more informal approach and merges with adult education in the principle of lifelong learning. In some countries, VET is used as a vehicle for delivering basic-skills training (including literacy and numeracy) related to health, nutrition, parenting, communication, governance, and dozens of other critical life skills. In this way VET can also provide life skills and assist people in gaining the confidence to participate in employment and to engage as citizens with the wider society.
4. *VET and Indigenous knowledge.* For many Indigenous people, vocational employment has meant training to work in extractive industries on or near Indigenous lands. This has certainly contributed to the deep ambivalence some feel about VET. In recent years, however, there has been a growing interest in sustainability, and Indigenous lands, often in remote areas, are sometimes among the most ecologically intact and environmentally significant and sensitive within a country. There is increasing awareness across the world of the importance of protecting this natural heritage coupled with expanding recognition of the economic value of Indigenous knowledge of plants and of strategies for land and resource management. Shaping VET to enhance and protect this knowledge and to provide skills to enable local people to work effectively in these areas shows great promise in many parts of the world.
5. *Articulation with national training bodies and national qualification frameworks.* In some countries, Indigenous people express anxiety about the degree to which the VET they are offered is up to standard. This is particularly true in countries with Indigenous populations in remote areas and where training is sporadic, often poorly coordinated, and unmonitored. In some developed countries, Indigenous issues are a major focus of national training bodies and extra efforts are made to ensure Indigenous training is integrated into a national quality framework. The result is typically a more consistent, higher-quality VET system.
6. *Reducing barriers to access.* Many studies of Indigenous participation in education identify relatively simple barriers to access. A lack of child care, for example, often stops women from participating in education or training. Similarly, Indigenous trainees sometimes struggle with structured learning within a foreign system; counselors, tutors, and student-support strategies often make the difference between a person staying in a training program and dropping out. These can be extended to something akin to pastoral support and can be especially effective in the context of workplace training where an employer provides additional training or exposure to knowledge and skills for life (e.g., literacy or health) and not just those needed to perform workplace tasks.
7. *Flexible delivery.* In many Indigenous communities, patterns of pastoral mobility or hunting, agricultural seasons, and ceremonial cycles can disrupt training. Given the relatively higher levels of mortality and

morbidity among Indigenous people in most countries, ill-health and the need to attend funerals often result in students falling behind and eventually withdrawing from training. The most strategic response to these realities is to build VET systems that can accommodate or incorporate such cultural and local needs. Similarly, training that is locally based, hands-on, and culturally sensitive, greatly increases the quality of the outcomes.

Box 4 Factors leading to improved outcomes in vocational education and training for Indigenous people, Australia

A systematic review of research found identified seven factors leading to improved outcomes in vocational education and training for Indigenous Australians:

- Community ownership and involvement.
- The incorporation of Indigenous identities, cultures, knowledge, and values.
- The establishment of true partnerships.
- Flexibility in course design, content, and delivery.
- Quality staff and committed advocacy.
- Extensive student support services.
- Appropriate funding that allows for sustainability.

Conclusion

A vast majority of Indigenous peoples in the world today remain committed to their languages, their cultures, and their futures as distinct peoples. Many struggle for recognition and for equity in law, health, education, economic participation, and social justice. They often face challenges of racism, discrimination, and socioeconomic marginalization. Yet, for Indigenous people everywhere, VET is one vital path to the future, promising not just access to employment and income, but also increased opportunities for participation in the home country and in the wider world.

Introduction

Vocational education and training (VET) is an important avenue for improving work-related skills. VET contributes to organizational effectiveness, productivity growth, and national competitiveness. It also plays an important role in assisting the less-advantaged members of society, including those who are disadvantaged due to a disability. The balance between these two different emphases is one of the tensions in VET.

There are responsibilities at the societal level for ensuring that VET provides effective assistance for students with a disability. The many significant stakeholders in VET (e.g., students, training institutions, governments, and employers) all have a role to play, but the primary responsibility rests with governments and with VET providers, especially those supported by public funding (Smith and Ferrier, 2004).

In making decisions about whether to participate in, or support, VET (and when, where, and in what form), all VET stakeholders are influenced by the costs they face and the benefits they expect to receive. From a societal perspective, the relationship between the total costs of provision and the total benefits from individuals participating in VET (including individuals with a disability) is crucial for decisions about resource allocation. Overall benefits need to exceed costs, and the more they do so, the stronger becomes the case for societal action. Australian studies suggest that increasing the participation in VET of people with disabilities would result in substantial economic gains, that is, societal benefits would significantly outweigh costs (Dockery *et al.*, 2001). When overall benefits exceed costs, but costs exceed benefits for individual enterprises or providers (e.g., small providers), then public authorities can tilt the balance by subsidizing costs, augmenting the benefits received, or some combination of the two.

Definitions of disability vary across nations and education sectors, but distinctions are commonly made between intellectual disabilities, learning disabilities, and physical disabilities. For educational institutions, a primary consideration is whether, and to what extent, the disability impacts on the ability of students to participate in academic programs and to complete them successfully. Those with multiple disabilities are recognized to be particularly disadvantaged. The adverse implications of a disability can also be cumulative: for example, poor literacy and numeracy outcomes at school contribute to below-average learning prospects in VET and fewer opportunities for satisfactory employment.

The ability of students with disabilities to participate successfully in educational programs can also be affected by the impact of their disabilities on aspects of their day-to-day living, such as housing, transport, health, or personal needs. Difficulties in these areas can have a negative impact on the individual's interest in learning, his/her ability to attend and participate in classes, to access and use available supports, and to participate in work placements. They can also affect the student's subsequent capacity to obtain employment and to advance at work. The broader society shares responsibility with governments and education authorities and providers for providing assistance in such areas. There is also an important role for industrial bodies, including employers and unions, in assisting people with disabilities when changes in the workplace have a disproportionately adverse impact and in making transitions from education to employment.

International Issues and Approaches

Across international settings, there are many common issues and concerns regarding students with disabilities in postsecondary VET. Common goals, ideas, and types of initiatives to address inequalities, inadequacies, and inefficiencies are complemented by some diversity in policy and practical approaches reflecting local contexts and objectives.

A wealth of studies, reports, and discussion papers provides evidence of substantial attention in many settings to the creation of more accessible and inclusive education and training systems; to improving the range, type, and effectiveness of programs and supports for students with disabilities; and to supporting students with disabilities to achieve better outcomes from their studies. Governments and policymakers are wrestling with similar questions concerning how best to support and encourage people with disabilities to participate in the labor market and to provide VET programs that will meet their needs, prepare them for employment, and support their transition from study to work (e.g., Kim and Zirkle, 2006; Zolkowska *et al.*, 2002; LSC, 2005; Kate *et al.*, 2003). In these matters, students with disabilities are considered as a broad group and funding models and cost issues receive special attention.

At the local level (education institutions), attention is centered on how best to support students with disabilities to complete their studies successfully and to obtain the

outcomes they seek. An important consideration is the capacity of staffing and other essential resources, including both general and tailored supports, to assist students with disabilities. In addition, education administrators and teachers are making efforts to gain a greater understanding of the needs of students with disabilities, including those with particular types of disabilities, and to improve learning arrangements and teaching practice. The international literature highlights the evolution of knowledge and practice around the impacts of particular types of disability, such as a learning disability, or a sight or hearing impairment. Many studies explore how best to assist students with specific types of disabilities, as well as students with disabilities in general.

At both government and institution levels, VET is rarely seen as an end in itself, but as a pathway to meaningful employment and greater social participation for people with disabilities. In the UK, for instance, the Learning and Skills Council (LSC) has adopted an approach to further education (FE) for students with disabilities that is guided by the concept of learning for living and work (LSC, 2006). The goal is to drive up participation and to enable people with disabilities to achieve ambitions including improving their lives, strengthening their career opportunities, and developing their skills. The Council notes that this will enable economic participation, the development of self-confidence, and help people of all ages to live autonomously and contribute to the communities in which they live (p. 5).

However, there is also an awareness that recruitment decisions by employers are made outside VET systems and that student success in study does not necessarily lead to labor-market success. Focusing on Europe, Corbett *et al.* (1999) note that people with disabilities comprise a peripheral labor force and tend to be seen as having few marketable skills. Employer attitudes are regarded as a major barrier to employment for people with disabilities. However, overcoming employer attitudes is regarded as only part of a broader struggle by people with disabilities to gain recognition of their potential (e.g., Harrison and Barnett, 2001; Kim and Zirkle, 2006; Waite *et al.*, 2006). A recent longitudinal study in the UK emphasized that while aspirations of young people with disabilities in their mid-teens are very similar to those of their peers without disabilities, by their mid-20s few have been able to reach the levels of education or to gain the employment that they sought and expected. The result can be disaffection and depression. The title of the report 'Frustrated ambition' appears well chosen (Burchardt, 2005).

Costs and Funding

Not all students with a disability require expensive supports to participate successfully in education and training. The extra costs that they and their enrolling institutions can incur vary greatly, depending on the nature and

extent of the disability. In some settings, VET providers have no indication in advance of the number of students who will be seeking disability supports, or of the nature of the supports that students will request. Consequently, they can experience difficulties in predicting the extra costs they will incur from year to year. These difficulties may be especially important where VET providers are small and have very limited resources to draw on in years when the number of students seeking disability support increases beyond budget expectations.

Andrews and Smith (1992) divided the supports required by students with disabilities into three groups: relatively low-cost support requirements, normally provided by educational institutions as student services; more costly supports provided by the institutions, which they consider appropriate for special funding (e.g., large print materials, special furniture); and support requirements related to unique needs for individual students (e.g., note takers or interpreters). They estimated that 6%, 24%, and 70% of total (recurrent) expenditure on supports for students with disabilities was in the three respective groups. High-cost supports were less frequently required, but consumed the largest proportion of the budget. While these estimates imply much higher training costs for VET students with disabilities, they are average costs: marginal costs are likely to be lower (Dockery *et al.*, 2001). Similarly, in relation to workplace training, the (extra) costs of accommodating an employee with a disability may be similar, whether or not the employee is engaged in training.

Two distinct funding models are widely used to allocate support to students with disabilities in different sectors of postsecondary education: funding allocated to students; and funding allocated to institutions (Devlin, 2000). Funding allocated to individual students to cover the costs of additional supports (perhaps on an entitlement basis up to an agreed limit) empowers students to make choices about supports and education providers. However, such funding can be difficult to administer; can place stress on students by requiring them to complete forms and to locate, price, and secure services; and can disadvantage students when negotiating the purchase of equipment or services. Providing funding directly to educational institutions has advantages, particularly for large institutions, which can plan services, adjust flexibly to changing circumstances, and take advantage of their bulk purchasing power.

In Australia, which is a federal country of six states and two territories, current funding arrangements for VET usually comprise a mixture of base funding to institutions and additional funding for special purposes, such as where students have particularly expensive support needs. However, within various VET institutions, a rather different emphasis can be placed on various elements in the funding mix. There are also some differences in the ways in which funds are bid for and allocated (for further details, see Smith and Ferrier, 2004: vol. 2).

Funding arrangements for students with a disability can be assessed using four criteria: portability (i.e., whether funding follows the student from one educational institution to another); whether additional funding reflects the actual cost of providing the support required for each student; administrative efficiency (i.e., whether the funding arrangements limit administrative costs and devolve administration as close to the client as possible); and respect for the autonomy of educational institutions (Devlin, 2000). An additional consideration is whether the funding arrangements offer incentives for VET providers to enrol and to support students with a disability (Buys *et al.*, 1999; Barnett *et al.*, 1996). An institution which gains a reputation for excellence in meeting student needs may encourage increasing enrolments and thus costs: the incentives for providers can be perverse (NBEET, 1994). As governments move from a supply-based to a more demand-based VET system, as in Australia and the UK, in recent years (Smith *et al.*, 2001), it has also become more important to ensure that the interests of those with limited choices, including people with disabilities, are safeguarded.

Some students with disabilities can take longer than other students to reach the required level of knowledge and skills. These students may be disadvantaged where there is little or no flexibility in systems and programs to accommodate their need for additional time (e.g., NEADS, undated; Waite *et al.*, 2006). This is not solely an issue about teaching practice, but also has implications for the methods used to allocate program funding and for the timeframes that are used to evaluate program outcomes and effectiveness. The Australian study (Smith and Ferrier 2004) noted that while students with a disability often require extra time to complete a VET qualification, this was not often recognized in public funding arrangements. Barnett (2004) indicates that resource-allocation processes need to take a longer-term view of outcomes for students with disabilities. Waite *et al.* (2006) suggest a stronger focus on lateral (rather than linear) progress of students with disabilities.

Participation

A common challenge in obtaining a comprehensive picture of participation in VET by people with disabilities is that data can be unreliable. Where self-reporting of a disability is the basis for data collections, enrolments can be understated, for there may be disincentives to disclosure. For instance, students may fail to report a disability for fear that they will be treated differently, offered fewer opportunities, or will encounter negative attitudes about their ability. They may also fail to report a disability because they do not expect to need any accommodations or additional support to complete their study successfully. A further difficulty is inconsistencies in definitions of disabilities

used by different education systems and sectors and by a range of other agencies, for instance, between health and education systems and between schools and post-compulsory-education institutions.

Despite such difficulties, it is widely acknowledged that compared with other students, those with disabilities tend to leave school early and when they enrol in vocational programs, they tend to choose courses leading to lower level qualifications – or to qualifications outside formal-recognition frameworks. For instance, Australian data show that in 2000, only 30% of VET students with disabilities had successfully completed a school-Year-12 qualification, compared with 43% of all VET students (NCVER, 2002); and in 2003 more than half (55%) had left school at or before the end of Year 10, compared with 40% of all VET students (NCVER, 2005).

A study from the UK notes that the scope and level of aspirations of 16-year-olds with and without disabilities are very similar. Differences are apparent only for some small groups: those with mental health problems; with severe impairments or more complex needs; or who became disabled later in childhood (Burchardt, 2005: xi). This represents a considerable change from the past: the study cites a 1958 study of young people which found that the proportion of those with disabilities aspiring to semi-skilled or unskilled jobs was six times the proportion of those without disabilities. Rising aspirations may be one of the reasons the UK's LSC reports growth in participation in FE and work-based learning by students with disabilities. Other contributing factors are the rising incidence of learning disabilities as diagnostic procedures improve and the aging of the population and the associated rise in the rate of acquired disabilities. In 2001/02, 336 537 learners in FE and work-based learning identified themselves as having a learning difficulty and/or disability. In 2004/05, the number had risen substantially to 477 417. The LSC expects growth in participation to continue as the population ages and as more students in compulsory education aspire to access FE and work-based learning (LSC, 2006).

Supporting Students with Disabilities

Addressing the needs of VET students with a disability is complicated by the range and diversity of disabilities. In Australia, “of all disability types, VET students with hearing or vision disabilities have the highest probability of passing assessed subjects, and the highest employment outcomes, whereas VET students with intellectual or learning disabilities have the lowest, and well below the average level for all VET students with a disability.” Thus the type of disability does matter and “different improvement strategies may be necessary for different groups” (NCVER, 2005: 6).

Staff development is a key factor in improving much of the acknowledged uneven quality of education-and-training

provision for students with disabilities. The international literature acknowledges that many staff in institutions offering VET lack understanding of the impact of disabilities and knowledge about effective and appropriate teaching practices and other strategies to support such students. Many studies thus explore ways to respond to the impacts of particular types of disability on students' learning and participation, and to identify the administrative and teaching practices that will be most effective in assisting students with a disability (e.g., Perin, 1990; Ofsted, 2007; Onnela, 2003).

In the UK, a carrot-and-stick approach is being taken to raising the quality of provision for students with disabilities. Innovative delivery, the sharing of ideas, and good practice across the system (including through collaboration) are being promoted, performance measures are being implemented, and intervention occurs where there are no improvements. Centers of excellence are being established as trailblazers to lead system-wide improvements. The LSC also notes that the range and complexity of learning difficulties and disabilities will demand the development of both generalist and highly specific specialist training opportunities (LSC, 2006). Staff-development initiatives include initial training pathways for specialist learning support staff and teachers of learners with learning difficulties and/or disabilities.

The creation of inclusive systems and the adoption of inclusive practices can improve the student experience in VET and the outcomes they achieve (e.g., LSC, 2005). From the US Hart *et al.* (2006) describe a model of inclusive postsecondary education for students with disabilities that is based on collaboration across education sectors and between multiple agencies. It has a strong focus on the individual student's aspirations; and on the provision of services and supports to enable their achievement. Individualized services include an educational coach, tutors, technology, and natural supports. The focus is on establishing a student-identified career goal that directs the course of study and employment experiences (such as internships, apprenticeships, or work-based learning). The authors envisage a collaborative approach between agencies and sharing of costs.

Similarly, a UK study of work-related learning for students with learning difficulties (Waite *et al.*, 2006) notes the need for an increased emphasis on the value of educational diversity and greater opportunities for this group of learners to participate in education in ways that are meaningful and enable them to participate fully as adult citizens. One specific difficulty identified in the study is the current reliance on competence-based testing, which can reinforce students' experience of failure.

Developing an inclusive VET system that "enables individuals to reach their full potential and maximise their abilities" (p. 106) will also lead to the creation of a more inclusive society (Barnett, 2004). However key attitudinal,

resource, knowledge, skill, and systemic barriers affect people with a disability. Good-practice exemplars and learning the lessons of past experience can contribute to the dismantling of such barriers and improve policy and practice (Kate *et al.*, 2003; Barnett, 2004). In Australia, VET providers currently offer a range of services to support students with disabilities, for instance, public providers employ disability officers to liaise with individual students and arrange specific supports such as note-taking and access to adaptive technology. These officers also often have some responsibility for promoting improvements to the physical aspects of the institutional environment (such as access to buildings). However, the nature and extent of the supports that providers can offer is limited by funding and other resources and VET providers can offer only limited assistance with the wider issues that affect a student's capacity to study successfully, such as transport, housing, or activities of daily living (Smith and Ferrier, 2004).

Outcomes from VET

VET systems are strongly linked to employment. They seek to provide the skills sought by industries and employers and enable learners to achieve success and satisfaction in their working lives. However, regardless of differences between VET systems and the structure of economies, VET students with disabilities often experience poorer employment outcomes than other students.

Poorer employment outcomes for VET students with disabilities reflect the experience of people with disabilities in labor markets more generally. People with disabilities remain one of the most marginalized groups, especially when considering access to the mainstream labor market (European Union, 2006). While participation in learning can help to increase employability, action is needed to counter discrimination and employer concerns, such as the efficiency of workers with disabilities and possible additional costs of providing supports. The European Union (EU) is encouraging its member states to offer wage subsidies to employers of workers with disabilities and compensation for additional expenses. It hopes that "such aid may have a significant impact on ... employment opportunities" for people with disabilities.

Conditions that are more conducive to the employment of people with disabilities may be created by the spread and advance of technology. For instance, the EU's Disability Strategy Plan for 2004/05 identified that "new technologies ... empower people with disabilities and therefore facilitate access to employment" (European Union, 2006: 5, footnote). However, difficulties remain. A study from Korea (Kim and Zirkle, 2006) identified that the shift from an agrarian economy to a high-tech one has not met expectations of improved employment opportunities for people with disabilities. Employers remain unwilling to hire them.

In the context of labor-market discrimination and/or reluctance, the ability of VET institutions and systems to support transitions to employment by students with disabilities is limited, but there are things they can do. Studies show that collaborations between education institutions and employers can overcome some of the negative attitudes that influence recruitment practices (e.g., Harrison and Barnett, 2001; DET, 2001). Work placements during educational programs also can help students with disabilities to adapt to workplaces and employment requirements and can help to overcome the negative attitudes of some employers. But “careful preparation (is) required to develop good relationships and to restructure tasks to support work placements” (Waite *et al.*, 2006: 587).

Two other major factors contribute to poorer outcomes from VET for students with disabilities. The first is the problematic nature of transitions for these students – between schools and other education and training institutions; between postsecondary institutions; between programs; and between education, training, and employment. Studies from the UK and the US. identify transition difficulties relating to the lack of transfer of reliable information about learners (Perin, 1990; Ofsted, 2007; Nuehring and Sidlington, 2003). Students can miss out on required supports and costly new diagnostic assessments may also be required – and there is the fact that the necessary expertise might not be available. In Australia, the self-identification of students with disabilities in postsecondary education institutions, and differences in definitions of disability between education sectors are pertinent. Barnett (2004) suggests individuals can be trapped by intersectoral boundaries (or fall between them). There is, she suggests, a primary policy gap at key transition points and thus a need for cross-sectoral approaches.

The second factor is quality, particularly of guidance for students with disabilities and of the student experience in VET. Harrison and Barnett (2001) identify that students with disabilities may have difficulties in navigating and coordinating a complex array of educational opportunities. Appropriate guidance in choosing programs is thus essential. However, studies point to low expectations of students with disabilities, leading to inadequate academic challenges and placement in inappropriate programs. Other quality concerns include: insufficient efforts to integrate students with disabilities into the social life of the educational institution; less-than-required access for students to supports, equipment, and resources; and lack of use of appropriate and effective teaching practices for students with disabilities (Burchardt, 2005; Corbett, *et al.*, 1999; LSC, 2005; Ofsted, 2007). Inclusive approaches may help to counter these.

Conclusions

There is a growing recognition and acknowledgement of the potential of people with disabilities to learn and

to engage as full adult citizens in work and society, and of the important role of VET in assisting and supporting them to fulfill their potential. Typical of such views is Barnett’s statement that “the commitment to building a society which values difference and the need to enable all its citizens to contribute as well as receive, has to be the ultimate reward for building an inclusive training and vocational education system” (Barnett, 2004: 106).

Considerable progress is being made. Governments and policymakers are seeking ways to encourage and support people with disabilities to engage more actively in education and work, and at the institution level, knowledge of the impact of disabilities in general and of particular disabilities is growing and new and more effective teaching practices are emerging alongside initiatives including collaborations with employers. However, considerable scope for improvement remains. The quality of provision, of supports, and of guidance for students with disabilities is uneven. The experiences of students with disabilities in VET can be difficult and unhelpful. Inclusive systems and practices that welcome and support all students are needed. From an efficiency perspective, there is considerable scope for improved use of resources, while from an equity perspective there are significant possibilities for improving access, participation, and outcomes. Improvements can be made in education and training; in employment; and at the points of linkage (e.g., between school and VET or between VET and employment), where those with a disability are especially vulnerable.

Prisoner Education and Training

S Dawe, S H Wynes and J Misko, National Centre for Vocational Education Research Ltd., Adelaide, SA, Australia

In the Nordic countries, prisoners participate in mainstream adult education, including VET, while most other European countries emphasize personal development, especially access to basic education. The risk-need' model, identified in Canada in the 1990s, aims to reduce reoffending through programs which target factors directly related to the offence (including antisocial attitudes, gambling, substance abuse, and anger). This model of cognitive-behavioral programs has strongly influenced correctional systems in North America, United Kingdom, and Australia.

The experiences in these countries suggest that VET interventions should aim to meet the needs of individual prisoners, by creating activities that enable inmates to engage with learning. In this way, it can help to support prisoners' personal development as well as equip them to go on to further education and sustainable employment when they return to their community.

Introduction

Prison has traditionally had two major purposes: punishment and rehabilitation. A dramatic rise in the rate of incarceration in the last two decades in many Western countries has seen an increased focus on principles of punishment as the major way of controlling crime (see Crayton and Neusteter, 2008). At the same time, there has also been an effort to provide prisoners with education to aid them in rehabilitation and to prevent recidivism (i.e., reoffending and re-incarceration). Education is also seen as having a major role in ameliorating the behavioral problems that lead people into crime.

Incarceration alone does not prevent repeat offences; for example, around 50% of adult prisoners in the United States return to prison. However, vocational training and general education in prison has been found to produce some of the largest net economic benefits for adult programs in prison. Training programs help prisoners acquire the skills they need to reenter and stay in the community as law-abiding citizens. These programs cover basic education, literacy, language and communication skills, and employability preparation – as well as specific industry job skills – given that prisoners have generally low educational achievement and often lack life skills for coping in mainstream society (e.g., see the Irish Prison Adult Literacy Survey 2003 report by Morgan and Kett, 2003).

In this article, we outline the main characteristics of prisoner education and training programs in Europe, North America, and Australia. We find that whether these programs are underpinned by a human rights approach or a more instrumental one, there are common threads in all successful education and training programs. These include ensuring that the programs are tailored to meet the needs of individuals, create activities that will allow inmates to reconcile themselves with learning, and support prisoners' personal development as well as help to equip them to go on to further education and sustainable employment when they return to their community.

Key Approaches to Prisoner Education and Training

There is no uniform approach to prisoner education within and between prison systems in Europe, North America, and Australia. There are, however, two broadly similar streams of activity. The first is usually mandatory and aimed at changing or managing the behaviors and attitudes of prisoners (including for anger management or reducing drug and alcohol abuse); the other strives to improve the basic, general, and vocational education of individuals. The tenor of both streams of prisoner education is to improve knowledge and behavior so that prisoners have a second chance.

Prisoner Control and Rehabilitation Through Behavior Management Training

The behavior management model dominates those programs that assist offenders to confront and understand their criminal activity, and to develop techniques to control their behavior and avoid situations that may lead to further offending when released from custody or supervision. Such rehabilitation programs are often mandatory, and are also critical to the management of prisoners in prison. Since the 1990s, this approach has been particularly influential in Canada, Australia, and the United Kingdom.

In the Canadian model of the 1990s, referred to as the risk-needs model, risk is assessed in terms of static risk factors that are not amenable to intervention (including age of first offence, and criminal history), and dynamic risk factors that might change over time (such as family and social factors, substance abuse, educational factors,

and nonsevere mental health problems). These dynamic risk factors are also referred to in the literature as criminogenic needs.

Learning interventions are based on psychological theories of behavior management and take account of offender age, ethnicity, gender, disability, and socioeconomic status (Andrews and Bonta, 1998). Andrews (2001) concluded that reductions in recidivism can be maximized for high-risk offenders if they are involved in learning programs which target factors directly related to the reasons for offending (including antisocial attitudes, gambling, substance misuse, and anger). (This title is derived from the often-cited article by Martinson (1974): 'What works? – Questions and answers about prison reform' which reviewed 231 studies of prison rehabilitation programs and concluded that offender treatment programs had been largely ineffective. Critics of the nothing works doctrine actively challenged the assumptions and empirical evidence presented by Martinson (1974) and colleagues. Martinson (1979) also acknowledged errors in his earlier reviews, and cited findings from new studies which demonstrated that some treatments did work.)

In contrast, prisoner behavior management education in the United States of America has been influenced by a sociological perspective. (A Roadmap to Strengthening Public Safety, Correctional Service of Canada (CSC) Review Panel, 2007.) One example of this is the breaking-the-cycle program which has been trialed in three states (Alabama, Florida, and Washington) aimed at asserting the coercive power of the justice system to reduce drug use among offenders (Harrell *et al.*, 2003).

In Australia, prison arrangements vary across state and territory governments, but all have intervention programs that address the factors that impinge on the likelihood of reoffending. Here, the prisoner's sentence may mandate an intervention program aimed at reducing antisocial behavior (including substance abuse and anger) or other criminal conduct. The prisoner may also be involved in prison work.

In the United Kingdom, majority of prisoners are required to work while in prison. These work activities

may involve them in gardening, farming, and animal husbandry to provide food for prisons, as well as laundry, kitchen, bakery, gardening, and maintenance duties. Prisoners also work in industries and workshops supplying goods or services to the outside community on a commercial basis. Such mandatory programs are aimed at controlling and altering the behavior and attributes of prisoners, while also imparting skills to help them integrate back into the community.

Improving Rehabilitation Through Education and Training

In the Nordic countries (Denmark, Sweden, Finland, and Norway), North America, Australia, United Kingdom, and Ireland, prison systems generally recognize the need to provide prisoners with basic education – language, literacy, and numeracy. Prisoner participation in these forms of education is not mandatory. In the Nordic countries, the focus is on ensuring that prisoners have the same rights to education as do citizens outside prison, and that the prisoners have opportunities to participate in all forms of education, including vocational and higher education. In the United States, Canada, Australia, United Kingdom, and Ireland, the focus is on prisoners acquiring basic literacy and numeracy skills to enable them to participate in training that will provide them with the best prospects for employment on their release (see Table 1). In all countries, the aim is to use education and training as a pathway to rehabilitation and, subsequently, to reduce recidivism.

The Nordic Model: Ensuring that Prisoners Have Rights to All Forms of Education and Training

In Denmark, Finland, Norway, and Sweden education and training for prisoners is organized as part of the regular education system, with the same objectives as adult education in the community (Nordic Council of Ministers, 2005).

Table 1 Focus of prison education across various countries

Country	Focus	Provision
Nordic countries	Right to all forms of education and training in the regular education system	Schools in prisons or educational institutions in the community
United States	Focus on basic education and training as a route to further education and employment	Often in partnership with local schools and colleges
Canada	Focus on adult basic education pathways to assist with rehabilitation	
Australia	Focus on basic education and accredited vocational education and training to assist with employment outcomes	Registered training organizations using a learner-centered approach
United Kingdom and Ireland	A focus on providing skills for employment	Partnerships between government training organizations and prison systems

This approach is underpinned by the principle that the only deprivation that prisoners should suffer is the loss of liberty.

In Denmark, most prison schools are designated local adult education centers. The Prisons and Probation Service has traditionally employed prison teachers whose duties include both teaching and case management. When individuals complete a basic adult education program they become eligible for further vocational and educational courses. If a prisoner wishes to pursue a vocational program, while serving his or her sentence, this has to be done in cooperation with an enterprise in an industry outside the prison. Often, it is possible for the prisoner to complete the first parts of the program at the prison workshop and later have day-release privileges to participate in training and to work in the industry in question.

Prison education in Finland is organized in cooperation with and under the supervision of educational institutions in the community, which are responsible for pedagogical guidance and teacher management. Some teachers work both in prison schools and at other schools, some only at prison schools. In prisons, teachers are not normally involved in the general case management of prisoners.

Vocational education and prison work have always gone hand in hand. In recent times, there has also been a shift toward more apprenticeship training. In these programs, the foreman of the prison workshop gives the practical training, while the educational institution provides the theoretical education.

In Norway, prisoners are assured of all their rights as citizens. An upper-secondary school takes the overall responsibility for the education offered in each prison. The prison school operates as a branch of that main school. Formally, the teachers are in the employment of the main school. Many of the workshops in Norwegian prisons have been granted the status of educational workplaces, which means that they can train prisoners as apprentices and trainees. The prison workshop (or the prison) receives a grant of a specific sum per prisoner who has been accepted as an apprentice or trainee. If there is good cooperation between the prison school and the prison workshop, prisoners will receive theoretical education in the classroom and practical training in the workshop.

In Sweden, prisoners are also encouraged to participate in education and training that will help them reintegrate into society. The provision of vocational training in Sweden is based on an agreement between the Prison and Probation Service and the Swedish National Labour Market Administration. This agreement guarantees that prisoners will have the same rights to services and programs as other citizens (Nordic Council of Ministers, 2005).

Despite general support in the Nordic countries for prisoners having access to the same education as other

citizens, a study of prison education (Nordic Council of Ministers, 2005) has found that prisoners' rights to education and training are not clearly defined, and needed to be stipulated in the legislation. (The case in Australia is similar where only one state has legislation providing education as a right for prisoners; see de Graaf, 2007.)

The Nordic study also noted the low level of schooling of most prisoners, and supported enabling individuals to access education and training while in prison, to provide them with the skills and knowledge required for employment. Without these arrangements they would continue to be excluded from the labor market. The report also concluded that education and training in prisons should be considered as investment in crime prevention. It also recognized the need for teachers in prisons to identify and address the different learning needs of the individual prisoners, language, religion, and culture (Nordic Council of Ministers, 2005).

Prison Education in North America: A Focus on Basic Qualifications as a Route to Further Education, Employment, and Rehabilitation

There is no universal approach to prison education across the different states of the United States. The general focus is on ensuring that prisoners who participate in training should be able to complete their basic high school qualification with a view to providing them with better opportunities to move into further education and training or gain employment. This form of education is often provided in partnership with local schools and colleges.

The United States Re-entry Policy Council's Report (Council of State Governments, 2005) concluded that coordinated action by government agencies, nongovernment service providers, and the community is critical to support prisoners and ex-prisoners in getting and retaining a job, obtaining housing and healthcare, and establishing social and family support networks in the community. (The Council of State Governments is a nonpartisan, public, nonprofit organization that provides information, research, and training to state officials in all three branches of government in every state and US territory.)

Since 2004 a range of federal government grants have been available for communities to establish prisoner reentry programs, which focus on the community environment and the ex-offender's employment, education, health support and housing needs in that community. (The Prisoner Re-entry Initiative is supported by the US Department of Justice (DOJ), Office of Justice Programs (OJP), and its federal partners: the US Departments of Education, Health and Human Services, Housing and Urban Development, and Labor. This initiative is a comprehensive effort that addresses both juvenile and adult populations of serious, high-risk offenders.)

The most convincing evidence that education for prisoners has a positive effect on post-release behavior of prisoners in the USA was provided by the Three-State Recidivism Study. (The Three-State Recidivism Study was funded by the US Department of Education, Office of Correctional Education, and conducted in 1999 by the US Correctional Education Association; Steurer *et al.*, 2001.) This study, conducted in the states of Maryland, Minnesota, and Ohio, compared two groups of offenders, those who had participated in education while in prison and those who had not. It found a 30% reduction in recidivism for participants than for nonparticipants. This study was also designed to assess the impact of prison education on employment outcomes after release from prison. The authors concluded that education for prisoners enhances employment opportunities, decreases criminal behavior, and, in so doing, reduces the overall cost of crime to the community.

Another study by Aos *et al.* (2006) set out to measure the economic benefits of prisoner education. It found the marginal cost of vocational training (VT) programs to be \$1182 per prisoner. This was offset by the marginal savings to the taxpayer from lower criminal justice costs of \$6806 per prisoner. (The Prisoner Re-entry Initiative is supported by the US DOJ, OJP, and its federal partners: the US Departments of Education, Health and Human Services, Housing and Urban Development, and Labor. This initiative is a comprehensive effort that addresses both juvenile and adult populations of serious, high-risk offenders.) For general education, the marginal costs were \$962 per person and the taxpayer savings were \$5306. The study went further to add victim savings, finding the net benefit for VT programs was calculated as \$13 738 per inmate and for general education, \$10 669 per inmate. These were for reductions of 9% and 7% in recidivism for VT and general education programs, respectively.

There is also a substantial body of work from the Urban Institute that shows remedial intervention programs are required to help prisoners with low-level skills in reading, writing, mathematics, and oral communication to become law-abiding citizens in the community. (The Urban Institute is a nonpartisan economic and social policy research organization that publishes studies, reports, and books on timely topics worthy of public consideration.) These are also important in reducing recidivism rates. A study by Solomon *et al.* (2006) found that programs which were successful in helping ex-prisoners to find suitable employment and reintegrate into society typically provided intensive job-placement services and ongoing monitoring and support. In one pilot study, a network of employers has demonstrated their willingness to hire former prisoners. (The Returning Home: Understanding the Challenges of Prisoner Re-entry study was piloted in Maryland and was implemented in its entirety in Illinois, Ohio, and Texas.)

Individuals in Canadian prisons may access adult basic education programs at primary, secondary, and post-secondary levels, as well as vocational education programs. This provision was promoted by Porporino and Robinson (1992) who suggested that specific intellectual skills gained through adult basic education could equip offenders to deal more effectively with daily problems encountered in the community. These researchers noted that the sense of achievement and confidence that might result from successfully completing such a program could encourage offenders to make further positive changes in their lives. More recently, the Correctional Services of Canada Review Panel (2007) noted the need to make prison work more meaningful to prisoners to enhance their skills, hence employment opportunities when they are released from prison. The panel recommendations include a more structured workday to allow for the proper allocation between work, education, and correctional programs.

Prisoner Education in Australia: A Focus on Accredited Vocational Education and Training to Improve Employment Outcomes

In Australia, prisoners' participation in education and training and in prison work is voluntary and is encouraged by a payment dependent on good behavior and participation. While there is a major focus on basic education, especially English language and literacy, the aim is also to involve prisoners in training to help improve their labor-market outcomes. This approach was announced in the National Strategy for Vocational Education and Training for Adult Prisoners and Offenders in Australia which aimed "to provide adult prisoners and offenders with educational and vocational pathways which will support their productive contribution to the economic and social life of the community" (Australian National Training Authority, 2001: 3).

In all states and territories, accredited training for inmates is provided by local registered training organizations (which are subject to mainstream independent quality audits). Typically, they will use learner-centered approaches to encourage prisoners to engage in further learning that will help improve their employment prospects on release. Learning may be self-directed, undertaken in small groups, or while on the job when working in prison services or industries.

Connecting vocational education and training (VET) in prisons to the national VET system has a number of benefits. It enables prisoners to obtain nationally recognized, industry-specified qualifications, and in turn can be used to enhance the prospects for employment of ex-prisoners. Callan and Gardner (2005) found in their study of Queensland correctional institutions, 32% of those who did not

participate in VET before their initial release returned to custody within 2 years, while only 23% of VET participants returned to custody within the same period.

Giles *et al.* (2007), in Western Australia, found that significantly more prisoners undertaking VET courses expect better labor-market futures (such as work, more enjoyable work, and more money) than those undertaking nonvocational education courses or solely engaged in prison work alone. (Nonvocational courses are defined as educational activities without a direct link to the labor market, and mostly relate in adult- and community-learning contexts to arts, crafts, and leisure.)

In 2003, a government-commissioned study undertaken by the Australian Institute of Criminology assessed the interventions available for prisoners returning to the community (Borzycki, 2005). The study noted that prisoners were not a homogeneous group and that the needs of certain subgroups needed to be addressed. These included prisoners with mental health problems, those with an intellectual disability, females (especially those with dependent children), Indigenous prisoners, and those who have been incarcerated, or on remand, for very short periods of time. (Offenders charged but not convicted may be held in the custody of correctional services on remand while awaiting trial, when the judge has not granted them bail to live in the community (i.e., provide surety that they will appear at their trial).)

This evaluation also concluded that, if prisoners were to make successful reentry into society, effective through-care strategies were required. (Throughcare describes the process of delivering continuous care – providing consistent services and support to prisoners within and beyond prison in an holistic program of rehabilitation, ideally commencing at first contact between the offender and the justice system; see Borzycki, 2005.) It was essential that government agencies, nongovernment services providers, and the community organizations coordinated activities even before prisoners were released to ensure that ex-prisoners did not fall through the service gaps between agencies post-release (Borzycki, 2005).

Prison Education in the United Kingdom and Ireland: Partnerships between Government Training Agencies and Prison Systems

Findings about the high unemployment rate among ex-prisoners and subsequent higher reconviction rate among those who remain unemployed have influenced the development of major policies and programs dealing with prisoner education in the United Kingdom. In 2006, the government published its three priorities for reducing reoffending through skills and employment. These include engaging employers through a corporate alliance to employ ex-offenders; building on the offender learning and skills

service; and reinforcing the emphasis on skills and jobs (Department for Education and Skills, 2006).

In practice, this means a partnership between the National Offender Management Service and the Learning and Skills Council to design and fund the Integrated Offender Learning and Skills Services program, which caters to offenders in custody and in the community. The program aims to ensure that prison industries and workshops provide more meaningful work and prepare prisoners more effectively for jobs in the community. (Most prisoners are required to work while in prison: prison work usually refers to those activities which supply services to the prison such as laundry, kitchen and bakery duties, cleaning, gardening, and maintenance. This may also include horticulture, e.g., growing fruit and vegetables, or farming and animal husbandry such as dairy to provide food for prisons. Prison industries and workshops usually refer to specific industry work which supply goods or services to the outside community or customers on a commercial basis. These may include metal work production, plastic products, repairing electronic goods, or other manufacturing or catering services depending on the resources available in the prison.) This includes working more closely with employers to meet their needs. The hope is that employers would employ the prisoner on completion of their sentence. Prior to the integrated Offenders Learning and Skills Services program being implemented in August 2005, researchers from the Learning and Skills Development Agency conducted an interim evaluation of prototype activities in the three development regions. (The interim report titled: *Evaluation of Regional Plans for the New Integrated Offender Learning and Skills Service*, highlights findings and lessons learned from evaluation workshops and interviews with key stakeholders in each region (Walker *et al.*, 2005).) The evaluation noted that successful transition to the community can be helped by one-to-one support and motivation for prisoners who move through the gate.

Conclusion

The rights-based approach implemented in the Nordic countries and the more vocationally oriented systems adopted in the Anglophone countries are underpinned by different philosophies. However, their main aims are to engage prisoners in education and training to help them control problem behavior and prepare for a return to the community and to gain employment.

Prisoners are not a homogeneous group; therefore, it is important to tailor education and training to their individual needs, especially when these differ significantly from the mainstream.

Helping prisoners meet the variety of challenges they will face on release is often beyond the scope of

correctional service agencies. In this regard, VET can create opportunities for inmates to re-engage with learning, as well as provide them with opportunities for personal development.

Vocational Education and Training and the School-to-Work Transition

G Hayward, University of Oxford, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

It is taken for granted that the path from schooling to employment is an increasingly perilous one for young people compared to the situation only a few years ago. While the idea of a golden age is perhaps exaggerated, both academic researchers and policy commentators seem to agree that school-to-work transitions, defined here as the period between the end of compulsory schooling and the attainment of full-time stable employment (Ryan, 2001), have become more complex and difficult, at least for some young people (cf. Furlong and Cartmel, 1997; OECD, 2006, 2007; Ryan, 2001; Vickerstaff, 2003).

Indicators of School-to-Work Transition Problems

A wide variety of indicators are used to compare and contrast school-to-work transition processes across Organization for Economic Cooperation and Development (OECD) countries (see Quintini and Martin, 2006). On an average between 1995 and 2005:

- Youth unemployment rates fell by 0.8 percentage points.
- The youth to adult employment ratio has risen from 2.4 in 1995 to 2.7 in 2005, indicating that the relative position of youth has deteriorated in more than two-thirds of OECD countries.
- Long-term unemployment declined, although some Eastern European countries and Japan have seen rises.
- Youth employment rates deteriorated. While this may be a good thing if it indicates increased time in education, in many countries the fall was associated with a rise in youth unemployment.
- The proportion of young people Not in Education, Employment or Training (NEET) fell between 1996 and 2003 but remains high at 17% on average for 20–24-year-olds.

The outflow from NEET status is high in some countries, such as France, Finland, and the United States so that this status is of short duration. In some countries, however, a proportion of young people are long-term NEET (more than 5 years) – in Italy 30%, Greece 20%, and more than 10% in several other European countries. A major contributor to these high figures is school failure: on an average

more than 14% of young people in OECD countries leave school without upper-secondary qualifications. These young people are overrepresented in the NEET group.

Even for those who acquire adequate levels of qualification, transition to employment can be long in European countries, an average of 2 years after leaving school. Participation in temporary and part-time work by youth has increased, particularly for initial labor-market entrants. This may not be a problem if such jobs represent a first step to more stable employment, as is the case in many countries. In others, such as Spain, temporary work traps are more prevalent for young workers. Young people are also more likely to experience low pay. However, outflow from these jobs to better paid ones is high, certainly higher than exit from unemployment: it is better, in terms of progressing in the labor market to have a low-paid job than no job at all (Quintini and Martin, 2006).

Rates of over-education, when young people have jobs which require much less skill than that acquired in initial education, have also increased: one in five youth in OECD countries was over educated in 2005. The prevalence of over-education is much higher among young workers in part-time and temporary jobs compared to those in full-time and/or permanent employment. Young people are also more likely to engage in job shopping as they seek to match their skills to employer demands – a process leading to job churn which may be an indicator of healthy labor-market functioning rather than necessarily being a problem.

School-to-work transition rates vary along predictable lines of disadvantage with, in most cases, young people with low educational attainment, from poorer socioeconomic backgrounds, and minority ethnic groups experiencing greater challenges than their more privileged counterparts. In some countries, young women remain at greater risk of unemployment and lower wages than men. Aboriginal young people often face the greatest disadvantage (OECD, 2008a).

Collectively, trends in these various indicators paint a complex picture but they speak to the continuing challenge of school-to-work transition for some young people. However, it would be inaccurate to speak of a crisis. A vast majority do make a successful transition to stable employment, but a small and important minority of disadvantaged and marginalized youth struggle (Marks, 2005; Hayward *et al.*, 2008; Pring *et al.*, 2009).

Policy Responses

It is important to recognize that no country employs a single type of policy response, such as providing improved access to vocational education and training (VET), in order to improve transitions into the labor market for young people. Other policy measures may include macroeconomic measures to stimulate economic growth, labor-market deregulation, subminimum wages for young people, promoting early retirement, and providing subsidized employment in addition to a range of employment and training policy initiatives. Which of these components is employed in the policy mix changes over time and across countries depending upon their particular national congeries of school-to-work transition institutions (such as school employer recruitment networks and mass apprenticeship), macroeconomic climate, stage of the business cycle, labor-market structure, experience-based trends in labor demand, and national pay determination systems. In turn, these can be linked to larger cultural processes such as the model of capitalism and associated forms of the welfare state that have developed in different countries (Hall and Soskice, 2001; Iversen, 2005). However, given weak macroeconomic growth and the historically poor performance of labor-market policies to tackle youth joblessness (Ryan, 2001), attention has increasingly focused on education and training interventions. (Evaluating the effectiveness of any policy measure is beset by a myriad of measurement and econometric analysis problems. These lie beyond the scope of this article but are well reviewed by Grubb and Ryan (1999) and Ryan (2001). Strong claims about the effectiveness of particular interventions need to be treated with caution unless experimental designs have been used or appropriate statistical methods adopted to deal with selection bias, such as Heckman two-stage procedures.) These form the focus of the remainder of this article.

Theories of Action

The theory of action underpinning VET reform is predicated on there being a vocational effect, an improvement in an individual's chances of making a successful school-to-work transition compared to those leaving with lower-secondary education or following an academic upper-secondary education (Ianelli and Raffe, 2007). The nature of the predicted vocational effect varies across theoretical traditions. Human capital theory would predict a positive effect in terms of improved employment and earnings as a result of further investment in education. By contrast, signaling and job queue theories predict a negative effect, as VET participation stigmatizes young people relative to their academic counterparts. Network theories would predict a positive effect if VET participation affords access to networks that support transition to employment. Social reproduction

theorists argue that VET participation simply cools out lower attaining, primarily working-class youth (the diversion hypothesis). Such young people are socialized into economic roles that, while affording transition into employment (the safety-net hypothesis), have little effect on other labor-market outcomes such as wages or occupational status (Ianelli and Raffe, 2007).

Such predictions are highly contingent on the distinction between academic and vocational programs, and employers' preferences for different types of qualifications. Furthermore, the underpinning processes are not mutually exclusive but operate differentially in different national transition systems constituted by the institutional and structural arrangements which shape young people's transitions. Such arrangements include distinctions between internal and occupational labor markets, the degree of labor-market regulation, the degree of stratification of the education system, the linkages between education systems and the labor market, and the occupational specificity of VET.

Schröder (2004) characterizes such transition regimes in a two-dimensional model: one dimension is formed by the strength of linkage between the education system and the labor market, the other by the degree of labor-market regulation. Education systems with strong linkages to the labor market are characterized by a high degree of occupationally specific human capital formation, strong employer/trade union engagement with and influence over the VET system, and good communication of labor-market signals to the VET system. Such linkage should produce a positive vocational effect by enhancing human capital formation in a way that employers value by developing knowledge and skills needed in the labor market, and reducing information asymmetries that stigmatize VET graduates, as employers have direct knowledge of the content of the programs. Regulated labor markets are those where contracts and wages are strictly regulated by law or by collective bargaining, flexible labor markets are then the converse of such arrangements. Taking account of such dimensions is crucial in evaluating the impact of VET programs.

Improving Retention Rates in Full-Time Education

School-to-work transition problems are particularly pronounced for the least well educated in most countries. Data for 2005 indicate that across the OECD, as a whole, completing upper-secondary education reduces the unemployment ratio of nonstudents as a percentage of the 20–24-year-old age cohort by 7.3% and by 7.1% among 25–29-year-olds. In most OECD countries, completing tertiary education reduces this ratio further for 25–29-year-olds, but this is not the case in Greece, Italy, and Turkey, and is only the case for young women in Spain (OECD, 2007). Thus, while more education and training is a usual prescription for problems of school-to-work

transition, it is not a panacea. This is largely because such policy prescription does not pay sufficient attention to structural macroeconomic problems that affect the supply of jobs, and the interaction of macro- and microeconomic factors with the sustainability of certain types of training provision, for example, apprenticeship in Germany.

The variation in indicators of transition success across countries indicates the problems in making direct comparisons of the effectiveness and efficiency of different VET initiatives in supporting young people in their journey from education to the labor market. Nonetheless, one of the strongest findings in the economics of education is that additional years of education is correlated with better transitions into the labor market, both in terms of securing decent, stable employment and improved future earnings. Most OECD countries have witnessed a sustained increase in upper-secondary educational enrolments and attainment over the last three decades. However, the nature of upper-secondary education institutions and curricula may vary radically between countries with historically similar success in promoting successful school-to-work transitions. Contrast, for example, Germany with its tradition of part-time VET grounded in apprenticeship with Japan's full-time upper-secondary education system providing mainly general education (Ryan, 2001).

The last three decades have witnessed both the introduction and the substantial reform of existing VET programs to effect greater postsecondary enrolment and graduation rates by providing more practical and motivating curricula. In addition, some countries are turning to mandates designed to force participation. For example, the Netherlands 2007 Qualification Law (*Kwalificatieplicht Wet*) requires young people who have acquired a basic education qualification (the *Startkwalificatie*, the equivalent of an upper-secondary degree) to follow a full-time education program until the age of 18. For those aged 18–27, who have not successfully completed secondary education, the intention is to introduce mandatory study/work programs by 2009 (OECD, 2008b). Similarly, English policymakers intend to raise the compulsory participation age from 16 to 18 years by 2015. Such mandates speak to the challenge of encouraging voluntary participation in post-secondary education among some early school leavers even when offered more VET provision.

The impact of such vocational curricula and work-based curricula are difficult to evaluate statistically, given the likely effect of selection around unobservables (ability, motivation, and social class), the almost total lack of experimental studies, and the paucity of prior labor-market experience to use in econometric models (Ryan, 2001). In addition, the necessary longitudinal data required to control for selection bias are almost always too time limited to evaluate the longer-term impact of participation in VET on outcomes, such as occupational status and lifetime earnings. Where long-time-run longitudinal data are available, for example, from the UK's National Child Development

Studies, then the evidence indicates larger returns to participation in general education than in VET programs, but positive returns to participation in most upper-secondary VET provision when compared to those not undertaking any upper-secondary education. Such effects are stronger for employment than for other labor-market outcomes, such as occupational status and wages. Further, the sign and magnitude of the effects varies by gender and the type of vocational programs followed and the qualifications obtained (Dearden *et al.*, 2000). Such evidence mirrors that from the US which suggests that traditional vocational curricula are only selectively associated with higher pay, for example, females taking commercial courses and where there is good job matching (Ryan, 2001). Such weak signals from the labor market about the value of vocational qualifications can reduce the incentives to participate (Keep, 2009).

The lack of any general pay gains from participation in vocational education leads to questions about its efficiency given the higher costs associated with vocational as compared to general education programs. Nonetheless, it does appear that participation in upper-secondary VET does produce a positive vocational effect for some young people under some circumstances (given data limitations). In particular, there seems to be robust evidence for strong employment benefits for young people who have participated in postsecondary VET programs. However, evidence from Australian research utilizing the Longitudinal Survey of Australian Youth disputes the generalizability of employment gains from undertaking postsecondary VET. Experience in the labor market, including part-time work, in the first year after school for nonuniversity-bound youth increases the odds of being employed 4 years later compared to participating in nonuniversity study (Marks, 2005). Using the same data, Anlezark *et al.* (2006) found that participation in school VET programs increased retention between years 10 and 11 in Australian secondary schools but reduced retention between years 11 and 12. While transition to employment, at a time of a buoyant labor market, was smoother for those who had undertaken VET in upper-secondary school, the effect diminished with time. The research also found that school VET programs did not align well with out-of-school VET programs that may reflect better real labor-market training needs.

Most research provides very inconclusive evidence about the significance, size, and direction of the vocational effect. In general, the effect is positive for those completing upper-secondary VET programs compared to those with lower-secondary education alone, but negative relative to general upper-secondary education. Transition rates to higher education are lower for those with VET rather than general upper-secondary qualifications (Hölscher *et al.*, 2008). There is often a positive effect in terms of entering employment, but a highly variable effect on wages and occupational status depending upon the type of qualification obtained, mode of study, and gender (Dearden *et al.*, 2000; McIntosh, 2007; Jenkins *et al.*, 2007).

The only possible conclusion to be drawn is that there is no consistent association between participation in upper-secondary VET programs and subsequent transitions to the labor market. This is not to deny the positive motivational effects that can be provided by access to more vocational programs but it does call into question general conclusions of the effectiveness of such reforms in promoting more successful school-to-work transitions (Stanley, 2007). In particular, it should raise questions about their efficiency given the higher costs associated with providing VET.

In part, the different conclusions reached by different studies may be a product of the problems of data limitations and selection bias (Ryan, 2001, 2003; Ryan and Grubb, 1999). In part, they reflect inadequate attention being paid to the characteristics of transition systems in cross-national studies. Ianelli and Raffe (2007) focus on education-labor-market linkages as key determinants of national transition patterns. They distinguish between VET systems which have an employment logic aligned with Schröder's strong linkage and those with an education logic where links to employment and the differentiation between general and vocational education are weaker. Such a framework allows for the development of both characterizations of transition systems in different countries and stronger hypotheses about the relative size of the vocational effect under different transitional arrangements. These hypotheses can then be assessed using econometric techniques, provided appropriate and adequate data are available. It remains too early to assess fully the promise of this type of approach but initial results at least point to interesting new insights (Ianelli and Raffe, 2007; Schröder, 2004).

Apprenticeship

Apprenticeship clearly follows an employment logic but is also often used as a vehicle to support general education for young people. The design of apprenticeship provision varies considerably between countries. For example, in the UK there is no requirement for school-based part-time study as part of an apprenticeship program in contrast to the dual systems of Austria, Denmark, Germany, Norway, and Switzerland. The extent of participation in apprenticeship also varies considerably between countries, providing the majority of VET opportunities in Germany but a minority in Australia, France, the Netherlands, and the UK.

One of the enduring debates about vocationalism is the relative benefits of full-time VET delivered in schools and colleges, and apprenticeship systems in supporting successful transitions to employment. The historical success of apprenticeship in supporting positive school-to-work transitions in countries, such as Germany and Switzerland, is often taken as *prima facie* evidence of its efficacy. Australian evidence also points to the improved employment outcomes is associated with participation in apprenticeship and traineeship compared to participation in upper-secondary VET programs, but only for women (Marks, 2005).

Strong rhetorical messages are used to promote the advantages of apprenticeship both to employers and young people in the UK (Hayward *et al.*, 2004, 2005). Econometric analysis that seeks to directly compare the relative merits of school-based VET and apprenticeship is, however, relatively sparse. It is best where apprenticeship and school-based VET programs lead to the same qualifications, as can be the case in France, the Netherlands, and the UK. However, selection problems remain; for example, negative selection into apprenticeship programs by ability but positive selection by motivation in France. In the UK, there seems to be differential selection effects by ability depending upon the sector and occupation (Hayward, 2005). The alternative comparator group is those who enter the labor market and/or labor-market programs rather than remain in upper-secondary education. Here, apprenticeship performs well, both in terms of employment and improved wages.

Cross-national comparisons indicate a strong employment effect associated with participation in apprenticeship in countries with larger apprenticeship systems, with youth accessing jobs in skilled occupations in high-wage sectors. Micro-econometric evidence suggests that in France, the UK, and the US apprenticeship leads to improvements in early labor-market experiences for some young people relative to full-time VET programs. However, in France, acquisition of a vocational qualification matters more than the way it is obtained for longer-term outcomes. In the USA historically, apprenticeship has provided increased wage premia relative to full-time tertiary education but this may be due to the concentration of apprenticeship in highly unionized manual crafts in the construction sector. With the exception of Germany, in general, apprenticeship does less for young women than men, although in the case of the UK this may be in part the result of not controlling for occupational concentration of female apprenticeship in areas such as hairdressing. In the UK, the positive employment benefits of apprenticeship for young men only apply in some sectors, primarily those with a history of apprenticeship provision (Ryan, 2001; McIntosh, 2007).

Overall, the message about the benefits of apprenticeship is not a general one. It does seem to provide better early career opportunities and experiences but the subsequent impact of participation in apprenticeship on wages and occupational status outcomes compared to those obtaining vocational qualifications through school-based VET provision is less clear and often negative for some groups, such as women, in some countries. Compared to early participation in the labor market and labor-market VET programs the outcomes of apprenticeship are positive (Ryan, 2001).

Labor-Market Policies

To combat joblessness, a range of labor-market policies has been implemented. Passive policies aim at deregulating

the labor market to make it more flexible in order to help people move into work, for example, increasing pay flexibility. Such policy interventions enable employers in offering younger workers lower wages, and weaker employment contracts often on a fixed-term basis. The outcome of such policies may have led to improved employment prospects for young people, as is claimed for Canada (OECD, 2008a). But problems of measurement and selection effects make evaluation results difficult to interpret (Ryan, 2001). Other passive labor-market measures involve changes to rules about access to unemployment and other social security benefits, for instance, in the UK changes in such rules make those aged less than 18 years ineligible for unemployment benefit.

Active Labour Market Programmes (ALMPs) are more voluntary policies, often targeted at specific groups which aim to promote labor-market entry and access to better employment. They include a variable mixture of training and basic skills (language and mathematics) education, work experience, job-search assistance, and direct job creation. Only education and training measures are considered here. Education and training form the active measure which attracted the greatest investment in the European Union 15 (EU-15) countries in 2003 and the second most important in accession states after job creating through subsidized employment and public work opportunities (Descy and Tessaring, 2007).

The shape and role of ALMPs aimed at youth varies depending upon a country's transition structure. For example, there seems to be a greater propensity to intervene in transitions in country's with stricter labor-market regulation unless the barriers to entry are reduced by strong school-employment linkages. Those countries with the highest barriers to labor-market entry and with subsequent large-scale ALMPs tend to target broad groups of those at risk of making poor transitions (Schröder, 2003).

European-training-based ALMPs do seem to yield more positive results in most cases compared to other types, especially job-creation programs (Hujer *et al.*, 2004). However, Martin and Grubb (2001) report that although training measures are the most expensive types of ALMPs, their efficacy is far from clear. Descy and Tessaring's (2005) review of selected studies carried out in North European countries suggest that it is difficult to draw firm conclusions about the effectiveness of training measures from evaluation results. These are contingent on external labor-market conditions and the type of target group.

Conclusions

Some young people still find it difficult to make the transition from schooling to work. The magnitude of this effect varies between countries and may be linked to the regulatory frameworks surrounding their labor markets and other aspects of the design of their national transition

systems. For most young people this is not a crisis but for disadvantaged youth the transitions can be especially problematic. Furthermore, we still have much to understand about the reasons for cross-national variation in school-to-work transition indicators, and this requires further research working with better-quality longitudinal data sets.

Despite widespread support for the further development of upper-secondary VET programs to retain young people for longer in the education system, the impact of such initiatives is highly variable, often zero and sometimes negative. Apprenticeship does seem to provide a more certain route to employment, but it still has certain drawbacks and is proving difficult to sustain in the face of global economic pressures. VET provided through ALMPs is the most variable and ambiguous in its impact. Collectively, and given the expense of implementing good-quality VET programs, the research calls into question the effectiveness and efficiency of VET in supporting young people experiencing difficulties with school-to-work transition to enter the labor market. Nonetheless, providing more VET remains a popular policy choice because of the political need to do something about youth joblessness among certain segments of the population, and the undoubted motivational impact of more practical learning opportunities for many young people.

Part of the problem with supporting policy learning in this area is the way that VET initiatives are often designed, implemented, and evaluated. Often such initiatives are conceived as entities that can be developed quickly, implemented alongside other social institutions, and then evaluated independently of those other social institutions. This is what Grubb and Ryan (1999) term as program view, whereby VET programs are developed and evaluated as self-contained and independent entities. Energy is put into the continual development of new initiatives and their frequent abandonment after relatively short periods of time when program evaluation indicates their relative ineffectiveness.

This can be contrasted with a systems perspective, which views VET programs developing within a larger system that evolves synergistically over time. Energy is now devoted to institution building over a longer period of time that focuses on the linkage between learning opportunities that enables individuals to develop the knowledge, skills, and competences needed to enter and be successful in the labor market over the course of their working lives. Systemic evaluations then focus on a program's success (and the reasons for its success) in terms of articulation with other VET programs, linkage to employers' recruitment and hiring practices, its relationship with other established institutions and practices, and its sustainability and potential for replication.

Apprenticeships

Apprenticeship is an institution that, for centuries, has successfully effected entry into working life for young people, and has also been responsible for the maintenance of the skills base of many national economies. Apprenticeships began in medieval Europe when young people went to live in their masters' houses to learn trades, over a period of up to 7 years. Although apprenticeships have become less demanding of both master and apprentice, they have survived in many countries over the centuries (Lane, 1996). A typical dictionary definition of an apprentice (*Chambers Twentieth Century Dictionary*: 6) is "one bound to another to learn a craft," an apprenticeship is "the state of an apprentice: a time of training for a trade, or for any activity." There are two key points in these definitions: one is the employment relationship, and the closeness of that relationship. The apprentice is bound to the master, often by a formal contract and by unwritten understandings as well. The other key point in the above definitions is time: the focus is not only on what is learned, but also on the time period over which it is learned.

This article examines the meaning of apprenticeship, perspectives in the apprenticeship literature, the different nature of apprenticeship in different countries, and some challenges with which apprenticeship systems are grappling.

Formal and Informal Meanings of Apprenticeships

The term apprenticeship is used in many contexts. It is often used informally to describe any process of learning a job or a skill from another person, generally in the context of an older or more experienced person mentoring or coaching a younger and more junior person. It is also

used to describe processes of learning at work which are primarily work-based but include elements of formal off-the-job learning. For example, professional occupations such as nursing, accountancy, and law formerly followed this model, although they tend to be university-based these days. However for the purposes of this article we confine the discussion of apprenticeship to formal systems that aim to develop skilled workers, and that are in occupations serviced by the vocational education and training system rather than by university education.

The essential components of a formal apprenticeship are generally understood to be:

- a training regime set up by, or with the approval of, governments;
- a combination of off- and on-the-job training;
- the assumption of responsibility by the employer for the development of the apprentice; and
- the award of a qualification and/or licence and/or some other recognition that enables an occupation to be practiced independently once the apprenticeship is successfully completed.

Apprenticeships are often, but not always, intended for young people rather than older people, and often, but not always, incorporate a close relationship between a novice and a particular expert worker. They normally, but not always, involve the apprentice being actually employed in the enterprise where on-the-job training is carried out.

Perspectives on Apprenticeships

The literature reveals six major ways of looking at apprenticeships. These different viewpoints to some extent reflect the presence of different stakeholders in the

apprenticeship system, such as trade unions, educationalists, training policymakers, and youth commentators, and policymakers. These viewpoints are discussed briefly below.

Apprenticeship as a Passage to Adulthood

Many writers (e.g., Hamilton, 1990, in the United States and Sweet, 1995, in Australia) have been concerned with the uncertain transition from school to work for many young people. For writers with these concerns, apprenticeship is seen as being a safe way for young people to enter employment, providing job security and guaranteed development of skills. The notion of passage to adulthood incorporates the key point of time served. Worries about young people's employment future have become less prominent in some economies (e.g., UK, Australia) that have experienced economic boom during the twenty-first century, but in some countries that still have high unemployment, such as Germany, this issue is still of importance (Deissinger and Hellwig, 2005).

Apprenticeship as a Means of Industry and National Skill Formation

Gospel (1994: 51) maintains that "apprenticeship has constituted a collective source of skill formation supplying recognised skills to firms of all sizes." Many firms have long-established apprenticeship systems; in Australia and the UK, these systems became less important during the 1980s, partly as the result of economic recession but such systems have become re-established in many major Australian companies over the past decade. Governments have a considerable interest in monitoring and encouraging apprenticeships to assure the maintenance of the skill base of economies. However, not all countries use apprenticeship as a means of national skill formation. In the US, for example, the apprenticeship system is rudimentary and confined to only a few trades; there are fewer than half-a-million apprentices and they comprise only 0.3% of the workforce (Glover *et al.*, 2007: 477–478). Some authors regard the institution of apprenticeship as outdated and wasteful as a means of skill formation, because of the long time taken for apprentices to become fully skilled (e.g., Sweet, 1987). It has been argued that apprenticeship training does not coincide with the demand for skills: apprenticeship commencements always fall during periods of recession, but 3 or 4 years later, when apprentices finish their time, the recession may have ended and there is thus a skills shortage. This argument is, of course based on the premise that apprentices do not start doing useful work until the day they qualify, whereas many studies (e.g., the classic English study undertaken by Venables, 1967 and an Australian study by Smith, 1998) indicate that apprentices perform useful work from their early days.

Occupational Identity and Being a Craftsman

The completion of an apprenticeship is felt to confer a status in society (Unwin, 1996). An important part of apprenticeship is assuming this status. Shields (1992) maintains that, in the nineteenth century, "membership of the trade carried strong ideological and moral overtones ... 'the time-served man (was) set apart from 'inferior' workers.'" Therefore, apprentices have traditionally been taught not only the skills involved in the trade but also how to become a member of that trade (Venables, 1967; Smith, 1992). As McIntyre (1996: 44) puts it, "A person assumes the identity of (a carpenter, for example) and learns both to carry out activities (the practice) and learns the meaning of the practice." Becoming a tradesperson is signified by such rites of passage as acquiring the tools of one's trade and wearing particular types of clothing (Riemer, 1977). Winning (1993) goes further, suggesting that choosing to become a tradesperson involves the choice of a particular way of life. Brown (1997), however, has argued against assuming that occupational identity is central to all apprentices and tradespeople.

Apprenticeship as a Device for Occupational Restriction

Apprenticeships are often described, particularly in the industrial relations literature, as being a device for restricting the entry to certain trades, to ensure that the price of adult or skilled labor is kept artificially high. To assist this process, the number of apprentices is restricted, the employment of non-apprentice junior labor is prohibited, and there is a lengthy time needed to become skilled (Shields, 1995). It is often maintained that the skill in apprenticed occupations is socially constructed. Apprenticeship has been seen as a form of ritual servitude that legitimated an illusory division between skilled and unskilled work (Shields, 1995: 239). Feminist critiques focus on the fact that in Anglophone countries it is mainly male trades which have had the power to construct their trades as skilled while the skill involved in female work is undervalued (Korczynski, 2005). Littler (1982: 10–11) has provided a seminal discussion of this topic from a labor-process standpoint. During World War II, in Australia as in many other countries, women undertook many of the work roles previously undertaken by men who had been apprenticed. After the War, women were forced out of these roles and those people who had learned some of the job roles without undertaking a full apprenticeship were dismissively described as dilutees (Ray, 2001).

Economic Arguments about Apprenticeship

According to human capital theory (e.g., Becker, 1964), apprenticeship is a form of general training, and so the

cost should primarily be borne by the employee not the employer, in the form of low wage rates while in training. Historically, apprentices were often not paid (Lane, 1996), since the master provided all living expenses. Indeed, parents in medieval England often paid substantial sums of money to employers who were willing to train their children in the more desirable trades (Lane, 1996: 19). However, in order to attract people into apprenticeships, apprentices in the modern day generally have to be over-paid in terms of what human capital theory sees as their worth to employers. Without governmental subsidies, it is argued, employers would not employ apprentices. It is also argued that it is for this reason that apprenticeships are so long; employers require a long period of indentured service to recoup some of the loss in the early years. Empirical studies have been undertaken to investigate economic reasons for hiring of apprentices; for example, Dockery *et al.* (1998). Such studies generally conclude in bewilderment that, since there is little economic benefit to an employer in taking on an apprentice, other, non-economic factors must be involved. And, indeed, studies have shown that employers who take on apprentices tend to have a strong normative commitment to the notion of apprenticeships and the maintenance of a supply of skilled workers in the appropriate industries (e.g., Smith, 1998). Thus, it is doubtful therefore whether the level of wages of apprentices is really a serious issue either one way or the other. However, there seems to be more concern about the cost-benefits of apprenticeships in the dual-system countries (Walther *et al.*, 2005; Grollmann and Rauner, 2007).

Pedagogical Issues

Although learning is the basis of apprenticeship, there is relatively little literature on this issue compared with some of the other perspectives. Much of the pedagogical literature on apprenticeship focuses on the relationship between off-the-job and on-the-job learning. It is generally held that on-the-job training provides practical learning while theoretical learning is best undertaken off the job (Uwameiye and Iyamu, 2002). It is sometimes said that it is ideal for on-the-job experiences to enable apprentices to practice the exact skills that are concurrently learned at the training provider, but Australian studies of on- and off-the-job learning (e.g., Harris *et al.*, 1998; Smith, 2002) tend to conclude that apprentices are well able to cope with learning that takes place in different arenas and are able to integrate these into their own practice of the trade. There have been some studies specifically of off-the-job learning in apprenticeships; one interesting but not altogether surprising conclusion is that apprentices tend to prefer hands-on experiential learning rather than theory-based learning (Smith, 2003). Studies of on-the-job learning emphasize the progressive skilling of

apprentices (Smith, 1998), the introduction to a community of practice (Unwin and Fuller, 2003), and the importance of the planning of the work apprentices should do so that they gain a wide range of experiences. Such arrangements are described as expansive rather than restrictive learning environments by Unwin and Fuller (2003).

Different Models of Apprenticeships

Different countries have different expectations of apprenticeships and therefore regulate and manage their apprenticeship systems in different ways. This section provides a discussion of five issues: qualifications, employment status, examination of proficiency, coverage of occupations, and funding regimes. A case study of Australia follows which illustrates how these different issues interrelate to form a system of great complexity.

Qualifications

Earlier in this article, we have included the award of a qualification and/or licence as a common feature of formal apprenticeships in the modern era although in some countries such as Nigeria there is still no qualification involved (Evawoma-Enuku and Mgbor, 2005). In Australia, all apprenticeships and traineeships (see section entitled 'A case study of apprenticeship systems: Australia', for a discussion of traineeships) provide a formal qualification, usually at Certificate III level or higher. The curriculum for qualifications for apprenticeships and traineeships consists of units of competency taken from the sets of competency standards in national training packages (Smith and Keating, 2003). In general, apprentices attend a technical and further education (TAFE) college (TAFE – the public providers) or a private training provider on 1-day-a-week basis or for block periods, for 2 or 3 years. Trainees may also attend college in this way, but it is becoming increasingly common for trainees to be trained 100% on the job. However, even in the latter case, a training provider (known as a Registered Training Organisation (RTO)) must oversee the training and is responsible for the assessment and the award of the qualification. Similar diverse systems apply in the UK, with various ways of gaining the required qualification of a national vocational qualifications (NVQ) (Fuller and Unwin, 2007). In Germany, by contrast, the availability of qualifications is more regulated. Under the dual system, all apprenticeships involve off-the-job training and such training is only provided by public schools. In Australia and the UK, there is not usually any regulation associated with the on-the-job training provided by the employer, but in Germany there is regulation of the on-the-job training (Grollmann and Rauner, 2007).

Employment Status

As mentioned previously, most apprenticeships involve a contract of employment so that an apprentice is primarily a worker rather than a student. In some countries, training providers take a more central role. In the Netherlands, for example, apprenticeships may be training-provider-based or work-based; in training-provider-based apprenticeships, on-the-job training takes place in work placements rather than as a formal employment contract (Onstenk and Blokhuis, 2007). In Australia, would-be apprentices may commence part of the apprentice qualification through a pre-apprenticeship course at a training provider, (Dumbrell and Smith, 2007) but must gain employment before proceeding very far toward the qualification. It is thus assumed in Australia that the qualification is only of full utility when combined with considerable time spent on the job learning at work. In Germany, high unemployment has led to the growth of off-the-job training in full-time vocational schools alongside the dual system route, but the former suffer from a perception of low status (Deissinger *et al.*, 2006).

Examination of proficiency

In Australia, the completion of an apprenticeship formerly involved a trade test administered by the state training authority, along the lines of the final examinations managed by the Chambers in Germany (Grollmann and Rauner, 2007) but generally these days, in Australia, it is assumed that completion of the appropriate qualification negates the need for an additional trade test, although this assumption is not unchallenged. The award of a license to practice a trade is currently, in Australia, a separate process from the award of the qualification, with licensing bodies guarding their prerogative to decide who can practice a trade, although there have been attempts by national governments over the past 20 years to align the qualification-awarding and the licensing processes. In the UK, there has been some controversy over whether an NVQ is sufficient to pronounce an apprentice proficient.

Coverage of Occupations

As Western economies continue to move away from primary and secondary industries toward the service sector (Triplett and Bosworth, 2004; Barnes and Kennard, 2002), the apprenticeship system in some countries has struggled to meet these changing times. In the dual-system countries, apprenticeships have always covered a range of occupations including the service sector, and there is a system in place to incorporate new occupations into the apprenticeship system. But in other countries such as the UK, Australia, and the United States, systems have

needed to adapt and change. In Australia, the introduction of traineeships has addressed the need for apprentice-like arrangements in a wider range of occupational areas. Traineeships are discussed in detail in the Australian case study below. A similar process was undertaken in the UK, where modern apprenticeships (Fuller *et al.*, 2005) were introduced in the early 1990s by the UK government to broaden the reach of apprentice-like arrangements. As in Australia, the UK modern apprenticeships also had roots in the youth training schemes introduced at times of high youth unemployment, particularly in the early 1980s. This made them initially unpopular (Fuller *et al.*, 2005). In both of these countries, the newer apprentice-like arrangements have subsequently been moved under a broad umbrella simply called apprenticeships. In the US, only a limited range of occupations is covered (Glover *et al.*, 2007).

Funding Regimes

In order to support their apprenticeship systems, countries have many methods of funding apprenticeships. These funding arrangements are designed variously to encourage employers to employ apprentices, to provide funds for training providers to undertake the off-the-job training, and (for individual apprentices) to provide a living allowance for apprentices where there are no wages, or to provide supplementation of low wages. For example, in Nigeria, apprentices receive a monthly stipend equivalent to about 15% of the national minimum wage) and employers receive a payment for training an apprentice (Evawoma-Enuku and Mgbor, 2005). In the UK, apprentices who do not have employed status receive a training allowance (Fuller and Unwin, 2007) and funding is given to training providers under contract to the government. The Australian government provides funding to employers and training providers, as described in the detailed case study below, and also provides minor allowances such as tools allowances and living-away-from-home allowances for apprentices who must move to find employment as an apprentice. By contrast, in the US there is little government investment in apprenticeships. The federal government sponsors some minor programs and some state governments provide some funding for off-the-job training; otherwise, all costs are borne by the employer and sometimes trust funds created from a levy of employers (Glover *et al.*, 2007: 478).

A Case Study of Apprenticeship Systems: Australia

This section provides a description of the apprenticeship system in Australia, illustrating the interrelationship

between the six issues discussed in sections 'Apprenticeship as a passage to adulthood' through 'Pedagogical issues' and the additional points raised in sections 'Qualifications' through 'Funding regimes' that mark the differences among countries' systems. In Australia, the institution of apprenticeship is currently very strong. Twenty years ago apprenticeships in Australia were confined to a defined number of occupations, mainly male manual workers, but the advent of traineeships (which are included with traditional apprenticeships under the broad umbrella term Australian apprenticeships) has expanded both the numbers of apprentices and the types of jobs which have contracted training associated with them. This success story has been the product of very conscious planning by the federal government including the introduction of new agencies to promote apprenticeships and manage their quality. These agencies sit alongside preexisting organizations and mechanisms at the federal and state level.

In Australia, the apprenticeship system involving 3- or 4-year contracts of training in the traditional trades has existed since first settlement by Europeans. In 1985, short, 1- and 2-year traineeships (Kirby, 1985) were introduced. Traineeships expanded into many occupational areas that had not previously supported contracted training such as retail, tourism, and hospitality (Robinson, 2001). In 1997, the traditional apprenticeship and the traineeship systems were brought together under the umbrella of the new apprenticeship, now called Australian apprenticeship, system, although in common usage they are usually referred to separately (Dumbrell and Smith, 2007). The numbers of Australian apprenticeships escalated dramatically from about 120 000 in 1995 to over 400 000 by 2003, fueled mainly by traineeship growth. Around 35% are 4-year apprentices in traditional trade areas while the remainder are trainees (NCVER, 2004). The development of training packages – national sets of competency standards – for these occupational areas also stimulated growth, providing the basis for apprenticeship and traineeship qualifications. Training packages are developed by national industry skills councils, each overseeing a range of industry and occupational areas.

The proportion of workers in Australian apprenticeships represents 3.5% of the working-age population, one of the highest rates of contracted training in the developed world (Walters, 2003). This favorable picture is in part related to the strong Australian economy. However, the high proportion of workers in apprenticeships is also the result of very deliberate government policies over the past 20 years. These have included the widening of apprenticeship opportunities to part-time and mature, aged workers, and the availability of state government funding for off-the-job training by private RTOs as well as by the public provider, TAFE (Smith and Keating, 2003). This process, whereby employers, in conjunction supposedly with the apprentice himself or herself, are able to

select the RTO of their choice, is known as user choice. The availability of such funds to private training providers has enabled massive expansion in areas such as retail and aged care, where TAFE would not have been able to meet the demand. In addition to these policies, the growth of new bodies to manage apprenticeships has been important.

There are a number of regulatory arrangements associated with Australian apprenticeships. Contracts of training must be signed by employers, by employees (and by parents where the employees are aged under 18), and by the training provider (RTO). The contracts are registered with the state or territory training authority. Employment incentives are supplied by the federal government on commencement and completion, and off-the-job training is funded by the state training authority. State training authorities and the federal government alike maintain regional and local offices where staff work to promote apprenticeships and to manage the quality of apprenticeships. In addition to these long-established processes, apprenticeships are now promoted through school education systems (which in Australia are managed by state governments) because apprenticeships can be commenced on a part-time basis while students are still at school.

There have been a number of quality problems associated with the rapid growth of the apprenticeship and traineeship system in Australia (Schofield, 1999; Snell and Hart, 2007). These have been partially addressed by new policies, such as the introduction of the Australian quality training framework (AQTF) which aims to ensure good quality training in TAFE and RTOs by regulating the registration of training providers and the delivery of training (Smith and Keating, 2003). The AQTF, through state training authorities, is responsible for the quality of all vocational qualifications, not just those associated with Australian apprenticeships. The weighting of employment incentives toward completion of apprenticeships, instead of equal payments on commencement and completion, has also tended to improve quality. There is still a perception, however, among some commentators that employers of trainees may be overly influenced by the availability of employment subsidies (Snell and Hart, 2007).

There are two sets of agencies that directly contribute to the apprentice system and a number of others that make an indirect contribution. The two direct contributors are group training organizations (GTOs) formerly known as group training companies (GTCs) and Australian apprenticeship centers (AACs) formerly known as new apprenticeship Centers (NACs).

GTOs act as employers of apprentices, leasing them out to companies and thereby relieving companies both of the risk of taking on an apprentice for a lengthy period and of the paperwork associated with employing an apprentice (Dumbrell and Smith, 2007). There are 180 GTOs in Australia and they receive government funding through the joint group training program scheme whereby funding is

allocated primarily on the basis on numbers of apprenticeships and traineeships commenced and completed. JGTP funding is provided equally by federal and state governments, and around \$20 million a year flows to GTOs through JGTP (Hood *et al.*, 2007). A GTO, as the employer of the apprentice, also receives the normal government employment incentive. GTOs receive payments from the host employers, but this is usually only just enough to cover the wages that GTOs pay to the apprentices.

AACs are newer than GTOs and were set up in the mid-1990s to increase the number of people entering apprenticeships. AACs, acting under contract to the federal government, market apprenticeships to potential employers and apprentices, manage the signing-up process, and make sure that appropriate employment and completion incentives are paid. They also make employers aware of special incentives that may be available for employing apprentices from disadvantaged groups, for example, indigenous or disabled people. AACs also have a role in making sure that the employer-apprentice relationship proceeds smoothly and to report any problems to the appropriate authority, normally the local office of the state training authority (Smith *et al.*, in progress).

Besides these agencies, other agencies have some role in promoting apprenticeships. These are funded by either state or federal government and may also earn income through commercial activities. They include:

- RTOs. They have an interest in employers recruiting apprentices, because they can then access user choice funding by providing the training for the apprentices.
- Job network providers. These agencies provide an employment brokerage service. Often they place their clients in jobs that include a contract of training.
- Industry skills councils (ISCs). There are ten national industry skills councils covering the range of Australian industry, and in some states there are state counterparts. They promote apprenticeships and traineeships to industry because then there will be greater take-up of the training packages which ISCs oversee.

Challenges for Apprenticeship Systems

While only a relatively small number of countries have been mentioned in this article, the broad range of apprenticeship models discussed enables some general points to be made. Apprenticeship systems have been designed to serve many overt purposes: to transition young people into working life, to provide skills to the workforce, to maintain quality of skills, and to reduce unemployment rates. They also perform more covert purposes such as valorizing the status of some occupations above others and restricting access to some occupations. These many purposes are the

reason why there are many stakeholders in apprenticeships. This is a good thing because it means that apprenticeships are supported by diverse groups and are very firmly rooted into economies and societies. However, it is also a bad thing because change to apprenticeship systems can be fiercely resisted for a range of reasons. The number of stakeholders also means that apprenticeships are culturally specific and that it is difficult to read across from one country to another (Deissinger *et al.*, 2006).

Some challenges faced by apprenticeship systems include:

- Their ability to cope with fluctuations in economic prosperity and/or in the rate of unemployment. While apprenticeships are to some extent designed to soften peaks and troughs in employment, their role in this respect tends to be reactive rather than proactive. It is difficult in periods of economic boom for apprenticeships to provide qualified tradespeople at a high-enough rate to meet labour-market demands; and because apprenticeships are usually employment-based, numbers tend to drop when economic times are hard because employers cannot afford to hire them. Fairly robust government intervention is required to address these issues and proffered solutions may not be attractive to all stakeholders. In the end, apprenticeships rely, in most countries, on employers' willingness to employ apprentices, and so governments cannot effect rapid change autonomously.
- The question of 'Who pays?' While in some countries governments accept a considerable amount of funding responsibility for apprenticeship, in other countries this is not so. The Australian experience represents the results of heavy financial investment by the national government, but some argue that employers should take more financial responsibility.
- The extent to which systems embrace changing occupational patterns. While some countries have straightforward means of adding new occupations to the list of apprenticed trades, in others, the addition of occupations, especially where they compete for existing funding, may be resisted by interest groups representing traditional occupations.
- The extent of regulation. Regulatory requirements may apply to qualifications, contracts of employment, requirements for on-the-job training, wage rates, and so on. The high degree of regulation in some systems can be seen as problematic by employers and training providers.
- The invisible ingredient: pedagogy. The regulatory panoply associated with apprenticeships and the range of stakeholders mean that it is all too easy to see apprenticeship as a public policy artifact rather than a pedagogical process. In the end, though, it is the quality of learning that is important, and due attention needs to be paid to pedagogy.

Apprenticeships have shown themselves able to adapt to change over the centuries but some countries have managed change more effectively and with less conflict than others. Flexibility is difficult where stakeholders have firmly entrenched interests. There remains the issue of how much apprenticeships can change while still retaining their essential nature, and this core will always vary from country to country.

Skills Shortages: Concepts, Measurement and Policy Responses

C Shah and G Burke, Monash University, Clayton, VIC 3800, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

A level of anxiety currently exists about skills shortages globally, and its impact on the economy. In the developed countries, aging of the population is often cited as a cause of looming shortages.

Shortages could result in underutilization of capacity and, in turn, reduced production. If the response of employers is to bid up wages in ways that do not match productivity, then it could result in higher inflation, lower retention (due to higher job-to-job turnover), and less productivity.

Employers, employees, and policy analysts have varying perspectives on skills shortages. The lack of a common understanding of the concept often obscures analyses of problems, their causes, and possible solutions. Nearly half a century ago Arrow and Capron (1959) wrote: "some proposals for solving shortage problems stem from a misunderstanding of the causes of shortages as well as from an exaggeration of the evidence."

This article provides a discussion of the varying views on skill shortages and some of its causes. Issues of measurement and indicators of skills shortages are also discussed as are public policy responses to skills shortages.

Meanings, Perspectives on, and Causes of, Skills Shortages

What are Skills?

A skill is an ability to perform a productive task at a certain level of competence. Skills are often associated with a formal qualification, although an individual can acquire skills in other ways, including various forms of informal learning and on-the-job experience. As a job involves doing a number of tasks, a person must possess a bundle of skills to perform in a job.

Becker (1962) distinguished between general and specific skills. He defined general skills as those that are useful to many firms and specific skills as those that are generally useful to the firm providing the training.

The literature often distinguishes between basic (literacy, numeracy, and, increasingly, computer literacy), generic (problem solving, team working, and ability to improve personal learning and performance), and vocational/occupational-specific skills. Personal attributes related to motivation, attitude, leadership, and initiative are also considered desirable skills by some employers who put a high

value on them when hiring new employees (Green *et al.*, 1998), although Keep and Mahew (1999) argue that these are not really skills as such.

Differentiating Meanings of Skills Shortages

The three common meanings attached to skills shortages are as follows:

1. *Hard-to-fill vacancies.* These exist when employers have considerable difficulty filling vacancies in an occupation, within a reasonable period, and at current levels of pay and conditions of employment. They can coexist with relatively high overall unemployment in the occupation.
2. *Skills gap.* These occur where existing employees lack the required qualifications, experience, and/or specialized skills to meet the firm's skill needs to perform in a job. They may apply to new employees, where employers are unable to find suitable applicants for a job and recruit workers who need further training and/or experience to meet the firm's skill needs. Skills gaps do not necessarily relate to formal vocational or occupation-specific skills as sometimes the complaint is about generic skills or attitudes. When employers are not fully aware of the skills needed for optimal production, skills gaps can be latent.
3. *Recruitment difficulties.* These occur when employers have some difficulty filling vacancies in spite of adequate supply of skilled workers. Relatively low remuneration, poor working conditions, location hard to commute to, and ineffective recruitment or firm-specific and highly specialized skills needs are some of the causes of recruitment difficulties. Thus, recruitment problems generally do not constitute a market-wide skills shortage because with appropriate offers of wage compensation workers could be enticed to work in many of the situations described above.

Perspectives on Skills Shortages

Employer perspective

The employer perspective is usually in terms of recruitment difficulties experienced by individual employers. These do not necessarily lead to unfilled vacancies in the short run but can result in other labor-market difficulties or rising labor costs that the employer may regard as a shortage.

Green *et al.* (1998) show that although many employers equate skills shortages with hard-to-fill vacancies, a substantial number do not. The analysis showed that some employers viewed internal skills deficiencies, or gaps, in the same light as skills shortages. Others were declaring the existence of skills shortages when in fact they were unwilling to offer competitive wages.

In the short run, instead of recruiting new workers, some firms react to an increase in the product demand with a range of coping mechanisms that could involve the reallocation of resources within the internal labor market, increasing hours of work per employee, and changing the incentive system to increase worker effort and, thus, improve efficiency (Akerlof and Yellen, 1986; Solow, 1979). When a firm attempts to adjust employment to meet new product demand, then its response shifts to interaction with the external labor market.

Irrespective of whether the firm relies on the internal or external labor market to solve the problem of increased product demand, if costs increase at the margin then some firms might view this as a skills shortage. With continuing problems, some firms substitute skilled labor in short supply with differently qualified labor. Sometimes this necessitates additional training, either internally provided or purchased from an external provider. In such situations, even though the employer might feel a skills shortage exists, from a market perspective, the positions were filled and hence no shortage exists.

Union perspective

Skill is central to the bargaining between labor and management over wages (Rainbird, 1992). Unions generally want to improve the skill level of their members because higher skills increase their bargaining power in wage negotiations and help deliver better services.

In occupations with strong union representation, such as nursing and teaching, where demand is sometimes set against some desired staffing standards, it would appear to be in the interest of the union to overstate the extent of current and future skills shortages because it helps push up the wages of new entrants and increase union membership.

The monopoly powers of some unions enable them to restrict supply and assist in creating scarcity of skills. For example, some medical specialist groups have significant powers over who will be admitted for training and the numbers that will be trained (Borland, 2002; Seldon *et al.*, 1998; Friedman and Kuznets, 1945).

Causes of Skills Shortages

Slowness in the adjustment of wages

Much of the theory about defining and identifying occupational shortages developed from research that focused on wage movements (Blank and Stigler, 1957; Arrow and

Figure 1 Market with increasing demand for a particular skill. From Roy, R., Henson, H., and Lavoie, C. (1996). *A Primer on Skill Shortages in Canada, R-96-8E*. Hull: Human Resources Development Canada.

Capron, 1959). (See Roy *et al.* (1996) and Veneri (1999) for a review.)

The price–quantity graph in **Figure 1** provides a way to explain the role of wage adjustment in the dynamics of skills imbalance. It shows the initial demand curve for a particular skill at D_1 and the supply curve at S . The market is at equilibrium at point e_1 with wages W_e and supply of skills at Q_e . If the demand for the skill increases from D_1 to D_2 , then unless wages adjust instantaneously to the new equilibrium value of W_s , the quantity of skills supplied will be less than the quantity demanded by the amount, that is, the difference between Q_{max} and Q_e . Hence, under current market conditions, employers will be unable to hire workers with these skills and a shortage will occur.

In practice, however, wage adjustments are more gradual. Impediments include delays by employers in accepting the need for wage adjustment and the reluctance to disturb existing wage structures in order to raise the rates for new employees with the required skills (Arrow and Capron, 1959). In some situations, the firm might provide in-house training either to lesser-skilled employees in the firm or to new hires without the required skills to prevent wage inflation.

Arrow and Capron (1959) introduced the concept of a dynamic shortage in which demand for a skill grows faster than supply. The causes of a dynamic shortage included a rapid and persistent rise in demand and supply responding only slowly and less than proportionately to wage changes.

In sectors, such as health and education, the government influence on the supply of, and demand for, skills is significant, and the management of the market is more direct. Market equilibrium will be difficult to achieve in such instances because wage adjustments might respond very slowly to changes in demand or supply.

Figure 2 Market with equilibrium wage below a certain minimum. From Roy, R., Henson, H., and Lavoie, C. (1996). *A Primer on Skill Shortages in Canada, R-96-8E*. Hull: Human Resources Development Canada.

Skills shortages can occur when the equilibrium wage for a particular skill is below some minimum level. Here, the minimum wage could correspond to the wage equivalent of public welfare benefits payments (Roy *et al.*, 1996). **Figure 2** depicts one of these situations, typically encountered in low-skilled occupations. Initially, the equilibrium wage is W_e with demand D_1 , but no worker is willing to work at this wage because it is below the socially acceptable minimum wage of W_m . Under this situation, employers will report skills shortages or recruitment difficulties. If employers are allowed to hire workers from outside the country's labor market (e.g., through temporary or guest worker programs), the supply curve shifts to S_2 , and equilibrium is achieved at e_1 , but only if the socially acceptable minimum wage is inapplicable to the outside workers.

Slowness in the adjustment of supply

The main factors affecting the speed at which supply adjusts are the length of training required and the responses of the training institutions to changes in demand. In some occupations, education and training requirements can take a long time to complete, although refresher courses for those who are returning to the same occupation after an extended period of absence from it can accelerate the process.

Educational institutions adjust only slowly in offering places for particular courses, although this may vary across sectors. The time taken for training authorities to recognize a particular need, the internal budgetary processes in public institutions, and the current staffing patterns indicate that the number of places provided in areas that are in shortage adjust slowly over time. Making public funds for training contestable between the public and private providers of training has the potential to improve response times; however, against this is a risk of poor quality if providers cut corners to win contracts.

The expansion of publicly funded places is not the only factor affecting the numbers. Students must be

attracted to take up the new places, and in the case of apprentices, secure a contract with an employer which can be difficult if employers view training as a cost rather than an investment.

Student demand for places in a particular program can decrease if the program traditionally attracted particular types of students who now have other more attractive employment alternatives available to them. For example, nursing traditionally mainly attracted females but nowadays wider career opportunities have opened up for females, thus making it harder to fill training places in nursing in some developed countries.

Apparent shortages can arise because some employers may prefer employees from a certain demographic or ethnic group. They can also arise from the 2-year experience syndrome among some employers who are reluctant to hire employees without experience.

Workers leaving an occupation are a factor that reduces supply. The rate of turnover of workers varies by age and sex and across occupational groups. The net rate – the number leaving an occupation net of reentrants – tends to be lower in higher-skilled occupations than in lower-skilled ones (Shah and Burke, 2003).

Net immigration affects supply too and can vary over time with changes in migration policies. Governments generally have more control over immigration and less over emigration. The time lag from the moment a particular skills shortage is identified and when the first migrants with those skills arrive can be, however, long.

Lack of labor market information

The availability of good-quality labor-market information to firms, individuals, and education planners is the life-blood of an efficient market. Lack of reliable information can hamper the speed of the market-adjustment process and, therefore, the duration of shortages. Not only the time taken for information flow to workers regarding new opportunities but also the time taken by them to take advantage of those opportunities adds to the time lag. Since some workers might need training, inefficiencies arise when there is lack of transparency in the links between education and training courses and labor-market opportunities (Heijke and Borghans, 1998).

Identifying and Measuring Skills Shortages

To develop policy responses to skills shortages, it is necessary to have an indication of its size, its causes, how it affects production, and whether, on current trends and policy settings, it is likely to be a short-term phenomenon. As it is rarely possible to provide an unambiguous single measure of skills shortages, a range of measures should be used to indicate its existence and possible size. Approaches

to identifying shortages and estimating their extent are varied but generally fall in two broad classes (Roy *et al.*, 1996).

The first class of measures includes economic indicators, such as vacancy, hiring and separation rates, relative wage movements, and employment and unemployment changes, to infer imbalances for particular occupation groups. These measures provide a market-wide perspective and identify shortages only if there are insufficient number of appropriately skilled people in the market to fill vacancies at the going wage rates and employment conditions.

The second class utilizes employer-based surveys, interviews, and focus groups in the main, to make inference on imbalances. Typically, this involves collecting and collating employers' experiences in hiring workers with specific skills in particular occupations.

Initial Issues

Irrespective of the approach taken – economic indicators or employer-based surveys – to find evidence of skills shortages, the results critically depend on the practical definition of skills shortage adopted, the aggregation level, and the time and geographical dimensions. In practice, however, two factors will more or less determine the approach taken – availability and reliability of the data.

Level of aggregation of occupational and skills data

A high degree of aggregation is generally sufficient when producing broad information on the labor market or for vocational and educational guidance. In contrast, for specific publicly supported programs aimed at increasing the supply of particular skills in shortage, or the writing of curriculum for education and training programs, too high a level of aggregation of the data on skills imbalance may not be of much practical use (Roy *et al.*, 1996). It is worth noting that the likelihood of finding market imbalances is higher when the data are highly disaggregated. This is because imbalances tend to offset each other in aggregated data.

Time dimension

The period chosen for the analysis is likely to affect the results because in some cases no imbalance may be evident over a season or a business cycle. The characteristic of the occupational group and whether one is interested in the short-run or the long-run fluctuations, fundamental structural imbalances should be the main guide for determining the period for analysis.

Spatial dimension

The variable performance of labor markets across regions signifies that while some regions may have shortages of

particular skills, other regions may have surpluses. Inclusion of spatial dimension to the analysis is, therefore, important, as internal migration sometimes becomes part of the solution to the problem of skills imbalances. Since financial costs of moving relative to expected earnings are lower for a higher-skilled worker than a lower-skilled one, and training costs increase with skill level, relocation would be a more viable solution for higher-skilled workers (Roy *et al.*, 1996).

Spatial analysis of imbalances adds further pressure on the detail required in the data, especially if it is to be at a disaggregated level.

Indicators of Skills Shortages

Hard-to-fill vacancies and vacancy rates

Unfilled vacancy rates are sometimes used to assess the tightness in the labor market, although it should be noted that because of job-to-job turnover, vacancy statistics tend to overestimate market needs. A situation with a large number of unfilled vacancies that are hard to fill is indicative of a skills shortage.

There are, however, problems in interpreting unfilled vacancy statistics from employer-based surveys. These problems are mainly related to the inconsistent interpretation of various aspects of skills shortages by employers in self-reported surveys (Green *et al.*, 1998). For example, of the 570 000 vacancies estimated in England from the *Employers Skills Survey* in 2005, 204 000 were hard to fill; however, on closer analysis, only 143 000 of these were genuine market shortages, the rest were due to other recruitment difficulties (Learning Skills Council, 2006).

Unemployment rates

Occupational unemployment rates can provide indications of skills imbalances, but it would be naive to think that any positive unemployment rate is an indication of a surplus. There are numerous reasons why the observed and equilibrium occupational unemployment rates are never zero. The challenge with this type of analysis is in determining, at the occupational level, what is the normal (equilibrium) unemployment rate, above which would be considered a surplus situation. Furthermore, among the unemployed may be persons who are not qualified to work in the occupation and, therefore, the number of unemployed overestimates supply. Conversely, if there are persons qualified to work in the occupation but who are employed elsewhere, then unemployment numbers may underestimate supply.

Net vacancies

If both vacancy and unemployment statistics are available at the occupational level, which they are often not, then the unemployment–vacancy (UV) technique can be used to assess skills shortages (Roy *et al.*, 1996). A simple

interpretation would be that if the number of vacancies is larger (smaller) than the number of unemployed persons, then a shortage (surplus) could be inferred. At the aggregate level, the UV analysis shows us that at any point in time, unemployment and presence of vacancies coexist largely because of labor turnover.

A number of assumptions underlie this technique. First, it has to be assumed that vacancies and the unemployment level represent unmet demand and supply under current market conditions. This assumption does not always hold because, as discussed above, the unemployment rate can somewhat exaggerate supply. Therefore, if vacancies reflected true unmet demand, then the UV analysis is likely to bias results toward an absence of a shortage.

Wages

In a market economy, where wages and prices moved freely, occupational labor imbalance would translate to changes in relative wages over time. Changes in relative wages have, therefore, been used to study occupational labor-market imbalances.

There are, however, practical problems in interpreting the wage differential data because a proper analysis requires knowing the supply and demand elasticities, that is, how much the supply and demand will change in response to a change in wages.

Another practical problem with interpreting wages data arises when institutional factors, rather than increased demand, drive wages up. For example, anti-discrimination or minimum wage legislation can drive up wages in some occupational groups. Changes in wages could also reflect the power of the union representing the workers rather than a skills shortage in the occupation. Data on wages need to be of the recently hired because the normally available average or median occupational wage data can vary due to quality or quantity shifts within the occupational group. Wage data at this level of detail are rarely available.

Cross-country evidence shows wages are relatively inflexible and do not strongly respond to current market conditions (OECD, 1994). This is suggested to be the main reason for wide dispersion in unemployment rates across occupational groups. The result is persistent imbalances that will tend to clear through interoccupational mobility rather than wage adjustments (Roy *et al.*, 1996).

Other labor-market indicators

Other indicators, such as hours and intensity of work (i.e., overtime); production levels; changes in employment; flows of new entrants and leavers; training expenditure by firms; levels of subcontracting; hiring standards; and levels of immigration and emigration, have proved useful in analyzing skills imbalances. Their potential usefulness once again depends on data availability, reliability, and its careful interpretation.

Employer-based surveys

Employer-based surveys, to a great extent, rely on employers' perceptions of skills shortages. Laslett (1992) concluded that skill shortages identified from *ad hoc* employer surveys often disappeared when the problem was followed up. Furthermore, he concluded that it is always possible to elicit positive responses to questions about skills shortages.

As mentioned earlier, research conducted in England showed that employers' understanding of a skills shortage was broader than a hard-to-fill vacancy or a skills gap (Green *et al.*, 1998). This study underscores the importance of careful design, implementation, and interpretation of any employer-based survey of shortages.

Structural models

Structural models of firms adjusting to internal labor-market imbalance and of the economy-wide effects of supply and demand shocks have been used to assess current and future labor-market shortages (Wilson, 1992; Hughes, 1994; Heijke, 1994; Boothby *et al.*, 1995; Adams *et al.*, 1994).

An advantage of structural models is that they provide some initial baseline data for more rigorous study of imbalances. There are, however, drawbacks limiting their use in practice. First, in general, the models have very large requirements of quality data to calibrate and maintain them. Consequently, many of these models are highly aggregated and simplified. Second, most models project occupational demand requirements rather than current or future market imbalances, which somewhat limits their use unless ancillary information from other sources is available on turnover and supply.

In-depth studies

The above discussion suggests that finding evidence of apparent skills shortages is relatively easy, whereas assessing genuine market shortages is more difficult. A holistic, or in-depth, approach that considers a raft of measures for a group of interrelated occupations is more likely to provide robust information on imbalances (Roy *et al.*, 1996).

An in-depth study would ideally provide a framework within which to situate the labor market under investigation together with its structure in terms of its demographic, educational, and jobs characteristics as well as include analysis of all other relevant data such as on jobs growth, turnover, and job openings. The study would ascertain whether the imbalances had a geographic dimension or not and would provide indications of how, and how fast, the occupational market resolves imbalances.

In-depth studies are costly if they were to be done at an economy-wide level. Since these types of studies are time consuming, it may only be feasible to use the technique to investigate markets in which imbalances are persistent and adjustment periods are long.

Public Policy Responses to Shortages

In a competitive market, there always will be unfilled vacancies, and a proportion of these could be considered hard-to-fill vacancies. When the number of unfilled vacancies reaches some intolerable level, there are calls for intervention in the market. In some cases, however, the observed imbalance may be socially optimal for the particular labor market, and public intervention would simply be adding to costs of adjustment that are being borne by the market (Roy *et al.*, 1996). Therefore, when is it appropriate for government intervention? Equally important are the questions of why and what of government interventions.

Labor markets may be inefficient due to a range of factors – externalities, legislative or institutional. Externalities occur when an activity (e.g., training) undertaken by individuals or firms leads to benefits (or costs) to other individuals or firms. If the externalities are significant, then the result could be low level of training activity and a likelihood of skills shortages or gaps. Such factors as wages policy, subsidies, and lack of good market information can reduce the market-clearing role of prices and wages.

Once market imbalances, including their severity and causes, have been identified, the next question as to what government action, in terms of its effectiveness and cost, is to be taken arises. The course of action will depend on the specific labor market that is in imbalance and its geographical distribution, as each market may need a tailored solution.

Publicly Provided Training

Provision of publicly funded training places is one of the ways of overcoming skills shortages and gaps. Public provision is usually rationalized in terms of efficiency and equity arguments. Since economic performance is negatively affected by skills gaps, it is argued that more training will result in an adaptable workforce. The training has, however, to be appropriate to be effective.

Publicly funded training to satisfy employer needs requires a thorough and extensive knowledge of the workings of the particular labor market because not all such needs are most effectively satisfied through such means. While initially it may appear that government action is called for to do something about the shortage, it may not always be the best first option. Often, the market will take sufficient corrective actions to alleviate shortages. Government intervention may be counterproductive if its effect is too late or it overcorrects the problem.

The nature of the intervention will depend on whether the problem is a skills shortage, recruitment difficulties, or a skills gap. Recruitment difficulties may not need publicly provided training as a remedy, although raising employers' awareness to the causes of recruitment difficulties and possible solutions for them are important issues.

If it is concluded that there is a need for a training response, there are still important questions about its cost, how it should be financed, how will it be provided, and how will students or workers be attracted to it. The vocational education and training sector has an important role in any such solution. In some countries, such as Australia, the sector is generally considered to be responsive as it is able to tailor programs to meet particular needs fairly quickly. The policy choices need to be seen in the context of a commitment to lift the overall skill level of the workforce. It should also be remembered that the public system has a major role in promotion of equity and education for citizenship or personal development.

Encouraging Training in Industry

The greater the employers' awareness of the importance of training and the greater their involvement in planning and provision, the greater will be the employers' capacity to respond to shortages. Engendering a training culture among employers takes time, as it requires attitudinal changes and long-term perspective on training and its benefits for innovation and profits.

A way of increasing employer involvement and responsibility for training tried by various governments has been various types of training levies. Levies have a longer history in European countries than in the United States or Australia. It has been suggested that a training-levy system that is owned and controlled by industry groups, including unions, may have a better chance of success than a system that is nationally imposed, particularly for trade and low-skill occupations (Government of South Australia, 2003; Gasskov, 2002). Any training-levy system has to ensure equity of access to training for all workers, particularly those who are least qualified and who have the least bargaining power.

Employer training can also be encouraged by tax relief or subsidies to firms commensurate with the amount of training they provide their employees.

Labor Market Information

Transparency is essential for the efficient functioning of a market. Pertinent, reliable information about various aspects of the market that is up to date and available to all provides this transparency, and helps clear imbalances in the market. The information must relate to not just a particular market but also across all markets and must include current wage rates, rates of return, unemployment rate, job openings, job turnover, and labor supply.

Producing quality information is expensive. If this function is left to the free market, the provision is likely to be less than what would be regarded as socially adequate because of the public good nature of the information.

Hence, governments have an important role to play in providing such information.

Immigration

Immigration can be used as a policy instrument to solve skilled and unskilled labor shortage problems. Many countries, such as Australia and Canada, have permanent skilled migration programs to meet expected shortfall in particular types of skills. Generally, the programs are not open ended; annual quotas impose a ceiling to the numbers who are allowed in and occupations in the priority list change as well. One of the problems with the system is that arrival of migrants, with appropriate skills, often lags by a considerable time the actual occurrence of the shortage. This means that sometimes the market has already corrected itself by the time the migrants arrive. The result is that migrants often find themselves having to work in alternative, and sometimes lower-skill, occupations. Migrants' general preference for settling in large metropolitan areas means shortages in regional or remote areas often remain unaddressed.

More recent trends suggest temporary migration programs becoming increasingly popular, including in traditional immigration countries, such as Australia, that previously eschewed such programs. Temporary migration schemes usually begin as a short-term solution to labor shortages in particular sectors or geographical areas; however, they often become a permanent feature of the labor supply as the sector becomes dependent on them and native labor flees the sector because of lower wages and inferior working conditions. This is unlikely to be conducive to sustainable education and training programs or competitive advantage.

Immigration may solve the skills shortage problems of receiving, usually developed, countries but it has the potential to severely disrupt the labor market of the donor, usually developing, countries. When this happens in sectors such as health and education, which are crucial for the development of the human capital of the country, the impact can be quite detrimental. Generally, unless there is a bilateral government-to-government agreement, the donor country has no recourse to recoup the investment it had made in training the individuals who leave.

Encouraging Mobility

Assistance to encourage mobility may help alleviate imbalances in geographical skills, but an important issue is that qualifications are recognized across the different regions.

Internal migration programs are more likely to succeed if they are backed with comprehensive information systems, not only about the labor market but also about other services, such as schooling, health, and housing. Large

disparities in housing costs between different regions could inhibit worker flows. Whether governments should provide financial assistance for internal migration or not is a difficult policy issue and would depend on how strategic the problem is.

Concluding Remarks

This article has provided a review of the concepts, measurement issues about, and responses to, skills shortages. Economic theory suggests that skills imbalances are a permanent feature of a competitive market. Without major hindrances to the market-adjustment process and without externalities, these imbalances resolve over time and do not require intervention. There will always be unfilled vacancies coexisting with unemployment because of continual adjustment of the market toward equilibrium. Adjustment usually takes time because of the speed at which the information about the changes in the market is dissipated and the time it takes an individual to acquire new skills.

Real-world labor markets are, however, seldom perfect. Government action to correct the market may be justified if there is strong evidence showing sub-optimality. Before any effective policy is designed and implemented, it is important to understand the operation of the current market and to investigate reasons for its failure. Lack of good empirical knowledge of how markets adjust, and the time lag from when an imbalance is observed to the impact of a policy makes effective intervention difficult in practice.

With rapid technological changes, there will always be a skills gap in the workforce. The rate at which the gaps are bridged depends on the training system in place. If employers rely on the public training system to finance and bridge the gap, then the adjustment process will be longer because of the bureaucratic necessities and the time it takes a third party to gear up with new curriculum and delivery strategies. If the firms were to take greater responsibility to bridge the employee skills gap, then the adjustment will be much faster and the training could be tailored specific to the firm, thus reducing problems of externalities.

Glossary

Deductive learning – An approach to learning by which the training content is presented in a systematic manner involving definitions, steps, attributes, example, and non-examples. This approach is often thought of as expository learning.

Far transfer of training – The process by which information to be transferred to another setting is related to the information presented during the training.

Financial benefits of training – Training programs should be linked to performance issues, which can be equated in financial terms. When the performance issue is addressed through training, then the financial benefits can be calculated by determining the cost of the training, the value of the performance that results from the training investment, and the financial benefits that result from subtracting the training costs from the performance value.

Formal learning – The array of learning experiences that occur in settings that are explicitly intended for learning, such as a training classroom.

Human competence – The relative level of a person's ability – from novice to master – in respect to a particular unit of work.

Inductive learning – An approach to learning by which trainees acquire the content through the learning of the critical attributes first, and then synthesizing this information into a formal concept or principle. This approach is often thought of as discovery learning.

Informal learning – The array of learning experiences that occur in the context of other activities, such as working.

Knowledge work – The type of work that features the manipulation and dissemination of information as part of their work.

Near transfer of training – The process by which the information to be transferred to another setting is identical to the information presented during the training.

Planned training – A training program that has been developed using a systems approach, which requires that the training content be based on a set of training objectives and that the effectiveness of the training

be determined by comparing the training objectives with the training outcomes.

Structured on-the-job training – The planned process of using experienced employees to train novice employees in the work setting.

Training delivery – The sequence of events taken by which the training content is presented to learners. In terms of structured on-the-job training, there are five train events: (1) prepare the trainee, (2) present the training, (3) require a response, (4) provide feedback, and (5) evaluate performance.

Unplanned training – A learning experience that has not been developed using a systems approach.

The purpose of this article is to discuss the current practice, theory, and research related to training and learning in the workplace. There is a growing awareness of the strategic role of training and learning for organizational effectiveness. This article gives particular emphasis to the planned training and learning programs that occur in the context of the work setting or on the job. On-the-job training (OJT) and learning has garnered increased interest among researchers and practitioners because it addresses a number of practical and theoretical issues.

The article has the following sections: the first section discusses the context of workplace training and learning as it relates to the knowledge economy and implications for employee competence; the next section seeks to define workplace training and learning in terms of the nature of the setting – formal or informal – and the degree of planning that the learning experiences receive; the third describes structured OJT (S-OJT) as one example of workplace training and learning that has received considerable interest in organizations and the implementation of S-OJT; and the fourth section reviews the research on S-OJT and raise issues for future research.

Context of Training and Learning in the Workplace

Training and learning in the workplace can be best understood from the context of the competitive needs of organizations. That organizations have been subject to unique challenges as a result of the global economy should now be accepted without much surprise or dispute. Perhaps the

most well-known spokesperson for this perspective is Friedman (2005), who introduced the notion that instead of traditional markets comprising barriers across national boundaries, markets have now become more flat in a metaphorical sense. That is, because of advanced communications technology, an organization, say, in Taiwan can now compete on an equal basis with an organization in some other country to reach customers in a third country. By using its unique resources to best advantage, each company can ensure its distinctiveness in the marketplace to meet the demands of customers. A constant factor in this scenario is the complex relationship between suppliers and customers, in which each is driven to lower costs, provide higher service and product quality, and demonstrate flexibility in responding to changing market demands.

The emergence of the global economy has brought about two fundamental shifts in the work that people do. First, the nature of work has increasingly moved toward the inclusion of knowledge (Ackerman, 1998). Knowledge work is defined as when employees take in information from a variety of sources, use that information to derive a set of solutions, and, as a result, generate new sets of information (Mohrman, 2003). Thus, the inputs, processes, and outputs constitute the manipulation of information rather than objects or things. The emergence of knowledge work has shown to be relatively pervasive across jobs. For instance, Lee (2004) showed that among bank employees, knowledge work is no longer the monopoly of professionals or senior managers. Rather, movement toward knowledge work occurred across all levels of employees, though these changes seem to have affected frontline employees and middle managers more than senior managers.

The second shift regarding work is that the life cycle of job content has become increasingly shorter, with changes occurring on a more frequent basis. Job change is often a second-order result when organizations change in the way they operate. Osman-Gani and Jacobs (2001) reported that technology was the major driver for prompting job change among companies in Singapore across several business sectors. The introduction of technology, whether to enhance management or production capabilities, invariably causes a redefinition of the organization and roles. Lean manufacturing, for one major organizational change, often serves as one primary example of how job content dramatically changes as a result of changes in organizational structure.

These two fundamental shifts – the movement of jobs toward knowledge work and the shortened life span of job content itself – have heightened the need to better understand employee competence and how to find ways of responding to changing competence needs both effectively and efficiently. As shown in **Figure 1**, Jacobs (2002a) has proposed five levels of a taxonomy of employee competence, starting at the lowest level of knowledge and skill,

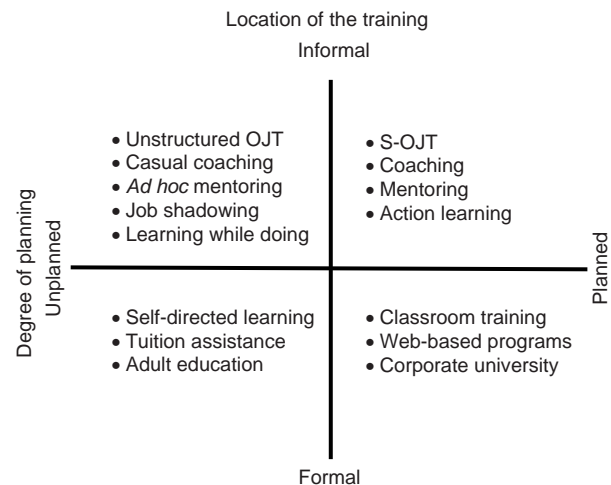

Figure 1 Training and learning in the workplace.

the novice level, and then moving upward to the highest level, the master level.

The five categories follow how individuals might progress in their learning of a specific unit of work. In this framework, a person's ability on a task should be conceived as a relatively narrow construct, not as an overarching ability. Thus, the taxonomy illustrates how individuals could experience a change in their competence when the organization undergoes change. For instance, an experienced engineer might be viewed as an expert in troubleshooting equipment problems in field settings. However, when a remote sensor technology was installed on the equipment, the troubleshooting process could be conducted in an office location instead, requiring an understanding of how to use the software and how to interpret the results to others. In effect, the experienced engineer's level of competence on this troubleshooting task dropped from being expert to perhaps a novice.

How organizations respond to such fluctuations in employee competence reflects how well the organization can remain competitive in the long term. While managers understand the importance of recruiting a qualified and skilled workforce at the outset, equally important is having the systems to respond to changes in job requirements over time. Beyond the absolute need to capably manage their physical and financial resources, organizations must also respond to their current and anticipated employee competence needs, mostly through wise investments in workplace training and learning programs, which have become the primary means to transmit this information.

Training and Learning in the Workplace

Training and learning in the workplace encompasses the various activities and processes used by organizations to impart job knowledge and skills. Previous descriptions of this information have focused on the various training

methods and media that have been used and their potential benefits, such as classroom presentation, computer-based training, or distance training. The most recent annual survey of the state of the workplace learning and performance industry from American Society for Training and Development (ASTD; Rivera and Paradise, 2006) reports the estimated average percentage of training hours per category of delivery method: live instructor led, self-paced, and noncomputer based. The report also compares the percentage of learning hours of instructor-led and technology-based training methods. While this information has importance for organizations seeking to benchmark their human resource development practices, it remains discrete without any conceptual framework to assist understanding.

Table 1 presents two dimensions for understanding training and learning in the workplace: (1) unplanned and planned and (2) informal and formal. The resulting four cells represent the training and learning approaches from the interaction of the dimensions. Unplanned training is often characterized by an *ad hoc* approach to the training. That is, there is uncertainty or lack of concern about the outcomes of the learning and the methods used for the learning. In a sense, unplanned training might be viewed as being phenomenological in that whatever occurs during and after the training might be viewed as being acceptable. The experience may itself be sufficient to warrant the individuals perceiving value from the training. Planned training suggests the use of a systems approach to develop the training. That is, a systems approach requires that the outcomes be specified first; then, the methods to achieve the outcomes are specified afterward. The relationship between means and ends is a prominent aspect of planned training.

Current perspectives about using a planned approach for designing training programs comes from a quality-management perspective. Increasingly, training is being viewed as a critical process that affects the organization's

ability to deliver products and services that meet customer requirements. In this sense, the International Standards Organization (ISO) 10015 Quality of Training standard has come to signify the importance of controlling training as a process. The standard has the following phases:

1. analyze performance problems;
2. identify training needs;
3. develop and plan the training;
4. provide for the training;
5. evaluate the training; and
6. monitor and improve the training (Liu *et al.*, 2005).

To be most effective, the phases of the standard should be connected to the quality-management system of the organization.

The dimension of informal–formal describes the location of the training. The distinction between informal and formal learning environments has been proposed by several authors, including MacLean and van der Pol (2006). Informal locations are environments that have not necessarily been designated for learning, but in which individuals learn naturally nevertheless (Beckett and Hager, 2002). Barnett (1999) proposes that learning and work need to be worked out at different levels, both organizational and personal, and in different modes, formal and informal. The key aspect of an informal learning environment is that it represents what occurs in an activity- or experienced-based situation. The workplace is the most commonly used example of an informal learning setting. Lohman (2005) described informal learning as involving those learning activities that employees initiate in the workplace, involving the use of physical or cognitive abilities, and result in the development of professional knowledge and skills. Informal learning settings typically engage individuals in a more holistic manner, in which entities such as peer learning and communities of practice might likely occur as a result (Hager, 2004).

In contrast, formal learning refers to the locations and processes that are designated as places for learning to occur. Sambrook (2005) differentiated work-related learning as learning at work and learning in work. Learning at work is associated with the more formal provision of education and training courses such as induction, mandatory health and safety, and a range of accredited and nonaccredited in-house courses. Learning in work is associated more with informal processes embedded in work activities, such as observing, asking questions, problem solving, project work, attachments, coaching, and being part of multidisciplinary teams. Instead of being a holistic experience, formal learning is often made up of discrete planned learning experiences that might have a more narrow and circumscribed boundary. Formal learning is usually institutionally sponsored and may occur in a classroom or similar setting in which the control of the learning is in the hands of the organization, and not the individual.

Table 1 Taxonomy of employee competence

Category	Description
Master	The real expert among experts. This person sets the standards for others
Expert	One who can do both the routine and nonroutine cases of the work
Experienced specialist	One who has performed the work repeatedly and can do it with ease
Specialist	One who can reliably perform most work; however, the range is limited
Novice	One who is new to the work and lacks the ability to meet requirements

Source: Jacobs, R. L. (2003). *Structured On-the-Job Training: Unleashing Employee Expertise in the Workplace*. San Francisco, CA Berrett-Koehler.

As stated, the interaction between the two dimensions – degree of planning and location of the training and learning – provide a framework for understanding different training approaches. The unplanned/informal cell represents what constitutes much of the employee learning that occurs in organizations, the most prominent of which might be called unstructured OJT, or follow-Joe training. Clearly, there is a role for these training approaches in terms of allowing some degree of exploration and discovery. However, the consequences of such training can be harmful to organizations and the individuals involved. The planned/informal cell represents an opportunity to have a planned program with predictable outcomes, but to have the training in the work setting. The following section provides more in-depth information about S-OJT, perhaps the most prominent training approach in this cell.

The unplanned/formal cell represents those training experiences that may have a clear intent, but it is uncertain how the information relates to the employee's expectations. The approaches in this cell might be considered more educational in nature, not training *per se*. Finally, the planned/formal cell represents the types of off-the-job training approaches that have characterized organizational training programs, such as classroom training and web-based training programs. Taken together, the four cells provide a relatively comprehensive view on how to understand the various training and learning programs used in organizations.

Structured OJT

Of all the training and learning approaches conducted in the workplace, the most attention has been paid to S-OJT. S-OJT has been defined as the planned process of having experienced employees train novice employees in the workplace or a setting similar to the work setting (Jacobs, 2003). From this definition, S-OJT benefits from providing a greater degree of predictability in the training outcomes, and from being conducted mostly by experienced employees.

Rationale for Using S-OJT

From a practical perspective, S-OJT offers some apparent advantages for managers because the training might be conducted when the employee need arises and without demanding any special resources from the organization, such as a classroom Internet connection. Beyond these reasons, the rationale for using S-OJT comes from an understanding of its potential to address three basic issues related to workplace training: (1) the extent of instructional contiguity, (2) the potential for the transfer of

training, and (3) the relevance of the content during the learning.

Instructional contiguity was first introduced by Gagne (19) and describes the temporal relationship among the three fundamental components of any instructional sequence: the presentation of the content, the opportunity for the learner to respond or make use of the content, and the feedback provided to the learner about the adequacy of the response. Contiguity relates to the association of phenomena because of the degree of proximity. Regardless of the theoretical perspective taken, however, contiguity remains an issue for all training approaches in how to reduce the spacing across the events as much as possible. The principle states that the closer the spacing among the events of the instructional sequence is, the more effective the learning. S-OJT has the potential of addressing this issue as much as any other training approach, if not more so, since the task is presented in the same setting in which it is practiced, with little delay between the two.

Transfer of training concerns the extent to which a person is able to take information learned in one setting and use that information in another setting (Broad, 2005). Perhaps, no other training issue is as important in organizations, that is, how to ensure that trainees actually use what they are asked to learn in the training. The literature suggests a combination of perspectives for viewing this issue. For one thing, the planned process used to design the training ensures that the training objectives are specified in a way to meet the needs of the organization and the interests of the individuals.

Another perspective suggests that transfer of training needs to be understood by the nature of the work environment or climate, in which individuals will be asked to use the learned information. This may be done through the extent of management support and knowledge of the training content. Interacting with these various perspectives is the underlying motivation of the individuals to learn and to perform in the first place.

Of particular relevance to S-OJT is the understanding that the match between the learning setting and the work setting facilitates the transfer of training (Jacobs, 2003). Since S-OJT is conducted in the work setting, or a setting that approximates the features of the work setting, and managers or supervisors often serve as trainers, the need to address transfer of training as a specific issue appears to be less critical. The characteristics of S-OJT inherently address transfer of training issues that would otherwise require attention if some other training approach might be used. For instance, how to provide concrete learning experiences and opportunities for meaningful responses continues to be an issue of concern for researchers studying online learning environments (e.g., Srinivasan *et al.*, 2006).

Finally, the rationale for S-OJT is based on the increased relevance of the training because of the location

in which it is conducted. There is an emerging understanding that cognition and its context are interdependent on each other in all learning situations (Stein, 2001). Situated learning posits that interactions between the physical and social contexts are integral aspects that determine what is learned. What is taken from the learning depends on how individuals construct meaning from the situation. The use of authentic learning experiences is preferred as these provide individuals the opportunity to manipulate things and symbols that have meaning beyond the immediate training session.

S-OJT as a System

As shown in **Figure 2**, facilitating the understanding of S-OJT is to view it as a type of training system (Jacobs, 2003). Similar to all training systems, a system view includes the inputs, processes, outputs, and the context of the system in relation to other systems. The S-OJT system shows that the inputs comprise the novice employee, or trainee, who is expected to have the motivation and readiness for the training. The experienced employee serves as the trainer and one who is expected to have sufficient knowledge of the task and is qualified by the organization to deliver the training. The training location identifies the criteria for selecting the exact location of the training. Oftentimes, S-OJT is intended to be conducted in the work setting, but there are constraints that do not allow this to occur as planned; therefore, an alternative setting needs to be identified without sacrificing the critical attributes of the work setting. The work to be learned is the unit of work that is being presented in the training, as represented by a training module format. S-OJT modules do not present an entire job *per se*, but only a defined task, assignment, or project that the trainee is expected to perform. Finally, the inputs include whatever

communications technology that may be necessary to manage or even help deliver the training. More and more S-OJT programs are relying upon some use of technology because the trainee and trainer may not be in the same location.

The processes include the activities that are done for the trainer to get ready to train, the training events used by the trainer when actually delivering the training, and the means used, such as performance ratings, follow-up observations, and periodic feedback, to ensure that the trainee has learned the content. The literature has differed somewhat on the training steps to be used by trainers. The original Training Within Industry (TWI) materials from the war production efforts of World War II prescribes four steps (Dooley, 1945). Jacobs (2003) suggests five steps to be followed by trainers:

1. prepare the trainee;
2. present the training;
3. require a response;
4. provide feedback about the response; and
5. evaluate the trainee.

The outputs of the S-OJT system are the results that occur in terms of accomplishing the training objectives, the impacts on the work, and the contribution that the training makes to the individual's own development progress. Finally, the organizational context includes the factors in the work setting that facilitate or constrain the system's components, such as the resources – time, people, and equipment – allotted to the training.

Viewing S-OJT as a system has benefits for both practice and research. For practice, the system view shows what issues need to be addressed when developing such a system. In addition, the components guide troubleshooting when seeking to improve the system once it is implemented. For research, the system view identifies the set of

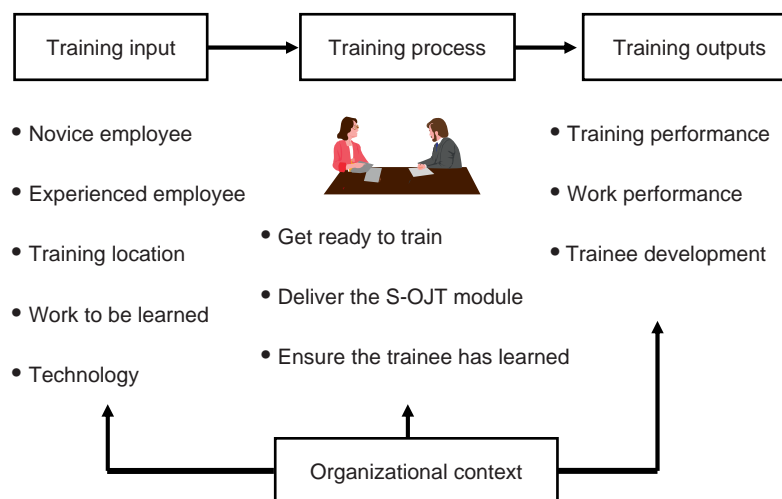

Figure 2 Structured on-the-job training represented as a system.

variables that together form a theoretical framework to guide what questions might be asked. For instance, one topic of continuing interest is research questions related to the background and behavior of the experienced employees who serve as S-OJT trainers (Johnson and Leach, 2001). The research suggests the difficulty of having individuals who are relative experts on the topic, but who are relatively ineffective in their ability to articulate the information to others.

Examples of S-OJT

Numerous examples of S-OJT programs have been reported in the literature, both from scholarly and practitioner sources. With some exceptions, most of the case studies have described the use of S-OJT for technical training, rather than it being for managerial or awareness training. Mafi (2001) proposed a model on how S-OJT might be used for managerial training for supervisors and managers. The model suggests that S-OJT used for managerial training must be connected to specific work expectations and the training should have the following sequence of events:

1. Present why the current approach is not working.
2. Present a model or process to follow.
3. Present techniques on how to use the model or process.
4. Ask the trainee to respond in a role play situation.
5. Evaluate the trainee.

Additional information about the use of managerial training, which used S-OJT to help newly promoted supervisors understand the organization's mission and core values, was reported by Jacobs (2003). Experienced supervisors served as the trainers, though their role was more of a coach than a trainer *per se*. The sessions between the new and experienced supervisors were conducted in office or conference room settings and used an inductive questioning approach.

Table 2 presents a listing of published S-OJT case studies. The table identifies the organization, the positions involved, and the reported results. The cases are taken from a variety of refereed and nonrefereed sources.

Jacobs and Osman-Gani (2005) collected case studies with an emphasis on how organizations in international situations have used forms of S-OJT. The cases illustrate both the similarities and differences based on cross-cultural considerations. Cases include organizations from Japan, Taiwan, the United Kingdom, the Netherlands, and Singapore. Perhaps the largest use of S-OJT comes from a reported project to develop new-hire engineers in a refinery setting in Kuwait (Al-Muzaini *et al.*, 2002). The project is also unique because its focus is on employees who are at the professional–technical level, rather than a frontline employee, such as a call center representative or production worker.

Regardless of the context, the various S-OJT case studies have some aspects in common. The training is conducted in the work setting, not a classroom or some other formal setting. It is delivered either by an experienced peer employee or manager. The training is accompanied by a set of materials that document the unit of work being presented during the training. Finally, it connects, to a large extent, with specific work expectations.

Research on S-OJT

Research on S-OJT is just in an emerging status. Arguably, the first research study related to the effectiveness of OJT was the Lens Grinder Study (Dooley, 1945; reprinted in Jacobs, 2003) that was conducted in 1941. The study sought to establish the effectiveness of a planned approach to training on the job. The results showed that the length of time to train apprentice lens grinders could be reduced from 5 years to 6 months. The Lens Grinder Study was reported as part of the final report authored by Channing Rice Dooley, as he was closing the TWI project during the last months of World War II. Most observers suggest that the TWI project influenced much of current understandings of S-OJT.

Much of the early research on S-OJT focused on determining its financial benefits (Jacobs and McGiffin, 1987; Jacobs *et al.*, 1992; Jacobs and Hruby-Moore, 1998; Jacobs 2002b, 2005). Two areas of focus came from these various studies: training efficiency and training effectiveness. Training efficiency addresses the question whether

Table 2 S-OJT case examples

Organization	Job	Results
GM – US	Operators Supervisors	Reduced the number of wiring errors and implement JIT system
Truck manufacturer – US	Production Technicians	Reduced the number of leaky windshields
KLM	Cabin attendants	Provided more relevant customer service training experience
Regional Hospital – US	New supervisors	Provided information about the mission and vision faster
Large electric utility	Supervisors	Reduced the number of back injuries among production employees
Apple Computer-iBook	Skilled assemblers	Reduced training time and fewer assembly errors
Seagate – Singapore	Production	Reduced number of inspection errors
Pharmaceutical	New-hire lab techs	Reduced time required to complete job rotations
Abbott – Diagnostics Div	Lab technicians	Met ISO and FDA requirements

S-OJT took less time to deliver and whether the investment made to reduce the training time was more or less than the value of the outcome of the training. In general, the results related to training efficiency suggest that S-OJT takes less time to conduct and achieve the objectives when compared to unstructured OJT, classroom training, and blended versions of the training. In addition, the results suggest that the reduction in training time is accompanied by greater financial benefits. The proportion of the time savings and the financial benefits depend on the individual situations.

Training effectiveness addresses the question whether S-OJT leads to better training outcomes when compared to other training approaches and whether the investment to achieve those training outcomes results in financial benefits in terms of improved work outcomes. An illustrative study in this regard was reported by Jacobs (2002c), who compared the value of the work defects (leaks found in windshields in a truck assembly plant) when employees had received unstructured buddy training and S-OJT. The results are reported in the cost of defects reduced when using S-OJT, while also taking into consideration the cost of the training.

Additional research has been conducted to understand how S-OJT might be better understood and extended. For example, Lohman (1994) investigated the effectiveness of inductive training strategies compared to the more commonly used deductive training strategies. The research suggested that using an inductive strategy might be possible, but this changes, to a large extent, the role of the trainer and trainee. Cushnie (2000) conducted a qualitative study to investigate the extent to which mentor-mentee relationships naturally occur along expected norms as established in the literature. The results suggest that mentors and mentees may not have similar backgrounds in order for the relationship to be considered a success. Cho (2004) studied the unanticipated benefits of being an S-OJT trainer in a large Korean organization.

Barnard (2005) differentiated between near and far transfer as it relates to training outcomes. S-OJT has long been considered effective in achieving near transfer of training, or enabling the trainee to perform exactly what was presented during the training. On the other hand, far transfer of training proposes that if an individual learns more general principles, they might be able to extrapolate that information and use it in related, but not identical, situations later on (Kim and Lee). Barnard found some differences in the way supervisors viewed their expected level of performance in performing a coaching task.

Additional survey research has been conducted to understand the impact of organizational change on the training and learning decisions made in organizations. Osman-Gani and Jacobs reported that technological advancements were the most frequent driver of change

among organizations in Singapore, and that S-OJT was the most frequently used training approach used to respond to these changes. Quazi and Jacobs surveyed organizations involved in ISO 9001 and found that their training and development activities had dramatically increased during and continued on after this effort. Learning on the job was identified as the most frequently used training approach for frontline employees.

Implications of Workplace Training and Learning

It is clear that the workplace training and learning will have growing importance in organizations. The emergence of flexible work systems, flatter organizational structures, and a downsized workforce will be ever more dependent on developing employees to perform a wider range of skills. How managers respond to this landscape will have implications on workplace training and learning. Three related implications are presented here for discussion.

First, while the article has emphasized S-OJT, there is also a need to explore the possibilities of other informal training approaches, regardless of whether they are planned in nature. Watkins and Marsick (1990) continue to espouse the value of learning in informal settings based on the notion that learning and knowledge generation oftentimes go hand in hand (Watkins, 2005). Learning in informal work settings has been shown to be a social process (Enos *et al.*, 2003). Planned learning assumes that the knowledge has been previously defined and ready to be imparted to the trainee. An alternate perspective is to have the learner become involved in the learning experience through the sharing of stories, action learning, collaborative inquiry, and questioning strategies. Such processes bring a unique richness to the learning setting that may not be possible otherwise.

The second implication proposes that, given the value of informal learning settings, there should be a strategic blend of both planned and unplanned approaches used within situations. How to view planned and unplanned approaches as being complementary is yet to be accomplished in practice. However, given the demonstrated value of each, it makes sense to view them as each having potential to contribute. For instance, when developing new-hire engineers, it seems appropriate to use S-OJT as a means to provide known information about the position. However, similar to many positions that require making decisions in sometimes-ambiguous situations, an action learning approach might be used to help the engineers untangle especially complicated and uncertain incidents they might encounter.

The final implication is that whatever approach might be taken, there needs to be continued awareness that the

learning experience should meet both the needs of the organization and the individuals alike. Past discussions about the foundational purpose of the human resource development field – whether it is intended for improving organizational performance or to promote individual learning – appear moot at this point of time. In truth, one goal cannot likely be accomplished without considering the other as well. That is, the goals are both distinct and complementary at the same time. That seems the fundamental challenge of ensuring the most effective use of workplace training and learning programs.

Training in Small Businesses

H Matlay, Birmingham City University, Birmingham, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

As a topic of research, training in small businesses has progressed a long way from its humble beginnings as a minor subtopic of human resource management (HRM). Interestingly, during its long infancy, researchers and practitioners have invested a great deal of time and resources in an attempt to mold large business training solutions into small firm employee-development programs. It was not until the 1970s, when the importance of the small business sector began to be acknowledged, that training in small businesses broke free from its conceptual and contextual straightjacket and evolved into a research topic of its own. Currently, this topic occupies a central position within the wider training debate and relevant dissemination represents a major contribution to the fast-growing small business and enterprise development field of research (Matlay, 2004).

There are a number of important reasons why training in small businesses is considered important to the modern economy. First, small businesses represent a vast proportion of the modern economy, amounting to about 99% of all economic units in both developed and developing countries. Second, they make a significant contribution to job creation and mitigate the unemployment caused by the restructuring and downscaling tendencies of large businesses and multinational corporations. Third, due to their flatter managerial structure and inherent flexibility, small firms can offer fast and focused responses to rapid changes in local, regional, and global competitive conditions (Westhead and Matlay, 2006). Thus, a healthy and growing small business sector is widely recognized as an important contributor to the socioeconomic and political infrastructure of a nation.

In many countries, due to the importance attributed to the small business sector, governments invest considerable resources in their drive to increase the uptake of training and improve productivity and competitiveness. Small business owner/managers are encouraged to evaluate their employees' training needs and to develop specific programs that would upskill, motivate, and enhance their workforce (Matlay, 1999a). In turn, small business employees are offered incentives to develop and enhance their job-specific skills. Researchers in this area, however, have noticed that, as compared to larger organizations, training uptake in small businesses is relatively low and that there remain critical factors that act as barriers to employee development in smaller-sized economic units.

In this article we undertake a critical review of the most important aspects of training in small businesses and offer some constructive recommendations to mitigate persistent barriers and difficulties (Matlay, 1999b).

Conceptual and Contextual Considerations

There exists a considerable body of empirical as well as practitioner knowledge that emphasizes the importance of training in small businesses. Conventional wisdom attributes considerable benefits to all the parties involved in the training contract. The rhetoric relating to training in smaller firms states that providing training for employee development and upskilling confers a wide range of benefits to employers, employees, and society as a whole. In theory, employers could take advantage of free or subsidized training, expect to recover their investment in employee development, and benefit from increased productivity and competitiveness. Similarly, to better-trained and upskilled employees, there would accrue benefits in terms of improved job security, commensurable pay increments, and increased job satisfaction. In practice, however, small business owner/managers distrust government intervention, have difficulty in locating and securing relevant subsidies, and tend to operate mostly on short-termist strategies that invariably construe training as a cost to the firm rather than an investment in employee skills and/or productivity. Most small business employees cannot find the time or cover the cost of personal development and resent investing in their training for the benefit of employers who are reluctant to provide job-specific programs.

From an academic and practitioner perspective, there is recognition of, and convergence on, the importance of the skill levels and training needs of individuals employed in smaller business. Unfortunately, there appears to be little agreement on how much and what type of training should be provided in small businesses. Similarly, various studies on this topic have generated a mass of contradictory results, ranging from praise to condemnation of small business owner/managers for their efforts, level of investment, and consistency of training provision in their firms. Much of the confusion in this field originates in conceptual and contextual difficulties that are inherent in small business research. For instance, there are no standard or widely accepted definitions of training and human

resource development. Similarly, there is no general agreement as to what constitutes a small business. To complicate matters, there are also considerable methodological disparities across research studies that focus specifically upon the training needs of small business owner/managers and their workforce. Cumulatively, these problems make generalization and cross-country comparisons difficult and render most emergent results as situational and therefore only relevant to a narrow context.

To overcome some of the problems inherent in this research topic, it is decided to adopt a wide and convergent approach and avoid, as far as possible, definitional debate. Thus, a number of working definitions are used in order to minimize conceptual and contextual differences and maximize the generalization potential of emerging results. Training and employee development are used interchangeably to denote a wide variety of training opportunities provided and/or financed by employers. A small business is defined as an economically active and wholly owned independent unit, employing in addition to the owner(s) between one and 50 employees or full-time equivalent (FTE). References have been kept to a minimum and readers who are interested in the empirical aspects of the training debate are referred to the author's extensive publications in academic and practitioner journals as well as relevant chapters in textbooks and training monographs.

Motivation to Train

There are considerable similarities and differences in training between small and large organizations. Similarities involve issues relating to the motivation to train and the rates of return on investment in HRM. Differences tend to relate to outlook and expectations as well as to resource allocation and approaches to what are basically owner/manager controlled employee-development tasks. The motivation to train emerges as a crucial and overriding aspect of the training function, which affects most if not all of the aspects relating to management learning, employee training, and personal development in a small business context.

From a narrow perspective, Kitching and Blackburn (2002) argue that workforce training in small businesses has two purposes. First, training provides new employees with sufficient skills and job-specific knowledge to enable them to perform their tasks and roles to a minimum standard. Second, training is aimed to secure new employees' cooperation in relation to the small business owner/manager's aims and objectives. Cumulatively, these two motives accounted for 71% of training reasons in smaller firms. Other, less important reasons to train included: the introduction of new hardware and software, compliance

with legal obligations, and the provision of qualifications for employees.

In contrast, the author (see Matlay, 2002) takes a wider, interrelated approach to motivation to train in small businesses. This view includes a systemic as well as organizational perspective and highlights the complexities involved in training provision within a varied and heterogeneous small business sector. First, there is a considerable mismatch between the supply of, and the demand for, small business training on offer in an economy. This is mainly due to a combination of government interference in the training market and owner/manager reluctance or inability to purchase firm-specific provision at an economic price. Second, training needs in small businesses are increasingly characterized by multi-skilling and diversity of application. This is a reflection of inherent advantages of scope and scale as well as flexibility to fulfill short-term niche-market requirements. Third, the importance of the owner/managers to small business operation and their reluctance to relinquish overall control tend to add credence to the ignorance hypothesis in relation to their training decision-making processes. The author found that the main motive to train in small businesses relates to the pressures of gaining and sustainable competitive advantage under constrained resource allocation conditions, followed by legal compliance and delegation considerations.

Types of Training Provision

Small business owner/managers tend to provide mostly job-specific training that, in their perception, is directly relevant to their immediate operational needs. Unfortunately, the author found that few owner/managers in this category carry out regular skill audits or measure the training needs of their workforce. Thus, the vast majority of training provision in small businesses is reactive in nature and originates from immediate skills shortages or acute production crises. Consequently, there is seldom time to evaluate the specific training needs of employees or choose the best, most appropriate, and cost-effective training program or staff-development route. The author found only a handful of cases involving proactive training provision and these were invariably part of formal staff-development initiatives in the larger of the small firms in the research sample. Moreover, reactive training was mainly driven by the quality assurance or technological upgrading of productive or service capabilities requested by their main customers.

It should be noted that the incidence and intensity of both reactive and proactive training provision tends to increase in direct proportion with the size of the firm and can vary considerably across the widely heterogeneous small business sector. Importantly, training

provision closely reflects the preferred managerial styles of these owner/managers, which is also a function of size. Almost all the owner/managers of firms employing fewer than ten employees or FTE (i.e., micro-businesses) preferred informal managerial styles. Formative, mixed formal, and informal managerial styles were reported by respondents who employed between 11 and 30 individuals or FTE. In the larger of these small firms (e.g., those with 31 to 50 individuals or FTE) formal managerial styles were well established.

The three different types of training can be explained as:

1. **Formal training** – It involves structured and prescribed training courses and programs, directly relevant to the specific needs of small businesses. General managerial courses geared specifically for management development are also included in this category. This type of training course is formally structured and scheduled around well-defined objectives and in pursuit of specific outcomes. Formal training courses and programs in small businesses usually take place away from the immediate operational base of a firm and are delivered by qualified and/or designated trainers. Relevant feedback is collected from both the trainer and the trainee. Training outcomes are routinely discussed with the trainee and formalized. A detailed report and feedback comments are also sent to the owner/managers who chose and funded the training course or program.
2. **Informal training** – It includes a wide variety of casual, incidental, or accidental and largely unplanned training inputs, aimed narrowly at imparting knowledge and/or experience of isolated task or problem-solving solutions. These are mostly unstructured, of relatively short length, and in pursuit of a set of narrow outcomes. Typically, informal training takes place within the immediate operational base of a firm and can be delivered by owner/managers or better-trained or experienced employees. Usually, the training feedback stage is bypassed or ignored. This makes the measurement of outcomes difficult to collect, record, or analyze. Furthermore, a large number of informal training incidents are part of routine on-the-job supervision and management and not acknowledged or logged.
3. **Mixed formal and informal training** – This type of training incorporates elements of both formal and informal training intervention. This type of training often forms part of the personal development of managers or shadow managers in the more sizeable of small businesses, where owner/managers often coach or mentor some of the more capable individuals to take on managerial roles. In order to motivate and reward such individuals, owner/managers choose a number of formal training courses of various lengths and send them to widen their general and/or specialist managerial skills. Interestingly, formal training takes place

away from the firm, while informal aspects are undertaken on the premises and delivered by owner/managers. Incidents of relevant training feedback generally fall within the formal and informal patterns and stereotypes are observed in the relevant categories.

The Paradox of Training in Small Businesses

The specialist literature on training in small businesses claims that owner/manager attitudes determine their preferences in relation to this important organizational function. Our initial pilot study found a direct link between owner/managers attitudes to and actual provision of training (Hyland and Matlay, 1997). The wider, main study however established a paradox of training in small businesses, which is detailed and explained below:

1. **Attitudes to training:** It is generally acknowledged that small business owner/managers make most, if not all, the important decisions in their firms. As such, they are involved in all the important operational aspects of running their businesses, including the training function. The issue of who is or should be responsible for training in small and medium enterprises (SMEs) is a decisive aspect of training provision in smaller firms and tends to impact considerably upon related outcomes. Previous research on this topic has highlighted some attitudinal variations in smaller businesses as well as owner/manager ambivalence in relation to the degree of responsibility that they are prepared to accept for training and personal development within their firms. Longitudinal, cross-national research carried out by the author has established that just over 90% of small business owner/managers claim to have a positive or very positive attitude to training. Fewer than 10% of respondents claimed to be either indifferent or have negative attitudes to this important organizational function.
2. **Actual provision of training:** Research focusing upon actual provision of training small businesses has provided contradictory results (Matlay, 2000). Depending upon the measurement tools and definitions adopted, some studies established that about one-thirds of the respondents in their sample have provided some training. In contrast, the more optimistic results claimed that as much as two-thirds of the small business owner/managers interviewed had provided training for their workforce. Using consistent and comparable measurement tools and definitions, our research has established that just over 90% of owner/managers in the sample failed to provide any training during the calendar year preceding the interviews. Considering that a similar

proportion of respondents returned positive and very positive attitudes to training, the small percentage of training in small businesses is both surprising and worrying.

3. The small business training paradox: The emerging results of an empirically rigorous research study has established the existence of a small business training paradox: about 90% of owner/managers interviewed claimed to have a positive and very positive attitude to training while a similar proportion admitted that they have not provided any courses or programs to their workforce (Matlay, 1998). This compares unfavorably with the training provision in large organizations and multinational corporations. Considering the literature on employee recruitment, retention, and development, it becomes clear that a lack of training can have a detrimental effect upon the motivation and productivity of small business employees in general and firm competitiveness in particular. The next section outlines some of the more important factors that affect training in small businesses and their impact upon owner/manager provision of training.

Factors Affecting Training Provision

Owner/managers in our research sample highlighted two main categories of factors that influenced their decision-making processes in relation to the provision of training in their small businesses:

1. Directly relevant factors – These factors, such as the market positioning of a firm, prevailing economic conditions, and the availability of relevant training, were perceived as being of primary importance to the training-related, decision-making process of small business owner/managers.
2. Indirectly relevant factors – They were considered to be of secondary importance to the training strategies of these owner/managers, but still exerted a considerable influence upon the quantity and quality of the training provision in small businesses.

Individually and cumulatively, the effects of these factors can explain, to some extent, the gap that exists between the small business owner/managers' attitudes to, and the actual provision of, training in their firms. A brief analysis of both directly and indirectly relevant factors to affect training provision in small businesses is provided below:

1. Directly relevant factors
 - Market positioning – The market positioning of a small firm has emerged as the most important of the directly relevant factors to affect the provision

of training within the research sample. Market-positioning strategies were used by owner/managers in all sectors of economic activity to promote and discriminate their own products or services from those of their competitors. Thus, product- or service-related quality issues (arguably, the main discriminant factor at the disposal of an owner/manager) emerged as the most important determinant of training and human resource strategies in the small business sector.

- Prevailing economic conditions – The economic conditions prevailing at the time that training-related decisions were made was the second most important factor to directly affect the provision of training in smaller firms. Interestingly, periods of boom and bust tend to influence owner/manager perceptions. Thus, the relative growth in the demand for goods and services which occur during boom periods can have a positive effect on levels of recruitment and incrementally increase training needs. Conversely, recessionary conditions have an adverse effect upon training, when small business owner/managers shed some staff and become reluctant to spend on staff development.
 - Availability of relevant training – The availability of relevant training was the third of the directly relevant factors that small business owner/managers claimed to have affected the provision of training in their firms. In the majority of cases, the decision to train or retrain the workforce was implicitly or explicitly included in market-positioning strategies. During favorable economic conditions, owner/managers tend to scan the market in an attempt to identify the best sources of training. A lack of relevant, firm-specific training can significantly handicap small business human resource development strategies.
2. Indirectly relevant factors
 - Cost of training – Due to a lack of relevant and firm-specific training experienced by most of the respondents, the majority of owner/managers have been forced to pay the going market rate for training their workforce. It appears that they consider these rates as very expensive and inflated. Furthermore, almost all of them seem to have encountered difficulties in identifying and evaluating the cost of training schemes. It should be noted, however, that attempts to compute the full extent of actual, marginal, or incidental costs relating to training were rarely encountered.
 - Time constraints – Time constraints which resulted from short staffing appear to have imposed considerable constraints upon some small business

owner/managers. This affected the provision of training at various key stages in the process, including the assessment of training possibilities and choices as well as the cost effectiveness and feedback analysis of actual training schemes. Some owner/managers were forced by time constraints to delegate the training function to other managers or members of their family who, arguably, did not fully realize its importance to the overall business strategy.

- Lack of trainee cover – The lack of in-house trainers mainly reflected a respondent's preference for internal methods of training upon which s/he could have full control. In the smaller businesses in the sample, even one employee away from his/her usual workplace amounted to a significant loss in productive output.
- Lack of in-house trainers – Few small businesses can afford the luxury of in-house trainers or training managers. Arguably, a dedicated employee could take responsibility for training and relieve the pressure on the owner/manager. A small number of the larger firms in the sample employed part-time training managers or self-employed trainers.
- Lack of trainee motivation – Interestingly, a lack of motivation for undergoing training among employees sometime restricts training efforts in small businesses. Owner/managers are often reluctant to reward or promote trained employees in case they leave or are poached by competitors.
- Lack of trainee interest – This aspect is linked to staff motivation and can also have a negative effect on training strategies in small businesses. Employees can and often question the motives that owner/managers have for training their staff. In some cases, their suspicions have been confirmed when production line speeds were increased in accordance with post-training productivity expectations.

In terms of the training paradox identified in the small business sector, the directly relevant factors identified by owner/managers explain, at least partially, the gap between attitudes and actual provision. Most of these factors can act to restrict both reactive and proactive training strategies in small businesses. Arguably, by taking a more proactive approach toward the training function in their firms, small business owner/managers can mitigate or even avoid some of the financial costs associated with of the negative factors outlined above.

Concluding Remarks

The training function in small businesses differs significantly from training solutions adopted by large organization

and multinational corporations. Although there is a great deal of debate about all aspects of training, certain trends emerge that set this function in small businesses apart from training and human resource development in larger organizations. The main motive to train in small businesses relates to gaining and sustainable competitive advantage under constrained resource allocation conditions. In addition, legal compliance and delegation considerations as well as multi-skilling needs also affect owner/managers' motivation to provide training to their workforce. Much of the training provided is reactive rather than proactive in nature and reflects largely the informal management style preferred by most small business owner/managers.

The training paradox identified by the author relates to the wide gap that continues to exist between the owner/managers' overwhelmingly positive attitudes to training and their apparent reluctance or inability to provide it adequately in their firms. Two type of factors influence owner/managers' decision-making processes in relation to the provision of training in their small businesses: directly relevant and indirectly relevant factors. Directly relevant factors involve the market positioning of a firm, prevailing economic conditions, and the availability of relevant training. These were perceived to be of primary importance to the training-related, decision-making process of small business owner/managers. Indirectly relevant factors included the cost of training, time constraints, lack of trainee cover and in-house trainers, as well as a lack of trainee motivation and/or interest. Indirectly relevant factors were considered to be of secondary importance but were still influential to the training strategies of small business owner/managers.

Most small business owner/managers feel that the training market is supply oriented and that government initiatives tend to support training providers rather than their prospective customers. Similarly, much of the information related to training availability and relevant subsidies are directed toward training advisors and providers. Therefore, when seeking advice on training, owner/managers claim to notice a marked bias toward off-the-shelf training solutions that do not match their needs or expectations. Furthermore, researchers have noticed that most training initiatives are reviewed by commercial organizations or government-sponsored institutions. These reviews lack empirical rigor and credibility and invariably claim success, even when some initiatives blatantly failed to address their explicit small business training agenda. It is therefore suggested that training initiative should be aimed directly at specific needs of small business owner/managers and their workforce and should support the demand side of the training provision equation. Training information and relevant subsidies should be made available to owner/managers either through direct mail or via independent small business advisors or intermediaries.

When we speak or write about vocational education and training (VET) in any culture, we often use the language borrowed from government policy statements and diverse academic disciplines, occupations, and industry sectors.

We note that there are differences in language and terminology between countries and regions, for example, in Australia and in much of Europe, the term vocational education and training (VET) is used. The United States of America uses the term career and technical education (CTE) and vocational education. The United Kingdom uses the term further education (FE). South Africa uses the term further education and training (FET), while most of the Asian countries tend to employ the term technical and vocational education and training (TVET). The term TVET has also been favored by the Organization for Economic Cooperation and Development (OECD). Although different cultures have their own preferred names for VET, the sector generally aims to prepare people to enter specific trade-and-technician occupations, or make the transition from school or unemployment to work. It also provides opportunities for existing workers to upgrade their skills and qualifications, marginalized groups to have a second chance at education and training, and adults to engage in personal development. In the last 20 years or so, VET has been associated with the provision of lifelong learning.

In this article, we argue that there is no unique language for VET and provide some examples of how explanations of VET arrangements are influenced by the languages of different fields. We use the acronym VET (favored in this encyclopedia) for ease of discussion.

The article is divided into themes dealing with how terminology associated with particular fields has influenced the language of VET. We look in turn at government policy, economics, globalization and technological

innovation, skills, useful metaphors for VET structures and strategies, and teaching, learning, and assessment. We end the article by drawing some conclusions.

VET Uses the Language of Government Policy

During the last 20 years or so, many countries have used the terminology favored by governments to announce training-reform strategies aimed at furthering economic prosperity and competitiveness at home and abroad. From the mid-1980s onward, we see industrialized countries (including Australia, New Zealand, and the United Kingdom) reforming traditional VET systems to address increased competition from low-wage countries (including China, Indonesia, Malaysia, and Thailand) for low-skilled routine manufacturing jobs, and other OECD countries with higher levels of education (including Japan, Korea, and Germany) and innovative work practices (including Japan and Sweden) for high or intermediate-level skilled manufacturing jobs producing value-added goods. Increasingly, customer service and administrative jobs in a variety of industries (including telecommunications, information technology, financial services, tourism, and hospitality) are also being exported offshore to other low-wage countries including India and Thailand.

Across the world, the desire for a skilled and flexible workforce to enable domestic industry to compete in international markets has driven training reform. Terms like manpower development, human-resource development, workforce development and skills formation have been used as umbrella terms for government initiatives to increase the national skills pool. In Australia, with industry expected

to play a key role in developing these reforms, language describing VET as an industry-led system begins to emerge.

Due to its tight connection to the world of work, VET is the sector considered most able to help students move from the schoolyard to the workplace, especially for those not immediately bound for university. Terms like school-to-work transition become popular terminology for describing this movement.

Governments must also be concerned with addressing the needs of all citizens, whatever their socioeconomic or cultural background, and often espouse and provide funding to support goals which aim to provide citizens with fair and equitable opportunity and treatment in education, employment, and social life. Terms and concepts like access and equity, cultural diversity, social inclusion, and second-chance education are regularly used to describe government initiatives for addressing the needs of marginalized groups via VET.

Explanations which appeal to the need for VET to prepare workers for what has come to be called the knowledge economy, information economy, or knowledge society have also emerged in the VET literature. This type of language is used to help make a distinction between economies and occupations requiring complex cognitive processes and those requiring the lower-level cognitive processes needed for low-skilled routine jobs.

Rapid advances in information and telecommunications technology, workplace change, and workforce aging are regularly used to justify government policies aimed at encouraging workers to maintain their competitive edge in changing labor markets by upgrading their skills and knowledge. In countries with an aging workforce and declining proportions of younger people (like many OECD countries including China) governments have also considered the need to provide incentives to encourage workers, who might otherwise go into retirement, to continue working. As a result, we see increased use of terms like existing workers, mature-age workers, and older workers used in VET as it tries to customize training arrangements and teaching methodologies to the needs of these groups.

Perhaps the most pervasive of reform terminology that has moved from policy documents into the language of VET worldwide is lifelong learning. Across the globe, this refers to ongoing education and training aimed at improving current and future employment prospects or life in general. As VET has historically had more flexible approaches to admission and delivery than other sectors, it is especially equipped to help citizens participate in training or personal development throughout life.

In recent years, cross-border employability and transportability of skills and qualifications have been major preoccupations of governments as they deal with increased levels of cross-border mobility of labor. These issues have mainly dealt with improving the transparency and

portability of qualifications. The European concepts of the skills passport and the vocational certificate supplement and the Australian and New Zealand concept of mutual recognition have been introduced to help migrant workers gain appropriate work.

The concept of VET promoted by the European Union in its Copenhagen Declaration provides us with further examples of how terminology and rhetoric favored by governments and their representatives in international forums capture the way we think and talk about VET:

... Strategies for life-long learning and mobility are essential to promote employability, active citizenship, social inclusion and personal development. Developing a knowledge-based Europe and ensuring that the European labour market is open to all is a major challenge to the vocational educational and training systems in Europe and to all actors involved. The same is true of the need for these systems to continuously adapt to new developments and changing demands of society. (Copenhagen Declaration, 2002)

This vision might be used to describe the aspirations that many countries have for their VET system (Table 1).

Useful to VET Are Economist Explanations and Predictions of Labor-Market Environments and Activity

The language of economics and economists plays a central role in explaining the VET environment. This increasing foray into a field traditionally occupied by the language of educators is buttressed by a perceived need for explanations and measurements used by economists to gauge the effectiveness of government reforms. Some of these measures are terms like returns on investment in training, student retention and attrition, program completions, reductions in unemployment rates (and especially long-term unemployment), improvement in human capital, and achievement of access and equity for marginalized groups. Another concern of economists which is reflected in the language of VET is unmet demand, that is, when the demand for training outstrips the supply of training.

The analytical tools generally applied by economists are also used to predict the supply and demand for training. Increasingly, attention has focused on responding to the impact of demographic change and responding to the needs of an aging workforce. The concept of the market and the terminology associated with it has also been used extensively to describe the VET environment (Table 2). Terms like training market and labor market (including these for adults and youth) have been used in turn to explain the arenas in which training providers compete for students and courses, and individuals compete for jobs.

Table 1 Terms used in policymaking and governance which have entered the language of VET

Access and equity	An umbrella term for enabling equality of access to education and training and employment for marginalized groups
Cultural diversity	A recognition that VET should address the range of individuals from non-mainstream or marginalized groups
Employability skills	A set of personal skills and attributes that enable an individual to compete successfully for jobs
Information economy, Knowledge economy	An economy concerned with the production and trading of knowledge and information services rather than material goods and services (Porat, 1977).
Knowledge society, Information society	A society 'whose processes and practices are based on the production, distribution and use of knowledge' (CEDEFOP, 2005)
Knowledge workers	These are workers whose main activities are concerned with the transformation of information into commodities rather than the production of material goods. (Drucker, 1992)
Life-long learning	On-going education and training throughout one's lifetime
Manpower development Workforce development Human resource development	National or provincial arrangements for increasing the national skills knowledge pool
Marginalized groups	Groups who are disadvantaged in education, employment, and life in general
Portability/Transportability of qualifications	The ability of the skills and qualifications gained locally to be accepted across provincial and national borders.
Skilled and flexible workforce	Workers who have the technical skills and personal skills to adapt themselves to the changing requirements of workplaces
Social inclusion	An umbrella term for ensuring that VET addresses the needs of all marginalized groups so that they can participate effectively in society
Technological innovation	New developments in technology used in different industries and, always supported by electronic hardware and software
Training reform	The process of introducing new training arrangements or modifying existing ones to meet national and provincial goals for economic competitiveness at home and abroad
Transition from school to work	The process of leaving school with the appropriate skills and qualifications to gain employment
Transparency	An attribute which reveals the true meanings of a process, practice, or other piece of information; often used for accountability purposes

Table 2 Terms reflecting explanations of environments and measures used by economists

Completion rates	The proportion of students who commence a program of training and stay on until they have successfully finished the training
Demand for training	The desire for training programs by students and workers
Human capital	The stock of knowledge and skills embodied in people. Includes education and training, health, intelligence, expertise, access to networks, and ability to work and learn
Labor market	An arena in which employers compete for labor and workers compete for jobs
Labor mobility	Ability of individual workers to move within and between labor markets at home and abroad
Long-term unemployment	The proportion of the working age population that has not been in employment for a specific amount of time (generally 12 months or over)
Marginalized groups	Groups who are economically and culturally disadvantaged because of low socioeconomic backgrounds, remoteness, ethnicity, and race
Open training market	A market in which public and private providers of training compete for students and funding
Returns on investment in training	Financial and nonfinancial benefits received by individual workers, employers, and governments who pay for or subsidize training
Student retention	Students remaining in school or programs of training until completion
Tight labor market	A labor market where jobs are plentiful
Training market	The arena in which training is bought and sold
Training supply	The training programs provided or made available by training providers
Unemployment rates	The proportion of the working-age population that is not in work and is looking for work
Unmet demand	Occurs when the number of students wanting to do a particular course outstrips the training places available
Weak labor market	A labor market where jobs are scarce
Youth labor market	An arena in which employers compete for young workers (generally between the ages of 15 and 19) and young workers compete for jobs

The teenage or youth labor market is a special concern for VET. In an open training market, all providers are able to compete for government resources and students; in a closed training market only certain providers have access to specific sorts of government funds. In a tight labor market, jobs are plentiful while in a weak labor market, jobs are scarce. In addition, the phrase *making smooth transitions to the labor market* is used regularly to describe what are considered to be key objectives for VET. The concept of labor mobility has also been used to explain reasons for developing more transparent and portable VET qualifications.

The Effects of Globalization and Technological Innovation have been a Special Focus for VET

Globalization, the term for the multiplicity of linkages and interconnections between the states and societies that make up the current world system (VOCED Thesaurus), has also moved into the vocabulary of VET. It is now widely used to explain increased labor mobility. It is also quoted as a key reason for advanced economies wishing to compete with low-wage countries to focus on what are called value-added goods and services. For many advanced economies, like Australia, this includes education and training, health services, insurance and superannuation, information technology, and telecommunications, and bio-medical and environmental expertise. For countries like Japan and South Korea, it includes manufacturing expertise and products in electronics and computer technology. Many countries, including Germany, Australia, and Britain, are also involved in exporting their technical and vocational education offshore and importing student clients to their onshore programs. Terms like international education,

transnational education, borderless education, and cross-border education have also been used to describe training arrangements for nondomestic students.

Accelerated take-up of technological innovation in the developed countries has also produced a range of concepts and terms which have generally dealt with training responses to help workers become and remain more competitive in the labor market (Table 3). New metaphors like digital divide and information rich and information poor have been used to explain divisions between those who have or do not have access to the infrastructure and telecommunications technology that is making domestic and international communication easier and faster.

VET is About Developing Technical, Technological, and Personal Skills

The language of VET has been infused by the concept of skills training. Although associated in great part with the language of psychology, the idea of skills training (also called skills formation, skills development, and skill acquisition) in VET incorporates training required for acquiring specialist technical skills for specific occupations and industries (content-specific skills), and generic and/or transferable skills which can be easily transported across workplace, community, and regional contexts. There is a major focus on practical skills appropriate and relevant to industry needs. As VET aims to develop skilled and flexible workers, the concepts and terminology related to multiskilling, reskilling, and upskilling have also gained currency. Bodies which provide governments and industry with information on training needs and market information have also adopted the term skills.

Table 3 Terms associated with globalization and its effects that have influenced the language of VET

Borderless education	Education where students, teachers, providers, programs, curricula, and course materials cross national borders
Cross-border education	
Transnational education	
Digital divide	Refers to the division between those who have and do not have equitable access to both the technology (i.e., the hardware and software) and the skills to use it
Information poor	Refers to individuals and countries (generally in the developing economies or among marginalized groups in advanced economies) that do not have equitable access to information technology and resources
Information rich	Refers to individuals and countries (generally advanced economies) who have abundant access to information technology and resources
International cooperation	Used to indicate the internationalization of the worlds of education and work
International education	Education which is provided to students from different countries either within country or at host country
International educational exchange	Exchange of students and programs between domestic and international institutions
International market	A market for international students
International program	A program provided for international students at home or abroad
International student	A student who studies in an institution which is not a domestic institution
Internationalization	The increasing geographical dispersion of economic activities across national borders
Offshore training	Training that is provided abroad by domestic institutions
Onshore training	Training for overseas clients that is provided by domestic institutions at home

Australia has industry skills councils, the United Kingdom has sector skills councils, and New Zealand has industry training organizations. Although in Germany such bodies are called chambers, they are also involved in providing governments with industry advice about training for occupational skills. Societies concerned with increasing the level of high-order skills among citizens are referred to as high-skill societies.

The language of the environmentalist and biologist has also infiltrated VET and we note a preoccupation with the development of sustainable skills and identification and maintenance of skills ecosystems. There is a concern for ensuring that we have appropriate and relevant skills for the twenty-first century and many countries have developed policy statements identifying the types of skills that VET must aim to deliver. The hope shared by countries internationally is for VET to develop skilled workers for a more internationally competitive economy and a more equitable society.

In recent years, there has also been a debate about whether traditional apprenticeship training should provide broad-based occupational skills or should just prepare tradespersons to perform a subset of such skills also called skill sets. Employee associations mainly want to preserve the marketability of individuals by ensuring that they have the full repertoire of skills belonging to an occupation, while the majority of employers may want to support a system of skill sets, which address their immediate and particular skill needs.

Key personal skills and attributes critical for obtaining, maintaining, and progressing through jobs are also a focus for VET. Although configurations of such skills may differ across cultures, they are about competencies that underpin all work tasks and can be transported between jobs

(Table 4). These are called key competencies, generic skills, and employability skills in Australia; core skills in England and Germany; essential skills in New Zealand; workplace know-how in the United States; and social skills in Sweden.

Systems, Frameworks, Pathways, and Cultures Are Useful Metaphors for VET Structures and Strategies

Concepts and terminology used in organizational theory, engineering, building, and anthropology have also appeared in the language of VET, providing useful metaphors for the organization, delivery, and recognition of training.

Systems Are Useful Metaphors for Describing VET Arrangements

There has been a dependence on the term system (often used by organizational theorists) as an umbrella term which brings together a number of related components. What is referred to as the VET system in Australia is called the FE system in the United Kingdom. The training of apprentices in Germany is called the dual system, in the United Kingdom and New Zealand it goes by the name modern apprenticeship system, while in Canada it is called the apprenticeship system. In Australia, training reforms have brought about a number of name changes (often with the change of governments) to what is generally known as the apprenticeship and traineeship system. Apprentices and trainees undertake what are called contracts of training (formerly indentures) in Australia, training contracts in Germany, and apprenticeship contracts in Canada.

Table 4 The types of skills and economic and social environments associated with VET

Broad-based occupational skills	Technical skills and personal attributes associated with all aspects of an occupation.
Generic (basic, core, essential or employability) skills	Skills and personal attributes that underpin all task focused skills and are portable from job to job (often includes communication, self organization, literacy and numeracy, working with teams, problem-solving, initiative independence, resilience, job flexibility, willingness to learn)
High skills economy High skills society	Refers to economic and social environments in which 'high levels of workforce skills ... are combined with ... high wages and high labour productivity' (Brown <i>et al.</i> , 2001)
Multiskilling	This is applied to ensure that all workers are able to develop and use a variety of skills to get work done. In Australia it was originally applied to breaking down traditional demarcations between what different occupations were allowed to do according to industrial awards.
Reskilling/upskilling	Although available for all workers these are particularly focused on existing and older workers who need to gain more or better skills to maintain their employability
Skill sets	Skill sets provide a clearly defined statement of the skills and knowledge required by an individual to meet either industry needs or a licensing or regulatory requirement.
Skill ecosystems	A skill ecosystem is a concentration of workforce skills and knowledge in an industry or region (for example, cleaning industry, family support services, wine district) (Finegold, 1999)
Specialist skills	Technical skills that are identified with a specific occupation or parts of an occupation
Sustainable skills	Skills which enable individuals to compete effectively in labor markets which are constantly changing
Transferable skills	Skills that transfer from one workplace to another, from one occupation to another, from one country or region to another

Arrangements for the recognition of qualifications are also explained in terms of systems, that is, qualification-recognition systems. For example, the mutual recognition of qualifications refers to the process of recognizing the qualifications awarded by a similarly accredited training organization. This can apply to qualifications awarded by domestic or international organizations. In Australia, providers registered to provide national qualifications (registered training organizations (RTOs)) must recognize qualifications and statements of attainment (detailing any subjects or credits gained in a course) awarded by any other RTO. Australia has the mutual-recognition agreement, between the Commonwealth government and the governments of the states and territories, intended to establish a scheme for the implementation of mutual-recognition principles for goods and occupations for the purpose of promoting the goal of freedom of movement of goods and service providers in a national market. Australia and New Zealand have signed the Trans-Tasman Mutual Recognition Agreement which states that a person registered to practise an occupation in one country is entitled to practise an equivalent occupation in the other country without the need to undergo further testing or examination. In Europe, the European Credit System for Vocational Education and Training (ECVET) describes arrangements for the recognition of cross-border vocational qualifications.

Frameworks Are Useful Conceptual Structures Which Explain Key Arrangements in VET

The term framework to describe fundamental structures has also crept into the language of VET. Generally used in the fields of architecture and building and construction to refer to an external scaffolding, it is used in VET to explain how a nation, province, or state will arrange and deliver training and assessment services, award qualifications, and ensure the quality of VET.

Australia has the National Training Framework (NTF) which depicts the national approach to VET. This broad umbrella framework comprises the Australian Qualifications Framework (AQF) and the Australian Quality Training Framework (AQTF). The first describes 15 nationally recognized qualifications awarded in secondary education, VET, or university sectors. The second comprises two sets of quality-assurance standards: one is for the acquisition and maintenance of RTO status, the other is for agencies which have the responsibility of issuing such qualifications. New Zealand and South Africa have also established a national qualifications framework (NQF, and South Africa Qualifications Framework (SAQF) respectively). Scotland has developed a credit accumulation and transfer framework. The European Commission is in the process of developing the European Qualifications Framework (EQF). Besides, in Europe, the 'Tuning of educational structures in Europe' project is

intended to aid the development of the European Credit Transfer System (ECTS) into an overarching pan-European credit accumulation and transfer framework. Also being developed in Europe is the Common Quality Assurance Framework for VET in Europe.

Pathways Help to Describe Routes to Work and Further Training

Recently, the main objective of VET systems in most countries is to open up access to training to enable easier movement between different qualifications or levels of courses and to ensure that access is not blocked as a result of earlier decisions or constraints. The concept of pathways has been adopted in VET as a useful metaphor for describing routes to qualifications and employment.

Associated with the concepts of merging or diverging routes to qualifications (often called flexible pathways) are mechanisms to allow this movement to occur, including credit transfer (the transferring of results from one course or institution to another) and formal recognition of learning, experience, and skill that an individual has acquired either at work, in community activities, or in life. Australia and New Zealand use the term recognition of prior learning (RPL); the accreditation of prior experiential learning (APEL) is favored in the United Kingdom. A variant of these processes dealing in assessments of the currency of a competency or skill is called recognition of current competency (RCC) in Australia.

Learning Cultures Are Environments Committed to Learning

The term culture (as in learning culture) has been applied to describe a holistic approach to learning in VET and in other sectors. It is based on concepts of acculturation favored by anthropologists in describing how individuals acquire understanding of the norms and values of the societies in which they are born. When it is applied to discussions of VET, it highlights the importance of organizations displaying a commitment to learning by providing workers with incentives and resources to continuously upgrade their skill and knowledge (**Table 5**). Terms like learning organization, learning town, city, or community are also used in the language of VET to describe environments where all component parts are committed to learning.

The concept is especially pertinent to the education of Indigenous Australians in VET. The Australian strategy 'Partners in a Learning Culture: Australia's National Aboriginal and Torres Strait Islander Strategy for Vocational Education and Training 2000–2005' aimed at identifying strategies to use a learning culture approach to ensure the provision of culturally appropriate VET to

Table 5 Terminology associated with systems, frameworks, and learning cultures, organizations, and cities

Accreditation and registration systems	Arrangements for determining the eligibility of providers to provide training leading to nationally recognized qualifications
Apprenticeship system	Arrangements for the employment and training of apprentices
Competency-based training system	Arrangements for the delivery of training based on industry-competency standards
Dual system	Arrangements for the training of apprentices in Germany and other European countries using similar approaches
Further education system	Arrangements for the provision of postschool VET in the United Kingdom
Learning cities, towns, regions and communities	Cities, towns, regions, and communities which promote the development of economic, cultural, and social networks and activities for developing the skills, knowledge, and potential of individuals and enterprises
Learning culture	An environment of shared beliefs, values, and principles which support learning
Learning organization	Organizations committed to learning new and better ways to achieve corporate strategic objectives, improve organizational practices, and develop the talents and potential of all staff
Mutual recognition systems	Arrangements for reciprocal recognition of qualifications between countries and VET institutions
National training frameworks	Conceptual structures describing key elements of national approaches to VET
Qualification frameworks	Conceptual structures for describing national qualifications
Quality assurance systems	Arrangements for assuring the quality of VET training, assessment, and certification
Recognition of current competency	Formal assessments of the currency of skill and experience gained through prior learning or experience
Recognition of prior learning (RPL), Accreditation of prior experiential learning (APEL)	Formal assessments of learning, skill, and experience gained in work, in the community, or life in general

improve education, training, and employment outcomes for Indigenous Australians.

In the United Kingdom, there has been a concerted attempt to develop a culture of lifelong learning for all. Here, the minister for lifelong learning recently declared that what was required was the creation of a special culture to underscore the need for people to make their own decisions about what, when, where, and how they learn. That is, “a culture where everyone knows the value of learning and expects to learn throughout life, from pre-school years to post-retirement” (BBC news report).

The Language of Teaching, Learning, and Assessment Continues to Be Integral to the Way We Understand VET

The language of teaching, learning, and assessment is necessarily woven into the way we talk about VET. Concepts of formal, nonformal, and informal learning make it easy for us to understand how different arrangements, structures, and environments contribute to the development of skills and knowledge that are required in employment and life.

VET also aims to increase learner independence and self-management in preparation for the modern workplace. In doing so, it has implemented flexible models of training which give learners the responsibility of determining how, when, what, and where they learn. Terminology like flexible delivery, self-paced learning, or individual learning are used to describe these models of

training. More recently, terms like personalized learning have been introduced to describe training arrangements which tailor training objectives to take into account the personal histories and aspirations of individual learners.

All have required a change in the way VET practitioners deliver training. Increasingly, they trade the role of conveyors of information for the role of facilitators of learning. As facilitators, they are required to advise, motivate, and assist students who are working independently or in groups through learning programs, which may be delivered in classrooms, in the workplace, online, or a combination of these.

When institution-based staff or external consultants go into workplaces to assess the work of students or workers, or conduct RPL assessments, they are referred to as workplace assessors. When suitably qualified or experienced, workplace tradespersons and other employees are given the responsibility of the training and assessment of apprentices and trainees, and they are generally referred to as workplace supervisors. Those who provide in-house training that is not of a technical nature may be called personnel trainers, staff-development officers, professional-development officers, or more recently human-resource consultants.

We also find concepts of coaching (borrowed from the language of sports) and mentoring (borrowed from the language of business) in the language of VET. These have been increasingly used to describe the provision of assistance and guidance to new or existing workers by colleagues, supervisors, or executives (including external consultants).

One of the major reforms of the mid-1980s and the early 1990s in Australia, New Zealand, and the United Kingdom was the introduction of the competency-based training (CBT) approach to training. Integral to this approach was the development of what were called industry competency standards to provide guidelines for the type of performance that was to be demonstrated in a practical way by students hoping to acquire a certain competency. RPL, APEL, and RCC assessments and challenge tests were used to avoid the need to duplicate already acquired skills and knowledge.

It was common to speak about criterion-based assessment, which made judgments of demonstrated performance of individuals against a defined standard. This had taken the place of normative assessment where such performance was judged against the performance of others. In such a system, students who were successful were assessed as competent, those who were not were deemed to be not competent or not-yet competent. As time went by, VET practitioners and employers began to be frustrated with drawbacks of the criterion-based assessments. The principal drawback of these was the inability of such an approach to provide sufficient information about varying

levels of performance. The term ‘graded competency’ then entered the language of VET. Key assessment issues continued to be reliability and validity of assessments in VET while in Australia registered providers (called RTOs) also ensured that their assessments were flexible and fair.

Thinking and speaking of students and employers as clients or customers has also become increasingly common as has measuring training needs and client satisfaction with training. This is where VET terminology has borrowed from the language of business and human resources. Providers identify what their clients want from the training system by undertaking the processes called needs analyses, which are used to compile individual training plans and measure the extent to which such needs are met via client-satisfaction surveys.

There is also terminology borrowed from the language favored by human-resource professionals, like on-the-job training to denote training which happens during the production process, and off-the-job training which refers to training away from the process of work (in company training rooms or at training institutions) (Table 6). These distinctions are especially pertinent in apprenticeship training which in many cases combines both these forms.

Table 6 Terminology associated with teaching, learning, and assessment that has crept into the language of VET

Challenge test	A test used by individuals to demonstrate that they have acquired a certain competency and so do not have to repeat the training
Competency-based assessment (criterion-based assessment)	Assessment in which candidates must demonstrate the ability to perform a certain skill to a pre-determined standard. Differs from normative-based assessment which compares the performance of individuals to others taking the assessment
Competency-based training	A form of training which aims to prepare students to acquire competencies identified by industry to prepare students for the workplace
Facilitator	A VET teacher or trainer who provides learning support and assessment services for students engaged in self-paced learning
Flexible delivery	Training arrangements which are customized to the needs of individual students and employers
Formal learning	Learning which occurs in schools, VET institutions, and universities leading to recognized qualifications
Graded competencies	Assessments which recognize the performance of individuals according to the quality of the performance
Informal learning	Learning which occurs as a result of experience in the workplace, community, and in the family
Mentor	An experienced and knowledgeable individual who provides advice and assistance to those with less experience
Nonformal learning	Learning which occurs in structured training programs outside recognized educational institutions
Recognition of current competency	Formal assessments which take into account evidence of an individual's current ability to perform a given skill to a desired standard
Recognition of prior learning (RPL), Accreditation of prior learning, Accreditation of prior experiential learning (APEL)	Formal assessments which take into account evidence of learning gained through experience in the workplace, in the community, or at home
Self-paced learning	A model of learning where individuals decide how, when, where, and what they will learn and progress through learning at their own pace
VET practitioner	Individuals who are engaged in delivering training and assessment in VET institutions and enterprises
Workplace assessor	Individuals who have the responsibility of assessing the workplace competencies of students and existing workers
Workplace supervisor	Suitably qualified and experienced individuals with the responsibility of on-the-job training of apprentices and trainees

Conclusion

Identifying the language of VET is not always a straightforward task in view of the variety of ways that different countries (and sometimes local states and provinces) have adapted for describing their concepts and structures for VET and in view of the difficulty of ascribing a particular influence to a specific event or catalyst. However, it is clear that even within and sometimes across cultures, a broadly common language is emerging to describe the aims and objectives, policy initiatives, organizational infrastructure and training delivery, assessment mechanisms, and quality-assurance procedures. This has been shaped by the economic environment in which VET operates and the sharing, exporting, or importing of knowledge and expertise across cultures. It has also been influenced by the wish for VET qualifications (wherever they are acquired) to have currency within and across provincial and national borders.

Research on Vocational Education and Training

J Robson, London Metropolitan University, London, UK

B Bailey, University of Greenwich, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Vocational education and training (VET) takes place in a huge variety of contexts and equivalence in the meaning of terms across national and sector boundaries cannot be assumed. In particular, there is debate about whether VET refers to formal programs and qualifications, and structures and systems, or whether the term might also encompass a wider range of formal and informal experiences that relate to work (Stasz and Wright, 2004). In many countries, VET takes place in a range of settings, including schools, colleges, workplaces, adult education, and training institutes and universities. This fragmentation, as well as the range of levels involved (from basic instruction to higher professional training) and its potential to embrace all occupations and trades, makes it more difficult to present a systematic account of research in the area than may be possible for primary, secondary, or higher education. Similarly by its very nature, VET is susceptible to a wider range of outside social and economic interests and to a wider range of research approaches and disciplinary perspectives. The research agenda may be more likely to be set in line with the needs of industry, for example, than is the case for schools research. In policy and practice, there is also confusion about the purposes of VET (Lovat, 2003; Stanton and Bailey, 2005).

This article focuses on research into the VET that takes place outside university systems. Since there is also debate about what constitutes research in this context (see Stanton, 2000), some clarification is needed here, too.

Although the two may be linked (and some would argue should be linked more often than they are), a distinction needs to be made between research enquiry for development (with its emphasis on practical outcomes and knowledge, e.g., relating to new curricula or changes to specific practices in local settings) and pure research (with its emphasis on new theoretical understandings, on methodological rigor and reflexivity, and the capacity for generalization to or the drawing of analogies with other contexts). Much development work in VET now takes place in response to policy or funding initiatives (e.g., those requiring the development of new programs, or the audit and routine evaluation of provision, or the close monitoring of institutional performance) and there is no doubt that such data have value and are frequently underexploited. However, the article mainly focuses on investigations and

activities that primarily aim at the enhancement of theoretical understandings and knowledge which, to a greater or lesser extent, may have general relevance for learners, teachers, trainers, policymakers, funders, or managers of VET in a range of contexts. We are principally concerned with VET research published in English since 1994, and relating to provision in the UK, Canada, the USA, Australia, New Zealand, and Europe.

An Emerging Field

It has become a commonplace in recent years to observe that in most countries research in VET is limited and sparse by comparison with research in other educational sectors. In part, this can be attributed to the fragmentation of VET provision (mentioned above), to its complexity, to a lack of understanding about the nature of the research that may be relevant, as well as to the difficulty of identifying sector boundaries (Stanton, 2000). A tendency in Anglo-Saxon culture to favor academic over vocational interests (DES, 1991; Raggatt and Williams, 1999), and an associated preoccupation with the royal route to higher education that has dominated debate about 14–19 education and training at least in the UK (Brown *et al.*, 2004) may also help to explain the relative paucity of research in vocational areas.

The lack of specialist networks and journals is also a contributing factor.

However, in recent decades, governments of Western capitalist democracies have placed greater political emphasis on the importance of the development of VET provision and so have actively sought to promote research into aspects of VET. This has led to some limited allocation of resources for research. A concern with competitiveness, productivity, and economic performance in Australia and Britain, for example, has prompted the development of policies based on raising participation in VET, on standards and quality, the expansion of user choice, and the encouragement of a significant input from industry (Bailey, 2003).

Calls for such policies to be based on evidence and for the strengthening of links between research communities and government departments have been accompanied as often as not by an insistence that what works is what counts. The nature of the desired evidence has been in contention (with a clear preference in some official circles for quantitative data, longitudinal studies, and large-scale

surveys). In the UK, a report by Rendall (2003) was commissioned in response to “widespread concern about the state of quantitative studies in post-16 education and training.” The document identified a number of issues, including difficulties in recruiting researchers with quantitative data analysis skills. Bates *et al.* (1997) argued for research that focused on democratic and social justice rather than on economic imperatives; even after a decade, it still appears significantly easier to obtain funding for the evaluation and review of official VET policies and initiatives relating directly to national economic interests rather than to broader and more critical social questions.

There is a lack of capacity for VET research in many institutions with a research focus, and within relevant government departments, fewer staff are likely to have knowledge and experience of vocational programs and to be familiar with the complexities and issues requiring investigation. However, a number of private contractors are emerging, keen to pick up funded consultations and projects. Many have fewer institutional constraints (than those, e.g., in university departments may have), but they may also be more isolated from the VET community, from its various teaching, training, and learning contexts. Even within universities, feelings of isolation among VET researchers may be prevalent since most colleagues are likely to be focused on the work of schools. In universities, increasingly, some staff are employed as career researchers, with research-only roles, and they tend to lack background expertise in VET and familiarity with the post-compulsory sector generally (Stanton, 2000). Those who do have VET backgrounds may lack formal research training (Smith, 2004). Concern with research capacity in the UK led to the establishment of a dedicated network for capacity building in 2002, as part of the Economic and Social Science Research Council (ESRC)-funded Teaching and Learning Research Programme (TLRP, 2002). Recently, and also in the UK, funding has been available from the Learning and Skills Council (LSC) for the secondment of teachers in further education to research partnerships and collaborations with university staff or external consultants. Such initiatives are increasingly seen by some managers as providing important opportunities for the professional development of teachers (Robson, 2006).

Funding and Organization

Funding for VET research comes from a variety of sources. These include international organizations such as the World Bank, the United Nations Educational, Scientific and Cultural Organization (UNESCO), the Organization for Economic Cooperation and Development (OECD), the European Commission, and large corporations such as RAND. National governments also fund VET research,

through their various departments and agencies (e.g., the Learning and Skills Research Council in England) and funding is also available through research councils, charitable and independent trusts, and publicly funded educational organizations such as universities, colleges, and some awarding and inspection bodies.

Huge variations exist, of course, in the research priorities of these organizations, the amount of funding they have available at any point in time, the degree of competitiveness that may be involved in accessing it, and the constraints associated with it. Most of these funders are more focused on other sectors of education and likely to fund VET research less often. As noted above, it is likely to be significantly easier to obtain official funding for the evaluation of specific policy initiatives and such funding is also likely to bring constraints with regard to time allocation and the dissemination of findings, for example (Bates *et al.*, 1997). Some research carried out to official specifications never reaches a wider audience, and funders may be particularly inclined to constrain dissemination if the findings are discomforting or unwelcome. Some sources of funding (such as research council funding) may carry greater academic prestige and wide dissemination is usually a requirement of such awards.

The official focus on VET that is increasingly evident in many countries has resulted in the establishment of some national centers for the promotion of VET research activity, such as the National Centre for Vocational Education Research (NCVER) in Australia (a nonprofit-making company owned by government) and in the USA, the National Research Centres for Career and Technical Education, funded by the US Department of Education. Funding from the European Commission has led to the establishment in all European Union (EU) and European Economic Area (EEA) member states of National Resource Centres for Vocational Guidance (NRCVG), but these are focused predominantly on promoting occupational mobility throughout Europe. They undertake activities or enquiries aimed at the development of training modules or the identification of innovative practices, for instance. In Europe, a number of universities host centers for vocational education research (such as the Research Centre for Vocational Education located at the University of Tampere in Finland, and the *Institut d'Economie Scientifique et de Gestion* (IESG) in France) and their funding comes both from their host universities and from a range of external sources.

Next, we elaborate some selected and indicative examples of VET research undertaken in a range of countries.

The ESRC-Funded TLRP, UK

The TLRP in the UK was set up in response to public criticism of the quality of much educational research

(Pollard, 2005). The ESRC manages the program on behalf of its funders (the largest of which is the Higher Education Funding Council). The program is the largest research program currently being managed by the ESRC and represents a significant investment in educational research. The first projects began in 2000 and publications will continue into 2010.

Over 60 research projects cover all phases of education, from early years to compulsory schooling, further education, higher education, and lifelong learning. Several research projects focus on the teaching and learning that take place following (or, in some cases, alongside) compulsory schooling in vocational and work-related contexts. The project titled Transforming Learning Cultures in Further Education took the view that learning and teaching could not be decontextualized from broader social, economic, historical, and political forces and that study of the complexity of relationships between teachers, teaching, learners, learning, and, the wider contexts of learning, was key to understanding what might be most useful for the purposes of informing policy and practice (Hodkinson and James, 2003). When researchers examined a range of VET courses within 14–19 provision, on a variety of sites, they found that the most effective ones were likely to have close and synergistic links with employers. However, this could make it difficult to challenge existing workplace practices and values, such as gender stereotyping, and tensions between learning sites sometimes arose. VET courses without such strong links with employers were less likely to provide effective progression routes into employment. Where students could commit themselves to a specific vocational area, the courses appeared to work well, but for students who were or became unsure of their future direction, VET provision was much less well suited. Researchers recommended, among other things, that VET provision should recognize and support career uncertainty by adopting more flexible structures (Hodkinson and Colley, 2006).

The TLRP project titled Literacies for Learning in Further Education in England and Scotland aimed to find out how reading and writing enhanced learning in vocational and academic subjects in further education (Ivanic, 2006). Researchers studied literacy involved in learning across 11 further-education curriculum areas and found a vast range of texts in use, including booklets, graphical user interfaces, websites, letters, handouts, overhead presentations, textbooks, logbooks, file notes, labels, maps, diagrams, board writing, measurements, and lists. Some of the literacies involved in demonstrating learning (e.g., in hospitality and catering) bore little relation to what was being learned or to the futures for which courses were preparing their students. Further, the assessment of literacy capabilities tended to be decontextualized or at best simulated. Project researchers recommended, among other things, that the demands made by the specialist texts and

literacy practices of each curriculum area should be recognized and that specialist teachers of communication work alongside subject specialists.

The Community College Research Centre at the University of Columbia, USA

The Community College Research Centre (CCRC) was established by the Alfred P. Sloan Foundation in 1996 and is located in Teachers' College, Columbia University, New York. Its work is funded through contributions from the Sloan and other foundations, and federal agencies such as the Office of Vocational and Adult Education (OVAE). CCRC has a research mission to establish a basis of research data and findings which contributes to the development of practice and policy and to students' improved achievements. It undertakes national surveys and studies with particular regard to equity in access and participation in postsecondary education and claims status as the leading independent authority on the community colleges in USA.

The CCRC's research issues include: distance education, student retention and progression patterns, minority and low-income students' access and success, and workforce education.

A recent national field study involved detailed case studies of 15 colleges including interviews with students and staff, which provided the findings for the publication, *Defending the Community College Agenda* (Bailey and Morest, 2006). This report investigates the challenges faced by the 2-year colleges in their mission to provide access and success for their students who constitute nearly 50% of the college students but a disproportionately high number of those from poorer, ethnic minority and academically underprepared students. Chief among the challenges is the loss of state funding which has led to increases in tuition fees, and to difficulties for colleges as they try to maintain the teaching and support services needed by the growing and diverse student body. The changing context requires the colleges to address the barriers to learning faced by students after their admission to college and to improve their on-course success and progression into employment.

The NCVER in Australia

The Technical and Further Education National Centre for Research and Development was established in 1981. The name was changed to NCVER in 1992. NCVER is the national body which undertakes research in-house and manages a continuous program of VET research. This strategy takes the form of priorities and aspects for investigation for which expressions of interest are invited

as part of a competitive grants program. Projects which contribute to the research strategy are commissioned to be undertaken by researchers in universities, by staff in VET providers, and in private organizations. Current priorities for investigation include: basic skills, access, equity, participation, e-learning, and higher education/vocational linkages. Rather than a small number of large projects, NCVER funds a range of smaller projects on aspects of, for example, students and individuals (student satisfaction and destinations), the VET system (quality framework criteria), industry, and employers (apprenticeships and traineeships). One theme of research in recent years has been the changing role and identity of the teacher professional in VET. One such project examined the effects of changes in the VET system in Australia (e.g., the introduction of a competitive market for VET provision) on practitioners at a variety of VET sites across the country (Chappell and Johnston, 2003). Through interviews it was established that in the new commercial environment different roles were required of teachers and other staff. Although the practitioners interviewed maintained their educational identity, they were faced with business discourses which tested their understanding of VET as an educational activity and public good. This led them to place great importance on the teacher–learner relationship and on the educational values and norms of conduct on which that relationship is grounded.

NCVER also collects and makes available the findings of VET research from around the world on the (UNESCO-funded) Vocational Education and Training Research Database (VOCED) and is the center for the collection and analysis of Australian national statistics on VET.

Federal Institute for Vocational Education and Training, Germany

The Federal Institute for Vocational Education and Training (*Bundesinstitut für Berufsbildung* BIBB), under the Federal Ministry of Education and Research, is a national center for research on VET and its progressive development. It was established in 1970 and its research, development, and advisory work are aimed at identifying future trends, promoting innovation, and developing practice-oriented solutions in VET. Current research work, reflecting the circumstances of postunification Germany and EU policies, includes projects on the training market and the world of employment, VET for particular groups including, and the internationality of VET. The wider European agenda includes moves toward a European VET area through agreement on a credit transfer and qualifications which develop a European Qualifications Framework and BiBB is currently involved in a cross-national project on this. Another collaborative task has been that with the social research center in Halle on VET in the eastern states ('Between

market forces and subsidization: The effectiveness and future of VET structures in Eastern Germany'). This research investigation showed that only 4% of trainees in the western states of Germany learn their occupation through an external training provider rather than at a company which provides in-house training alongside practical work experience. This compared with the 30% of trainees in the eastern states who are trained in government-funded schemes organized by external providers of education and training in which the trainees have work placements in local firms. The study examines these innovative collaborative arrangements which develop and add to Germany's dual system of VET, and considers the implications of demographic trends in the east which will lead to a sharp reduction in the demand for training places in that part of the country.

In order to make VET research more readily accessible to a wider circle of users, the BiBB has developed a knowledge map which takes the form of a thematic catalog of issues, activities, and results of German VET research. Since the beginning of the 1990s, the BiBB has operated the Literature Database for VET (LDBB) which currently comprises references to VET and VET research since 1988.

Dissemination and Impact

It is not easy to estimate the impact of research on VET policies and practice. Clearly, the processes of any influence on the making and implementation of policies with regard to VET are not linear and immediate, since events can be expected to be ahead of the agenda and the output of the research community. Despite the absence of a one-to-one relation between research findings and practice, the interest of governments and their agencies in funding and making use of research studies of aspects of VET, as is shown in the exemplars outlined above, has increased in recent decades. This reflects the greater official emphasis on VET in many countries as a contributor to the development or the modernization of national economies in the global economic competition. It may also, of course, reflect governmental interests in shifting traditional attitudes and practices in the workplace and workforce.

Whatever the drivers behind it, the increase in VET research activity in many countries in recent years, mainly on the part of governments and their agencies, has been striking and has led to important changes in the nature of research in VET and in other sectors of education systems. The first of these is the centralization of the setting of the research agenda and of control over the ownership of research findings. As has been shown, different structures and centers for research have been established in different countries, and standards of research practice appear to have improved as a result of greater transparency in the setting up of projects and the publication of

results. As already noted, however, some funders insert copyright clauses into their contracts with researchers effectively to constrain the publication of research findings, particularly when they are seen to run counter to a policy decision, choice, or preference.

Much VET research is susceptible to the criticisms leveled against educational research in general. That is, it is not cumulative in building on earlier work, it is sometimes opaque and inaccessible to the nonspecialist reader, and has little connection with the practice of education and training. One way of meeting the first of these objections is the availability of databases which provide comprehensive and up-to-date information about research publications in report, article, and book forms. VOCED in the NCVER in Adelaide is perhaps the best known of these; others include the Current Educational Research in the UK (CERUK) and the European Centre for the Development of Vocational Training (CEDEFOP) and those maintained by the national centers, described above.

In addition, in many countries, the dissemination of research is being improved through the planned provision of opportunities for researchers to discuss their work with practitioners and other users of research. While there will be debate as to what or who a user or user group is, the exchanges between the researchers and the other stakeholders in formal contexts or in informal settings, such as conferences and seminars, can lead to better understanding on both sides of the purposes and possibilities of research. The Australian Vocational Educational Research Association (AVETRA) is an example of this, while the Nuffield 14–9 Review in England (2003 to date), as part of its way of working, has invited participants from all sectors to discuss the agenda of the review and the contributions of researchers and others. There is an increasing trend to write into research briefs, as a requirement, the place and the form of dissemination as part of the researchers' duties (as is the case with projects funded by NCVER in Australia and the ESRC-TLRP in the UK).

Conclusion

Since 1994, as indicated above, VET research has undergone a number of changes. Alongside the greater volume of published research, there is the wider range of methodological approaches. Traditionally, VET research was predominantly quantitative in its approach, appropriate perhaps when interest focused on often large-scale analyses of age participation rates, school-to-employment transitions, student numbers recruited, qualifications gained, etc. Studies referred to above include studies of learners' and teachers' experiences in VET which inevitably use qualitative methods like action research and semi-structured interviews. Further, the range of issues investigated is wider and it is probably accurate to say that the quality of much research

is better than was the case earlier. These developments show that there have been real advances in VET research in recent years.

Vocational Education and Training Information Resources

L-A Harris, R Naidu, and M Saunders, National Centre for Vocational Education Research, Station Arcade, SA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Introduction

There are numerous sources of information available to researchers, both in electronic and online formats as well as the traditional, print-based media. This article describes information resources related to research in the field of vocational education and training (VET) and offers the reader a road map for finding information about VET. Information sources covered comprise databases, directories/search engines/subject portals, citation indices, books and library catalogs, journals, newspapers, organizations/government departments/associations/networks, conferences, statistics, glossaries, dictionaries and thesauri, research in progress, and social software tools.

Throughout the course of identifying relevant English-language information sources and tools to include in this article, it quickly became evident that VET-specific resources are small in number and not always easily identified. Those resources that are not VET specific in coverage generally have the topic of VET listed within the social sciences and humanities discipline. These resources have been included in this article as they provide access to valuable VET-related research information that could otherwise be overlooked.

Databases

Databases, which can be both bibliographic and full text, contain information in electronic format. Bibliographic databases include details about authors, title, date, and, often, an abstract describing the document. Full-text databases, as the name suggests, provide the full document. Databases may index specific types of information, such as books, journals, conferences, statistics, or a combination of resources. They may be general in coverage such as library catalogs that index a range of resources held in a library's collection or they may be subject specific.

The two comprehensive VET subject-specific databases accessible online are VOCED, the VET research database, produced by Australia's National Centre for Vocational Education Research (NCVER) and VET-Bib, database of VET literature in Europe, the European Centre for the Development of Vocational Training (CEDEFOP). A smaller VET-focused database detailing information about European national research, research papers, and researchers is the European Research

Overview (ERO). For further information about these and other key online bibliographic databases covering the subject of VET, see **Table 1**.

Online databases may be accessed freely on the Internet or by subscription to commercial services, where bibliographic information produced by publishers about materials and/or the full text of articles, reports, etc. is provided. Examples of these subscription services include EBSCO, ProQuest, and Dialog. The most common way to access and search the databases made available by subscription is via a library (university, college, public, or private), although the library's selection of database services may be largely dependent upon the institution's focus. Even though access to full-text information may be restricted to subscribers only, the ability to search the content of the databases for free makes them useful resources in identifying material on a particular topic.

Directories/Search Engines/Subject Portals

Directories and search engines are in essence large databases containing links to information across a broad range of topics, while subject portals provide a pathway or guide to information and related services that can be tailored to the needs of users, usually on specific topics. Search engines are useful starting points to provide a broad coverage of information on a particular research topic. Caution should be used with search results as each search engine produces its listing of results using different ranking methods and, more often than not, the more academic or scholarly results are listed deeper in the search results. Directories, on the other hand, provide a narrower focus on the research topic because their structure is organized by subject. As subject portals provide access to information under one topic, for example, education or government, any information identified will generally be pertinent to the research topic.

Directories

Directories are topical lists of resources, arranged hierarchically, usually browsed but can be searched as well. These directories differ from search engines in one major way – the human element involved in collecting and updating the information. A directory is a useful resource

Table 1 Key online bibliographic databases

<i>Name</i>	<i>Description</i>	<i>Subject coverage</i>	<i>Availability</i>
VOCED	Research database comprehensive for Australia, with key international English-language resources	Vocational education	Free to search www.voced.edu.au
VET-Bib	Research database of vocational education and training (VET) literature in Europe	Vocational education	Free to search www.cedefop.europa.eu
ERO base	Information on European experts/researchers, projects (European Union and national) and papers	Vocational education. Human resource development	Free to search www.trainingvillage.gr/etv/Projects_Networks/ERO
edna	Online resources for education, training, and research Australian with links to international resources	Education broadly and vocational education component	Free to search www.edna.edu.au
Educational Resources Information Center (ERIC)	Predominately North American and increasingly from other countries	Education broadly and vocational education component	Free web search Fee-based via commercial vendors www.eric.ed.gov
Australian Education Index (AEI)	Australian education research and information	Education broadly and vocational education component	Fee based www.acer.edu.au
British Education Index (BEI)	UK literature which supports educational research, policy, and practice	Education broadly and vocational education component	Fee based Free to search latest additions www.leeds.ac.uk
Education Research Complete	Worldwide, predominately full-text education journals.	Education broadly and vocational education component	Fee based www.ebsco.com
ProQuest Career and Technical Information	Worldwide, predominately full text	Vocational, technical, and career education	Fee based www.proquest.com

Table 2 Key directories

<i>Name</i>	<i>Description</i>	<i>Subject coverage</i>	<i>Availability</i>
Intute: social sciences	Social sciences is one of a collection of key education subject directories. Provides access to key resources in the subject area	Further education; adult education; vocational education; and educational policy	www.intute.ac.uk
Infomine	Organized collection of annotated and indexed links to university level research and educational tools. Social sciences and humanities constitute the subcategory listing VET-related information	Vocational education; vocational guidance; career development; and technical education	http://infomine.ucr.edu
Librarians' Internet Index	Directory of websites selected, evaluated, described, and organized by librarians. Society and social science is the subcategory listing VET-related information	Adult education; career education; education research; and research institutes	http://lii.org
Vocational Information Center: career and technical education resources	Comprehensive coverage of US resources with some international links	Career and technical education; vocational education; and adult education	www.khake.com

when wanting to identify specific information about a particular topic. Vocational education usually appears under the broad subject category of social sciences and humanities. Examples of directories that provide access to information on the topic of vocational education or to related topics, such as adult education and career education, are provided in **Table 2**.

Search Engines

No search engine exists that is dedicated to the topic of vocational education and no one search engine is comprehensive in its coverage. It is therefore important to consider using more than one when searching for information. To assist in identifying which search engine or

directory best suits the information topic, websites such as Beaucoup and Search Engines 2 list search engines, directories, and indices in subject categories (such as education under which vocational education is generally listed), or by scope to help narrow the choice. Access details of these are given in **Table 3**.

Subject Portals

A portal is a website containing an aggregation of subject-specific links leading to other websites. It can be a useful resource as it offers high-quality service targeted to the identified needs of its audience and presents a one-stop-shop approach to finding relevant information. While undertaking the scoping exercise to identify relevant VET-specific resources for this article, two VET-subject-specific portals were identified – CEDEFOP and WIFO the gateway to research on education in Europe. There are also numerous education subject portals that provide avenues to VET-related links and examples of these along with further details on the CEDEFOP and WIFO portals are provided in **Table 4**.

Citation Indices

A citation index shows where a piece of work has been cited, how often, and provides a research trail forward from the year a piece of work was first published.

Their main purpose is to provide information about who is citing whom, to find articles that are related to each other, and to indicate the impact of individual articles.

As VET generally falls under the subject category of social science, the relevant fee-based citation index is the Social Science Citation Index (SSCI). It provides access to current and retrospective (from 1970 onwards) bibliographic information, author abstracts, and cited references from over 1700 social science journals. Google Scholar's cited-by feature is a free alternative to fee-based citation indices which allows researchers to determine the frequency with which a specific article is cited by others, the relationships between articles, and authors citing articles on the same topic. While Google Scholar searches across many of the same databases as SSCI, it does not provide access to as many succinct results as the fee-based citation indices do (especially to full-text academic articles). It does, however, search across a broad range of open-access repositories and a range of other materials deemed as scholarly or academic. **Table 5** illustrates several key citation indices that can be used to identify VET-related information.

Books and Library Catalogs

Books (monographs) usually contain a broad overview or an in-depth exploration of a topic and range from popular to scholarly publications. Books on a broad topic may contain chapters or essays on a topic which are often not

Table 3 Search engine resources

<i>Name</i>	<i>Description</i>	<i>Availability</i>
Beaucoup	Provides links to 2000+ search engines, directories, and indices	www.beaucoup.com
Search Engines 2	Over 12 500 links to local, regional, national, foreign, and meta-Internet search engines and web directories	www.search-engines-2.com
Choose the best search engine for your information need	A question-and-answer cheat sheet to help match the information need to the most appropriate resource. Located under 21st Century Literacies – Information Literacy links	www.noodletools.com

Table 4 Key subject portals

<i>Name</i>	<i>Description</i>	<i>Availability</i>
CEDEFOP	Provides access to the European Union reference centre for vocational education and training	www.cedefop.europa.eu
edna.au	Online resource collection and collaborative network for the education and training community. Predominantly Australian but with international information	www.edna.edu.au
British Education Internet Resource Catalogue	Database of information about professionally evaluated and described Internet sites which support British educational research, policy, and practice (includes further/ vocational education)	http://brs.leeds.ac.uk/~beiwwww/beirc.htm
WIFO	Provides access to resources in the field of European education, with a focus on vocational education and human resource development.	www.b.shuttle.de/wifo

Table 5 Citation indices

<i>Name</i>	<i>Description</i>	<i>Availability</i>
Arts and Humanities Citation Index (A&HCI)	Provides access to cited references from arts and humanities journals and relevant items from science and social sciences journals	Fee based http://scientific.thomson.com
Google Scholar	Provides access to cited references to papers, theses, books, and articles from academic publishers, professional societies, preprint repositories, universities, and other scholarly organizations	Free to search http://scholar.google.com
Scopus	Provides access to cited references to peer-reviewed titles and includes open-access journals, conference proceedings, trade publications, and book series	Fee based www.info.scopus.com
Social Sciences Citation Index (SSCI)	Provides access to cited references found in scholarly social sciences journals covering a range of disciplines	Fee based http://scientific.thomson.com

indicated by the book's title. The bibliography in a book is a useful place to find additional sources, while the index at the back of a book provides a guide to the coverage of a specific topic.

Books and out-of-print material on VET can be bought from specialized bookstores and online bookstores. There are thousands of online general bookstores that sell new, used, and out-of-print books and textbooks. Some of the well-known online stores include AbeBooks.com; Amazon.com, and BarnesandNoble.com. There are also commercial publishers including Springer and Routledge (an imprint of the Francis and Taylor Group); university presses such as Oxford University Press; and organizations such as the Office for Official Publications of the European Communities, Organization for Economic Cooperation and Development (OECD), and the National Centre for Vocational Education Research that specifically deal with vocational education; or one can use a one-stop ecommerce search engine such as BookFinder.com that searches for over 125 million books for sale. Many publishers also offer regular e-mail alerts to keep one updated with the latest educational publications.

Books can be borrowed or ordered on inter-library loan from libraries. Most libraries use the Dewey Decimal Classification System (DDC) to organize library collections. The broad Dewey numbers to use when browsing the library shelves are 370 for education and 370.113 for vocational education. Some of the most comprehensive online library catalogs are either national in focus or combine several catalogs in the one search. The most common searches are by author, title, keyword, or subject heading. Library of Congress Subject Headings are used in the majority of library catalogs. The base subject heading for VET is vocational education. Some of the more comprehensive catalogs are shown in **Table 6**.

Book reviews can be found in traditional sources such as journals and newspapers and also from reader reviews posted to online bookstores and catalogs. Commercial resources include BooksinPrint.com, Book Review Index,

and H-Net Review, which review academic books in the social sciences.

In recent times, there has been a push to convert books into digital form to create a large library of e-books (electronic books) available from the Web. The DigitalBookIndex is an online meta-index for most major e-book sites, including the Gutenberg Project, the Library of Congress, the British Library, and hundreds of university libraries, university presses, and commercial publishers.

For an in-depth analysis of current international developments concerning VET, some useful books include the UNESCO-UNEVOC series *Technical and Vocational Education and Training: Issues, Concerns and Prospects*, the *International Handbook on Education for the World of Work* published by Springer, and *Vocational Education: International Perspectives and Development* published by Routledge.

Journals

Journals and periodicals are continuing resources, issued in a succession of discrete parts that contain current information. While to some extent the decision as to what constitutes a scholarly journal is subjective, they do have certain characteristics – sometimes refereed or peer-reviewed and have undergone a rigorous approval and editing process by experts in the field before acceptance for publication; appearance is serious in format and generally include an abstract, literature review, methodology, results, conclusion, and bibliography; there is little advertising; the authors are professionals and researchers in the discipline; and the language is technical and the purpose is to inform, report, and make research available to the rest of the community. The two reference books Ulrich's International Periodical Directory and Magazines for Libraries contain detailed information on journals published throughout the world and also designate refereed titles.

Table 6 Library catalogs

<i>Name</i>	<i>Description</i>	<i>Availability</i>
Library of Congress online catalog	Catalog of the collections of the Library of Congress. Contains records of approximately 14 million items	http://catalog.loc.gov
Libraries Australia	Database of holdings of over 850 major libraries around Australia. Contains more than 40 million items.	http://librariesaustralia.nla.gov.au Enhanced version available on subscription and at some libraries
British Library integrated catalogue	Catalog of the collections of the British Library. Contains more than 13 million volumes	www.bl.uk
WorldCat	A combined catalog of thousands of international libraries affiliated with OCLC (Online Computer Library Center). It includes more than 52 million records in 400 languages	www.worldcat.org Fee based product with additional features available through institutional subscription. at www.oclc.org/worldcat
Libweb	Connects directly to the online catalogs of libraries in 135 countries	http://lists.webjunction.org/libweb
Google Book Search	Identifies and catalogs books provided by publishers and library partners	www.google.com.au/books
Copac academic and national library catalogue	Provides access to the merged online catalogs of major university and national libraries in the UK and Ireland, including the British Library	http://copac.ac.uk
European library	Offers access to the combined resources of the 43 national libraries of Europe, including the British Library. You can search across libraries or make a specific selection	www.theeuropeanlibrary.org
Libdex	Index to the library catalogs of over 18,000 libraries world wide	www.libdex.com

Journal impact factors and article citation counts are methods used to evaluate an author's published research. Article citation counts can be determined by using citation indices, while journal impact is used to determine the expected influence and worth of individual papers within a core set of the highest-quality scholarly journals determined by ISI Thomson Scientific. ISI's Journal Citation Reports social sciences edition evaluates over 1700 of the world's leading social science journals and their impact and influence in the international research community.

The advent of the open-access movement, which brings free and unrestricted online access to articles in scholarly journals, has raised the issue of how to distinguish between web impact – readership or downloading – with actual citation impact. Recent studies on the impact of educational research indicates that there is little relationship between an author's most highly cited articles and articles with the most website hits (Martin, 2007), although publishing articles on the Web is having an effect on the immediacy of articles being cited (Shin, 2004).

The major journal publishers in vocational education are SAGE Publications, Routledge – Taylor & Francis Group, and Blackwell Publishing. To find articles, publishers' websites can be searched or the numerous educational databases and citation indices can assist in identifying and finding relevant journal articles. Many of these sources provide online access to selected journals in full text and also offer services to alert users to the most recent issue of a

particular journal. Some additional journal resources with specific vocational education content include Highwire Press which contains over 4000 VET-related articles and ProQuest's commercial databases – Sociological Abstracts and Education Abstracts.

There are many educational journals which provide some coverage of VET-related topics. The journals currently in print that consistently produce high-quality articles on VET, based on an analysis of the content in the VOCED and Education Research Complete databases, are included in **Table 7**.

Newspapers

Newspapers can provide very up-to-date information on topics relevant to VET, including changes in government policy and current trends affecting the sector. All the major search engines, including Google and Yahoo, have electronic news services that provide the ability to keyword search across thousands of news sources found on the Web. Some also allow alerts to automatically track regular queries. Two commercial databases that supply news services of material not available free on the Web are Factiva and LexisNexis New & Business. Factiva provides full-text coverage from nearly 9000 sources in 22 languages, including local, national, and international newspapers, business magazines, trade publications, and newswires. LexisNexis News & Business

Table 7 Key VET journals

<i>Name</i>	<i>Description</i>	<i>Publisher</i>
<i>Career and Technical Education Research (CTER)</i>	Three issues per year. Covers research and development activities related to career and technical education	Association for Career and Technical Education Research, National Research Center for Career and Technical Education
<i>Education + Training</i>	Nine issues per year. Addresses vocational learning and highlights the changing nature of the partnership between the worlds of work and education	Emerald Publishing Group Limited
<i>Human Resource Development International</i>	Four issues per year. Looks at the practice and research issues of learning and performance by individuals, groups and organizations	Routledge–Taylor & Francis Group
<i>International Journal of Training and Development</i>	Four issues per year. Scholarly research on the determinants of training, training and development practice and policy	Blackwell Publishing
<i>International Journal of Vocational Education and Training</i>	Bi-annual. Features articles on research, theory, and practice broadly related to international VET	International Vocational Education and Training Association
<i>Journal of Education and Work</i>	Five issues per year. International academic research that focuses on the interplay of education and economic systems	Routledge–Taylor & Francis Group
<i>Journal of Further and Higher Education</i>	Four issues per year. Represents the entire field of post-16 education and training	Routledge–Taylor & Francis Group
<i>Journal of Vocational Education and Training</i>	Four issues per year. Looks at the development of practice and theory in work-related education and in particular the study of all aspects of vocational and pre-vocational education throughout the world	Routledge–Taylor & Francis Group
<i>Journal of Workplace Learning</i>	Eight issues per year. Focuses on research into individual, group and team learning in, from and for the workplace	Emerald Group Publishing Limited
<i>Studies in Continuing Education</i>	Three issues per year. Covers all aspects of adult, continuing and professional education and lifelong learning	Routledge–Taylor & Francis Group

provides the full text of thousands of newspapers, newswires, and magazines worldwide. LexisNexis also offers a free to search, pay per view AlaCarte! service.

There are also websites that help to find newspapers from around the world by title, or by region, country, or city, and link to their online equivalents. General news portals include ABYZ News Links, NewsVoyager, Newspapers.com, online newspapers.com, and world-newspapers.com. Only a few news services are on education and their coverage of VET is specific to either the United States or the United Kingdom as shown in **Table 8**.

Organizations/Government Departments/Associations/Networks

National organizations, government departments, member/industry associations, and networks (both formal and informal), whose primary focus is VET, provide useful sources of information. A primary tool for disseminating information about and by these bodies are their websites through the provision of up-to-date information about policy, practice, research, trends, and key topics. Some

of these minor bodies may not have a web presence, although information about these may generally be sourced by other means such as subject directories or via a search engine.

Organizations

National research organizations that have a specific focus on the broad topic of VET or a more specialized interest such as the economics of education, provide access to the most recent research information produced by that organization. The links area of an organization's website can provide access to other related organizations on the same topic/subject. **Table 9** highlights some key vocational education organizations from various regions.

Government Departments

Many national governments have departments whose responsibilities may range from policy development and implementation and administration of the VET system in that country to providing funding for specific or topical programs or areas of research. In some instances, the

Table 8 News services

<i>Name</i>	<i>Description</i>	<i>Availability</i>
Education Week on the Web	A daily update of education news from US newspapers, magazines, and journals	www.edweek.org
Education News	Claims to be the number one source of education news; emphasis on the United States	www.ednews.org
ED.gov	The United States Education Department compiles department related news on its website	www.ed.gov
News Centre	The United Kingdom Department of Innovation, Universities and Skills press releases	www.dius.gov.uk
EducationGuardian	Daily news updates from the UK Guardian newspaper	http://education.guardian.co.uk

Table 9 Key vocational education research organizations

<i>Name</i>	<i>Description</i>	<i>Availability</i>
UNEVOC International Centre for Technical and Vocational Education and Training (TVET)	The Centre assists UNESCO's 192 member states to strengthen and upgrade their TVET systems. Is a specialized center for TVET and the hub of a worldwide Network of TVET institutions	www.unevoc.unesco.org
European Training Foundation (ETF)	Assists countries outside of the European Union to develop quality education and training systems	www.etf.europa.eu
National Centre for Vocational Education Research (NCVER)	Australia's principal provider of VET research and statistical information	www.ncver.edu.au
SEAMEO VOTTECH	Aims to strengthen the VTET systems in SEAMEO Member Countries (Southeast Asia) through collaborative efforts incorporating research and development, program initiatives, networks, partnerships, and information services	www.vottech.org.bn
Bundesinstitut für Berufsbildung (BiBB) (Federal Institute for Vocational Education and Training)	Germany's national center for research into and development of initial and continuing VET	www.bibb.de English language version www.bibb.de/en
Centre d'études et de recherches sur les qualifications (Center for Research on Education, Training and Employment)	French center undertaking research and statistical surveys on the training-employment relationship and the acquisition and certification of vocational skills and job mobility	www.cereq.fr English language version http://mimosa.cereq.fr/angl
Korea Research Institute for Vocational Education and Training (KRIVET)	KRIVET is involved in conducting policy-oriented research on a national basis in the areas of VET, industrial labor policy, VET and the qualification system, and the development, provision and evaluation of VET programs	www.krivet.re.kr
National Center for Career and Technical Education (NCCTE)	Focus is on career and technical education at local, state and national levels in the United States	www.nccte.org

primary responsibility may be for the education sector as a whole of which VET is one component. An example of this, in Australia, is the Department of Education, Science and Training (DEST) whose responsibility is to develop and implement policies in school education, higher education (universities), and VET sectors. Unlike some national government departments, the United States Department of Education has an office specifically focused on vocational and adult education (OVAE). This office acts as the principle adviser to the US Education Department Secretary on departmental matters related to high school, career, technical, adult education, and lifelong learning as well as community colleges, workforce, and economic

development. In Europe, member states of the European Commission are responsible for their education and training systems; however, The European Commission, Directorate-General for Education and Culture works with member states to help achieve common goals by providing policy coordination and funding of programs such as the Lifelong Learning Programme.

As the names and focus of government departments often vary with changes in national government, keeping track of relevant and up-to-date government information can be challenging. To help alleviate this problem, many search engines, such as Google, Ask.com, and MSNSearch, provide an option to limit a search query by a particular

generic domain name. For example, to identify US government materials on the Web, add the site limit syntax to the query, that is, add site:gov in the search box along with the search term. For other countries, include the country code with the site name, for example, site:gov.au (Australian government websites). Alternatively, an online resource such as the University of Michigan Library's Foreign Government Resources on the Web, which provides links to official government websites and documents organized by country, may be used.

Associations and Networks

Vocational education industry and member associations and networks are a useful source of current information on an international, national, or regional basis. An example of an international VET association whose worldwide membership consists of practitioners, researchers, and students in the field of VET as well as institutions, organizations, and companies engaged in human resource development is the International Vocational Education and Training Association (IVETA). IVETA hosts an annual conference with a theme representing current issues in the VET field and publishes the refereed *International Journal of Vocational Education and Training*. Examples of key associations and networks are included in **Table 10**.

Table 10 Key associations and networks

Name	Description	Availability
International Vocational Education and Training Association (IVETA)	Members include vocational educators, vocational skills training organizations, business and industrial firms, and other interested individuals/groups involved in VET worldwide	Restricted free access Membership fee to join www.iveta.org
Vocational Education and Training Network (VETNET)	Provides news and information about VETNET activities and forms the basis for a community of practice in VET research in Europe	Free to access Members only area www.vet-research.net
Australian Vocational Education and Training Research Association (AVETRA)	A national, independent association of research stakeholders and researchers from the TAFE, university, industry and government sectors	Free to access Membership fee to join www.avetra.org.au
Further Education Research Association (FERA)	Aims to disseminate advances in good practice, research findings and policy evaluation relevant to the further education and training sector	Free to access www.fera.uk.net

Table 11 Online conference directories

Name	Description	Availability
AllConferences.com	Provides information about conferences, conventions, exhibits, seminars, workshops, events, trade shows and business meetings. The advanced search allows searching by keyword (e.g., vocational education), date, country or category (e.g., education)	www.allconferences.com
edna.edu.au	The Events link lists conferences, scholarships, celebrations and competitions held for education and training, categorized by events in Australia and outside Australia	www.edna.edu.au
International Congress Calendar	Details of scheduled key future meetings of international organizations	Fee based subscription at www.uia.org

Conferences

Conference papers are listed, along with books and journal articles in the main education indexing services and are increasingly made available on the Web simply by conducting a search engine query. **Table 11** lists online directories which are international in scope.

Statistics

Statistical information relevant to VET can be found in a number of ways, through a variety of sources, and in both raw data formats and processed formats. Most countries have a bureau that publishes official statistical data that include education and training statistics. International organizations like OECD, International Labour Organization (ILO), the United Nations Educational, Scientific and Cultural Organization (UNESCO), and the World Bank also have data banks that include education and training statistics. The National Centre for Vocational Education Research in Australia and the National Center for Education Statistics in the US are examples of organizations offering VET statistics specific to their respective countries. Other key statistical agencies and organizations are listed in **Table 12**.

Table 12 Statistical agencies and organizations

<i>Name</i>	<i>Description</i>	<i>Availability</i>
Career/Technical Education Statistics (CTES)	CTES derives its data from existing National Center for Education Statistics' (NCES) surveys. NCES is the primary entity for collecting education-related data in the U.S. and other surveys it conducts include those relating to post-secondary education and adult literacy	http://nces.ed.gov
Eurostat	The European Commission's statistical portal serving the statistical needs of the European Union. Included under its theme Population and social conditions is the sub-theme Education and training. Available in German, English, and French	http://epp.eurostat.ec.europa.eu
International Labour Organization (ILO), Bureau of Statistics	Provides core official labor statistics, surveys and key indicators for different countries. Products include LABORSTA – database of labor statistics – and Key Indicators of the Labour Market (KILM)	www.ilo.org
Library of Statistics	A unit of Statistics Finland and has a large collection of national and international statistics. It provides links to public agencies and research institutions that produce statistics and its Webstat database can be used to search for statistics by topic and country	www.stat.fi/index_en.html
OECD Statistics Portal	Provides free access to some OECD databases and extracts from other databases. It covers 26 topics that include Education and training and labor	www.oecd.org/
UNESCO Institute for Statistics	Provides global and internationally comparable statistics on education, science, technology, culture, and communication	www.uis.unesco.org
World Bank Data & Statistics	National and international data are provided. Specific topics, including education and labor and employment have their own online databases. Country-specific information is also provided	www.worldbank.org

Glossaries, Dictionaries, and Thesauri

Glossaries contain technical/specialized terms related to a specific topic/subject with accompanying definitions which are usually more detailed than that provided in a dictionary, although subject dictionaries do provide detailed definitions/explanations. Glossaries are usually published as part of a publication where they cover terms used within that publication, but there are also subject-specific stand-alone glossaries. Thesauri contain headings or descriptors used in a particular database, catalog, or index. A thesaurus is used to search for synonyms, related terms, and preferred terms. Its purpose is to provide a controlled vocabulary list of terms from which subject headings are assigned and which aid in information retrieval. A selection of key resources are listed in **Table 13**.

Research in Progress

There is no easy way to stay in touch with what new research in VET is underway or for checking for early dissemination of findings, which are sometimes produced as preprints or as working papers prior to official publication. To find current research in the VET field a search of government education and educational research organizations and centers' web pages will often lead to a research-in-progress section or an online institutional

repository which may include preprint material. These repositories are usually also searchable via Google Scholar. Many institutions are still in the early stages of populating their repositories with data from their own institutions but over time these repositories should become a valuable resource for both research in progress and research publications.

Social Software Tools

The natural evolution of the Web has seen the emergence of social software tools such as wikis, blogs, RSS feeds, and podcasts that facilitate collaboration and sharing between users. The use of these tools in the delivery of VET is still in its infancy, although recent research suggests that using social software can be an effective strategy for knowledge sharing, capability development, and for enhancing teaching and learning in VET. Two tools that are of particular interest are social bookmarking and mailing lists. Social bookmarking involves saving the URLs of websites to a public website and sharing these bookmarks with other users. Tagging them with keywords allows them to be classified and organized into categories. Examples of social bookmarking services are Delicio.us and Furl. Mailing lists continue to play an important role in providing forums for discussions. JISCmail, the National Academic Mailing List Service based in the UK, provides a forum for users from higher and further education and research communities worldwide.

Table 13 Glossaries, dictionaries, and thesauri

Name	Description	Availability
Australian VET Online Glossary	Covers Australian VET terms and includes VET organizations and acronyms in Australia. Also includes some key international terms, organizations and acronyms	www.ncver.edu.au
The Jargon Buster	Covers common terms relating to adult learning in England and Wales. Published in 2005, the print copy is available from the National Institute of Adult and Continuing Education (NIACE) online bookshop	www.niace.org.uk
Jargon Buster (Learning and Skills Network)	Covers terms relating to learning and skill development in the UK	www.lsc.gov.uk/Jargonbuster
Terminology of vocational training policy: a multilingual glossary for an enlarged Europe	Covers key terms used in VET policy in Europe in six languages: English, French, German, Czech, Hungarian, and Polish. Published in 2004, it is available from the European Training Village Bookshop	www.trainingvillage.gr
ERIC Thesaurus	Contains descriptors (controlled-vocabulary) of education-related terms	www.eric.ed.gov
Multilingual Thesaurus of Vocational Training	Contains terms in six languages (English, French, German, Italian, Portuguese, and Spanish). Published in 1992, it is available from the European Training Village Bookshop	www.trainingvillage.gr
VOCED thesaurus	Contains descriptors used in searching the VOCED database. Based on the original APSDEP Thesaurus produced by the International Labour Organization's Asian and Pacific Skills Development Programme (ILO/APSDEP)	www.voced.edu.au

Conclusion

The advent of the Internet and the emergence of new technologies have made information much more accessible to a wider audience of users. At the same time, the Internet has created a tangled maze for the researcher trying to find specific data, particularly, in the area of VET which is often only found after delving deep into the disciplines of the social sciences and education. It is further predicted that more data will be created in the next 5 years than has been collected in the whole of human history resulting in a deluge of information and the challenge will remain to find and extract relevant information. This article has attempted to guide the researcher through the maze to the key information resources pertaining to VET.

What Are Employability Skills?

The Concept of Generic Skills: International Developments

As Brown *et al.* (2003: 107) state, “political and business leaders consistently tell us that efficiency and justice depend on people acquiring the knowledge, skills, and capabilities that employers need in an increasingly knowledge-driven economy.” It is generally accepted that such knowledge, skills, and capabilities encompass not only technical skills but also generic skills. Generic skills, sometimes known as key competencies or key skills, have been on the international education policy agenda for some time. International differences exist relating to which competencies should be designated as key (Weinert, 2001). The US SCANS list, produced in 1991, for example, has three foundation areas: basic skills, thinking skills, and personal qualities, that underpin five competencies that relate to resources, infraction, interpersonal systems, and technology (Nash and Korte, 1997). The Australian key competencies list (Australian Education Council (AEC)/MOVEET, 1993), which reigned for approximately 10 years until the introduction of the Employability Skills Framework, had seven key competencies:

- collecting, analyzing, and organizing information;
- communicating ideas and information;
- planning and organizing activities;
- working with others and in teams;
- using mathematical ideas and techniques;
- solving problems; and
- using technology.

Much to the regret of many stakeholders, an eighth key competency – cultural understanding – was considered but not eventually included. The Russian list of key competencies for school education is broader and involves specific application. It comprises competencies in the spheres of: cognitive activities, civil–social activities, socio-working activities, household, and culture/leisure activities (Pavlova, 2005: 348). Despite these differences among countries, it is clear that the notions of a desired list of generic skills, and of their development at least partly through formal education, is well known and well accepted.

Skills for Work or Skills for Life?

In the past decade, there has been a shifting of nomenclature from key skills or key competencies to employability skills. The official definition of employability skills that has been adopted in Australia is as follows:

The skills required to gain employment or establish an enterprise, (and) also to progress within an enterprise or expand employment capability, so as to achieve one’s potential and contribute successfully to enterprise strategic directions. (Department of Education, Science and Training (DEST), 2002)

A similar definition, albeit with a more critical edge, is proposed by Brown *et al.*:

Employability can be defined as the relative chances of acquiring and maintain different kinds of employment. (Brown *et al.*, 2003: 111)

In this definition, relative means relative to other employees or would-be employees.

Employability Skills Framework

The Australian Employability Skills Framework as adopted in 2002 is discussed here as follows.

Skills

- Communication skills that contribute to productive and harmonious relations across employees and customers;
- Team work skills that contribute to productive working relationships and outcomes;
- Problem-solving skills that contribute to productive outcomes;
- Initiative and enterprise skills that contribute to innovative outcomes;
- Planning and organizing skills that contribute to long- and short-term strategic planning;
- Self-management skills that contribute to employee satisfaction and growth;
- Learning skills that contribute to ongoing improvement and expansion in employee and company operations and outcomes; and
- Technology skills that contribute to effective execution of tasks.

Attributes

Loyalty, commitment, honesty and integrity, enthusiasm, reliability, personal presentation, common sense, positive self-esteem, a sense of humor, a balanced attitude to work and home life, an ability to deal with pressure, motivation, and adaptability are the attributes of the prospective employees (DEST, 2002).

The major difference in the skills list from the earlier Australian list of key competencies is the addition of initiative and enterprise skills, self-management skills and learning skills, and the removal of mathematics skills and collecting information. Another key difference is the addition of a list of desired personal attributes. Some controversy raged about this inclusion, and after quite a short time it was agreed that these attributes were not to be taught, but that learners may be familiarized with them as an awareness-raising activity (Australian Chamber of Commerce and Industry, 2007: 59). The final key difference is that each competency is given a descriptor that relates to workplaces; for example, "Communication that contributes to productive and harmonious relations across employees and customers." Thus, it has been said that the employability skills framework "is focused directly on the requirements of an employer and his/her workplace, whereas the key competencies relate to the individual's

capacity to learn and develop key skills that can be utilized in any workplace" (Association of Independent Schools of Victoria (AISV), 2003: 7).

The shift toward a workplace focus in generic skills development is part of a more general tension between general education and vocational education, and is mirrored in differing conceptions of lifelong learning policies (Chapman *et al.*, 2005) who identify three elements of lifelong learning in OECD documents: "learning for a more highly skilled workforce, learning for a better democracy and an inclusive society, and learning for a more personally rewarding life." Thus, to return to the quote from Brown *et al.* (2003) which opened this section, employability skills are said to be necessary for both efficiency and justice.

While this article focuses on the vocational education and training (VET) setting, employability skills are also in the foreground in school education and in university education (e.g., Precision Consultancy, 2007). In school education in Australia, the VET-sector employability skills are addressed in school curriculum in each state and territory in various ways, having replaced key competencies in this role. In university education, employability skills are incorporated within lists of graduate qualities or graduate attributes, which have been developed by all Australian universities. A typical list of graduate attributes is compared with VET-sector employability skills in **Table 1**.

While the university list is broader and at a higher level, conceptually, the lists are fairly similar, partly reflecting the fact that there has been involvement of business groups in setting the employability skills agenda in the university sector as there has been in schools and VET.

The Australian VET sector has thus moved very firmly toward a skills-for-work rather than a skills-for-life approach to generic skills. The prominent role of industry is in line with international trends that have been noted by Trier (2001). The set of employability skills described above, that has become firmly embedded in Australian VET, was developed by the two largest employer peak bodies, the Australian Chamber of Commerce and Industry and the Business Council of Australia. This capture of the employability skills agenda by employer peak bodies has not been without its critics. Sheldon and Thornthwaite (2005) argue that "employer associations in Australia have forged a VET policy agenda that highlights preferred employee attitudes and behaviors."

They suggest that this is a response to a tighter labor market. A focus on employability skills was originally a response to high unemployment because it makes prospective employees more acceptable to employers, but in many Western countries unemployment is now very low and there are labor shortages. In such situations, argue Sheldon and Thornthwaite (2005: 405), the purpose of a focus on employability skills, from an employer's perspective, is to align workers' attitudes to those of management, thereby increasing commitment and reducing labor turnover.

Table 1 List of graduate attributes and VET-sector employability skills

<i>Key competencies</i>	<i>ATN graduate attributes</i>
Initiative and enterprise skills that contribute to innovative outcomes	
Communication skills that contribute to productive and harmonious relations across employees and customers	Communicates effectively in professional practice and as a member of the community
Planning and organizing skills that contribute to long- and short-term strategic planning	
Team work skills that contribute to productive working relationships and outcomes	Can work both autonomously and collaboratively as a professional
Self-management skills that contribute to employee satisfaction and growth	
Problem-solving skills that contribute to productive outcomes	Is an effective problem solver, capable of applying logical, critical, and creative thinking to a range of problems
Technology skills that contribute to effective execution of tasks	
	Operates effectively with and upon a body of knowledge of sufficient depth to begin professional practice
	Demonstrates international perspectives as a professional and as a citizen
	Is committed to ethical action and social responsibility as a professional and citizen
Learning skills that contribute to ongoing improvement and expansion in employee and company operations and outcomes	Is prepared for life-long learning in pursuit of personal development and excellence in professional practice

Data from Ainley *et al.* (2006). Australian Report, MCEETYA.

are simply taken for granted. The perceived preference for employability skills is the stated reason why employer associations lobby for the inclusion of employability skills training in educational institutions. Similarly, in the university context, in a South African study, a government officer was reported as saying “The product that walks out does not meet the needs of industry,” thus leading to a wish to change the university curriculum to improve the product (i.e., graduates) (Kruss, 2004: 679).

However, there is another group of learners not in work: those who are temporarily out of work. Virgona and Waterhouse (2004) studied workers who had become unemployed and noted that the shift from generic to employability skills had been accompanied by a shift of responsibility for career management from employer to employee. They noted that displaced workers had a need to learn how to recognize and articulate the employability skills that they possessed and how to apply them in new situations (Virgona and Waterhouse, 2004: 119).

In disciplines outside education, such as labor market studies, the major focus in discussions of employability skills is on unemployed people and on the factors beyond the individual that create difficulties for people in finding or progressing within employment; these factors are becoming increasingly important as governments attempt to move people from welfare to work (Gore, 2005: 342). Debates in this literature revolve around supply-side approaches (relating to the need for individuals to make themselves more employable) versus demand-side theories (including employer attitudes, the availability of suitable education and training, and assistance for job-seekers). Hillage and Pollard (1998), in McQuaid and Lindsay, (2005: 207–208), discuss employability skills within a framework of employability assets (belonging to the individual), presentation (the use of these assets to get a job), deployment (i.e., use of assets within an organization and the labor market more generally), and context factors (the interaction of personal circumstances and the labor market).

Who Needs Employability Skills?

As implied by the definitions given above, everybody who wishes to work needs employability skills: those in work and those not yet in work. Employability skills are needed to get jobs, to keep them, and to get on at work. As Virgona and Waterhouse (2004: 120) put it, “generic skills develop throughout life and are not simply ‘acquired’ in a single ‘dose’ which can then be applied everywhere.”

Within VET, most attention has been focused on developing employability skills among learners who are not yet in full-time work, that is, young people. It is said that most employers value employability skills above technical competence in new entrants (e.g., ACCI, 2003: 3), although such responses may indicate that technical skills

How Can Employability Skills be Developed?

Inclusion in Qualifications

In Australia, generic skills are required to be included in training packages, which are the industry and occupational-based documents that collect together units of competency and package them into qualifications (Smith and Keating, 2003). The way in which the former key competencies were addressed varied considerably. Sometimes, there were discrete units of competency addressing, for example, communication skills; sometimes, the key competencies were directly mentioned within units, and sometimes key competencies formed a separate part of the unit which

explained how they might be developed; and sometimes with examples from the relevant industry area (Julian, 2004). Employability skills are now replacing key competencies in training packages, with Industry Skills Councils being required to review their training packages and make the required changes. The preferred method of including employability skills in training packages is for advice to be given in each qualification about how employability skills might be developed, rather than including advice in each unit of competency. For example, the Training and Assessment Training Package contains the following advice about problem-solving skills in the Certificate IV in Training and Assessment:

- Identifying hazards and assessing risks in the learning environment;
- Using time management skills in designing learning programs;
- Calculating cost of programs, logistics of delivery, and accessing appropriate resources; and
- Generating a range of options to meet client needs.

Source: National Training Information Service, <http://www.ntis.gov.au/Default.aspx?/trainingpackage/TAA04/qualification/TAA40104/eskills>.

A similar list is provided for each of the other employability skills.

Training packages are also required to address the level at which the relevant employability skill is to be developed. There are three levels, with level 3 being the most sophisticated (Down, 2003).

In Australian schools, employability skills are required to be taught in VET-in-schools subjects, which are now undertaken by over one-third of senior secondary students. The employability skills as indicated in the training package are transferred to the relevant school curriculum document. In addition, though, employability skills are recognized as being important in general school curriculum and are addressed, for example, through teaching programs designed to prepare students in general terms for entry into the workforce.

University curriculum is decided at a local rather than of the national level. Australian universities generally require some attention to be paid to graduate qualities or graduate attributes at the level of formal curriculum documents. In some cases, this is translated into documentation for individual subjects; for example, the University of South Australia requires documents for each subject to show clearly which graduate qualities are addressed at what level. Academic teaching staff may also use their own versions of employability skills; for example, lecturers in an English information technology course developed employability skill sets that they embedded in course design (Cox and King, 2006); an Irish university used VET-sector key skills in a mapping exercise (Tariq *et al.*, 2004).

Teaching

It is all very well to include employability skills in qualifications and curriculum documents, but these inclusions must be accompanied by teaching and training strategies. It has been noted that for this to happen, implementation strategies must be devised that assist teachers to teach the skills, and professional development for teachers should be provided (Down, 2003).

While employability skills can be successfully developed in workplaces, as will be discussed later, there are sound arguments, and strong political lobbying, for employability skills development to take place within educational institutions. As we have seen, within an educational institution context, employability skills may be developed within individual subjects, across subjects or within specific nonsubject programs. The latter is easier to achieve in a school than a VET or university context, because within schools, extra-curricular activities are offered that do not relate to specific units of study. For example, communication skills can be developed through debating competitions, drama productions, or leadership training; teamwork may be developed through programs such as the Duke of Edinburgh award (AISV, 2003: 9).

Another and perhaps more authentic way to develop employability skills is through the introduction of a workplace component into an education course. Periods of work experience, work placements, and internships have often been used for this purpose, in all sectors of education (e.g., Cox and King, 2006). While such placements often have a focus on the development of technical skills, some are more generic. In Australia, for example, short work-experience programs undertaken by school students in Year 10 are likely to be generic in nature, and employers are often asked explicitly to focus on key competencies or employability skills when a student is placed with them (Smith and Green, 2001).

In the absence of the opportunity for such programs, simulated or real enterprises may be set up within, or attached to, the educational institution. These are usually designed to develop particular vocational skills as well as employability skills. For example, a mock office may be set up for students to practice business administration skills (Deissinger *et al.*, 2006). Realistic work flows are set up to simulate the real world and institutions may link with each other to increase verisimilitude. Sometimes, these enterprises take on real work and earn money. These enterprises may be as simple as, for example, the production of greetings cards (Erebus Consulting Partners, 2003) or may be sophisticated enterprises that service large numbers of customers, such as TAFE training restaurants.

While the above suggestions link the development of employability skills to workplaces or simulated workplaces, it is of course possible to develop these generic

skills in contexts that do not relate to workplaces. It could well be argued that much general education aims at the development of such skills and that teachers naturally seek to develop them in their students. However, in the current context of competency-based VET curriculum that focuses greatly on the development of specific technical skills, it could be that this process is almost, by definition, under-developed in VET. Brogan (2006) suggests that employability skills are best taught when the intent to teach them is made clear to learners and learners are required to reflect on their achievements. He suggests that they are appropriately developed within a problem-based learning framework. Reflection may also assist learners transfer their generic skills into workplaces by assisting them to recontextualize and repackaging them (Yashin-Shaw *et al.*, 2004: 401).

A great deal of employability skills development takes place in workplaces. In many countries, young people start work part-time at a young age while still at school (Smith and Green, 2001) and hence are already working before much formal employability skills development is included in their formal education curriculum. A project investigating the ways in which employers managed and developed such very young workers found that employers had a range of strategies to develop employability skills (Smith and Comyn, 2003). These included strong induction programs, buddying arrangements, the allocation of increasing responsibility, and task rotation. The research also produced recommendations for other methods, including a work experience model, individual induction programs, project learning, and training or information for supervisors and co-workers.

A work experience model. Preparing employers for a novice worker in much the same way as they are prepared for work experience would assist the employer in understanding what a novice worker's needs were and how employability skills could most effectively and most speedily be developed.

Individual induction programs. Encouraging employers of novice workers to develop 6-month plans for their new staff would enable a range of experiences and opportunities for feedback to be planned.

Project learning. Engaging novice workers in authentic but small projects, which are of immediate use to the workplace could improve novice workers' confidence.

Training or information for supervisors and co-workers. Structured training for supervisors, buddies, and co-workers in dealing with novice workers and developing their employability skills would be valuable.

Assessing

Assessment of employability skills has long been recognized as a problematic issue (AISV, 2003). As Curtis (2004)

points out, generic skills constitute a complex construct and assessment cannot be straightforward. In assessing generic skills, we are to some extent assessing the learner as a person, and this is not only complex, it is also problematic (Williams, 2005). As Williams (2005: 45) says

an assessor must necessarily position themselves (sic) within the regime of dominant cultural norms which defines competency standards and informs the assessment ... (generic skills) are necessarily an attempt at normalization to the values, beliefs and expectations of the dominant culture which defines them.

Curtis (2004) suggests that the assessment of generic skills may be undertaken in one of four ways: holistic judgment by a teacher or panel of teachers; portfolio assessment; assessment in the workplace; and a standardized assessment instrument such as that used for university entry purposes in some countries. In universities, capstone assessment tasks may draw together learning from a whole course to illustrate the development of graduate attributes. This is the case, for example, in Charles Sturt University's VET teacher-training degree where a final subject includes an assignment where students are required to map and reflect on their progress in each of the graduate qualities during the lifetime of the course.

Clayton *et al.* (2004) suggest that whichever assessment method is selected, transparency and the provision of multiple opportunities to demonstrate achievement are key factors in good assessment. A well-known exemplar of the portfolios system within the Australian VET system is LINKup, a system utilized in the engineering discipline within TAFE in South Australia. In this system, students are asked to enter their own evidence to show their achievement of generic skills (Denton, 2005). This online system allows students to view the descriptors for the employability skills in detail and provides examples of evidence that might be provided.

Recording

Recording of assessment of generic skills is a key issue and one tied intimately to the assessment process, particularly in a portfolio approach. While schools in Australia, in some jurisdictions, report on employability skills as part of school-to-work portfolios, in VET institutions, there is no requirement to report on the attainment of employability skills. In fact, there is no place for such recording on official transcripts for qualifications. Universities, at least in Australia, have not adopted standard methods for the recording of achievement. In the light of such confusion, an agreement was reached at a national policy level in Australia that the best method of recording was to make each individual person responsible for recording his or her own

achievement of employability skills over a working lifetime (DEST, 2004). This method is only possible due to the advent of online technologies allowing each person's record to be continuously updated. As a consequence, funding was provided to an organization to develop a website for this purpose with the idea that individuals would record their development of employability skills through education, employment, community, and recreational activities.

Emerging Trends

Where Does the Responsibility Lie?

Underlying the whole employability skills debate – and also the methods of teaching, assessment, and recording – is the question of whose is the responsibility for developing employability skills in individual people. While industry often advocates for the development of these skills in educational institutions, and it has been stated that employers are “resistant to the idea that they have a positive contribution to make to improving employability” (Gore, 2005), it is also the case, as shown above, that they can be most appropriately developed in context, at work. There are reasons why workplaces are appropriate, and even vitally important, sites for their development. Employability skills are developed throughout one's working life, and hence employers need to view the process of employability skills development as a whole-of-workforce issue, not just one that relates to new entrants in their first jobs. The range of employability skills possessed by young workers starting their first jobs varies greatly. Some may have well-developed skills and others, sometimes through no fault of their own, poorly developed skills. Employers need to be prepared for the full range of employability skills, particularly when they are recruiting younger teenagers and in the current tight labor market where they cannot pick and choose. Employability skills are context-bound in that different industries and employers value and weight the skills and attributes quite differently. Hence, there are sound economic reasons for employers contributing to the cost of their development. Moreover, the worth of employability skills can only be fully appreciated in the workplace where the consequences of such skills can be seen.

However, not everyone has access to workplaces, and hence development within institutions must always take place to some extent. Further, many of the employability skills are those which underpin a sound general education and would therefore naturally be addressed in schools, VET providers, and universities. Individuals must also bear some of the responsibility, and the portfolio methods of assessment and reporting reflect this assumption.

Mismatch Between Learners' and Employers' Viewpoint

Employability skills are mentioned by employers as being vitally important in recruiting workers (e.g., ACCI, 2007). Yet, it is not easy for learners to understand this. There is certainly some evidence that learners tend to undervalue generic skills compared with technical skills (e.g., Saunders *et al.*, 2004), and this is perhaps an inevitable consequence of what some perceive as an overly vocational curriculum. Does this mean that VET courses should be restructured to focus much more explicitly on employability skills? Or merely that individuals need to take more responsibility for their own employability skills? But would an increased focus on employability skills reduce and/or devalue necessary technical content?

What Skills Do Teachers and Others Need to Develop Employability Skills in Learners?

It has been recognized that teachers need specific skills to develop these skills in their learners, but there has been little work done to identify what particular skills are needed (AISV, 2003: 6). In the current Australian minimum qualification for VET teachers, the Certificate IV in Training and Assessment, there is no explicit mention of employability skills in units or elements of competency. A study in Australian TAFE Institutes in 2003 (Callan, 2004) found that teachers were not well prepared to teach generic skills. Students also reported that teachers left them “to guess or infer the actual importance of many (generic) skills” (Callan, 2004: 61).

Smith and Comyn (2003) found evidence, based on their study of companies that recruited large numbers of part-time teenage workers (e.g., fast food outlets) that attention was paid to developing skills in those supervising and training such workers. It was suggested that training for the supervisors and trainers needs to include an understanding of what it is like to begin working life, as well as suggested processes for assisting the development of employability skills. There was little standardization of learning procedures except in large companies which routinely recruited large numbers of teenagers. In one large fast food company, part of the performance management of managers depended on their ability to develop employability skills in young workers. It is possible that this model could be transferred to the education sector, so that performance appraisal of VET teachers includes their ability to develop employability skills in their learners.

Conclusion

It is generally agreed that employability skills are important for everybody, but there remain important areas of

disagreement that will probably never be resolved. Some of these areas of disagreement are as follows:

- What is the nature of employability skills: should they be weighted toward what employers are seen to want, or more broadly conceptualized?
- How much responsibility should the education system (as opposed to employers and/or individuals) take for their development?
- In particular, what should be the responsibility of the sectors of education that provide education for young people before they start their first full-time jobs?
- How can awareness of a desired set of employability skills be raised among learners, teachers/trainers, and employers?
- How can employability skills be best taught, assessed, and reported?
- How can teachers, trainers, and others responsible for the management of learning in students and workers be better trained to develop employability skills in those for whom they have responsibility?

These areas are all interrelated, and so it is likely that there will always be tension around the concept of employability skills. This tension is productive rather than otherwise.

Learning Styles in Vocational Education and Training

J Vorhaus, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

This article provides an overview of research on learning styles, in the context of vocational education and training (VET). Since there are over 70 models of learning styles, attention is largely given over to the secondary literature – to reviews and analyses of learning-styles research. These tend to draw attention to the complexity of the field, and the uncertainty that exists about the accuracy and reliability of many of the models now widely in use. We identify the characteristics of the best-known models, the implications for teaching and training, and the empirical evidence of their impact on learning and performance. We review what is known about the learning styles of vocational learners, and how far teachers and trainers take account of these. This requires acknowledgment of the distinguishing features of VET as a teaching and learning environment. Research has recently focused on situated and informal learning, communities of practice, and legitimate peripheral participation, and we explore how learning styles theory and practice are related to these themes.

Definitions

Any review of definitions of learning styles would take up most of this encyclopedia; no account is beyond dispute, but the following is probably less controversial than most.

In a review of research, Adey *et al.* (1999) distinguished between learning styles, learning strategies, and learning skills. A learning style is an individual's deep-rooted preference for a particular type of learning; the example is given of folding one's arms – each person has a preferred way of doing this, and while we can all learn to fold our arms in different ways this would be less natural and harder to achieve as compared with our preferred way of going on. Equally, if some theories of learning styles are correct, there are people who are imagers – they prefer to learn from pictures and diagrams – and there are people who are verbalizers, preferring to learn from words. Imagers can learn from words and verbalizers can learn from images, but in both cases this would represent the harder option.

Learning skills are likened to tricks – they are specific, teachable, and designed for individual tasks. An example of a learning skill is the use of a mnemonic as an aid to memory – as when we recite “Richard of York Gave Battle in Vain” to help remember the seven colors of the rainbow.

Between these two options are learning strategies, which denote the groups of skills acquired by a learner

for particular purposes, such as setting objectives, and selecting and formulating questions (*ibid.*: 2).

In their review, Entwistle and Peterson offer a similar account. Learning styles are defined as “consistent preferences for adopting learning processes, irrespective of the task or problem presented”; learning strategies, on the other hand, are “specific to education and training, being more context-specific ways of tackling learning tasks that involve characteristic combinations of intentions, learning processes and study activities” (Entwistle and Peterson, p. 2).

Learning-Style Models

As with definitions, there are numerous models of learning styles; this article offers only a brief summary, identifying a small sample that has influence in the context of VET.

Witkin (1977) explored individual differences in perceptual processing, and developed a theory of perception that drew attention to field dependence and independence. While some people find it easy to see a figure embedded in a background display, others find that hard to do. Witkin suggested that field-independent people see the figure easily when they are not confused by what surrounds it. This was extended to the notion of a learning style: some people are able to analyze something in isolation from surrounding issues, while others need to take account of the surround throughout the learning process. In a similar vein, Pask (1976) suggested that there are those who learn by taking individual items in turn, before putting these together to form a whole; others prefer to grasp the whole right from the start. In other words, some learners tend to be serialists and others tend to be holists.

Marton and Säljö (1976) argued that some learners are more typically ‘deep processors,’ while others are ‘surface processors.’ Deep processors generally seek to understand underlying concepts and theories, and aim to make connections between these and their existing knowledge. Surface processors are more likely to settle for knowing the facts or techniques without, at the same time, acquiring an understanding of the underlying theory.

A widely used model of learning styles was developed by Kolb (1976). He suggested that individuals learn and solve problems by progressing through a four-stage cycle: concrete experience, reflective observation, abstract concepts, and active experimentation. Concrete experience and abstract concepts represent two ends of one spectrum,

and active experimentation and reflective observation represent two ends of a second spectrum. Kolb identified four learning styles: accommodator, assimilator, diverger, and converger – and these are usefully summarized in Coffield (2004a: 62):

- The accommodating style (concrete, active): emphasises concrete experience and active experimentation; likes doing things, carrying out plans; good at adapting to changing circumstances; solves problems in an intuitive trial-and-error manner; at ease with people but sometime seen as impatient and 'pushy'.
- The assimilating style (abstract, reflective): prefers abstract conceptualisation and reflective observation; likes to reason inductively and to create theoretical models; is more concerned with ideas and abstract concepts than with people; thinks it more important that ideas be logically sound than practical.
- The diverging style (concrete, reflective) emphasises concrete experience and reflective observation; is imaginative and aware of meanings and values; views concrete situations from many perspectives; adapts by observation rather than action; interested in people and tends to be feeling-oriented.
- The converging style (abstract, active) relies primary on abstract conceptualisation and active experimentation; good at problem solving, decision making and the practical application of ideas; does best in situations like conventional intelligence tests; is controlled in the expression of emotion and prefers dealing with technical problems rather than interpersonal issues.

According to Kolb, while someone may prefer one learning style in one situation, and another style in another situation, the preferred style is likely to remain the same within the same learning context.

Honey and Mumford (1992: 1) define a learning style as "a description of the attitudes and behaviour which determine an individual's preferred way of learning," and they identify four learning styles under the headings of activists, reflectors, theorists, and pragmatists (Honey and Mumford, 2000).

Activists' strengths include a tendency to be flexible, open minded, and prepared for new situations. Weaknesses include a tendency to take the immediately obvious action without thinking through the consequences and taking unnecessary risks. Reflectors' strengths include a tendency to be careful, thorough, and methodical; weaknesses include a tendency to hold back from direct participation, being slow to reach decisions, and being too cautious and risk averse. Theorists' strengths include a tendency to be logical, rational, and objective, and to ask probing questions. Weaknesses include a low tolerance for uncertainty and ambiguity, and impatience with the intuitive and subjective. Pragmatists strengths include an eagerness to test things out in practice, being practical,

down-to-earth, and realistic. Weaknesses include a tendency to reject anything without an obvious application, impatience with indecision, and being more oriented toward tasks than people (Coffield, 2004a: 81).

The two primary uses of the Honey and Mumford Learning Styles Questionnaire (Honey and Mumford, 2000) are to devise personal development plans and to show managers how to assist staff by, for example, choosing activities that are suited to the learning style of the learners. However, they point out (Honey and Mumford, 2000: 52): "managers, if they encourage learning at all, will tend to do so in ways consistent with their own learning styles."

Cognition-Centered Approaches

Allinson and Hayes developed the Cognitive Styles Index (CSI) for use in adult organizational contexts. The items of the CSI reflect their view that: "intuition, characteristic of right-brain orientation, refers to immediate judgement based on feeling and the adoption of a global perspective. Analysis, characteristic of left-brain orientation, refers to judgement based on mental reasoning and a focus on detail" (Allinson and Hayes, 1996: 122).

At one end of the wholist-analytical dimension of cognitive style are those who break down information into its component parts (the analytics), while others prefer a global or overall view of information (the wholists) (Riding, 1997: 30). Among holists, there is a tendency not to pay sufficient attention to the distinctions between the parts of a problem; among analytics, there is a tendency to focus on the parts at the expense of other parts or the whole.

While acknowledging that cognitive style can be shaped by culture and altered by experience, Allinson and Hayes argue that it may prove to be useful in work settings – through fitting people to jobs and, where feasible, adjusting job demands to what best suits the individual. Intuitive managers were found to be more liked, irrespective of the style of their subordinates, and matched styles were found often to be effective in mentoring relationships.

According to Riding (1997), verbalizers "consider the information they read, see or listen to, in words or verbal associations"; while imagers, when they read, listen to or consider information, experience "fluent spontaneous and frequent pictorial mental pictures" (Riding, 1994: 48). Riding (1991) has devised a computer-administered assessment of the verbal-imagery dimension of cognitive style (the Cognitive Styles Analysis (CSA)), and he suggests that learning is affected by the interaction of verbal-imagery cognitive style and the form in which material is presented. For example, Riding and Watts (1997) presented participants with a choice of three instructional formats (unstructured verbal, structured verbal, and structured pictorial) and found that most verbalizers selected the verbal version while most imagers selected

the pictorial version. Riding (2001: 61) concludes: “imagers generally learn best from pictorial presentations whereas verbalisers learn best from verbal presentations.”

In research carried out with high school students and trainees in industry, Riding and Pearson (1994) suggest that the wholist-analyst dimension interacts with the structure of teaching material to affect learning performance. Riding and Al-Sanabani (1998) observed an interaction between gender and wholist-analyst style in their effect on learning from materials that varied in their use of headings and subdivisions of textual content. Sadler-Smith and Riding (1999) explored the learning preferences of business and management undergraduates and observed that analytics preferred to have control themselves whereas the wholists had no preference (Riding *et al.*, 1997; Glass and Riding, 2000).

The State of the Field
