Markov property – This property states that to make predictions of the behavior of a system in the future, it suffices to consider only the present state of the system and not past history.

Order Statistics – Original random sample arranged in order of magnitude.

Probability integral transformation – A transformation that transforms an arbitrary distribution to the uniform distribution.

Robust estimators – Estimators that are efficient in presence of outliers in the sample.

Two sample problem – A hypothesis testing problem verifying whether two sample are identically distributed or not.

The Subject of Order Statistics

The independent and identically distributed random variables, which can be interpreted as results of an experiment measuring values of a certain random variable arranged in order of magnitude, are called order statistics. In the statistical model of many experiments, for instance, in reliability analysis, life time studies, the analysis of time to graduation of students, and testing of strength of materials, the realizations arise in nondecreasing order; therefore, the use of order statistics is necessary. Order statistics are extensively used in statistical inferences: in estimation theory and hypothesis testing.

Let X_1, X_2, \dots, X_n denote a random sample from a population with cumulative distribution function (cdf) $F(x)$. Suppose that the elements of this sample are arranged in order of magnitude and $X_{(1)}$ denotes the smallest; $X_{(2)}$ denotes the second smallest; etc., and $X_{(n)}$ denotes the largest of the set X_1, X_2, \dots, X_n . Then $X_{(1)} \leq X_{(2)} \leq \dots \leq X_{(n)}$ denotes the original random sample arranged in increasing order of magnitude, and these are called the order statistics of the sample X_1, X_2, \dots, X_n . We call $X_{(i)}$, for $1 \leq i \leq n$ the i th order statistic. The subject of order statistics deals with the distributional properties of $X_{(i)}$ itself, and some functions of the subset of the n order statistics and their applications. If, for example, the scores of n students in the exam are X_1, X_2, \dots, X_n then $X_{(n)}$ represents the score of the best student; $X_{(1)}$ is the score of the weakest; the sample range $W = X_{(n)} - X_{(1)}$ is a measure of dispersion; the sample median, defined as $(X_{(n/2)} + X_{(n/2 + 1)})/2$ for an n even and as $X_{[(n+1)/2]}$, for n odd, is a measure of location and estimate the central tendency of scores. Here, $[a]$ is the integer part of the number a . The sample midrange, defined as $(X_{(1)} + X_{(n)})/2$, is also a measure of central tendency.

Order statistics have wide applications in many areas where the use of an ordered sample is important. Order statistics are among the most fundamental tools in non-parametric statistics, because the transformation $U_{(i)} = F(X_{(i)})$ produces a random variable which is the i th order statistics from the uniform population on the interval $(0, 1)$, and therefore $U_{(i)}$ is distribution free, that is, its distribution function is independent of the distribution function F of the original sample. This transformation is called the probability integral transformation.

It is well known from classical statistical theory that the natural estimate of an unknown distribution function is the empirical distribution function, which is a function of order statistics. Therefore, many important statistics in estimation theory and hypothesis testing appear to be an integral functional of the empirical distribution function, and can be expressed in terms of order statistics. Order statistics do not change their order under probability integral transformation, namely if $U_{(i)} = F(X_{(i)})$, $i = 1, 2, \dots, n$, then $U_{(1)} \leq U_{(2)} \leq \dots \leq U_{(n)}$. Due to unique distribution free properties, they are widely used in nonparametric interval estimation and hypothesis testing.

Order statistics and their properties have been extensively studied since the early part of the last century, and recent years have seen a particularly rapid growth of studies. The multiauthored book *Contributions to Order*

Statistics, edited by A. H. Sarhan and B. G. Greenberg, appeared in the Wiley series in probability and statistics in 1962. The first monograph, *Order Statistics* by H. David appeared in 1970 in the same Wiley series and has served as a text, a survey of growth, and a general introduction. The second edition appeared in 1981 and the third, coauthored with H. Nagaraja, in 2003. For further reading the reader is referred to Arnold *et al.* (1992) and Balakrishnan (2007).

Basic Distribution Theory

The elements of the sample X_1, X_2, \dots, X_n are independent and identically distributed (iid), but the order statistics $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ are dependent random variables. The distribution of the r th order statistics can be derived using the independence of the random variables X_1, X_2, \dots, X_n and observing that the event $\{X_{(r)} \leq t\}$ occurs if and only if at least r of the observations X_1, X_2, \dots, X_n falls below t . Therefore, taking into account the fact that the probability of occurrence of exactly i of events $\{X_k \leq x\}$ in n independent Bernoulli trials is $\binom{n}{i} F^i(x)(1-F(x))^{n-i}$, the cdf of $X_{(r)}$ can be written as

$$F_r(x) = P\{X_{(r)} \leq x\} = \sum_{i=r}^n \binom{n}{i} F^i(x)(1-F(x))^{n-i} \quad [1]$$

If F is absolutely continuous with probability density function (pdf) f , then [1] can also be rewritten as follows:

$$F_r(x) = \frac{n!}{(r-1)!(n-r)!} \int_0^{F(x)} u^{r-1}(1-u)^{n-r} du \quad [2]$$

Formula [1] holds true for both discrete and continuous distribution functions. Formula [2] is true only for absolutely continuous distributions. Given the realizations of the n order statistics to be $x_{(1)} < x_{(2)} < \dots < x_{(n)}$, the original random variables X_i are restrained to take on the values $x_{(i)}$ ($i = 1, 2, \dots, n$) which by symmetry assigns equal probability to each of the $n!$ permutations of $(1, 2, \dots, n)$. Therefore, the joint pdf of all n order statistics is

$$f_{1,2,\dots,n}(x_1, x_2, \dots, x_n) = n! \prod_{i=1}^n f(x_i) \text{ for } x_2 < x_1 < \dots < x_n$$

Since $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ are dependent random variables, then their joint distributions are important. The expressions for the joint pdf's of two or more order statistics can be found in David (1981).

Order statistics from uniform distribution on $[0, 1]$ are important when one needs to generate the order statistics from any distribution using Monte Carlo simulation. If $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ are order statistics from the population with cdf F and $F^{-1}(u) = \inf\{x: F(x) \geq u\}$ is the inverse of F , then $F^{-1}(U_{(i)}) = X_{(i)}$, the equality here is in distribution. There are various methods of generating uniform random

variables. Using computer simulation we generate sample U_1, U_2, \dots, U_n from the uniform distribution in $[0, 1]$ and then order the sample. The $X_{(i)}$ value then can be calculated as $X_{(i)} = F^{-1}(U_{(i)})$. For various methods of generating order statistics, see Tadikamalla and Balakrishnan (1998).

The pdf of $W_{rs} = X_{(s)} - X_{(r)}$ when the parent population is uniform in $[0, 1]$ depends only on $s-r$ and not on r and s individually. In addition, the pdf of the sample range $W = X_{(n)} - X_{(1)}$ is $fW_{1n}(x) = n(n-1)x^{n-2}(1-x), 0 \leq x \leq 1$.

Let $X_{(1)}, \dots, X_{(n)}$ be the order statistics based on the sample X_1, X_2, \dots, X_n with cdf $F(x) = 1 - \exp(-\lambda x), x \geq 0$. Then the spacings $Y_1 = X_{(1)}, Y_2 = X_{(2)} - X_{(1)}, \dots, Y_n = X_{(n)} - X_{(n-1)}$ are independent; furthermore, the random variables $Z_r = (n-r+1)\lambda(X_{(r)} - X_{(r-1)}), r = 1, 2, \dots, n$ are iid with cdf $F(x) = 1 - \exp(-x), x \geq 0$, where $X_0 = 0$. If n units are placed under strength test and X_1, X_2, \dots, X_n are independent random variables with exponential distribution and represent the life lengths of these units, then the lengths of time intervals $X_{(r)} - X_{(r-1)}, r = 1, 2, \dots, n$ between two failures are independent and identically distributed random variables. Then $X_{(r)} = \sum_{i=1}^r Z_i / \lambda(n-i+1)$ that is, $X_{(r)}$ can be represented as a sum of i random variables. Then the conditional distribution of $X_{(r+1)}$ given $X_{(1)} = x_1, X_{(2)} = x_2, \dots, X_{(r)} = x_r$ is the same with the conditional distribution of $X_{(r+1)}$ given $X_{(r)} = x_r$. This means that $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ satisfy Markov property and form an additive Markov chain. The Markov property states that to make predictions of the behavior of a system in the future, it suffices to consider only the present state of the system and not the past history. The sequence of dependent random variables satisfying the Markov property is called the Markov chain. This property helps in establishing the Markovian dependence structure of order statistics from the sample with any continuous distribution. It follows that the order statistics $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ from a population with continuous cdf form a Markov chain.

There are some interesting properties of order statistics connected with truncation of these ordered observations. For instance, let $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ be order statistics of the sample X_1, X_2, \dots, X_n with absolutely continuous cdf F and pdf f . Then given $X_{(r)} = x, X_{(s)} = y$ the joint pdf of $(X_{(r+1)}, X_{(r+2)}, \dots, X_{(s-1)})$ is the same with the joint pdf of the order statistics $(Y_{(1)}, Y_{(2)}, \dots, Y_{(s-r)})$ from the sample Y_1, Y_2, \dots, Y_{s-r} size $s-r$, where Y_i has pdf of the random variable X_i given $x < X_i < y$.

A counting process $\{N(t), t \geq 0\}$ representing the total number of event A occurring up to time t is called a Poisson process if it has stationary and independent increments. Note that, a stochastic process $\{N(t), t \geq 0\}$ is said to have independent increments if, for all $t_0 < t_1 < t_2 < \dots < t_m$, the random variables $N(t_1) - N(t_0), N(t_2) - N(t_1), \dots, N(t_m) - N(t_{m-1})$ are independent. It possesses stationary increments if $N(t+b) - N(t)$ has the same distribution for all t . There is an interesting connection

between the interarrival times of the occurrence of event A and the order statistics. Let $N(t)$ be a Poisson process with rate λ , $\lambda > 0$, then $P\{N(t) = k\} = e^{-\lambda t}(\lambda t)^k/k!$ ($k = 0, 1, 2, \dots$). Denote by X_1 the time of the first event, X_2 the time between the first and the second event, X_n the time between $(n-1)$ th and n th event. Then the sequence $\{X_n\}_{n \geq 1}$ is called the sequence of interarrival times. It is well known that X_1, X_2, \dots, X_n are iid exponential random variables having a mean of $1/\lambda$. Another quantity is $S_n = \sum_{i=1}^n X_i$, $n \geq 1$, the arrival time of, or waiting time until, the n th event. Then given that $N(s) = n$, the n arrival times S_1, \dots, S_n have the same distribution as the order statistics corresponding to the independent random variables uniformly distributed on the interval $[0, s]$, i.e.

$$\begin{aligned} P\{S_1 \leq t_1, S_2 \leq t_2, \dots, S_n \leq t_n | N(s) = n\} \\ = P\{U_{(1)} \leq t_1, \dots, U_{(n)} \leq t_n\} \\ = \frac{n!}{s^n}, 0 < t_1 < t_2 < \dots < t_n, \end{aligned}$$

where $U_{(i)}$ is the i th order statistic from uniform in $[0, s]$ distribution.

Order Statistics in Statistical Inference

Order statistics are essential in several optimal inference procedures and hypothesis testing problems. In many cases when the underlying distribution has finite support, the order statistics themselves become sufficient statistics and, thus, provide minimum variance unbiased estimators and the most powerful test procedures for the unknown parameters. Note that, if the random variable X takes values from the interval $[a, b]$, then we say that this random variable has support $[a, b]$, $-\infty \leq a < b \leq \infty$. If the random variable has finite support and if the support involves the parameters of distribution of this random variable, then many of estimates of parameters involve order statistics. For example, let X be uniform in $[0, \theta]$ random variable, that is, the pdf of X is $f(x; \theta) = 1/\theta$ if $0 \leq x \leq \theta$. It is well known that $X_{(n)}$ is a sufficient, and complete statistic for θ and $\frac{n+1}{n}X_{(n)}$ is an unbiased estimator of θ .

The order statistics appear in a natural way in the inference procedures when the sample is censored and only part of the sample values are available. The censored samples appear in the life-testing experiments when n items are kept under observation until failure. These items could be technical systems or their components, patients under certain drug or clinical conditions, or candidates undergoing exams in complex conditions or under time pressure.

In measuring performance on examinations many teachers use average $\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i$ and sample variance $S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2$, where X_1, X_2, \dots, X_n are test scores of students. It is well known that poor lecture

attendance is associated with lower test scores (see, e.g., Myles and Henderson, 2002, Williams *et al.*, 2002; Balch, 1992). The presence of a student with poor attendance will probably lead to a lower test score for the class, and this outlier will affect the sample mean \bar{X} and variance S^2 . Therefore, the existence of outliers will result in misestimation of class performance. To avoid this kind of problem in applications, we need to find estimators only minimally affected by the presence of outliers. In statistical literature such estimators are called robust estimators. One popular robust estimator of the center of a symmetric distribution is the symmetric trimmed mean

$$\hat{\theta}_r = \frac{1}{n-2r} \sum_{i=r+1}^{n-r} X_{(i)}, \quad 0 \leq r \leq \left[\frac{n-1}{2} \right]$$

where we have trimmed the top r and the bottom r order statistics. The trimmed means give less weight to the sample extremes and are suggested as robust estimators. They are robust against the presence of a small number of outliers and highly efficient in their complete absence. Barnett and Lewis (1994) describe an estimator:

$$\hat{\theta} = \begin{cases} \hat{\theta}_0, & \text{if } \max\{(\bar{X} - X_{(n)}), (X_{(n)} - \bar{X})\} < c \\ \hat{\theta}_1 & \text{otherwise} \end{cases}$$

for the mean μ of a sample from an $N(\mu, 1)$, where *distribution suspect one of the values is from $N(\mu + \delta, 1)$* , and $\hat{\theta}_0$ and $\hat{\theta}_1$ are trimmed means and c can be the specified percentile of the distribution of $\max |X_i - \bar{X}|$. This statistic is used for testing for a single extreme outlier. Balakrishnan (2007) computed the bias and mean square error of robust estimators constructed in the base of order statistics and presented tables of numerical values for $n = 10$. For a further reading on robust statistics, see Huber (1981), Andrews *et al.* (1972), and David and Ghosh (1985).

Order Statistics and Education

Order statistics play an important role in educational statistics. In many statistical analyses, the information from a random sample is utilized through the ordered values of the sample. At the beginning of the course 'nonparametric statistics' the students face the nontrivial operation of ordering of a random sample. On the one hand, theoretically the elements of the random sample are random variables, that is, measurable functions $X_1(\omega), X_2(\omega), \dots, X_n(\omega)$ ($\omega \in \Omega$) given in the probability space $\{\Omega, F, P\}$, where Ω is a sample space, F is a σ -algebra of subsets of the sample space, and P is a probability measure. On the other hand, the sample values X_1, X_2, \dots, X_n are considered as realizations of the experiment measuring values of the random variable X , namely, they are numbers. In deriving the cdf of r th order statistics for better

understanding of the idea of proof, we consider the random sample as numbers, when they are actually random variables. Understanding the structure of order statistics presents difficulties when considering the original sample as functions. For example, the distribution function of the maximal order statistic $X_{(n)}$ is $F_n(x) = P\{X_{(n)} \leq x\}$ and if we consider X_1, X_2, \dots, X_n as numbers, then the maximum is less than or equal to x if all numbers are less than or equal to x . Therefore, the event $\{X_{(n)} \leq x\}$ occurs if and only if all the members of original sample are less than or equal to x , namely $\{X_1 \leq x, X_2 \leq x, \dots, X_n \leq x\}$. Now, since the original X 's are independent and all have the same cdf F we can state

$$F_n(x) = P\{X_{(n)} \leq x\}$$

$$P\{X_1 \leq x, X_2 \leq x, \dots, X_n \leq x\} = F^n(x)$$

In general, the cdf of r th order statistic, $P\{X_{(r)} \leq x\} =$

$$P\{\text{at least } j \text{ } X\text{'s are } \leq x\} = \sum_{i=j}^n \binom{n}{i} P\{\text{exactly } i \text{ } X\text{'s are } \leq x\},$$

here again we use the independence of the original sample. This approach is useful for understanding the structure of order statistics that are actually measurable functions of the elements of sample space.

As pointed out above the probability integral transformation $U = F(X)$ transforms the order statistics $X_{(1)}, X_{(2)}, \dots, X_{(n)}$ to uniform order statistics $U_{(1)}, U_{(2)}, \dots, U_{(n)}$ and preserves the order. In hypothesis testing and confidence intervals, the field of nonparametric statistics relies on the concept known as distribution-free property. For the distribution-free hypothesis test, the significance level remains constant over a class of underlying distributional assumptions. The distribution-free or invariant confidence interval has a constant confidence level holding over a class of distribution functions. The test statistic $S = S(X_1, X_2, \dots, X_n)$ is designated distribution free over some class of distributions, say \mathcal{F} if the distribution of S is the same for every distribution in \mathcal{F} . The view that many students have difficulties understanding these concepts seems to be a common one among my colleagues teaching nonparametric statistics. However, this problem can be overcome using order statistics to construct effective examples. For example, let $\mathcal{F} = \mathcal{F}_\theta$ be a scale parameter class; this means that if $F_\theta(x) \in \mathcal{F}_\theta$ then $F_\theta(x) = F(x/\theta)$, for some distribution function F and parameter θ . Then the distribution of statistic defined as midrange divided by the range, that is,

$$T = \frac{1X_{(n)} + X_{(1)}}{2X_{(n)} - X_{(1)}}$$

does not depend on parameter θ ; in other words, this statistic is distribution free for the class \mathcal{F}_θ . As another example, let $\mathcal{F} = \mathcal{F}_c$ be the class of all continuous distribution functions and X_1, X_2, \dots, X_n be a sample from the

population with distribution function $F \in \mathcal{F}_c$, and let X_{n+1} be the $(n+1)$ th observation from the same population independent of X_1, X_2, \dots, X_n , then the probability that X_{n+1} falls into interval $(X_{(r)}, X_{(s)})$ is $(s-r)/(n+1)$. This probability is the same for all distribution functions F from the class \mathcal{F}_c , which means that the interval $(X_{(r)}, X_{(s)})$ constructed by the order statistics is the distribution-free confidence interval for the future observation X_{n+1} . It is interesting to note that if the distribution is continuous under some regularity conditions, the interval $(X_{(r)}, X_{(s)})$ is the only distribution-free interval for the future observation X_{n+1} (see Bairamov and Petunin, 1990).

The importance of order statistics can also be seen in teaching the theory of the ranking statistics used in two-sample problem with unknown shift parameters. The sample observation X_i is said to have rank R_i among X_1, X_2, \dots, X_n if $X_i = X_{(R_i)}$, where $X_{(R_i)}$ is the R_i th order statistic. Let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m be independent random samples from continuous distributions with distribution functions $F(x)$ and $G(x) = F(x - \theta)$, respectively, where $-\infty < \theta < \infty$ is an unknown shift parameter. The Mann-Whitney-Wilcoxon nonparametric test for verifying the null hypothesis $H_0: \theta = 0$ against alternative $H_1: \theta > 0, \theta < 0$ or $\theta \neq 0$ is constructed based on the distribution-free property of the rank statistic $W = \sum_{i=1}^n R_i^*$ under hypothesis H_0 , where R_j is the rank of R_j among the m X 's and n Y 's combined and treated as a single set of observations. In a general two-sample problem, when $H_0: F = G$ is to be tested against a general class of alternatives $H_1: F \neq G$, the Kolmogorov-Smirnov test based on the distance $D_{n,m} = \sup_{-\infty < x < \infty} |F_n(x) - G_m(x)|$ of two empirical distribution functions $F_n(x)$ and $G_m(x)$ of the samples X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m , respectively, is one of the most important consistent hypothesis tests. The empirical distribution function $F_n(x)$, defined as the number of observations X_1, X_2, \dots, X_n less than or equal to x divided by n , has the following expression in terms of order statistics:

$$F_n(x) = \begin{cases} 0, & \text{if } x < X_{(1)} \\ \frac{k}{n} & \text{if } X_{(k)} \leq x < X_{(k+1)} \\ 1 & \text{if } x \geq X_{(n)} \end{cases} \quad \text{for } k = 1, 2, \dots, n-1$$

Example

The selection of students from different schools for a scholarship shortlist has been an issue of public interest. In many countries there is a general consensus on the existence of bias in selection of candidates. Fairness has been defined in a variety of ways; Torndike (1971) proposed a definition of fairness; Cole (1973) made a fundamental assumption in the reviewed models that the applicants are independently and identically distributed

random variables. The model proposed by Olkin and Stephens (1993) used ordered scores of students, namely, order statistics. More specifically, let X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m be test scores for two groups of students representing two different high schools A and B , respectively. We assume that X_1, X_2, \dots, X_n and Y_1, Y_2, \dots, Y_m are random samples from continuous distributions F_1 and F_2 , respectively. The $m + n$ scores are pooled and jointly ranked, and the top k students are shortlisted for scholarships. Let R be the number of students from the first group that enter the shortlist. We are interested in the probability $P\{R = r\}$ that exactly r students from high school A appear in the shortlist. Olkin and Stephens (1993) provide an elegant solution to this problem. If $F_1 = F_2$, in other words, we consider two different groups of students from identical high schools, then this probability depends only on n, m, r , and k and can therefore be easily calculated. For the special case of choosing a single candidate, that is, $r = k = 1$, the probability that exactly one student from high school A will appear in the shortlist is equal to $n/(n + m)$, which is the probability that the maximal score $X_{(n)}$ of the first group is greater than the maximal score of the second group $Y_{(m)}$, where $X_{(1)} \leq X_{(2)} \leq \dots \leq X_{(n)}$ and $Y_{(1)} \leq Y_{(2)} \leq \dots \leq Y_{(m)}$ are the ordered scores of two groups. A numerical analysis shows that when n is low relative to m , this probability is low, which may mean that a student from a small but prestigious school has considerably less chance of being shortlisted when in competition with a larger school. Some numerical values of probability that exactly r students from the high school A enter the shortlist for $r = 1$ and $r = 2$, and $k = 1, 2, \dots, 10$ are given below:

1. $n = 9, m = 30$

k	1	2	3	4	5	6	7	8	9	10
$P\{1, k; 9, 30\}$	0.11	0.12	0.23	0.34	0.37	0.42	0.45	0.46	0.47	0.47

2. $n = 3, m = 25$

k	1	2	3	4	5	6	7	8	9	10
$P\{1, k; 3, 25\}$	0.	0.01	0.02	0.04	0.07	0.10	0.14	0.17	0.21	0.25

Let \mathbf{P} denote the probability of the event that the best candidate from school A with score $X_{(n)}$ is included in the top group of k candidates; thus, at least one student from A is in the list. We provide a numerical example of $n = 9$ and $m = 30$:

k	1	2	3	4	5	6	7	8	9	10
\mathbf{P}	0.23	0.41	0.56	0.67	0.75	0.82	0.878	0.91	0.93	0.95

From the table it can be seen that a shortlist of size at least $k = 4$ is needed in order to guarantee that the probability of at least one student from the group of size $n = 9$ being included in the shortlist is at least 0.905.

In the general case, when $F_1(\cdot) \neq F_2(\cdot)$, the probability that exactly r students from high school A appear in the shortlist is equal to $P\{X_{(n+1-r)} > Y_{(m+r-k)}\} - P\{X_{(n-r)} > Y_{(m+r-k+1)}\}$. In particular, when $F_1(x)$ is $N(\mu, 1)$ distribution and $F_2(y)$ is the $N(0, 1)$ distribution, selected values of the probability that r out of n students from the second high school are chosen on a shortlist of length k are presented in Olkin and Stephens (1993).

Summary

The theory of order statistics is essential in statistical analysis and its applications. Order statistics play an important role in inferential problems including estimation of unknown parameters of distributions in considered statistical models and in hypothesis testing. Before 1970s, most studies were on cases where order statistics originated from independent and identically distributed random variables. In the early 1970s however the robustness issues motivated the study of order statistics from outliers models. Recent years have seen the appearance of a number of studies on both single- and multiple-outlier models and more generally on order statistics from independent and nonidentically distributed random variables. The theory of order statistics from independent but nonidentically distributed random variables involves permanents which is similar to that of the determinants but without the alternating sign. Barnett and Lewis (1994) mainly discuss the single-outlier models. In an excellent review article, Balakrishnan (2007) describes more general model of order statistics from independent and nonidentically distributed random variables, including many important issues such as distributional properties, characterizations, estimation, outliers, robustness. Continuing from the International Conference on Order Statistics and Extreme Values, Theory and Applications 18–20 December 2000 in Mysore, India) organized by N. R. Mohan and H. N. Nagaraja, a series of international conferences devoted to order statistics in Warsaw, Poland (2002–04); Izmir, Turkey (2005); Mashad, Iran (2006); Amman, Jordan (2007) and Aachen, Germany (2008) provided international forums for presentation and discussion of topics related to ordered statistical data. In these conferences, both reviews of previously existing results and new results involving order statistics were presented in the context of topics such as approximations, characterizations, distribution theory and probability models, stochastic ordering, inequalities, censoring, statistical inference, applications of ordered data, information and entropies, nonparametric methods, ranked set sampling,

and asymptotic theory. The special issue on ordered statistical data, approximations bounds and characterizations of Taylor and Francis' journal *Communications in Statistics-Theory and Methods*, vol. 36, no. 7 edited by I. Bairamov consists of selected articles presented at the international conference OSD-2005, Izmir, Turkey.

The elegant theory of order statistics and general models of ordered statistical data is likely to arouse the interest of many scientists working in the area of statistical theory and applications.

Glossary

Bayesian inference – A method of statistical inference which exploits both the information arising from the data, summarized by the likelihood function, and the experimenter's belief before observing the data, represented by the prior distribution. The name Bayesian comes from the use of the Bayes' theorem, from the work of Reverend Thomas Bayes, in the inferential process.

Estimator/estimate – An estimator is any sample statistic which is used to estimate an unknown population parameter; the sample mean is an example of estimator of the population mean. An estimate is the value of the estimator that is obtained for an observed sample.

Item response theory (IRT) – A body of theory concerning models for the analysis of data collected by the administration of test items aimed at measuring a certain latent trait of interest, such as the ability of a student in a certain field. IRT models are based on the assumption that the probability that a subject responds correctly to an item is a function of the latent trait.

Likelihood function – The likelihood function is the probability or the density of the observed sample expressed as a function of the parameters of interest. It plays a central role in statistical inference and, in particular, for the maximum likelihood estimation method.

Parameter – A parameter is an index used to represent a certain population characteristic. The mean of a variable, such as the income of every resident in a certain region, is an example of parameter. Typically, the parameter is unknown and, then, it has to be estimated. In the classical approach to inference, the parameter is a fixed unknown constant. On the contrary, in Bayesian inference, the parameter is a random variable with a probability distribution representing the uncertainty on its knowledge.

Point estimation – A statistical inference method consisting of assigning a single value, called point estimate, to each unknown parameter.

Random sample – A subset of the population units which is selected by a random mechanism. It is the basis of any method of statistical inference.

Statistic – Any mathematical function used to summarize the information in the sample data.

Statistical inference – The process of using the information in a sample to draw conclusions about the population from which the sample is drawn.

Introduction

The general goal of statistical inference is to provide some conclusions about the distribution of a variable of interest (X) in a certain population on the basis of a random sample, that is, a subset of the population units randomly chosen. Often, the interest is on a particular statistical index describing the distribution of X , which is called parameter (θ); examples are the average income of the population living in a certain region or the variance of the number of employees in the population (in the sense of set) of firms operating in a certain field. In a parametric setting, we assume that the distribution of X is described by a certain statistical model, that is, a family of distributions indexed by the parameter θ , $\{f(x; \theta), \theta \in \Theta\}$, where $f(x; \theta)$ denotes a probability mass function (pmf) or a probability density function (pdf) and Θ is the parameter space. Note that θ may also be a vector of parameters of suitable dimension; however, we will not use a special notation for this case. Provided that the statistical model holds, knowledge of the true value of θ is equivalent to the full knowledge of the distribution of interest.

In this setting, a random sample of size n may be defined as the random vector $X = (X_1, \dots, X_n)$, whose components are mutually independent and identically distributed with marginal distribution $f(x; \theta_0)$, where θ_0 denotes the true value of the parameter of interest. Note that, in the presence of a finite population, sample units have to be drawn with replacement in order to have independence between the random variables X_i , $i = 1, \dots, n$. Another important concept for what follows is that of sample space, which is the set of all the possible samples of size n . This set may be discrete or continuous

according to the nature of the support of X . An observed sample is denoted by $x = (x_1, \dots, x_n)$. Because of the independence of the sample units, its pmf or pdf is simply given by $f(x) = \prod_{i=1}^n f(x_i)$. The information on θ contained in the sample is typically summarized by a sample statistic, which is defined as a mathematical function of the random sample, that is, $T = t(X)$. Examples of sample statistics are the sample mean, $\bar{X} = \sum_{i=1}^n X_i/n$, and the sample variance, $S^2 = \sum_{i=1}^n (X_i - \bar{X})^2/(n-1)$. Since X is a random vector, any sample statistic is a random variable with a distribution which is referred to as the sampling distribution.

Different inferential methods are available in the statistical literature. For a unitary description of these methods and related approaches, see Barnett (1999) and Casella and Berger (2002). In the following, we deal, in particular, with point estimation, which consists of assigning to θ a single value out from the parameter space.

Point Estimation Methods

An estimator of the unknown parameter θ may be defined as any sample statistic $T = t(X)$ used to estimate θ . An estimate $t = t(x)$ is the value of the estimator for an observed sample. The statistical theory on point estimation mainly focuses on methods of evaluating estimators and methods of finding estimators.

Evaluation of an Estimator

Methods of evaluating an estimator are necessary because, in principle, different estimators can be used for the same parameter.

The most well-known criterion to compare different estimators is based on the mean squared error (MSE) which, for an estimator T of θ , is defined as the expected value of its (squared) error, that is, $\text{MSE}_\theta(T) = E_\theta[(T - \theta)^2]$. According to this criterion, the estimator T is better than another estimator T^* if the MSE of the first is uniformly smaller than that of the second, that is, $\text{MSE}_\theta(T) \leq \text{MSE}_\theta(T^*)$ for all $\theta \in \Theta$, with at least one value of θ for which the inequality strictly holds. In this case, we say that T is more efficient than T^* . Note that other measures of error, such as $E_\theta(|T - \theta|)$, are possible to evaluate the performance of an estimator. However, MSE is usually preferred because it is easier to treat analytically. Moreover, it may be decomposed as follows:

$$\text{MSE}_\theta(T) = \text{Var}_\theta(T) + \text{B}_\theta(T)^2$$

where $\text{Var}_\theta(T) = E_\theta\{[T - E_\theta(T)]^2\}$ is the variance of T and $\text{B}_\theta(T) = E_\theta(T) - \theta$ is its bias. The first is a measure of dispersion of the distribution of the estimator around its

mean and the second is a measure of its systematic error. Both quantities need to be small in magnitude in order to have a small MSE.

It has to be clear that comparing two estimators on the basis of the MSE is not always possible since it may happen that, between T and T^* , the first is better for certain values of θ , whereas the second is better for other values of θ . Then, in real problems, we cannot expect to find the most efficient estimator, that is, the estimator which has the minimum MSE, for all θ in Θ , among all the possible estimators of the same parameter.

The indeterminacy problem described above is usually dealt with by restricting the class of possible estimators to that of the unbiased estimators. An estimator T of θ is said to be unbiased if its expected value is always equal to the parameter value or, equivalently, it always has null bias; in symbols,

$$E_\theta(T) = \theta \text{ or } \text{B}_\theta(T) = 0, \forall \theta \in \Theta$$

Examples of unbiased estimators are \bar{X} , when the parameter of interest is the population mean (μ), and S^2 , when the parameter of interest is the population variance (σ^2).

For any unbiased estimator, the MSE is equal to its variance and then, within the class of the unbiased estimators of the same parameter, that with minimum MSE corresponds to the uniformly minimum variance unbiased estimator (UMVUE), that is, the unbiased estimator T , such that

$$\text{Var}_\theta(T) \leq \text{Var}_\theta(T^*), \forall \theta \in \Theta$$

for any other unbiased estimator T^* of θ . Different methods are available in the statistical literature to check when an estimator of a certain parameter is the UMVUE. Fundamental results on this topic are represented by the Cramer–Rao inequality, the Rao–Blackwell theorem, and the Lehman–Scheffé theorem. For a detailed illustration of these results and the related theory, see Lehmann and Casella (1998).

Statistical theory on point estimation is also focused on the asymptotic properties of an estimator, which concern its performance when the sample size grows to infinity. The most important of these properties is known as consistency. In particular, an estimator T of θ is consistent if

$$\lim_{n \rightarrow \infty} P_\theta(|T_n - \theta| < \epsilon) = 1, \quad \forall \epsilon > 0$$

where the subscript n has been added to T in order to recall that the distribution of the estimator depends on the sample size. Intuitively, this property says that as the sample size grows and, then, the available amount of information increases, we expect the estimator to attain values closer and closer to the true parameter value. Related properties are those of asymptotic unbiasedness and consistency in MSE. We refer to Cox and Hinkley (1974) and Lehmann (1999) for a detailed description.

Methods of Finding Estimators

Often, intuition can lead us to find an estimator for the parameter of interest. However, more methodical ways of finding estimators are needed. In the following, we discuss three general methods: method of moments, maximum likelihood method, and, under a different inferential approach, Bayesian estimation. The first two methods are formulated following a frequentist approach, which only exploits the information contained in the sample. This is in contrast with the Bayesian approach, which also exploits *a priori* information, that is, the knowledge or subjective opinions about the parameter of interest before any data have been observed.

Method of Moments

One of the oldest and simplest methods of finding estimators is the method of moments, which dates back to K. Pearson in the late 1800s. Suppose that the random sample is drawn from a statistical model depending on a parameter vector $\theta = (\theta_1, \dots, \theta_k)$ of dimension k . This method consists of equating the first k population moments to the corresponding sample moments and solving the resulting system of equations with respect to θ . The population and the sample moments of order r are defined, respectively, as

$$\mu_r(\theta) = \int_{-\infty}^{+\infty} x^r f(x; \theta) dx \text{ and } M_r = \frac{1}{n} \sum_{i=1}^n X_i^r$$

Thus, the system of equations to be solved with respect to θ is

$$\begin{aligned} \mu_1(\theta) &= M_1 \\ &\vdots \\ \mu_k(\theta) &= M_k \end{aligned}$$

In general, the estimators obtained by the method of moments are consistent, asymptotically unbiased, and have asymptotic normal distribution. However, their efficiency can usually be improved upon. For a detailed description of this method see Bowman and Shenton (1985).

Maximum Likelihood Method

The maximum likelihood method is the most popular technique for deriving estimators. It is based on the likelihood function which, for an observed sample \mathbf{x} , is defined as the probability (or density) of \mathbf{x} expressed as a function of θ ; in symbols

$$L(\theta) = \prod_{i=1}^n f(x_i; \theta)$$

This function provides a measure of plausibility of each possible value of θ on the basis of the observed data. Then,

the method at issue consists of estimating θ through the value of θ which maximizes $L(\theta)$ since this corresponds to the parameter value for which the observed sample is most likely. The estimate found in this way, that is,

$$\hat{\theta} = \hat{\theta}(\mathbf{x}) \text{ such that } L(\hat{\theta}) = \sup_{\theta \in \Theta} L(\theta)$$

is the maximum likelihood estimate (mle) of θ . When expressed as a function of the random sample \mathbf{X} , we have the maximum likelihood estimator (MLE) $\hat{\theta}(\mathbf{X})$. Obviously, this method of finding estimators is in agreement with the likelihood principle, which says that the inferential conclusions on θ based on two different sampling schemes must be the same when these schemes give rise to proportional likelihood functions; see Casella and Berger (2002) for a formal definition of this principle.

In order to find the mle of θ , we have to solve an optimization problem. It is usually simpler to maximize the log-likelihood

$$\ell(\theta) = \log L(\theta) = \sum_{i=1}^n \log f(x_i; \theta)$$

instead of $L(\theta)$. Since the logarithmic function is monotonic increasing, the two maximization problems are equivalent. In the single-parameter case ($k = 1$), the usual procedure to maximize $\ell(\theta)$ is based on solving the likelihood equation

$$\frac{\partial \ell(\theta)}{\partial \theta} = \sum_{i=1}^n \frac{f'(x_i; \theta)}{f(x_i; \theta)} = 0$$

In order to be sure that the found root is the global maximum of $\ell(\theta)$, we also have to verify that

$$\frac{\partial^2 \ell(\theta)}{\partial \theta^2} = \sum_{i=1}^n \frac{f''(x_i; \theta)f(x_i; \theta) - f'(x_i; \theta)f'(x_i; \theta)}{f(x_i; \theta)^2} < 0$$

and evaluate $\ell(\theta)$ at the boundary of the parameter space.

In the multiparametric case, in which $\theta = (\theta_1, \dots, \theta_k)$ with $k > 1$, the problem is usually more complex as it is based on the solving the system of linear equations

$$\frac{\partial \ell(\theta)}{\partial \theta_i} = 0, \quad i = 1, \dots, k$$

An explicit solution for this system is seldom available and, therefore, we need to use iterative algorithms to maximize the log-likelihood. Starting from an initial guess, these algorithms update θ in an appropriate way until convergence, that is, until a stationary point of $\ell(\theta)$ is found. The most popular of these algorithms is known as the Newton–Raphson algorithm. At the $(t + 1)$ -th iteration, it updates θ as

$$\theta^{(t+1)} = \theta^{(t)} + \mathcal{J}(\theta^{(t)})^{-1} s(\theta^{(t)})$$

where $\theta^{(t)}$ is the current value of the parameter, $s(\theta)$ is the score vector, that is, the first derivative vector of $\ell(\theta)$,

whereas $\mathcal{J}(\theta)$ is the observed information matrix, that is, the second derivative matrix of $\ell(\theta)$ with negative sign. A variant of the Newton–Raphson algorithm is the Fisher-scoring algorithm which, at each iteration, updates θ as

$$\theta^{(t+1)} = \theta^{(t)} + I(\theta^{(t)})^{-1} s(\theta^{(t)})$$

where $I(\theta)$ is the Fisher information, that is, the expected value of the observed information matrix. Using the observed or the Fisher information matrix is equivalent if $f(x; \theta)$ belongs to the regular exponential family. Through these algorithms it is usually possible to find a local maximum of the log-likelihood; however, in general, it is not guaranteed that this also corresponds to the global maximum. When there are more than one local maxima, a crucial point is that of the choice of the starting values for the algorithm; often, the method of moments is used to obtain reasonable starting values.

One of the main reasons of the great popularity of the maximum likelihood method is that the resulting estimator has many interesting properties. These properties hold under certain regularity conditions which are not very restrictive, albeit quite technical. In the following, we provide a brief summary of these properties; for a detailed description we refer to Cox and Hinkley (1974), Azzalini (1996), Lehmann and Casella (1998), Lehmann (1999), and Severini (2000).

One of the most important properties is the invariance property, according to which if $\hat{\theta}$ is the MLE of θ , then $\tau(\hat{\theta})$ is the MLE of $\tau(\theta)$. Note that this property also holds when $\tau(\theta)$ is not a one-to-one function of θ . Moreover, the maximum likelihood method is in agreement with the so-called sufficiency principle. This is because the estimator depends on the sample only through a sufficient statistic for θ , which represents the only relevant information on the parameter; thus, if θ is the only parameter of interest, further information contained in the sample can be discarded. Another property is that if an UMVUE exists and suitable regularity conditions hold, then the MLE coincides with this estimator.

The previous properties are finite-sample properties. Estimators formulated with the maximum likelihood method also have interesting asymptotic properties. First, $\hat{\theta}_n$ is a consistent estimator of θ . The consistency of the MLE also holds for the estimator $\tau(\hat{\theta})$ of $\tau(\theta)$. Moreover, the MLE is an asymptotically efficient estimator, in the sense that its variance tends to the lower bound of the Cramér–Rao inequality, and, for large samples, the standard deviation of the MLE may be approximated by the square root of the diagonal elements of the inverse of the information matrix. Finally, a very important property is that the estimator has asymptotic normal distribution. This allows us to easily construct confidence intervals and to test hypotheses on the parameter of interest.

Bayesian Estimators

In the frequentist approach, the parameter θ is considered an unknown, but fixed, quantity and only the information coming from the sampling data is relevant for inference. Thus, we do not take into account the prior belief on the parameter. On the contrary, in the Bayesian approach, the parameter θ is considered as a random variable with a certain probability distribution, referred to as the prior distribution, whose role is that of representing the experimenter's belief before observing the data. Within this approach, the prior distribution is updated on the basis of the likelihood function through the Bayes' theorem. The resulting distribution is referred to as the posterior distribution and summarizes the information in both the prior distribution and in the data.

Let $\pi(\theta)$ denote the prior distribution and let $f(x|\theta)$ denote the conditional distribution of the sample given θ . Note that $f(x|\theta)$ is equivalent to the likelihood function discussed earlier. According to the Bayes' theorem, we can derive the posterior distribution of θ on the basis of the observed sample x as

$$\pi(\theta|x) = \frac{f(x|\theta)\pi(\theta)}{m(x)}$$

where $m(x)$ is the marginal pdf (or pmf) of the data, which is given by

$$m(x) = \int_{-\infty}^{+\infty} f(x|\theta)\pi(\theta)d\theta$$

The mean, which is often used to summarize the posterior distribution of the parameter, is a Bayesian point estimator of θ . Sometimes, the mode or the median of the posterior distribution is used instead.

A great variety of textbooks on Bayesian inference now exist. For an accessible introduction we suggest Ghosh *et al.* (2006), whereas for more advanced treatment, we suggest Gelman *et al.* (2003) and Robert and Casella (2005) for related computational methods.

Item Response Theory Models

Item response theory (IRT) models are tailored to the analysis of data arising from the administration of a questionnaire made of a series of items which measure a common latent trait, that is, a characteristic of the human being which is not directly observable; for a review see the work by Hambleton and Swaminathan (1996). The main application of these models is in educational assessment, where the latent trait corresponds to a certain type of ability of an examinee.

In the following, after a brief summary of the main assumptions of IRT models for dichotomously scored items, we focus on maximum likelihood methods for

their estimation. For an updated and detailed description of these methods, see Baker and Kim (2004).

Suppose that a questionnaire made of r items is administered to a sample of n subjects, and let y_{ij} , $i = 1, \dots, n$, $j = 1, \dots, r$, be a categorical response variable for the j th item administered to the i th subject. Depending on the context, y_{ij} will denote a random variable or one of its realizations. In educational assessment, the response variable is often binary; in particular, y_{ij} is equal to 1 if subject i responds correctly to item j and to 0 otherwise.

With reference to the binary case, the main assumptions of IRT models may be summarized as follows:

- *Unidimensionality*. For each subject i , the responses to the r items depend on the same latent parameter ϕ_i , which is unidimensional.
- *Local independence*. For each subject i , the responses to the r items are independent given ϕ_i .
- *Monotonicity*. The probability of a correct response of the i th subject to the j th item, in symbols $p_j(\phi_i) = p(y_{ij} = 1 | \phi_i)$, is a monotonic increasing function of ϕ_i .

The probabilities $p_j(\phi_i)$ are modeled via a function which is usually referred to as the item characteristic curve (ICC) or item response function. Different models arise according to the assumed parametrization of the ICC. The most well known is the one parameter logistic (1PL) parametrization, according to which

$$p_j(\phi_i; \beta_j) = \frac{e^{\phi_i - \beta_j}}{1 + e^{\phi_i - \beta_j}}$$

where β_j is the difficulty level of item j . The resulting model is usually referred to as the Rasch model (Rasch, 1960). More general parametrizations were proposed by Birnbaum (1968) and rely on further parameters to describe the item characteristics.

Maximum Likelihood Estimation

In the following, we describe three different methods based on the maximum likelihood paradigm for the estimation of the above IRT models for dichotomously scored items.

Joint maximum likelihood method

The joint maximum likelihood (JML) method consists of maximizing the likelihood of the model, corresponding to the probability of the observed data matrix, with respect to the ability and item parameters jointly.

Under the assumption of local independence, the joint distribution of the response vector $\mathbf{y}_i = (y_{i1}, \dots, y_{ir})$ may be expressed as

$$p(\mathbf{y}_i | \phi_i, \psi) = \prod_j p_j(\phi_i; \psi_j)^{y_{ij}} [1 - p_j(\phi_i; \psi_j)]^{1-y_{ij}}$$

where ψ is the vector of the item parameters, which depend on the IRT model of interest. Under the 1PL model, it only contains the parameters β_j .

Assuming that the response vectors for the subjects in the sample are independent each other, the conditional probability of observing the response matrix Y with elements y_{ij} , $i = 1, \dots, n$, $j = 1, \dots, r$, is equal to

$$p(Y | \phi, \psi) = \prod_i \prod_j p_j(\phi_i; \psi_j)^{y_{ij}} [1 - p_j(\phi_i; \psi_j)]^{1-y_{ij}}$$

where ϕ is the vector of the ability parameters. Then, for an observed matrix of responses Y , the JML method consists of estimating the model parameters by maximizing the joint likelihood

$$L_{\mathcal{J}}(\phi, \psi) = p(Y | \phi, \psi)$$

with respect to ϕ and ψ .

For the Rasch model, the joint likelihood becomes

$$L_{\mathcal{J}}(\phi, \psi) = \frac{e^{\sum_i t_i \phi_i - \sum_j s_j \beta_j}}{\prod_i \prod_j (1 + e^{\phi_i - \beta_j})}$$

where $t_i = \sum_j y_{ij}$ is the number of correct responses provided by subject i and $s_j = \sum_i y_{ij}$ is the number of subjects who responded correctly to item j . The corresponding log-likelihood is equal to

$$\ell_{\mathcal{J}}(\phi, \psi) = \sum_i t_i \phi_i - \sum_j s_j \beta_j - \sum_i \sum_j \log(1 + e^{\phi_i - \beta_j})$$

For each IRT model, the joint likelihood is invariant with respect to certain transformations of the item and ability parameters. Then, suitable constraints have to be put on these parameters in order to make the model identifiable. The following constraints may alternatively be used for the Rasch model:

- $\beta_1 = 0$: in this way, the first item is taken as a reference item and, then, β_j , $j = 2, \dots, r$, has to be interpreted as the difficulty of item j with respect to the first one.
- $\sum_i \phi_i = 0$: in this way, the average ability of the subjects is fixed at 0 and ϕ_i , $i = 1, \dots, n$, is interpreted as the ability of subject i with respect to the average of the group.

These constraints are equivalent in the sense that the maximum value of the likelihood that may be reached under each of them is the same, which is also equal to the unconstrained maximum of the likelihood. Further constraints need to be used for more sophisticated models.

The algorithm to maximize $\ell_{\mathcal{J}}(\phi, \psi)$ that is commonly used is based on a series of Newton–Raphson steps to be performed until convergence. Explicit expressions for the derivatives used in these steps are available; see Hambleton and Swaminathan (1996) and Baker and Kim (2004). We note that the point at convergence does not depend on the starting values chosen for the parameters since, provided that the JML estimate exists, the log-likelihood is a strictly concave function over the full parameter space.

It has to be recalled that the JML estimate is not ensured to exist. A set of conditions on the matrix Y which ensures this existence was derived by Fischer (1981). A necessary condition is that there exist neither subjects who respond correctly or incorrectly to all items nor items to which all subjects respond correctly or incorrectly. These subjects and items must be removed from the dataset when they exist. Moreover, the JML estimator is not consistent as n grows to infinity with r fixed. This does not mean that the estimates obtained by using this method are unreliable. Indeed, if the number of subjects and that of items are large enough, the bias of the JML estimator is expected to be low.

Conditional maximum likelihood

The conditional maximum likelihood (CML) method may be only applied to the Rasch model and it is typically used to estimate its difficulty parameters. The method is based on the maximization of the conditional likelihood of these parameters given a set of minimal sufficient statistics for the ability parameters.

Let $\beta = (\beta_1, \dots, \beta_r)$ denote the vector of item parameters under the Rasch model. First of all, consider that the conditional probability that subject i attains score t_i , given the ability parameter ϕ_i , is equal to

$$p(t_i | \phi_i, \beta) = \sum_{\mathbf{y} \in \mathcal{Y}(t_i)} p(\mathbf{y}_i = \mathbf{y} | \phi_i) = \frac{e^{\phi_i t_i}}{\prod_j (1 + e^{\phi_i - \beta_j})} q_i$$

where $q_i = \sum_{\mathbf{y} \in \mathcal{Y}(t_i)} \exp\{-\sum_j y_j \beta_j\}$, with $\mathcal{Y}(t)$ denoting the set of all the binary vectors $\mathbf{y} = (y_1, \dots, y_r)$ with elements having sum t . These vectors have t elements equal to 1 and $r - t$ elements equal to 0. Consequently, for each subject i , the conditional probability of the response configuration \mathbf{y}_i given the sufficient statistics t_i is equal to

$$p(\mathbf{y}_i | t_i, \phi_i, \beta) = \frac{p(\mathbf{y}_i | \phi_i, \beta)}{p(t_i | \phi_i, \beta)} = \frac{e^{-\sum_j y_{ij} \beta_j}}{q_i} \quad [1]$$

which does not depend on ϕ_i and, then, may be denoted by $p(\mathbf{y}_i | t_i, \beta)$.

The conditional likelihood exploited within the CML method is

$$L_C(\beta) = \prod_i p(\mathbf{y}_i | t_i, \beta)$$

Note that the subjects who respond correctly or incorrectly to all the items do not contribute to this likelihood. Then, the corresponding log-likelihood may be expressed as

$$\ell_C(\beta) = -\sum_j s_j^* \beta_j - \sum_i d_i \log q_i \quad [2]$$

where $d_i = 1\{0 < t_i < r\}$ is a dummy variable equal to 1 if subject i contributes to the likelihood and to 0 otherwise and $s_j^* = \sum_i d_i y_{ij}$. An identifiability problem also arises in this case; for this reason, we must use the constraint $\beta_1 = 0$ or, alternatively, $\sum_j \beta_j = 0$.

In order to maximize $\ell_C(\beta)$, we may use a Newton–Raphson algorithm. Efficient methods to compute the conditional log-likelihood and its derivatives, in a way which is viable even when r is large, are available in the statistical and psychometric literatures (Formann, 1986; Gustafson, 1980; Liou, 1994).

Certain conditions need to be fulfilled for the existence of the CML estimate (Fischer, 1981). In most situations, a condition which ensures this existence is that there do not exist items to which no subjects or all subjects respond correctly. Finally, we have to stress that the main advantage of the CML method is that the resulting estimator is consistent for r fixed as n grows to infinity. For a detailed description of the asymptotic properties of this estimator, see Andersen (1970); see also Andersen (1972).

Marginal maximum likelihood

The marginal maximum likelihood (MML) method is tailored to IRT models formulated under the assumption that the ability is a random parameter. The method consists of maximizing the likelihood corresponding to the manifest probability of the observed responses, that is, the marginal probabilities of these responses once the ability parameters have been integrated out.

Let $f(\phi_i)$ denote the distribution for the ability parameters. The manifest distribution of \mathbf{y}_i is given by

$$p(\mathbf{y}_i | \psi) = \int_{\mathbb{R}} p(\mathbf{y}_i | \phi_i, \psi) f(\phi_i) d\phi_i$$

Moreover, the manifest probability of Y is $p(Y | \psi) = \prod_i p(\mathbf{y}_i | \psi)$ and, for an observed matrix of responses, it corresponds to the marginal likelihood on which the MML method is based. This is denoted by $L_M(\psi, \eta)$, where η is the vector of parameters on which $f(\phi_i)$ possibly depends. The corresponding log-likelihood is denoted by $\ell_M(\psi, \eta)$. The latter is maximized by a version of the EM algorithm of Dempster *et al.* (1977) which is based on the complete likelihood, that is, the likelihood that we could compute if we knew the ability level of each subject. The MML estimator of the item parameters is denoted by $\hat{\psi}_M$ and that of the parameters for the distribution of the ability is denoted by $\hat{\eta}_M$.

A crucial assumption for the implementation of the MML method concerns the distribution of the ability. The most common assumption is that the ability has a normal distribution with unknown mean and variance, which are estimated together with the item parameters. More advanced solutions consist of assuming that the ability has a discrete distribution with a suitable number of support points and weights. The first paper discussing this kind of approach is that of Bock and Lieberman (1970). Further developments are due to Bock and Aitkin (1981), Thissen (1982), Lindsay *et al.* (1991), Pfanzagl (1993), and Schilling and Bock (2005).

Example

In order to provide an illustration of the maximum likelihood estimation methods outlined above, we describe an application based on a dataset which was provided by the Educational Testing Service. The dataset concerns the responses of 1510 students to 12 publicly released items on mathematics collected in 1996 within a project called National Assessment of Educational Progress (NAEP); for details, see Bartolucci and Forcina (2005).

By using the JML method, for the Rasch model we obtained the estimates of the item and ability parameters which are displayed in **Table 1**. Note that we adopted the identifiability constraint $\beta_1 = 0$ and, consequently, we took the first item as a reference item.

The estimates of the item parameters allow us to evaluate the difficulty level of each item. In particular, we can conclude that the last item is the most difficult, whereas the fourth item is the easiest. Moreover, the standard errors and the confidence intervals may be used to assess whether the difficulty level of each item is significantly different from that of the first item. We observe that the second item is not significantly different from the first in terms of difficulty since the corresponding confidence interval includes zero. The same cannot be said about, for example, the third item. Finally, the estimates of the ability parameters can be used to assess the students to whom the questionnaire was administered. We conclude, for instance, that the second and third students have the same ability level as they provided the same number of correct responses, and this ability level is higher than that of the first student.

As an illustration of the CML method, we show in **Table 2** the estimates of the item parameters obtained with this method.

Table 1 JML estimates of the item and ability parameters of the Rasch model for the NAEP dataset

	Estimate	SE	95% Conf.int.	
β_1	0.000	—	—	—
β_2	-0.051	0.097	-0.241	0.138
β_3	0.755	0.093	0.574	0.936
β_4	-1.140	0.111	-1.357	-0.923
β_5	1.672	0.092	1.491	1.853
β_6	0.014	0.096	-0.175	0.202
β_7	0.724	0.093	0.542	0.905
β_8	1.305	0.092	1.125	1.485

β_{10}	0.574	0.093	0.391	0.756
β_{11}	2.697	0.098	2.505	2.888
β_{12}	2.751	0.098	2.558	2.944
ϕ_1	-0.080	0.674	-1.400	1.241
ϕ_2	1.193	0.662	-0.104	2.491
ϕ_3	1.193	0.662	-0.104	2.491
ϕ_4	0.770	0.649	-0.501	2.041
ϕ_5	-0.080	0.674	-1.400	1.241
\vdots	\vdots	\vdots	\vdots	\vdots
ϕ_{1510}	2.158	0.750	0.689	3.626

The results are similar to those previously obtained, except that only the estimates of the item parameters are now available. This is because the ability parameters are removed by conditioning on the corresponding sufficient statistics. By comparing the results in **Table 2** with those in **Table 1**, we note that the CML estimates are very similar to the JML estimates and, therefore, the items are equivalently ranked. This is because, with 12 items, we can also obtain reliable estimates with the JML method. To this regard we recall that, in contrast to the JML estimator, the CML estimator is in general consistent.

Finally, we applied the MML method based on a discrete latent distribution for the ability. In this case, we have to choose the number of support points of the latent distribution, which is equivalent to the number of latent classes in the population. Following a standard practice in this field, we make this choice by using the Bayesian Information Criterion of Schwarz (1978) which is based on the minimization of the index:

$$\text{BIC} = -2\ell_M(\hat{\psi}, \hat{\eta}) + \log(n)\#\text{parameters}$$

In practice, we fit the model with an increasing number of classes until this index does not start to decrease. Then, we choose the number of classes of the model with the smallest BIC. For the NAEP data, this procedure leads to the results shown in **Table 3**.

We clearly choose three latent classes. A probability and an ability level are associated to each of these classes. The estimates of these parameters are shown in **Table 4**.

Table 2 CML estimates of the item parameters of the Rasch model for the NAEP dataset

	Estimate	SE	95% Conf.int.	
β_1	0.000	—	—	—
β_2	-0.047	0.092	-0.229	0.134
β_3	0.691	0.088	0.517	0.864

β_5	1.521	0.088	1.349	1.693
β_6	0.013	0.092	-0.168	0.193
β_7	0.662	0.089	0.489	0.836
β_8	1.191	0.088	1.019	1.363
β_9	0.334	0.090	0.158	0.511
β_{10}	0.525	0.089	0.351	0.700
β_{11}	2.427	0.092	2.246	2.607
β_{12}	2.474	0.093	2.292	2.655

Table 3 Selection of the number of classes for the latent class Rasch model applied to the NAEP dataset

#Classes	$\ell_M(\hat{\psi}, \hat{\eta})$	#Parameters	BIC
1	-11009	12	22106
2	-10242	14	20586
3	-10166	16	20450
4	-10163	18	20458

Table 4 MML estimates of the ability parameters of the Rasch model for the NAEP dataset (three latent classes)

Class	Ability	Probability
1	−0.645	0.165
2	0.970	0.457
3	2.432	0.378

We can observe that the classes are well separated in terms of ability level. The first class, which includes subjects with the lowest ability level, is also the smallest in the population (it has the smallest probability), whereas the other two classes have a comparable size. The corresponding estimates of the item parameters are, in practice, equal to those obtained with the CML method which are displayed in **Table 2**. This is in agreement with the theory of Lindsay *et al.* (1991) about the equivalence between CML and MML estimation methods for the Rasch model which holds under certain regularity conditions.

Glossary

Eigenvalue – It is a number calculated from a square matrix, such as a correlation matrix. There are as many eigen values as columns (or rows) in the matrix and their relative values tell us something about the structure of the matrix.

Eigenvector – It is a set of numbers, having the same dimension as the matrix, each of which is associated with one of the eigenvalues.

Metrical variable – It is a variable measured on a continuous or discrete scale such as length or number of siblings.

Scree diagram (or plot) – It is a diagram showing the variances of principal components plotted in decreasing order of magnitude.

Introduction

The origin of principal components analysis (PCA), as we now know it, is in a paper by Hotelling (1933) published in the *Journal of Educational Psychology*. The place of publication indicates the intended field of application where it has been used for many years alongside factor analysis. Since then it has been used in many other fields, including the biological, physical, and engineering sciences. Its prime purpose is as a means of reducing the dimensionality of a multivariate data set and, also, of illuminating its interpretation by identifying a smaller number of variables which, in a certain sense, summarize the larger set.

The starting point of PCA is the matrix of correlation coefficients derived from the original data set. Strictly speaking, the rationale behind the method requires that the correlations be obtained from variables measured on some continuous scale. In practice, these variables may be precisely continuous, as with something like length or weight, or they may be discrete as when the variable is something we have counted. It is convenient to treat the two in the same way and we may conveniently refer to them collectively, as being metrical (i.e., measured). The method is sometimes used when the correlation coefficients have not been calculated from metrical variables. Such an analysis is not valid but, in spite of this, the method may give a useful, if rough, summary of the structure of the data.

A Preview

Although PCA has many applications, we shall use a single type of example in this exposition. This is because it is one of the most important and typical applications. The simplest way of conveying the basic idea is to take the case where there are only two variables. This we shall do in the following section. First, however, we shall look at a more realistic example to show what we can expect to achieve and to make some preliminary points.

It frequently happens that we have a set of test or examination scores, on a set of pupils. Such a dataset might appear as shown in Table 1.

We have left the number of pupils unspecified and given only the first four rows and the last two rows of the table; similarly, we have given the first four columns and the last. With a class of, say, 100 pupils and 20 subjects, or variables, there is a large amount of information to assimilate and PCA provides one way of summarizing that data in a meaningful way. A common way of making a summary, used by teachers for many years, is to sum or average the elements in each row. If these were marks obtained in the same subject over a period of time this might seem a reasonable thing to do. However, we would still need to consider the fact that the figures in the third column are larger than those in the others. Do we wish to give them greater weight in the final total? Perhaps they have resulted from the conflation of the marks obtained on two occasions, in which case giving them double weight seems just. But if they were marks awarded by a marker who, quite arbitrarily, decided to mark each paper out of 200, instead of 100 like the others, there is no reason for giving them extra weight. This simple illustration makes a point which occurs widely in the social sciences and which needs to be taken account of when carrying out PCA. The question is: Does the scale in which the marks are measured matter? That is, does it convey any relevant information? The answer is important because PCA depends upon it. As a general rule in social science, the units in which variables are measured is arbitrary and it is therefore customary to express them in units of their standard deviations. Equally, we need to consider whether the origin from which the marks are measured is arbitrary. If not, they should all be measured from the same common origin. If our table of data consisted only of marks scored on a scale 0–100 say, these questions do not arise because there is a common origin and scale at the outset, but in general we may impose these features by standardizing the

variables in the manner described. In practice, therefore, PCA is almost always carried out on standardized variables, which means that the product moment correlation coefficients are the starting point.

Before proceeding further with the analysis, it is highly desirable to inspect the correlation matrix carefully. All of the information in the original set of data is contained in the correlation matrix and nothing we do subsequently can alter that – it merely displays it in a different way. Such a preliminary inspection may reveal anomalies in the data and a practiced analyst will also be able to see the broad lines of the structure which PCA will reveal. We shall illustrate this procedure below.

The Case of Two Variables

In order to introduce the main ideas of PCA, we use an example with two variables and a sample size of five. Such a trivial example as this needs no analysis because the whole position can be taken in at a glance. It is, however, sufficient to lay the foundations for a fuller treatment. The data are given in **Figure 1**.

The two variables called x_1 and x_2 are plotted on the two axes of the left-hand diagram. They show roughly equal scatter in the horizontal and vertical directions but there is a marked tendency for x_2 to increase with x_1 . In the right-hand diagram, the points are shown in relation to a line drawn along a direction at, roughly, 45° to the horizontal. This line is, in fact, the first principal component. It is constructed so that it is nearest to the points in

the sense that the sum of squares of the distances of the points from the line is a minimum. If we now describe the positions of the points in relation to the first principal component, we shall note that the variation along the direction of the line is greater than the variation at right angles to the line. We have thus replaced one specification of the points, given by the left-hand diagram, by another as given on the right. Why might this be a useful thing to do? If we were told that the positions of the points had to be described by only one number, instead of two, their locations along the first principal component would be more informative than either of the values of x_1 or x_2 . By looking at the first principal component alone, we have made a useful reduction in dimensionality at the price of losing the variation at right angles to the line. Furthermore, if we could attach some meaning to the first principal component, it would be all the more useful. To make these points more general, we move on to a more realistic, but still simple, example.

A Simple Educational Example

The following example appears to have been first given by Lawley and Maxwell (1963) but the treatment here is based on Bartholomew *et al.* (2008). We start with the correlation matrix which is given in **Table 2**.

As recommended above, we begin with an inspection of the correlations. Their most obvious feature is that they are all positive though none is particularly large. This means that pupils who do well in one subject tend to do well in all. This suggests that there may be some skill or ability underlying all these subjects. A second point to notice is that there is variation in the values of the coefficients; some pairs of subjects are more highly correlated than others. There tend to be relatively high correlations among the three mathematical subjects as there are among the three humanities subjects. However, the inter-correlations among pairs formed by taking one from each group tend to be lower. This suggests that the subjects may be meaningfully grouped in this way. We would expect these two features to be evident in the formal PCA.

In the simple example with only two variables used earlier, we were able to picture the situation because the data could be plotted in two dimensions. With the six variables we now have, the geometrical approach fails, though we can still use the terminology in a suggestive way. Thus, if we imagine the ability scores plotted in six dimensions, we would be looking for the direction of greatest variability to find the first principal component. In practice, we now have to resort to algebra. A direction in the geometrical case becomes a linear combination in algebra. A component will thus be of the following form:

$$y = a_1x_1 + a_2x_2 + \dots + a_6x_6$$

Table 1 Typical layout of marks for pupils (rows) in a number of columns

53	30	80	61	...	37
49	20	116	55	...	32
62	24	150	53	...	44
43	76	98	71	...	76
...
40	57	158	76	...	39
62	69	146	18	...	25

Figure 1 Illustration showing first principal component.

Table 2 Pairwise correlation coefficients between subject marks

	<i>Gaelic</i>	<i>English</i>	<i>History</i>	<i>Arithmetic</i>	<i>Algebra</i>	<i>Geometry</i>
Gaelic	1.00					
English	0.44	1.00				
History	0.41	0.35	1.00			
Arithmetic	0.29	0.35	0.16	1.00		
Algebra	0.33	0.32	0.19	0.59	1.00	
Geometry	0.25	0.33	0.18	0.47	0.46	1.00

The first principal component is determined so that the variance of y is a maximum subject to the total variance remaining fixed. The second principal component is calculated to be uncorrelated with the first and to have the maximum variance and so on as far as the sixth principal component, in this case. In practice, the components are determined very easily by computer software which are available in virtually every package intended for multi-variate analysis. The successive principal components are distinguished by subscripts and their corresponding coefficients (the a s) by inserting a second subscript.

Since the prime object of the analysis is to effect a reduction in dimensionality, an important part of the analysis is to decide whether a small number of components, can, effectively replace the original variables. In the case of two variables, we argued that there was much more variation along the line than at right angles to it. In algebraic terms, we must look at the relative contributions made by the components. We then discard those whose contribution is judged to be too small.

We now illustrate how this is done using the standard computer output for the example of this section. **Table 3** gives the variance of each component expressed on a standard scale and also as a percentage of the total. **Table 3** also includes the cumulative percentages which help in selecting the number of components to discard. The same information can be presented graphically as in **Figure 2**. The latter is sometimes known as a scree plot.

It is clear that the first principal component accounts for almost half the variation and the first and second together for about two-thirds. Thereafter, the succeeding components account for less and less. The scree plot shows, for example, that beyond the third there is little variation left to be accounted for. There is no absolute rule for deciding when to stop including variables and it is here that practical considerations of interpretation come into play. One recommendation is to look for an elbow in the scree plot – that is, where it begins to flatten out. This occurs here at the third component. Another is to stop when the variance falls below 1. The rationale for this is that, on the standard scale we are using, each variable has unit variance and so there is little point in including a component which accounts for less variation than a single observation.

Table 3 Variance explained by each principal component, subject marks data

<i>Component</i>	<i>Variance explained</i>		
	<i>Variance</i>	<i>%</i>	<i>Cumulative %</i>
1	2.73	45.48	45.48
2	1.13	18.81	64.29
3	0.62	10.26	74.55
4	0.60	10.05	84.59
5	0.52	8.71	93.30
6	0.40	6.70	100.00

**Figure 2** Scree plot showing variance plotted against number of principal components, subject marks data.

The second aspect of interpretation concerns the interpretation which can be put on the components. For this we look at the coefficients of the principal components. Those for the first two principal components are given in **Table 4**.

From the first column, we notice that the coefficients are all positive and roughly equal. In effect, this component is not very different from a total or average. In looking for an interpretation, we are asking what such a function measures. It is clearly something to which all the test scores contribute roughly equally and it may thus be reasonably called general academic ability as it indicates something which makes a similar contribution, whatever the subject.

In the second column, the first three coefficients are positive and roughly equal; similarly, the second three are

Table 4 Loadings for the first two principal components, subject marks data

Subject	Loadings	
	First component	Second component
Gaelic	0.66	0.44
English	0.69	0.29
History	0.52	0.64
Arithmetic	0.74	– 0.42
Algebra	0.74	– 0.37
Geometry	0.68	– 0.35

roughly equal but this time they are negative. What the first three contribute is therefore an ability to do well in humanities subjects and the second does the same for the mathematical subjects. The second principal component, however, measures the difference between these two abilities. It, therefore, indicates the extent to which a candidate's abilities favor mathematics rather than humanities.

Although this is a fairly simple set of data, the example illustrates the main elements of a typical PCA.

The General Case

There is little to add to the example we have given for six variables because it sets the pattern for the general case. In mathematical language, we have to calculate the eigenvalues and eigenvectors of the correlation matrix. The eigenvalues correspond to the variances of the principal components as given in **Table 3**. The corresponding eigenvectors provide the coefficients of the variables in the components. Both of these operations are carried out in a routine fashion by the standard software. How many components are to be retained can be judged in the same way as above by means of a scree plot or by identifying the point at which the eigenvalues become less than 1. With larger problems, the question of the interpretability of the resulting components assumes greater prominence. In a correlation matrix where most correlations are positive, the first principal component often turns out to be a general factor measuring the magnitude of something which all individuals possess. Bipolar components, like the second one above, are also common but beyond that it may be more difficult to provide ready interpretations.

Relationship with Factor Analysis

PCA and factor analysis are very similar and it is not uncommon to find PCA regarded as one method of factor analysis – as in some computer packages. The reason for this has its roots in the fact that in the early days, until the arrival of computers, there was very little difference in the

methods of calculation used for both methods. These involved numerical operations on the correlation matrix, or a matrix derived from it, by replacing the diagonal elements by positive numbers between 0 and 1. PCA differed from other methods of factor analysis only in that the diagonal elements were all made equal to unity. In a contemporary treatment, factor analysis starts from a probability model and its parameters are estimated by maximum likelihood or some near-equivalent efficient method. A detailed account of the relationship between the two methods is given in Chapter 7 of Bartholomew *et al.* (2008).

Sampling Issues

We have treated PCA as a purely descriptive method for studying the dimensionality of a multivariate data set. If the data were obtained as a random sample from some population, we might be interested in inferring something about the structure of the population. For this we would need to know the form of the population from which our sample had been drawn and from that we would need to deduce the sampling distributions of the eigenvalues and the elements of the eigenvectors. Some results are available if the population sampled is multivariate normal but in most educational research, these results have been little used and probably cannot be justified.

What Is Probability?

Probabilistic thinking plays an important role in most fields of scientific research. This role is central in disciplines engaged in large-scale data collection and interpretation. A probabilistic model formulates relationships among the observables – relationships that are not supposed to hold exactly for each observation but still give a description of the fundamental tendencies governing their behavior. Probabilistic models allow the researchers to incorporate uncertainty into the fundamental laws they use to describe their findings. In educational research and assessment, uncertainty occurs for two main reasons. First, in the case of individual assessment, the ability or knowledge to be measured usually can be observed, not directly, but through the performance with respect to a certain battery of test items. Uncertainty naturally arises with respect to how the person tested would have performed, if confronted with other similar test items or if the testing had taken place under different conditions. Second, when the aim is to assess the status, achievement, motivation, knowledge, and so on, of a larger population, usually, only a sample from this population is observed, and uncertainty arises whether or not the observed performance of those not sampled would have been the same as that of those in the sample. The first type of uncertainty is called epistemic and is fundamentally related to the difficulty of learning some of the characteristics of interest. The second type of uncertainty is called aleatoric and may be reduced by the application of appropriate sampling methods.

Probability theory is often considered to be a mathematical subject, with a well-developed and involved literature concerning the probabilistic behavior of various systems (see Feller, 1968), but it is also a philosophical subject – where the focus is the exact meaning of the concept of probability and the ways in which it relates to the fundamental aspects of our reasoning (see Kopylov, 2008; Shackel, 2008). There is also a considerable body of psychological research available on the perception of probability and economists have also made important contributions in modeling and understanding human behavior in probabilistic settings (Kopylov, 2008; Shackel, 2008). Given the large number of different approaches, it may not be a surprise that even today – nearly 500 years after the concept of probability was first used – there are competing ways of defining its exact meaning. These differences do have consequences with respect to some of

the statistical analyses one performs but, fortunately, it is usually the actual problem at hand that determines which view one can adopt.

The most generally adopted view of probability is that it is a numerical characteristic of observations or experiments that may be performed repeatedly. This numerical value influences the relative frequencies of the possible outcomes. The larger the number of repetitions, the closer one may expect the observed relative frequency of an outcome to be to its probability. This is the frequentist concept of probability. Probabilities are assumed to be existing independently of the observations made – that is, the frequentist view considers probability to be objective. The goal of a statistical analysis in the frequentist tradition is to reveal the probabilities or some of their relevant properties using the available data. Because a relative frequency always lies between zero and one, probabilities are also between zero and one and some other properties of probability are also implied. There are several applications where the frequentist view seems convincing. For example, when a random sampling procedure chooses a sample from a population, the probability of having an observation with a certain characteristic may be identified with the population fraction of those possessing that characteristic (or a known function thereof, depending on the sampling procedure).

Another approach to the concept of probability considers it to be the degree of belief an individual associates with the occurrence of certain observations. This is called subjective probability. Subjective probability also applies to observations that may not be repeated. For example, a student may associate a probability with his/her passing a certain exam even though that particular exam is not something that could be repeated (a retake is a different exam, taking all its conditions into account).

The goal of the statistical analysis in a probabilistic model, in the subjective sense, is to update the subjective expectations based on the available data. This usually leads to the application of Bayesian methods of statistics. Fortunately, the mathematical properties of probability in the subjective interpretation are essentially the same as in the frequentist interpretation.

Although there is a fundamental difference between the frequentist and subjective interpretations of probability, many of the probabilistic models that are used often in statistics have meanings from both perspectives and so do many of the common statistical procedures.

The split between the frequentist and subjective interpretations of probability developed during the twentieth

century. The first steps of probabilistic thinking (in the sixteenth century) concentrated around the determination of rules of winning strategies in simple games of chance. Later, the study of demography led to the discovery of laws that were probabilistic in nature and, finally, the analysis of measurement errors led to deep and useful results related to probability (Stigler, 1986). The development of mathematical tools to describe probability culminated during the first third of the twentieth century when Kolmogorov (1956) formulated the axioms of probability, with the expectation that all properties of (mathematical) probability may be derived from the axioms. The axioms have been criticized by various researchers but they remain the fundamental framework of the mathematical theory of probability.

The Mathematical Theory of Probability: Axioms

The mathematical theory of probability is based on three fundamental assumptions or axioms. These are not derived or proved based on other considerations but are posited to capture the essence of probability. The axioms refer to the probabilities associated with events that may be observed. The observable events reflect the substantive problem at hand to which the probabilistic model is applied. For example, when 20 students take an exam, the relevant events may be associated with the number who pass it – that is, 0 or 1 or 2 or ... or 20 if it is irrelevant, who passes and who does not. As the example illustrates – when the events of interest are selected – the irrelevant aspects of the problem at hand are disregarded. The fundamental requirement is that following the experiment, one has to be able to determine for every event whether or not that even occurred. If, for example, only Mary, John, and Jim passed the test, the event stating that three students passed has occurred and the others have not. Usually, the impossible event (that never occurs) and the sure event (that always occurs) are also included. There are certain operations that may be applied to events. The two most important operations are addition (union) and product (intersection). If A and B are two events, their sum

$$A + B$$

is also an event and it occurred if and only at least one of A and B occurred. The product

$$AB$$

is also an event and it occurred if and only if both of A and B occurred. With repeated application of these operations, one can generate events such as ‘at least 5 passed’. When the intersection of two events is impossible,

$$AB = \emptyset$$

we say that the events exclude each other.

The above operations may be – and often have to be – applied infinitely many times, one after the other. For example, if one tosses a coin and the question of interest is how many times the coin needs to be tossed before the first tail occurs, this number does not have an upper bound in the sense that no larger value may be observed than the bound. Rudas (2004) gives an intuitive description of the precise meaning of applying the operations infinitely many times. One may think that such infinitely long experiments are not possible in practice, but many procedures and arguments in statistics are asymptotic. This implies that they give a good approximation for large samples but, strictly speaking, are only true for infinitely large samples.

The axioms relate these operations to probabilities.

First, the probability of any event is a number between 0 and 1

$$0 \leq P(A) \leq 1.$$

Second, the probability of the impossible event is

$$P(\emptyset) = 0.$$

Third, if two events exclude each other, then the probability of their sum is the sum of their probabilities

$$P(A + B) = P(A) + P(B), \text{ if } AB = \emptyset.$$

This is, of course, the axiom of the greatest interest. It means that if, for example, no student can go to two classes during the same period, then the probability that a randomly selected (i.e., each student has the same chance of being selected) student in the school goes to the science class or the physical education (PE) class, is the sum of the probabilities that the student goes to the science class and that the student goes to the PE class. This is the additivity of probability, which is its fundamental property.

Note that all the assumed properties hold true for relative frequencies. This is because the axioms are selected to be the basis of a mathematical construction that is intuitively related to the relative frequencies. There are several properties that may be derived from the axioms. For example, that the probability of the certain event is 1 or that the property in the third axiom is also true for more than two events. For example, it is true for all subjects taught in school. In fact, usually one postulates a more general variant of the third axiom, namely that it is true for infinite sequences of events:

$$P(A_1 + A_2 + \dots) = P(A_1) + P(A_2) + \dots, \text{ if } A_i A_j = \emptyset \text{ for all } i \text{ and } j$$

where the meaning of the union of an infinite sequence of events is that at least one of them occurs and the meaning of the sum of an infinite sequence of probabilities is the limit of the finite partial sums (for details see Rudas, 2004).

A question of fundamental importance is whether the mathematical construction of probability that is based on the above axioms possesses the fundamental property

which characterized the frequentist interpretation of probability. The question is of lesser importance in the case of subjective probability that is not necessarily supposed to follow any rules (Kopylov, 2008). It is possible to construct a model with an event that has a fixed probability and imagine an infinitely long sequence of independent observations of the experiment with the relative frequency of the event recalculated following each observation. One obtains a sequence of numbers indicating the relative frequency of the event during the first 1, 2, 3, 4, . . . repetitions of the experiment. Then, mathematical methods – based on the axioms – can be used to show that this sequence, indeed, converges (i.e., gets closer and closer as the number of repetitions increases) to the probability of the event. In other words, the basic conceptual assumption behind the frequentist view of probability is implied by the axioms.

Conditional Probability

It, very often, happens to be the case that the probability of an event is of interest knowing that another even occurred. For example, in educational testing if A and B are two items and one knows that 99.5% of those who got item A correctly will also get item B correctly and only 0.1% of those who did not get item A correctly will be able to answer item B correctly, then it makes very little sense to ask item B following item A , because knowing the result of asking item A will almost certainly determine whether the answer to item B is correct. A formal approach to the intuitive concept used in this argument is that of conditional probability. The conditional probability that B is correct, given that A was correct is 0.995 and the conditional probability that B is correct if A was incorrect is 0.001 in the previous example. It turns out that the conditional probability of B given A has to be defined as

$$P(B|A) = P(AB)/P(A).$$

When $P(B|A)=P(B)$, the two events are independence, because knowing that A occurred does not influence the probability of B . In this case,

$$P(AB) = P(A)P(B).$$

Finding independent structures is of central importance in statistical analysis of data. In most of the social sciences – education not being an exception – most of the observables are related to each other and our understanding of their structure is greatly enhanced if certain independencies or conditional independencies may be assumed. Conditional independence of events A and B , given event C is defined as

$$P(AB|C) = P(A|C)P(B|C).$$

This concept may be extended to more general observables than events, called random variables.

Random Variables

Random variables are among the most important concepts used in probability and statistics. Intuitively, these are models of random quantities and are used in all cases when the observations that are possible may be characterized by a number. For example, there is uncertainty associated with the grade point average (GPA) values students in a class will have by the end of the academic year. These quantities may be modeled with random variables. For an unknown quantity to be a random variable, certain events have to possess probabilities in the sense described earlier. These events are defined by constructing a subset of the real numbers and the events are that the actual value of the random variable belongs to this subset. Interestingly, all such probabilities may be obtained by computing the probabilities of simple events, namely those that the value of the random variable does not exceed a given real number, a

$$P(X \leq a) = F_X(a)$$

for all real a values, where X denotes the random variable. The notation $F_X(a)$ refers to the fact that these probabilities – for a fixed random variable X – may be considered as a function of a . This is the (cumulative) distribution function of the random variable X . Distribution functions have certain properties, including that they cannot decrease if a increases; if a goes to minus infinity, then the value of the function converges to zero; and if a goes to infinity, the value of the function converges to one.

Although distribution functions are very useful in the mathematical study of random variables, another kind of functions – called density functions – are used often to characterize the distribution of random variables. Density functions – usually denoted as $f_X(a)$ – are non-negative functions and their value for a real number a is related to the change in the value of the distribution function around a . More precisely, the change in $F_X(a)$ around a may be measured by

$$\frac{F_X(a + \varepsilon) - F_X(a - \varepsilon)}{2\varepsilon}$$

where ε is a small positive number. This quantity may converge to a number when ε goes to zero. This number is the value of the density function of the random variable X at a . The name of the density function comes from the fact that, in areas where the density function has a higher value, the observations from the random variable occur more frequently – with larger density – than in areas where the function takes on smaller values.

For statistical modeling of observed data, it is important to distinguish between continuous and discrete random variables. The distribution function of continuous random variables is, in fact, a continuous function. Such a random variable takes on all its values with zero probability. Therefore, the concept of probability in this case is not

appropriate to describe the difference between possible observations. The density function, however, distinguishes among the different values also in this case. The value of the density function at a is called the likelihood of value a . Some values have a higher, and others lower, likelihoods. Random variables with a discrete distribution have values that may occur with positive probability and their distribution functions have jumps at such values and are horizontal between two such neighboring values. In this case, there is no density function because the above ratio does not converge to a number for all values of a . Here, the individual probabilities are identified with the likelihoods. The concept of a discrete random variable may be applied to the case when the values are not numbers, rather arbitrary categories. For example, a random variable indicating the educational level of an individual may take on the values elementary, high school, and college. In this case, one does not have a distribution function but each value is observed with a certain probability and these constitute a probability distribution – that is, the values are nonnegative numbers that sum to 1.

Independence of Random Variables

Generalizations of the concept of independence applied to random variables are among the most important ways in which simple models are formulated and tested in statistical analysis. If the random variable A takes on the values a_1, a_2, \dots, a_I and another random variable, B , takes on the values b_1, b_2, \dots, b_J , then observing a_i or observing b_j are events – just like observing both of them, $a_i b_j$. Then the random variables A and B are independent if

$$P(A = a_i, B = b_j) = P(A_i B_j) = P(a_i)P(b_j)$$

for all $i=1, 2, \dots, I$ and $j=1, 2, \dots, J$. The probabilities of the events $A_i B_j$ are the joint distribution of the two random variables. This joint distribution is greatly simplified when the two variables are independent. In this case, the joint distribution if A and B may be described by the marginal distributions $P(A_i)$ and $P(B_j)$. If, for example, $I=5$ and $J=3$, then – instead of the $IJ-1=14$ probabilities in the joint distribution – one has to know only $I-1+J-1=6$ probabilities in the marginal distributions. Perhaps more important is the simplification of the joint distribution as a product of the two marginal distributions. If the categories of variable A denote five different countries and the categories of B three different educational levels, then the appropriate fractions may be interpreted as probabilities and independence would mean that the numbers of inhabitants with a certain level of education within a country are proportional to the population sizes of the countries.

A similar generalization of the concept of conditional independence of two events, given a third one, to random

variables, is also possible. While independence of variables rarely occurs in education or, more generally, in the social and behavioral sciences, conditional independence may be observed surprisingly often – in particular, when conditioning is not on one variable, rather on a combination of variables, which is also a random variable. Sometimes, conditioning on an unobserved (latent) variable is useful. For example, in educational measurement, it is often observed – and sometimes assumed as part of a model (see, e.g., Bond and Fox, 2007) – that the responses of people at the same level of ability to two items are independent from each other. In this case, one variable is the response to one item (right or wrong), the other is the response to the other test item and the variable upon which conditioning occurs is the level of ability.

The concepts of independence and conditional independence may be extended to continuous random variables. In this case, the events are those defining the cumulative distribution function. Two random variables X and Y are independent if

$$F_{XY}(ab) = F(X \leq a, Y \leq b) = F(X \leq a)P(Y \leq b) = F_X(a)F_Y(b)$$

for all possible values of a and b . The function on the left-hand side is known as the joint cumulative distribution function of the two variables. The extension to conditional independence uses the conditional distribution functions of the variables, given a particular value of the conditioning variable.

Normality

In many physical systems, uncertainty is introduced by measurement error and a model may be appropriate in which the measured value Y is assumed to be the sum of the true value X and of a measurement error E

$$Y = X + E$$

where the behavior of the measurement error is a characteristic of the measuring instrument itself. Such an error may be described probabilistically and E may be thought of as a random variable. For example, the usual method of measuring blood pressure gives a value which may not be equal to the real blood pressure – rather, it is the sum of the true value (Y) and some measurement error (E). Very often in practice, the density of E is characterized by having a specific shape – that of a normal distribution. The family of normal distributions consists of distributions with different expected values (averages) and different variances (dispersions). If an instrument's error has a negative expectation then, on the average, it will report smaller values than the truth and if it has positive expectation, then, on the average, it reports larger than true values. When the expectation is zero, the measurement

(process using the instrument) is unbiased. The individual values in this case are likely to deviate from the true value and the typical size of the deviation is about the square root of the variance, the standard deviation. It is customary to use unbiased measurements and instruments with smaller dispersion are preferable to instruments with larger dispersion.

The family of normal densities is characterized by symmetry around the expected value (if it is zero, positive and negative errors are equally likely) and by large errors being less likely than small errors. In fact, with a normal distribution, it is quite unlikely to observe a value more than three standard deviations away from the expected value.

In many cases, statistical analysis is greatly simplified if the variables observed are supposed to have a normal distribution. Note that while the simplification means that the analysis is easier and more reliable for small sample size than it would be without the normality assumption, it has the disadvantage that the normality assumption may exclude potentially important characteristics of the data (such as multimodality or the presence of higher order interactions) from the analysis. An even stronger assumption is joint or multivariate normality of the variables. Such an assumption, however, needs to be justified based on substantive knowledge.

In addition to the measurement-error model, there is another – perhaps more important – way in which normality occurs in probability theory and statistics and this is related to the asymptotic behavior of sequences of random variables.

Asymptotic Theory

The asymptotic behavior of sequences of random variables – that is, the behavior of infinitely long sequences of random variables – is an involved mathematical concept but it has important implications for the statistical analysis of data from large samples. The link between random variables and samples is that each observation in a sample may be regarded as an observation of a random variable – where randomness is induced by sampling and /or measurement error. We have already seen that the sequence of recalculated relative frequencies of an event converges to the probability of the event. This is implied by the so-called law of large numbers that states that the sample mean converges to the population mean.

It turns out, however, that if the sum of the observations is divided by \sqrt{n} , instead of n , then this quantity does

not converge to a number, but remains a random variable asymptotically. To put it differently, the sample mean itself may also be considered a random variable: it is a function (the average of) other random variables (the observations). If the sample mean is multiplied by \sqrt{n} (i.e., the sum is divided by \sqrt{n}), then it will continue to have a distribution asymptotically (as opposed to being concentrated to one value). Quite surprisingly, the asymptotic distribution, often, does not really depend on the original distribution of the variables the averages of which are taken. For the asymptotic result to apply, it is sufficient (disregarding some technical conditions usually fulfilled in practice) that they are independent. In all such cases, the asymptotic distribution will be normal.

This result is called the central limit theorem and it explains the dominant role played by normal distributions. The average of arbitrary independent random variables – if appropriately scaled – tends to have a normal distribution, disregarding what was the shape of the original densities.

Recursive Partitioning

S Landau, King's College London, De Crespigny Park, London
S Barthel, GlaxoSmithKline, London

© 2010 Elsevier Ltd. All rights reserved.

Regression-type models, for example, multiple linear regression, logistic regression, generalized linear models, linear mixed models, or generalized linear mixed models, can be used to predict a future object or individual's value of the response variable from its explanatory variable values. However, as with all statistical modeling, the resulting predictions might not be valid if the underlying assumptions are not met. Departures from model assumptions might arise due to a mis-specified relationship between response and explanatory variables; for example, by incorrectly assuming linear relationships with covariates or omitting higher-order interactions between some of the explanatory variables.

An alternative prediction approach has evolved to overcome some of these potential problems. Recursive partitioning techniques provide a prediction rule by forming subgroups of objects (individuals) within which the response variable is relatively homogeneous, on the basis of their values on a set of predictor variables, and assigning each subgroup a predicted response. Future objects can then be allocated to one of these subgroups and the value of their response predicted. The allocation of an object to a subgroup operates recursively, in that the final subgroup is derived at a succession of 'yes/no' decisions. Parent groups or nodes are split into two subgroups or daughter nodes on the basis of the value of a single explanatory/predictor variable at a time. For continuous or ordinal predictor variables x a group can be split on the basis of high and low values; for example, allocate object i to left daughter if $x_i < 10$ and to right daughter if $x_i \geq 10$. For nominal variables, splits that separate the categorical variables into disjoint subsets are allowed; for example, for a nominal outcome z with possible categories A, B, C, or D allocate object i to left daughter if $z_i \in \{A, C\}$ and to right daughter if $z_i \in \{B, D\}$.

The resulting collection of partitioning rules can be conveniently summarized by means of a decision tree. We present some examples below. In the context of predicting the value of a continuous response, the resulting tree is called a *regression tree*; and, in the context of predicting the category of a nominal variable or classification, this is known as a *classification tree*. The recursive partitioning technique itself is also frequently called *classification and regression trees* (CARTs) in reference to the original program for fitting trees to data (Breiman *et al.*, 1984). Note that recursive partitioning for predicting the value of a categorical variable is an example of a supervised learning

with a training sample, which also comprises techniques such as discriminant analysis. In contrast, unsupervised learning to detect as-yet unknown groupings is the domain of cluster analysis.

Classification Trees

We begin by detailing the recursive partitioning method for classification. As an example, consider the data in **Table 1** from the Drumcondra study of educational achievement (Greaney and Kelleghan, 1984) previously analyzed by (Raftery and Hout, 1985). Educational transitions were determined for a sample of 500 Irish school-children aged 11 in 1967 when tuition fees for secondary education were removed. Here, the focus is on predicting taking a leaving certificate (binary variable Y) for the 463 pupils who entered secondary education. The following sociodemographic variables were considered as predictors: gender of pupil, Drumcondra Verbal Reasoning Test score (DVRT), a prestige score of father's occupation (higher = more prestige), and type of school (secondary or specialized vocational).

To derive the best classification rule, the following general steps are usually carried out:

- growing a large initial tree;
- pruning the tree; and
- evaluation of its predictive performance.

The tree is grown – or in other words, the sequence of “if this then that” decision rules generated – by using all or part of the sample as a training sample. The decision tree starts with an initial or root node that comprises all objects. To split the sample into two subgroups (1) every allowable split on each potential predictor variable is examined and (2) the best of these splits is determined on the basis of some criterion and executed to create left and right daughter nodes. Steps (1) and (2) are then re-applied to each of the daughter nodes to determine the node on which to perform the next split. The process is repeated until some stopping rule is met (more on this below). To determine the best split of a node G into left and right daughter nodes, G_L and G_R , a numerical *split function*, $\phi(G, G_L, G_R)$, which measures the improvement in node purity due to splitting, is evaluated for each possible (G_L, G_R) . The best split then corresponds to the node G_0 and daughters $(G_{0,L}, G_{0,R})$ for which

Table 1 Irish education data (first seven pupils)

ID	Sex	DVRT* (70–140)	Leaving certificate from secondary education	Prestige score for father's occupation (18–75)**	School
1	Male	113	Not taken	28	Secondary
3	Male	110	Taken	69	Secondary
4	Male	121	Not taken	57	Secondary
5	Male	82	Not taken	18	Vocational
6	Male	85	Not taken	28	Vocational
8	Male	98	Not taken	43	Vocational
9	Male	92	Not taken	33	Vocational

*Drumcondra Verbal Reasoning Test.

**Score constructed by Raftery, A. E. and Hout, M. (1985). Does Irish education approach the meritocratic ideal? A logistic analysis. *Economic and Social Review* 16, 115–140.

$$\phi(G_0, G_{0,L}, G_{0,R}) = \min_{G, G_L, G_R} [\phi(G, G_L, G_R)] \quad [1]$$

For categorical response variables, a number of split criteria have been suggested. They tend to be based on an *impurity function*, which is a function of the proportions of the training sample belonging to the different possible categories of the response variable, here denoted $p_{G,C_1}, p_{G,C_2}, \dots, p_{G,C_k}$ for node G and k possible response categories C_1, C_2, \dots, C_k . Suitable measures of impurity should take their maximum when a node in the tree contains an equal number of objects from each of the categories (as it is then impossible to associate the node with a response variable category). The function should take its minimum when the node is completely pure; that is, all objects in the node belong to the same response variable category. Two candidates for impurity functions are the *Gini index of diversity*,

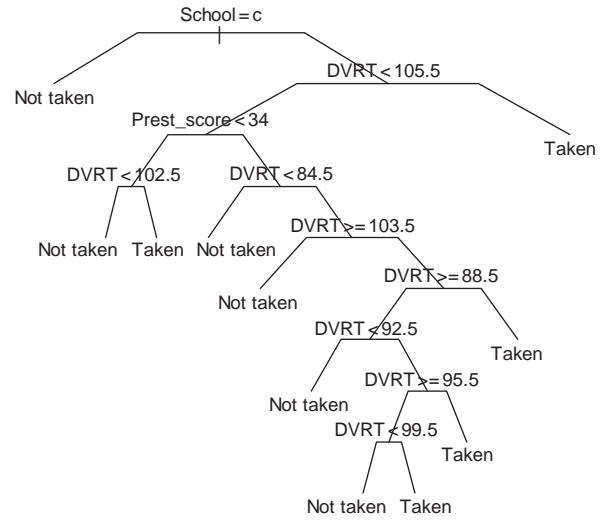

$$\begin{aligned} I_1(p_{G,C_1}, p_{G,C_2}, \dots, p_{G,C_k}) &= \sum_{j=1}^k \sum_{j' \neq j} p_{G,C_j} p_{G,C_{j'}} \\ &= 1 - \sum_{j=1}^k p_{G,C_j}^2 \end{aligned} \quad [2]$$

and the *information index*

$$I_2(p_{G,C_1}, p_{G,C_2}, \dots, p_{G,C_k}) = - \sum_{j=1}^k p_{G,C_j} \ln(p_{G,C_j}) \quad [3]$$

(where $0 \ln(0)$ is taken to be the limit of this function and set to 0). Split functions can then be defined by measuring the improvement in impurity after splitting node G into daughters, G_L and G_R , that is,

$$\begin{aligned} \phi(G, G_L, G_R) &= I_m(p_{G,C_1}, p_{G,C_2}, \dots, p_{G,C_k}) \\ &\quad - \left[\frac{n_{G_L}}{n_G} I_m(p_{G_L,C_1}, p_{G_L,C_2}, \dots, p_{G_L,C_k}) \right. \\ &\quad \left. + \frac{n_{G_R}}{n_G} I_m(p_{G_R,C_1}, p_{G_R,C_2}, \dots, p_{G_R,C_k}) \right], \quad m=1,2 \end{aligned} \quad [4]$$

**Figure 1** Large initial classification tree for Irish Education data based on the Gini index.

where n_G, n_{G_L}, n_{G_R} denote the sizes of the respective nodes.

Figure 1 shows a classification tree for the Irish education data resulting from applying the splitting function derived from the Gini criterion [2]. The first split is made on the basis of the school variable. The left daughter node consists of pupils attending a vocational school and they are predicted not to take the leaving certificate ($Y = 0$). The right daughter node consists of pupils attending a secondary school. They are further split in the next step according to verbal reasoning scores with those achieving higher scores (above 105.5) predicted to take the leaving certificate ($Y = 1$). Those in secondary school with lower verbal reasoning scores are further separated according to their father's prestige rating and following this split into increasingly smaller subgroups according to the DVRT variable. Recursive partitioning on the basis of the information criterion [3] was also carried out. In this instance, it made no difference in terms of decision rules nor final node labels, suggesting that the tree is not sensitive to the choice of splitting criterion.

When growing trees by splitting nodes, to maximize a homogeneity criterion, smaller and smaller nodes of progressively increased homogeneity are generated. Simple stopping rules exist for declaring terminal nodes. Commonly, a node is declared terminal when its size drops below a threshold value – as shown in **Figure 1**. The size of the tree was governed by setting the minimum size of a node to be considered for further splitting to 30 pupils and by restricting terminal nodes to contain at least ten pupils. An alternative rule is to stop when the node is homogeneous enough, for example, when the splitting criterion in [4] falls below some threshold. A more flexible approach to determining the number of branches of a tree is to use

a pruning algorithm. This involves growing a very large decision tree initially and then collapsing later branches using what is referred to as cost–complexity pruning to generate a nested sequence of decision trees. The latter operates by minimizing a cost–complexity function. This function is made up out of the cost of the final tree as measured by the average terminal node impurity

$$\text{Cost}(G_1, G_2, \dots, G_q) = 1/n \sum_b n_{G_b} I_m(p_{G_b, C_1}, p_{G_b, C_2}, \dots, p_{G_b, C_k}) \quad [5]$$

where G_1, G_2, \dots, G_q are the terminal nodes, and the number of terminal nodes q by defining a cost–complexity function as:

$$\text{CC}_\alpha(G_1, G_2, \dots, G_q) = \text{Cost}(G_1, G_2, \dots, G_q) + \alpha q \quad [6]$$

The number $\alpha \geq 0$ is called the complexity parameter. The aim is to simultaneously minimize both the cost and the complexity of the tree, with α determining the trade-off between the two. Under the extreme case $\alpha = 0$ the function is allowed splitting to a point where each terminal node contains only a single observation and so is 100% pure, which clearly bears the danger of overfitting. The larger the value of the complexity parameter the shorter the pruned tree with terminal nodes G_1, G_2, \dots, G_q as the increase in complexity increasingly outweighs the reduction in cost. (The extreme case is given by $\alpha > 0$ that leads to a single terminal node.)

Having said that, selecting a final decision tree still requires the user to specify an arbitrary threshold. This might be in the form of a simple stopping rule or by means of the complexity parameter when carrying out cost–complexity pruning. Therefore, how does one determine the best tree in an objective manner? In practice, the best pruned decision tree is chosen to be the one that best fulfills the goal of predicting the value of the response variable. A nested sequence of competitor trees is constructed, for example, by using a series of values for the complexity parameter. Predictive performance of each competitor tree is evaluated by means of some index and the tree that maximizes the index is chosen. In the context of predicting the values of categorical variables, terminal nodes are assigned to the most frequent category and the tree's predictive performance is typically measured by the percentage of cases that have been correctly classified.

However, as with all statistical model fitting, when (future) predictive performance is evaluated from the same sample that was used to develop the model/decision rule estimates tend to be too optimistic. (This is akin to R^2

in regression being upwardly biased.) To avoid such bias, separate training and test samples can be used to develop and measure the predictive performance of the decision tree, respectively. However, samples are often too small to provide sufficient numbers for reliable tree construction and independent testing. In prediction, an approach that provides the best of both worlds, that is, uses most of the available information to develop the tree and provides unbiased estimates of its predictive performance, is cross-validation. The latter operates by randomly dividing the sample into V parts of equal size, n_v . Each of the V groups is in turn set aside to temporarily serve as a test sample. A decision tree is developed on the basis of the remaining $n - n_v$ objects and predictive performance evaluated on the set-aside cases. If this process is repeated for each of the V subsamples, then the average performance index provides an unbiased estimate of the tree's predictive power. It has been suggested that little is gained by more than ten partitions, so V is often taken to be in the 5–10 range. (Note that some software packages provide the leave-one-out rule for prediction where $V = n$ and $n_v = 1$. This means each subject is set aside exactly once and requires the whole recursive partitioning process to be performed n times.)

Table 2 shows the predictive performance of a nested sequence of decision trees to predict Y generated by cost–complexity pruning. Increasingly larger choices of the complexity parameter α lead to increasingly pruned trees. The tree shown in **Figure 1**, which had been derived by using a simple stopping rule, corresponds to cost–complexity pruning with $\alpha = 0$ and is very complex. Increasing the value of the complexity parameter eventually leads to the best pruned tree shown in **Figure 2** which corresponds to $\alpha = 0.0135$. This value for the complexity parameter and its associated pruned tree maximizes the predictive performance as measured by the cross-validated percentage of cases correctly classified (**Table 2**). (Note that when cross-classification is used to select the complexity parameters, the computer algorithm needs to ensure that nested sequences of decision trees are being evaluated. Most software for recursive partitioning, e.g., the R package *rpart* (Therneau and Atkinson, 1997) used here, ensure this by deriving all cost–complexity pruned trees within each cross-validation step.) Thus, the tree in **Figure 2** represents our best collection of partitioning rules to predict Y . We now conclude that pupils with lower DVRT and attending secondary school scores should be further separated only on father's prestige

Table 2 Cross-validated predictive performance of cost complexity pruning for Irish education data

Number of splits on original sample	0	1	3	4	5	10
Corresponding complexity parameter (α)	0.4730	0.0293	0.0135	0.0090	0.0045	0.0000
Percentage correctly classified by cost complexity function (estimated using $V = 50$ -fold cross-validation)	52.1%	74.7%	76.5%	74.1%	71.9%	74.1%

Values in bold indicate optimal pruning.

score with pupils with higher prestige scores (>34) predicted to take the leaving examination. We estimate that this set of decision rules classifies 76.5% of pupils correctly (compared to 52.16% correctly classified if we simply suggested that every pupil takes the final examination). The graph uses a mosaic plot to illustrate the distribution of the two certificate classes within each terminal node which helps to visualize the uncertainty of assigning the terminal nodes to their most frequent class.

Regression Trees

The recursive partitioning method for predicting the value of a continuous variable, that is, the construction of a regression tree follows the same basic steps as that of a classification tree. The tree is grown by successively splitting nodes into right and left daughter nodes. The heterogeneity of a node with regard to a continuous outcome is typically measured by the sums of squares criterion

$$SS(G) = \sum_{i \in G} (y_i - \bar{y}_G)^2 \quad [7]$$

Figure 2 Pruned classification tree ($\alpha = 0.0135$) for Irish Education with class distribution in the terminal nodes depicted by mosaic plot.

where y_i denotes value of the response variable for object i in group G and \bar{y}_G the group average. The split function to be optimized across nodes and daughter nodes G_L and G_R can then be derived as:

$$\phi_{SS}(G, G_L, G_R) = SS(G) - [SS(G_L) + SS(G_R)] \quad [8]$$

As for classification trees, various simple or complex rules can be used to prune the tree. In the context of cost-complexity pruning, the cost of the tree with terminal nodes G_1, G_2, \dots, G_q is measured by the total terminal node heterogeneity:

$$\text{Cost}(G_1, G_2, \dots, G_q) = \sum_{v=1}^q SS(G_v) \quad [9]$$

and the cost-complexity function is simply defined as before in [6] using this cost definition. To determine the best regression tree, the predictive performance of the tree can again be evaluated by means of a test sample or by cross-validation. Terminal nodes are assigned a location summary, typically the mean, and the predictive power of the tree can simply be measured by the cost of its terminal nodes. Alternatively, if a scaled version is preferred, the proportion of variability in the response variable that can be explained by the predictions, that is,

$$R^2(G_1, G_2, \dots, G_q) = \sum_{v=1}^q SS(G_v) / SS(G_0) \quad [10]$$

where G_0 denotes the root node, which is familiar from regression, can be used.

As an example, consider the Forbes list of 2000 leading companies, collected by *Forbes Magazine* for the year 2004 (available in the Handbook of Statistical Analysis Using R (HSAUR) package in R). Available company information includes its name, world ranking, the country the company is situated in, a category describing what the company produces, amount of sales of the company, and its profits, assets, and market value (Table 3). Here, we want to develop a decision tree for predicting profits from sales, assets, and market value. Initial growing of a regression tree based on the sums of squares splitting criterion resulted in the tree displayed in Figure 3. (Here

Table 3 Forbes 2000 data (top 6 ranked companies)

Rank	Name	Country	Category	Sales (billion US\$)	Profits (billion US\$)	Assets (billion US\$)	Market-value (billion US\$)
1	Citigroup	United States	Banking	94.71	17.85	1264.03	255.30
2	General Electric	United States	Conglomerates	134.19	15.59	626.93	328.54
3	American Intl. Group	United States	Insurance	76.66	6.46	647.66	194.87
4	Exxon Mobil	United States	Oil and gas operations	222.88	20.96	166.99	277.02
5	BP	United Kingdom	Oil and gas operations	232.57	10.27	177.57	173.54
6	Bank of America	United States	Banking	49.01	10.81	736.45	117.55

a simple stopping rule based on a low cost–complexity parameter of $\alpha = 0.1$ was used.) Since we are now predicting the value of a continuous variable, the predicted profit value is depicted for each terminal node of the tree. **Table 4** shows the predictive performance for a series of cost–complexity pruned trees. The decision tree corresponding to the complexity parameter with the best R^2 is shown in **Figure 4**. The initial eight terminal nodes have been merged back to four terminal nodes. According to our cross-validation estimate, the regression tree can explain 23.3% of the variability in profits. The boxplots underneath the decision tree in **Figure 4** illustrate the unexplained variability in profits. The final tree suggests that market value is a predictor of profits.

Extensions

An alternative approach to growing trees and then pruning them back to avoid overfitting, is the use of p -values, possibly adjusted for multiple comparisons, for evaluating the quality of a split. To construct a so-called conditional *inference tree*, a significance test of the null hypothesis, that the response variable and a two-level group factor are not associated, is performed at each node of the tree, and the split chosen for which the test statistic most exceeds a prespecified nominal level. For example, to carry out a likelihood ratio test of association with a nominal response, we would use the deviance test statistic which is simply the splitting criterion resulting from the information index multiplied by $2n_G$, and compare it against a nominal level derived from a chi-squared distribution

with 1 degree of freedom. (The latter also illustrates that the p -value depends on both the reduction in impurity as well as the node size.) Alternatively, to stay within a strictly nonparametric framework and avoid assumptions regarding the sampling process, (conditional) permutations tests can be employed. This connects recursive partitioning to classical statistical test problems and so addresses the issue of overfitting; for more information see Hothorn *et al.* (2006). **Figure 5** shows the conditional inference tree for the Irish Education data (created in R package party, Hothorn *et al.* (2005)) obtained by setting the nominal significance level to 5%. Like the best pruned classification tree in **Figure 2**, this approach results in four terminal nodes. However, the recursive splits performed to allocate pupils to one of the terminal nodes differ. While **Figure 2** splits the secondary school pupils with lower DVRT score on father's prestige score in the last partition, the conditional regression tree splits the secondary school pupils with higher DVRT score.

There are further extensions to the basic recursive partitioning principle. For example, parent nodes can be split into more than two daughter nodes and it is also possible to consider splits on a linear combination of two or more continuous or ordinal predictor variables (Breiman *et al.*, 1984). Furthermore, various weighting schemes can be used. Object weights can be incorporated into the split functions. Such weights may reflect predefined varying importances of different objects. Other weights might also be used like inverse probability weights to counteract the effects of nonrandom sampling. Alternatively, predictor variables can be assigned different weights to reflect differential costs occurring when employing them. Finally, for classification trees, prior class probabilities or a loss matrix describing the cost incurred by misclassifying objects for each possible class, can be used. The ability to specify prior probabilities might be particularly useful in case control studies to achieve unbiased estimation of performance indices such as percentage correctly classified, positive predictive value (PPV, proportion of cases in those predicted to be cases), and negative predictive value (NPV, proportion of noncases in those predicted not to be cases) which depend on prevalence; for more on evaluating prediction rules see Hand (1997). (All these weights are, implemented in part (Therneau and Atkinson, 1997)).

Predictions might be subject to substantial uncertainty. Such uncertainty may, for example, manifest itself by

Figure 3 Large initial regression tree for Forbes 2000 data based on the sums of squares criteria.

Table 4 Cross-validated predictive performance of cost–complexity pruning for Forbes 2000 data

Number of splits on original sample	0	1	2	3	4	5	6	7
Corresponding complexity parameter (α)	0.2375	0.04600	0.0426	0.0203	0.0185	0.0110	0.0108	0.0100
R^2 achieved by cost complexity function (estimated using $V = 10$ -fold cross-validation)	0.00%	15.85%	13.82%	23.34%	21.50%	21.25%	19.24%	22.24%

Values in bold indicate optimal pruning.

different decision trees generated during cross-validation. For example, during the cross-validation of the Forbes 2000 data set we noticed that while the mode number of splits suggested was 3, split numbers as low as 1 or as high as 7 also occurred. *Bagging or bootstrap aggregation* is a technique that can be used with many classification or regression methods to reduce the variance associated with predictions and so improve predictive performance. The basic procedure involves sampling objects in the training sample with replacement, generating predictions for each such bootstrap sample, and obtaining an overall prediction by averaging across bootstrap samples. Since regression trees predict the value of the response variable by its mean in a local sample, the variance of the bagged prediction is reduced compared to that of the initial prediction due to averaging over multiple samples. A similar argument can be made for classification trees or more generally for local prediction methods. However, note that bagging is a black

box machine learning approach – we can no longer follow a single succession of yes/no decisions to arrive at our prediction. As an example, we bootstrapped the Forbes 2000 data 1000 times, generated a regression tree (using a stopping rule based on cost-complexity pruning with $\alpha = 0.01$) and associated profit predictions each time and averaged these predictions over only the predictions of profits which had not been included in the respective bootstrap sample. This provided a cross-validated estimate of predictive performance of $R^2 = 25.6\%$, which is somewhat better than the performance achieved by simple CART with optimal cost-complexity pruning (cf. **Table 4**). The bagging procedure is a special case of a more general approach called random forest (Breiman, 2001) which is available, for example, in the R package randomForest (Breiman *et al.*, 2005).

Conclusion

Recursive partitioning are essentially fairly simple non-parametric techniques for prediction and classification. When used in the standard way, they provide trees which display the succession of rules that need to be followed to derive a predicted value or class. This simple visual display explains the appeal to decision makers from many disciplines.

The prediction techniques are nonparametric in that they do not rely on any particular assumption about the type of dependence of the dependent variable on the

Figure 4 Pruned regression tree ($\alpha = 0.0203$) for Forbes 2000 data with the distribution of profits in the terminal nodes depicted by boxplots.

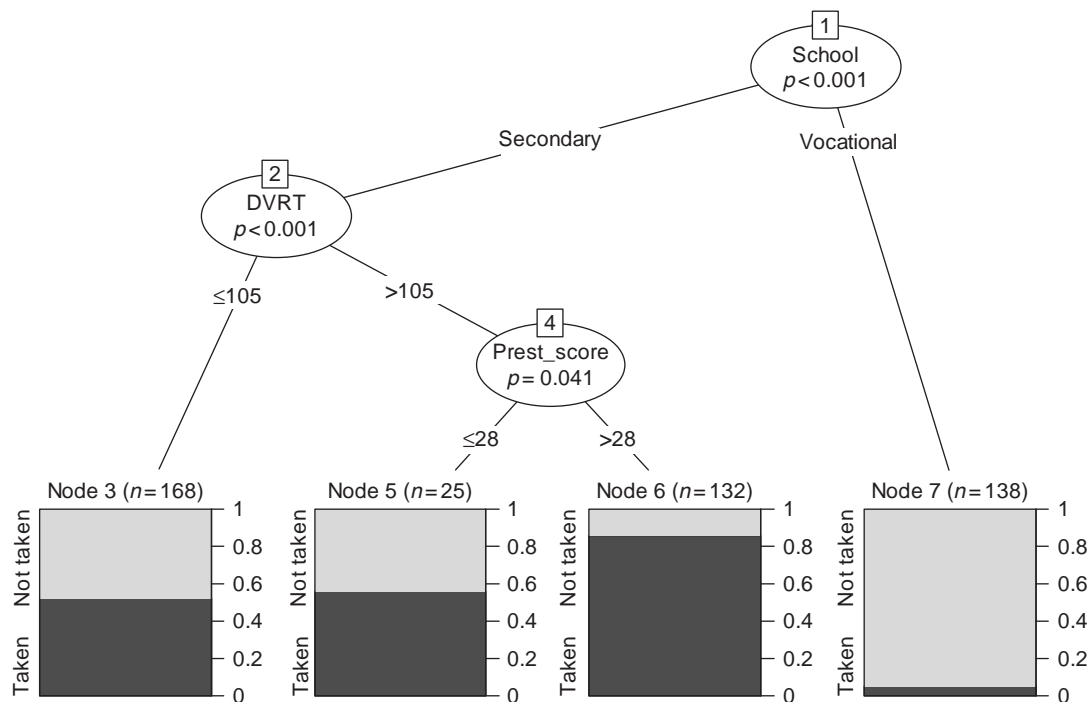

Figure 5 Conditional inference tree for the Irish Education data.

predictors. This distinguishes them from regression models where the relationship between response and predictor variables is parameterized *a priori*, for example, by assuming linear relationships. (However, note that the final tree model can be written as a regression model containing suitably defined indicator variables as explanatory variables.) This nonparametric property is seen as an essential practical advantage of prediction by recursive partitioning over prediction by regression when *a priori* information about the variables is limited.

However, it needs to be emphasized that recursive partitioning is an exploratory rather than an inferential technique. Regression or classification trees can provide a visualization of the main structures of a regression relationship. But users need to be reminded that the fine graining of identifiable subgroups is limited by the available predictors and their strength of relationship with the outcome. Tree information might be useful for developing a model of the nature of the relationship between response and explanatory variables. Once an appropriate population model is identified, inferential techniques can then be applied to a new data sample to make statements about its parameters.

Sampling

J Qian, Educational Testing Service, Princeton, NJ, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Cluster sampling – It is a sample design that selects one or several clusters of sampling elements.

Design effect – It is the ratio of the variance of a statistic from the complex design over the variance from the SRS with the same sample size.

Equal probability of selection method (EPSEM) – It is a sample design that samples all units with equal probability.

Horvitz–Thompson estimator – It is a weighted unbiased estimator of population total for the complex design with unequal selection probabilities.

Population – It is the full specified set of elements being studied.

Primary sampling units (PSUs) – They are the clusters on the sampling frame pertaining to the first stage of multiple-stage sampling, such as the public schools in the state.

Probability samples – It is a sample design that uses the methods based on probability theory to minimize subjectivity in the choice of units to survey.

Sample – It is a subset of units/elements drawn from a population.

Sample design – It specifies the method for selecting every possible sample from a sampling frame.

Sample weights – They are values that are used to correct for unequal selection probabilities due to complex sample designs and to adjust for nonresponse or nonparticipation in surveys. The base weight for a sample element usually equals the inverse of its probability of selection.

Sampling error – It is the variation between the estimates based on samples and the true characteristics of a population.

Sampling frame – It is a list of the units or the groups of units in the population.

Sampling unit – It is an element or an aggregate of elements about which information is measured at different stages in a sampling process.

Simple random sampling (SRS) – It is a sample design in which all units are selected with equal probability with no application of stratification and clustering techniques.

Stratified sampling – It is a sample design in which a population is partitioned into strata based on a certain characteristic that is known for every

sampling unit in the population, and then selecting samples independently from each stratum.

Two-stage sampling – It is a sample design that selects primary sampling units (PSUs) for the first stage of selection and then selects the elements in the selected PSUs for the second stage.

Introduction

With the growing importance of sample survey in understanding the world today, sampling plays an essential role in the gathering of information on individuals, households, institutions, businesses, and environmental resources.

The sampling techniques used in gathering information reflect the scope and purposes of a survey. Currently, many modern sample surveys are conducted for a variety of different purposes. One example is the National Assessment of Educational Progress (NAEP), an educational sampling survey (Allen *et al.*, 2001). NAEP, the only ongoing measure of what students in the United States know and can do in a variety of subject areas, reports scores for different demographic groups such as gender, ethnicity, school type, school location, and individuals making use of testing accommodations. It provides objective information on student performance to educators and policymakers at the national, state, and local levels.

Basic Concepts in Sampling

The population (the fully specified set of elements being studied) and the sample (a subset of units/elements drawn from a population) are two basic concepts in sampling. A sampling unit refers to an element or an aggregate of elements about which information is measured at different stages in a sampling process. The size of the sample depends on the accuracy of estimation required given the purpose of the study. A parameter refers to a numerical value, such as the mean or standard deviation, which characterizes the population. Survey sampling creates statistics, which are numerical values derived from the sample, designed to estimate one or more parameters of a particular population. The fundamental idea of sampling is to estimate the parameters of an entire population or to make inferences about a population based on statistical

models and data derived from only a sample of that population. Thus, the intent of sampling is not to describe the particular units that, by chance, are in a sample but instead to obtain a composite profile of a population. In fact, reporting protocols for survey results at times require that individual respondents never be identified. For instance, NAEP, under the provisions of federal laws governing the protection of information, must ensure the protection of individually identifiable data from unauthorized disclosure (National Center for Education Statistics, 2003).

Sample Design and Probability Sampling

Conducting a sampling process entails the successful coordination of several different steps: (1) defining the population of study and specifying the sampling frame; (2) creating a sample design, specifying a sampling method, and determining the necessary sample size; and (3) implementing a sampling plan, which includes sample selection, data collection, and sometimes a weighting process.

Sampling frame is a list of the units or the groups of units in the population. Sample design specifies the method for selecting every possible sample from a sampling frame. Trained statisticians usually specify a sample design using methods based on probability theory to minimize subjectivity in the choice of units to be surveyed. Samples drawn using these methods are called probability samples. The estimates of the characteristics of a population will generally vary from sample to sample. Variation between the estimates based on samples and the true characteristics of a population is referred to as sampling error, which is often expressed in terms of the standard error and bias of estimates. In statistical theory, the sampling errors will converge to zero as the sample size increases. Probability samples provide the basis for calculating the sampling error; the sample design will assign a nonzero probability for each sample to be selected. A special sample design is the equal probability of selection method (EPSEM), which samples all units with equal probability. Occasionally, the sample design only defines the rules for including sample units instead of specifying the explicit inclusion probabilities. Then the inclusion probabilities have to be derived from statistical models (Qian, 2008). The sample design determines the procedure for sample selection and the choice of an estimator of a population parameter, such as a sample average or a Horvitz–Thompson estimator (Cochran, 1977), the latter of which is discussed later.

Sometimes, nonrandom sampling approaches are also used in data collection. Typical nonrandom sampling approaches are convenience sampling and quota sampling. A convenience sample is composed of units that

are available, rather than units that are selected from a sampling frame. An example is a group of students who respond to a flyer posted on a bulletin board on a university campus that seeks participants in a survey. A quota sample sets quotas, using convenience sampling, to obtain the samples. For instance, a quota sample might be filled by some number of customers at shopping malls in different locations who are willing to be interviewed. In practice, the cost of nonrandom sampling is low, but the level of representation of the sample is not under control. Often, a sample of nonrepresentative respondents will yield a poor estimate that severely deviates from the true parameter; in the example of the campus flyer above, only students who are interested in the topic of the study or who are financially strained might respond. Such deviation, or bias, persists even if several samples under the analogous sampling plan are collected. These sampling approaches will cause selection bias because the approaches tend to under/overrepresent certain kinds of units from the sample, and cause response bias because they tend to include those who are willing to be interviewed. These kinds of errors caused by nonrepresentative sampling, which are a type of nonsampling errors, are much harder to quantify than sampling errors. Other types of nonsampling errors can be caused by an inadequately specified sampling frame, a poorly designed questionnaire, or coding and measurement errors. In particular, a well-specified sampling frame is essential to the success of a sampling plan. Possible defects in specifying a frame include noncoverage, undercoverage, overcoverage, duplication, or misclassification (Kish, 1965).

In general, a good sample design for survey research should be characterized by good representation, randomization, and realism (Kish, 1987). Here realism refers to the practical aspects involved with a survey; in particular, realism implies that the sampling plan is implementable in the field and that the cost of the study is under control.

Five Basic Probability Sampling Methods

The five basic probability sampling methods are simple random sampling (SRS), stratified sampling, cluster sampling, multistage sampling, and systematic sampling, all detailed below. More complex sample designs are generally developed based on these five fundamental approaches.

Simple Random Sampling

SRS is the most basic type of probability sampling. For a sample of size n selected by SRS, each sampling unit in the sample has the same chance of selection, and all the possible subsets in the population of size n have the same chance of being chosen as a sample. Note that the SRS design is a type of EPSEM. To draw an SRS sample, the units in the sampling frame may be selected based on

numbers from a table of random numbers or from a random number generator on a computer. In practice, sampling without replacement is generally preferable to sampling with replacement because the former avoids including any sampling unit more than once and thus yields more efficient samples. To gain the same accuracy in estimation, an SRS sample without replacement requires a smaller sample size than the one with replacement, but the units sampled without replacement from a finite population will not be independent because each draw after the first is dependent on the prior draws (Horvitz and Thompson, 1952). This is undesirable because dependence is not a typical assumption and causes complexity in analysis, particularly in variance estimation. SRS is conceptually simple but requires a complete sampling frame, which again may not be an option in practice. Even if a complete frame is specifiable, large-scale surveys, such as NAEP, rarely find it operationally or economically feasible to select an SRS sample of units across a wide area, such as a country. Instead, many practical designs make use of more refined techniques such as stratification, clustering, multistage sampling, and sampling with unequal probabilities of selection.

Stratified Sampling

Stratified sampling designs involve partitioning a population into strata based on a certain characteristic that is known for every sampling unit in the population, and then selecting samples independently from each stratum. This design offers flexibility of sampling methods in different strata and gains improved precision of estimates of target parameters when each stratum is composed of units that are relatively homogenous. In practice, strata are often determined by field conditions, such as geographic regions or administrative structures. Stratified sampling design also enables specific segments of the population to be easily targeted. For example, in the combined NAEP national and state samples (Rust, 2004), the design treated each jurisdiction in the United States as a stratum; therefore, state results can be separately reported and be compared to each other.

Stratified sampling is often made with disproportionate sample allocation across strata, meaning that the stratum proportions in the sample do not represent the corresponding proportions in the population. To remedy this problem, stratum weights, defined for each stratum as the proportion of the size of that stratum to the total population, need to be applied in estimation. When this is done, the mean or proportion estimators for each stratum are unbiased and the estimator for the population, which equals the sum across strata of the stratum weights multiplied together with the corresponding stratum estimator, is also unbiased. Existence of an unbiased estimator for each stratum implies that the average of the estimates

over all possible samples in the stratum for the same design is equal to the true parameter being estimated. If stratum weights are not properly computed, it introduces bias in estimation. In general, the weighted mean of a proper stratified sample has less variability than the arithmetic mean of an SRS sample of the population. The stratum weights should also be employed in variance estimation for stratified data.

Cluster Sampling and Multistage Sampling

Instead of selecting sampling elements, cluster sampling design selects clusters, which are naturally occurring groups of elements. Examples of clusters are schools or residential blocks; a sample will then include all the elements in the selected clusters. Compared with SRS, this is a cost-efficient design because it reduces the number of schools and cities that need to be visited when constructing a sample. Sometimes selecting clusters is also necessary for practical reasons; an English listening test might need to be administered to a room of examinees all at the same time. The problem with the cluster sample design is that it causes an increase in the standard error of estimation when compared to SRS, which is called clustering effect. The clustering effect is mainly due to two factors: homogeneity of the elements within clusters and the average cluster size. The homogeneity within clusters can be measured by the intraclass correlation (Cochran, 1977). In practice, to reduce the homogeneity of the students in each sample of a listening test, students can be randomly selected from across all of a school's classrooms to form a cluster with better representation than a design in which all students in the cluster are taken from an intact classroom. Lowering the average cluster size will yield smaller standard errors.

In general, cluster sampling and stratified sampling reflect different statistical strategies. Cluster sampling focuses on operational feasibility, while stratified sampling stresses targeting specific segments of the population. Cluster sampling includes only elements in the clusters selected, whereas stratified sampling draws random samples from all its predefined strata. For better estimation, the stratified sample design should involve partitioning the population into groups with relatively homogeneous elements, whereas the cluster sample design should involve the forming of clusters with heterogeneous elements.

Despite its practical advantages, cluster sampling could still be costly due to the design requiring that the sample includes all the elements in large selected clusters. An improvement over cluster sampling is the multistage cluster sampling design. For instance, a combined NAEP national and state assessment draws a state sample by using two-stage cluster sampling. In selecting an NAEP state sample, the clusters in the sampling frame pertaining

to the first stage of sampling, called primary sampling units (PSUs), consist of all the public schools in the state; the elements in the selected clusters for the second stage, called secondary sampling units (SSUs), would then consist of the students within each PSU (Rust *et al.*, 2001). The first stage selects schools with probability proportionate to size (PPS) from the sampling frame. This method selects larger schools with a greater probability and smaller schools with a lower probability. The second stage randomly selects students within each sampled school. The total number of students selected within each sampled school is approximately equal. Although it is not an SRS, this design yields an EPSEM sample, which includes students in the sample with approximately equal probability. An example of a three-stage cluster sampling is the General Social Survey (GSS), which is based on the National Opinion Research Center's (NORC) 1990 National Sample (Tourangeau *et al.*, 1993).

Systematic Sampling

Systematic sampling, often applied in selecting samples in the EPSEM design, yields results that are equivalent to those derived from SRS. Moreover, systematic sampling can be used in implementing multistage cluster sampling designs, especially for those using the PPS method in the first or second stage selection process.

A systematic sampling with a random start involves three steps: (1) computing the sampling interval, say p , which equals the population size divided by the desired sample size; (2) randomly selecting an element from the sampling frame between 1 and p , denote this as k ; and (3) including all elements $k+p$, $k+2p$, ... in the sample. To illustrate, let population size N be 90 and sample size n be 6. The sampling interval is 15. Let the first randomly selected number be 8. Then the six elements included in the sample are {8, 23, 38, 53, 68, 83}. In case p is not an integer, p needs to be rounded to the nearest integer. The elements on the frame, instead of being lined up as a queue, needs to be arranged as a circle. Then, an element between 1 and N is randomly selected, and every p th element is selected thereafter until n elements have been selected.

The systematic sampling design is an EPSEM design; the method, in this sense, provides results equivalent to those from random sampling. However, if the elements on the frame have a cyclic pattern, the sampling interval must avoid periodicity in its sampling within the elements or risk having estimates with serious bias. In case of periodicity, one way to avoid it is to sort the elements in a different order.

For a multistage cluster sampling design that employs PPS sampling in its first stage of selection, such as the NAEP state assessment, systematic PPS sampling with a random start can be used to select PSUs. This method of

sampling gives each PSU a selection probability proportional to its size. From sampling frame, a cumulative record of counts is first created that tallies counts of units for all PSUs on the list. The sampling interval is calculated by dividing the total number of units in the file by the number of PSUs to be selected. Then a random start, a number within the range of sampling interval, is picked. The first PSU is selected when the random start hits the range of the PSUs in the cumulative record. Subsequent selection of PSUs is determined by the prior number plus the sampling interval. This process continues until the end of the cumulative record is reached.

A systematic sample can be more efficient and represent the population better if the units on the frame are sorted by certain demographic variables before selection. Sorting in this manner places similar PSUs next to each other on the frame and guarantees that the PSU sample will include a mix that is representative along the dimensions used to sort the list. For example, in the sample design of the General Social Survey (GSS), PSUs were sorted by region (Northeast, Midwest, South, and West), by state within region, by minority quartile within state, and by per capita income within minority quartile.

Sample Size

Sample size is mainly determined by the sample design, required accuracy of estimates, and resource constraints. For a particular design, sample size can be determined by the level of accuracy required, or confidence interval at a given confidence level desired (Cochran, 1977: 75–78). A pilot study can yield estimates of the parameters used in computation by providing useful information for determining sample design and sample size. An increase in sample size will reduce sampling error, although the relationship is not linear. On the other hand, a small sample is easier to manage and will introduce less nonsampling error. In statistical theory, it is sample size and not population size that determines the accuracy of estimates, unless the sample size is relatively large, say greater than 5% of the population. The resource constraints of a study enforce an upper limit on the sample size.

The HT Estimator

The Horvitz–Thompson estimator estimates the population total by its weighted sample total, which equals the sum of all the observed values times the corresponding case weights,

$$\hat{Y} = \sum_{i \in R} \frac{y_i}{\pi_i}$$

where $1/\pi_i$ is the case weight, y_i is the measured value of case i , and R is the set of sampled cases of size n .

This estimator is unbiased with respect to the total population (Horvitz and Thompson, 1952).

Sample weights are used to correct for unequal selection probabilities due to complex sample designs and to adjust for nonresponse or nonparticipation in surveys. Otherwise, the estimator based on observed cases in the sample will be biased. The base weight for a case equals the inverse of its probability of selection. When the target parameter is a mean or proportion, the HT estimator can be estimated by a ratio estimator, which equals the Horvitz–Thompson estimator of the population total divided by the sum of the weights.

The base weights are subject to adjustment for nonresponse, the causes of which could be noncontact or noncooperation. Both types of nonresponse could lead to bias in estimates. In the adjustment, each base weight is multiplied by a nonresponse factor, which equals the inverse of the response rate in each adjustment class (a class formed by the demographic variables of interest, such as gender and ethnicity (Kish, 1992)). So the weighted counts, the sum of weights in the adjustment classes, are equal to the sampled counts of units by design. This adjustment is based on the assumption that the responses missing within each adjustment class are random.

After a nonresponse adjustment, some variables, such as gender proportions, could show considerable differences between a weighted sample distribution and its corresponding population distribution. Poststratification and raking can be used to correct for these differences, to improve the precision of the survey estimates by reducing their mean squared error, and to enhance the comparability of the survey data under study with data from other surveys. Poststratification adjustment matches the weighted sample cell counts to the population cell counts by applying a proportional adjustment to the weights for certain groups (Kish, 1965). The population distributions are often obtainable from census data or other resources. A raking procedure, also called the Deming–Stephan algorithm, iteratively adjusts the case weights in the sample to make the weighted marginal distributions of the sample agree with the marginal distributions of the population on specified demographic variables (Deming and Stephan, 1940; Haberman, 1979).

Variance Estimation

In reporting survey results, one should always provide a summary of sampling error associated with particular results. Nonsampling errors are generally not provided due to the difficulty in measuring them solely from a sample. The sampling error for an estimate is often quantified by a standard error or a confidence interval that is associated with each of the results. The sampling error is mainly determined by three factors: sample size, sample

design, and the weighting effect. Although population size also plays a role, compared with sample size, its effect on sampling error is minor. The weighting effect is measured by the coefficient of variation of weights, which equals standard deviation of weights divided by the mean of the weights.

For SRS with replacement, many textbooks provide the formula for estimating the variance of a mean or proportion estimator. For more complex sampling designs, it is important to ensure that a method appropriate for the design be used for variance estimation; these estimates must reflect the features resulting from the complex design. Variance estimation often requires more complex replication methods, rather than the exclusive use of formulas. Even though a variance formula is available for a Horvitz–Thompson estimator for the cluster sampling design without replacement, there will always be information needed for computation that is missing or unknown (namely, joint probabilities of selection, weights, stratum, and PSU codes). Popular replication methods for a complex sampling design include bootstrap repeated replication, jackknife repeated replication (JRR), and balanced-repeated replication (BRR); the Taylor-series method can also be used in variance estimation, although it is based on linear approximation. In an application, the replicate samples are also subject to the adjustment for the impact of nonresponse, poststratification, and raking. When replication methods are used, the number of replicates should be large enough to enable stable variance estimation (e.g., >30) but small enough for efficient calculation.

The JRR approach, used in NAEP, provides a good example of how replication methods work in practice. Ordinarily, the JRR approach drops one case in each replicate, but in the analysis of data in large-scale assessments such as NAEP, the JRR approach often drops a group of k cases in each replicate (Shao and Wu, 1989). The delete- k JRR approach provides a balance between the number of replicates and the sizes of clusters. This flexibility enables testing programs to comply with diverse requirements from varied studies and variations in sample designs. The computation of the delete- k JRR approach mainly consists of two steps: calculating replicate estimates and estimating the jackknifed variance. The replicate estimates, also known as the pseudo-values of the estimate, are calculated from the replicate samples that are formed by dropping one group of k cases each time from the sample. Let \mathcal{J} be the number of replicates. Let \bar{y} be the mean estimate and $\bar{y}_{(j)}$ be the j th replicate estimate. Then, the jackknife variance of \bar{y} is estimated by $\mathcal{J} - 1$ times the sample variance of the replicate estimates as (Wolter, 2003)

$$\nu_{\mathcal{J}}(\bar{y}) = \frac{\mathcal{J} - 1}{\mathcal{J}} \sum_{j=1}^{\mathcal{J}} (\bar{y}_{(j)} - \bar{y})^2$$

The preferred way to derive appropriate variance estimates is to use a software package that uses statistical techniques such as the Taylor-series extension or the replicate methods mentioned above that do not assume SRS and independently distributed errors. The accessibility information of these packages, such as SUDAAN, WesVar, DAS, and Stata, can be found on the Web.

An estimator based on a complex design will often have a larger variance than the corresponding estimator of an SRS sample of the same size; the ratio of the variance from the complex design over variance from the SRS is defined as the design effect (Kish, 1965). Because of the clustering effect and the variation in weights, the design effect is usually larger than one.

In some situations, advanced models, such as multi-level models, can be used to produce variance estimates that take into account some aspects of complex survey design (Raudenbush *et al.*, 2003). Any design variables and weights, such as those associated with strata or measures of size, should also be taken into account during the modeling process.

An Application of Sampling Techniques in Computerized Adaptive Testing

The application of sampling techniques in item-selection procedures for computerized adaptive testing (CAT; Chang and Ying, 1999) is a recent development. One basic sample design, *a*-stratified multistage CAT with *b*-blocking, partitions the item pool according to the *a* parameters (item-discrimination parameters) of the three-parameter logistic model and requires *b* parameters (item-difficulty parameters) to be evenly distributed across all strata (Chang *et al.*, 2001). A multi-phase sampling approach is applied in item selection. The items with lower *a* parameters are designed to be selected in the early phases of a test, and items with higher *a* parameters are selected in later phases. The CAT sampling approach allows the implementation of different types of constraints on item selection, such as constraints used to balancing content, constraints on lowering item-exposure rate, and constraints that allow application of the shadow-test approach.

Sequential Probability Ratio Test

T J H M Eggen, Cito, Psychometric Research Center, Arnhem, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

The sequential probability ratio test (SPRT) was developed more than 60 years ago by Wald (1947) for quality-control problems. It is a statistical procedure in which a choice is made between two simple hypotheses and was initially used to determine whether majority of products (e.g., 80%) in a production process meet specifications or if this was true in fewer cases (e.g., 50%). The statistical properties of the SPRT have since been well established. Various extensions of the original testing procedure have been proposed in the literature and their statistical optimality properties have been studied extensively (see, e.g., Ghosh and Sen, 1991). In this article we will not go into detail regarding the statistical properties of the SPRT, but will focus on to some successful applications of it in educational testing.

In education, practitioners make use of test results for many different purposes, but from an educational measurement point of view, it generally suffices to distinguish between two main aims of testing: the precise estimation of a person's ability in a certain domain or the classification of a person in one of a limited number of proficiency classes. For the latter purpose, the SPRT has often been very successfully applied. In what is called sequential mastery testing (Lewis and Sheenan, 1990), Ferguson (1969) used a basic application of the SPRT to decide whether a student is a master or nonmaster in a certain domain. Since then, starting with Reckase (1983), many algorithms for computerized adaptive testing (CAT) have been developed (e.g., Eggen, 1999) using the SPRT methodology as their basis.

This article discusses the use of SPRT in CAT. After describing the SPRT and the basic elements of CAT, the way the SPRT is used in CAT will be treated. The situation considered is how, on the basis of a test, can be decided whether or not a certain criterion or standard is met. Lastly, this one cutting-point situation is extended to more than one, together with some other extensions.

The Sequential Probability Ratio Test

In sequential testing it is not only the observations X , that are random variables, but also the number of observations, K . Inspired by the Neyman and Pearson (1933) lemma, which provides a method of constructing a most powerful statistical test for deciding between two simple hypotheses, Wald (1947) proposed the SPRT. In his treatment of the problem, Wald considered random variables X with two

possible values: $x=1$ if a product meets the criteria and $x=0$ otherwise. Next, two statistical hypotheses are formulated: the null hypothesis, $H_0: p = p_0$, and the alternative $H_1: p = p_1$ in which p is the unknown proportion of all products meeting the criteria.

If we denote a series of k observations by $\underline{X}_k = (X_1, \dots, X_k)$ and the probability distribution of X_i with $P(X_i = x_i; p) = p^{x_i}(1-p)^{1-x_i}$, then the probability of these k observations is given by

$$P_{0k} = \prod_{i=1}^k p_0^{x_i} (1-p_0)^{1-x_i} \text{ if } H_0 \text{ is true}$$

and

$$P_{1k} = \prod_{i=1}^k p_1^{x_i} (1-p_1)^{1-x_i} \text{ if } H_1 \text{ is true}$$

The SPRT then chooses two constants A and B with $A < B$ and, after making every observation, computes the ratio of the probabilities P_{0k}/P_{1k} and the decision is made as follows:

1. if $P_{1k}/P_{0k} \geq A$, then reject H_0 ;
2. if $P_{1k}/P_{0k} \leq B$, then accept H_0 ; and
3. if $B < P_{1k}/P_{0k} < A$ (the critical inequality of the procedure) then take another observation.

Intuitively, the procedure is: if the outcomes have much larger probability under H_1 than under H_0 , that is, the likelihood ratio is large, then reject H_0 ; if the ratio is small, accept H_0 ; and if the ratio has values within the critical interval, no decision is taken and sampling is continued. The constants A and B are dependent on the size of the acceptable decision errors.

In practice, the log likelihood ratio is evaluated. This ratio is equal to the sum over i of the terms

$$Z_i = \ln \left[\frac{p_1^{x_i} (1-p_1)^{1-x_i}}{p_0^{x_i} (1-p_0)^{1-x_i}} \right] \quad [1]$$

If the acceptable decision errors are specified by

$$P(\text{reject } H_0 | H_0 \text{ is true}) \leq \alpha \text{ and } P(\text{accept } H_0 | H_1 \text{ is true}) \leq \beta \quad (\alpha, \beta \text{ small constants}), \quad [2]$$

then the SPRT procedure is

1. if $\ln B < \sum_{i=1}^k Z_i < \ln A$: take another observation
2. if $\sum_{i=1}^k Z_i \geq \ln A$: reject H_0 [3]

3. if $\sum_{i=1}^k Z_i \leq \ln B$: accept H_0 .

Wald (1947) has shown that the decision error rates are met if

$$A = \frac{1 - \beta}{\alpha} \text{ and } B = \frac{\beta}{1 - \alpha} \quad [4]$$

Furthermore, this SPRT procedure will then stop, with probability 1, with a decision in a finite number of observations.

The SPRT was initially developed for situations in which there is a random sample of a variable with a discrete or continuous distribution with one parameter variable and two simple hypotheses on the value of that parameter. But the theory is generalized in various directions. For our purposes two more general situations are important:

1. Although the SPRT stops with a finite number of observations with probability 1, in educational measurement, it is absolutely necessary to define a maximum test length k_{\max} . The procedure is then called the truncated SPRT (TSPRT).
2. The observations are not random draws from the same distribution, but are independent variables from not necessarily the same distribution.

In the first application by Ferguson (1969), a maximum length was already specified, but the answers on the items were assumed to come from the same binomial distribution, which implies that all items have the same difficulty. In the CAT application, described next, this is not the case.

Computerized Adaptive Testing

In computerized adaptive tests, the construction and administration of the test is computerized and individualized. A different test is constructed for every testee by selecting items from an item bank tailored to the ability of the testee as demonstrated by the responses given thus far. Computerized adaptive tests assume the availability of an item bank, which is calibrated with an item response model. Confining ourselves to item banks with items which are dichotomously scored, logistic item response models are commonly used. In item response theory (IRT), a relation is specified between the non-observable ability θ that is to be estimated and the probability of correctly answering item i . The exact relationship is determined by the parameters of the items. A commonly used IRT model is the two-parameter logistic model (2PL):

$$p_i(\theta) = P(X_i = 1 | \theta) = \frac{\exp(a_i(\theta - b_i))}{1 + \exp(a_i(\theta - b_i))} \quad [5]$$

in which b_i is the location or difficulty parameter and a_i the discrimination parameter.

In computerized adaptive tests the parameters of the IRT model are always assumed to be estimated with such precision that they can be considered to be known. In a computerized adaptive test, the likelihood function of a student's ability, θ , plays a central role in the inference on the student. Given the scores on k items $x_i, i = 1, \dots, k$, this function is given by

$$L(\theta, \underline{x}_k) = L(\theta; x_1, \dots, x_k) = \prod_{i=1}^k p_i(\theta)^{x_i} (1 - p_i(\theta))^{1-x_i} \quad [6]$$

which states the probability of getting the observed scores on the items as a function of θ .

In computerized adaptive tests where the main aim is the efficient estimation of the ability θ of an examinee, this likelihood function [6] is the basis for estimating the ability of an examinee as well as for the selection of items. The maximum likelihood (ML) estimate of the ability after administering k items follows from the maximization [6] with respect to θ . Because of less bias, the weighted maximum likelihood (WML) method proposed by Warm (1989) is a good alternative for ML. WML follows, in the case of the 2PL model [5], from

$$\hat{\theta} = \max_{\theta} \left[\left(\sum_{i=1}^k I_i(\theta) \right)^{1/2} L(\theta; \underline{x}_k) \right] \quad [7]$$

where $I_i(\theta)$ is the Fisher information function of item i , which is defined as the (statistical) expectation of the squared relative change of the likelihood function

$$I_i(\theta) = E \left(\frac{\partial L(\theta; x_i) / \partial \theta}{L(\theta; x_i)} \right)^2$$

which, in the 2PL model is given by

$$I_i(\theta) = a_i^2 p_i(\theta) (1 - p_i(\theta)) = \frac{a_i^2 \exp(a_i(\theta - b_i))}{(1 + \exp(a_i(\theta - b_i)))^2}$$

This information function is commonly used for item selection in computerized adaptive tests : an item is selected if it gives maximum information at the current ability estimate. This method ensures that each examinee is administered items which fit his ability and, consequently, his ability is estimated efficiently.

The SPRT in CAT

When classification in one of two categories is the purpose of testing in CAT, SPRT can be applied as follows. On the latent ability scale, a decision or cutting point θ_0 is given which distinguishes between, for example, a master and nonmaster, or between an examinee who passes and an examinee who fails an exam. A small region on both sides of this point, a so-called indifference zone, is selected. The widths of these regions are δ_1 and δ_2 .

The indifference interval expresses the fact that, owing to measurement errors, making the right decision about examinees very near the cutting point can never be guaranteed. One could also say that the interval expresses the indifference of an examiner to the classification of the examinees who are very near to the cutting point. Next, the statistical hypotheses are formulated:

$$H_0: \theta \leq \theta_0 - \delta_1 = \theta_1 \text{ against } H_1: \theta \geq \theta_0 + \delta_2 = \theta_2 \quad [8]$$

If the acceptable decision error rates are specified as in [2], the test meeting these decision error rates uses as the test statistic, as mentioned above, the ratio of the likelihood function under H_1 and H_0 :

$$LR_k(\theta_2; \theta_1) = \frac{L(\theta_2; x_1, \dots, x_k)}{L(\theta_1; x_1, \dots, x_k)} \quad [9]$$

and involves the following procedure:

If Decision

$\beta/(1 - \alpha) < LR_k(\theta_2; \theta_1) < (1 - \beta)/\alpha$ administer another item

$LR_k(\theta_2; \theta_1) \leq \beta/(1 - \alpha)$ accept H_0

$LR_k(\theta_2; \theta_1) \geq (1 - \beta)/\alpha$ reject H_0 [10]

It can easily be shown (Eggen and Straetmans, 2000) that if the 2-PL model [5] is used, the critical inequality of this test can be written as

$$\frac{\ln\left(\frac{\beta}{(1-\alpha)}\right) - C}{\theta_2 - \theta_1} < \sum_{i=1}^k a_i x_i < \frac{\ln\left(\frac{(1-\beta)}{\alpha}\right) - C}{\theta_2 - \theta_1} \quad [11]$$

In this

$$\begin{aligned} C &= \sum_{i=1}^k \ln\left(\frac{1 + \exp(a_i(\theta_1 - \beta_i))}{1 + \exp(a_i(\theta_2 - \beta_i))}\right) \\ &= \sum_{i=1}^k \ln\left(\frac{1 - p_i(\theta_2)}{1 - p_i(\theta_1)}\right) \end{aligned} \quad [12]$$

which depends only on the parameters of the items on θ_1 , θ_2 , which are all known constants in the procedure. This makes clear that the application of the SPRT is easy because the observed weighted score is compared to known constants.

Example

The following example of a simulation study with an operational item bank (Eggen, 1999) illustrates the performance

of the SPRT in CAT. This item bank contains 250 mathematics items which are used in adult education. Most of the items have an open-ended short answer format, but all the items are scored dichotomously. The items were shown to fit the one-dimensional 2-PL model. The scale was fixed by restrictions on the item parameters. The mean item difficulty is 0, and the geometric mean of the discrimination parameters is 3.09. On this scale, the distribution of the ability in the population was estimated to be normal with a mean of 0.294 and a standard deviation of 0.522.

The simulations were conducted as follows. An ability of a simulee was randomly drawn from $N(0.294; 0.522)$. Three relatively easy starting items were selected and subsequent items were selected with the criterion of maximum Fisher information at the current ability estimate. The simulee's response to an item was generated according to the IRT model and this procedure was repeated for $N = 5000$ simulees.

For varying acceptable decision error rates and widths of the indifference zone (δ is respectively 0.2, 0.3, and 0.4 times the standard deviation of θ), the performance of the procedure was evaluated with the mean number of items required to make a decision \bar{k} and the classification accuracy expressed in the percentages of correct decisions (%cor).

The cutting point on the ability scale in the simulations was $\theta_0 = 0.1$, and the maximum test length was $K_{\max} = 25$. The SPRT adaptive testing procedures were conducted for three different error rates and three different widths of the indifference zone.

As a benchmark, the SPRT procedure was compared to a CAT procedure based on statistical estimation. The procedure proposed by Weiss and Kingsbury (1984), but using the Warm estimate of the ability [7], was conducted. After each item is administered, an estimate is made of the examinee's ability $\hat{\theta}_k$ and of its standard error $se(\hat{\theta}_k)$. Next, a confidence interval $(\hat{\theta}_k - \gamma \cdot se(\hat{\theta}_k), \hat{\theta}_k + \gamma \cdot se(\hat{\theta}_k))$ for the examinee's true ability is constructed, in which γ is a constant that is determined by the required accuracy. The procedure delivers another item as long as the cutting point $\theta_0 = 0.1$ is within the interval. If not, the appropriate decision is made. In the comparison, the value for γ was chosen such that about the same accuracy is reached as with the acceptable decision errors in the SPRTs. The results are given in **Table 1**.

Table 1 Mean number of required items (\bar{k}) of percentage of correct decisions (%cor) in a problem with one cutting point $\theta_0 = 0.1$

	SPRT						Estimation	
	$\delta = 0.11$		$\delta = 0.16$		$\delta = 0.21$		\bar{k}	%cor
Error rate	\bar{k}	%cor	\bar{k}	%cor	\bar{k}	%cor	\bar{k}	%cor
$\alpha = \beta = 0.05$	23.24	95.76	15.37	95.16	11.37	95.20	15.41	94.58
$\alpha = \beta = 0.075$	20.35	95.32	13.54	95.02	9.89	94.70	13.40	94.56
$\alpha = \beta = 0.1$	18.72	95.60	12.51	94.90	9.10	93.94	12.97	94.46

The results show that applying the SPRT instead of a traditional estimation procedure possibly improves the performance of the CAT. A striking result is that the chosen acceptable decision error rates and also the chosen width of the indifference zone hardly influence the percentages of correct decisions, but have a major influence on the average number of items needed for taking this decision. It is clear that the number of items needed is larger with lower allowed error rates and with wider indifference zones. The small differences in the percentage correct decisions are always in the expected direction.

Some Extensions of the Application of SPRT

The SPRT procedure described above can also be applied to other IRT models and used for polytomously scored items (Lau and Wang, 1998). Next, three other extensions of the SPRT application will be addressed.

The SPRT in a Three-Category Classification Problem

The Cat application of the SPRT is readily generalized to the case in which there are more than two decision categories. Following Eggen (1999), the generalization to three categories will be described. In this case, there are two cutting points, θ_1 and θ_2 , by which three levels of ability are distinguished. An indifference zone is identified around each cutting point. This is sketched schematically in **Figure 1**.

Two pairs of hypotheses are formulated:

$H0_1: \theta \leq \theta_1 - \delta_{11} = \theta_{11}$ against $H1_1: \theta \geq \theta_1 + \delta_{12} = \theta_{12}$
 $H0_2: \theta \leq \theta_2 - \delta_{21} - \delta_{22}$ against $H1_2: \theta \geq \theta_2 + \delta_{22} = \theta_{22}$

The SPRT described in [10] is applied for each pair of hypotheses. The specifications of the acceptable decision errors are α_1, β_1 and α_2, β_2 , as defined in [2]. Next, the two SPRTs are combined in one procedure. The decisions to assign a person to a certain category are given in **Table 2**.

This combination procedure of the SPRTs originates from Sobel and Wald (1949). It can be shown that, by using the 2-PL IRT model [5] or any other model

belonging to the exponential family, the simultaneous acceptance of the null hypothesis $H0_1$, and the rejection of $H0_2$ cannot occur. It is noted that Spray (1993) proposed extensions of the use of the SPRT for classification in three and more categories. Her generalization is based on the combination procedure developed by Armitage (1950) which uses the simultaneous application of three SPRTs for classification into three categories instead of only the two needed in the Sobel and Wald (1949) combination procedure proposed here. It is beyond the scope of this article to discuss in detail the properties of these two combination procedures of SPRTs.

In the practical applications, the combined procedure operates as follows:

if
 Decision

$$\text{Level 1} \quad \sum_{i=1}^k a_i x_i < \frac{\ln\left(\frac{\beta_1}{(1-\alpha_1)}\right) - C}{\theta_{12} - \theta_{11}}$$

$$\text{Level 2} \quad \frac{\ln\left(\frac{\beta_2}{(1-\alpha_2)}\right) - C}{\theta_{22} - \theta_{21}} < \sum_{i=1}^k a_i x_i < \frac{\ln\left(\frac{(1-\beta_1)}{\alpha_1}\right) - C}{\theta_{12} - \theta_{21}}$$

$$\text{Level 3} \quad \sum_{i=1}^k a_i x_i < \frac{\ln\left(\frac{(1-\beta_2)}{\alpha_2}\right) - C}{\theta_{22} - \theta_{21}}$$

In all other cases Continue testing

In this procedure C is as in [12] with the appropriate corresponding constants filled in. From this it can be easily seen that if the width of the indifference intervals, for example, $\theta_{22} - \theta_{21} = \delta_{12} + \delta_{22}$, increases, a shorter test can probably be used to take a decision.

Stochastic Curtailment of the TSPRT

Finkelman (2004, 2008) recently introduced the application of stochastic curtailment to enhance the performance of the TSPRT in educational testing. The idea of this method is to stop testing sooner without losing accuracy. The method of curtailment determines whether further

Figure 1 Schematic representation of the classification problem with three categories.

Table 2 Decisions based on combination of two SPRTs

	<i>Decision on test 1 $H0_1: \theta \leq \theta_{11}$ against $H1_1: \theta \geq \theta_{12}$</i>	
<i>Decision on test 2 $H0_2: \theta \leq \theta_{21}$ against $H1_2:$ $\theta \geq \theta_{22}$</i>	Accept $H0_1$	Reject $H0_1$
Accept $H0_2$	Category 1	Category 2
Reject $H0_2$		Category 3

testing will possibly change a classification decision which would be taken if testing were stopped directly. Stochastic curtailment (Lan *et al.*, 1982) also extends the observation to the case in which a change in decision is possible but unlikely. In an example, Finkelman (2004) showed that in the case of one cutting point, a reduction of 20% in the number of items needed, while keeping the same accuracy, can be reached by applying stochastic curtailment.

Conclusion

The SPRT has been shown to be a very useful statistical procedure. In this article the applications in the context of educational testing were explored. If classification in a limited number of categories is the main goal of computerized adaptive testing, the (combination of more) SPRT gives very efficient algorithms.

Introduction

In a sequential mastery test (SMT), the decision of interest is to classify a student as a master or a nonmaster, or to continue testing and administering another random item. The main advantage of SMT is that it provides shorter tests for students who have clearly attained a certain level of mastery (or, clearly, nonmastery) and longer tests for those students for whom the mastery decision is not as clear cut. One of the earliest approaches to SMT dates back to Ferguson (1969) using Wald's well-known sequential probability ratio test (SPRT), originally developed as a statistical quality control for light-bulbs in manufacturing setting. In Ferguson's (1969) approach, the probability of a correct response, given the student's (latent) ability is modeled as a binomial distribution. Modeling response behavior by this distribution function assumes that – given the student's ability – each item has the same probability of being correctly answered, or that items are sampled at random. It should be noted that this assumption is not realistic, because items are, in fact, mostly of different difficulty, implying that the same probability of a correct answer is not realistic as well. Reckase (1983) has proposed an alternative approach to SMT within an SPRT framework. Unlike Ferguson (1969), Reckase (1983) did not assume that items have equal characteristics but allowed them to vary in difficulty and discrimination by using an item response theory (IRT) model instead of a binomial model.

As indicated by Ferguson (1969), three elements must be specified in advance in applying the SPRT framework to sequential mastery testing. First, two values p_0 and p_1 on the proportion-correct metric must be specified, representing points that correspond to lower and upper limits of levels of ability at which a mastery and nonmastery decision will be made, respectively. In addition, these two values mark the boundaries of the small region (i.e., indifference region) where we can never be sure to take the right classification decision, and, thus, in which sampling of another item will continue. Second, two nominal error probabilities α and β must be specified – reflecting the relative costs of the false positive (i.e., type I) and false negative (i.e., type II) error types. Wald (1947) showed that the actual error rates observed in practice, α^* and β^* , are bounded from above by functions of the nominal rates; that is, $\alpha^* \leq \alpha/(1-\beta)$ and $\beta^* \leq \beta/(1-\alpha)$. Intervals can be derived as functions of these two error rates for which mastery or nonmastery is declared, respectively, and for

which testing is continued (Wald, 1947) – that is, mastery is declared if the likelihood ratio $L(\text{response pattern} | p_1)/L(\text{response pattern} | p_0)$ is larger than $(1-\beta)/\alpha$, nonmastery if this likelihood ratio is smaller than $\beta/(1-\alpha)$; otherwise sampling is continued. Third, a maximum test length must be specified in order to classify, within a reasonable period of time, those students for whom the decision of declaring mastery or nonmastery is not as clear cut. It should be emphasized, however, that the SPRT framework might also be applied to SMT if no maximum test length is specified.

A major drawback of the SPRT framework is that it does not take costs of testing explicitly into account. The purpose of this article, therefore, is to derive optimal rules for the SMT that takes costs of testing explicitly into account. Decision rules are hereby prescribed for each possible observed response pattern, that is, what action (i.e., declaring mastery/nonmastery or continuing testing and administering another random item) has to be taken. The framework of Bayesian sequential decision theory will be used (e.g., DeGroot, 1970; Lehmann, 1959).

Bayesian Sequential Principle Applied to SMT

This section indicates how the framework of Bayesian sequential decision theory – in combination with the binomial distribution for modeling response behavior (i.e., the measurement model) and adopting threshold loss for the loss function involved – is applied to SMT.

Framework of Bayesian Sequential Decision Theory

Three basic elements can be identified in Bayesian sequential decision theory. In addition to a measurement model and a loss function, costs of administering one additional item must be explicitly specified in this approach. By doing so, posterior expected losses corresponding to the mastery and nonmastery decisions can now be calculated directly at each stage of testing. As far as the posterior expected loss corresponding to continuous testing is concerned, this quantity is determined by weighting the posterior expected losses corresponding to each of the possible future classification outcomes with the probability of observing those outcomes (i.e., the posterior predictive distributions).

Optimal rules (i.e., Bayesian sequential rules) are then obtained by minimizing the posterior expected losses associated with all possible decision rules at each stage of testing, using techniques of backward induction (i.e., dynamic programming). This technique starts by considering the final stage of testing (where the option to continue testing is not available) and then works backward to the first stage of testing.

Notation

Within the framework of Bayesian sequential decision theory, optimal rules can be obtained without specifying a maximum number of items to be administered. In order to classify, within a reasonable period of time, those students for whom the decision of declaring mastery or nonmastery is not as clear cut, however, an SMT is supposed to have a maximum length of n ($n \geq 1$). Let the observed item response at each stage of testing k ($1 \leq k \leq n$) for a randomly sampled student be denoted by a discrete random variable X_k with realization x_k . The observed response variables X_1, \dots, X_k are assumed to be independent and identically distributed. Further, let the values 0 and 1, respectively, denote the incorrect and correct responses to an item. Furthermore, let the observed number-correct score following the k items that have been administered be denoted by a discrete random variable $S_k = X_1 + \dots + X_k$ with realization $s_k = x_1 + \dots + x_k$ ($0 \leq s_k \leq k$).

The student's true level of functioning is unknown due to measurement and sampling error. All that is known is his/her observed number-correct score s_k . In other words, the mastery test is not a perfect indicator of the student's true performance. Therefore, let the student's (unknown) true level of functioning be denoted by a continuous random variable T on the latent proportion-correct metric, with realization t ($0 \leq t \leq 1$).

Finally, a criterion level t_c ($0 \leq t_c \leq 1$) on T must be specified in advance by the decision-maker using methods of standard-setting. A student is considered a true non-master and true master if his/her true level of functioning t is smaller or larger than t_c , respectively.

Threshold Loss and Costs of Testing

Generally speaking – as noted before – a loss function evaluates the total costs and benefits of all possible decision outcomes for a student whose true level of functioning is t . These costs may concern all relevant psychological, social, and economic consequences (e.g., remedial instruction) which the decision brings along. The Bayesian sequential approach allows the decision-maker to incorporate, into the decision process, the costs of misclassification. In this case, the well-known threshold

Table 1 Table for threshold loss function at stage k ($1 \leq k \leq n$) of testing

True level of functioning	Decision	$T \leq t_c$	$T > t_c$
Declaring nonmastery		ke	$l_{01} + ke$
Declaring mastery		$l_{10} + ke$	ke

loss function is adopted as the loss structure involved. The choice of this loss function implies that the total costs and benefits of all possible consequences of the decisions can be summarized by possibly different constants – one for each of the possible classification outcomes.

An obvious disadvantage of the threshold loss function is that, as can be seen from **Table 1**, it assumes the same constant loss for students to the left or to the right of the criterion level t_c – no matter how large their distance from t_c . For instance, a student who is declared a non-master with a true level of functioning just above t_c gives the same loss as a misclassified true nonmaster with true level of functioning far above t_c . It seems more realistic to suppose that for the misclassified true nonmasters the loss is a strictly increasing function of t . Moreover, the threshold loss is discontinuous; at point $T = t_c$ this function jumps from one constant value to another. This sudden change seems unrealistic in many decision-making situations. In the neighborhood of this point, the losses for correct and incorrect classification decisions should change smoothly rather than abruptly. To overcome these shortcomings, van der Linden and Mellenbergh (1977) proposed a continuous loss function which is a linear function of the true level of functioning t . Although a linear loss function is probably more appropriate for the sequential mastery problem, following Lewis and Sheehan (1990), in the present article, a threshold loss function is adopted for reasons of simplicity and computational efficiency. Another reason for using threshold rather than linear loss is that a linear loss function may be more appropriate in the neighborhood of t_c , indeed, but that the further away from t_c , however, the losses can be assumed to take, more and more, the same constant values again for the possible classification outcomes.

For the sequential mastery problem – following Lewis and Sheehan (1990) – a threshold loss function can be formulated as a natural extension of the one for the fixed-length mastery problem at each stage of testing k as follows:

The value e represents the costs of administering one random item. For the sake of simplicity, these costs are assumed to be equal for each classification outcome as well as for each testing occasion. It has been shown in the literature (e.g., Luce and Raiffa, 1957) that positive linear transformations are allowed to loss functions, that is, multiplying with a positive constant and adding a constant to the loss function are so-called admissible transformations. Applying such an admissible positive linear transformation,

and assuming the losses l_{00} and l_{11} associated with the correct classification outcomes are equal and take the smallest values, the threshold loss function in **Table 1** was rescaled in such a way that l_{00} and l_{11} were equal to zero. Hence, the losses l_{01} and l_{10} must take positive values.

The ratio l_{10}/l_{01} is denoted as the loss ratio R , and refers to the relative losses for declaring mastery to a student whose true level of functioning is below t_c (i.e., false positive) and declaring nonmastery to a student whose true level of functioning exceeds t_c (i.e., false negative).

The loss parameters l_{ij} ($i, j = 0, 1$; $i \neq j$) associated with the incorrect decisions have to be empirically assessed; several methods have been proposed for this in the literature. Most texts on decision theory, however, propose lottery methods (e.g., Luce and Raiffa, 1957) for assessing loss functions empirically. In general, the consequences of each pair of actions and true level of functioning are scaled in these methods by looking at the most and least preferred outcomes. However, in principle, any psychological scaling method can be used.

Measurement Model

Following Ferguson (1969), in the present article the well-known binomial model will be adopted for the probability that, after k items have been administered, s_k of them have been answered correctly. Its distribution at stage k of testing for a given student's true level of functioning t , $P(s_k | t)$, can be written as follows:

$$P(s_k | t) = \binom{k}{s_k} t^{s_k} (1 - t)^{k-s_k} \quad [1]$$

If each response is independent of the other, and if the student's probability of a correct answer remains constant, the distribution function of s_k – given true level of functioning t – is given by [1]. The binomial model assumes that the test given to each student is a random sample of items drawn from a large (real or imaginary) item pool (e.g., Wilcox, 1981). Therefore, for each student, a new random sample of items must be drawn in practical applications of the sequential mastery problem.

Optimizing Rules for the Sequential Mastery Problem

This section shows how optimal rules for SMT can be derived using the framework of Bayesian sequential decision theory. By doing so – given an observed item response vector (x_1, \dots, x_k) – first, the Bayesian principle will be applied to the fixed-length mastery problem by determining which of the posterior expected losses associated with the two classification decisions is the smallest. Next – applying the Bayesian principle again – optimal rules for the sequential mastery problem are derived at

each stage of testing k by comparing this quantity with the posterior expected loss associated with the option to continue testing.

Applying the Bayesian Principle to the Fixed-Length Mastery Problem

As noted above, the Bayesian decision rule for the fixed-length mastery problem can be found by minimizing the posterior expected losses associated with the two classification decisions of declaring mastery or nonmastery. In doing so, the posterior expected loss is taken with respect to the posterior distribution of T . It can easily be verified from **Table 1** and [1] that mastery is declared when the posterior expected loss corresponding to declaring mastery is smaller than the posterior expected loss corresponding to declaring nonmastery, or, equivalently, when s_k is such that

$$(l_{10} + ke)P(T \leq t_c | s_k) + (ke)P(T > t_c | s_k) < (ke)P(T \leq t_c | s_k) + (l_{01} + ke)P(T > t_c | s_k) \quad [2]$$

and that nonmastery is declared otherwise. Rearranging terms, it can easily be verified from [2] that mastery is declared when s_k is such that

$$P(T \leq t_c | s_k) < 1/(1 + R) \quad [3]$$

and that nonmastery is declared otherwise.

$P(T \leq t_c | s_k)$ denotes the probability of the student's true level of functioning being equal to or below the criterion level t_c – given his/her number-correct score s_k . In fact, this probability is one minus the cumulative posterior distribution of T (i.e., the decumulative posterior distribution of T). Assuming a beta prior for T , it follows from an application of Bayes' theorem that, under the assumed binomial model from [1], the posterior distribution of T will be a member of the beta family again (the conjugacy property, see, e.g., Lehmann, 1959). In fact, if the beta function $B(\alpha, \beta)$ with parameters α and β ($\alpha, \beta > 0$) is chosen as prior distribution (i.e., the natural conjugate of the binomial distribution) and the student's observed number-correct score is s_k from a test of length k , then the posterior distribution of T is $B(\alpha + s_k, k - s_k + \beta)$. Hence, assuming a beta prior for T , it follows from [3] that mastery is declared when s_k is such that

$$P[B(\alpha + s_k, k - s_k + \beta)] < 1/(1 + R) \quad [4]$$

and that nonmastery is declared otherwise.

The assumption, in this article, is that uniform distribution on the standard interval $[0, 1]$ is a noninformative prior, which results as a special case of the beta distribution $B(\alpha, \beta)$ for $\alpha = \beta = 1$. In other words, prior true level of functioning can take on all values between 0 and 1 with equal probability. It then follows immediately from [4] that mastery is declared when s_k is such that

$$P[B(1 + s_k, k - s_k + 1)] < 1/(1 + R) \quad [5]$$

and that nonmastery is declared otherwise. The beta distribution has been extensively tabulated (e.g., Pearson, 1930). Normal approximations are also available (Johnson and Kotz, 1970). In general, if t has a beta distribution with parameters (α, β) , then this distribution can be approximated by a normal distribution with mean $\alpha/(\alpha+\beta)$ and variance $\alpha\beta/[(\alpha+\beta)^2(\alpha+\beta+1)]$.

Derivation of Bayesian Sequential Rules

Let $d_k(x_1, \dots, x_k)$ denote the decision rule yielding the minimum of the posterior expected losses associated with the two classification decisions at stage k of testing, and let the posterior expected loss corresponding to this minimum be denoted as $V_k(x_1, \dots, x_k)$. Bayesian sequential rules can now be found by using the following backward-induction computational scheme: First, the Bayesian sequential rule at the final stage n of testing is computed. Since the option to continue testing is not available at this stage of testing, it follows immediately that the Bayesian sequential rule is given by $d_n(x_1, \dots, x_n)$, and its corresponding posterior expected loss by $V_n(x_1, \dots, x_n)$.

To compute the posterior expected loss associated with the option to continue testing at stage $(n-1)$ until stage 0, the risk $R_k(x_1, \dots, x_k)$ will be introduced at each stage k ($1 \leq k \leq n$) of testing. Let the risk at stage n be defined as $V_n(x_1, \dots, x_n)$. Generally, given response pattern (x_1, \dots, x_k) , the risk at stage $(k-1)$ is then computed inductively as a function of the risk at stage k as:

$$R_{k-1}(x_1, \dots, x_{k-1}) = \min V_{k-1}(x_1, \dots, x_{k-1}), \quad E[R_k(x_1, \dots, x_{k-1}, X_k | x_1, \dots, x_{k-1})] \quad [6]$$

The posterior expected loss corresponding to administering one more random item following $(k-1)$ items have been administered, $E[R_k(x_1, \dots, x_{k-1}, X_k) | x_1, \dots, x_{k-1}]$, can then be computed as the expected risk at stage k of testing as

$$E[R_k(x_1, \dots, x_{k-1}, X_k | x_1, \dots, x_{k-1})] = \sum_{X_k=0}^{X_k=1} R_k(x_1, \dots, x_k) P(X_k = x_k | x_1, \dots, x_{k-1}) \quad [7]$$

where $P(X_k = x_k | x_1, \dots, x_{k-1})$ denotes the posterior predictive distribution of X_k at stage $(k-1)$ of testing. Computation of this conditional distribution is deferred until the next section. Note that [7] averages the posterior expected losses associated with each of the possible future classification outcomes with weights corresponding to the probabilities of observing those outcomes.

The Bayesian sequential rule at stage $(k-1)$ is now given by: Administer one more random item if $E[R_k(x_1, \dots, x_{k-1}, X_k) | x_1, \dots, x_{k-1}]$ is smaller than $V_{k-1}(x_1, \dots, x_{k-1})$; otherwise, decision $d_{k-1}(x_1, \dots, x_{k-1})$

is taken. The Bayesian sequential rule at stage 0 denotes the decision whether or not to administer at least one random item.

Computation of Posterior Predictive Distributions

As is clear from [7] the posterior predictive distribution $P(X_k = x_k | x_1, \dots, x_{k-1})$ is needed for computing the posterior expected loss corresponding to administering one more random item at stage $(k-1)$ of testing. Assuming the binomial distribution as measurement model and the uniform distribution $B(1,1)$ as prior, it was shown (e.g., Lehmann, 1959) that $P(X_k = 1 | x_1, \dots, x_{k-1}) = (1 + s_{k-1})/(k+1)$, and, thus, that $P(X_k = 0 | x_1, \dots, x_{k-1}) = [1 - (1 + s_{k-1})/(k+1)] = (k - s_{k-1})/(k+1)$.

Determination of Appropriate Action for Different Number-Correct Scores

Using the general backward-induction scheme discussed earlier, for a given maximum number n ($n \geq 1$) of items to be administered, a computer program was developed to determine the appropriate action (i.e., nonmastery, continuation, or mastery) at each stage k of testing for different number-correct score s_k .

As an example, the appropriate action is depicted in **Table 2** as a closed interval for a maximum of 20 items (i.e., $n = 20$). Students were considered true masters if they knew at least 60% of the subject matter. Therefore, t_e was fixed at 0.60. Furthermore – on a scale in which one unit corresponded to the constant costs of administering one random item (i.e., $e = 1$) – the loss parameters l_{01} and l_{10} were both assumed to be equal to 100 (i.e., $R = 1$). These numerical values reflected the assumption that the losses corresponding to taking incorrect classification decisions were rather large relative to the costs of administering one random item.

As can be seen from **Table 2**, at least four random items need to be administered before mastery can be declared. However, in principle, nonmastery can be declared after administering only two random items. Of course, in practice, it can be decided to start making classification decisions only after a certain number of random items have been administered to the student.

Simulation of Different Mastery Testing Strategies

In a Monte Carlo simulation, the Bayesian sequential strategy is compared with other existing approaches to

Table 2 Appropriate action calculated by stage of testing and raw score

Stage of testing	Appropriate action by raw score		
	Nonmastery	Continuation	Mastery

mastery testing in terms of average test length (i.e., the number of items that must be administered before a mastery/nonmastery decision is made), classification accuracy, and average loss.

Description of the Testing Strategies Used for Comparison

The first comparison is made with a conventional fixed-length mastery test (CT) in which student performance was recorded as the proportion of correct answers. The student was declared a master for answering 60% or more items correctly after completion of the test, whereas nonmastery was declared otherwise.

The second comparison is made with Wald's SPRT procedure. The limits of the indifference region in which testing will continue were set symmetrically around 0.6 (i.e., the fixed value of t_c) with a bandwidth of 0.1. Hence, the proportion-correct values p_0 and p_1 were set at 0.5 and 0.7, respectively. Furthermore, the error rates α and β were each set equal to 0.1. These values reflected the fact that the losses associated with the false positive decision (i.e., l_{10}) and false negative decision (i.e., l_{01}) in the Bayesian sequential strategy were assumed to be both equal to 100.

According to the SPRT procedure, after k items have been administered with s_k of them being answered correctly, mastery was now declared if the likelihood ratio

$L(x_1, \dots, x_k | p_1) / L(x_1, \dots, x_k | p_0) = [(0.7)^{s_k} (0.3)^{k-s_k} / (0.5)^{s_k} (0.5)^{k-s_k}]$ was larger than $(1-\beta)/\alpha = (1-0.1)/0.1 = 9$, nonmastery if this likelihood ratio was smaller than $\beta/(1-\alpha) = 0.1/(1-0.1) = 0.11$, and otherwise sampling was continued. For those students who could not be classified as either a master or nonmaster before the item pool was exhausted, a classification decision was made in the same way as in the CT procedure, using a mastery proportion-correct value of 0.6.

Type of Test and Item Response Generation

The simulation study was conducted using a set of items that were perfect replications of each other. More specifically, it was assumed that each item could be described by a one-parameter logistic model (Rasch, 1960) with discrimination parameter a of 1 and equal difficulty parameter b of 0. This item pool reflected the choice of the binomial distribution for modeling response behavior in the Bayesian sequential procedure. Maximum test length (MTL) varied from ten to 50 items.

Item responses for 1000 simulated students – drawn from a $N(0,1)$ distribution – were generated for each item in the pool. For known ability of the simulated student and given item difficulty, first the probability of a correct answer was calculated using the one-parameter logistic model. Next, this probability was compared with a random number drawn from the uniform distribution in the range from 0 to 1. The item administered to the simulated student was scored correct or incorrect if this random number was either less or greater than the probability of a correct answer, respectively.

Furthermore, a simulated student was supposed to be a true master if his/her ability used to generate the item responses was higher than a prespecified cut-off point on the $N(0,1)$ -ability metric. Since a value of 0.6 on the proportion-correct metric corresponded following conversion with a value of 0 on the $N(0,1)$ -ability metric, the cut-off point on the $N(0,1)$ -ability metric was set equal to 0.

Results of the Simulation Study

Table 3 indicates that the Bayesian sequential strategy yielded shorter average test lengths than the other two strategies at each MTL level, whereas the phi correlations between true and estimated mastery status (i.e., classification accuracy) were generally somewhat lower at each MTL level. To examine which strategy is most efficient, therefore, we computed – for the other two strategies – the average test length at each MTL level for achieving the same phi correlation as under the Bayesian sequential strategy. In addition, as demonstrated by **Table 3**, it turned out that the Bayesian sequential strategy was

Table 3 Average number of items to be administered and classification accuracy

Strategy	Maximum test length			Maximum test length		
	10	25	50	10	25	50
	Average number of items			Classification accuracy		
CT	10	25	50	0.652	0.787	0.718
SPRT	8.64	14.47	17.42	0.584	0.723	0.718
BAYES	5.84	9.46	11.15	0.610	0.620	0.692

most efficient (i.e., combination of highest phi correlation and shortest average test length) at each MTL level.

Conclusions and Discussion

This article describes the deriving of optimal rules for the sequential mastery problem (non-mastery, mastery, or to continue testing), in the context of education, using the framework of Bayesian sequential decision theory. It should be emphasized, however, that the Bayesian sequential principle is especially appropriate when costs of testing can be assumed to be quite large. For instance, when testlets (i.e., blocks of parallel items) rather than single items are considered. In addition, the proposed strategy might be appropriate in the context of sequential testing problems in psychodiagnostics. Suppose that a new treatment (e.g., cognitive-analytic therapy) is to be tested on patients suffering from some mental health problem (e.g., anorexia nervosa). Following each exposure of a patient to the new treatment, it is desirous to make a decision concerning the effectiveness/ineffectiveness of the new treatment or to continue testing and exposing the new treatment to another randomly selected patient suffering from the same mental health problem. In such

clinical situations, costs of testing generally are quite large and the Bayesian sequential approach might be considered an alternative to fixed-length mastery tests (Vos, 2001).

Signal Detection Theory

H Abdi, The University of Texas at Dallas, Richardson, TX, USA

© 2010 Elsevier Ltd. All rights reserved.

Overview

Signal detection theory (often abridged as SDT) is used to analyze data coming from experiments where the task is to categorize ambiguous inputs which can be generated either by a known process (called the signal) or be obtained by chance (called the noise in the SDT framework). For example, a radar operator must decide if what she sees on the radar screen indicates the presence of a plane (the signal) or the presence of parasites (the noise). This type of applications was the original framework of SDT (see the founding work of Green and Swets, 1966). But the notion of signal and noise can be somewhat metaphorical in some experimental contexts. For example, in a memory recognition experiment, participants have to decide if the input they currently see was presented before. Here the signal corresponds to a familiarity feeling generated by a memorized input, whereas the noise corresponds to a familiarity feeling generated by a new stimulus.

The goal of signal detection theory is to estimate two main parameters from the experimental data. The first parameter, called d' , indicates the strength of the signal (relative to the noise). The second parameter called C (a variant of it is called β) reflects the strategy of response of the participant of being more willing to say, for example, yes rather than no. SDT is used in very different domains from psychology (psychophysics, perception, memory), medical diagnostics (do the symptoms match a known diagnostic or can they be dismissed as irrelevant), to statistical decision (do the data indicate that the experiment has an effect or not).

The classic work on SDT is Green and Swets (1995), a basic introduction is McNicol (1972), two recent comprehensive references are Macmillan and Creelman (2005) and Wickens (2002).

A few examples of SDT to education can be found in McDermott *et al.* (1992), more recent examples can be found in McFall and Treat (1999), DeCarlo (2005), and DeCarlo and Luthar (2000).

The Model

It is easier to introduce the model with an example, so suppose that we have designed a face memory experiment. In the first part of the experiment, a participant was asked to memorize a list of faces. Then the participant is presented with a set of faces one at a time. Some of these

faces were seen before (these are old faces) and some were not seen before (these are new faces). The task is to decide for each face whether this face was seen (response Yes) or not (response No) in the first part of the experiment.

What are the different types of responses? A Yes response given to an old input is a correct response, it is called a Hit; but a Yes response to a new input is a mistake, it is called a False Alarm (abbreviated as FA). A No response given to a new input is a correct response, it is called a Correct Rejection; but a No response to an old input is a mistake, it is called a Miss. These four types of response (and their frequency) can be organized as shown in Table 1.

The relative frequency of these four types of response is not all independent. For example, when the signal is present (first row of Table 1) the proportion of Hits and the proportion of Misses add up to one (because when the signal is present, the subject can say either Yes or No). Likewise when the signal is absent, the proportion of FA and the proportion of Correct Rejection add up to one. Therefore, all the information in the table is given by the proportion of Hits and FAs.

Even though the proportions of Hits and FAs provide all the information in the data, these values are hard to interpret because they crucially depend upon two parameters. The first parameter is the *difficulty* of the task: the easier the task, the larger the proportion of Hits and the smaller the proportion of FAs. When the task is easy, we say that the signal and the noise are well separated, or that there is a large distance between the signal and the noise (conversely, for a hard task, the signal and the noise are close and the distance between them is small). The second parameter is the *strategy* of the participant: a participant who always says No will never commit a FA; on the other hand, a participant who always says Yes is guaranteed all Hits. A participant who tends to give the response Yes is called *liberal* and a participant who tends to give the response No is called *conservative*.

The SDT Model

So, the proportions of Hits and FAs reflect the effect of two underlying parameters: the first one reflects the separation between the signal and the noise and the second one the strategy of the participant. The goal of SDT is to estimate the value of these two parameters from the experimental data. In order to do so, SDT creates a

model of the participant's response. Basically, the SDT model assumes that the participant's response depends upon the intensity of a hidden variable (e.g., familiarity of a face) and that the participant responds Yes when the value of this variable for the input is larger than a pre-defined threshold.

SDT also assumes that the stimuli generated by the noise condition vary naturally for that hidden variable. As is often the case elsewhere, SDT, in addition, assumes that the hidden variable values for the noise follow a normal distribution. Recall, at this point, that when a variable x follows a Gaussian (aka Normal) distribution, this distribution depends upon two parameters: the mean (denoted μ) and the variance (denoted σ^2). It is defined as

$$\mathcal{G}(x, \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp \left\{ -\frac{(x - \mu)^2}{2\sigma^2} \right\} \quad [1]$$

In general, within the SDT framework, the values of μ and σ are arbitrary and therefore we choose the simpler values of $\mu = 0$ and $\sigma = 1$ (other values will give the same results but with more cumbersome procedures). In this case, eqn [1] reduces to

$$\mathcal{N}(x) = \frac{1}{\sqrt{2\pi}} \exp \left\{ -\frac{1}{2}x^2 \right\} \quad [2]$$

Finally, SDT assumes that the signal is *added* to the noise. In other words, the distribution of the values generated by the signal condition has the same shape (and therefore the same variance) as the noise distribution.

Table 1 The four possible types of response in SDT

Reality	Decision (participant's response)	
	Yes	No
Signal present	Hit	Miss
Signal absent	False Alarm (FA)	Correct Rejection

Figure 1 The SDT model.

Figure 1 illustrates the SDT model. The x -axis shows the intensity of underlying hidden variable (e.g., familiarity for the face example). As indicated above, the distribution of the noise is centered at zero (i.e., mean of the noise is equal to zero), with a standard deviation of 1. So, the standard deviation of the noise is equivalent to the unit of measurement of x . The distribution of the signal is identical to the noise distribution, but it is moved to the right of the noise distribution. The distance between the signal and the noise distributions corresponds to the effect of the signal (this is the quantity that is added to the noise distribution in order to get the signal distribution): this distance is called d' . Because the mean of the noise distribution is zero, d' is equal to the mean of the signal distribution.

The strategy of the participant is expressed via the choice of the threshold. There are several ways of expressing the position of this threshold, among the possible candidates we will mention four of them denoted B , D , C , and β . The first quantity B (sometimes called ϑ) gives the position of the threshold on the x -axis. In the example illustrated in **Figure 1**, this value is equal to 2, and so the participant corresponding to the figure has decided that any input with a value of x larger than 2 comes from the signal distribution and is given the response Yes. The position of the threshold can also be given relative to the signal distribution (because the noise has zero mean, B is the distance of the threshold relative to the noise distribution), as the mean of the signal is equal to d' we can compute D as $D = d' - B$ (a value equal to -1 in our example, see **Table 2**).

The most popular way of expressing the location of the threshold, however, is neither from the distribution of the noise nor from the distribution of the signal but relative to what is called the *ideal observer*. The ideal observer minimizes conjointly the probability of a Miss and of an FA. When each type of errors has the same cost, the criterion of the ideal observer is positioned on the average of the means of the signal and the noise distribution. In our example, the threshold of the ideal observer would be equal to $\frac{1}{2}d' = \frac{1}{2} = 0.5$. The value of C is the distance from the actual threshold to the ideal observer; it can be computed as $C = B - \frac{d'}{2} = 2 - 0.5 = 1.5$. The sign

Table 2 The probability or the four possible types of response according to **Figure 1**

Reality	Decision (participant's response)		
	Yes	No	Total
Signal present	Hit	Miss	
Signal absent	False Alarm (FA)	Correct Rejection	
	Pr {Hit} = 0.1587	Pr {Miss} = 0.8413	1
	Pr {FA} = 0.0228	Pr {Correct Rejection} = 0.9772	1

of C reveals the participant's strategy: when $C = 0$, we have the ideal observer; when C is negative the participant is liberal (i.e., responds Yes more often than the ideal observer); when C is positive the participant is conservative (i.e., responds No more often than the ideal observer).

An alternative way of expressing the position of the participant's criterion is given by the quantity called β . It corresponds to the ratio of the height of the signal distribution to the noise distribution for the value of the threshold. Because the distributions of the noise and the signal are normal with variance equal 1, we can compute β from eqn [2] as

$$\beta = \frac{\mathcal{N}(D)}{\mathcal{N}(B)} = \frac{\mathcal{N}(1)}{\mathcal{N}(2)} = \frac{0.2420}{0.0540} \approx 4.4817 \quad [3]$$

Some rewriting can show that eqn [3] can be rewritten as

$$\beta = \exp \{d' \times C\} \quad [4]$$

The quantity β has the advantage of being a likelihood ratio and can be used to interpret SDT within a statistical framework. For practical reasons, it is often easier to compute the logarithm of β ; for example, from eqn [4], we get

$$\ln \beta = d' \times C = 1 \times 1.5 = 1.5 \quad [5]$$

The model illustrated by **Figure 1** generates a specific pattern of response probabilities which can be computed from integrating the normal distribution. So, for example, the probability of a FA is obtained as the probability (i.e., area under the normal distribution) of finding a value larger than 2 with a normal distribution of mean 0 and variance 1 (this can be computed with most statistical packages or from tables such as the ones given in Abdi *et al.*, 2009). This quantity is also called the probability associated to the value 2, in our example it is equal to 0.0228. Along the same lines, the probability of a Hit is obtained as the probability (i.e., area under the normal distribution) of finding a value larger than 2 with a normal distribution of mean 1 (i.e., the mean of the signal) and variance 1, this is equivalent of finding the probability (i.e., area under the normal distribution) of finding a value larger than $2 - 1 = 1$ with a normal distribution of mean $1 - 1 = 0$ and variance 1. This value is equal to 0.1587.

SDT in Practice

The previous example was describing the performance of a participant who behaved according to the SDT model. However, in practice we do not know the values of the parameters of SDT, but we want to estimate them from the performance of the participants. In an experimental paradigm, the only observable quantities are the

Table 3 The performance of a wine taster trying to identify Gamay in a Pinot Noir wine

Reality	Decision (taster's response)		Σ
	Yes (Gamay)	No (Pure Pinot)	
Signal present (Gamay)	Hit	Miss	
	# {Hit} = 9 Pr {Hit} = 0.9	# {Miss} = 1 # {Miss} = 0.1	10 1
Signal absent (Pure Pinot)	False Alarm (FA)	Correct Rejection	
	# {FA} = 2 Pr {FA} = 0.2	# {Correct Rejection} = 8 Pr {Correct Rejection} = 0.8	10 1

participant's responses from which we can derive the number of Hits and FAs.

To illustrate this problem suppose that we want to evaluate the performance of a wine taster whose task is to detect if a wine labeled as made from Pinot Noir has been tempered by the addition of some Gamay (generally considered an inferior grape). Here, the signal corresponds to presence of Gamay. Our wine taster tasted (blindfolded) 20 glasses of Pinot (half of them tempered with some Gamay and half without). The results are reported in **Table 3**, and show that the proportion of Hits and FAs are respectively 0.9 and 0.2. In order to find the values of d' and the criterion, we need to inverse the formulas given above (i.e., eqns [3]–[5]). We need one new notation: for a normal distribution with zero mean, we denote by Z_P the value of the normal distribution whose associated probability is equal to P (e.g., $Z_{0.25} = 1.96$). We denote as Z_H and Z_{FA} the values corresponding to the proportions of Hits and FAs. With these new notations and after some (minor) algebraic manipulations, we find the following set of formulas. The estimation of d' is obtained as

$$d' = Z_H - Z_{FA} = Z_{0.9} - Z_{0.2} = 1.28 - (-0.84) = 2.12 \quad [6]$$

The estimation of C is obtained as

$$\begin{aligned} C &= -\frac{1}{2} [Z_H + Z_{FA}] = -[Z_{0.9} + Z_{0.2}] \\ &= -\frac{1}{2} [1.28 + 0.84] = -0.22 \end{aligned} \quad [7]$$

and $\ln \beta$ is obtained as

$$\ln \beta = d' \times C = 2.12 \times -0.22 = -0.47 \quad [8]$$

(β is obtained as $\exp\{\ln \beta\} = 0.63$).

How to interpret these results? The taster is clearly (but not perfectly) discriminating between Pinots and tempered Pinots (as indicated by a d' of 2.12), this taster is also liberal (in case of doubt the taster will rather say that the wine has been tempered rather than not).

Small Area Estimation

A Noble, Massey University, Palmerston North, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Sample surveys are commonly used for data collection in many academic areas, particularly the social sciences. The data collected are then used to estimate statistics of interest and the sample sizes are determined so that those statistics are estimated with an acceptable sampling error. Frequently, there is a demand for estimates at smaller geographic areas or finer cross-classifications of categorical variables, as in **Figure 1**. In the literature, there are a number of terms used to denote these smaller groups; small area, local area, and small domain are common. The term small area is used in this article.

Normally, it will not be possible to obtain direct estimates with acceptable errors for small areas because of the small sample sizes in the smaller partitions. Small-area estimation may then be used to improve the estimates for these smaller areas or cross-classifications. Additional data or a model with assumptions, or both, are needed to improve the estimates. A range of techniques have been developed to apply to this problem. These methods borrow strength from related or similar small areas through explicit or implicit statistical models that connect the small areas via supplementary data. In other words, data are available at the small-area level, which can be used – via a model and often requiring auxiliary data – to estimate parameters for the unknown data at the small-area level.

Their historical use has largely been driven by the data that were available in a particular application. In the earlier methods of small-area estimation, census data were generally available from an earlier time and the objective was to update estimates with data collected more recently or by using historical relationships in the variable of interest over time from more than one census – for example, a linear trend.

More recently, sample survey data – collected for other purposes – have been combined with different information with regard to the small areas – from another source – to produce the estimates. These other sources may include a census.

Marker (1999) demonstrated that most of the historical small-area estimation methods could be placed in a framework of the linear regression model expressed in the equation

$$Y = X\beta + \epsilon \quad [1]$$

Most often, Y will be the vector of estimates for the small areas. The X matrix may be a matrix of data or of indicator

variables, to denote membership of groups, or a mixture of the two. ϵ will be an error term which will, generally, have normal distribution with mean zero.

The methods can be loosely grouped into the following:

- Demographic methods.
- Synthetic and related methods.
- Symptomatic regression.
- Structure-preserving estimation (SPREE).
- Models with area-specific effects.
- Empirical best linear unbiased prediction (EBLUP), empirical Bayes, and hierarchical Bayes approaches.
- Spatial statistics.

This article considers each of these methods in more detail.

Demographic Methods

These methods are also described as symptomatic accounting techniques (SAT). All of these were developed for estimating human population sizes and use particular available information to improve estimates from other data, possibly an earlier census. The literature is not consistent in its classification of these older techniques but they are, generally, extensions of a very simple model in which a previously known estimate – usually from a census – is updated by adding or subtracting births, deaths, immigration, and migration counts for each small area. They are commonly used for predicting future rolls of schools for administrative uses.

In this model, there is no stochastic part as it is assumed that the values are known exactly and it is merely an arithmetic problem.

As administrative records do not, usually, detail all arrivals and departures from each area, various methods have been developed to estimate these from symptomatic variables – that is, variables that reflect the arrivals and departures. These methods include the following: administrative records (ARs), housing unit (HU), vital rates, composite method, and composite method II (CMII). References for these are presented in Ghosh and Rao (1994).

Synthetic and Related Methods

Gonzalez (1973) describes synthetic estimates as follows: “An unbiased estimate is obtained from a sample survey

Figure 1 Generation of small areas. Subdivisions of geographic regions or divisions that cut across the divisions used for sampling.

for a large area; when this estimate is used to derive estimates for sub areas under the assumption that the small areas have the same characteristics as the large area, we identify these estimates as synthetic estimates.” They have been used in a number of contexts because:

- they are simple to use,
- they can be applied to general sampling designs, and
- there exists the potential to increase accuracy by borrowing information from similar small areas.

There are a number of related methods which will be described.

Synthetic Estimation

Synthetic estimation uses survey data to estimate proportions of different subgroups – for example, age by sex by ethnicity subgroups, and the estimates for the small areas are derived by taking the appropriate weighted average of these for each small area. The standard formulation for these estimates is

$$\hat{Y}_a = \frac{\sum_j N_{aj} \bar{y}_j}{N_a} \text{ where}$$

\hat{Y}_a is the estimated mean for each small area a , N_{aj} is the size of the population of small area a and subgroup j , N_a is the total population in area a , and \bar{y}_j is the sample average for Y for subgroup j across all small areas.

Symptomatic Regression

Two past censuses are used to define a regression relationship between the variable of interest and ratios of the symptomatic variables at each census. These ratios are then found for the last census and the present time and used to update the variable of interest.

Ratio Correlation

Let $t = \{0, 1, 2\}$ denote two consecutive census years and the current year, note that the 3 years represented may not

be equally spaced. Further, N_{at} and S_{ajt} are the population total and the value for the j th symptomatic variable for the a th local area ($a = 1, \dots, A$) in the year t , respectively.

Further, let: $p_{at} = \frac{N_{at}}{\sum_a N_{at}}$ and $s_{ajt} = \frac{S_{ajt}}{\sum_a S_{ajt}}$ be the corresponding proportions and write $R'_a = \frac{p_{a1}}{p_{a0}}$, $R_a = \frac{p_{a2}}{p_{a1}}$ (which is unknown as p_{at} is what we are trying to estimate) and $r'_{aj} = \frac{s_{aj1}}{s_{aj0}}$, $r_{aj} = \frac{s_{aj2}}{s_{aj1}}$

Using the data ($R'_a, r'_{a1}, \dots, r'_{aj}; a = 1, \dots, A$) and multiple regression we first fit

$$R'_a = \hat{\beta}_0 + \hat{\beta}_1 r'_{a1} + \dots + \hat{\beta}_j r'_{aj}$$

where the $\hat{\beta}$'s are the estimated regression coefficients that link the change, R'_a , in the population proportions between the two census years to the corresponding changes, r'_{aj} , in the proportions for the symptomatic variables. Next, the changes, R_a – in the postcensal period – are predicted as $\hat{R}_a = \hat{\beta}_0 + \hat{\beta}_1 r_{a1} + \dots + \hat{\beta}_j r_{aj}$ using the known changes in the symptomatic variables in the postcensal period and the estimated regression coefficients. Finally, the current population counts are estimated as

$$\tilde{N}_{a2} = \hat{R}_a p_{a1} \left(\sum_a N_{a2} \right)$$

where the total population across all local areas is found from other data.

The difference correlation method uses the same process; however, differences between the proportions at the two time points are used rather than their ratio.

These procedures use regression coefficients in the last inter-censal period and it is assumed that these parameters are applicable to the change from the last census to the present time. Significant changes in the statistical relationship can lead to errors in the current estimates. Such changes are quite likely if the censuses are at intervals of 10 years as the ratios are based on data that will be between 10 and 20 years old.

The methods described, thus far, use only census data. Use of sample survey data can help to reduce the problem of changes in the statistical relationship and give accurate current data for some small areas.

The Sample-Regression Method

The problem of out-of-date data can be avoided by using sample estimates of R_i for those local areas where data exist. The sample regression estimators are then obtained for all areas using the known symptomatic ratios.

The sample regression method has similarities with symptomatic regression, except that, instead of using census data from two past censuses, data are used from a sample of the small areas and the most recent census. Thus, it is assumed that the sample of small areas is

representative of all of them. A version of this method using a logistic model has been used for state-level estimates for the Private School Survey (Causey *et al.*, 1999).

An alternative is to develop a regression model for the variable of interest from the survey data and then make predictions for the whole population using census values for the variables in the regression model. The small-area estimates can then be derived by summing or averaging the variable of interest over the areas. This has the advantage of providing estimates for areas that have no representation in the sample, on the assumption that the model developed from the survey applies in areas not surveyed as well as those surveyed. This methodology has been used in conjunction with the International Adult Literacy Survey data to predict proportions of residents with low literacy levels in small, population wise, administrative areas in New Zealand (Culligan *et al.*, 2004). It is also used by the World Bank for estimating poverty in developing countries (Elbers *et al.*, 2003).

Components of Variance Regression

The methods considered, so far, have considered data at the area level but the components of variance method considers data at the element level, k . The error term has two components – one is random and the other is small-area specific.

The model is

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\varepsilon}$$

$\boldsymbol{\varepsilon}$ is the vector of errors with elements ε_{ak} .

$$\boldsymbol{\varepsilon} = \mathbf{v} + \mathbf{u}$$

\mathbf{v} is the vector of small-area effects; these will be the same for all individuals in each small area, hence \mathbf{v} has elements v_a ; \mathbf{u} is the vector of random errors with elements u_{ak} .

$$\mathbf{v} \sim N(\mathbf{0}, \Sigma_{vv}) \text{ and } \mathbf{u} \sim N(\mathbf{0}, \Sigma_{uu}).$$

This estimate is not optimal unless all of the n_a are equal.

The least square estimates of $\boldsymbol{\beta}$ are then $\hat{\boldsymbol{\beta}} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{Y}$. The average residual for each small area can be calculated and assigned the assumed error structure $E(v_a | \bar{\varepsilon}_a) = \bar{\varepsilon}_a G_a$ where $G_a = (\Sigma_{vv} + n_a^{-1} \Sigma_{uu})^{-1} \Sigma_{vv}$. Using the survey data for that small area and the estimate for average error for each area, an estimate of v_a for each small area can be found.

Structure-Preserving Estimation

Purcell and Kish (1980) propose structure-preserving estimation (SPREE) as a generalization of synthetic estimation in the sense that it makes fuller use of reliable direct estimates. SPREE commonly uses the well-known method of iterative fitting of margins in a multiway table

Original data (census data)			New margins (survey data)		
	Male	Female		Male	Female
Age 1	3	5	8	Age 1	6
Age 2	4	7	11	Age 2	15
	7	12	19	9	12
				21	

Figure 2 Data requirements for SPREE for a very simple table.

(iterative proportional fitting (IPF)), where the margins are direct estimates. Although this method is based on ratios – as in the previous method – the IPF procedure guarantees that the ratio estimates are adjusted to conform to the margins.

In the very simple example in **Figure 2**, the data in the body of the table – on the left – are generated from a census and the margins – on the right – from the survey. The margins are available for the different categories but not for all of the combinations. The data in the body of the table are then adjusted to agree with the margins. This adjustment is achieved by first adjusting the rows then the columns and repeating this until convergence. The interactions between the variables are set by the census data, except for any that may be defined in the new margins. The interactions that are defined by the census data remain unchanged through the iterative process. Only the effects defined by the survey data are changed to agree with the new margins. (The Structure of the table is PREserved in the Estimation, hence SPREE.)

Noble *et al.* (2002) demonstrated that SPREE can be described by two generalized linear models – one for the census data and one for the survey. Terms which are unknown in the sample survey model are substituted from the census model.

This method is commonly used in the estimation of unemployment and for updating census data.

Composite Estimation

The composite estimators cover a wide range of examples – all of which can be characterized by a weighted average of two estimators. The most common simply apply a weighted average to a direct estimator and one of the estimators described above. The weights are based on the variance or mean square error of the two estimators. The composite estimator is intended to offset the bias in the indirect estimator and the variability in the direct estimator. In cases where few areas in the model have direct estimators, there is little advantage in the composite estimator. Synthetic estimators tend to be biased, direct estimators may be unstable. An obvious way to reduce these two effects is to take a weighted average of the two estimates. Such estimators may be written

$$\hat{Y}_a^C = w_a \hat{Y}_{1a} + (1 - w_a) \hat{Y}_{2a} \quad [2]$$

where \hat{Y}_{1a} is a direct estimator and \hat{Y}_{2a} is an indirect estimator, and w_a is a suitably chosen weight ($0 \leq w_a \leq 1$). A number of possible choices of weights have been proposed. Care needs to be taken in their choice as none work well in all situations.

Best Linear Unbiased Prediction

Holt *et al.* (1979) proposed a best linear unbiased prediction (BLUP) estimator of \hat{Y}_i under the following model for the finite population:

$$y_{agk} = \mu_g + e_{agk} \quad k = 1, \dots, N_{ig}; g = 1, \dots, G; \quad k = 1, \dots, m$$

where y_{agk} is the y -value of the k th unit in the cell (a, g) for small area a in domain g , μ_g 's are fixed effects, and the errors e_{agk} are uncorrelated with zero means and variances σ_a^2 .

N_{ag} denotes the number of population elements – in the large domain g – which belong to the small area a . Suppose n_{ag} elements in a sample of size n fall in the cell (a, g) and let \bar{y}_{ag} and $\bar{y}_{\cdot g}$ denote the sample means for (a, g) and g , respectively.

The BLUP estimator of Y_i is given by

$$\hat{Y}_a^B = \sum_g \hat{Y}_{ag}^C = \sum_g \left(\frac{n_{ag}}{N_{ag}} \hat{Y}_{ag} + \left(1 - \frac{n_{ag}}{N_{ag}} \right) \hat{Y}_{\cdot g}^S \right)$$

where $\hat{Y}_{ag} = N_{ag} \bar{y}_{ag}$ and $\hat{Y}_{\cdot g}^S = N_{ag} \bar{y}_{\cdot g}$ or $\hat{Y}_a^B = \sum_g (n_{ag} y_{ag} + (N_{ag} - n_{ag}) \bar{y}_{\cdot g})$ which, in effect, sums the values in the sample from that cell and estimates the total for the rest in that cell by the mean across the g th group multiplied by the number not in the sample. If the sample size for that cell is large the estimate tends to the direct estimator, if it is small it tends to the synthetic estimator. If the sample fraction is small for all of the groups, then no account is made of the relationship between, between-area, and within-area variation. This problem can be reduced by more sophisticated models.

Models with Area-Specific Effects

Two types of models – with area-specific effects – have been proposed.

In the first, area-specific auxiliary data $\mathbf{x}_a = (x_{a1}, \dots, x_{aJ})^T$ is assumed to be known and the parameters of interest, θ_a , are assumed to be related to \mathbf{x}_a .

In particular, we assume that $\theta_a = \mathbf{x}_a^T \boldsymbol{\beta} + v_a$ $a = 1, \dots, A$.

The z_a 's are known positive constants, $\boldsymbol{\beta}$ is the vector of regression parameters, and the v_a 's are iid random variables with $E[v_a] = 0$ and $V(v_a) = \sigma_a^2$.

In the second type, element-specific auxiliary data $\mathbf{x}_{aj} = (x_{aj1}, \dots, x_{ajJ})^T$ are available for the population elements. The variable of interest y_{aj} is assumed to be related to \mathbf{x}_{aj} through a nested error regression model.

$$y_{aj} = \mathbf{x}_{aj}^T \boldsymbol{\beta} + v_a + e_{aj} \quad j = 1, \dots, N_i; a = 1, \dots, A \quad [3]$$

where $e_{aj} = \tilde{e}_{aj} k_{aj}$ and the \tilde{e}_{aj} 's are iid random variables independent of the v_a 's with, $E(\tilde{e}_{aj}) = 0$, and $V(v_a) = \sigma^2$, the k_{aj} 's being known constants and N_a being the number of elements in the a th area.

For making inferences under the first model, some assumptions are required that may be quite restrictive in some applications. Violation of these assumptions will introduce bias to the estimates.

Assuming that direct estimators $\hat{\theta}_a$ are available and that $\hat{\theta}_a = \theta_a + e_a$, we obtain the model $\hat{\theta}_a = \mathbf{x}_a^T \boldsymbol{\beta} + v_a z_a + e_a$, which is a special case of the general mixed linear model. This model is commonly referred to as the Fay–Herriot model as Fay and Herriot (1979) used this model to estimate *per capita* income for small places in the United States.

In the second model, the assumption is made that the sample values also obey the model – while this will be true under simple random sampling it may not be appropriate under more complex sampling designs. The model can, however, be extended to account for such features.

The model in eqn [3] can be written in a matrix form as

$$\mathbf{y}_i^p = \mathbf{X}_i^p \boldsymbol{\beta} + \mathbf{v}_i \mathbf{1}_i^p + \mathbf{e}_i^p$$

The mean of each small area \bar{Y}_a can be written as $\bar{Y}_a = f_a \bar{y}_a + (1 - f_a) \bar{y}_a^*$ where $f_a = \frac{n_a}{N_a}$ and \bar{y}_a, \bar{y}_a^* denote the means for sampled and nonsampled elements, respectively. Estimation of the overall mean can be viewed as prediction of the mean of the nonsampled elements, given the data.

EBLUP, Empirical Bayes, and Hierarchical Bayes Approaches

Lahiri (1996) combines these approaches under the heading of composite estimation, which was discussed above. They are characterized by a weighted average of two estimates – the direct estimate and a synthetic estimate.

$$\hat{\theta}_a^C = w_a y_a + (1 - w_a) \mathbf{x}_a^T \hat{\boldsymbol{\beta}}$$

which is essentially the same as eqn [2].

The choice of weight, w_a , constitutes the difference between the three approaches.

These approaches are useful when direct estimates are available for a reasonable number of the small areas; if they are not, then the weight, w_a , is equal to zero for most areas and the estimate is simply the synthetic estimate.

They are an attempt to combine the zero bias of the direct estimate with the smaller variance of the synthetic estimate.

Spatial Statistics

The basic assumptions made in most simple statistical analysis are that the data are independent and identically distributed. In several circumstances, neither of these assumptions hold true. Spatial data contradict these assumptions. It is intuitively sensible to assume that data collected from some connected geographical regions – defined by arbitrary political boundaries – are likely to be correlated. Cressie (1993) is an authoritative book on spatial statistics.

Data collected in a wide range of situations have long been recognized as having spatial variation. Initially, most research was focused on reducing the effect of spatial dependence in the results. R.A. Fisher – at Rothamstead Experimental Station in England, in the 1920s and 1930s – went to great lengths to remove it, largely, by designing experiments with replication, randomization, and blocking. Since that time, the emphasis has moved to explicitly modeling the spatial variation – both in the types of agricultural experiments that Fisher was involved with and in a wider range of problems. This wider range of problems includes applications in geostatistics, particularly mining, atmospheric science, soil science, epidemiology, public health, and analysis of data from satellites. This range of applications continues to expand rapidly.

Spatial approaches to small-area estimation are many and depend on the available data. In a simple case, direct estimates for each small area may be smoothed by defining a local correlation structure. This will reduce the variance of the estimates by assuming that areas close by are similar. This correlation may be fixed for neighbors or may decay as the distance between sites increases. This distance may be Euclidean or measured on some other metric.

The analysis of such correlated data has seen many advances, particularly in the last 25 years or so of the last century and there are now some fairly standard approaches that can be used. These analyses assume some kind of known structure – generally, a correlation structure – which is defined and parameters are estimated.

Often, there are a number of possible structures that could be investigated. We may consider that areas close to each other or areas with similar demographics could be similar. School attendance in inner-city areas could be similar despite the cities being distant from each other.

These spatial correlations can be included in the analysis by an appropriate covariance matrix and the investigator considers the inclusion of this correlation in the analysis. Many models of spatial dependence could then

be fitted. One which is commonly used is the conditional autoregressive model (CAR).

Gaussian conditional autoregressive processes have been used in spatial statistics to describe the association between random variables observed at fixed sites in some Euclidean space (Cressie, 1993). We can extend the simple model in eqn [1] by adding a spatial term

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{z} + \boldsymbol{\varepsilon}$$

The spatial dependence is modeled by the covariance matrix, which includes terms for adjacent areas. This matrix must be symmetric (if i is adjacent to j , then j must also be adjacent to i).

$$\mathbf{z} \sim \text{Gau}(\boldsymbol{\mu}, (\mathbf{I} - \mathbf{C})^{-1}\mathbf{M})$$

where \mathbf{z} is the vector of data values ($z(s_1), \dots, z(s_n)$), $\boldsymbol{\mu}$ is vector of means, \mathbf{C} is the $(n \times n)$ matrix of c_{ij} where $c_{ii} = 0$, $c_{ik} = 0$ where i and k are not adjacent areas and $c_{ij}^2 = c_{ji}^2$ and \mathbf{M} is the diagonal $(n \times n)$ matrix $\text{diag}(\tau_1^2, \dots, \tau_n^2)$.

In effect, the error term is decomposed into two parts – one of which is a latent term explaining variability due to similarities between areas or cells in the table.

In spatial models, there is often a problem of what to do with areas that are on the edge of the lattice. Similar to the surface tension in a liquid, these areas pulled in toward the areas within the lattice with no effect from outside. This may need to be considered in particular examples.

Discussion

Small-area estimation does not seem to be used prevalently in educational research. One explanation of this is that there are copious amounts of data to analyze at very fine levels of detail and direct estimators are available at the small-area level. Most developed countries have highly organized reporting systems that produce information down even to the individual student level. The necessity for small-area methods is not strong.

A new development in the previous 20 years has been a number of international assessments that have been carried out. Examples of these include

- Trends in International Mathematics and Science Study (TIMSS).
- Progress in International Reading Literacy Study (PIRLS).
- Adult Literacy and Lifeskills Survey (ALL).

The first two are conducted by the International Association for the Evaluation of Educational Achievement (IEA) and the Organization for Economic Cooperation and Development (OECD)'s Program for International Student Assessment (PISA) and the last one is conducted by Statistics Canada and the OECD.

These are all in the form of samples surveys from the participating countries and include some auxiliary variables. There exist many possibilities for combining the data from these surveys with census data to make predictions for small areas within the countries surveyed.

Statistical Analysis of Functional Data

F Ferraty, P Sarda, and P Vieu, Toulouse University, Toulouse, France

© 2010 Elsevier Ltd. All rights reserved.

In many applications, the object of interest is a function $X = X(t)$ depending continuously on a variable t which may be time, a vector of spatial position, etc. In practice, for each individual i , one observes the function X on a grid t_1, t_2, \dots, t_p and the statistical sample contains the values of $X_i(t_1), \dots, X_i(t_p)$ for $i = 1, \dots, n$ (i.e., n individuals). One encounters such data, for instance, in longitudinal studies (when the measurements t_1, t_2, \dots are dates), in chemistry (i.e., t_1, t_2, \dots could be wavelengths), in image analysis (i.e., t_1, t_2, \dots are a two or three-dimensional vector), etc. Finally, the collected data consist in either a population of discretized curves (spectrometric curves, radar waveforms, electricity consumptions, growth curves, digitized voice recordings, etc.), a collection of surfaces, multidimensional images (digitized pictures, satellite images, multispectral images, hyper-spectral images, times series of images), or a set of any other higher dimensional (discretized) functions. With the development of modern technology, the data are recorded on finer and finer grids, and so one can consider the observed data in a continuous manner. Such data are called functional data, and a new branch of statistics, called functional data analysis (FDA), has emerged with the aim of developing models and methodologies that are able to study such high dimensional data and integrate specific information. The terminology functional variable is also used to indicate a statistical variable whose observations lead to functional data. This recent statistical topic is motivated by numerous domains of applications: biology, biomechanics, chemometrics, computer sciences, ecology, econometrics, medical sciences, industry, etc. Problems encountered in FDA are of the same nature as in general statistics: analyze variability and find structures (factorial analysis, classification, etc.) in a set of functional data, predict a (functional or scalar) variable depending on the variations of a functional predictor (regression), depicting a distribution of functional data, identifying outliers, etc. The reader can find a good overview on FDA methodologies in Ramsay and Silverman (2005) and several case studies in Ramsay and Silverman (2002). A more recent book on FDA from Ferraty and Vieu (2006) deals with general statistical models and discusses the estimation of a distribution of a population of curves and some related features. Functional data can also be studied in the setting of time series (see Bosq, 2000).

Why developing specific statistical strategies for functional data? The starting point of FDA comes from the inability of standard multivariate technics to extract all

the functional richness of such high dimensional data. For instance, a standard multivariate linear regression generally fails when one aims to predict a scalar response from a functional explanatory variable. Thus, our goal is to present the usefulness of FDA as well as its potentialities.

This contribution is organized as follows. We start with a general description of functional data by means of several real examples coming from a wide scope of applied scientific fields (chemometrics, computer sciences, geophysics). Then we discuss why the standard multivariate linear regression (through a spectrometric functional data set) fails when one considers an explanatory functional variable. In a third section, one proposes to give an idea on what one can do with FDA by giving a sample of functional statistical studies (unsupervised classification, regression on functional variable, curves discrimination, and functional prediction). Our main goal is to stress situations where FDA is potentially pertinent. We conclude by opening some motivating perspectives for educational purposes.

A Few Functional Data Sets and Problematics

Let us first introduce some illustrating examples depicting what is called functional data. The first one comes from the food industry and will be the unifying thread throughout this article. It concerns a quality control problem. One has at hand 215 small pieces of meat (i.e., 215 individuals). Each piece of meat is analyzed through a Tecator Infratec Food and Feed Analyzer. This apparatus allows to obtain, for each unit, one spectrometric curve (i.e., near-infrared spectrum in the wavelength range 850–1050 nm). Finally, one collects 215 spectrometric curves (i.e., $\{X_i(t); t \in [850, 1050]\}_{i=1, \dots, 215}$), one per piece of meat. Of course, in reality, one has at hand 215 discretized curves at 100 measurements t_1, \dots, t_{100} (i.e., for the i th unit one gets the discretized curves $X_i(t_1), \dots, X_i(t_{100})$). However, the difference between two consecutive grid points (i.e., $|t_j - t_{j+1}|$) is so small that the discretized curves (see Figure 1) can be considered as continuous ones as in Figure 2.

At this stage, several questions could interest the practitioners: Can we explore this population of curves? Can we extract pertinent informations? Is it possible to build several groups in order to classify such spectrometric curves? Can we depict the distribution of such a population of curves? (median curve?, modal curve?, etc.).

Other interesting questions arise if there are additional variables. Indeed, throughout an analytical chemical process, it is possible to obtain, for each piece of meat, the fat content (i.e., a scalar response Y), and one has to study the sample $\{X_i(\cdot), Y_i\}_{i=1, \dots, 215}$ where $X_i(\cdot)$ refers to the curve $\{X_i(t); t \in [850, 1050]\}$. A natural question could be: can we explain the Y_i 's from the $X_i(\cdot)$'s? Or, in other words, can we predict the unknown fat content for an incoming new curve $X_{216}(\cdot)$? In the chemometrician community, this type of problem is called calibration problem (see Martens and Naes, 1989, for a good overview on this topic). The practical interest of finding a solution to this regression problem resides in the fact that the analytical chemical process to find Y_i 's is much more expensive than the use

Figure 1 Sample of 15 discretized curves.

of a spectrometer to find $X_i(\cdot)$'s. From a statistical point of view, this is clearly a regression problem where the explanatory variable is the functional one $X(\cdot)$ and the response is the scalar one Y . Another problem could emerge if one splits our population of curves into several groups. For instance, assume that a first group contains the curves with a fat content smaller than 20% and the other with a fat content greater than 20%. So, the class membership for each curve is known. A usual question in such a setting could be the following one: for a new curve $X_{216}(\cdot)$, are we able to assign this curve to a group? Typically, this is a supervised curve classification (or curve discrimination) problem.

One can find numerous studies dealing with functional data sets and devoted to similar or new problematics. For instance, a curve discrimination arises with the following speech recognition data. This data set contains the digitized recordings of speakers of 32 ms duration and concerns five speech frames corresponding to five phonemes transcribed as follows: 'sh' as in 'SHe' (group 1), 'iy' as in 'shE' (group 2), 'dcl' which is the symbol for coding the sound D as in 'Dark' (group 3), 'aa' as the vowel in 'dArk' (group 4) and 'ao' as the first vowel in 'wAter' (group 5). Finally, for each unit, one observes a log-periodogram which is a discretized curve sampled on a fine grid (150 measurements). **Figure 3** displays a sample of 10 log-periodograms for each phoneme (i.e., group).

The question of interest is how to determine the class membership of an incoming logperiodogram, thus leading to a problem of (supervised) classification of a set of curves.

The third example focuses on the monthly time series of sea surface temperature (El Niño) from June 1950 to

Figure 2 215 spectrometric curves.

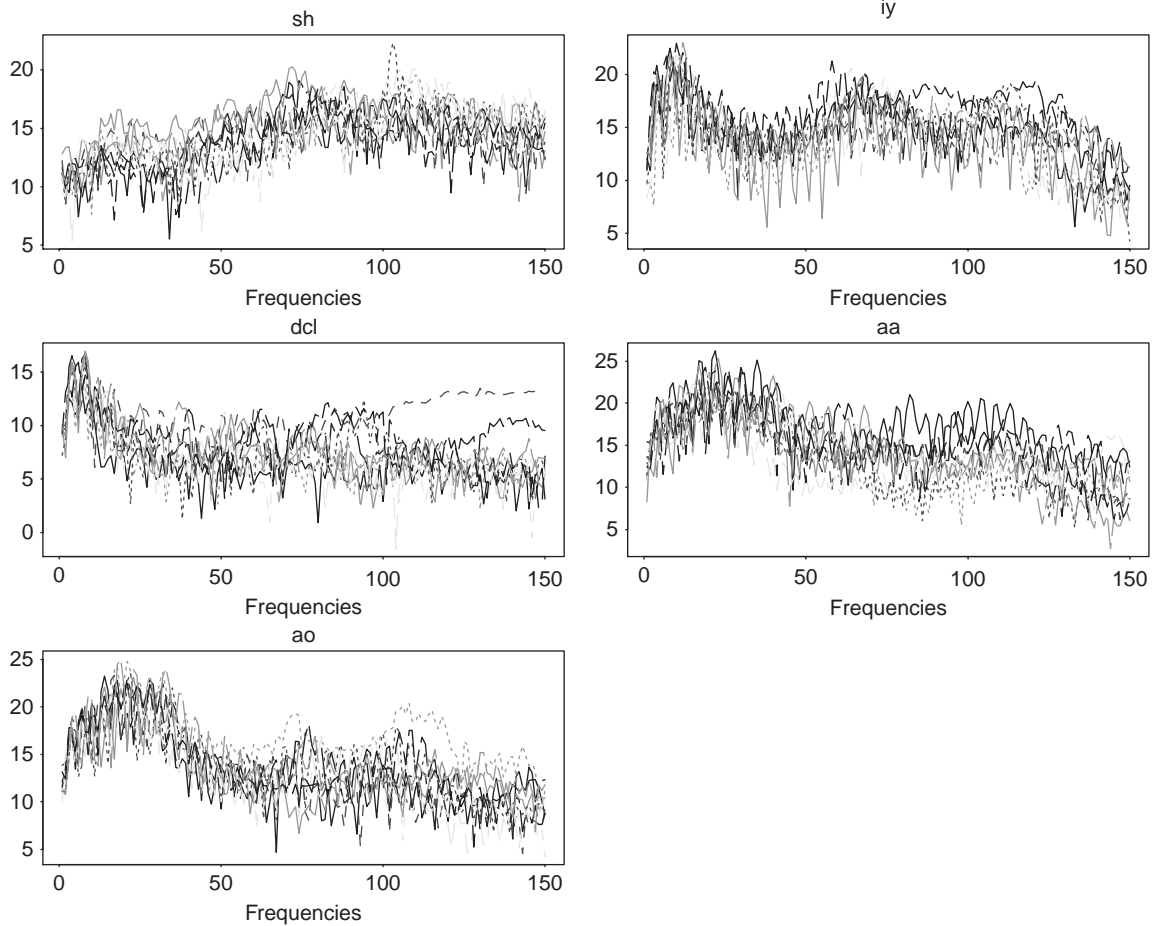

Figure 3 Sample of log-periodograms.

May 2004. The temperatures correspond to an average over the area defined by the coordinates 0–10° South and 90–80° West. **Figure 4** displays this time series, whereas **Figure 5** plots the same data but year by year. In this way, the whole time series is cut into 54 dependent curves (one per year), which can be considered as functional data. Some interesting questions arising in such a situation are the following: Can we forecast future values? Can we predict the maximum temperature for the next year from the previous ones?, etc. This forecasting setting can be viewed as a regression problem with scalar response and functional predictor, but with nonindependent statistical sample.

In all cases, solutions of the presented statistical problems can be found in the recent literature on Food and Drug Administration (FDA).

Why Do Multivariate Methods Fail with Functional Data?

We explain at this point why a standard multivariate method for studying functional data could fail. Let us focus on the spectrometric data presented before. A standard multivariate

point of view would treat each discretized spectrometric curve as one observation of the 100 variables $X(t_1), \dots, X(t_{100})$. Consequently, a standard multivariate linear model for explaining the response Y from the 100 variables is given by $Y = \sum_{j=1}^{100} a_j X(t_j) + \text{error}$. In such a statistical situation, one has ‘to’ estimate the 100 unknown parameters a_1, \dots, a_{100} . Clearly, two crucial problems arise. First high correlation could appear between variables $X(t_j)$ and $X(t_{j'})$ for j and j' close enough (i.e., $\text{corr}(X(t_j), X(t_{j'})) \simeq 1$). To see that, one considers a zoom on the discretized spectrometric curves (**Figure 1**) by focusing on the first 10 measurements (see **Figure 6**). Indeed, **Figure 6** shows that the observations obtained for consecutive measurements are very similar. This results in collinearity in the regression, and hence, to high standard error of estimates.

The second important weakness is that the number of variables can be large in comparison with the sample size. Once again, this leads to poor estimates.

Although some works have been proposed to adapt multivariate methods to this situation, a successful way to overcome the problems described before is to consider the functional data as a functional mathematical object (i.e., $X_i(t_1), \dots, X_i(t_p)$ is the discretization of the random

Figure 4 Monthly sea surface temperature.

Figure 5 Temperatures year by year.

function $\{X_i(t); t \in T\}$). Unlike multivariate approaches, it is possible to operate on such a functional object some standard mathematical calculus such as differentiation and integration, whereas more sophisticated techniques such as approximation and smoothing can be useful.

Some Modeling Aspects

The main goal of this section is to give some basic ideas on modeling functional data. FDA techniques consist in

developing statistical methods that are able to take into account the richness of the functional features of such data by using functional mathematical tools. For instance, if one considers the sample $\{X_i(\cdot), Y_i\}_{i=1, \dots, m}$ the functional linear regression model is defined by

$$Y_i = \int \rho(t) X_i(t) + \text{error}_i, \quad i = 1, \dots, n$$

(instead of its multivariate version $Y_i = \sum_{j=1}^p a_j X_i(t_j) + \text{error}_i$). A useful mathematical tool consists in expanding the functional parameter $\rho(\cdot)$

Figure 6 Zoom on spectrometric curves.

onto some fixed function basis (i.e., $\rho(\cdot) = \sum_{k=1}^K b_k B_k(\cdot)$) and also in introducing some smoothness constraints on $\rho(\cdot)$ through a penalized least-squares criterion:

$$C_\rho = \sum_i \left(Y_i - \int \rho(t) X_i(t) dt \right)^2 + \lambda P(\rho)$$

where $P(\rho)$ measures the smoothness of the function ρ (e.g., the L_2 -norm of its second derivative) and λ controls the regularity (the larger the λ , more smooth is the functional parameter). An estimator $\hat{\rho}(\cdot)$ is such that $\hat{\rho}(\cdot) = \min_\rho C_\rho$. If one considers the expansion of $\rho(\cdot)$ in terms of the basis set, minimizing over ρ amounts to minimizing over the vector of coefficients $\mathbf{b} = (b_1, \dots, b_K)$. Let $\hat{\mathbf{b}}$ be the minimizer of C_b over \mathbf{b} : $\hat{\rho}(\cdot) = \sum_k \hat{b}_k B_k(\cdot)$. From a statistical modeling point of view, the functional linear

regression model assumes a linear relationship between the functional variable and the scalar response. Contrary to the multivariate case, one has no graphical tool that is able to display the relationship between a functional variable and a scalar one. In such a context, assuming linearity becomes critical and an alternative consists in proposing more general models, called nonparametric functional models, allowing us to investigate nonlinear relationship. So, a nonparametric functional model is defined by

$$Y_i = R(X_i) + \text{error}_i, i = 1, \dots, n$$

where the regression operator $R(\cdot)$ (which has to be estimated) is assumed to satisfy some mathematical smoothness properties (continuous, lipschitzian, etc.). The linear

regression model can be viewed as a particular case by taking $R(u) = \int \rho(t)u(t)dt$. Concerning the estimation of $R(\cdot)$, kernel-type estimator ideas have been extended to the functional setting:

$$\hat{R}(x) = \sum_{i=1}^n Y_i w_{i,b}(x)$$

with

$$w_{i,b}(x) = K(b^{-1}\delta(X_i, x)) / \left[\sum_{j=1}^n K(b^{-1}\delta(X_j, x)) \right]$$

This estimator is just a weighted average of the responses (i.e., $\sum_i w_{i,b}(x) = 1$). K is a positive decreasing function, $\delta(\cdot, \cdot)$ measures the proximity between two curves (distance, semi-metric, etc.), the smoothing parameter b , called band-width, controls the regularity of $\hat{R}(\cdot)$. So, the principle of such a kernel estimator is very simple: closer x is to X_b , larger is the weight assigned to Y_i (i.e., $w_{i,b}(x)$). Both the bandwidth and the index of proximity $\delta(\cdot, \cdot)$ have to be selected (generally through a criterion based on the quality of the predictions). It is clear that the main feature of the kernel-type estimator is to focus on local properties of the distribution of the functional variable. From a probabilistic point of view, one studies this local behavior through the small balls probabilities defined by $\text{Prob}(\delta(X_i, x) \leq b)$.

It is worth noting that kernel estimator ideas can be applied to settings other than the regression one. For example, the simple kernel-type estimator

$$\hat{f}(x) = \text{const} \times \sum_{i=1}^n K(b^{-1}\delta(X_i, x))$$

is a useful statistical tool for deriving what we call the modal curve (i.e., $x_{\text{mod}} = \sup_x \hat{f}(x)$). One can also define the median curve as the one which minimizes $\sum_{i=1}^n \delta(X_i, x)$ over x . These distribution features are good tools for depicting samples of curves and an interesting by-product concerns the unsupervised classification.

Several other statistical methodologies such as generalized functional linear model, conditional distribution given a functional variable (conditional mode, conditional quantiles, etc.), curves discrimination, survival analysis with functional explanatory variable, testing procedures, etc., have been investigated.

FDA in Action

Spectrometric Data

It is time to give an idea on what one can do with FDA. At first, let us consider the functional data concerning the population of spectrometric curves. We investigate the

local behavior (i.e., small ball probabilities evaluated at each curve $X_i(\cdot)$) of the sample of curves in order to split it into several subgroups. The homogeneity of a subgroup is computed by means of features like median curve, modal curves, etc., and a general homogeneity index is computed for the obtained partition. Finally, an automatic unsupervised classification method for curves is built (the algorithm stops as soon as the gain in terms of homogeneity between two successive partitions is smaller than a threshold). For the spectrometric curves, the proximity index δ is based on their second derivatives and defined by $\delta(X_i, X_j) = \sqrt{\int (X_i''(t) - X_j''(t))^2 dt}$; the derivatives are calculated by using a numerical approximation. This choice of δ is based on the experience of chemometricians and also on a data-driven procedure. The result of this functional classification based on this index leads to three groups. **Figure 7** plots for each obtained group, the original curves, their second derivatives, and the corresponding modal curve (the curve of the sample which maximizes a kernel-type estimator of the distribution function of the population of curves). This example gives a good idea on the usefulness of FDA methods. In particular, modal curves are very interesting features for depicting a distribution of curves.

Now, if one takes into account the responses (i.e., the fat content), the problematic changes as one can try to predict the fat content from the spectrometric curve. This is typically a regression with scalar response and explanatory functional variable. Precursor works as regression on principal components, ridge regression, or partial least-squares extended standard multivariate methods. Recent advances in FDA extended these methodologies by exploiting systematically mathematical background of function spaces. In particular, a nonparametric FDA (with kernel estimator) allows to make fat content predictions as the one plotted in **Figure 8**. The solid line displays a perfect prediction: the proximity of the points with this line indicates a good accuracy of the predictions obtained with FDA. Instead of collecting the accurate fat content, one can have at hand only two groups (G_1 and G_2). For instance, the first one contains the curves corresponding to a fat content smaller than 20% and the second one the other curves. This is typically a curve discrimination (or supervised classification) problem: for an incoming curve X_{n+1} , one has to assign it to one group. Once again, one can find in FDA several methods for discriminating these spectrometric curves into these two groups. Such supervised curves classification methodologies can give very low rates of misclassification. For instance, if one implements the kernel estimator of the posterior probabilities $\text{Prob}(Y_{n+1} \in G_k | X_{n+1})$, one assigns the new curves X_{n+1} to the class of highest estimated posterior probability. This curve discrimination method leads us to a rate of around 2%; one affects (on average) to the right group 98 spectrometric curves over 100.

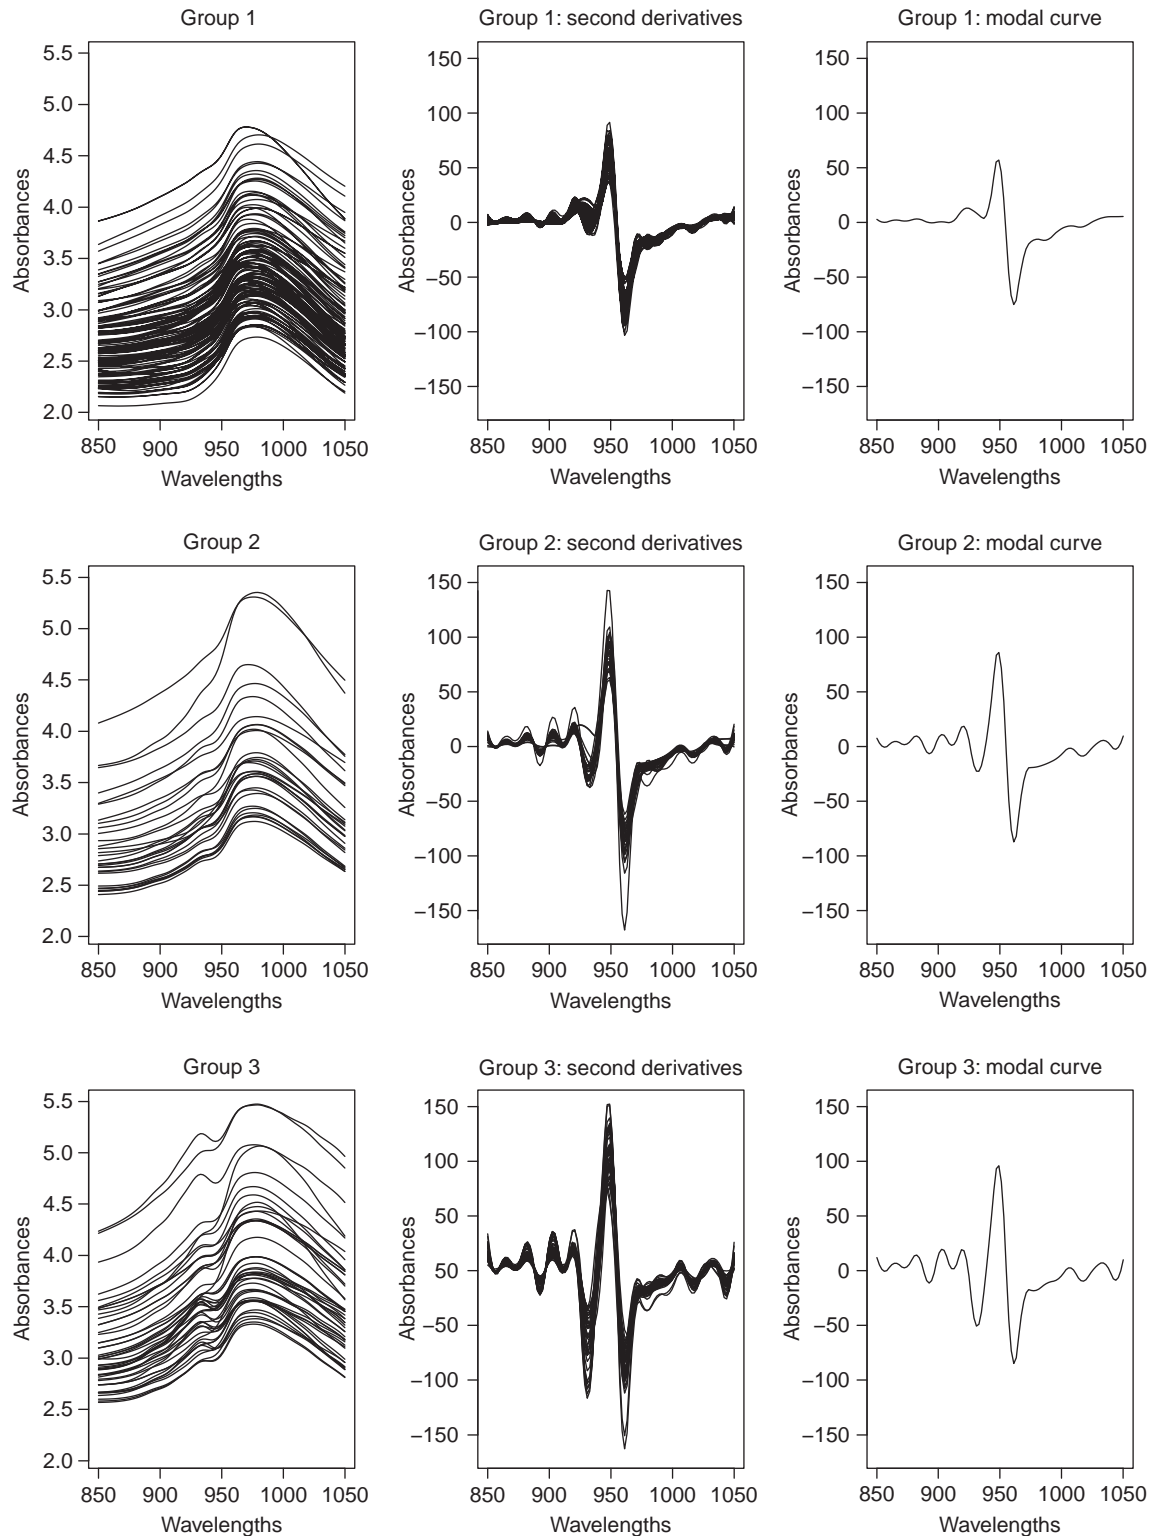

Figure 7 Unsupervised curves classification.

Phoneme Data

If one focuses on the phoneme data set (i.e., log-periodograms) which is also a curves discrimination problem, one can get a rate of misclassification around 8% (according to the functional methodology implemented).

El Niño Time Series

Let us consider now the time series El Niño. In this forecasting situation, FDA allows one to predict future values in an accurate way. **Figure 9** gives an idea of the pertinence of using such statistical methods. The solid

Figure 8 Observed responses vs predicted ones.

line corresponds to the observed values for the last year available in the used El Niño sample and the dashed one displays the forecasted temperatures.

Of course, the previous examples are not an exhaustive presentation on what one can do with FDA. There are several other settings not considered here. An important one occurs when a functional data set proposes a population of curves with measurements changing from one unit to another one (i.e., one has at hand the values $X_i(t_{i_1}), \dots, X_i(t_{i_{p_i}})$, where the measurements $t_{i_1}, t_{i_2}, \dots, t_{i_{p_i}}$ depend on the individual i). This means that, from a standard multivariate point of view, the variables $X_i(t_{i_1}), \dots, X_i(t_{i_{p_i}})$ (even their number) are not the same from one individual to another one, which prevents the use of any standard multivariate statistical analysis. Such data sets are called unbalanced functional data. For instance, this situation can occur when the starting point of the measurements is not the same for each unit. In order to analyze such data sets, preprocessing procedures like curves registration methods or time-warping techniques have been developed. Another interesting case of functional data appears when, for each curve, one gets a few measurements. In such a situation, one says that the functional data are sparse. Such functional data sets require specific methodologies. Other useful developments covering a large

Figure 9 Forecasted/observed values.

number of statistical situations and extending the generalized linear model to the functional data setting have been investigated. Good recent overviews on FDA methodologies as well as potentialities in terms of applications can be found in special issues of various statistical journals entirely devoted to this area: Davidian *et al.* (2004), González-Manteiga and Vieu (2007), and Valderrama (2007) (see also the recent proceedings edited by Dabo-Niang and Ferraty, 2008).

Conclusion

FDA covers a wide area of statistics. Indeed, according to recent works on this topic, one can imagine that several standard statistical methods will be extended in order to take into account functional data. One can also imagine the huge potential of such new statistical methodologies in terms of applications. Indeed, the newness of FDA implies that numerous fields of potential applications are underdeveloped or not investigated up to now. This is the case about educational data. However, phoneme

functional data could be a good example in relation with educational domain. It is clear that one can obtain measurements on children and with FDA techniques, identify some of them with problems such as speech defects. Any study which allows one to get a continuous trajectory for each individual can be analyzed through functional data methods.

It is clear that we have given here a concise overview on FDA in a pedagogical manner. Therefore, only functional data as curves have been presented. In order to complete this curve-based point of view on functional data, it is worth mentioning that FDA can deal with populations of any more high dimensional objects. For instance, with the progress of technologies, it is now possible to collect samples of images (2D-images, multispectral images, hyper-spectral images, etc.). These result in spatio-functional data. This promising recent area in terms of applications is underdeveloped, but certainly future investigations will enlarge our knowledge in this domain.

Statistical Inequalities

H M Mahmoud and J L Gastwirth, The George Washington University, Washington, DC, USA

Markov's Inequality

Discovered around 1905, Markov's inequality bounds a probability for a non-negative random variable by its mean. The inequality is usually stated in the following form.

Let X be a nonnegative random variable, with finite mean μ . Then, for any $a > 0$,

$$P(X \geq a) \leq \frac{\mu}{a} \quad [1]$$

We shall not give many proofs in this article, but shall provide this derivation, which is indicative of the type of proof involved in a class of inequalities related to or derived from this basic one.

The proof proceeds by decomposing the range of possible values for the expression of the mean (expected value) into two parts. For a continuous random variable X with density $f(x)$,

$$\begin{aligned} E[X] &= \mu \\ &= \int_{x=-\infty}^{\infty} xf(x)dx \\ &= \int_{x=0}^a xf(x)dx + \int_{x=a}^{\infty} xf(x)dx \\ &\geq \int_{x=a}^{\infty} xf(x)dx \\ &\geq \int_{x=a}^{\infty} af(x)dx \\ &\geq aP(X \geq a), \end{aligned}$$

which establishes the inequality.

The proof is the same for discrete random variables, with the integrals being replaced with sums. In fact, in the more general theory, the proof is the same, with all integrals being assumed to be Lebesgue integrals (and then, discrete sums and standard integrals follow as special cases).

To illustrate the bound obtained from Markov's inequality, suppose X is a Poisson(3) random variable (with mean 3 and variance 3), following the probability law

$$P(X = k) = \frac{3^k e^{-3}}{k!}, \text{ for } k = 0, 1, 2, \dots$$

The probability that X exceeds its mean, is the probability that X is at least 4. With $\mu = 3$ and $a = 4$, Markov's inequality (1) gives the bound

$$P(X \geq 4) \leq \frac{3}{4} = 0.75$$

In this case, one can calculate the exact probability from the Poisson distribution, namely

$$P(X \geq 4) = \sum_{k=4}^{\infty} \frac{3^k e^{-3}}{k!} \approx 0.32768,$$

well below Markov's bound. In general, one does not expect Markov's inequality to be sharp, as it is general; it is valid for all distributions, and only uses the mean. Two different distributions can have the same mean but quite different tail probabilities.

Chebyshev's Inequality

A special interpretation of Markov's inequality yields an inequality attributed to Chebyshev, which is widely used.

Consider the random variable $|X - \mu|$ (which is, of course, always non-negative), where μ is the mean of X . Then

$$P(|X - \mu| \geq a) = P((X - \mu)^2 \geq a^2) \leq \frac{E[(X - \mu)^2]}{a^2} = \frac{\sigma^2}{a^2} \quad [2]$$

where σ^2 is the variance of X .

The variance form is the most common in application, but it should be noted that it is a special case of a more general inequality, which takes the form

$$P(|X - \mu| \geq a) \leq \frac{E[\phi(X)]}{\phi(a)}$$

where $\phi(u)$ is a symmetric nonnegative function that is increasing on $(0, \infty)$. For example, with $\phi(u) = u^4$, and $\mu = 0$, we have a bound involving the fourth moment:

$$P(|X| \geq a) \leq \frac{E[X^4]}{a^4}.$$

Generally speaking, the inequality is sharper when higher moments are used; that is why the usual Chebyshev's inequality [2] is preferable to Markov's inequality [1].

One does not expect Chebyshev's inequality to always be sharp, since it is valid for all distributions. For most distributions, and values of a , formula [2], gives a conservative upper bounds. For example, suppose Z is the standard normal random variate, with mean 0 and variance 1. According to Chebyshev's inequality, the probability that Z falls within two standard deviations away from 0, is bounded above:

$$P(|Z| \leq 2) \geq 0.75.$$

Using the fourth moment instead, one obtains a closer bound

$$P(|Z| \leq 2) \geq \frac{E[Z^4]}{2^4} = \frac{3}{16} = 0.8125,$$

as $P(|Z| \leq 2) = 0.95$ (approximately).

It should also be pointed out that Chebyshev's inequality provides the sharpest inequality that is valid for all distributions. This can be demonstrated by the following example, where the inequality is attained. Consider the three-valued family of random variables

$$X = \begin{cases} \mu + k\sigma, & \text{with probability } \frac{1}{k^2}; \\ 0, & \text{with probability } 1 - \frac{1}{2k^2}; \\ \mu - k\sigma, & \text{with probability } \frac{1}{k^2}. \end{cases}$$

The mean of this random variable is σ and the variance is σ^2 . Typically, one desires a bound on events of the type $|X| \geq k\sigma$. Chebyshev's inequality gives

$$P(|X| \geq k\sigma) \leq \frac{1}{k^2}.$$

In this specific example,

$$P(|X| \geq k\sigma) = P(|X| = k\sigma) = \frac{1}{k^2}.$$

so, Chebyshev's inequality is attained.

Gauss' Inequality

We mentioned that in the absence of additional information, Chebyshev's inequality is sharpest. Nonetheless, additional knowledge, such as symmetry of the distribution, or unimodality, leads us to craft sharper inequalities. When both properties are known to hold, there is the classic inequality, due to Gauss: for a symmetric unimodal random variable X , with mean μ and variance σ^2 , the inequality

$$P(|X - \mu| \geq t) \leq \frac{4\sigma^2}{9t^2}. \quad [3]$$

holds for $t^2 \geq \frac{4}{3}\sigma^2$. Note that this is sharper than Chebyshev's inequality, because the factor $\frac{4\sigma^2}{9t^2}$ is less than $\frac{\sigma^2}{t^2}$ (the bound in Chebyshev's inequality), but keep in mind that the validity of Gauss inequality is restricted to symmetric unimodal distributions.

Again consider the event $P(|Z| \leq 2)$, where Z is a standard normal variable (which is symmetric and unimodal). Using Gauss' inequality [3] gives us the lower bound

$$P(|Z| \leq 2) \geq \frac{8}{9} \approx 0.8889,$$

which is a noticeable improvement over the lower bound of 0.75 obtained from Chebyshev's inequality and is quite close to the actual value of about 0.95.

Cantelli's Inequality

It should be noted that there is a less-known inequality similar in nature to Chebyshev's: Cantelli's inequality (also known as the one-sided Chebyshev's inequality). Let X be a random variable with mean μ and variance σ^2 . For any $a > 0$,

$$\begin{aligned} P(X - \mu \geq a) &= P(X - \mu + x \geq a + x) \\ &\leq P(|X - \mu + x| \geq a + x) \\ &\leq \frac{E[(X - \mu + x)^2]}{(a + x)^2} \\ &= \frac{\sigma^2 + x^2}{(a + x)^2}, \end{aligned}$$

valid for every $x > 0$. In particular, it is valid for the positive value of x that minimizes the right-hand side. By differentiation, the value $x_0 = \sigma^2/a$ can be shown to minimize the function $(\sigma^2 + x^2)/(x + a)^2$. It follows that

$$P(X - \mu \geq a) \leq \frac{\sigma^2 + x_0^2}{(x_0 + a)^2} = \frac{\sigma^2}{\sigma^2 + a^2}, \text{ for any } a \geq 0. \quad [4]$$

In terms of distances measured in standard deviations, the inequality is

$$P(X - \mu \geq k\sigma) \leq \frac{1}{k^2 + 1}.$$

Cantelli's inequality can be tight. Consider, for example, a Bernoulli ($\frac{1}{2}$) random variable B , which assumes the value 0 with probability $\frac{1}{2}$ and the value 1 with probability $\frac{1}{2}$, and take $a = \frac{1}{2}$. Cantelli's inequality gives

$$P(B - \frac{1}{2} \geq \frac{1}{2}) \leq \frac{1}{2}.$$

However,

$$P(B - \frac{1}{2} \geq \frac{1}{2}) = P(B \geq 1) = P(B = 1) = \frac{1}{2}.$$

so, Cantelli's bound is attained.

Let us revisit the Poisson(3) example we discussed in the section on Markov's inequality [1], and consider the event that it exceeds 5. According to Cantelli's inequality [4], a random variable X with this distribution satisfies

$$P(X \geq 5) = P(X - 3 \geq 2) \leq \frac{3}{3 + 4} \approx 0.42857,$$

while Markov's inequality gives

$$P(X \geq 5) \leq \frac{3}{5} = 0.6,$$

while both exceed the true value 0.185 (approximately), clearly Cantelli's inequality is sharper.

Inequalities for Moments

So far, the common inequalities for the probability of an event have been described and they all involve moments.

It is useful to have inequalities for the moments themselves. We shall very briefly sketch the most salient ones. These inequalities appear more often in advanced topics and measure-theoretic proofs, where a careful argument is usually made about the existence of the moments involved. In the following, the moments are assumed to exist and are finite.

Jensen's Inequality

This inequality states that for any random variable X and convex function ϕ ,

$$\phi(E[X]) \leq E[\phi(X)].$$

A standard use of this inequality assures that the variance

$$\text{Var}[X] = E[X^2] - (E[X])^2$$

is non-negative. This follows from convexity of the function $\phi(u) = u^2$.

Hölder's Inequality

Suppose $p, q > 0$, such that $\frac{1}{p} + \frac{1}{q} = 1$. For two random variables X and Y , we have,

$$E[|XY|] \leq (E[|X|^p])^{1/p} (E[|Y|^q])^{1/q}.$$

The quantity $(E[|X|^p])^{1/p}$ is called the p th norm of X , and is often denoted by $\|X\|_p$ (it has all the properties of distance function in the space $\|X\|_p$ of random variables). Hölder's inequality can then be expressed in the notation

$$E[|XY|] \leq \|X\|_p \|Y\|_q.$$

The special case $p = q = 2$ is known as the Cauchy–Schwarz inequality.

Minkowski's Inequality

Hölder's inequality takes a multiplicative form. It is used in the proof of a moments inequality in additive form, called Minkowski's inequality. This inequality generalizes the triangle inequality. For $p \geq 1$,

$$\|X + Y\|_p \leq \|X\|_p + \|Y\|_p.$$

Lyapunov's Inequality

Lyapunov's inequality follows immediately from Hölder's. For any $0 < r < s$,

$$\|X\|_r \leq \|X\|_s.$$

It is usually employed in arguments used to show that specific moment exists. Once it is known that s th moment exists (i.e., it is finite) for some $s > 0$, all lower order moments exist. For instance, if one knows that the fourth moment exists, one is assured of the existence of the first three moments. A typical application is when the second moment exists. In this case, the first moment (the mean) also exists.

Concluding Remarks

We discussed the most common types of inequalities for the probabilities of random variables. There are other families of inequalities that apply to sums of independent random variables. Kolmogorov's inequality stands out as an epitome of the members of the family (see Billingsley, 1995). Another type of inequalities uses the moment-generating function to bound probabilities. Two important inequalities from this class are Chernoff's and Hoeffding's inequalities (see Chernoff, 1952; Hoeffding, 1963).

Statistical Paradoxes

Y-K Tu, University of Leeds, Leeds, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

There are many statistical paradoxes in the literature. They gain the reputation as paradoxes, because they often generate confusion or a misleading interpretation of simple data presentation for the unprepared mind. In particular, these paradoxes challenge our ability to decipher causes and effects from nonexperimental observations. This article discusses two well-known statistical paradoxes that have pervaded quantitative research for more than a century. One is the reversal paradox also known as Simpson's paradox in contingency table analysis or Lord's paradox in the analysis of covariance, and the other is regression to the mean. These paradoxes are not only interesting puzzles for intellectual amusement but potentially have a serious impact on the interpretations of evidence from observational educational studies and, more importantly, on public policymaking. In this article, we discuss how these paradoxes occur and how to resolve them.

Simpson's Paradox, Lord's Paradox, and Reversal Paradox

Simpson's paradox, or more appropriately Yule's paradox, is a well-known statistical phenomenon. It is observed when the relationship between two categorical variables is reversed after a third variable is introduced to the analysis of their association, or alternatively where the relationship between two variables within subgroups is different from that of the aggregated data. Although first discussed by Karl Pearson in 1899, it is George Udny Yule, once Pearson's assistant, who provides a detailed treatment of this problem in 1903. A famous example of Simpson's paradox in education is that given by Bickel and co-workers in 1975, regarding real admission rates of male and female students to the University of California, Berkley. Overall admission rates were significantly lower for females than males, yet, females tended to have higher admission rates than males within individual departments. The explanation is that the number of female applicants as a proportion of the total female applicants tended to be high within departments that were also hard to gain entry to and low in those that were easier to enter.

Lord's paradox was named after two short articles published in the psychology literature by Frederick M Lord regarding the use of analysis of covariance (ANCOVA) within nonexperimental studies. Lord's paradox refers

to the relationship between a continuous outcome and a categorical covariate being reversed when an additional continuous covariate is introduced to the analysis. The additional covariate is often a measure made at the start of a study, or at baseline within a longitudinal study, where the outcome is the same variable measured some time later (e.g., following an intervention). The aim is to measure change in the outcome by adjusting for the baseline measurements, and the categorical covariate might be the intervention/control groups – this is the familiar design for ANCOVA. However, Lord's paradox may occur in circumstances not related to the use of ANCOVA, where a covariate is measured at baseline or at the same time as the outcome.

Using Lord's original hypothetical example, consider a group of first-year university students, where body weight is measured on entrance and again 1 year later, to investigate whether or not refectory food has any impact on their weight, and moreover whether or not any such impact differs by gender. Body weight data are then subjected to two types of statistical analysis. The first is to use a paired *t*-test for the difference in weight between measurement occasions. Results reveal no significant difference across all students, and similarly for each gender separately. The independent *t*-test also shows no differences in the changes of weights between genders. One might therefore conclude that refectory food has no significant impact upon body weight among male and female students. The second approach is to use ANCOVA, since it is observed that there are weight differences among males and females at baseline and since ANCOVA adjusts for baseline differences. Results reveal that, after adjustment for baseline weights, males gained weight on average, whereas females lost weight. This is clearly contradictory to the conclusions of the first analysis. The question is which is correct. Specifically, did refectory food have any differential gender effect on student weights? This controversy was first discussed in 1910 between Karl Pearson and Arthur C Pigou when they debated the role of parental alcoholism and its impact on the performance of children; the whole incident is discussed by Stephen Stigler in the first chapter of his book, *Statistics on the Table*.

Both Simpson's paradox and Lord's paradox are the manifestations of the generic reversal paradox, that is, the relationship between two variables is reversed when a third variable is adjusted for. In Simpson's paradox the three variables involved are all categorical variables, whereas in Lord's paradox two are continuous and one

is a categorical variable. Reversal paradox can also occur among three continuous variables. The reverse of the associations between variables after the adjustment of another one is not uncommon in statistical modeling: a problem known as collinearity or multicollinearity. From a purely mathematical viewpoint, the direction of association between two variables (one outcome and one explanatory variable) is determined by their correlations with other explanatory variables in the model, and it should therefore be anticipated that the relationship between two variables in simple regression or correlation may sometimes become different from that in multiple regression or partial correlation in terms of the effect size or even the direction.

So why do we still feel fascinated or confused when the reversal paradox does occur? Although the mathematics behind the reversal paradox is not overly complex, it can be quite cumbersome to make causal interpretation of the results in the context of real life research. For instance, in a recently published study on the effect of pupil movement on school differences in educational achievement, it has been found that the normalized mathematics scores assessed at key stage 2 (KS2, year 6 in primary schools in England) were positively associated with pupils' ages (in months) at this stage of schooling (0.029, standard error = 0.003) in 9226 pupils of 241 schools in Staffordshire, England. The authors stated that this finding is expected as it is known that age is related to attainment at this stage of schooling because older children may develop better cognitive ability. However, this positive association was reversed when the test scores at key stage 1 (KS1, assessed at year 2) were included as a covariate in the so-called traditional value-added analysis. The association between KS2 mathematics scores and ages was reversed from 0.029 to -0.014 ($SE = 0.002$), whereas the association between KS2 and KS1 mathematics was, as expected, positive (0.754, $SE = 0.006$). The interpretation given by the study is that given their KS1 performance younger children do better, indicating that they tend to catch up over this period. A similar finding has been found previously. Statistically, this reverse in the direction of association between KS2 performance and age is not hard to explain: (1) the positive correlation between age and math performance was stronger at KS1 than at KS2 and (2) KS1 and KS2 math scores were also positively correlated. Hence, the positive association between age and KS2 math score in the multiple regression was reversed due to collinearity. The standard interpretation as suggested by textbooks on regression analysis would be that after adjusting for their KS1 math score, there is a difference of 0.014 standard deviation in KS2 math score between pupils with 1-month difference in their age. In other words, the advantage of being older in school in terms of KS2 math score in the simple regression analysis seems to turn into a disadvantage in multiple regression analysis after the adjustment of

KS1 math score. The key question is: are older children doing better or worse than younger ones in KS2 math performance?

To simplify our discussion, let us assume all other confounders, for example, parents' ethnic group, and educational and socioeconomic background, are not correlated with both the math performance and pupils' ages. According to the simple regression analysis, older children, for example, who were born in September, October, or November, were doing better in KS2 math performance than those who were born in August, July, and June of the following year. Therefore, teachers may be expected to give additional attention to younger children. However, according to the results of the multiple regression analysis, the reverse is true, and teachers are expected to give more attention to older children in the class. Which is true?

Let us consider the explanation given by the authors of the original study. As the focus of the original study is not the relationship between pupils' age and math achievement, the authors only gave their interpretation in passing. According to the authors, the reversal of the association between age and KS2 math score after adjusting for KS1 math score seems to suggest that younger children catch up over the period between year 2 and 6, that is, the advantage of being older was more evident in early schooling than later, probably because up to a certain age, all children will on average develop the same level of cognitive ability in mathematics. Therefore, the authors' interpretation seems to be quite plausible. However, this does not directly answer the question: are older children doing better or worse at KS2? And what is the relationship between pupils' age and their math performance at KS2?

The paradox is mainly caused by the difference in the results of unconditional (simple regression) and conditional (on KS1 math score in multiple regression) analysis. Had the regression coefficient not been reversed, it would probably not be a problem at all. The main challenge is to properly interpret the conditional relationship between pupils' age and KS2 math score. If we imagine that pupils' age is a binary variable (i.e., old vs. young), statistically speaking, the unconditional analysis is to compare the sample means of KS2 math scores between different age groups, but the conditional analysis is to compare the adjusted means (i.e., the predicted means for the age groups if they had the same KS1 score) between the age groups. In the latter analysis, we statistically coerce children of different age groups to have the same KS1 math score and then compare their expected means. **Figure 1** illustrates the differences in the comparisons of group means between the unconditional and conditional analyses. The average math test scores of older children at KS1 and KS2 (O_{KS1} and O_{KS2} , respectively) were better than those of younger children at both KS1 and KS2 (Y_{KS1} and Y_{KS2} , respectively).

However, when KS1 was adjusted for as a covariate, the adjusted mean of KS2 for younger children moved up and right along the parallel regression slope (the gray line on the top) and the adjusted mean of KS2 for older children moved down and left along the slope (the other gray line in the figure). The difference in the adjusted means was the difference in the vertical height of the two parallel slopes (the short black line between the ends of the two arrows).

From a causal point of view, did pupils' age cause better or poorer performance in KS2 math? **Figure 2** is a directed acyclic graph which has become popular in statistics and epidemiology in recent years with regard to the discussion of making causal inference in nonexperimental studies. To keep our discussion simple, we again assume that all other confounding variables can be safely ignored. The arrows in **Figure 2** show that Age causes better math scores at both KS1 and KS2. Note that although Age is the pupils' age at key stage 2, older (younger) children in the class were already older (younger) when they first started school. The arrow from KS1 to KS2 means that pupils who achieved better scores at KS1 also performed better at KS2. As KS1 is on the causal pathway from Age to KS2, and therefore should not be adjusted for, if our aim is to assess the overall impact of Age on KS2. The adjustment of KS1 gives rise to a counterfactual interpretation that if all pupils had the same KS1 score, older children did less well than younger ones, whereas older children actually achieved better KS1 score.

Figure 1 Illustration of reversal paradox – KS1: mathematics scores at key stage 1; KS2: mathematics scores at key stage 2; O_{KS1} : KS1 for older children; Y_{KS1} : KS1 for younger children; O_{KS2} : KS2 for older children; and Y_{KS2} : KS2 for younger children.

Figure 2 Directed acyclic graph for the causal relationships between KS1, KS2, and Age.

So what do the results of conditional analysis really suggest? The conditional analysis suggests that for younger children who did as well as older children at KS1, they would do better than older children at KS2. This may be plausible, as those young children might be brighter than average, so they could achieve the same score as the average older children at KS1 and then do better at KS2. Therefore, the interpretations of the relationship between pupils' age and their KS2 math score between the conditional and unconditional analysis are no longer contradictory, as the unconditional analysis refers to a general statement on the relationship between pupils' age and their performance at KS2, whereas the conditional analysis refers to a more restricted situation where only a subgroup of young children were selected to compare to average older children.

Regression to the Mean

In December 2007, a report for a charity called the Sutton Trust in the United Kingdom appeared as a headline on the BBC news. By analyzing data from children born in 2000 and 2001 (from the Millennium cohort) in the UK, the study claimed that less bright children from rich families are catching up with bright children from poor families in developmental tests between ages 3 and 5 and are expected to overtake them by the age of 7 (**Figure 3(a)**). Therefore, this study seemed to suggest that the environment in which children grow up has a dominant influence on their test performance in school even at a very early stage of cognitive development. If this conclusion is valid, it would have very important implications for policymaking. Indeed, one major political party leader in the UK referred to these results in an interview with the BBC in April 2008, when he was talking about the vision of his party. Though **Figure 3(a)** seems to suggest that children from poor families who did well in the tests at age 3 did less well at age 5 and children from rich families who did poorly in the tests at age 3 did better at age 5, this converging trend in the test results of cognitive development between these two groups of children may be, however, due to the way in which the data are presented. To help clarify why the observed convergence in the test results does not provide evidence for an association between cognitive development and inequality in family background, it is very useful to revisit how Sir Francis Galton discovered the phenomenon of regression to the mean, more than a century ago, when he was studying the inheritance of body height.

Galton and Regression to the Mean

Galton was interested in the inheritance of human intelligence, as he was an important figure in the eugenic

Figure 3 Trends in the children vocabulary test scores between age 3 and 5 when children are grouped by their scores at age (a) 3 or (b) 5.

movement in nineteenth-century Britain. However, as there were no reliable measures for intelligence, he turned to human body measurements. Galton invited families to his laboratory to measure their body heights. As men on average were taller than women, women's heights were multiplied by 1.08. He then plotted the average of both parents' heights (he called it mid-parent height) against their offspring's height. To his great surprise, although adult children of tall parents were still taller than most people, they were on average shorter than their parents. On the other hand, adult children of short parents, while still short, were on average taller than their parents. Galton named this phenomenon regression toward mediocrity, and we know it today as regression to the mean.

Nevertheless, discussions in the literature tended to overlook one important subtlety in Galton's body heights example. Galton's data not only showed that adult children of tall parents were shorter than their parents and adult children of short parents were on average taller than their parents, it also showed that parents of tall children were shorter than their parents and parents of short children were on average taller than their parents. Using the data from Galton's famous study, **Figure 4(a)** shows the trend of body heights across two generations by grouping families according to the parents' heights. Parents with body heights greater or equal to the average height (68 inches) were grouped as tall parents, and their mean body height was 69.51 inches. Parents with body heights less than 68 inches were grouped as short parents, and their mean body height was 66.66 inches. The mean body height of adult children from tall parents was 68.79 inches, and that of adult children from short parents was 67.12 inches. Therefore, human heights looked to be converging across the two generations, suggesting perhaps that, after many generations, there would be fewer very tall or very short people.

Yet, **Figure 4(b)** shows the trend of body heights across the two generations by grouping the families according to adult children's heights. Children with body heights greater or equal to 68 inches were grouped as tall children, and their mean body height was 69.89 inches. Children with body heights less than 68 inches were grouped as short children, and their mean body height was 65.77 inches. The mean body height of parents of tall children was 68.87 inches, and that of parents of short children was 67.58 inches. Therefore, human heights looked to be diverging, and after several generations there might be many more very tall or very short people. Two contradictory conclusions could thus be deduced from the same data, yet neither was true. The reason for two contradictory conclusions is that the correlation between parents and their children's heights was not perfect, and regression to the mean occurs when children's heights were regressed on their parents' heights or vice versa. Both analyses and misinterpretations suffer regression to the mean.

What Is Regression to the Mean?

Suppose Galton could have obtained the records of body heights of grandparents for his families. What would the trend have looked like? If families were grouped according to the children's heights, the trend of human body heights would look like **Figure 4(c)**. If families were grouped according to the grandparents' heights, the trend of human body heights would look like **Figure 4(d)**. The phenomenon of regression to the mean would become more notable between grandparents and children because the correlation between them was smaller than that either between grandparents and parents or between parents and children. In other words, the resemblance in the appearances between grandparents and children would be

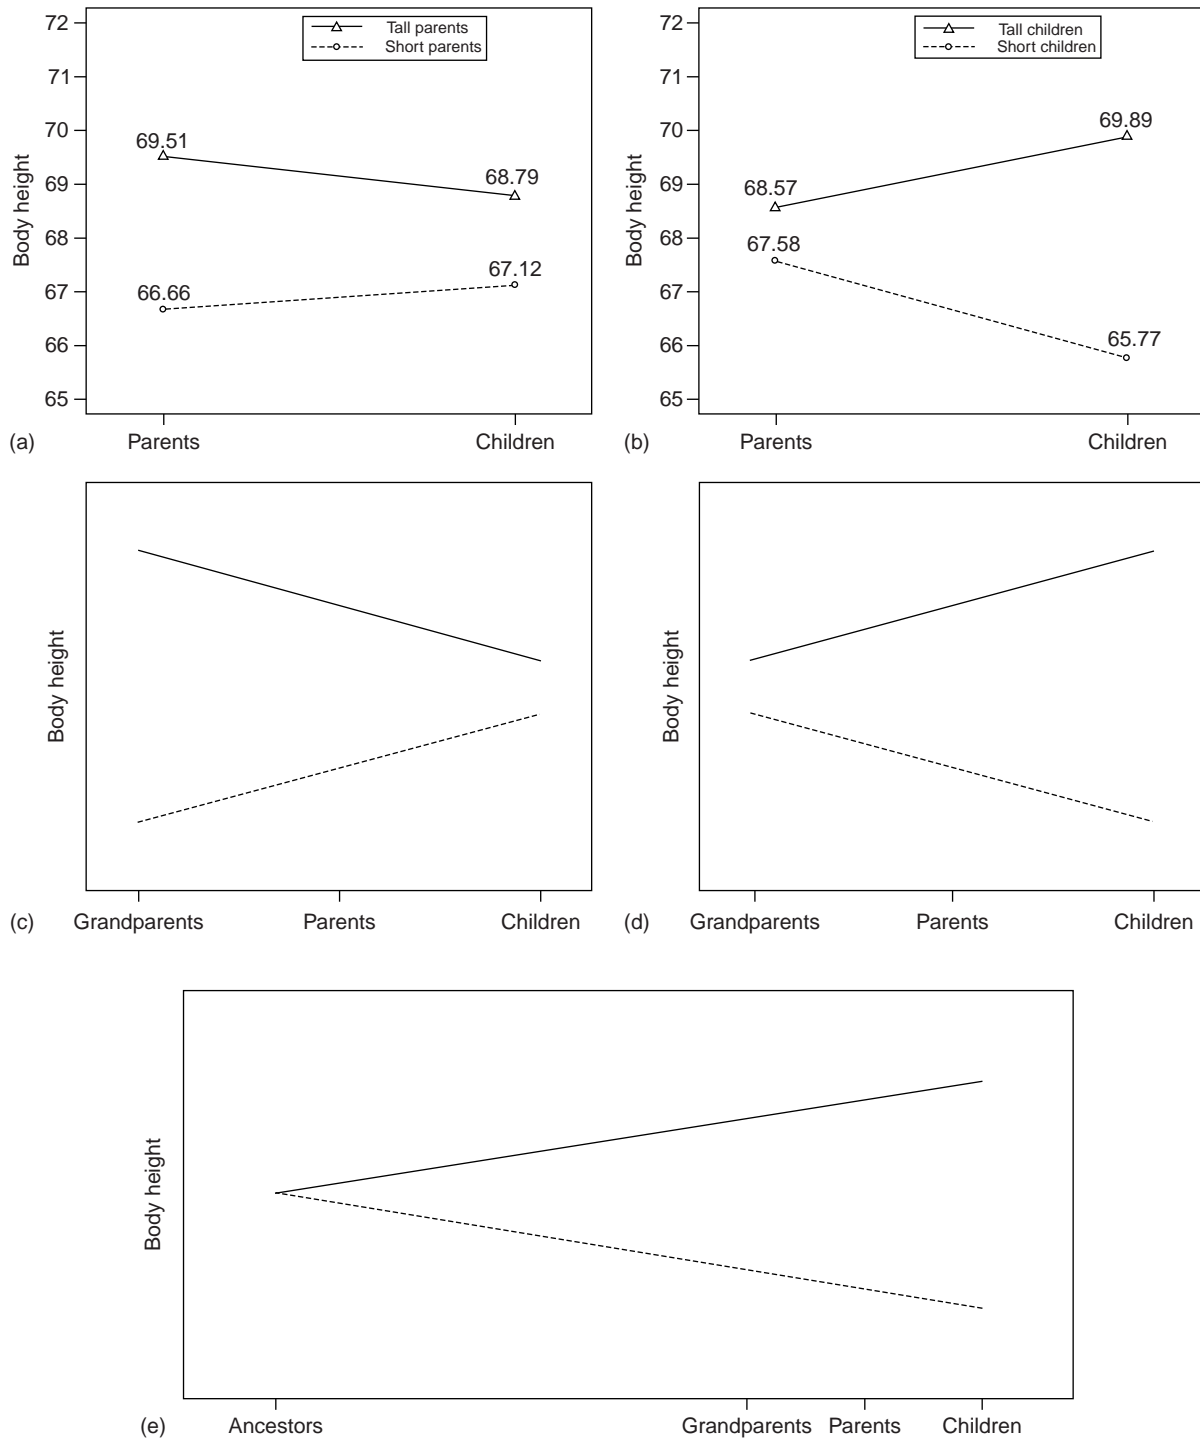

Figure 4 Trends in the body height across generations in Galton's data (a, b) and in hypothetical scenarios (c–e).

less than that either between grandparents and parents or between parents and children.

What if there was a long historical record of body heights for these families; what might the evolution of human body heights throughout several generations look like? If the families were grouped according to the heights

of children (i.e., the last generation), the trend of human body heights would look like **Figure 4(e)**. The resemblance of ancestors and descendants would diminish with time. Our appearances and characteristics have more resemblance with our parents than with our grandparents, and the resemblance between us and our ancestors

will diminish further with each increasing generation. Eventually, the resemblance between us and our distant ancestors would become unrecognizable, and, therefore, our ancestors are no more like us than an average person in their generation. This is why it is called regression to the mean, or as Galton named it regression toward mediocrity. In his seminal paper in 1886, Galton explained that the child inherits partly from his parents, partly from his ancestry. Speaking generally, the further his genealogy goes back, the more numerous and varied will his ancestry become, until they cease to differ from any equally numerous sample taken at haphazard from the race at large. Their mean stature will then be the same as that of the race; in other words, it will be mediocre.

From a statistical viewpoint, positive correlations between body heights of successive generations become smaller the farther back the genealogy goes; as a result, the phenomenon of regression to the mean becomes more remarkable. **Figure 5** is a generalization of regression to the mean between two continuous variables X_1 (ancestors' heights) and X_2 (descendants' heights), when the data are grouped according to the mean value of X_2 (as with Galton's data). When the correlation between X_1 and X_2 (r_{12}) is perfect and positive (i.e. 1), the two lines depicting the trend or trajectories in the evolution of human body heights are parallel (**Figure 5(a)**). When $0 < r_{12} < 1$, body heights appear to be diverging (**Figure 5(b)**). When $r_{12} = 0$, there is no difference in the mean of X_1 between the two groups (**Figure 5(c)**). When $-1 < r_{12} < 0$, body heights not only look to be diverging, but the two lines cross at some point between X_1 and X_2 (**Figure 5(d)**).

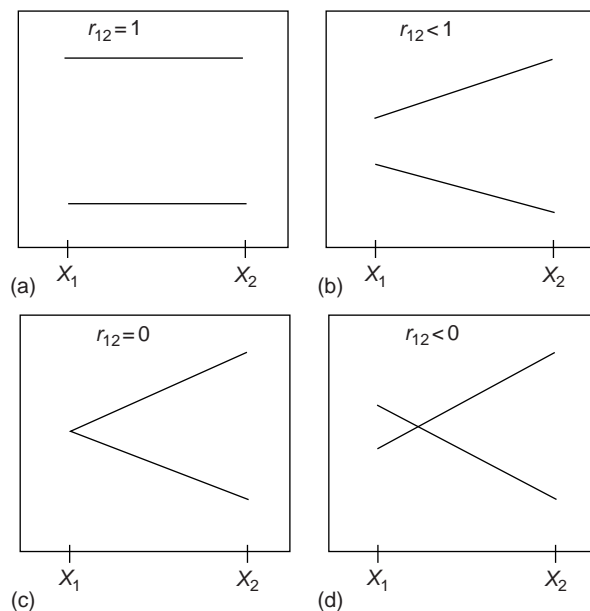

Figure 5 Patterns of trends for two repeated measurements, X_1 and X_2 . r_{12} is the correlation between X_1 and X_2 .

Revisiting the Convergence in Developmental Tests

We use the same data from Millennium Cohort analyzed by the original Sutton Trust report to produce the apparent convergence pattern in developmental tests (**Figure 3**). The variable of interest was Naming Vocabulary ability score assessed at age 3 and 5. The raw scores were then transformed into percentiles. Children were first divided into four groups by their test score in quartiles assessed at age 3. They were then further divided into rich or poor family groups according to their parents' job (professional vs. non-professional). **Figure 3(a)** shows the comparison of high-ability group (i.e., children in the top quarter of test scores) and low-ability group (children in the lowest quarter of test scores) in both rich (parents with professional jobs) and poor (parents with nonprofessional or no jobs) families. Children in the high-ability group from both rich and poor families actually did poorer in the test at age 5, although they on average still did better than those in the low-ability group whose scores were better than previously but still below the average. If this trend continues, the original report suggested that rich children in the low-ability group will overtake poor children in the high-ability group by the age of 7. Even if this convergence trend is genuine (which it is not), it is obvious from **Figure 3(a)** that all children in the high-ability group will be overtaken, irrespective of their being rich or poor.

Following our previous discussion of Galton's data, we now group children according to their test scores assessed at age 5 and their family background at age 3. The results are shown in **Figure 3(b)** in which the test performance appears to be diverging. If we follow the same line of interpretation in the original report, we may conclude that poor children in the high-ability group are doing better and better than rich children in the low-ability group. Yet, neither of the conclusions is supported by the data. Mathematically speaking, this phenomenon is due to the conditional variance of one variable being smaller than its observed variance. Because the variance of both test scores has been constrained to be equal, the variance of test scores at age 5, conditional on the scores at age 3, will become smaller than the variance of age 3. This is why we observe a convergence trend in test scores. The same applies when the variance of test scores at age 3 is conditional on test scores at age 5, and we will therefore observe a diverging trend. Grouping individuals according to their baseline or final values to investigate the trend in the change is in general misleading and should be avoided. Many people, including prominent statisticians and economists, have fallen into this trap.

The investigation of whether inequalities in socioeconomic background have a dominant influence on children's development of cognitive ability is important and will require longitudinal observations. One approach will

be looking at the general trend in the cognitive development for children from different socioeconomic backgrounds. If environment is influential, we may simply observe that rich children in general make greater progress than poor children, or if family background is more important to children with low ability, we may observe a smaller variance of test scores in children from rich families than that of children from poor families, that is, there will be a convergence within rich children.

Conclusion

With the increasing power of personal computers and wide availability of user-friendly statistical software packages, most statistical analyses only take seconds to get the results. However, the reduction in time for computing does not reduce the need for proper understanding and careful thinking. The two statistical paradoxes discussed in this article remind us that there are many traps on the road to our quest for truth, waiting for the unwary to fall into. To infer causality from nonexperimental observations is notoriously difficult, and the two examples in this article illustrate that even simple analysis and data presentation can be seriously misleading. These statistical paradoxes have been discovered a long time ago and repeatedly discussed in the literature, but, as Stigler commented, they never lose their power to surprise.

Statistical Power Analysis

Glossary

Intraclass correlation – In two stage samples that first sample intact groups (statistical clusters) and then sample individuals with the groups, the intraclass correlation is the ratio of between-group variance to total variance. It is used to describe the degree of clustering within samples.

Multilevel (multistage) sample – A sample that first obtains a sample of intact groups (statistical clusters) and then samples individuals within the groups. Statistics based on multilevel samples (also called multistage samples) have different properties than those based on simple random (one level) samples.

A critical aspect of planning any research design is ensuring that it is well enough designed to provide definitive evidence for the phenomenon under investigation. Power analysis is used to ensure that a study will have an appropriate chance of yielding a statistically significant result, given the treatment effect that is expected. Power analyses are required as part of proposals for funding research, and it would be almost unthinkable to embark on a large-scale study without conducting a power analysis. This article is an introduction to power analysis for research designs that are most often used in education research.

Statistical Hypothesis Testing

The dominant form of statistical inference in educational research involves hypothesis testing. A null hypothesis that is inconsistent with the research (or alternative) hypothesis of the investigation is formulated. If the observed data would have only a very small chance of occurring if the null hypothesis were true, then the null hypothesis is rejected in favor of the research hypothesis.

Formal hypothesis testing usually requires the explicit specification of how unlikely the test statistic must be to lead to rejection of the null hypothesis. This is typically a small number such as 5% (0.05) or 1% (0.01). This small number is called the significance level (often denoted by the Greek letter α).

Statistical power is the probability of making the correct decision to reject the null hypothesis when it is false. The statistical power of a research design represents the

chance that, if the researcher's substantive hypothesis is correct, the research design will lead to the correct conclusion that the research hypothesis is true.

Statistical power always depends on the research design, the statistical significance level (α), the effect size, and the sample size. The power of the design depends on how that design is organized (e.g., if covariates are used, how the sampling and/or randomization is carried out). All other things being equal, a smaller significance level reduces power. All other things being equal, a design with a larger sample size will have higher statistical power. Finally, statistical power depends on the effect size, which is a quantification of how false the null hypothesis is. All other things being equal, the larger the effect size, the higher the power. In more complex designs, there are also additional factors that affect power.

Only the type of research design, the significance level, and the sample size can, in principle, be changed by the investigator. However, there are often practical constraints on the research designs that can be used. Moreover, a strong scientific convention makes it virtually impossible to utilize significance levels larger than 0.05. The effect size is determined by the phenomenon under investigation, so it cannot be changed. This implies that sample size is usually the only factor that can be easily changed to increase statistical power.

Statistical Power Analysis

Statistical power analysis involves deciding on a specific type of design and a statistical significance level (frequently $\alpha = 0.05$) and then investigating the three inter-related factors of sample size, effect size, and power.

Power analysis might start with a particular sample size and an effect size (often the smallest effect deemed by the investigator to be of scientific interest) and then compute the statistical power. If the statistical power is unacceptably low, the investigator may choose to increase the sample size or change the research design in fundamental ways (such as introducing covariates) to obtain higher power.

Alternatively, power analysis might start with a desired power (e.g., 0.80) and an effect size, and compute the smallest sample size that yields the specified power. Or, power analysis could start with the desired power and the sample size and then compute the smallest effect

size that would yield the specified power, called the minimum detectable effect size.

Retrospective power analyses are sometimes conducted after a study has been completed to better interpret a finding of no statistically significant effect. The question is whether the study had sufficient power to detect the smallest effect size that is scientifically important. If not, failure to reject the null hypothesis does not provide strong confirmation that the effects are too small to be scientifically important.

Procedures for Power Analysis

Regardless of the type of research design involved, the procedure for carrying out statistical power analyses is the same, utilizing tables that relate power to significance level, sample size, and effect size. Different designs have different natural effect size measures that will be used in power analysis. The exact procedure depends on the specific goal of the power analysis, but generally the specific design and a significance level (usually $\alpha = 0.05$) is chosen first. We illustrate the procedure using **Table 1**, a table of power values obtained using the noncentral t -distribution that is appropriate for several designs.

Computing power for fixed sample size and effect size

Finding the power associated with a given sample size and effect size involves entering the table at the row for the appropriate sample size and then moving to the column of that row for the appropriate effect size and reading the entry, which is the power value. This procedure is the same regardless of whether it is conducted prospectively or retrospectively.

Computing sample size for fixed power and effect size

Determining the sample size that will result in a fixed power (often 0.80) for a fixed effect size can also be accomplished with a table such as **Table 1**. First, enter the table in the column corresponding to the appropriate effect size. Then, read down the column until the power value for a row is as large as desired or larger. The sample size corresponding to that row is the desired sample size. Some sources (such as Cohen, 1988) make the process easier by providing different tables giving the minimum sample sizes necessary to obtain a specified power (usually 80%) for various effect sizes.

Computing the minimum detectable effect size

Using a table such as **Table 1**, enter the table on the row corresponding to the appropriate sample size. Then, move across the row until the power is at least the desired value (e.g., 0.80). This value will be approximately the minimum detectable effect size. The value is approximate because

the desired power value may not occur exactly in that row for any tabulated effect size, so that the desired power occurs for an effect size that is in between those defining columns of the table. A more accurate value of the minimum detectable effect size can be obtained by interpolation.

Designs Comparing Independent Groups Using Simple Random Samples

Perhaps the most common research design compares the outcomes in independent groups that differ in a specific way (e.g., receive different treatments). Experiments with completely randomized designs and quasi-experiments using the nonequivalent control group design are examples of these designs. In this section, we consider only experiments that use simple random samples (e.g., subjects all in one school or sampled independently from several schools) and not experiments with more complicated sampling designs (such as those that assign whole schools to the same treatment). Some of these more complicated designs will be considered later.

Effect size

The statistical analyses of these designs may involve the analysis of variance to test a null hypothesis that several groups have identical means. However, such designs are almost always planned by examining the power of the contrast between a particular pair of groups, such as a control group with one of the treatment groups. As a consequence, the most relevant power analysis for planning the design would be the power of that contrast. The effect size for comparing two groups is Cohen's d , defined by

$$d = (\mu_1 - \mu_2) / \sigma$$

where μ_1 and μ_2 are the population means and σ is the within-treatment group standard deviation in the experiment.

How should an effect size be chosen for power analysis?

Choosing the smallest effect size that is scientifically important is a matter of judgment and experience. The effect size d is intuitive to many educational researchers and is widely used in meta-analysis. Consequently, there are many sources of data on d values actually obtained in educational research. Compendia of effect sizes in meta-analyses by Lipsey and Wilson (1993) and other compendia by Bloom *et al.* (2007) may be particularly useful. A somewhat outdated and potentially misleading guideline was offered by Cohen (1988): an effect size of $d = 0.20$ is small, $d = 0.50$ is medium, and $d = 0.80$ is large. These guidelines should be used only if there is no

other information that could be used to judge the smallest effect size that is likely to be scientifically important.

Example of computing power using Table 1

Suppose that we are interested in determining the statistical power of an experiment that contrasted a treatment group with a control group with $\alpha = 0.05$ level of significance, a sample size of $N = 30$ per group, and an effect size of $d = 0.30$. Entering **Table 1** on the row for $N_0 = 30$ and moving across to the column for an effect size of $d_0 = 0.30$, we read the power value of 0.21. How large would the sample size have to be in order to obtain a power of 0.80? To find it out, we enter the table in the column for the effect size of 0.30 and move down the rows until we reach a power value of 0.80 or larger. Doing so yields a sample size of $N = 180$ per group. Alternatively, we might ask what the minimum detectable effect size is for a power of 0.80 and a sample size of $N = 30$. Entering the table on the row for $N_0 = 30$ per group and moving across the columns of the table, we see that an effect size of $d_0 = 0.70$ yields a power of 0.76 and an effect size of $d_0 = 0.80$ yields a power of 0.86; thus, the minimum detectable effect size is between $d = 0.70$ and $d = 0.80$. Interpolating, we see that a power of 0.80 is 4/10 of the way between 0.76 and 0.86, so the minimum detectable effect size is approximately 4/10 of the way between $d = 0.70$ and $d = 0.80$, or $d = 0.74$.

Designs Utilizing Covariates to Increase Power in Comparing Independent Groups Using Simple Random Samples

The use of covariates can dramatically increase precision in designs comparing independent groups. The covariate is often a pretest of some kind, but it could be any variable that is correlated with the outcome and is measured before treatment begins. In designs that involve covariates, power depends not only on significance level, sample size, and effect size, but also on the effectiveness of the covariate in explaining variance in the outcome variable. Nonetheless, the computations using covariates can be carried out using almost the same procedures as without covariates. The only difference is that instead of using the actual effect size and the sample size to directly compute power, a slightly modified version of each, called the operational effect size and operational sample size, is used.

Operational effect size and operational sample size

Suppose that the actual effect size of interest is d , the actual sample size in each group is N , and the correlation (or multiple correlation if there is more than one covariate) between covariate(s) and the outcome is R . Then, the

operational sample size per group is $N_0 = N - q/2$, where q is the number of covariates used, and the operational effect size d_0 is

$$d_0 = \left(d / \sqrt{1 - R^2} \right) \left[\sqrt{2N / (2N - q)} \right] \quad [1]$$

If the number of covariates is small (e.g., 1), it may be sufficiently accurate to use $N_0 = N - 1$ and

$$d_0 = d / \sqrt{1 - R^2} \quad [2]$$

as the operational sample size and effect size, respectively. The actual effect size d has the same scientific interpretation in this design as in the design without covariates and should be chosen in the same way. The operational effect size is simply a convenient device that allows us to compute statistical power from standard tables.

Example of computing power using Table 1 in a design using covariates

Suppose that, as in the earlier example, we are interested in determining the statistical power of an experiment that contrasts a treatment group with a control group with the $\alpha = 0.05$ level of significance, a sample size of $N = 30$ per group, and an effect size of $d = 0.30$. Now, we introduce a covariate that is correlated ($R = 0.66$) with the outcome variable. The operational sample size is $N_0 = 30 - 1/2 = 29.5$ and the operational effect size is

$$d_0 = \left(0.30 / \sqrt{1 - 0.66^2} \right) \left[\sqrt{(2 \times 30) / [(2 \times 30) - 1]} \right] = 0.403$$

Note that if we had ignored the last term in brackets, we would have computed

$$d_0 = 0.30 / \sqrt{1 - 0.66^2} = 0.399$$

which is the same to two decimal places (namely $d_0 = 0.40$). Because $N_0 = 29.5$ is between 29 and $N_0 = 30$, we will have to interpolate between rows. Entering **Table 1** on the row for $N_0 = 29$ and moving across to the column for an effect size of $d_0 = 0.40$, we read the power value of 0.32, and on the row for $N_0 = 30$ for an effect size of $d_0 = 0.40$, we read the power value of 0.33; thus, the power value is between 0.32 and 0.33 or about 0.325. Note that introducing the covariate has increased the power by approximately 50% (from 0.21 to 0.325) compared to the design with no covariate. How large would the sample size have to be in order to obtain a power of 0.80? To find it out, enter the table in the column for the (operational) effect size of 0.40 and move down the rows until we reach a power value of 0.80 or larger. Doing so yields an (operational) sample size of $N_0 = 100$ per group, or a true sample size of $N = 101$, which is much less than without covariates. Alternatively, we might ask what the minimum effect size that yields a power of 0.80 is for a sample size of $N = 30$ per group when the covariate is included

(the minimum detectable effect size for a power of 0.80 and an operational sample size of $N_0 = 29$). Entering the table on the row for $N_0 = 29$ per group and moving across the columns of the table, we see that an effect size of $d_0 = 0.70$ yields a power of 0.75 and an effect size of $d_0 = 0.80$ yields a power of 0.85; thus, the minimum detectable operational effect size is between $d_0 = 0.70$ and $d_0 = 0.80$. Interpolating, we see that a power of 0.80 is 1/2 of the way between 0.75 and 0.85, so the minimum detectable effect size is approximately 1/2 of the way between 0.70 and 0.80 or about 0.75. Note, however, that this is the minimum detectable operational (not actual) effect size. We can translate this minimum detectable operational effect size into the minimum detectable actual effect size by inverting eqn [2] to obtain

$$d = d_0 \sqrt{1 - R^2} = 0.75 \sqrt{1 - 0.66^2} = 0.56$$

which is much smaller than without covariates.

Designs Comparing Independent Groups Using Multilevel (Clustered) Samples

Many research designs in education compare the outcomes in independent groups but obtain their sample via a multilevel (multi-stage) sampling process. For example, many educational studies obtain the groups of participants by first obtaining schools and then assigning all of the students or teachers in the same school to the same treatment. Cluster-randomized (hierarchical) experiments and many quasi-experiments patterned after them are examples of designs in this category. The term ‘cluster-randomized’ refers to the concept of first sampling intact groups (statistical clusters), then sampling individuals within groups to obtain a two-stage (two-level) cluster sample and then randomly assigning whole clusters to treatments. We discuss here only designs with two levels of sampling (e.g., schools assigned to treatments with students nested within schools).

The use of multilevel samples and cluster randomization can dramatically decrease statistical power in designs comparing independent groups as compared with designs wherein simple random sampling and individual randomization to treatment are used. However, these designs are commonly used either because they are much less costly than the alternatives or because it is politically infeasible to assign individuals within the same school to different treatments. It is also the only alternative to evaluating treatments that must be administered to the entire school because of theoretical considerations (e.g., whole school reforms).

In designs that involve two-level sampling, the power depends not only on significance level, the sample size, and the effect size but also on the amount of clustering in the sample. The amount of clustering is measured by a

quantity called the intraclass correlation, which measures the proportion of the total variance in the outcome that is between (as opposed to within) clusters (e.g., schools). Intraclass correlations range from 0 to 1, but values between 0.05 and 0.30 are most common in educational research. An additional complication is that power in these designs depends not only on the total sample size, but also on the number of clusters in each treatment group, m , and the number of individuals, n , within each cluster (assumed to be the same for each cluster). Choosing a reasonable intraclass correlation value is important for the accuracy of the power computation, so it is desirable to choose on the basis of empirical evidence from populations similar to those in the experiment. One extensive set of intraclass correlation values from representative samples of the United States population was compiled by Hedges and Hedberg (2007).

Power computations for multilevel samples such as cluster randomized experiments can be carried out using almost the same procedures as for experiments with singlelevel samples. The only difference is that, as in the case of singlelevel experiments with covariates, operational effect size and operational sample size are used.

Operational effect size and operational sample size

Suppose that the actual effect size is d , the actual number of clusters assigned to each treatment is m , the sample size in each cluster is n , and the intraclass correlation is ρ . Then, the operational sample size is $N_0 = m$. The operational effect size, d_0 , is

$$d_0 = d \sqrt{\frac{n}{1 + (n-1)\rho}} \quad [3]$$

Note that unless $\rho = 1$, the operational effect size d_0 is always larger than the actual effect size d . However, the operational sample size, $N_0 = m$, is smaller than the actual sample size, mn , so the power in the design with clustering will always be smaller than in the design without clustering.

Example of computing power in a multilevel design using Table 1

Suppose that we are interested in determining the statistical power of a multilevel experiment that contrasted two treatment groups using an $\alpha = 0.05$ level of significance, a sample size in each group of $m = 20$ schools, $n = 25$ students in each school, and an actual effect size of $d = 0.30$. Assume that the intraclass correlation is $\rho = 0.15$. The operational sample size is $N_0 = 20$ and the operational effect size is

$$d_0 = 0.30 \sqrt{\frac{25}{1 + (25-1) \times 0.15}} = 0.700$$

Entering **Table 1** on the row for the operational sample size $N_0 = 20$ and moving to the column for an operational effect size of $d_0 = 0.70$, we see that the power is 0.58. Note that the total sample size is $2 \times 20 \times 25 = 1000$, which is rather large, yet the power is not particularly large. A study using a simple random sample of this size would have had power in excess of 0.99.

How many clusters would be required to obtain a power of 0.80? To find it out, enter the table in the column for the (operational) effect size of 0.70 and move down the rows until we reach a power value of 0.80 or larger. Doing so yields a sample size on $m = 33$ clusters (each with $n = 25$ individuals) per group. We might have wondered how increasing the total sample size by increasing the number of individuals within each cluster (increasing n) and keeping the number of clusters fixed at $m = 20$ would affect the power. It can be shown that the largest operational effect size can possibly be, even if n is infinitely large, $d_0 = 0.78$, which (with $N_0 = m = 20$) corresponds to a power of about 0.67. Thus, increasing sample size by increasing clusters is a much more effective way to increase power in multilevel designs than is increasing the number of individuals within the clusters. This example illustrates that, even an infinite sample size, if it was obtained by increasing the number of individuals within the clusters and not increasing the number of clusters, may not increase the power to 0.80.

Designs Comparing Independent Groups with Multilevel Samples Using Covariates

The use of covariates can dramatically increase precision in designs comparing independent groups using multilevel samples. In designs with two-level sampling and covariates, the power depends not only on the significance level, sample size (the number m of clusters and sample size n within each cluster), effect size, and the amount of clustering in the sample (measured by the intraclass correlation ρ) but also on the effectiveness of the covariate(s) in explaining variance in the outcome variable at the cluster level and the individual (within-cluster) level. Typically, covariate effectiveness is measured by the multiple correlations R_1 and R_2 between the covariate(s) and the outcome at the individual and cluster levels, respectively.

Power computations using covariates can be carried out using a procedure similar to what was used without covariates. The only difference is in how the operational effect size and operational sample size are defined.

Operational effect size and operational sample size

Suppose that the actual effect size is d , the number of clusters assigned to each treatment is m , the sample size

within each cluster is n , the intraclass correlation is ρ , there are q_1 covariates used at the individual level and q_c covariates used at the cluster level, and the multiple correlations between the covariate(s) and outcome at the individual and cluster level are R_1 and R_2 , respectively. Then, the operational sample size is $N_0 = m - q_c/2$. The operational effect size, d_0 , is

$$d_0 = d \sqrt{\frac{n}{1 + (n-1)\rho - R_1^2 - (nR_2^2 - R_1^2)\rho}} \left[\sqrt{\frac{2m}{2m - q_c}} \right] \quad [4]$$

The operational effect size d_0 is always larger than the operational effect size that would have been computed if there were no covariates.

If the number of covariates is small (e.g., 1), it may be sufficiently accurate to use $N_0 = m - 1$ and

$$d_0 = d \sqrt{\frac{n}{1 + (n-1)\rho - R_1^2 - (nR_2^2 - R_1^2)\rho}} \quad [5]$$

as the operational sample size and effect size, respectively.

The covariate–outcome correlations at both the individual and (especially) the cluster level have important effects on the accuracy of the power computation, so they should be chosen on the basis of empirical evidence gathered from populations similar to those in the experiment. One extensive compilation of covariate–outcome correlations at the individual and school level from representative samples of the US population is Hedges and Hedberg (2007).

Example of computing power in a multilevel design with covariates using Table 1

Suppose that we are interested in determining the statistical power of a multilevel experiment that will contrast treatment groups using a $\alpha = 0.05$ level of significance, a sample size in each group of $m = 20$ schools and $n = 25$ students in each school, and an effect size of $d = 0.30$. Assume that the intraclass correlation is $\rho = 0.15$ and that the individual- and cluster-level-squared multiple correlations between the $q_1 = q_c = 1$ covariate and outcome are $R_1^2 = 0.60$ and $R_2^2 = 0.50$ at the individual and cluster levels, respectively. The operational sample size is approximately $N_0 = 20 - 1 = 19$ and the operational effect size is approximately

$$d_0 = 0.30 \sqrt{\frac{25}{1 + (25-1) \times 0.15 - 0.60 - (25 \times 0.50 - 0.60) \times 0.15}} = 1.008$$

Entering **Table 1** on the row for the operational sample size $N_0 = 19$ and moving to the column for an operational effect size of $d_0 = 1.00$, we see that the power is 0.85, so the power of this design is approximately 0.85. Note that if we had used the more complicated expression for the operational effect size given in eqn [4], we would have obtained $d_0 = 1.02$ and essentially the same power.

Conclusion

The procedures described in this article can be used to carry out statistical power analysis with the goal of finding statistical power for a fixed sample size and effect size, finding the sample size that will provide acceptable power for a fixed effect size, and finding the minimum detectable effect size for a fixed sample size and power. One complication that arises is that within treatment group sample sizes or (in designs with clustering) within cluster sample sizes may not be equal. In this case, using the harmonic mean of the sample sizes yields reasonably accurate power computations. Thus, in the case of designs involving simple random samples, we would use $N = 2N_1N_2/(N_1 + N_2)$. In designs wherein the number of clusters in the treatment and control groups are unequal, we would use $m = 2m_1m_2/(m_1 + m_2)$. When the cluster sizes are unequal, we would use $n = m(n_1n_2 \dots n_m)/(n_1 + n_2 + \dots + n_m)$ as the cluster size in formulas involving n .

Statistical Significance Versus Effect Size

Statistical Significance

Statistical Significance Testing

There has been a long history of statistical significance testing, and specifically, of null hypothesis significance testing (NHST). The fundamental concept underlying statistical significance test is sampling variation, or sampling error. Assuming a researcher has two treatment conditions, A (a new math instructional approach) and B (the business-as-usual approach currently in use). The researcher is interested in knowing if A is more effective than B (research hypothesis, or RH: A is better than B). To help decide if the RH can be supported, the researcher set up another hypothesis (null hypothesis of no difference, or NH) that A and B are equally effective (i.e., students under A and B will have equal learning outcomes).

Because of sampling variation, even if A and B are equal in terms of instructional effectiveness, it is possible that the method A sample may have higher average score than the method B sample. Therefore, the simple observation that students under method A performed better than those under method B does not constitute sufficient evidence that method A is more effective than method B, because we have not ruled out sampling error as one possible explanation for the observed difference.

If treatments A and B are indeed the same (NH of no difference is true), a small performance difference between A and B samples is more likely to occur by chance than a large performance difference. The question is, how much higher should the method A sample average score be than the method B sample average score before we can say, with reasonable confidence, that the observed difference is not due to sampling variability (i.e., chance)? Once we decide statistically that the sampling variability is unlikely to be a viable explanation for the observed difference, the NH is rejected. The rejection of NH constitutes statistical evidence supporting the RH, because our statistical significance test helps us rule out sampling error, or chance, as a viable explanation for the observed difference between the two samples.

In statistical significance testing, we assess the probability of observing sample statistic values equal to or more extreme than that obtained from a sample data (D) if the NH (H_0) is true, that is, $p(D|H_0)$. If $p(D|H_0)$ is sufficiently small (e.g., $p < 0.05$), the NH can be considered as not viable, and will be rejected. So, statistical significance (i.e., the rejection of the NH) tells us that the random sampling variability is unlikely a viable explanation for

the observed difference between observed sample value and the hypothesized population value, but it does not really inform us about the magnitude or practical importance of our observed sample results. Going back to the example of Methods A and B in teaching math, the rejection of the NH (NH: A and B are equally effective in teaching math) means that it is highly unlikely that sampling error could have been the cause for the observed difference. As a result, we conclude A and B are most likely not equally effective (i.e., rejection of NH). This conclusion, however, does not give us a clear indication about how much more effective method A is than method B in the practical sense. More detailed discussion about hypothesis testing can be found elsewhere in the encyclopedia.

Criticisms of Statistical Significance Test

In the past several decades, NHST has received a considerable amount of criticism. The criticism has centered on the use (or misuse, overuse) of statistical significance in research practice, rather than on the logic of statistical significance test. For example, Kirk (1996) discussed

1. significance testing does not tell researchers what they want to know, but rather, it creates the illusion of probabilistic proof by contradiction;
2. statistical significance testing is often a trivial exercise, as it simply indicates the power of the study design (i.e., sample size); and
3. significance testing “turns a continuum of uncertainty into a dichotomous reject-do-not-reject decision,” and this may lead to a situation in which different researchers obtain identical treatment effects but draw different conclusions, simply due to slight differences in design (e.g., sample size differences).

Kirk (2003) later stated, “it is evident that the current practice of focusing exclusively on a dichotomous reject–non-reject decision strategy of NH testing can actually impede scientific progress . . . The focus of research should be on our scientific hypotheses, what data tell us about the magnitude of effects, the practical significance of effects, and the steady accumulation of knowledge” (p. 100). Vacha-Haase and Thompson (2004) pointed out, statistical significance only evaluates the probability or likelihood of the sample results under the assumption of true NH, but it cannot evaluate the importance of the sample results. Meehl (1978) discussed that the NH, taken literally, is always false. Because of this, statistical significance often

becomes a matter of having sufficiently large sample in order to have enough statistical power to reject the false NH.

At this time, there is a general consensus that, in educational research practice, the importance attributed to statistical significance has exceeded what it deserves, almost to the point that statistical significance becomes the literal equivalent of importance of research findings. Undoubtedly, this situation has been compounded by the unfortunate misnomer of significance in this context.

Effect Size

The criticism of statistical significance has led quantitative researchers to consider other information, such as effect size, to supplement or complement statistical significance test in research practice. As a result, the use of effect size measure has gained popularity in recent years. Effect size is usually a scale-free index that quantifies the difference between the observed sample results and the NH. For example, when the NH states that methods A and B are equally effective in math instruction (i.e., no performance difference between the two approaches), if the observed sample means are 80 and 80, respectively, the effect size is zero. If the observed sample means are not equal (e.g., 80 and 90, respectively), the effect size will be nonzero. The motivation for effect size is to have a scale-free index for the difference, because the actual difference (e.g., a ten-point difference in the example above) is often not interpretable due to arbitrary measurement scaling that is typical in social and behavioral sciences. For example, a 15-point difference on one measure (e.g., Wechsler intelligence quotient (IQ) score scale with $\mu = 100$ and $\sigma = 15$) is drastically different from a 15-point difference on another measure (e.g., the Graduate Record Examination (GRE) score scale with $\mu = 500$ and $\sigma = 100$).

Effect Size Measures

Different effect size measures have been developed for different analytical techniques. In general, most commonly used measures of effect belong to one of two broad categories: (1) measures of effect size, which are based on standardized group mean differences; and (2) measures of association strength, which are based on shared proportion of variance (or variance accounted for).

Standardized Mean Difference as Effect Size

Univariate d

The first category of effect size measure is based on standardized group mean difference. This category is best represented by Cohen's d , or another variation of it (e.g., Glass's Δ). In a generic form, Cohen's d is estimated from a sample as:

$$d = \frac{\bar{X}_{Group1} - \bar{X}_{Group2}}{sd_{pooled}}$$

where \bar{X}_{Group1} and \bar{X}_{Group2} can be sample means from two groups in an experimental design (e.g., $\bar{X}_{Treatment}$ and $\bar{X}_{Control}$), or from any two naturally occurring groups (e.g., male and female group comparison). The sd_{pooled} represents the pooled standard deviation across the two samples.

In an experimental design study, if the researcher believes that the treatment may affect not only the performance level of the treatment, but also the variation of the treatment group, one may consider Glass's Δ of using the control group's standard deviation ($sd_{control}$) to replace sd_{pooled} to calculate d . In a situation where only one group is involved (e.g., a sample is being compared against a hypothesized population value), d can be obtained as:

$$d = \frac{\bar{X}_{sample} - \mu}{sd_{sample}}$$

Multivariate D_M

For multivariate group comparison (e.g., comparison of two groups on multiple outcome variables, as in a Hotelling T^2 test or multivariate analysis of variance (MANOVA)), Mahalanobis distance (D_M) is the multivariate counterpart of d :

$$D_M = \sqrt{(\bar{X}_{G1} - \bar{X}_{G2})' S_{pooled}^{-1} (\bar{X}_{G1} - \bar{X}_{G2})}$$

where \bar{X}_{G1} and \bar{X}_{G2} are the mean vectors of the two groups in the comparison, $(\bar{X}_{G1} - \bar{X}_{G2})'$ is the transposed mean vector difference, and S_{pooled}^{-1} is the inverse of the pooled covariance matrix.

Variance-Accounted-for Measures as Effect Size

The second broad category, variance-accounted-for measures, is based on the relationship strength between variables, and is often represented as an index representing the proportion of variance in the outcome variable that is associated with predictor(s) or independent variable(s). In this category, there are variance-accounted-for measures, and their bias-corrected counterparts.

Variance-accounted-for measures

The most widely known variance-accounted-for measures are η^2 or R^2 . These two are fundamentally the same, but they may be used in slightly different contexts. The general form is:

$$\eta^2 (R^2) = \frac{SS_{source}}{SS_{total}}$$

The numerator is the sum of squares (SS) from a source of research interest, while the denominator represents the

total variance of the outcome variable. In a model that contains only one explanatory factor (predictor), that factor (predictor) is the source of interest. For a model containing multiple factors (predictors), the source of interest may be one variable, a subset of variables, or the full model with all the explanatory variables (predictors). R^2 is usually used in the context of regression analysis, while η^2 is often preferred in the context of analysis of variance (ANOVA). In addition, if the source represents the full model (i.e., all factors in an ANOVA model), R^2 is often used. It should be noted that these contextual nuances in the use of η^2 and R^2 are not really statistically meaningful, as all these analytical models (e.g., t -test, regression, ANOVA) can be considered as part of the general linear model (GLM). In this sense, η^2 and R^2 are fundamentally the same.

In regression analysis, researchers are often interested in evaluating the unique contribution of one or more additional predictors over and above some other predictors already in the model. In this context, R_A^2 researchers often use

$$R_A^2 = R_{k+j}^2 - R_k^2$$

where R_k^2 is the R^2 from the model with k predictors (reduced model), and R_{k+j}^2 is the R^2 for the model with $k+j$ predictors (the full model containing the k predictors, plus some additional j predictors).

In the case of a GLM, when a model contains multiple independent variables, most likely, these variables are non-orthogonal (i.e., correlated; orthogonality may be achieved in an experimental study with balanced design). As a result, the SS attributable to each of the variables is not additive. The standard practice is to use the type III SS (SS_{III} : unique SS), which has been adjusted for the effects of all other variables in the model. As a result, SS_{III} for the effects do not sum up to the total SS . In a model involving multiple variables, their η^2 's do not add up to be more than 100%.

η^2 versus partial η^2

In educational research practice, there appears to be some confusion about η^2 and *partial* η^2 , and we have seen instances where partial η^2 was used and interpreted as if it were η^2 as defined above. For clarification, we consider the definition of partial η^2 :

$$\text{Partial } \eta^2 = \frac{SS_{\text{source}}}{SS_{\text{source}} + SS_{\text{error}}}$$

Obviously, partial η^2 can be quite different from η^2 , because the denominator in the above formula is not the total sum of squares. η^2 and partial η^2 are the same only when the model contains one independent variable (factor). Whenever the model contains more than one independent variable (e.g., categorical factors and/or continuous

predictors), η^2 and partial η^2 will have different (often-times, very different) values. In addition, the sum of partial η^2 's from multiple variables may exceed 100%. The following hypothetical example illustrates the differences between η^2 and partial η^2 :

It is obvious that η^2 and partial η^2 are defined differently. It is also obvious that partial η^2 cannot be interpreted as proportion of variance associated with a factor, and they (partial η^2 's) can add up to be more than 100% in many situations. Instead, partial η^2 represents proportion reduction in residual variance by a factor. A large reduction in residual variance may only represent a very small proportion of the total variance. For this reason, for a model with multiple independent variables, to interpret partial η^2 as if it were η^2 will overestimate (sometimes greatly) the effect of each variable. Partial η^2 is readily available from SPSS package (SPSS GLM procedure), and some SPSS users might have unintentionally misinterpreted partial η^2 as if it were η^2 .

Effect size in HLM

Intraclass correlation coefficient (ICC) is sometimes considered as an effect size measure for random effects (coefficients) model, which subsumes hierarchical linear modeling (HLM) analysis. However, in HLM, proportion reduction in (residual) variance at a given level is probably the most common effect size measure. In a generic form, proportion reduction in variance is (also see Raudenbush and Bryk, 2002: 74) given by

$$\text{Proportion Reduction in Variance} = \frac{\sigma_{\text{residual}}^2(\text{null}) - \sigma_{\text{residual}}^2(\text{full})}{\sigma_{\text{residual}}^2(\text{null})}$$

where $\sigma_{\text{residual}}^2$ is the residual variance at any given level (e.g., level-2 residual variance), and (null) represents a model with no (or fewer) predictors at this level, and (full) represents a model with more predictors at the same level. Basically, this is a measure of proportion of variance explained. But it is not proportion of variance explained out of the total variance, but only the proportion of variance explained out of the variance at a given level. As such, caution is warranted in interpreting this measure, as a large proportion reduction in variance at a given level may only represent a very small proportion of the total variance.

Corrected variance-accounted-for measures

Samples η^2 and R^2 have positive bias, and their bias-corrected counterparts have been proposed. For R^2 , adjusted R^2 in the following form is readily available from any statistical analysis software package (e.g., SAS, SPSS):

$$R_{\text{adjusted}}^2 = 1 - \frac{N - 1}{(N - k - 1)(1 - R^2)}$$

where N is the sample size, and k is the number of predictors in a model. The R_{adjusted}^2 is always smaller than R^2 ,

and the algebraic adjustment can make $R^2_{adjusted}$ negative, even though R^2 is conceptually a positive entity. A negative $R^2_{adjusted}$ suggests that one cannot trust R^2 at all! The adjustment penalizes small sample size and more predictors. With the increase of sample size relative to the number of predictors in the model, the difference between R^2 and $R^2_{adjusted}$ becomes smaller, and eventually negligible.

For fixed-effect ANOVA, omega squared (ω^2) is a widely known bias-corrected counterpart of η^2 :

$$\omega^2 = \frac{SS_{source} - (df_{source})(MS_{error})}{MS_{error} + SS_{total}}$$

ω^2 is always smaller than η^2 , and using the example in **Table 1**, ω^2 for factor A would be:

$$\omega^2 = \frac{20 - (1)(\frac{30}{26})}{(\frac{30}{26}) + 100} = 0.19$$

In addition to the widely known η^2 and R^2 and their bias-corrected counterparts, there are other measures of association strength. In the simplest case, Pearson correlation coefficient itself (or preferably, its squared value) is a variance-accounted-for measure of effect. In many multivariate analytic techniques (e.g., MANOVA), the test statistic Wilk's Λ is related to η^2 ($\eta^2 = 1 - \Lambda$). For canonical correlation analysis, the squared canonical correlation coefficient (R_c^2) is a variance-accounted-for measure of association strength, as it represents the shared amount

of variance between two canonical variates. **Table 2** presents some effect size measures associated with some widely used statistical analysis. More detailed description of many effect size measures and their computational details can be found in other sources (e.g., Cohen, 1988; Grissom and Kim, 2005; Kline, 2004).

Relationship Between Different Measures of Effect Size

Some seemingly different types of effect size measures (e.g., d vs. R^2) may actually be the same statistically. For example, the two major categories of effect size measures (standardized mean difference effect size, e.g., d , and variance-accounted-for effect size, e.g., R^2) are related. As is widely known, many seemingly different analytic approaches (e.g., a two-sample t -test vs. a correlation analysis) are special cases of the GLM. As such, these techniques are statistically related. For example, a two-sample t -test is equivalent to testing that the Pearson correlation coefficient between the outcome variable and dummy-coded group membership is zero. In this case, d and r are related:

$$r = \frac{d}{\sqrt{d^2 + 4}}$$

or

$$d = \frac{2r}{\sqrt{1 - r^2}}$$

Table 1 Illustration of η^2 and partial η^2

Source	df	SS (type III)	η^2	Partial η^2
Model	3	70 ^a		
Factor A	1	20	20/100 = 0.20	20/(20+30) = 0.40
Factor B	1	20	20/100 = 0.20	20/(20+30) = 0.40
A*B	1	10	10/100 = 0.10	10/(10+30) = 0.25
Error	26	30		
Total	29	100		

^aIt is assumed that, to non-orthogonality of the factors (A,B, A*B), their SSs do not sum up to be Model SS of 70.

Table 2 Some common effect size measures

Analysis	Effect size measures
Correlation analysis (continuous, rank-ordered, dichotomous variables)	r (r^2): Pearson r , Spearman r , phi (ϕ) coefficient
Contingency table	Cramer's V , phi (ϕ) coefficient ^a
Independent t -test	d (η^2 , ω^2)
ANOVA	η^2 , ω^2
Regression analysis	R^2 , R^2_A , $R^2_{adjusted}$
Multivariate group comparison (Hotelling T^2 , MANOVA)	D_M , η^2 (1 - Wilk's Λ)
Canonical correlation	R_c^2
Discriminant function analysis	η^2 (1 - Wilk's Λ)
Hierarchical linear modeling (HLM)	Proportion reduction in variance, ICC

^aFor 2×2 contingency table analysis: Cramer's $V = |\text{coefficient}|$.

Therefore, the two types of measures of effect size (standardized mean difference and variance-accounted-for) are not really different statistically.

Use of Effect Size

As statistical significance shows in probabilistic terms how likely to obtain sample statistic values equal to or more extreme than the observed sample statistic if the NH is true, but does not inform about the magnitude of effect or whether the findings are practically meaningful, the use of effect size as an indicator of practical meaningfulness has been widely advocated in recent years (Kirk, 2001; Kline, 2004). The APA Task Force on Statistical Inference recommended to always provide some effect-size estimate when reporting a p value (Wilkinson and The APA Task Force on Statistical Inference, 1999). The most recent *Publication Manual of the American Psychological Association* (5th edition) states:

For the readers to fully understand the importance of your findings, it is almost always necessary to include some index of effect size or strength of relationship in your Results section. . . . to provide the reader not only with information about statistical significance, but also with enough information to assess the magnitude of the observed effect or relationship. (American Psychological Association, 2001: 25, 26)

There is a general consensus that the role of effect size should be enhanced, and the role of statistical significance should be reduced. However, there is disagreement about how much the role of statistical significance should be reduced. On the one hand, statistical significance test has been criticized as representing obstacles to scientific inquiry (e.g., Falk and Greenbaum, 1995; Hunter, 1997; Meehl, 1978). On the other hand, researchers have argued for the legitimate role for the correct use of significance testing (e.g., Cortina and Dunlap, 1997; Hagen, 1997).

Interpreting Effect Size

Based on the observed typical results in social science literature, Cohen (1969, 1988) proposed some tentative benchmarks for what may be considered as small, medium, and large effects:

- small effect: $d \approx |0.2|$; $\eta^2 \approx 1\%$;
- medium effect: $d \approx |0.5|$; $\eta^2 \approx 10\%$; and
- large effect: $d \geq |0.8|$; $\eta^2 \geq 25\%$

This tentative interpretive framework for effect size has been useful for research practitioners, and this is probably a good impetus for the increasing popularity of effect size in research practice (Kirk, 1996). For a better understanding of these tentative benchmarks ($d = 0.20, 0.50$, and

0.80), readers may consult Henson (2006) for easy-to-understand visual graphs of these effect sizes. These interpretive benchmarks, however, should not be considered as a one-size-fits-all rule of thumb, as it is very likely that what can be considered as a small or a large effect will vary across substantive disciplines; for the same effect size (e.g., small effect), the practical importance may be quite different across disciplines. In research practice, the tentative benchmarks for effect size should be considered in light of the typical results in the discipline (Thompson, 2001).

As there are so many different types of effect size measures (Cohen, 1988; Grissom and Kim, 2005; Kline, 2004), and different effect size measures can be very different numerically (e.g., d and η^2), it is critical that the specific effect size measure is reported. It would not be helpful to simply say that an effect size of 0.30 is obtained, because, without knowing what the effect size measure is, this information is not interpretable.

Effect Size and Its Confidence Interval

Sample effect size itself is a random variable. This means that sample effect size is subject to sampling variability, and the degree of its sampling variation is inversely related to sample size. In other words, sample effect size from small samples may deviate farther from the population effect size than that from larger samples. For small sample size conditions, a medium, or even a large, effect size could occur due to sampling error (i.e., by chance) when the true population effect size is zero (Fan, 2001).

The fact that sample effect size is a random variable has been widely known (e.g., Hedges and Olkin, 1985), although some education researchers may have not paid sufficient attention to this. It is not uncommon to hear the discussion to the effect that the outcome of a statistical significance test is influenced by sample size (true!), so attention should be paid to effect size, as if effect size were not influenced by sample size. Undoubtedly, the use of effect size measure makes good quantitative and common sense. However, the use of effect size serves a different purpose from that of statistical significance: while statistical significance test evaluates the probability of obtaining the sample outcome by chance, effect size provides some indication for the magnitude and practical meaningfulness. On the one hand, statistical significance test may detect a trivial effect (sufficient statistical power due to large sample size), or it may fail to detect a meaningful or obvious effect (lack of statistical power due to small sample size). On the other hand, under small sample size conditions, a seemingly meaningful (e.g., medium or even large) effect can occur by chance, thus not trustworthy (Fan, 2001). Because of these considerations, statistical significance and effect size complement each other, but they do not substitute for one another.

		Effect size		
		Small	Medium	Large
Statistical significance				
No		<ol style="list-style-type: none"> 1. It appears that there is neither statistical nor practical effect. 2. Unless future research indicates otherwise, the hypothesis of no or little effect is favored in both statistical and practical sense. 	<ol style="list-style-type: none"> 1. The effect looks promising, but caution is warranted in interpreting the effect size by itself, as medium effect size could have occurred because of sampling error. 2. Type II error (i.e., you fail to statistically detect a true effect) may be a concern, and you may consider the power of your design (e.g., Is your sample too small to statistically detect a meaningful effect?). 	<ol style="list-style-type: none"> 1. You have some evidence for a meaningful effect. However, some caution is still warranted, because a large effect could have been the result of sampling error when the sample size is very small. 2. You may take a critical look at the possible lack of power of your study design.
		<ol style="list-style-type: none"> 1. The statistical significance is not accompanied by practical significance, and it could have been the result of statistical power (i.e., large <i>N</i>). 2. Caution is warranted in interpreting the statistical significant findings, and they may not be interpreted as something practically important. 	<ol style="list-style-type: none"> 1. It is unlikely that the observed effect is due to sampling error. 2. The magnitude of effect is likely to be practically meaningful in many fields of social and behavioral sciences. 3. Conclude that effect is meaningful both statistically and practically. 	<ol style="list-style-type: none"> 1. There is high degree of certainty that the observed effect is not due to chance statistically, and the magnitude of the effect is also practically meaningful. 2. Conclude with confidence that effect is meaningful in both in statistical and practical sense.

The vertical and horizontal arrows indicate the increase of certainty for statistical and practical meaningfulness of the observed effect.

Thompson (2002, 2007) proposed the use of confidence intervals for sample effect size. This approach combines the sample size information with effect size measure, and provides variability estimate for a sample effect size. This approach represents a balance between the descriptive use of sample effect size and statistical significance. More importantly, “Confidence intervals for effect sizes are especially valuable because they facilitate *meta-analytic thinking* and the interpretation of intervals via comparison with the effect intervals from related prior studies” (Thompson, 2002: 25, emphasis original). Ultimately, for translating research findings to education practice, a researcher should not only ask if a sample result is likely, but also if an effect is practically noteworthy and replicable.

Conclusion

Statistical significance and effect size are two components that complement each other, but one does not substitute for the other. Statistical significance and effect size serve complementary purposes, and the sole reliance on either can be misleading. Good research practice requires that both should be taken into consideration for making sound quantitative research decisions. **Figure 1** provides some practical guidelines for combining the information of statistical significance and effect size to make sound decisions in research practice.

Stochastic Processes

F Baudoin, Purdue University, West Lafayette, IN, USA

Introduction and Historical Perspectives

A stochastic process is a mathematical tool that describes a random phenomenon evolving in time.

Let us for instance consider an economist who decides to focus every day on the price of a barrel of oil over the next year. The price at $t = 1, \dots, 365$, say X_t , can not be predicted with absolute certainty, though some prices are more likely than others. This price can then be mathematically modeled by the concept of a random variable: X_t is random. The set, $(X_t)_{t=1, \dots, 365}$ of these random variables is an example of a stochastic process.

The first stochastic process that has been extensively studied is the so-called Brownian motion, named in honor of the botanist Robert Brown (1773–1858), who observed and described in 1828 (see Brown, 1827) the random movement of particles suspended in a liquid or gas. One of the first mathematical studies of this process goes back to the mathematician Louis Bachelier (1870–1946), who presented in 1900, a stochastic modeling of the stock and option markets. However, mainly because of the lack of a rigorous foundation of probability theory at that time, the seminal work of Bachelier was ignored by mathematicians for a long time. However, in his 1905 paper (see Einstein, 1905), Albert Einstein (1879–1955) brought this stochastic process to the attention of physicists by presenting it as a way to indirectly confirm the existence of atoms and molecules. The rigorous mathematical study of stochastic processes really began with the mathematician Andrei Kolmogorov (1903–1987). His monograph (Kolmogorov, 1956), published in Russian in 1933, built up probability theory rigorously from the fundamental axioms in a way comparable to Euclid's treatment of geometry. From this axiomatic approach, Kolmogorov gives a precise definition of stochastic processes. His point of view stresses the fact that a stochastic process is nothing else but a random variable valued in a space of functions (or a space of curves). For instance, if an economist reads a financial newspaper because he/she is interested in the price of a barrel of oil every day over the last year, then he/she will focus on the curve of these prices. According to Kolmogorov's point of view, saying that these prices form a stochastic process is then equivalent to saying that the curve that is seen is the realization of a random variable defined on a suitable probability space. This point of view is mathematically quite profound and provides existence results for stochastic processes (Daniell-Kolmogorov existence result, 1933) as well as pathwise regularity results (Kolmogorov, 1956).

Joseph Doob (1910–2004) writes in the introduction to his famous book *Stochastic Processes* (see Doob, 1953).

[a stochastic process is] any process running along in time and controlled by probability laws ... [more precisely] any family of random variables X_t [where] a random variable ... is simply a measurable function ...

Doob's point of view, which is consistent with Kolmogorov's and built on the work by Paul Lévy (1886–1971), is nowadays commonly given as a definition of a stochastic process. Relying on this point of view that emphasizes the role of time, Doob's work, developed during the 1940s and the 1950s, has quickly become one of the most powerful tools available to study stochastic processes. During the same period in the 1940s, using Kolmogorov's and Doob's results, Kiyosi Itô (1915–) developed the basic tools of the theory of stochastic calculus (see Itô, 1944). This theory makes it possible to define the integrals of stochastic processes as against other stochastic processes and gives sense to the notion of differential equation driven by a random signal (stochastic differential equations).

These different seminal works contributed to give to the theory of stochastic processes a rigorous basis that led to many further developments within and outside mathematics. For further reading on the mathematical theory of stochastic processes, we refer to the book by Revuz and Yor (1999) or the book by Protter (2004). In the next section, we present some examples of stochastic processes and their applications.

Examples and Applications of Stochastic Processes

Markov Chains

Markov chains are among the most important stochastic processes. They are stochastic processes for which the description of the present state fully captures all the information that could influence the future evolution of the process.

Predicting traffic flows, communications networks, genetic issues, and queues are examples where Markov chains can be used to model performance. Devising a physical model for these chaotic systems would be impossibly complicated but doing so using Markov chains is quite simple. Modeling the to-and-fro communications traffic over the Internet is a prime example of what Markov chains can do. Nowadays, the Internet has become exceedingly complex, and traffic moves in a random

way between network nodes. Markov chains are commonly used to describe not only the traffic, which is inherently unpredictable, but also how the network will perform, despite the complexity of its structure. The PageRank of a webpage as used by Google is defined by a Markov chain.

It is also worth mentioning that Markov chains have been recently used in education (see Duys and Headrick, 2004). This study examined the efficacy of an infrequently used statistical analysis in counselor education research. A Markov chain analysis was used to examine hypothesized differences between students' use of counseling skills in an introductory course.

Beyond Markov Chains, Fractional Brownian Motion

In engineering applications of probability, stochastic processes are often used to model the input of a system. Recent studies of communication networks show that real inputs exhibit long-range dependence: the behavior of a real process after a given time t depends not only on the situation at t but also on the whole history of the process up to time t . Moreover, it turns out that this property is far from being negligible because of the effects it induces on the expected behavior of the global system. Therefore, Markov chains cannot be used. Another property that the processes have encountered in communication networks is the self-similarity: their behavior is in distribution of the same, up to a space-scaling, whatever the time-scale is: this is to say that the process $\{X_{at}, t \in [0,1]\}$ has the same distribution as the process $\{a^H X_b, t \in [0,1]\}$, where H is called the Hurst parameter. Several estimations on real data tend to show that H often lies between 0.7 and 0.8, whereas, for instance, the usual Brownian motion has a Hurst parameter equal to 0.5. Processes that satisfy these two properties, long-range dependence and self-similarity, are nowadays being studied extensively. Among them, the so-called fractional Brownian motion introduced by Kolmogorov to model turbulences phenomena is one of the simplest.

Brownian Motion and Financial Mathematics

As pointed out in the section titled 'Introduction,' the Brownian motion is one of the first stochastic processes that has been studied. Since the seminal observation by L. Bachelier

It seems that the market, the aggregate of speculators, can believe in neither a market rise nor a market fall, since, for each quoted price, there are as many buyers as sellers.

and the work by Black and Scholes (see 1973) and Merton (1973), Brownian motion is at the basis of the mathematical modeling of financial markets. It can be used to model the fluctuations of stock prices. This modeling has in particular led to a rational option: the pricing theory. An option is a contract written by a seller that extends to the buyer the right but not the obligation to buy (in the case of a call option) or to sell (in the case of a put option) a particular asset at some time. In return for granting the option, the seller collects a payment (the premium) from the buyer. This premium can be computed by using models involving the Brownian motion (the so-called Black–Scholes formula). For further reading on this topic, we refer the interested reader to the book of Karatzas and Shreve (1998).

Two-Dimensional Brownian Motion and Related Processes

The study of the two-dimensional Brownian motion and of related stochastic processes (SLE) has made it possible to solve many conjectures of physicists concerning critical phenomena in dimension 2. The Fields medal was awarded in 2006 to W. Werner for his work in this domain. For further reading on this topic, we refer readers to the book of Lawler (2005).

Structural Equation Models

Introduction

In educational science, substantive theory usually involves manifest (observed) and latent variables. Manifest variables are those that can be measured directly, like test scores and grade point average. Very often, it is required to deal with latent variables that cannot be directly measured by a single manifest variable. Examples are intelligence, personality, quantitative ability, and so on. In practice, the characteristics of a latent variable can be partially assessed by a linear combination of some manifest variables. For instance, quantitative ability of secondary school students can be reflected by their test scores in mathematics, physics, and chemistry. In most substantive research in education, it is important to establish an appropriate model to evaluate a series of simultaneous hypotheses about the impacts of latent variables and manifest variables on the other variables, and take the measurement errors into account. Structural equation models (SEMs) are well recognized as the most important statistical method to serve the above purpose. They have been widely applied to many educational problems for example, for measuring the growth of intelligence and its relationship with personality and school environment. At present, there are more than a dozen of commercial software for fitting linear SEMs to data, such as LISREL VIII (Jöreskog and Sörbom, 1996), and EQS6 (Bentler and Wu, 2002), among others. Moreover, due to the strong demand in various fields, the growth of SEM has been very rapid. Many subtle models and statistical methods have been established for better analyses of more complicated data. The objective of this article is to provide a brief description of the standard linear SEMs and some of its generalizations that are useful in educational research, including the nonlinear SEMs, SEMs with ordered categorical variables, and multilevel SEMs. In addition to the maximum likelihood approach, we also introduce the Bayesian approach and the freely available software WinBUGS for statistical inferences, including estimation and model comparison.

Linear Structural Equation Models

In a confirmatory factor analysis (CFA) model, correlations among latent factors can be assessed by their covariance matrix; however, latent variables are never regressed on the other variables. The basic goal of linear SEMs is to

generalize the CFA model for assessing how the latent variables affect each other in various ways. A typical representation of linear SEMs is the LISREL model (Jöreskog and Sörbom, 1996), which consists of two parts, the measurement equation and the structural equation. The structural equation, which specifies relationships among the latent variables, is defined by the following equation:

$$\eta = \Pi\eta + \Gamma\xi + \delta \quad [1]$$

where $\eta(q_1 \times 1)$ is a vector of endogenous (dependent) latent variables and $\xi(q_2 \times 1)$ is a vector of exogenous (independent) latent variables, $\Pi(q_1 \times q_1)$ and $\Gamma(q_1 \times q_2)$ are unknown matrices of regression coefficients that represent the causal effects among η and ξ , and $\delta(q_1 \times 1)$ is a random vector of error measurements or residuals. It is assumed that ξ is distributed as $N[0, \Phi]$, δ is distributed as $N[0, \Phi_\delta]$, and ξ is uncorrelated with δ . The latent vectors η and ξ are related with the manifest random vectors by the measurement model which composes the following CFA models:

$$x_1 = \Lambda_1\eta + \varepsilon_1 \quad [2]$$

$$x_2 = \Lambda_2\xi + \varepsilon_2 \quad [3]$$

where $x_1(r \times 1)$ and $x_2(s \times 1)$ are random vectors of the manifest variables which are the respective indicators for η and ξ , $\Lambda_1(r \times q_1)$ and $\Lambda_2(s \times q_2)$ are loading matrices, and $\varepsilon_1(r \times 1)$ and $\varepsilon_2(s \times 1)$ are random vectors of error measurements. It is assumed that ε_1 and ε_2 are normally distributed with zero means and diagonal covariance matrices. Moreover, ε_1 and ε_2 are uncorrelated, and they are also uncorrelated with η , ξ , and δ . Let $y = (x_1^T, x_2^T)^T$, $\omega = (\eta^T, \xi^T)^T$, and $\varepsilon = (\varepsilon_1^T, \varepsilon_2^T)^T$, eqns [2] and [3] can be expressed as

$$\begin{aligned} y &= \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} \Lambda_1 & 0 \\ 0 & \Lambda_2 \end{pmatrix} \begin{pmatrix} \eta \\ \xi \end{pmatrix} + \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \end{pmatrix} \\ &= \Lambda\omega + \varepsilon \end{aligned}$$

Hence, linear SEMs are formulated as a CFA model in which the latent factors satisfy a linear structural equation.

Like many statistical models, linear SEMs (and their generalizations discussed in subsequent sections) rely on substantive knowledge in building a model. It is a confirmatory tool rather than an exploratory tool. In applications, we usually have a clear objective of the study, and some basic background about the key structure of the model that is obtained either from the subject knowledge or from preliminary data analysis. This basic background

will be used in model identification, specification, and interpretation. In substantive applications, the basic background of the manifest variables in y suggests a structure of Λ in relating the manifest variables with the latent factors (variables). Often, a nonoverlapping structure of Λ , in which each indicator only measures one of the latent variables, is used to provide clear interpretation of the latent factors. The structure of Λ (e.g., the nonoverlapping structure with fixed loadings at appropriate entries) may be sufficient for identifying the model. Otherwise, more constraints have to be imposed. There are no sufficient and necessary conditions for identification, and the issue has to be considered on a problem-by-problem basis.

Nonlinear Structural Equation Models

As interactive effects of the exogenous latent variables may have substantial impact on the endogenous latent variables, nonlinear SEMs have been developed for establishing more meaningful and correct models (see Kenny and Judd, 1984; Schumacker and Marcoulides, 1998). For the model perspective, nonlinear SEMs are straightforward extensions of linear SEMs, in which the structural equation accommodates nonlinear terms of the exogenous latent variables for predicting the endogenous latent variables. More specifically, the model is defined as follows (see Lee *et al.*, 2003):

$$y_i = A c_i + \Lambda \omega_i + \varepsilon_i \quad [5]$$

$$\eta_i = \Pi \eta_i + B x_i + \Gamma F(\xi_i) + \delta_i \quad [6]$$

where c_i and x_i are vectors of fixed covariates, A and B are unknown matrices of regression coefficients, $\omega^T = (\eta^T, \xi^T)^T$, $F(\xi) = (f_1(\xi), \dots, f_a(\xi))$ is a vector-valued function with linearly independent, nonzero, known, and differentiable functions, $a \geq q_2$, and the definitions of other terms are the same as before.

In this model, more care is needed to interpret the mean vector of y . Let A_k^T and Λ_k^T be the k th row of A and Λ , and let y_k be the k th element of y . For $k = 1, \dots, p$, it follows from [5] that $E(y_{ik}) = A_k^T c_i + \Lambda_k^T E(\omega_i)$. Although $E(\xi_i) = 0$, it follows from [6] that $E(\eta_i) \neq 0$ if $F(\xi)$ is a nonlinear function of ξ . Hence, $E(\omega) \neq 0$ and $E(y_{ik}) \neq A_k^T c_i$. Let $\Lambda_k^T = (\Lambda_{k\eta}^T, \Lambda_{k\xi}^T)$ be a partition of Λ_k^T that corresponds to the partition of $\omega = (\eta^T, \xi^T)^T$. Because $E(\xi) = 0$ and $\eta = (I - \Pi)^{-1} [Bx_i + \Gamma F(\xi)]$, it follows from [6] that

$$\begin{aligned} E(y_{ik}) &= A_k^T c_i + \Lambda_{k\eta}^T E(\eta_i) + \Lambda_{k\xi}^T E(\xi_i) = \\ &= A_k^T c_i + \Lambda_{k\eta}^T (I - \Pi)^{-1} [Bx_i + \Gamma E(F(\xi))] \end{aligned}$$

As $F(\xi)$ is usually not very complicated in most practical applications, $E(F(\xi))$ is not very complex and the computation of $E(y_k)$ is not difficult.

For a linear SEM, the saturated model is defined by $y = \mu + \varepsilon^*$, where ε^* is distributed as $N[0, \Sigma]$, in which Σ is a generic covariance matrix without any structure. The above model cannot be regarded as a saturated model for assessing the goodness of fit of a hypothesized nonlinear SEM, because the distribution of the corresponding ε^* is not normal when the structural equation is nonlinear. Hence, we will consider this issue as a model comparison problem, by comparing a linear model with a nonlinear model having nonlinear terms of exogenous latent variables.

Structural Equation Models with Ordered Categorical Data

Ordered categorical data are frequently encountered in educational research. As the histograms of most ordered categorical variables are either skewed or bimodal, routinely treating them as normal will lead to erroneous conclusions (see Olsson, 1979). A common method for treating ordered categorical variables is thought a threshold approach, in which the categorical data are regarded as manifestation of an underlying normal variable.

Suppose we are interested in a linear SEM or a nonlinear SEM. Now, for each y , we have $y = \{y_o, y_u\}$, where y_o is a subset of variables whose exact continuous measurements are observable, while y_u is the remaining subset of variables such that the corresponding continuous measurements are unobservable. The information associated with y_u is given by an observable ordered categorical vector z as follows. For the k th variable in z ,

$$z_k = m \text{ if } \alpha_{k,m} < y_{uk} < \alpha_{k,m+1} \quad [7]$$

where m is an integral value in $\{0, 1, \dots, b_k\}$, and $\alpha_{k,0} < \alpha_{k,1} < \dots < \alpha_{k,b_k} < \alpha_{k,b_k} + 1$ are the thresholds. In general, we set $\alpha_{k,0} = -\infty$ and $\alpha_{k,b_k+1} = \infty$. For the k th variable in z , there are $b_k + 1$ categories which are defined by the thresholds $\alpha_{k,j}$. Note that an additional indeterminacy is induced by the ordered categorical variables. To tackle this problem, we propose to fix the thresholds at both ends, $\alpha_{k,1}$ and α_{k,b_k} , at preassigned values. This approach implicitly picks measures for the location and the dispersion of y_k . For instance, the range $\alpha_{k,b_k} - \alpha_{k,1}$ provides a standard for measuring the dispersion. For scale invariant models, the choice of the preassigned values for the fixed thresholds only changes the scale of the estimated covariance matrix (see Lee *et al.*, 1990). One common method is to fix $\alpha_{k,1} = \Phi^{*-1}(f_{k,1}^*)$ and $\alpha_{k,b_k} = \Phi^{*-1}(f_{k,b_k}^*)$, where $\Phi^*(\cdot)$ is the distribution function $N[0, 1]$, and $f_{k,1}^*$ and f_{k,b_k}^* are the frequencies of the first category and the cumulative frequencies of categories with $z_k < b_k$, respectively. These restrictions imply that the mean and the variance of the underlying

continuous variable y_k are 0 and 1, respectively. They have been frequently used in Bayesian analyses of SEMs with ordered categorical variables (see Lee, 2007).

Two-Level Structural Equation Models

In educational research, it is common to encounter hierarchical data that are collected from units nested within a large number of clusters. Examples could include random sample of students from within random samples of schools. As individuals within a group share certain common influential factors and hence lead to correlated observations, the assumption of independence among observed observations is violated. Clearly, ignoring the correlated structure of data and analyzing them as independent observations will give erroneous results. Moreover, it is also desirable to establish a meaningful model for the between-groups levels and study the effects of the between-groups latent variables on the within-groups latent variables. Consequently, it is necessary to develop two-level SEMs that take into consideration the correlated structure of data.

Consider a collection of p -variate random vectors y_{gi} , $i = 1, \dots, N_g$, within groups $g = 1, \dots, G$. The sample sizes N_g may differ from group to group so that the data set is unbalanced. At the first level, we assume that, conditional on the group mean v_g , random observations in each group satisfy the following measurement model (see Song and Lee, 2004):

$$y_{gi} = v_g + v_{gi} = v_g + \Lambda_{1g}\omega_{1gi} + \varepsilon_{1gi}, \quad [8]$$

$$g = 1, \dots, G, i = 1, \dots, N_g$$

where Λ_{1g} is a $p \times q_1$ matrix of factor loadings, ω_{1gi} is a $q_1 \times 1$ random vector of latent factors, and ε_{1gi} is a $p \times 1$ random vector of error measurements that is independent of ω_{1gi} and is distributed as $N[0, \Psi_{1g}]$, where Ψ_{1g} is a diagonal matrix. Note that due to the existence of v_g , y_{gi} and y_{gj} are not assumed to be independent. To account for the structure at the between-groups level, we assume that the group mean v_g satisfies the following factor analysis model:

$$v_g = \mu + \Lambda_2\omega_{2g} + \varepsilon_{2g}, \quad g = 1, \dots, G, \quad [9]$$

where μ is the mean vector, Λ_2 is a $p \times q_2$ matrix of factor loadings, ω_{2g} is a $q_2 \times 1$ vector of latent variables, and ε_{2g} is a $p \times 1$ random vector of error measurements that is independent of ω_{2g} and is distributed as $N[0, \Psi_2]$, where Ψ_2 is a diagonal matrix. Moreover, the first- and second-level measurement errors are assumed to be independent. It follows from equations [8] and [9] that

$$y_{gi} = \mu + \Lambda_2\omega_{2g} + \varepsilon_{2g} + \Lambda_{1g}\omega_{1gi} + \varepsilon_{1gi} \quad [10]$$

For assessing the interrelationships among the latent variables, latent vectors ω_{1gi} and ω_{2g} are partitioned as

$\omega_{1gi} = (\eta_{1gi}^T, \xi_{1gi}^T)^T$ and $\omega_{2g} = (\eta_{2g}^T, \xi_{2g}^T)^T$, respectively; where η_{1gi} ($q_{11} \times 1$), ξ_{1gi} ($q_{12} \times 1$), η_{2g} ($q_{21} \times 1$), and ξ_{2g} ($q_{22} \times 1$) are latent vectors, with $q_{j1} + q_{j2} = q_j$, for $j = 1, 2$. The distributions of ξ_{1gi} and ξ_{2g} are $N[0, \Phi_{1g}]$ and $N[0, \Phi_2]$, respectively. The structural equations in the between-groups and within-groups models can be linear or nonlinear. For brevity we consider the following linear structural equations:

$$\eta_{1gi} = \Pi_{1g}\eta_{1gi} + \Gamma_{1g}\xi_{1gi} + \delta_{1gi} \quad [11]$$

$$\eta_{2g} = \Pi_2\eta_{2g} + \Gamma_2\xi_{2g} + \delta_{2g} \quad [12]$$

where Π_{1g} ($q_{11} \times q_{11}$), Π_2 ($q_{21} \times q_{21}$), Γ_{1g} ($q_{11} \times q_{12}$), and Γ_2 ($q_{21} \times q_{22}$) are unknown parameter matrices, δ_{1gi} is a vector of error measurements and is distributed as $N[0, \Psi_{1g\delta}]$, δ_{2g} is a vector of error measurements and is distributed as $N[0, \Psi_{2\delta}]$, and $\Psi_{1g\delta}$ and $\Psi_{2\delta}$ are diagonal matrices. In the within-groups structural equation, we assume as usual that ξ_{1gi} and δ_{1gi} are independent. Similarly, in the between-groups structural equation, we assume that ξ_{2g} and δ_{2g} are independent. Moreover, we assume that the within-groups latent vectors η_{1gi} and ξ_{1gi} are independent of the between-groups latent vectors η_{2g} and ξ_{2g} . Hence, it follows from [11] that η_{1gi} is independent of η_{2g} and ξ_{2g} . The proposed two-level SEM can be identified by the common method of fixing appropriate elements in Λ_{1g} , Π_{1g} , Γ_{1g} , Λ_2 , Π_2 , and Γ_2 at preassigned known values. Similar as before, the proposed model can accommodate ordered categorical variable through the threshold approach as described in the following section (see Lee, 2007).

The Maximum Likelihood Approach For Analysis of SEMs

Let D_o be the observed data set that may contain different kinds of data and let D_u be the latent data set that contains the unobserved continuous measurements that are underlying the corresponding observed data. For example in an SEM with ordered categorical data, $D_o = \{Y_o, Z\}$ and $D_u = \{Y_u\}$, where $Y_o = \{y_{io} : i = 1, \dots, n\}$, $Y_u = \{y_{iu} : i = 1, \dots, n\}$, and $Z = \{z_i : i = 1, \dots, n\}$. Let M be a general SEM that is proposed to fit D_o . This model could be a general SEM which may be a linear model, a nonlinear model, a two-level model, or any combination of the above models. Moreover, let Ω be the collection of all latent vectors in the model, and let θ be the vector of unknown parameters.

For linear SEMs, the traditional maximum likelihood (ML) approach is the most common method in estimating the unknown parameter vector θ on the basis of the covariance structure analysis framework. Several user-friendly packages, such as AMOS, EQS6, and LISREL, can be used to conduct the ML analysis. For more complicated SEMs, for example those presented in the earlier

sections, the Monte Carlo Expectation-Maximization (MCEM) algorithm (Wei and Tanner, 1990) will be utilized to obtain the ML estimates. This algorithm involves the E-step and the M-step. Let $L_c(D_o, D_u, \theta)$ be the logarithm of complete-data likelihood function. At the r th iteration with a current value $\theta^{(r)}$, the E-step is completed by approximating the expectation of $L_c(D_o, D_u, \theta) | D_o, \theta^{(r)}$ with a sufficiently large number of observations simulated from the conditional distribution of D_u given D_o , and $\theta^{(r)}$ through some Markov chain Monte Carlo (MCMC) method, such as the Gibbs sampler (Geman and Geman, 1984). The M-step, which maximizes $Q(\theta | \theta^{(r)})$ to update $\theta^{(r)}$ to $\theta^{(r+1)}$, will be completed through a sequence of conditional maximization steps (see Meng and Rubin, 1993). Some useful applications of MCEM algorithm in the ML analysis of complicated SEMs can be found in Lee and Song (2005, 2007) and Song *et al.* (2008).

A Bayesian Approach for the Analysis of SEMs

In recent years, the Bayesian approach received much attention in SEM (see, for example, Lee (2007) and references therein). This popular statistical approach has the following good features: (1) It directly incorporates genuine prior knowledge in the analysis. In educational studies, good prior information on the parameters in the whole model may be available from various sources, for example, from previous studies or subject experts. (2) The Bayesian methods do not rely on asymptotic theory and give reliable statistical inference even with small sample sizes (see Lee and Song, 2004). (3) The Bayesian methods produce latent variable estimates with good statistical properties, and reliable model comparison statistics, etc.

In a Bayesian approach, θ is considered to be random with a distribution (called prior distribution), and an associated (prior) density function, say, $p(\theta | M) = p(\theta)$ (see Berger, 1985). Bayesian inference is conducted on the basis of the following posterior density function, $p(\theta | D_o, M)$, which is proportional to $p(D_o | \theta, M)p(\theta)$. In large samples, the Bayesian and maximum likelihood approaches are asymptotically equivalent. However, for moderate and small sample, accurate prior information can be incorporated in $p(\theta)$ for achieving better results (see Lee, 2007). Let β_k be a row vector in the regression matrices (e.g. A , Λ , Π , or Γ), ψ_k be a variance in the diagonal matrices of the residuals, and Φ be a covariance matrix of the exogenous latent vector. The following conjugate prior distributions are most common in Bayesian analysis of SEM:

$$\beta_k \stackrel{D}{=} N[\beta_{k0}, H_{k0}], \psi_k \stackrel{D}{=} \text{inverted gamma}(\alpha_{k0}, \gamma_{k0}),$$

$$\text{and } \Phi \stackrel{D}{=} IW(R_0, \rho_0)$$

where β_{k0} , α_{k0} , γ_{k0} , and ρ_0 are given hyperparameter values, H_{k0} and R_0 are given positive-definite matrices, and IW denotes the inverted Wishart distribution (see Lee (2007) for the choices of hyperparameters that are associated with informative and non-informative prior inputs).

The Bayesian estimate of θ , $\hat{\theta}$ is usually defined as the mean of the posterior distribution with density function of cf $p(\theta | D_o, M)$. As this distribution is complicated, $\hat{\theta}$ is obtained as the sample mean of a sufficiently large number of observations of θ that are simulated from the joint posterior distribution $p(\theta, D_u | D_o, M)$ by means of some MCMC methods. The freely available software WinBUGS produces Bayesian estimates of the parameters and the latent variables for various kinds of SEMs, including those mentioned above (see Lee, 2007).

Suppose we need to compare K competing models, M_1, \dots, M_K . A Bayesian model comparison statistic that takes into account the number of unknown parameters in the model is the deviance information criterion (DIC) (see Spiegelhalter *et al.*, 2002). Under a competing model M_k with a vector of unknown parameter θ_k of dimension d_k , we define

$$DIC_k = -\frac{2}{J} \sum_{j=1}^J \log p(Y | \theta_k^{(j)}, M_k) + 2d_k$$

where $\{\theta_k^{(j)}, j = 1, \dots, J\}$ is a sample of observations simulated from the posterior distribution. In model comparison, the model with the smaller DIC value is selected. In analyzing a hypothesized model, WinBUGS (Spiegelhalter *et al.*, 2003) also produces a DIC value for model comparison. As pointed out in the WinBUGS User Manual (Spiegelhalter *et al.*, 2003) in practical application of DIC, it is important to note the following: (1) If the difference in DIC is small, for example, less than 5, and the models make very different inferences, then just reporting the model with the lowest DIC could be misleading. (2) DIC can be applied to nonnested models. (3) Moreover, DIC gives clear conclusion to support the null hypothesis or the alternative hypothesis. Detailed discussion of DIC can be found in Spiegelhalter *et al.* (2002).

An Illustrative Example

We illustrate the Bayesian approach with WinBUGS by an analysis of quality of life for stroke survivors. For stroke survivors, handicap, activities of daily living, and depression have significant impact on health-related quality of life (HRQOL). This example aims to study how these variables relate to HRQOL in the sub-acute phase of stroke recovery. The data set contains 500 Chinese stroke survivors who could complete a QOL questionnaire. Outcome variables include: World Health Organization quality of life measure (total) scores on four domains: physical,

psychological, social, and environment; London handicap scale (LHS) scores, which measures the level of handicap in six dimensions: mobility, independence, occupation, social integration, orientation, and economic self-sufficiency; modified barthel index (MBI) score, which measures the activities of daily living; and geriatric depression scale (GDS) score, which measures the depression of patients. The first four continuous variables form the latent variable of HRQOL, η . The next six variables, which are ordered categorical with a six-point scale, form the latent variable of LHS, ξ . The last two continuous variables are the covariates of MBI, x_1 and GDS, x_2 , respectively. Let y_i denote the $10 \times$ random vector of observable and unobservable continuous variables. A nonlinear SEM with linear covariates (see eqns [5] and [6]) was proposed, in which $A = 0$, $\omega_i = (\eta_i, \xi_i)^T$, $\Pi = 0$, $B = (b_1, b_2)$, $x_i = (x_{i1}, x_{i2})^T$, $\Gamma = (\gamma_1, \gamma_2)$, $F(\xi_i) = (\xi_i, \xi_i^2)^T$, and

$$\Lambda^T = \begin{pmatrix} 1 & \lambda_{21} & \lambda_{31} & \lambda_{41} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & \lambda_{62} & \lambda_{72} & \lambda_{82} & \lambda_{92} & \lambda_{10,2} \end{pmatrix} \quad [13]$$

Hence, the nonlinear structural equation is written as

$$\eta_i = b_1 x_{i1} + b_2 x_{i2} + \gamma_1 \xi_i + \gamma_2 \xi_i^2 + \delta_i \quad [14]$$

On the basis of the above model settings, Bayesian estimates of the unknown parameters and their standard error estimates are obtained. The path diagram, together with the estimated results, is depicted in **Figure 1**. The details of less important thresholds are not reported. It is observed that activities of daily living, handicap, and depression are all important predictors of HRQOL. Activities of daily living (MBI) positively impact on HRQOL, which means the more capable the patients are in their daily living, the better the HRQOL. Depression and handicap, however, negatively impact on QOL, which means bad mood and handicap would reduce the HRQOL of the patients. The important finding of this analysis is that the depressive mood in the subacute phase of stroke recovery has the most significant effect on the HRQOL of stroke survivors. Therefore, more attention should be paid to the detection and management of post stroke depression.

To illustrate the use of DIC for model comparison, we let M_1 be the nonlinear SEM defined by [13] and [14]. The two competing models M_2 and M_3 are considered as follows. M_2 is a linear SEM defined by the same measurement equation [13] and a linear structural equation: $v_i = b_1 x_{i1} + b_2 x_{i2} + \gamma_1 \xi_i$. M_3 is a nonlinear SEM

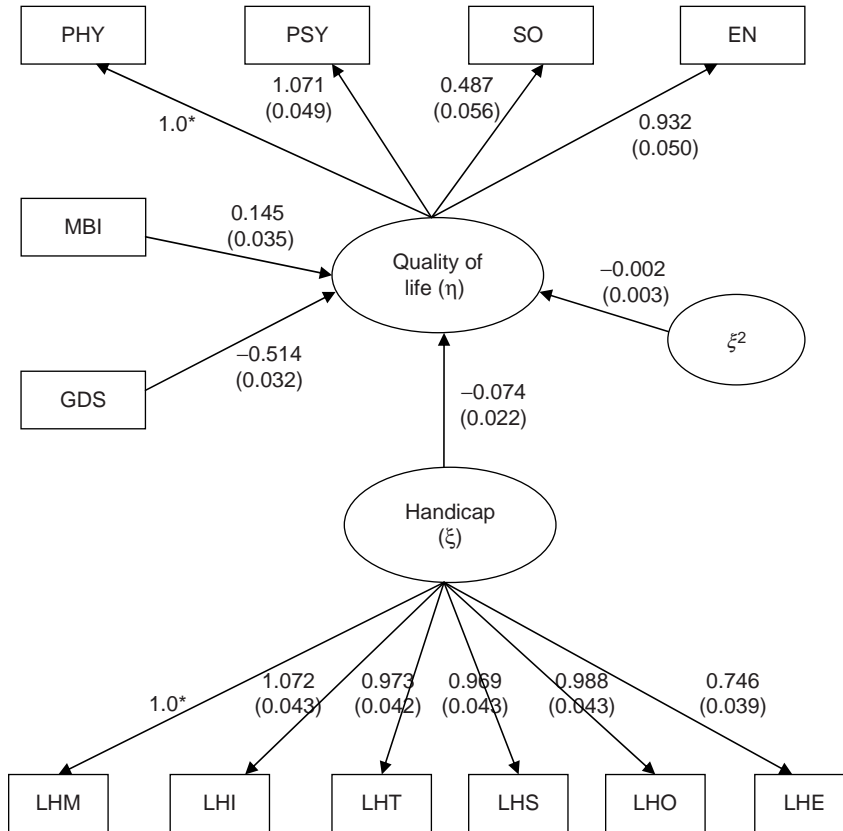

Figure 1 The path diagram and estimated results of the proposed model in analyzing the QOL data, where PHY, PSY, SO, and EN, respectively, denote the HRQOL scores in the four domains; LHM, LHI, LHT, LHS, LHO, and LHE, respectively, denote LHS measured in the six dimensions.

defined by the sample measurement equation [13], and a nonlinear structural equation with the absence of covariates: $v_i = \gamma_1 \xi_i + \gamma_2 \xi_i^2$. Using WinBUGS, we found that the DIC values corresponding to M_1 , M_2 , and M_3 are, respectively, equal to $DIC_1 = 12524.6$, $DIC_2 = 12523.1$, and $DIC_3 = 12575.7$. As DIC_3 is significantly larger than DIC_1 and DIC_2 , the nonlinear SEM without covariates was rejected. Since the estimate values of DIC_1 and DIC_2 are very close, the parsimonious model M_2 should be chosen. Actually, when looking at the estimate of γ_2 and its standard error estimate, we found that the effect of quadratic term is very close to zero and is not statistical significant.

Survival Data Analysis

A F De Champlain, National Board of Medical Examiners, Philadelphia, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Censored observation – Observations that survived to a certain point in time before dropping out from the study for a reason unrelated to the primary outcome of interest (e.g.: insufficient time for an observation to meet the event).

Cox proportional hazards model – A regression method described by D.R. Cox for modeling survival times, generally as a function of several covariates or predictors of interest. It is referred to as the proportional hazards model because it assumes that the underlying hazard rate (rather than survival time) is solely a function of the independent variables and consistent over time.

Event – A qualitative event that can be localized in time.

Hazard function – The function that describes the probability of failure during a very small time interval (assuming that no failures have occurred prior to that time). Hazard is the slope of the survival curve- a measure of how rapidly subjects are having the event (passing an exam, meeting an outcome of the study, etc).

Kaplan-Meier method – Nonparametric method, also known as the product-limit estimator, that is used to compute survival curves.

Log-rank test – A nonparametric test of significance for the difference between two survival curves.

Survival function – The function that denotes the probability that an examinee survives longer than a defined point in time.

Survival curve – The graphical representation of the survival function.

Introduction

Longitudinal outcomes and related studies are commonplace in educational research. Studies have been undertaken to model time to graduation at the college level (Chimka *et al.*, 2008) – and to estimate teacher attrition and student dropout rates (Willett and Singer, 1991) – as a function of various socioeconomic and curricular variables.

In psychometrics, the advent of computer-based testing (CBT) in the admissions, certification, and licensure

arenas, has significantly altered the testing landscape over the past decade (Mills *et al.*, 2002). By virtue of its continuous delivery nature, CBT does, however, require a shift in the way examinee performance trends are analyzed, interpreted, and reported. Longitudinal data are often not amenable to common methods of analysis.

Limitations of Common Regression Models to Analyze Performance Trends

There are several limitations associated with the use of common regression models for estimating performance trends and other longitudinal problems in education. First, it is difficult to accommodate time-varying explanatory variables in typical regression models. One straightforward approach might entail dummy coding the time-varying explanatory variable such that each of its levels (e.g., day, week, month, etc.) is an indicator of the predictor at a given point. However, the latter strategy rests on the assumption that the indicators are predicting the event, while they might very well be their consequences. For example, studies aimed at modeling recidivism rates as a function of whether someone is employed or not at various points in time is a common study problem in criminology (Finn, 1998). In this case, we could fit a model predicting arrest as a function of employment status on a weekly basis. In a linear regression context, this would require dummy coding employment status on a weekly basis for the duration of the study. However, employment status might be an outcome of the event rather than its predictor – that is, being arrested will undoubtedly impact on whether one is subsequently employed or not. This example illustrates why common regression models are inappropriate in this context.

Another important limitation of conventional regression models for analyzing educational data relates to the difficulty in incorporating censored observations, or data missing due to cases that have not yet experienced the event of interest by the end of the study period. Consider the example of an examinee that has taken a test and still has not passed (and presumably still in the pool of potential future masters). These observations are referred to as being right censored, that is, the event time is greater than some constant (the length of the study period). In educational settings, right censoring is far more common than left censoring (event time is less than some constant) or interval censoring (event time is between two numbers a and b). How could this examinee's outcome be coded at

the end of a study aimed at modeling passing rates using linear regression? Two simple approaches to censoring could be considered with linear regression modeling, although both are potentially problematic. The first approach involves discarding cases that have not yet experienced the event of interest – that is, treating them as missing observations. This solution might be defensible if the number of censored cases is very small, but would be unadvisable with data sets containing a large proportion of examinees that still have not passed the examination of interest by the end of the study period, for example. The second approach entails setting a common arbitrary event value for all censored cases. For example, the researcher might decide to fix event times for all censored cases at a value that corresponds to the length of the study period. Adopting this strategy is ill-advised as event times will be underestimates of their true values.

Irrespective of the model being estimated, the presence of censored data requires special estimation procedures or the resulting parameter estimates could be severely biased – as illustrated in the previous example (Bacik *et al.*, 1998). The survival data models that will be outlined in this article make use of information from both censored and noncensored cases to produce consistent parameter estimates. Additionally, these models can more readily accommodate time-varying explanatory variables.

An Overview of Survival Data Analysis

Brief History

Survival data analysis is attractive in that it overcomes limitations of common regression models and appears to be ideally suited to several educational problems – including longitudinally tracking performance trends for various cohorts of examinees, estimating student and faculty attrition rates, as well as any other problem that centers on modeling time to event data (Cox and Oakes, 1984).

Survival analysis is generally acknowledged to have stemmed from Graunt's publication of the first Weekly Bill of Mortality in the seventeenth-century London as well as the printing of the first life-table by Healy (Lee and Go, 1997). However, the development of survival models that are now routinely used can be traced back to studies undertaken in World War II to assess the durability or the survival of military equipment – a critical issue at that time. In the decades that followed these investigations, survival data models were further devised and applied to address problems in a variety of areas. These models are now routinely used to study a host of issues in the pure and social sciences, including recidivism rates (event-history analysis), survival rates in clinical trials, and longevity of components in engineering (reliability analysis).

Some Basic Terminology

A survival data-analysis set consists of a response variable that reflects the duration of time until a prescribed event occurs – that is, the survival time, T , and possibly a set of covariates thought to be associated with T . The basic goal of survival analysis is to model the underlying distribution of the time to event outcome – either with or without intervening covariates. An event is defined as a qualitative change that can be localized in time (Allison, 1995). A covariate corresponds to a predictor, potentially impacting the time to event outcome. To illustrate, consider the problem of modeling time to graduation in a PhD program (the event) as a function of age, gender, and school (the covariates).

The random survival time variable T can be described by the following three functions:

$$S(t) = 1 - F(t), \quad [1]$$

where $S(t)$ is the survival function or the probability of surviving past time t , while $F(t)$ is the cumulative distribution function of T ,

$$f(t) = \frac{dF(t)}{dt}, \quad [2]$$

where $f(t)$ is the probability density function, also referred to as the unconditional failure rate, and

$$b(t) = \frac{f(t)}{S(t)}, \quad [3]$$

where $b(t)$ is the hazard rate or the conditional failure rate.

The graph of $S(t)$ is generally referred to as the survival curve. The survival curve provides estimates of the probability of still being at risk of experiencing an event at various points in time during the study period. The hazard ratio, $b(t)$, can loosely be interpreted as the instantaneous probability of event occurrence at time t . However, it is not really a probability in that it has no upper bound and can, therefore, exceed unity. In the presence of covariates, it is also interpreted as the relative risk of experiencing the event, given covariate values. Survival data-analysis models are, generally, categorized as being either nonparametric/semiparametric or parametric in nature (Lee, 1992). This article aims to provide a broad overview of these models to educational researchers who may be interested in the general topic of survival data analysis.

Nonparametric and Semiparametric Survival Data-Analysis Models

The Kaplan–Meier Product-Limited Method

For data sets with exact times of censoring and events, the Kaplan–Meier (K–M) Product-limited Method is useful for obtaining an initial indication of the shape of the time to event curve prior to fitting more complex models (Kaplan and Meier, 1958).

The K–M method is essentially akin to a nonparametric maximum likelihood estimation technique. The survival estimate obtained by the K–M method is the product of a series of estimated conditional probabilities. The probability of surviving past time period z , for example, is given by:

$$\hat{P}(T > z) = \hat{S}(z) = p_1 \cdot p_2 \cdot p_3 \cdot \dots \cdot p_z$$

where, p_1 is the proportion of examinees surviving to at least time period 1, p_2 is the proportion of examinees surviving to the second time period (after they have survived the first time period), p_3 is the proportion of examinees surviving to the third time period (after they have survived the second time period), and p_z is the proportion of examinees surviving to time period z , (after they have survived to time period $z - 1$).

The probability of surviving past time t , that is, the probability of still being at risk of experiencing the event past time t , is given by

$$\hat{S}(t) = \prod_{j: t_{(j)} \leq t} \left(1 - \frac{d_j}{r_j}\right) \quad [4]$$

where

$\hat{S}(t)$ = the survival function;

r_j = the number at risk just prior to time t_j ; and

d_j = the number of events at time t_j .

Conversely, the estimate of failure, that is, the cumulative probability of experiencing an event at time t is simply given by

$$\hat{F}(t) = 1 - \hat{S}(t) \quad [5]$$

The use of the K–M method is illustrated with a sample of 80 computer programmers completing a 50-item exam aimed at assessing knowledge of a recently completed technical module. The sample is evenly divided between male and female examinees. Additionally, half of the sample completed the module in a half-day in-house training session whereas the remaining group learned the content online. Passing the examination constitutes the event, within a 30-day test-administration window. Surviving, in this instance, is synonymous with not passing the exam and still being at risk of experiencing the event at various points in time. Survival rates $\hat{S}(t)$ are plotted and shown in **Figure 1** for this set of 80 examinees.

The plot shows a steep drop in the curve within the first week or so of the testing window, suggesting that a large proportion of the cohort met the event (passed the test) early on. In fact, the median survival time for this curve was 10 days, further supporting the claim that a large proportion of the group successfully completed the examination in the earlier stage of test administration. Censored observations are symbolized by the + sign. For example, one examinee attempted to pass the test on day 4, but failed to meet the event. This examinee subsequently

Figure 1 Kaplan–Meier curve for total group-training example.

did not re-attempt the exam (within the 30-day window) and this observation is right censored at day 4.

It may also be of interest to compare two survival curves to see whether event times differ across two treatment groups – for example, as a function of instructional modality (in-house vs. online in the previous example). One useful test to assess whether survival times do differ significantly across strata is the log-rank test. This test is based on the computation of a series of 2×2 contingency tables – one for each time point – of the general form given below,

	<i>Failed</i>	<i>Surviving</i>	<i>At risk</i>
Group A	d_A	$n_A - d_A$	n_A
Group B	d_B	$n_B - d_B$	n_B
Combined	d	$n - d$	n

If there is insufficient evidence to reject the null hypothesis (equal median survival times in both groups), we would expect the total number of failures, d , to be distributed between the two groups A and B in the ratio of the group sizes.

The expected number of failures in group A at time t is given by

$$E_{At} = d \cdot (n_A/n),$$

while the expected number of failures in group B at time t can be obtained by

$$E_{Bt} = d - E_{At}$$

The log-rank test is then computed as,

$$\chi^2 = \frac{(d_A - E_A)^2}{E_A} + \frac{(d_B - E_B)^2}{E_B} \quad [6]$$

where,

d_A = the total number of observed failures in group A;
 E_A = the expected total number of failures in group A;
 d_B = the total number of observed failures in group B; and
 E_B = the expected total number of failures in group B;

It is important to point out that the log-rank test weighs all points of the survival curve equally, that is, it assumes that hazard functions in two groups are proportional over time (they do not cross). Based on our previous example, we were interested in comparing whether the survival functions differed significantly for those examinees that completed the instruction in a traditional fashion (in-house training) versus online. Survival plots for both groups are provided in **Figure 2**. This figure clearly shows that those examinees who completed the in-house training session had a significantly shorter survival time (median survival = 8 days) than those who did the session online (median survival = 15 days), χ^2 (log-rank) = 65.37, $p < 0.0001$.

Cox's Proportional-Hazards Regression Model

In educational research, it is often of interest to assess whether several variables are related to the occurrence of a given event. For example, do sociodemographic and educational variables impact time to graduation, dropout rates, etc? Nonparametric models cannot provide a measure

of the effect of each covariate (adjusted for other predictors in the model) nor can they help the researcher determine which covariate, in a set, is significantly associated with the probability of experiencing an event. Nonetheless, they do constitute useful screening tools to guide subsequent analyses.

Among the many survival data models that have been proposed in the literature, Cox's proportional hazards (PH) regression model (Cox, 1972) is especially useful and popular due to its flexibility in analyzing time-to-event data. The general hazard function for the PH model can be expressed as follows,

$$b(t) = b_0(t) * e^{\beta x} \quad [7]$$

where,

$b_0(t)$ = An arbitrary, non-negative baseline hazard function which does not involve predictor variables.

β_x = Linear combination of p regression coefficients $\{b_1x_{1i} + b_2x_{2i} + \dots + b_px_{pi}\}$.

It is referred to as the PH model because the ratio of the hazards for any two examinees with covariates $x_1 = (x_{11}, x_{21}, \dots, x_{p1})$ and $x_2 = (x_{12}, x_{22}, \dots, x_{p2})$ does not vary with time t , that is,

$$\frac{b_1(t)}{b_2(t)} = \frac{b_0(t)e^{\beta x_1}}{b_0(t)e^{\beta x_2}} = \frac{e^{\beta x_1}}{e^{\beta x_2}}$$

In practice, this function might allow us to model the risk of failing an examination at time t , given the function of time t and the impact of explanatory covariates measured at time t (if applicable). One straightforward way of assessing whether the proportionality assumption holds is to produce a graph plotting the $\log(-\log(\text{survival}))$ versus the log of survival time for the predictor(s) of interest. For illustrative purposes, the latter plot is provided in **Figure 3** for the instruction modality predictor from our previous example. The assumption of proportionality holds for a given predictor when the curves for each level are parallel. As shown in **Figure 3**, the $\log(-\log(\text{survival}))$ versus log of survival time curves are parallel for both groups and support the proportionality assumption.

Cox's PH model is deemed semiparametric in nature as no distribution of survival times is specified. Cox's unique contribution was to devise a means by which to estimate the covariate terms in the model without any consideration of $b_0(t)$, the hazard for an examinee with the value 0 for all the covariates, or the baseline hazard at time t . Since the baseline hazard $b_0(t)$ is not completely specified, it is difficult to use the full likelihood (joint distribution of failure times) to estimate the regression coefficients. Cox (1972) proposed an estimation method which entails maximizing a partial likelihood, as opposed to the full likelihood. The likelihood function for data in a PH model can be factored into the following two parts,

Figure 2 Kaplan-Meier curves by training modality.

$$L = A(\beta) * B(\beta, b_0(t)) \quad [8]$$

where part A contains information relating to the covariates only while part B contains information pertaining to both β s and $b_0(t)$. During the estimation, part B is disregarded and part A is treated as an ordinary likelihood function. Note that part A depends solely on the order that events occurred in, not the exact times. The partial likelihood is then given for all observed events by,

$$L(\beta) = \prod_{k=1}^K \left[\frac{\exp\left(\sum_{j=1}^p \beta_j x_{jk}\right)}{\sum_{l \in R(t_k)} \exp\left(\sum_{j=1}^p \beta_j x_{jl}\right)} \right] \quad [9]$$

where K is the total number of events in the sample and $R(t_k)$ is composed of all examinees whose survival times are at least t_k . Additional computational details on how the partial likelihood is estimated are beyond the scope of this article and can be found in Cox (1972).

Figure 3 Testing the assumption of proportionality in the Cox PH Model for the training example: Plot of the $\log(-\log(S(t)))$ vs. $\log(t)$.

Cox's PH model has been used in educational research to model a variety of time to event research issues, including passing rates in computer-delivered examinations as a function of educational and background variables (De Champlain *et al.*, 2004, 2006), graduation rates (Chimka *et al.*, 2008; Visser *et al.*, 2007), and response times in CBT (Schnipke and Pashley, 1997).

The fit of the following Cox's PH model was assessed with our previous example, where we attempted to model the time to passing the module examination as a function of gender and instructional method,

$$b(t) = b_0(t)e^{\alpha(t) + \beta_1 x_1 + \beta_2 x_2} \quad [10]$$

where

$b(t)$ = the hazard (risk) of passing the examination at time t ;
 $b_0(t)$ = the hazard for an examinee with the value 0 for all the covariates, i.e., the *baseline hazard* at time t ;

$\alpha(t)$ = function of time t ;

$\beta_1 x_1$ = regression coefficient for gender covariate; and
 $\beta_2 x_2$ = regression coefficient for mode of instruction covariate (traditional or online).

There were no time-dependent covariates in this model – that is, values were assumed to be fixed at all levels of time t .

Initial results suggest that there is sufficient evidence to reject the null hypothesis that all covariate regression coefficients are equal to zero, $LR\chi^2(2) = 58.61, p < 0.0001$. Sixty-eight examinees (85%) had experienced the event by the end of our study period – that is, passed the exam – whereas 12 (15%) were classified as censored observations and presumed to still be at risk of passing in the future. **Table 1** provides the results from Cox's PH model. Regression parameter estimates and their associated standard errors, Wald chi-square tests of significance, and associated type I error rates for each term in the model are shown. It is important to point out that the impact of each covariate is assessed while controlling for other variables in the model. Results show that gender was not significantly related to meeting the outcome – that is, passing the examination, $\chi^2(1) = 0.78, p = 0.38$. Instructional modality was, however, significantly related to meeting the event, $\chi^2(1) = 16.55, p < 0.0001$. Exponentiating the regression parameter value for a given covariate provides one with an estimate of the adjusted hazard ratio, or the relative risk of experiencing an event. Examinees who completed the in-house training (median time to

Table 1 Cox's proportional hazards model: Parameter estimates, standard errors, tests of significance, and type I error rates for training-examination example

Variable	DF	$\hat{\beta}$	$SE(\hat{\beta})$	$\hat{\beta}(95\% CI)$	χ^2	p-value
Gender	1	0.22	0.25	-0.27–0.71	0.78	0.38
Training modality	1	2.81	0.46	1.91–3.71	37.30	<0.0001

event = 8 days) were nearly 17 times more likely ($e^{2.80647} = 16.55$) to experience the event (pass the test) than those who completed the training online (median time to event = 15 days).

Parametric Models in Survival Data Analysis

Parametric approaches for estimating survival curves are appealing – in that, the properties of these models can be used to compute the probability of experiencing an event at different points in time. Unlike Cox's PH model, the latter models are fully parametric – that is, the probability distribution needs to be specified. They also include a scale parameter and are thus sometimes referred to as location-scale models. Popular distributions that have been proposed for this purpose include the Exponential, Weibull, and Log-logistic distributions, to name a few (Lee, 1992).

The exponential model is the oldest and can be viewed as a special case of the more complex Weibull distribution. The hazard function for the exponential model is given by,

$$b(t) = \lambda \quad [11]$$

where λ is a constant hazard function ≥ 0 . This model assumes that T – the function denoting the time of event occurrence – follows an exponential distribution with a constant hazard rate. The hazard function for the Weibull distribution is given by,

$$b(t) = \lambda\gamma(\lambda t)^{\gamma-1} \quad [12]$$

where γ is a parameter reflecting the shape of the hazard function and λ is the scale parameter. Note that the exponential case corresponds to a Weibull distribution with a shape parameter of 1 – that is, a constant hazard rate as time increases. The Weibull model provides greater flexibility in modeling the hazard rate and, as such, has broader application. The hazard rate increases when $\gamma > 1$ and conversely decreases when $\gamma < 1$, as values of time increase. Therefore, the Weibull model is useful for modeling survival rates that display either decreasing, constant, or increasing risk.

Finally, the log-logistic model is appropriate if T follows a log-logistic distribution. The hazard function for this model is given by,

$$b(t) = \frac{\lambda\gamma(\lambda t)^{\gamma-1}}{1 + (\lambda t)^\gamma} \quad [13]$$

where λ and γ , respectively, correspond to the scale and shape parameters of the log-logistic distribution. Unlike the previous parametric models, the log-logistic function has a nonmonotonic hazard function. It is, consequently, ideally suited to model time-to-event data when the researcher suspects that the hazard rate initially increases,

then declines as time values approach infinity. When $\gamma < 1$, the hazard rate for a log-logistic distribution decreases from infinity toward 0, while $\gamma = 1$ reflects a decrease from λ to 0. Finally, the hazard rate increases from 0 to a maximum and subsequently decreases toward 0, when $\gamma > 1$.

Following selection of the survival model, parameters are usually estimated using maximum likelihood. The maximum likelihood time-to-event function estimated in parametric models is given by

$$L = \prod_{i=1}^n f_i(t_i)^{\delta_i} S_i(t_i)^{1-\delta_i} \quad [14]$$

where,

$f_i(t_i)$ = the probability that the event occurs at time t and, $S_i(t_i)$ = the probability that an event occurs after time t (i.e., survival probability).

δ_i = a censoring variable that takes a value of 1 if t is uncensored and 0, if t is censored.

Based on this equation, it can be seen that the information from uncensored observations (those who experience the event) is factored into $f_i(t_i)$, while censored observations contribute to $S_i(t_i)$.

Fit of competing models is typically assessed by comparing the log likelihood values as well as by examining various plots of survival curves. In regard to the first approach, consider L_1 to be the maximum likelihood value for the first parametric model of interest and L_2 , the same value for the second model. A likelihood-ratio chi-square statistic can be computed to compare both models. This test assumes that model 2 is obtained by imposing k restrictions on the parameters of model 1.

For example, one could compare the fit of an exponential model versus a Weibull model, as the former is a restrictive case of the latter function. It is also, generally, recommended to assess fit via plots of various $\hat{S}(t)$ curves. Certain transformations of $\hat{S}(t)$ should be linear if the parametric model fits the data set. Specifically, for an exponential model, the plot of $-\log \hat{S}(t)$ versus time should be linear and pass through the origin.

For the Weibull distribution, the plot of $\log[-\log \hat{S}(t)]$ versus $\log(\text{time})$ should be linear. Finally, for the log-logistic model, the plot of $\log[(1 - \hat{S}(t)/\hat{S}(t))]$ versus $\log(\text{time})$ should be linear. In order to illustrate the use of some parametric survival models, the fit of the exponential and Weibull models to the previous data set was examined.

Results suggest that the Weibull model provided a significantly better fit of the data set than the exponential model, $LR\chi^2(1) = 91.53$, $p < 0.0001$. A plot of $\log[-\log \hat{S}(t)]$ versus $\log(\text{time})$, shown in **Figure 4**, further supports this finding (the trend is approximately linear). Parameters estimated in the Weibull model are shown in **Table 2**. Results are similar to those presented with Cox's PH model and suggest that training modality is significantly

associated with experiencing the event, $\chi^2(1) = 125.84$, $p < 0.0001$; whereas gender is not, $\chi^2(1) = 0.37$, $p = 0.544$. We can estimate the percentage of change in the event time for a unit increase in the predictor by calculating, $100(e^{\hat{\beta}_j} - 1)$, where $\hat{\beta}_j$ is the parameter estimate for predictor j . With regard to training modality, $100(e^{-0.8596} - 1) = -57.67$. Examinees who completed the in-house training program had survival times that were about 58% shorter than those who completed the course online – that is, in-house training examinees experienced the event (passed the exam) in a significantly shorter amount of time than those who chose the other instructional modality.

The usefulness of parametric models is, of course, directly related to the extent to which they fit the observed data set. Consequently, it is critical to assess the fit of each theoretical distribution of interest to the data set, using methods similar to those previously outlined. In practice, however, these models are somewhat restrictive in regard to the possible shape of the hazard function and may not adequately reflect the time to event curve. Another limitation of parametric models in the estimation of time-to-event curves is that they cannot readily accommodate time-dependent covariates in the model (Allison, 1995). Nonetheless, parametric models can be useful approaches to model time-to-event data in instances where the user has some hypothesis as to what the shape of the hazard function might be. Parametric models also allow the

researcher to test the fit of alternative hazard functions – something that is not possible with Cox's PH model.

Modeling Discrete Time Events: The Logit Model

The survival models that have been presented throughout this article were devised under the assumption that an examinee could experience the event at any given point within the study period. However, there are some instances where the units of time are quite large (months, years, etc.) relative to the rate of event occurrence (e.g., instance where a student can graduate at only one point in a yearly academic calendar). In the presence of discrete event-time data, the first step generally entails parsing down an examinee's survival history into discrete events. Once the latter events have been pooled, a logit model can be estimated to predict whether the event of interest did or did not occur at each (discrete) time point,

$$\log\left(\frac{P_{it}}{1 - P_{it}}\right) = \alpha_t + \beta_1 x_{it1} + \dots + \beta_k x_{itk} \quad [15]$$

where, P_{it} is an estimate of the conditional probability of experiencing the event for examinee i at time t given that the event has not yet been met by the examinee, where α_t is the baseline hazard at time t , and where β_k is the regression coefficient for explanatory x_k at time t for examinee i . Discrete survival models have been successfully applied to study a host of educational research issues pertaining to graduation rates (Zwick and Sklar, 2005), as well as student attainment and teacher/faculty attrition patterns (Singer and Willett, 1991, 1993).

Figure 4 Testing the fit of the Weibull Model: Plot of the log $(-\log(S(t)))$ vs. $\log(t)$.

Software for Survival Data Analysis

At present, the estimation of common nonparametric, semi-parametric, and parametric survival data-analysis models can be done using common statistical packages – including SPSS and SAS. Life-tables, K–M survival curves, and log-rank tests can be computed using the LIFETEST procedure in SAS while they are estimated using the SURVIVAL and KM analyses in SPSS. Parametric survival data analyses can be fit to data sets in SAS using the LIFEREG procedure.

Table 2 Weibull regression model: Parameter estimates, standard errors, tests of significance, and type I error rates for training-examination example

Variable	DF	$\hat{\beta}$	SE($\hat{\beta}$)	$\hat{\beta}$ (95% CI)	χ^2	p-value
Intercept	1	3.91	0.16	3.59–4.23	578.44	<0.0001
Gender	1	−0.05	0.08	−0.20–0.10	0.37	0.54
Training modality	1	−0.86	0.08	−1.01–0.71	125.84	<0.0001
Scale	1	0.31	0.03	0.26–0.38		
Weibull shape	1	3.18	0.30	2.65–3.82		

Although there is no dedicated procedure to estimate parametric survival data-analysis models in SPSS, common functions can be setup through either the constrained nonlinear regression (CNLR) or nonlinear regression (NLR) methods. The PH model can be run in SAS using the PHREG procedure and can be estimated in SPSS using the Cox Regression (COXREG) method. Finally, the logit model can be estimated in SAS using either the CATMOD, GENMOD, or LOGISTIC procedures. In SPSS, similar models can be estimated with the LOGLINEAR procedure.

The Normal Distribution and its Applications

J Tacq, Catholic University of Brussels, Brussels, Belgium

© 2010 Elsevier Ltd. All rights reserved.

Normal distribution is also called de Moivre distribution, Gaussian distribution, and Gauss–Laplace distribution, due to the work of Abraham de Moivre, Johann Carl Friedrich Gauss, and Pierre-Simon Laplace in the eighteenth century.

It is often called the bell curve, a name going back to Jouffret in 1872, because the graph of its probability density resembles a bell (Figure 1).

The name normal distribution was coined independently by Charles S. Peirce, Francis Galton, and Wilhelm Lexis around 1875.

Forerunners

Carl Friedrich Gauss became associated with normal distribution when he analyzed astronomical data. He defined the equation of its probability density function (PDF). But it was in fact Abraham de Moivre who first introduced normal distribution (a term used only since the second-half of the nineteenth century) in an article in 1733, which was reprinted in the second edition of his *The Doctrine of Chances*, 1738, as an approximation to the binomial distribution for large values of n . His result was extended by Laplace in his book *Analytical Theory of Probabilities* (1812).

Characterization and Probability Density Function

Normal distribution represents a family of continuous probability distributions, applicable in many fields. It may be defined by two parameters, location and scale: the mean (average, μ) and variance (variability, σ^2), respectively. To indicate that a real-valued random variable X is normally distributed with mean μ and variance σ^2 (≥ 0), we write: $X \sim N(\mu, \sigma^2)$ (Case study 1 and Figure 2).

The continuous PDF (Figure 3) of normal distribution is given by the following function:

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right), \quad x \in \mathbb{R}$$

This density function is symmetric about its mean value μ . The mean μ is also its mode and median.

The points of inflection of the curve (i.e., the points where the curve changes from slowly increasing to rapidly increasing, or from rapidly decreasing to slowly decreasing) occur at one standard deviation away from the mean, that is, at $\mu - \sigma$ and $\mu + \sigma$.

About 68% of values drawn from a normal distribution are within one standard deviation away from the mean, about 95% of the values are within two standard deviations (95.4 to be more precise), and about 99.7% lie within three standard deviations. This is known as the 68–95–99.7 rule or the empirical rule (Case study 2 and Figure 4).

Case study 1

An example of the combined action of location (central tendency) and scale (dispersion) is the sleeping behavior of students. In an inquiry among students at Leuven University, Belgium, 3 months before exams, 1 month before exams, and during exams, the number of sleeping hours were normally distributed. The means and variances appeared to be, respectively: (a) 8 and 9, (b) 7.5 and 1.56, and (c) 7 and 0.25. We see that not only the arithmetic means (8, 7.5, 7) but also the variances (9, 1.56, 0.25) are decreasing, the former meaning that students sleep less and less on the average and the latter indicating that the sleeping behavior becomes more and more homogeneous as the exams come nearer.

Case study 2

An example of practical use of the empirical rule is the length of first names given to babies. In a sociolinguistic inquiry of babies in the North of Belgium, a comparison of the number of letters used in first names of baby-boys and baby-girls was planned and a difference of means test was prepared. In order to perform this test, the researchers had to estimate the standard deviation of the population (σ) and – as they were in the dark about this – they used the empirical rule as follows. They assumed a normal distribution. The largest name, such as Marginus-Christianus-Reginus for boys or Cornelia-Elisabeth-Anastasia for girls, contained 26 letters. The shortest name, such as Jo for boys or An for girls, consisted of two letters. So, the range (highest minus lowest length) was $26 - 2 = 24$ letters. Now, we know that in a normal distribution almost 100% of the population (95.4%) is situated between $\mu - 2\sigma$ and $\mu + 2\sigma$ and that an extra standard deviation left and right does not add much (only 2.3% extra according to the empirical rule). It follows that the range is approximately equal to 4 standard deviations. Therefore, the standard deviation σ was (roughly) estimated as $24/4 = 6$.

Figure 1

Figure 2

Cumulative Distribution Function

The cumulative distribution function (CDF) of a probability distribution contains the probabilities that a random variable X is less than or equal to X . The cumulative distribution function of the normal distribution (Figure 5) is expressed as follows:

$$\Phi(x) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) dx, \quad x \in \mathbb{R}$$

Standard Normal Distribution

In many applications in which some random variable X is normally distributed with mean μ and variance σ^2 , we will standardize X to obtain z -scores ($z = (X - \mu)/\sigma$). The distribution of the z -scores is the standard normal distribution, that is, the normal distribution with a mean of zero and a variance of one. Hence, if $X \sim N(\mu, \sigma^2)$, then $z \sim N(0, 1)$.

Figure 3

Figure 4

Figure 5

The probability density function of the standard normal distribution is as follows:

$$\varphi(z) = \frac{1}{\sqrt{2\pi}} \exp(-z^2/2), \quad z \in \mathbb{R}, \quad \text{where } z = (X - \mu)/\sigma$$

Standard normal distribution is tabulated, usually in the form of values of the CDF, Φ . As normal distributions are simple transformations of the standard one, the tabulated values of the CDF of the standard normal distribution can be used to find the values of the CDF of the normal distribution in many practical applications (Figure 6).

Figure 6

The standard normal distribution is very useful to calculate probabilities. Take the above-mentioned example of sleeping behavior of students at Leuven University. Three months before exams, the mean was 8 h per night and the variance was 9 h. If a student is selected at random, what is the probability of sleeping (a) less than 4 h per night, (b) more than 12 h, and (c) between 4 and 12 h? To find these probabilities, we have to first convert the values of variable X to values of the standardized variable z . The probabilities are then given by tables for the normal function. The solutions are as follows: (a) For $X=4$ we have a z -score of $(4-8)/3 = -1.33$. The area under the normal curve left of $z = -1.33$ is the same as the area right of $z = 1.33$ (because of symmetry), which is $1 - 0.9082 = 0.0918$ (tables). So, a proportion of 9% of the students sleep less than 4 h. (b) For $X=12$ we have $z = (12-8)/3 = 1.33$. This results in the same probability of 0.0918. So 9% of the students sleep more than 12 h. (c) For $X=4$ and $X=12$, we have z -scores of -1.33 and $+1.33$, respectively. The probability left of $z = -1.33$ was calculated to be 0.0918. The probability left of $z = 1.33$ is 0.9082. The difference is $0.9082 - 0.0918 = 0.8164$. So, there is a probability of more than 81% for a student to sleep between 4 and 12 h.

Properties of Normal Distribution

Some properties of normal distribution are applicable to a variety of statistical procedures:

1. If random variable X is normally distributed ($X \sim N(\mu, \sigma^2)$) and a and b are real numbers, then $aX + b$ is normally distributed with mean $a\mu + b$ and variance $(a\sigma)^2$, that is, $aX + b \sim N(a\mu + b, (a\sigma)^2)$.
2. Addition and subtraction of two independent normal random variables result in a normal distribution, but not so for multiplication and division (e.g., the ratio follows a Cauchy distribution, not a normal distribution). So, if $X \sim N(\mu_x, \sigma_x^2)$ and $Y \sim N(\mu_y, \sigma_y^2)$, then $X + Y \sim N(\mu_x + \mu_y, \sigma_x^2 + \sigma_y^2)$ and $X - Y \sim N(\mu_x - \mu_y, \sigma_x^2 + \sigma_y^2)$.
3. If X_1, X_2, \dots, X_n are independent standard normal variables, then the sum of their squares $X_1^2 + X_2^2 + \dots + X_n^2$ has a chi-square distribution with n degrees of freedom.

Central Limit Theorem

The importance of normal distribution as a model of quantitative phenomena in the natural and behavioral sciences is due to the central limit theorem. Under certain conditions (such as being independent and identically distributed with finite variance) the sum of a large number of random variables is approximately normally distributed – this is the central limit theorem. Many psychological measurements and physical phenomena (like noise) can be approximated well by the normal distribution. While the mechanisms underlying these phenomena are often unknown, the use of the normal model can be theoretically justified by assuming that many small, independent effects additively contribute to each observation.

From Binomial to Normal

The practical importance of the central limit theorem is that the normal cumulative distribution function can be used as an approximation to some other cumulative distribution functions, for example: a binomial distribution with parameters n and p is approximately normal for large n and for p not too close to 1 or 0. The approximating normal distribution has parameters $\mu = np$, $\sigma^2 = np(1-p)$, where an event (e.g., throwing heads with a coin) can occur or not occur and where p = the probability of occurrence of the event (heads) and $q = 1 - p$ = the probability of nonoccurrence of the event, that is, occurrence of the alternative event (tails). We say that the random variable X has a binomial distribution with parameters n and p and we write $X \sim B(n, p)$. In the example of throwing a fair coin, p and q are both equal to $\frac{1}{2}$. In that case, the binomial distribution is symmetrical. An example in which p and q are unequal would be random variable X = the number of left-handed children. In a school of 500 children with a probability of 10% of meeting a left-handed child, X will show a binomial distribution $X \sim B(500, 0.1)$. Such a distribution would be much skewed if p is extremely small or large, but when n is large, symmetry is restored. The binomial distribution almost corresponds to the normal distribution if p is close to 50% and/or the sample size is large. In the example of left-handed children p is only 10%, but as n is rather large (500) normal approximation holds.

The latter, the tendency of the binomial toward the normal distribution, is nicely illustrated by Galton's board. At the top is a funnel in which balls are dropped. In the middle we see metal bars at an equal distance from each other. At the bottom are receptacles. Each time a ball hits a bar it has just as much probability of falling to the right as to the left ($p = 50\%$). In order for a ball to fall into the receptacle at the extreme left, it must fall to the left each time it hits a bar. The probability that this will occur is, of course, small. The same holds for the extreme right.

The probability of landing in a centrally located receptacle is very great, because a ball may fall first to the right then to the left, and so on. The result with a large number of balls is the Gauss curve of normal distribution, as shown in **Figure 7**.

As the value of n increases and p does not deviate too much from $1/2$, the PDF of the binomial distribution will be obtained by the following form:

$$f(X) = \frac{1}{\sqrt{npq2\pi}} \exp\left(-\frac{(X - np)^2}{2npq}\right)$$

in which p and q have the same meaning as before and $\pi = 3.14$ and $e = 2.72$. This is the normal distribution with $\mu = np$ and $\sigma^2 = npq$. We can now illustrate the normal approximation of the binomial distribution by means of the example of left-handed children. The school has $n = 500$ children. The probability of meeting a left-handed child is $p = 0.1$. Suppose we want to calculate the probability of there being more than 60 left-handed children in the school. Making use of the formulas of binomial distribution, we would have to calculate p (more than 60) = $p(61) + p(62) + p(63) + \dots + p(500)$. This would be an enormous calculation task. Using the normal approximation makes the task rather easy. $X \sim B(500, 0.1)$ will be approximated by $N(50, 45)$, for we have $\mu = np = 500(0.1) = 50$ and $\sigma^2 = npq = 500(0.1)(0.9) = 45$. The standard deviation σ is $\sqrt{45} = 6.7$. Transformation to the standard normal distribution of a number of $X = 60$ left-handed children gives a standardized score of $z = (60 - 50)/(6.7) = 1.5$. From the table of areas under the (cumulative standard) normal curve we have $p(X \leq 60) = p(z \leq 1.5) = 0.93$. It follows that $p(X > 60) = 1 - 0.93 = 0.07$,

Figure 7

which means that the probability of there being more than 60 left-handed children is 7% (**Figure 8**).

When $p = q = \frac{1}{2}$, we can make a similar calculation to show what is the probability of obtaining between 470 and 530 heads, when 1000 fair coins are thrown. The binomial distribution $B(1000, 0.5)$ is approximated by the normal distribution $N(500, 250)$, for the mean is $\mu = np = 1000(\frac{1}{2}) = 500$ and the variance is $\sigma^2 = npq = 1000(\frac{1}{2})(\frac{1}{2}) = 250$. The standard deviation is $\sqrt{250} = 15.8$. The values $X = 470$ and $X = 530$ have standardized scores of $z = (470 - 500)/(15.8) = -1.9$ and $z = (530 - 500)/(15.8) = 1.9$, respectively. From the table of areas under the (cumulative standard) normal curve we obtain the following probabilities: $p(X \leq 470) = p(z \leq -1.9) = 0.03$ and $p(X \leq 530) = p(z \leq 1.9) = 0.97$. The difference 0.94 is the requested probability of obtaining heads numbering between 470 and 530 heads (**Figure 9**).

Examples, Occurrence

It has been repeated again and again, in a great number of textbooks that (approximate) normal distributions occur in many situations, as a result of the central limit theorem, for, when there is reason to suspect the presence of a large number of small effects acting additively and independently, it is reasonable to assume that observations will be normal.

We would like to call in question this overrating of the bell curve, for effects can also act in a multiplicative (rather than additive) fashion. In that case, the assumption of normality is not justified and it is rather the logarithm of the variable of interest that is normally distributed. The distribution of the directly observed variable is then called log-normal. Financial variables are a good example. Financial indicators such as stock values and commodity prices exhibit multiplicative (rather than additive) behavior because of the exponential nature of inflation, and normal distribution does often not apply to them.

Another example of non-normality is the truncated distribution, which seems to occur in a great many cases of social science investigations (**Case study 3** and **Figure 10**).

Looking at positive examples of normality, the most-quoted applications occur in the area of measurements, for example, measures of length, height, skin area, (for weight sometimes the logarithm thereof), and the length of appendages like hair, claws, nails, and teeth. Another

Figure 8

Figure 9

Figure 10

Case study 3

A truncated distribution is a distribution in which the top or the bottom has been removed. An example could be the number of weapons owned. In an inquiry among legislators supporting or opposing a bill on gun control, one of the variables was the number of weapons they owned. The distribution had almost the shape of a normal curve, but was truncated at zero, because a negative number of weapons is impossible. The mean was equal to 2, the standard deviation was approximately equal to 2, the range was between 0 and 6, and one had the impression that, if a negative number of weapons would have been possible, a beautiful bell curve would have emerged ranging from -2 to 6 with the mean of two weapons owned in the middle. The truncation at zero seemed to cause a deviation from normality.

In many examples in social science there seems to be such a left or right truncation.

example of measurement is the blood pressure of adult humans, which is supposed to be normally distributed for males and females separately.

Normality is more particularly the central assumption of the mathematical theory of errors. For example, repeated measurements of the same quantity are expected to yield results which are clustered around some value. If all major sources of errors have been taken into account, it is assumed that the remaining error must be the result of a large number of very small additive effects, and hence normal (because of the central limit theorem).

Similarly, in statistical model-fitting, an indicator of goodness of fit is that the residuals (=errors) be independent and normally distributed.

Many intelligence quotient (IQ)-tests lead to IQ-scores being normally distributed for a variety of populations in society. However, the question whether intelligence itself is normally distributed is more involved, among other reasons because intelligence is a latent variable; therefore, its distribution cannot be observed directly. This question whether or not intelligence represents a bell curve is the topic of the next section.

The Myth of the Bell Curve

Variation in intelligence became the subject of scientific study in the nineteenth century, stimulated by Charles Darwin's theory of evolution. Francis Galton, Darwin's young cousin, tried to devise an intelligence test as we understand the term today. It was his most influential successor, a French psychologist, Alfred Binet, who developed the technique to measure IQ which is still used today. He determined which problems could be solved at which age and then analyzed whether a person had a mental age above or under his real age. By dividing mental age by real age, he obtained a quotient, called IQ. Then, in 1904, a former British Army officer named Charles Spearman made a statistical breakthrough in using factor analysis as a technique for finding what different mental tests have in common, and a conceptual breakthrough in

hypothesizing that all different forms of intelligence can be reduced to one general trait, which he named g for general intelligence.

In line with the central limit theorem, the idea became widespread that a person's intelligence might be the sum of many small random variations in genetic and environmental factors, and that, consequently, IQ-scores are normally distributed. It was for a long time generally accepted that the mean of this distribution is 100 with a standard deviation of 15.

It was common to consider an IQ-score of 70 or less, that is, two or more standard deviations below the mean, as the borderline for 2.5% of the people needing special care and training, who have been labeled moron, imbecile, idiot, cretin, feeble-minded, backward, and the like. As sensitivity, kindness, and political correctness became an issue, these terms were replaced by educationally subnormal, in special needs, educable mentally retarded, trainable mentally retarded, etc. Severity of mental retardation is sometimes broken down into four levels: 50–70 – mild mental retardation, 35–50 – moderate mental retardation, 20–35 – severe mental retardation, and <20 – profound mental retardation.

At the other side of the distribution, an IQ-score of 130 or more, that is, two or more standard deviations above the mean, represents the top 2.5%, who are labeled bright, highly gifted, brilliant, genius, etc. Genius IQ is generally considered to begin around three standard deviations above the mean, that is, 145, representing 0.15% of the population (see the empirical rule explained above: $(1 - 99.7)/2 = 0.15$). A rough guide for levels of brightness is as follows: 135–144 – highly gifted (intellectuals), 145–154 – genius (professors), 155–164 – genius (Nobel prize winners), 165–179 – high genius, 180–200 – highest genius, and >200 – unmeasurable genius. Cyril Burt (1963) names John Stuart Mill, Sir Hamilton, Lord Macaulay, Lord Kelvin, and Sir Francis Galton, whose IQ must have been approximately 200. Einstein was considered to have an IQ of only about 160.

The middle group between one standard deviation below and above the mean, representing 68% of the population (see the empirical rule), is considered normal (**Figure 11**).

In the 1960s, a new controversy about intelligence tests emerged that continues to this day. Psychometricians had long-time debated whether intelligence is almost entirely produced by genes or whether the environment also plays a role, the so-called nature–nurture debate. By the 1960s, the point of contention had shifted dramatically. It became controversial to claim that genes had any effect at all on intelligence. When Arthur Jensen wrote – in 1969 – that education program had yielded disappointing results, and concluded that success in school depended to a considerable degree on IQ, that IQ had a large heritable component, and also that historically blacks had exhibited average IQs substantially below those of whites, the reaction was immediate and violent. Dozens of books and hundreds of articles appeared arguing that mental abilities are determined by environment, with genes playing a minor role and race none at all. A best seller was *The Mismeasure of Man*, published by Harvard paleobiologist Stephen Jay Gould, who argued that intelligence is a bankrupt concept, is culturally biased (they measure white IQ, not black IQ), IQ scores are not constant over an individual's life span and are unrelated to earnings, occupation, productivity, and other important measures of success. There is not just one primary ability, g for – so Gould argued – other scientists have hypothesized many more, two according to Raymond Cattell, half-dozen in Louis Thurstone's theory, a hierarchy in Philip Vernon's, and 120 or more in Joy Guilford's, and moreover, a simple rotation of the factor analysis solution shows that the general factor g disappears.

In this context of discussion, a controversial best-selling book *The Bell Curve* appeared in 1994, which was written by Harvard professor Richard Herrnstein and political scientist Charles Murray, and which ran against the current. Its central point is that intelligence – which is 60–80% determined by nature and 20–40% by nurture – is a better predictor of many factors including financial

Figure 11

income, job performance, unwed pregnancy, and crime, than parents' socioeconomic status or educational level. The authors write that the debate about whether and how much genes and environment have to do with ethnic differences remains unresolved, and yet the media and many scholars condemned the book, notwithstanding their subtle and balanced text. The discussion has dominated the 1990s and thereafter and one can really fill a whole library with the debate about fueling racism. The short sentence of the long debate is that all the discussions boil down to the nature–nurture debate, so that we really seem to end where we started, albeit on a higher level of mental power. Recommended to the reader!

Applications in Statistics

Normal distribution arises in many areas of statistics. For example, the sampling distribution of the sample mean is approximately normal, even if the distribution of the population from which the sample is taken is not normal, on the condition that the sample is sufficiently large. This principle, which is an application of the central limit theorem, is widely used in statistical estimation and testing.

Many scores are derived from normal distribution, including percentiles, normal curve equivalents, stanines, z -scores, and T -scores.

Normal distribution is also most widely used in statistical tests, because many tests, such as T -tests and ANOVAs, are based on the assumption of normality.

In many cases, for example, when tests are based on the assumption of normality, this assumption has to be tested by means of a normality test, that is, a check whether a given set of empirical data show similarity to normal distribution. The null hypothesis is that the data set is similar to normal distribution; therefore, a sufficiently small p -value indicates deviation from normality. Existing tests of normality are:

- Kolmogorov–Smirnov test,
- Lilliefors test,

- Anderson–Darling test,
- Ryan–Joiner test,
- Shapiro–Wilk test,
- Normal probability plot, and
- Jarque–Bera test.

Special applications of normal distribution can also be found in Q -factor analysis. A generalization is the multivariate normal distribution, which is discussed elsewhere in this encyclopedia.

Glossary

AIC – Akaike's information criterion, eqn [18], used to select the orders p and q of an appropriate ARMA model to represent observations of a stationary time series.

AICC – A version of the AIC criterion, corrected to improve model selection for short time series.

ARIMA process – A time series which, after differencing one or more times, becomes an ARMA process.

ARMA process – A stationary time series satisfying difference equations of the form [12].

Autocorrelation function – For a stationary time series $\{Y_t\}$, the correlation $\rho(h)$ (eqn [5]) between Y_{t+h} and Y_t is independent of t for every h , and the function $\rho(h)$, $h = 0, \pm 1, \pm 2, \dots$, is called the autocorrelation function of the time series $\{Y_t\}$.

Sample autocorrelation function – From observed values y_1, \dots, y_n , of a stationary time series, the autocorrelation $\rho(h)$ is estimated by the sample autocorrelation function $\hat{\rho}(h)$, defined in terms of the observed data by eqn [8].

Stationary time series – A Sequence of random variables $\{Y_t\}$ satisfying eqn [4]. (The term '2nd-order stationary time series' is often used to distinguish this definition of stationary from that of 'strict stationarity'.)

observations which are made at uniformly spaced times. For this reason, the present article focuses on this case.

Example 1

Figure 1 shows the annual percentages of 18- and 19-year-olds enrolled in schools, colleges, universities, or professional colleges for the years 1947 through 2006. (US Department of Commerce, Census Bureau, Current Population Survey (CPS), October, 1970–2006). The graph shows a clear upward trend with apparently random fluctuations from year to year. For planning purposes, we would like not only to forecast this series, but at the same time produce estimates of the possible errors to be expected in the forecasts. This is a typical problem of time series analysis.

Example 2

Figure 2 shows the monthly birth rate (births per year per 1000 inhabitants) of New York City from January 1947 through December 1959 (Hyndman, R. J. Time Series Data Library). As is often the case with monthly data, the series strongly suggests the presence of a component which repeats itself every 12 months, in this case with a peak around July and a trough in February, corresponding to the seasons of the year. In addition, there appears to be a smooth upward trend and a random component accounting for irregular deviations from the sum of the trend and seasonal components.

Time Series Data

A time series is any sequence of observations recorded at specified times and usually displayed as a time-series plot. This is a graph in which the observations are plotted as a function of time. Examples are shown in **Figures 1** and **2**. Time series abound in all branches of science, engineering, sociology, and economics, and in fact in every field in which observations are recorded over a period of time. The set of times T at which observations are recorded may be a discrete set, as is the case when the observations are recorded at uniformly spaced times (daily rainfall, hourly temperature, annual income, etc.) or it may be a continuous interval, as when the data are recorded continuously (e.g., by a seismograph or electrocardiograph). A very large number of practical problems involve

Objectives

Time series analysis has many different objectives, depending on the field of application. These include forecasting future values of the series, extracting a signal hidden in noisy data, discovering the mechanism by which the data are generated, simulating independent realizations of the series to see how it might behave in the future (and hence, for example, to estimate the probability of extreme events like floods), and eliminating the seasonal component from data sets like the one in example 2 in order to reveal more clearly the underlying trend. In studying monthly economic statistics, for example, it is important to carry out this so-called deseasonalization so as not to confuse the long-term trend with the month-to-month seasonal variation. For all such applications, time

Figure 1 Annual percentages of 18- and 19-year-olds enrolled in educational institutions from 1947 through 2006 (Example 1).

Figure 2 Monthly birth rates in New York City, January 1947 through December 1959 (Example 2).

series analysis usually begins with an attempt to find a mathematical model which provides a good representation of the observed data.

Although it is rarely the case that there is a true mathematical model underlying empirical data, systematic procedures have been developed for selecting a good model, according to clearly specified criteria. Once this is achieved, the selected model can be used to address the questions posed in the preceding paragraph.

Time Series Models

As indicated above, the graph of the monthly birth rates in **Figure 2** suggests representing the rate x_t at time t as the sum of a slowly varying trend component, a period-12 seasonal component and a random component which accounts for the irregular deviations from the sum of the other two. In order to take account of the randomness, we suppose that for each t , the observation x_t is just one of

many possible values of a random variable X_t which we might have observed. This leads to the following classical decomposition model for the birth-rate series,

$$X_t = m_t + s_t + Y_t, t = 1, 2, 3, \dots, \quad [1]$$

where the sequence $\{m_t\}$ is the trend component describing the long-term movement of the series, $\{s_t\}$ is a seasonal component with known period (in this case 12) and $\{Y_t\}$ is a sequence of random variables with mean zero, referred to as the random component. If we can characterize m_t , s_t , and Y_t in simple terms and in such a way that the model [1] provides a good representation of the data, then we can proceed to use the model to make forecasts or to address other questions related to the series. Completing the specification of the model by estimating the trend and seasonal components and characterizing the random component is a major part of time series analysis. The model [1] is sometimes referred to as an additive decomposition model. Provided the observations are all positive, the multiplicative model,

$$X_t = m_t s_t Y_t, \quad [2]$$

can be reduced to an additive model by taking logarithms of each side to get an additive model for the logarithms of the data.

The general form of the additive model [1] supposes that the seasonal component s_t has known period d (12 for monthly data, 4 for quarterly data, etc.) and satisfies the conditions

$$s_{t+d} = s_t \text{ and } \sum_{t=1}^d s_t = 0, \quad [3]$$

while $\{Y_t\}$ is a stationary time series, that is, a sequence of random variables satisfying the conditions,

$$E(Y_t) = \mu, E(Y_t^2) < \infty \text{ and } \text{Cov}(Y_{t+b}, Y_t) = \gamma(b) \text{ for all } t, \quad [4]$$

with the additional property that $\mu = 0$. The function γ is called the autocovariance function of the sequence $\{Y_t\}$ and the value $\gamma(b)$ is the autocovariance at lag b . In the special case when the random variables Y_t are independent and identically distributed, the model [1] is a classical regression model and $\gamma(b) = 0$ for all $b \neq 0$. However, in time series analysis, it is the dependence between Y_{t+b} and Y_t which is of special interest and which allows the possibility of using past observations to obtain forecasts of future values which have a smaller expected squared error than would be obtained if we used the naive forecast, μ . A simple and useful measure of the dependence between X_{t+b} and X_t is provided by the autocorrelation function,

$$\rho(b) = \frac{\gamma(b)}{\gamma(0)}. \quad [5]$$

It measures dependence in the sense that the expected squared difference between Y_{t+b} and Y_t is maximum when $\rho(b) = -1$ and decreases to zero as $\rho(b)$ increases to 1 according to the relation, $E(Y_{t+b} - Y_t)^2 = 2\gamma(0)(1 - \rho(b))$.

From observed values y_1, \dots, y_n of a stationary sequence of random variables $\{Y_t\}$, good estimators of the mean $\mu = E(Y_t)$ and the autocovariance function $\gamma(b)$ are the sample mean and sample autocovariance function,

$$\hat{\mu} = \frac{1}{n} \sum_{i=1}^n y_i \quad [6]$$

and

$$\hat{\gamma}(b) = \frac{1}{n} \sum_{i=1}^{n-|b|} (y_{i+|b|} - \hat{\mu})(y_i - \hat{\mu}), -n < b < n, \quad [7]$$

respectively. The autocorrelation function of $\{Y_t\}$ is estimated by the sample autocorrelation function,

$$\hat{\rho}(b) = \frac{\hat{\gamma}(b)}{\hat{\gamma}(0)}. \quad [8]$$

Elementary techniques for estimating the trend and seasonal components, m_t and s_t , can be found in many texts on time series analysis (e.g., Brockwell and Davis, 2002).

More sophisticated techniques are employed in the packages X-11 and the updated version X-12 described in Findley *et al.* (1998), and used by the US Census Bureau. Once estimators \hat{m}_t of m_t and \hat{s}_t of s_t have been obtained, they can be subtracted from the observations to yield the residuals,

$$y_t = x_t - \hat{m}_t - \hat{s}_t. \quad [9]$$

A stationary time series model can then be fitted to the residual series to complete the specification of the model. The model is usually chosen from the class of autoregressive moving average (or ARMA) processes defined in the section titled ARMA and ARIMA processes.

Instead of estimating and subtracting off the trend and seasonal components to generate a sequence of residuals, an alternative approach, developed by Box *et al.* (1994), is to apply difference operators to the original series to remove trend and seasonality. The backward shift operator, B is an operator which when applied to X_t gives X_{t-1} . Thus

$$BX_t = X_{t-1}, B^j X_t = X_{t-j}, j = 2, 3, \dots$$

The lag-1 difference operator is the operator $\nabla = (1 - B)$. Thus

$$\nabla X_t = (1 - B)X_t = X_t - X_{t-1}. \quad [10]$$

When applied to a polynomial trend of degree d , the operator ∇ reduces it to a polynomial of degree $d - 1$. The operator ∇^d , denoting d successive applications of ∇ , therefore reduces any polynomial trend of degree d to a constant. Usually a small number of applications of ∇ is sufficient to eliminate trends encountered in practice. Application of the lag- r difference operator, $\nabla_r = (1 - B^r)$ (not to be confused with ∇^r), to X_t gives

$$\nabla_r X_t = (1 - B^r)X_t = X_t - X_{t-r}, \quad [11]$$

eliminating any seasonal component with period r . In the Box-Jenkins approach to time series modeling, the operators ∇ and ∇_r are applied as many times as is necessary to eliminate trend and seasonality and the sample mean of the differenced data subtracted to generate a sequence of residuals y_t which are then modeled with a suitably chosen ARMA process in the same way as the residuals [9].

Figure 3 shows the effect of applying the operator ∇ to the enrolment series of **Figure 1**. There is no longer any apparent trend and the differenced series is a good candidate for representation by a stationary time series model.

In the case of the New York birth-rate series, our first goal is to remove the seasonal component with period 12. This is achieved by application of the lag-12 difference operator $(1 - B^{12})$. **Figure 4** shows the resulting series which, like the series in **Figure 3**, is a good candidate for representation by a stationary time series model. Notice that the operator $(1 - B^{12})$ not only removed the seasonality but also the upward trend in the original series.

Had this not been the case, then further applications of the operator $(1 - B)$ would have been necessary to remove any remaining trend.

In cases where the variability of the observed data appears to change with the level of the data, a preliminary transformation, prior to detrending and deseasonalizing, may be required to stabilize the variability. For this purpose, a member of the family of Box–Cox transformations (see e.g., Brockwell and Davis, 2002) is frequently used.

ARMA and ARIMA Processes

For modeling the residuals $\{y_t\}$ (found as described above), a very useful parametric family of zero-mean stationary sequences is furnished by the autoregressive moving average (or ARMA) processes. The ARMA(p, q) process $\{Y_t\}$ with autoregressive coefficients, ϕ_1, \dots, ϕ_p , moving average coefficients, $\theta_1, \dots, \theta_q$ and white-noise variance σ^2 , is defined as a stationary solution of the difference equations,

$$(1 - \phi_1 B - \dots - \phi_p B^p) Y_t = (1 + \theta_1 + \dots + \theta_q B^q) Z_t, \quad t = 0, \pm 1, \pm 2, \dots \quad [12]$$

where B is the backward shift operator, the polynomials, $\phi(z) = 1 - \phi_1 z - \dots - \phi_p z^p$ and $\theta(z) = 1 + \theta_1 z + \dots + \theta_q z^q$, have no common factors and $\{Z_t\}$ is a sequence of uncorrelated random variables with mean zero and variance σ^2 . Such a sequence $\{Z_t\}$ is said to be white noise with mean 0 and variance σ^2 , indicated more concisely by writing $\{Z_t\} \sim \text{WN}(0, \sigma^2)$.

The eqn [12] has a unique stationary solution if and only if the equation $\phi(z) = 0$ has no real or complex root with $|z| = 1$; however, the possible values of ϕ_1, \dots, ϕ_p are usually assumed to satisfy the stronger restriction,

$$\phi(z) \neq 0 \text{ for all complex } z \text{ such that } |z| \leq 1. \quad [13]$$

The unique stationary solution of eqn [12] is then

$$Y_t = \sum_{j=0}^{\infty} \psi_j Z_{t-j}, \quad [14]$$

where ψ_j is the coefficient of z^j in the power-series expansion,

$$\frac{\theta(z)}{\phi(z)} = \sum_{j=0}^{\infty} \psi_j z^j, \quad |z| \leq 1.$$

Since Y_t in eqn [14] is a function only of Z_s , $s \leq t$, the series $\{Y_t\}$ is said to be a causal function of $\{Z_t\}$ and the condition [13] is called the causality condition for the eqn [12]. (Condition [13] is also frequently referred to as a stability condition.) The autocovariance function of the ARMA process [14] is

$$\gamma(b) = \sigma^2 \sum_{j=0}^{\infty} \psi_j \psi_{j+|b|}.$$

Under the condition [13], simple recursions are available for the numerical calculation of the sequence $\{\psi_j\}$ and of the autocovariance function $\gamma(b)$. Details can be

Figure 3 The differenced series $\{\nabla x_t\}$ derived from the annual percentage enrolment series shown in **Figure 1**.

Figure 4 The differenced series $\{(1 - B^{12})x_t\}$ derived from the monthly New York birth-rate series shown in **Figure 2**.

found in Brockwell and Davis (2002). A key feature of ARMA processes for modeling dependence in a sequence of observations is the extraordinarily large range of autocorrelation functions exhibited by ARMA processes of different orders (p, q) as the coefficients ϕ_1, \dots, ϕ_p , and $\theta_1, \dots, \theta_q$, are varied.

Example 3

The causal ARMA(1,0) or AR(1) process is a stationary solution of the equations

$$Y_t = \phi Y_{t-1} + Z_t, \quad |\phi| < 1, \{Z_t\} \sim \text{WN}(0, \sigma^2).$$

The coefficients ψ_j for this process are $\psi_j = \phi^j$ and the autocovariance function of $\{Y_t\}$ is $\gamma(b) = \sigma^2 \phi^{|b|} / (1 - \phi^2)$.

ARMA processes as defined above are mathematical models for zero-mean stationary time series. However, many of the time series encountered in practice, like examples 1 and 2, cannot be well represented by a stationary model (i.e., one which satisfies the conditions [4]) since such a model does not account for trend and seasonality. However we saw in the section titled ‘Time Series models’ how the operators $(1 - B)$ and $(1 - B^r)$ can be used to eliminate trend and seasonality respectively. If a sequence of zero-mean residuals $\{y_t\}$ is generated by applying the operator $(1 - B)^d$ to the original series $\{x_t\}$ and we find that a model of the form [12] is appropriate for $\{y_t\}$, then we are effectively saying that the original series can be represented by the model,

$$\phi(B)(1 - B)^d X_t = \theta(B)Z_t, \quad \{Z_t\} \sim \text{WN}(0, \sigma^2). \quad [15]$$

These equations are said to represent the original nonstationary series $\{x_t\}$ as an ARIMA(p, d, q) process. More generally, if the original series contains a trend and a seasonal component of period r , and if a sequence of zero-mean residuals $\{y_t\}$, obtained by applying the operators $(1 - B^r)$ and $(1 - B)^d$ to $\{x_t\}$, is found to be well-represented by equations of the form (12), then $\{x_t\}$ is well represented by the model,

$$\phi(B)(1 - B)^d(1 - B^r)X_t = \theta(B)Z_t, \quad \{Z_t\} \sim \text{WN}(0, \sigma^2) \quad [16]$$

and $\{X_t\}$ is said to be a seasonal ARIMA process. Notice that the fitting of ARIMA processes and seasonal ARIMA processes reduces, after the required differencing operations have been applied to the original data, to the fitting of ARMA processes to the residuals $\{y_t\}$. We consider this problem in the next section.

Model Selection and Estimation

Suppose for the moment that we know the orders p and q of the ARMA process [12] which is to be fitted to the residuals

y_1, \dots, y_n and suppose that $\beta = (\phi_1, \dots, \phi_p, \theta_1, \dots, \theta_q, \sigma^2)$, is the vector of parameters to be estimated. The Gaussian likelihood $L(\beta; y_1, \dots, y_n)$, is the likelihood computed under the assumption that the joint distribution from which y_1, \dots, y_n are drawn is multivariate normal. Thus

$$L(\beta; y_1, \dots, y_n) = (2\pi)^{-n/2} (\det \Gamma_n)^{-1/2} \exp\left(-\frac{1}{2} \mathbf{y}_n' \Gamma_n^{-1} \mathbf{y}_n\right) \quad [17]$$

where $\mathbf{y}_n = (y_1, \dots, y_n)'$, Γ_n is the matrix of autocovariances $[\gamma(i - j)]_{i,j=1}^n$ and $\gamma(b)$ is the autocovariance function of the model defined by [12]. Although direct calculation of L is a daunting task, L can be calculated recursively using a transformation of variables as described in Brockwell and Davis (2002). For given values of y_1, \dots, y_n , the likelihood L is then maximized numerically with respect to β , in order to obtain the maximum likelihood estimate $\hat{\beta}$ of the ARMA parameters.

At first glance, maximization of Gaussian likelihood when the observations appear to be non-Gaussian may seem strange. However if the noise sequence $\{Z_t\}$ in the model [12] is any independent identically distributed sequence (with finite variance), the large-sample joint distribution of the estimators (assuming the true orders are p and q) is the same as in the Gaussian case (see Hannan, 1973; Brockwell and Davis, 1991). This large-sample distribution has a relatively simple Gaussian form which can be used to specify large-sample confidence intervals for the parameters (under the assumption that the observations are generated by the fitted model).

The previous discussion assumes that the orders p and q are known. However, this is rarely if ever the case and they must be chosen on the basis of the observations. The choice of p and q is referred to as the problem of order selection. A systematic approach to the problem was suggested by Akaike (1973) when he introduced the Akaike Information Criterion (AIC). He proposed that p and q be chosen by minimizing $\text{AIC}(\hat{\beta}(p, q))$, where $\hat{\beta}(p, q)$ is the maximum likelihood estimator of β for fixed p and q and

$$\text{AIC}(\beta) = -2 \ln(L(\beta)) + 2(p + q + 1). \quad [18]$$

The term $2(p + q + 1)$ can be regarded as a penalty factor which prevents the selection of excessive values for p and q and the accumulation of additional parameter estimation errors. It has been shown in Shibata (1980) that although the AIC criterion does not give consistent estimation of p and q , it is optimal in a certain sense with respect to prediction of future values of the series. A refined small-sample version of AIC, known as AICC, has been developed in Hurvich and Tsai (1989) and a comprehensive account of model selection can be found in Burnham and Anderson (2002).

Having arrived at a potential ARMA model for Y_1, \dots, Y_n , the model should be checked for goodness of fit.

On the basis of the fitted model, the minimum mean squared error linear predictors \hat{Y}_t of each Y_t in terms of Y_s , $s < t$, and the corresponding mean squared errors s_t can be computed (see section titled 'Prediction'). In practice they are computed in the course of evaluating the Gaussian likelihood. If the fitted model is valid, the properties of the rescaled one-step prediction errors $(Y_t - \hat{Y}_t)/\sqrt{s_t}$ should be similar to those of the sequence Z_t/σ in the model (12) and can therefore be used to check the assumed white-noise properties of $\{Z_t\}$ and whether or not the assumption of independence and/or normality is justified. A number of such tests are available (see e.g., Brockwell and Davis, 2002).

Prediction

If $\{Y_t\}$ is a stationary process with mean, $E(Y_t) = \mu$, and autocovariance function, $\text{Cov}(Y_{t+b}, Y_t) = \gamma(b)$, it is well-known that the function $f(Y_1, \dots, Y_n)$ of the observations which is the best predictor of Y_{n+b} , $b > 0$, in the sense of minimizing the expected squared error, $E(Y_{n+b} - f(Y_1, \dots, Y_n))^2$, is the conditional expectation $E(Y_{n+b} | Y_1, \dots, Y_n)$. However this depends in a complicated way on the joint distributions of the random variables Y_t which are virtually impossible to estimate on the basis of a single series of observations y_1, \dots, y_n . However, if the sequence $\{Y_t\}$ is Gaussian, that is, if the joint distribution of (Y_1, \dots, Y_n) is multivariate normal for every n , then the best predictor of Y_{n+b} in terms of Y_1, \dots, Y_n is a linear function and can be calculated as described below.

The best *linear* predictor of Y_{n+b} in terms of $\{1, Y_1, \dots, Y_n\}$, that is, the linear combination $P_n Y_{n+b} = a_0 + a_1 Y_1 + \dots + a_n Y_n$ which minimizes the mean squared error, $E[(Y_{n+b} - a_0 - \dots - a_n Y_n)^2]$, is given by

$$P_n Y_{n+b} = \mu + \sum_{i=1}^n a_i (Y_{n+1-i} - \mu), \quad [19]$$

where the vector of coefficients $\mathbf{a} = (a_1, \dots, a_n)'$ satisfies the linear equation,

$$\Gamma_n \mathbf{a} = \boldsymbol{\gamma}_n(b), \quad [20]$$

with $\boldsymbol{\gamma}_n(b) = (\gamma(b), \gamma(b+1), \dots, \gamma(b+n-1))'$ and $\Gamma_n = [\gamma(i-j)]_{i,j=1}^n$. The mean squared error of the best linear predictor is

$$E(Y_{n+b} - P_n Y_{n+b})^2 = \gamma(0) - \mathbf{a}' \boldsymbol{\gamma}_n(b). \quad [21]$$

If an ARMA model is fitted to the data, the special linear structure of the ARMA process arising from the defining equations can be used to greatly simplify the calculation of the best linear b -step predictor $P_n Y_{n+b}$ and its mean squared error, $\sigma_n^2(b)$. If the fitted model is Gaussian, we can also compute 95% prediction bounds, $P_n Y_{n+b} \pm 1.96\sigma_n(b)$ (see e.g., Brockwell and Davis, 2002).

Example 4

In order to predict future values of the causal AR[1] process defined in example 3, we can make use of the fact that linear prediction is a linear operation and that $P_n Z_t = 0$ for $t > n$ to deduce that

$$P_n Y_{n+b} = \phi P_n Y_{n+b-1} = \phi^2 P_n Y_{n+b-2} = \dots = \phi^b Y_n, b \geq 1.$$

with mean squared error,

$$E(Y_{n+b} - P_n Y_{n+b})^2 = \sigma^2 \frac{1 - \phi^b}{1 - \phi^2}.$$

In order to obtain forecasts and prediction bounds for the original series which were transformed to generate the residuals, we simply apply the inverse transformations to the forecasts and prediction bounds for the residuals.

Example 5

Using the model selection procedure described in the earlier section, the minimum AICC model for the first 49 residuals shown in **Figure 3** (with the sample mean subtracted) is found to be the AR[1] process,

$$Y_t = -0.2519 Y_{t-1} + Z_t, \{Z_t\} \sim \text{WN}(0, 3.530).$$

Using this model and the results of example 4 we obtain the forecasts and prediction bounds for the last ten values (1997–2006) of the original series shown, with the actual observed values, in **Figure 5**.

The Frequency Viewpoint

The methods described so far are referred to as time-domain methods since they focus on the evolution in time of the sequence of random variables X_1, X_2, \dots representing the observed data. If however, we regard the sequence

Figure 5 Forecasts and 95% prediction bounds for the last 10 values of the series in **Figure 1** based on the model fitted to the first 50 values.

as a random function defined on the integers, then an alternative approach is to consider the decomposition of that function into sinusoidal components. The observations x_1, \dots, x_n have a Fourier representation

$$x_t = \sum_j a_j e^{i\omega_j t}, t = 1, \dots, n.$$

where $i = \sqrt{-1}$, $\omega_j = 2\pi j/n$ and the sum is over all integers j such that $-\pi < \omega_j \leq \pi$. Analogously, if X_1, X_2, \dots is a stationary time series, then it has a so-called spectral representation,

$$X_t = \int_{-\pi}^{\pi} e^{i\omega t} dZ(t), \quad [22]$$

where $\{Z(t), -\pi \leq t \leq \pi\}$ is a process with uncorrelated increments. A detailed discussion of this approach can be found, for example, in Bloomfield (1976), Brockwell and Davis (1991) and Priestley (1981), but is outside the scope of this article.

Multivariate Time Series

Many time series arising in practice are best analyzed as components of some vector-valued (multivariate) time series $\{X_t\} = (X_{t1}, \dots, X_{tm})'$ in which each of the component series $\{X_{tb}, t = 1, 2, 3, \dots\}$ is a univariate time series of the type already discussed. In multivariate time series modeling, the goal is to account for and take advantage of the dependence not only between observations of a single component at different times, but also between the different component series. For example, if X_{t1} is the daily percentage change in the closing value of the Dow-Jones Industrial Average in New York on trading day t , and if X_{t2} is the analog for the Australian All-Ordinaries Index, then $\{X_t\} = (X_{t1}, X_{t2})'$ is a bivariate time series in which there is very little evidence of autocorrelation in either of the two component series. However, there is strong evidence of correlation between X_{t1} and $X_{(t+1)2}$, indicating that the Dow-Jones percentage change on day t is of value in predicting the All-Ordinaries percentage change on day $t + 1$. Such dependencies in the multivariate case can be assessed by means of the covariance matrices,

$$\Gamma(t + b, t) = [\text{cov}(X_{(t+b),i}, X_{t,j})]_{i,j=1}^m, \quad [23]$$

where the number of components, m , is 2 in this particular example. Stationarity of the multivariate series $\{X_t\}$ is defined as in the univariate case to mean that all components have finite second moments and that the mean vectors $E(X_t)$ and covariance matrices $\Gamma(t + b, t)$ are independent of t . Multivariate white noise, $WN(0, R)$, is defined to be a sequence of zero-mean uncorrelated random vectors $\{Z_t\}$, each with mean vector 0 and covariance matrix R . Multivariate ARMA processes are defined in terms of multivariate white noise by equations analogous to those defining

univariate ARMA processes (for details see Brockwell and Davis, 1991).

State-Space Models

The study of state-space models has had a profound impact on time series analysis. A linear state-space model for a (possibly multivariate) time series $\{Y_t, t = 1, 2, \dots\}$ consists of two equations. The first, known as the observation equation, expresses the w -dimensional observation vector Y_t as a linear function of a v -dimensional state vector X_t plus noise. Thus

$$Y_t = G_t X_t + W_t, t = 1, 2, \dots, \quad [24]$$

where W_t has mean 0 and covariance matrix R_t , the sequence $\{W_t\}$ is uncorrelated and $\{G_t\}$ is a sequence of $w \times v$ matrices. The second equation, called the state equation, determines the state X_{t+1} at time $t + 1$ in terms of the previous state X_t and a noise term. The state equation is

$$X_{t+1} = F_t X_t + V_t, t = 1, 2, \dots, \quad [25]$$

where V_t has mean 0 and covariance matrix Q_t , the sequence $\{V_t\}$ is uncorrelated, $\{F_t\}$ is a sequence of $v \times v$ matrices and $\{V_t\}$ is uncorrelated with $\{W_t\}$ (i.e., $E(W_t V_s') = 0$ for all s and t). To complete the specification, it is assumed that the initial state X_1 is uncorrelated with all of the noise terms $\{V_t\}$ and $\{W_t\}$.

An extremely rich class of models for time series, including and going well beyond the ARIMA models described earlier, can be formulated within this framework (see Hannan and Deistler, 1988). In econometrics, the structural time series models developed in Harvey (1990), in which trend and seasonal components are allowed to evolve randomly, also fall into this framework. The power of the state-space formulation of time series models depends heavily on the Kalman recursions which allow best linear predictors and best linear estimates of various model-related variables to be computed in a routine way. Time series with missing values are also readily handled in the state-space framework.

More general state-space models, in which the linear relationships [24] and [25] are replaced by the specification of conditional distributions, are also widely used to generate an even broader class of models, including models for time series of counts such as the numbers of reported new cases of a particular disease (see e.g., Chan and Ledolter, 1995).

Additional Topics

Although linear models for time series data have found broad applications in many areas of the physical, biological, and behavioral sciences, there are areas where they have been

found inadequate. Consequently, a great deal of attention has been devoted to the development of nonlinear models for such applications. These include threshold models, Tong, 1990, bilinear models, Subba-Rao and Gabr, 1984, random coefficient autoregressive models, Nicholls and Quinn, 1982, Markov switching models, Hamilton, 1994 and many others. For financial time series, the ARCH (autoregressive conditionally heteroscedastic) model of Engle (1982) and its generalized version, the GARCH model of Bollerslev (1986) have been particularly successful. For a recent account of time series models specifically related to financial applications (see Tsay, 2001).

Glossary

Akaike information criterion – A measure of the overall quality of a model which takes account of both the complexity of the model and how well it fits the data.

Heteroscedasticity – Refers to the presence of different variances between two or more random variables. The complementary concept is homoscedasticity, which is usually assumed to apply to the error terms in a linear regression model.

Method of least squares – A well-founded technique for estimating the unknown parameters in a linear regression model, based on minimization of the sum of squared differences between observed and modeled responses.

Ordinary least squares – The method of least squares is also sometimes referred to as ordinary least squares to distinguish it from related techniques such as weighted least squares.

Raw residual – The value of an observed response minus the corresponding predicted response based on the regression model.

Residual analysis – Refers to the examination of residuals from a regression model in order to assess the validity of the assumptions underlying the model.

Standardized residual – A scaled version of a raw residual.

The problem of modeling the behavior of one random response variable in terms of one or more other explanatory variables is one of the most important aspects of modeling in statistics. When the variables are quantitative (as we shall assume for the most part in this article), regression modeling can be used. Regression models are wide ranging and have been used extensively in the education literature (see, e.g., Hsu, 2005).

In principle, we could attempt to describe multiple features of the distribution of the response in terms of the explanatory variables. However, in many applications it is sufficient to assume that only the mean (or expected) value of the response varies with the predictors, and that it does so in a linear fashion. Under these assumptions, we obtain the classical (multiple) linear regression model. One of the reasons for the widespread use of linear regression is that such models have a highly tractable

mathematical structure (e.g., Jørgensen, 1993). As a result, it has been possible to develop an extensive body of methods and theory for linear regression. This in turn provides the statistical practitioner with a comprehensive and well-understood set of tools for fitting, examining, comparing, and interpreting regression models.

In this article, a mathematical formulation of the linear regression model is provided. Model fitting by the method of least squares is described, and the application of regression models illustrated through an example. The underlying assumptions for regression modeling are discussed, and methods for examining their validity are examined. This article also covers the interpretation of regression models; selection of explanatory variables and comparison of models; and connections with other methods including analysis of variance (ANOVA) and hierarchical linear models.

Formulation of the Linear Regression Model

Suppose we observe a response variable Y and p explanatory (or predictor or regressor) variables x_1, \dots, x_p on n individuals or entities. In classifying one of them as the response, we are not treating the variables in a symmetric manner. Rather, we are focusing on the (stochastic) behavior of the response in terms of the other variables. Therefore, we will consider the explanatory variables to be fixed for the purposes of the regression model. In some applications, the explanatory variables will be fixed by an experimenter; for example, the length of time allocated to a student to complete some task for which we wish to measure a response. In other cases, the predictor variables will have arisen as the result of some random process, but the regression model will represent the behavior of the response conditional on the values of the predictor variables.

As a concrete example (to which we shall refer repeatedly), Guber (1999) describes data from 1994–95 for each of the $n = 50$ US states including the following variables: mean total SAT score (SAT); mean expenditure per pupil in thousands of dollars (EXP); mean pupil/teacher ratio (PTR); estimated mean annual salary of teachers in thousands of dollars (SAL); and percentage of all eligible students taking the SAT (PER). It is quite natural to think of modeling SAT as the response variable so as to understand its relationship with the other variables. While these

explanatory variables were not fixed by an experimenter, it is equally natural to think of modeling SAT conditional on their values so that one may use the model to predict SAT for any given set of values EXP, PTR, PER, and SAL.

The linear regression model is defined by the following equation:

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_p x_{ip} + \varepsilon_i \quad [1]$$

where Y_i is the response for the i th individual (e.g., SAT for the i th state); x_{ij} is the value of the j th explanatory variable for the i th individual (e.g., x_{i1} is the value of EXP in the i th state); and ε_i is the error term for that individual. The regression coefficients $\beta_0, \beta_1, \dots, \beta_p$ are model parameters whose true values are unknown and hence must be estimated from the data. When there is just one explanatory variable, the (multiple) linear regression model in eqn [1] reduces to the simple linear regression model defined by

$$Y_i = \beta_0 + \beta_1 x_i + \varepsilon_i \quad [2]$$

where x_i now denotes the value of the single explanatory variable for the i th individual.

It is usual to make the following four assumptions about a linear regression model, and more specifically, about the error terms in the model:

(A1) The mean error is zero, that is, $E[\varepsilon_i] = 0$. This assumption is equivalent to writing that

$$E[Y_i] = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_p x_{ip} \quad [3]$$

which is a statement that we have correctly specified the form of the mean value of the response variable.

(A2) The error terms $\varepsilon_1, \dots, \varepsilon_n$ are statistically independent.

(A3) $\text{Var}(\varepsilon_i) = \sigma^2$ is constant for all observations, $i = 1, \dots, n$.

(A4) The error terms $\varepsilon_1, \dots, \varepsilon_n$ are normally distributed.

We examine the consequences of failure of these assumptions, and methods for checking their validity, when we discuss model diagnostics.

The linear regression model can be expressed compactly and conveniently using matrix notation. Model [1] becomes simply

$$y = X\beta + \varepsilon \quad [4]$$

where $y = (Y_1, \dots, Y_n)^T$ is the vector of responses (with superscript T denoting matrix transposition); $\beta = (\beta_0, \dots, \beta_p)^T$ is the vector of regression parameters; and $\varepsilon = (\varepsilon_1, \dots, \varepsilon_n)^T$ the vector of random error terms. In [4]

$$X = \begin{pmatrix} 1 & x_{11} & \cdots & x_{1p} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & x_{n1} & \cdots & x_{np} \end{pmatrix} \quad [5]$$

is the design matrix for the regression. The rows of X correspond to given individuals while the columns correspond to given variables (with the initial column of ones corresponding to the intercept term β_0).

Fitting Regression Models

Application of a linear regression model to any given data set requires that the model parameters (including the regression coefficients $\beta_0, \beta_1, \dots, \beta_p$ and the error variance, σ^2) be estimated. The regression coefficients can be estimated using the method of least squares (sometimes also referred to as ordinary least squares (OLS) to distinguish it from related techniques such as weighted least squares). If the observed responses are y_1, \dots, y_n , then the least-squares estimates $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p$ of the regression coefficients are derived by minimizing the sum of squared discrepancies

$$SS(\beta_0, \dots, \beta_p) = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_{i1} - \dots - \beta_p x_{ip})^2. \quad [6]$$

Using matrix notation, the vector of least-square estimates can be expressed explicitly as

$$\hat{\beta} = (X^T X)^{-1} X^T y. \quad [7]$$

In practice, least-squares estimates are almost invariably calculated using statistical software packages. These use stable numerical algorithms (based on matrix decomposition techniques) to compute $\hat{\beta}$ rather than use a direct implementation of eqn [7].

The least-squares method is not only an intuitively plausible approach to computing estimates of the regression parameters, but is also well supported from a theoretical perspective. It can be shown under assumptions (A1)–(A4) that the least-squares estimates are also maximum likelihood estimates, and hence are optimal in a number of important statistical senses. Even if assumption (A4) fails, least-squares estimation still produces the so-called best linear unbiased estimates (BLUEs), courtesy of Gauss–Markov theory (see, e.g., Plackett, 1950).

Having obtained the least-squares estimates of the regression parameters, we may compute the fitted values,

$$\hat{\mu}_i = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \dots + \hat{\beta}_p x_{ip} \quad [8]$$

which estimate the mean responses. We may also calculate the residual sum of squares,

$$RSS = \sum_{i=1}^n (y_i - \hat{\mu}_i)^2 = \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_{i1} - \dots - \hat{\beta}_p x_{ip})^2 \quad [9]$$

which provides an overall measure of the discrepancy between the observed and fitted responses, and consequently forms the basis for estimating the error variance σ^2 .

Specifically, an unbiased estimator of the error variance is given by

$$s^2 = \frac{1}{n - p - 1} RSS. \quad [10]$$

Inference

The fitted regression model (i.e., the model with the regression parameters replaced by the least-squares estimates thereof) can be used for a number of purposes. These include estimation of the effect of each of the explanatory variables on the response; testing of hypotheses regarding the relationship between the response and one or more of the explanatory variables; and prediction of the response for a given set of explanatory variables.

To illustrate these ideas **Table 1** provides estimated regression coefficients (typical output from any standard statistics software package) from fitting the SAT data that were introduced earlier. The fitted model equation is hence

$$\widehat{SAT} = 1045.97 + 4.46EXP - 3.62PTR + 1.64SAL - 2.90PER. \quad [11]$$

As an example interpretation of the parameter estimates, the model indicates a 4.46 point increase in expected SAT for a unit increase in EXP (i.e., for a \$1000 increase in mean expenditure per pupil), but it is important to recognize that this assumes that all other variables are held constant (cf. Courville and Thompson, 2001).

The standard error associated with each variable is a measure of the precision with which the coefficient of that variable is estimated. Standard errors for regression coefficients are given by the square roots of the diagonal elements of the (estimated) variance-covariance matrix, $\widehat{Var}(\hat{\beta}) = s^2(X^T X)^{-1}$. The t value for the i th variable (which appears in standard computer output for a regression analysis, like **Table 1**) is the ratio of the variable's estimated coefficient to its standard error: $t = \hat{\beta}_i / SE(\hat{\beta}_i)$. This is an appropriate statistic for testing whether or not the true underlying parameter value is zero. A large t statistic provides evidence against the null hypothesis that the true value of the parameter is zero, and will produce

a small p -value (derived from the t -distribution with $n - p - 1$ degrees of freedom). For example, the p -value for EXP of $P = 0.674$ (from **Table 1**) provides no evidence to suggest that the coefficient of EXP is different from zero, and hence no statistically significant evidence that expenditure has an effect of SAT, having adjusted for the other variables in the model. Nonetheless, a simple linear regression of SAT on just EXP alone returns an estimated coefficient for EXP of $\hat{\beta}_1 = -20.9$ with corresponding p -value of $P = 0.006$, indicating that SAT score is related to expenditure but in a manner that is interrelated with the variables PTR, SAL, and PER.

Confidence intervals for regression parameters provide guidance on the size of the effect of an explanatory variable on the response. A $100(1 - \alpha)\%$ confidence interval for the coefficient of the i th variable is given by:

$$(\hat{\beta}_i - t_{\alpha/2} SE(\hat{\beta}_i), \hat{\beta}_i + t_{\alpha/2} SE(\hat{\beta}_i)), \quad [12]$$

where $t_{\alpha/2}$ is the appropriate critical point (i.e., the $(1 - \alpha/2)$ quantile) of the t -distribution on $n - p - 1$ degrees of freedom. For example, the 95% confidence interval for the coefficient of SAL is given by $(1.638 \pm 2.014 \times 2.387) = (-3.17, 6.45)$ using $t_{0.025} = 2.014$ for a t -distribution on 45 degrees of freedom. This interval includes zero, indicating that we cannot be sure (based on this analysis) that higher teacher salaries are associated with higher SAT scores (having adjusted for the other explanatory variables).

Point prediction from a regression model proceeds by substituting the requisite values of the explanatory variables into the fitted model equation. For example, if we wished to predict SAT results for $EXP = 9$, $PTR = 14$, $SAL = 50$, and $PER = 80$, then by substitution into eqn [11] we get $\widehat{SAT} = 885$ (to the nearest whole number) which is reasonably similar to the observed mean SAT score of 908 in Connecticut for which the values of the explanatory variables are similar to those chosen above. A prediction interval (which should be supplied as a matter of course) to accompany the point prediction \hat{y} can be computed by

$$(\hat{y} - t_{\alpha/2} PE(\hat{y}), \hat{y} + t_{\alpha/2} PE(\hat{y})) \quad [13]$$

where $PE(\hat{Y})$ is the prediction error. For the point prediction above the corresponding 95% prediction error is $PE(\widehat{SAT}) = 36.1$ (and $t_{0.025} = 2.014$ as earlier) so that the prediction interval is (812, 958).

Regardless of the other purposes to which a regression model is developed, it is almost always of interest to characterize the extent to which the explanatory variables can describe the behavior of the response variable. This can be quantified using the coefficient of determination, R^2 , which is equal to the square of the correlation coefficient between the observed and fitted values. It can be interpreted as the proportion of the variation in the

Table 1 Table of regression coefficient for the SAT data

	<i>Estimate</i>	<i>Std. error</i>	<i>t value</i>	<i>Pr(> t)</i>
(Intercept)	1045.97	52.87	19.78	0.000
EXP	4.46	10.55	0.42	0.674
PTR	-3.62	3.21	-1.13	0.266
SAL	1.64	2.39	0.69	0.496
PER	-2.90	0.23	-12.56	0.000

response which is attributable to the explanatory variables. For instance, for the SAT data $R^2 = 0.825$ indicating that over 80% of the variability in SAT scores can be explained by the variables EXP, PTR, SAL, and PER. It should be noted that all these comments on R^2 assume that the regression model in question includes an intercept term. For models without an intercept term (i.e., regression through the origin), R^2 does not have a particularly useful interpretation.

Model Diagnostics

The validity of any conclusions that we draw from a fitted regression model will be contingent on the correctness of the assumptions (A1–A4) listed earlier. Failure of A1 is particularly serious, since this indicates that the form of the regression function (as given in eqn [3]) is misspecified. In such circumstances, estimates of regression parameters will be biased and the model will be unreliable.

Failure of A2 occurs when the responses are dependent (e.g., because of clustering effects which may occur because of spatial proximity, or because the data include repeated observations on a given set of individuals). In this case, the least-squares parameter estimates will be unbiased (though somewhat inefficient) but standard errors computed in the usual way will be incorrect, leading to unreliable test statistics and confidence intervals. The same type of problems will occur if A3 is violated, that is, the errors are heteroscedastic. Failure of A4, that is errors which are not normally distributed, is of less concern. While in theory this invalidates t and F tests based on normality, versions of the central limit theorem and related asymptotic theory imply that the results of such standard tests will be quite reliable unless the sample size is very small.

A variety of diagnostic tools are available for assessing the validity of the model assumptions. These are typically based on the model residuals, and hence the application and interpretation of such diagnostics is often referred to as residual analysis. The raw residuals for the linear regression model are defined by:

$$e_i = y_i - \hat{\mu}_i \quad [14]$$

while the standardized residuals are given by

$$r_i = \frac{e_i}{s\sqrt{1 - b_{ii}}} \quad [15]$$

where b_{ii} is the i th diagonal element of the hat matrix, $H = X(X^T X)^{-1} X^T$. The raw residuals act as substitutes for the (unobserved) error terms, $\varepsilon_1, \dots, \varepsilon_n$, but these residuals have different variances as a result of the model fitting process. The standardized residuals are scaled to have unit variance and are therefore often preferred for diagnostic purposes.

One of the most commonly applied diagnostic tools is a plot of the residuals (either raw or standardized) against the fitted values. Such a plot can be used to spot a number of problems with the fitted model, including detection of:

- outlying observations, which will appear as points with extreme residuals;
- misspecification of the regression function (i.e., failure of A1), which may manifest itself through a discernible trend (e.g., curvature) in the plot; and
- heteroscedasticity in the error terms (i.e., failure of A3), which will typically lead to systematic variation (e.g., showing a funnel-shaped residual plot) in the vertical spread of the residuals from left to right in the plot.

A plot of the raw residuals against fitted values for the SAT data is given in **Figure 1**. It appears from this that West Virginia is an outlier, since the residual for this state is of a markedly larger size than the residuals for any other state. There is also a hint of curvature in the plot (with a downward trend at the left-hand side and an upward trend at the right-hand side of the plot) suggesting that the relationship between the SAT score and each of the explanatory variables may not be linear in every case. A plot of the residuals against each explanatory variable in turn can provide further insight. For instance, plots of the residuals for the SAT model against each of EXP, PER, PTR, and SAL (not shown) reveal clear curvature only for PER, indicating that the assumption of a linear relationship between SAT and this variable is questionable.

Assessment of the independence assumption (A2) can be difficult. A relatively common reason for failure of this assumption is the existence of serial correlation between observations with a clear time dimension (e.g., data collected on a monthly basis). In such cases, a plot of the residuals against the order in which the data were collected can sometimes be revealing although it may be more enlightening to apply standard time series methods to the residuals.

The standard tool for assessing normality of the error terms (A4) is a normal Q - Q (or normal probability) plot of the standardized residuals. This should appear as an

Figure 1 Plot of residuals vs. fitted values for SAT data.

approximately straight line if the assumption is reasonable. The Q - Q plot for the standardized residuals for the SAT data is given in **Figure 2**. Leaving aside the previously identified outlier (West Virginia), this plot does not suggest any major departure from normality in the distribution of the error terms.

As we have seen, the analysis of the SAT data may be complicated because of the existence of an apparent outlying observation – West Virginia. The extent to which this is likely to have a major impact on the model fit (and hence on inferences drawn from the model) depends on the influence that this data point exerts. At a general level, a data point with extreme values for one or more of its explanatory variables has the potential (depending on the value of the response) to have a more pronounced impact on the fit of the model than a data point for which the predictors sit near the center of the data. This potential can be measured by leverage, which is given by h_{ii} (as defined above) for the i th observation. A plot of the standardized residuals against leverage can therefore be illuminating. In addition, Cook's distance provides a measure of the influence for each data point which takes account of both the values of the predictors and the response variable. In essence, Cook's distance works by examining how the model fit would change were the data point under consideration excluded when estimating the regression parameters. Data points with a Cook's distance larger than 1 can be considered very influential and warrant close attention, while those with a Cook's distance between 0.5 and 1 might be described as moderately influential. A number of alternative measures of influence exist, with DFFITS (Belsley *et al.*, 1980) being arguably the most important.

To illustrate these methods, we plot the standardized residuals against leverage for the SAT data in **Figure 3**. It can be seen that West Virginia has rather low leverage and so has only a modest influence on the fitted model despite its extreme value for SAT (relative to its explanatory variables). This is reflected in the value of 0.11 for the Cook's distance for that state. The observation from

Utah appears of greater concern, but its Cook's distance of 0.47 (although the largest of all the observations) is not excessive.

When problems are found with a regression model, then it is necessary to take remedial action. When misspecification of the regression function is suspected, then one approach is to transform the response variable (e.g., by a logarithmic transformation), while another is to consider inclusion of polynomial terms in the explanatory variables. For example, for the SAT data it transpires that addition of the quadratic term in PER leads to a statistically significant improvement in the model fit ($P = 0.000$ when testing the coefficient of PER^2). An alternative is to employ nonparametric or semiparametric regression methods (e.g., Takezawa, 2006; Ruppert *et al.*, 2003). When there is evidence of heteroscedasticity, then the method of weighted least squares should be preferred to ordinary least squares, while failure of the independence assumption can be countered by explicit modeling of a more general covariance structure for the errors. These extensions to the standard linear regression model can both be described using the unifying theory of generalized least squares (e.g., Kariya and Kurata, 2004).

The handling of outliers can be a delicate matter. The first step is to check for transcription errors in the data and correct as necessary. One can consider discarding any remaining outliers (especially those with high influence) and then refit the model, but it is important to document that this has been done. Mindless and automated outlier deletion is to be avoided, since outliers are often of considerable interest. For example, outliers provided an early indication of the depletion of the ozone layer (Christie, 2004). An alternative to deletion is the use of robust statistical methods.

Model Comparison

When there are multiple explanatory variables available, then one can define a variety of alternative regression

Figure 2 Normal Q - Q plot for standardized residuals for SAT data.

Figure 3 Plot of standardized residuals against leverage for SAT data.

models based on different subsets of these predictors. The question then arises as to which of these models should be preferred, and hence we have need for methods for comparing models. A classical approach to the comparison of two nested models (where a small model contains a subset of the variables in a large model) is to employ F tests based on ANOVA. This reduces to t -testing for a coefficient (as described above) when the models differ by only a single variable. For example, comparison of a large model containing all four explanatory variables (EXP, PTR, SAL, and PER) with a small model containing just the three variables EXP, SAL, and PER can be achieved using the t -statistic for PTR. The value $t = -1.13$ from **Table 1** gives a p -value 0.266, and hence provides no significant evidence against the null hypothesis that the small model is adequate.

An alternative approach is to define some measure of overall quality for each model, and then choose the model for which this is optimum. In quantifying model quality, one should keep in mind two competing goals in model selection. First, we have the principle of parsimony, which in essence states that simple models are preferable to more complex models (other things being equal). Second, we want the model to fit as closely to the data as possible. For linear regression models, complexity can be measured by the number of regression parameters or explanatory variables, while the closeness of the model fit can be measured by residual sum of squares. This motivates measures of quality, Q , of the following form:

$$Q = \log(RSS)/\lambda + \gamma p + c \quad [16]$$

where RSS is the model residual sum of squares, p the number of explanatory variables, and λ , γ are tuning constants and c is an arbitrary constant. When conducting such a comparison, a smaller value for Q indicates a better model.

A number of so-called information criteria can be written in the form of eqn [16] with suitable values for the tuning parameters. The Akaike Information Criterion (AIC) is perhaps best known of these and is obtained by setting $\lambda = 1/n$ and $\gamma = 2$, while the Bayes (or Schwarz) Information Criterion (BIC) is obtained when $\lambda = 1/n$ and $\gamma = \log(n)$ (see Akaike (1974) and Schwarz (1978)). A related quantity is Mallows C_p (Mallows, 1973) in which $\gamma = 2$ and the first term on the right-hand side of eqn [16] is replaced by $RSS/\hat{\sigma}^2$, where $\hat{\sigma}^2$ is an estimate of variance which is assumed fixed for all models under comparison.

As an illustration of the application of the AIC, **Table 2** lists the values of AIC for five models for the SAT data, based on different subsets of explanatory variables. The best model (i.e., with lowest AIC) of those listed is M2, which regresses SAT score on the three variables PTR, SAL, and PER. However, models M1 and M3 are only a few units worse on the AIC scale, so there is little to choose between these and M2.

Table 2 Values of AIC for five regression models for the SAT data

<i>Model</i>	<i>Explanatory variables in model</i>	<i>AIC</i>
M1	EXP + PTR + SAL + PER	353.5
M2	PTR + SAL + PER	351.7
M3	SAL + PER	354.6
M4	PTR + PER	356.2
M5	SAL + PTR	425.3

When a large number of predictor variables are available, a direct comparison of all possible models will be highly computer intensive. A computationally cheaper methodology is then desirable. One approach is to employ a stepwise variable selection algorithm, where we consider systematically adding and/or removing variables in an iterative manner in order to improve the model quality. More specifically, at each step of this type of algorithm we compare the current best model with all alternative models which can be obtained by removing single terms from this model, or adding in single variables which are currently not part of the model. These comparisons may be conducted with F tests, or using AIC scores.

To illustrate the the AIC approach, we conduct variable selection starting with M1 (from **Table 2**) as the initial model. At the first step, we compare M1 with each of the four models defined by deleting one of the variables in M1. It transpires that out of these models and M1 itself, the lowest AIC belongs to model M2 (obtained by removing EXP from M1). Hence M2 becomes the current best model. At the next step, we consider all models that can be obtained by adding or deleting a single variable from M2. These models are M1 (obtained by adding EXP) and M3, M4, and M5 (obtained by deleting the variables PTR, SAL, and PER respectively). All these models have higher AIC values than M2, indicating that this model cannot be improved by a single addition or deletion. The algorithm then terminates, returning M2 as the model of choice.

Summary

Linear regression models are among the most commonly used statistical methods. They combine widespread applicability with a highly developed theoretical basis. Functionality for fitting linear regression models exists in every significant statistics software package (including Minitab, SAS, SPSS, and R) and also in some spreadsheet packages (e.g., Excel).

This article has focused on regression modeling with quantitative explanatory variables. The analysis of models with categorical explanatory variables is covered in the article on ANOVA in this volume, although both regression and ANOVA type models can be unified with the

general framework of the linear model (e.g., Cohen, 1968). Regression models for clustered data and other hierarchical data structures are described in the article on hierarchical linear model in this volume. Regression models for highly non-normal response variables (e.g., binary responses) are covered in the article on generalized linear models in this volume.

Value-Added Models

D F McCaffrey, The RAND Corporation, Pittsburgh, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Bias – It is the expected value of the difference between a statistical estimate and the quantity that is being estimated.

Fixed effects – Terms included as explicit explanatory variables in linear models in which model parameters are estimated via least squares or maximum likelihood methods. They are typically used to refer to models that include indicator variables for individual units such as schools, teachers, or students.

Longitudinal data – They are data from multiple units with repeated measurement on one or more units over time.

Precision – It is the reciprocal of the sampling variance of a statistical estimator.

Random effects – It is the term included in statistical models that are latent and assumed to be random variables from a common distribution.

General Background on Value-Added Modeling

The term value-added modeling (VAM) comes from the economics literature on the contribution of current inputs to outputs, after accounting for prior inputs. In the education literature, VAM refers to measuring the effects on student achievement of students' current teachers and schools, separate from other inputs. More broadly, the phrase often describes any analysis using longitudinal student test score data to study the effects of educational inputs on achievement.

The origins of VAM of teacher effects date back over 30 years; however, interest in these methods among researchers, policymakers, and educators grew precipitously following the publication of a technical report by William Sanders and June Rivers, in 1996, which found that teacher effects estimated using student test score gains predict student outcomes at least 2 years into the future, suggesting that teachers have persistent effects on their students' achievement and the accumulation of these effects could be substantial. The following year, Sanders and his colleagues published another paper claiming that teachers are the most important source of variance in

student achievement. Interest in VAM was further stoked by replication of the Sanders and Rivers results and several other papers finding that variability among teachers was large and that value-added estimates of teacher effects predict outcomes of teachers' future students. In the United States, the growing availability of student-achievement data due to increased emphasis on test-based accountability and the passage of the No Child Left Behind Act in 2001 led to explosive growth in empirical research on the effects of teachers on student outcomes.

Value-added models have two distinct uses: to assess programs, interventions, educator attributes, and educational practice; and to make inferences about the performance of individual teachers or schools for evaluation and accountability purposes. This article focuses primarily on issues related to accountability and evaluation of individual teachers, although the issues generally apply to inferences about schools and using the model to assess programs, interventions, and the like.

Causal Effects

The goal of value-added modeling is to understand how an educational input (e.g., a particular teacher) changes student achievement relative to other levels of the input (e.g., other teachers). Such an effect is commonly referred to as a causal effect. Statisticians generally define causal effects as differences between counterfactual or potential outcomes. For instance, a student has one potential outcome for the teacher she/he was assigned and a different one for every teacher she/he might be assigned. The difference between the student's potential outcome with his or her assigned teachers and the potential outcome for a different teacher is the causal effect of the assigned teacher relative to this specific alternative. Given that the goal of VAM is to compare the performance of many teachers, a relevant causal effect is the difference between a student's potential outcome for his or her assigned teacher and the average of his or her potential outcomes for all teachers. The average of the causal effects for individual students equals the teacher's overall causal effect. This average can be over all students in the population or over only students in or likely to be in a teacher's class.

To attribute this causal effect to the teacher and not to other factors, the only factor that can change with each potential outcome is the teacher; all other factors must remain the same, including the school and the other

students in the class. Teachers teach within the context of a school and a neighborhood and therefore two types of causal effects might be defined: the effect of a particular educational input (e.g., a teacher) independent of context or a causal effect of the input and the educational context that is likely to vary with that input (a teacher, the school, and the peers). The causal effect of an individual education input distinct from the context might be nearly impossible to estimate, whereas the combined effect of teacher and context might be more relevant to some stakeholders, and its estimation more feasible. The alternative value-added approaches described below make different attempts at separating the context from the teacher inputs. However, given the limitations of the available data, it is likely that all estimates will have some amount of interference from the changing context associated with different teacher assignments.

Advantages of the Value-Added Approach

The primary advantage of VAM compared with other measures used for accountability is its explicit accounting for competing inputs when estimating teacher or school effects. Other accountability metrics – such as comparing schools on average student scores or the percentage of students who surpass an achievement threshold (e.g., the percentage proficient) – typically make no distinctions between causal effects of schools and teachers and differences in other inputs that might exist between students in different schools or classrooms. Some alternatives to VAM use demographic and other broad descriptors of students rather than individual students' prior achievement in an attempt to account for differences in the populations served by different schools or teachers. However, these background characteristics often fail to control for many of the potential differences among schools and classrooms that can be controlled with prior achievement. Hence, compared with alternative approaches to accountability, value-added models place greater emphasis on measuring the inputs of schools and teachers and do so more effectively. However, VAM has its limitations as discussed in the remainder of this article.

Leading Modeling Approaches

The main approaches to VAM have been developed from three distinct perspectives: econometric modeling, statistical modeling, and *ad hoc* procedures. This section describes representative examples of the approaches and their essential features.

Econometric Models

The econometric modeling approach to VAM emerged from the cumulative achievement model. The model

starts with a general education production function for student achievement:

$$A_{it} = A_i[\mathbf{F}_i(t), \mathbf{E}_i(t), \mu_{i0}, \varepsilon_{it}] \quad [1]$$

where A_{it} , individual i 's achievement level at the end of the t th year of schooling, depends on the cumulative achievement function A_i and the entire input histories of family (including neighborhood), $\mathbf{F}_i(t)$, and school-based educational inputs, $\mathbf{E}_i(t)$, a composite variable representing time-invariant characteristics an individual is endowed with at birth (such as innate ability), μ_{i0} , and a normally distributed, mean-zero error, ε_{it} .

Economists make a series of assumptions to specify model [1] in a form that supports estimation of teacher effects using established estimators. In particular, they assume: the cumulative achievement function A_i does not depend on age and is additively separable (i.e., cumulative achievement equals the sum of the effects of the component inputs and the effect of any one input does not depend on the levels of the others); family inputs are time invariant and can be combined into a single term with student inputs; educational inputs can be separated into additive annual contributions of schools, teachers, peers, and other classroom inputs. Without further assumptions, estimation of the value added of the current teacher would require data on the school, teacher, peer, and classroom inputs for each student's current and entire prior schooling experience. Economists typically assume that all educational inputs decay geometrically at a rate λ because these data do not exist, and that the family inputs change at that same rate, yielding the following model:

$$A_{it} = \gamma_s S_{it} + \gamma_T T_{it} + \gamma_P P_{it} + \gamma_C Z_{it} + \varphi_i + \lambda A_{it-1} + \xi_{it}, \quad [2]$$

where T_{it} denotes teacher inputs and can be a single factor for a teacher effect; S_{it} , P_{it} , and Z_{it} denote school, peer, and other classroom inputs; φ_i is the fixed contribution of student and family; and the error term is $\xi_{it} = \varepsilon_{it} - \lambda \varepsilon_{it-1}$. A final assumption that $\lambda = 1$ leads to circumstances where a linear model for the first differences in achievement (gain scores) yields consistent estimators of certain effects, including those of current teachers. The parameters of the model are estimated using least squares with models that include indicators for students and teachers (i.e., student and teacher fixed effects) along with the other variables.

Numerous applications use variants of model [2] to study teachers. Some applications assume $\lambda = 1$; however, others have used $\lambda = 0$ which results in fixed-effects analysis on level scores rather than gain scores. In other applications, λ is estimated by including the lagged scores as a predictor in a linear regression model. Some of these applications treat φ_i as zero and some attempt to estimate both λ and the student coefficients while accounting for the complexities this creates for estimation.

If the students' potential outcomes for a teacher and the associated context are described by a model analogous to [2], then model [2] is a structural model and causal effects of teachers are defined by the contrasts of the coefficients in γ_T . Causal estimates can be obtained using linear regression techniques under the assumption that students assigned to any teacher's class differ from students assigned to other teachers' classes in terms of their general levels of family inputs (φ_i) and their prior achievement scores (A_{it-1}), but not in terms of unobserved factors related directly to their current level of achievement or to their achievement with their assigned teacher. That is, for students assigned to any given teacher, the distribution of the ζ_{it} must not differ from the distribution for other students, in particular it must have its mean as zero.

Statistical Models

Statistical models evolved from the hierarchical linear model (HLM) framework which specifies the sources of variance at each level of a hierarchical data structure linking repeated scores to students and students to classrooms, teachers, and schools. One example of this class of models is the layered model originally used by the Tennessee value-added assessment system. The HLM models are all variants of the following model, sometimes referred to as the variable persistence model, presented here for 3 years of scores on a single test:

$$\begin{aligned} A_{i1} &= \eta_1 + \gamma_{s1}S_{i1} + \gamma_{T1}T_{i1} + \gamma_{X1}X_{i1} + \zeta_{i1} \\ A_{i2} &= \eta_2 + \gamma_{s2}S_{i2} + \gamma_{T2}T_{i2} + \gamma_{X2}X_{i2} + \omega_{21}\gamma_{s1}S_{i1} + \\ &\quad \alpha_{21}\gamma_{T1}T_{i1} + \zeta_{i2} \\ A_{i3} &= \eta_3 + \gamma_{s3}S_{i3} + \gamma_{T3}T_{i3} + \gamma_{X3}X_{i3} + \omega_{32}\gamma_{s2}S_{i2} + \alpha_{32}\gamma_{T2}T_{i2} \\ &\quad + \omega_{31}\gamma_{s1}S_{i1} + \alpha_{31}\gamma_{T1}T_{i1} + \zeta_{i3} \end{aligned} \quad [3]$$

where η_t denotes overall means for the population each year, S_{it} is a vector of indicators identifying each school's share of the instruction for student i in school year t , and T_{it} is an analogous vector for teachers. The elements of γ_{st} and γ_{Tt} are normally distributed random variables representing school and teacher effects that are assumed to be independent across schools, teachers, and years. X_{it} denotes vectors of student variables. Finally, $\zeta_i = (\zeta_{i1}, \zeta_{i2}, \zeta_{i3})'$ are multivariate normal variables with mean zero and an unspecified covariance matrix Σ , and are independent of teacher, school, and other student effects. The α and ω parameters measure the fadeout of teacher and school effects and can be estimated from the data. Extensions to more years of testing or multiple tests are direct.

Restrictions to this model recover most of the other commonly used statistical VAM. For example, the layered model is a special case of model [3] with no school effects (i.e., all the elements of all the γ_{st} are set to zero), no explicit controls for students' characteristics (i.e., all the elements of all the γ_{Xt} are set to zero), and all the α

are set to one so that there is no fadeout of teacher effects. Cross-classified HLMs are a special case of model [3] where again the α (and ω) are all set to one and $\zeta_{it} = a_i + b_it$, with (a_i, b_i) assumed to be jointly normally distributed variables. Traditional HLMs with students nested within classrooms are special cases with α (and ω) set to zero and correlation among ζ_{it} treated as zero.

The model parameters, including the α (and ω) parameters, can be obtained via maximum likelihood or Bayesian methods. Bayesian methods have computational advantages and provide a principled method for making many desired inferences about teachers that account for uncertainty in all the model parameters.

There is little research directly linking model [3] to potential outcomes for students and causal modeling. Given that achievement in year $t > 1$ depends on teacher effects for prior years, the causal model will need to consider potential outcomes for the vector of teacher assignments, so that a student has a set of potential vectors of achievement scores for each set of teachers s/he might have in years 1–3. For the observed data to provide unbiased estimates of the structural model requires complex assumptions about the relationship of the vectors of assignments and a student's potential outcomes to hold true. Often analysts exclude school effects from model [3], so that the model provides no accounting for the school context and the teacher effects are a combination of the contributions of the teacher and the school context.

Ad hoc Models

In practice, the analysis of longitudinal data for evaluating teachers is sometimes less principled than the models above. For example, applications sometimes estimate teacher effects with simple averages of their students' gain scores or their residuals from a linear regression model predicting current achievement scores with a single prior score. Although these simple models might be special cases of the models listed above, they are applied in practice with the simple notion of measuring growth as a means of estimating value added. Research has shown that such simple approaches to VAM can provide poor estimates which confound student background variables with the estimated teacher effects.

In other applications, analysts create elaborate estimation procedures to create value-added measures of teacher effects that have face-validity to teachers and other stakeholders. The system devised for the Dallas Independent School District is an example of such a procedure. This method combines elements of statistical models into a multi-step procedure that was vetted by teachers and stakeholders as it was designed by school district analysts. Although this approach might be appropriate for developing an accountability system that is acceptable to educators, the statistical properties of the

resulting estimators are rarely evaluated and might be difficult to ascertain. If the estimated effects have undesirable statistical properties, these *ad hoc* methods might fail to achieve their goals. Therefore, methods that evaluate the properties of such *ad hoc* procedures are needed, as are tactics that emphasize the value of both face-validity and good statistical properties to educators and policymakers.

Concerns about Bias

Much of the research on value-added modeling has centered on how effectively the models produce estimates of individual teacher effects that accurately reflect their contributions to student learning rather than other factors. The three sources of bias that have consistently been raised as most problematic are: (1) nonrandom assignment of students to schools and teachers within schools; (2) improper assumptions about persistence/fadeout of different factors influencing student achievement; and (3) improper assumptions about test score scales.

Nonrandom Assignment

The fundamental problem of inferring teacher effects from observational data is that students are not randomly assigned to schools or teachers. The students taught by different teachers have systematically different characteristics, and unless properly controlled through statistical adjustment, these differences can introduce bias into estimated teacher effects. How well different modeling approaches correct for classroom selection is a hotly debated topic in VAM research.

The econometric approach accounts for nonrandom assignment through the assumptions that yield model [2] and the assumption that assignment depends only on observed data or time-invariant student and family inputs captured in φ_i . If these assumptions are correct, then potential bias due to differences among classes can be eliminated through the use of student fixed effects. Whether or not the assumptions hold in applications remains an issue of debate. Empirical results on achievement data from one state suggest that the assumptions were inappropriate for those data. However, alternative analyses comparing teacher effect estimates with historic data and the schools' regular assignment practices yielded teacher effects that were comparable to estimates for teachers estimated on randomly assigned classes, suggesting the VAM estimates were not biased. As the disparity in the two sets of empirical results suggests, the evidence on the validity of the assumptions of model [2] is equivocal and might depend on the specific application and the nature of the school and class assignments.

Many applications of the statistical models make no explicit allowances for nonrandom assignment of students.

Rather, the models do not include student covariates and assume that residual student error terms are independent among students and of teacher effects. Consequently, critics of this approach argue that all sources of variation in the data at the classroom level, including clustering of student achievement due to nonrandom assignment, are conflated with teacher effects. However, because the model allows correlation among the repeated measures from individual students, analytic results find this criticism is not necessarily correct: statistical modeling can effectively mitigate biases resulting from heterogeneity in average student achievement among classes, provided enough test scores are used in the modeling. With a fixed number of tests, the estimates cannot remove all the bias, and the models require at least five or more test scores per student to function most effectively at mitigating bias. Moreover, these theoretical assumptions do not apply if classroom assignments are dynamic in that they rely on annual data (e.g., test scores or classroom grades). In addition, as noted above, commonly used statistical models often do not include school factors, which limit inferences to the combined causal effects of teachers and their school contexts.

Some applications of statistical models have been criticized because they do not include student-level covariates. The results noted above suggest that under the right conditions and sufficiently many prior tests, covariates are unnecessary to control for heterogeneity among classrooms. In addition, because statistical models treat teacher effects as random and adjust for prior tests through correlation in the error term, controlling for covariates in these models when teacher effects are correlated with the covariates can overcorrect so that a portion of the true teacher effect is attributed to the covariates, biasing the estimated teacher effects. Methods exist for including student-level covariates without overcorrecting, but when applied to data they do not alter the estimated teacher effect relative to estimates from the layered model without student-level covariates; and the practice of excluding student-level covariates continues in some applications.

Both statistical and econometric models can be biased if there are classroom-level factors that affect achievement or if the student population is stratified such that there are groups of students and teachers in which students in some groups have no teachers in common with any of the students in other groups. Classroom-level variables cannot be included in models with fixed effects and are not accounted for by individual student test scores, so neither econometric nor statistical models could account for these variables. Similarly, fixed-effects estimates can be estimated only within strata and statistical models conflate difference in strata with differences in teachers. To date, there have been few studies on the existence and nature of strata in student-achievement data but in one study of four large countywide school systems in Florida,

stratification did not appear to be a significant problem because nearly all students and teachers were in a common stratum within each county.

Persistence of Inputs to Achievement

It is generally accepted that achievement is a cumulative process and that achievement measured by standardized tests reflects both past and current inputs of educational and other factors as shown in model [1]. As noted above, models make numerous assumptions about the persistence of past inputs to allow for estimation of the effect of current teachers. For instance, many applications, both statistical and econometric, either implicitly or explicitly assume that teacher effects persist undiminished in all future years of student achievement.

However, there is growing evidence that teacher effects fade on standardized assessments and this can result in biased estimates. Studies that estimate α s in model [3] find past teacher inputs into future test scores decay rapidly, declining to about 10–20% of their initial magnitude after only 1 year. Studies using alternative methods also find that effects fade rapidly and never find persistence close to 100%. Limited empirical results demonstrate that errors in the assumptions about persistence can lead to biased estimation of the variability of teachers and systematic errors in teacher effect estimates.

Scaling of Achievement Measures

All VAM estimates of teacher effects depend on achievement test scores, but different approaches place more or less stringent requirements on these tests. In all cases, value-added estimates can only exist in grades and subject areas in which testing occurs and prior achievement data exist. In addition, teachers can only be evaluated on the constructs measured by the achievement tests. Critics sometimes fault the standardized tests that are the foundation of VAM for being too narrow and not measuring higher-order thinking skills, and question the utility of VAM estimates derived from these test scores.

In addition to potential limitations in the range of content of standardized tests, psychometricians have raised concerns about comparability of scores from different grade-level tests even when tests are vertically linked to a single scale. The primary concern is that tests at each grade level measure multiple constructs, and shifts in the mix of constructs across grades can distort test score gains, invalidate assumptions of perfect persistence of teacher effects, and bias VAM estimates.

Model [3] makes less-stringent assumptions about scaling than models that assume complete persistence and this model or variants of it might be better suited for some test score data. However, limitations in the scale, such as floor and ceiling effects and measurement error,

that is, greater at the top and bottom of the scale might invalidate model [3]'s assumptions of normality and implicit linearity in the relationships between scores from pairs of years. Errors about linearity in the relationships among scores from multiple years can be particularly problematic when using these scores to control for differences among widely disparate classes, as is done implicitly in the statistical approaches to VAM. Linearity of scores can be explored empirically and models or scales should be adjusted if the model does not conform to the data.

Concerns about Precision

Bias in estimated effects is of particular concern because the goal of VAM is to evaluate teacher performance on student achievement without conflating teachers' effects with their students' backgrounds, but stakeholders remain skeptical that any evaluation system can meet this goal. However, bias is not the only threat to the utility of VAM estimates. Estimates might also lack sufficient precision to support desired inference. Studies that report precision of individual effects generally show that annual estimates have very large errors. For example, standard errors are typically sufficiently large that about two-thirds of estimated teacher effects are not significantly different from average. Confidence intervals are wide and rankings contain substantial errors, so that only about 30–35% of teachers ranked in either the top or bottom quintile in 1 year remain there the next year. Similarly, studies consistently find that the correlation of estimated effects from pairs of adjacent years is low, ranging from less than 0.2 to typically no higher than 0.5.

Summary

Value-added models are likely to play an increasing role in education research and practice. In particular, there is strong interest in these methods for evaluating teacher performance. Although there is no consensus about the best VAM, there is a general consensus that estimating effects with complex models like models [2] and [3] with multiple years of test scores provides more accurate estimates of teacher effects than simple approaches using just 2 years of scores (a pre- and a post-score). Estimating teacher effects with the average residuals from linear regression models predicting the current score with a single prior achievement score seems particularly prone to bias that favors teachers with classes of higher-achieving students.

However, none of the current VAM methods is robust to all three potential sources of bias: nonrandom assignment of students to classrooms, misspecification of the persistence of prior educational inputs, and the limitations of

achievement tests. Econometric models need to be expanded to allow for more flexible modeling of the persistence of effects and statistical models need to take advantage of flexible modeling of persistence and more fully account for classroom assignment and school inputs. Other problems that need to be addressed include the potential bias from the large number of students with incomplete test score data, general issues of data quality such as verifying student–teacher links, and accounting for teachers who provide only a portion of a student’s instruction. Future research will need to identify the most productive methods for pooling data to increase the precision of estimates. It will also need to explore appropriate ways to use these estimates to support decisions about teachers and train educators to make effective use of the data while minimizing unintended negative consequences that can arise in accountability systems based on limited performance measures. Regardless of the shortcomings of the current models and the need for significant additional research, value-added assessments are clearly an improvement over other metrics used in accountability and provide a valuable attempt to use sophisticated methods to draw the most from increasingly available longitudinal test score data.

Accreditation and Standards in Teacher Education Determining Long Term Effects of Teacher Education

Accreditation and Standards in Teacher Education

R J Yinger and K L Daniel, University of Cincinnati, Cincinnati, OH, USA

© 2010 Elsevier Ltd. All rights reserved.

Accreditation is a process by which an educational institution demonstrates its capacity to adequately educate and prepare its students. Accreditation most always includes institutional self-examination and external review processes designed to assure the government, citizenry, and other stakeholders that institutions and programs meet particular standards for educational quality. In the United States and in some provinces in Canada, accreditation review is conducted as a nongovernmental and peer-review process. In other countries, accreditation is seen as a government ministerial function or is conducted by public authorities in partnership with independent professional/occupational bodies.

This article considers the role and process of specialized accreditation as a mechanism for the profession of teaching to both demonstrate and improve the quality and effectiveness of teacher education programs. Central to determining the future of professional teacher education is a debate about the control and governance of accreditation processes. This debate involves two different conceptions of teaching. On the one hand, is the view that teaching is a skilled occupation that should either be regulated by local or national governments in the interests of the state or be deregulated such that it is governed by market forces. On the other hand, is the view that teaching is a profession, and as such, should be governed and regulated by teaching professionals themselves.

The Governance of Teacher Education

Gideonse (1993) describes three modes of governance for teacher education. A political mode of governance places primary responsibility on elected officials or government-appointed bodies to set teacher education policy and regulate its implementation. An institutional mode of governance places primary responsibility with the higher education or training institutions for design and implementation decisions. Occupational independence and self-regulation is the hallmark of the professional mode of governance. This usually takes the form of independent professional boards comprised largely of educational practitioners.

Historically, all three of these forms of governance for teacher education have existed in more or less pure forms or in combination with others. As education has become a significant national political issue in recent years, remaining instances of institutional forms of governance have declined. Worldwide, political modes of governance still dominate, but there has been increasing interest within teaching and teacher education to assert more influence through independent professional bodies. Young *et al.* (2007) provide three detailed cases that illustrate the kinds of debates and political contests playing out in the governance of teacher education recently in England and Canada.

In Europe, teacher education is currently dominated by political forms of governance. Among 30 countries recently surveyed with support from the European Commission's Directorate-General for Education and Culture, all but one have a regulated system for evaluating initial teacher education (Eurydice, 2006). In the majority of these countries, quality assurance evaluations are conducted by an agency, committee, or independent body acting on behalf of the public authorities. In the remainder, teacher education evaluation is the direct responsibility of the ministry of education, an inspectorate, or a combination of the two.

The Eurydice survey indicates that in 2006, about one-half of the countries used standards for teacher education to guide the quality-assurance process. Those countries who did not specify standards often used evaluation criteria to shape the evaluation process. Only six countries had no published criteria related to evaluation. Virtually all countries with teacher education regulations evaluate the content of teacher education, teaching methods, and student assessment. All but four countries reported taking into account teacher education student performance.

Though independent professional bodies were established as early as 1954 in the United States (National Council for the Accreditation of Teacher Education) and in 1966 in Scotland (General Teaching Council of Scotland), professional efforts by teachers and teacher educators gained maximum ground since the 1980s. Two Canadian provinces established colleges for teachers (British Columbia in 1987 and Ontario in 1997), which have sought to define professional standards for teachers and to influence government standards and regulations for teacher education.

In 2004, the Australian federal government funded the Australian Institute for Teaching and School Leadership (usually referred to as Teaching Australia) as an independent body to investigate the creation of national standards for teaching and a national accreditation process for teacher education. Currently, only the states of New South Wales, Victoria, and Queensland have legislation requiring formal accreditation or approval of teacher education programs. In June 2007, Teaching Australia released a proposal for a national system of teacher education accreditation including principles, standards, processes, and governance. Trials of this new system were proposed to begin in 2008.

The recent efforts to promote independent accreditation as the best means to improve the effectiveness of teacher education are grounded in notions of professionalism that emphasize the value of specialized knowledge and training for solving client problems and meeting social needs. Implementing this professional model requires a claim by the profession and the granting by society of a jurisdiction for the definition and conduct of this work and for the preparation of effective practitioners.

Jurisdictional Functions of Accreditation and Standards

Accreditation and standards play a central role in particular conceptions of professional work by scholars who focus on social jurisdiction and authority and who argue that professionalization involves establishing claims to specialized knowledge, expertise, and to a particular set of work tasks (Abbott, 1988). This conception is in contrast to theories that portray professionalism mainly as a project of collective mobility where professions struggle as occupations for market shelters and protection of economic interests (Krause, 1996). It also contrasts with an emerging body of theory that characterizes professionalism as a cultural and political development focusing on social responsibility and the public good (Sullivan, 2005).

According to the jurisdictional conceptions of professions, the distinctive work of professionals is the ability to effectively solve human problems using specialized, expert knowledge. Professional jurisdiction refers to claims of control and authority for dealing with particular kinds of problems, and these claims are based primarily on control of particular knowledge and skill. According to Abbott (1988), jurisdictional claims have three components: (1) claims to classify problems, (2) claims to reason about problems, and (3) claims to act on problems in particular ways. The essential ingredient to effectively accomplish these tasks, according to this theory, is the control of abstract knowledge.

The successful modern professions such as medicine, law, and engineering have tied their work to a system of knowledge that formalizes the skills by which professional deliberation and action proceed. In the last century, the formalization of this abstract knowledge has taken place in the university context, and scholars like Abbott assert that the ability of a profession to establish and sustain its jurisdictional authority lies partly in the power and prestige of its abstract, academic knowledge. The ability to control this knowledge and to set the standards for its transmission and application in university-based professional preparation programs is a central rationale for peer-regulated professional accreditation.

Efforts to professionalize teaching and teacher education have been ongoing in recent years, with most examples found in countries such as England, Canada, Australia, and the United States – all of which have a social history of independent professions in medicine, law, engineering, and the like. Because the United States has a long track record of professionalization efforts, including numerous national initiatives seeking to accomplish this goal, the history and current context of teacher education accreditation in the US will be used as a case study to raise major issues and aspects of professional accreditation processes.

Teacher Education Accreditation and Standards: A Case History

Accreditation and standards have played a central role in the professionalization strategy employed by educators in the US since the middle of the twentieth century. Modeled after strategies successfully used in the first-half of the twentieth century by medicine and law, the goal of this internal control strategy is to gather and consolidate control and jurisdiction for teachers' work by means of scientific and scholarly knowledge, university preparation, and internally generated standards for preparation and licensure (Yinger, 2005b).

Professionalism Ascending

The beginning of this professionalization process can be marked formally by the creation of the National Council for Accreditation of Teacher Education (NCATE) in 1954 and the development of consensus-based standards for what new teachers should know and be able to do and what university-based programs should do to produce this desired knowledge and skill (Wise, 2005). The 1980s and 1990s were times of ambitious reform initiatives for the teaching profession in the United States. There was growing recognition that professional standing for educators would require a concerted effort to establish professional standards, a scientific knowledge base, and a new status in relationship to education policy and policymakers. The National Board for Professional Teaching Standards to develop standards and assessments for the board certification of accomplished teaching, the Interstate New Teachers Assessment and Support Consortium to develop performance-based standards and assessments for initial teacher licensure, and teacher education reform organizations such as the Holmes Group and the National Network for Educational Renewal were established.

Central to these initiatives was an increasing sense of convergence and consensus on standards for teaching and teacher education and on the conception of teaching as a career-development process spanning initial teacher education, new teacher induction and support, and continuing professional development activities. These ideas found a crescendo in the 1996 report of the National Commission on Teaching and America's Future, *What matters most: teaching for America's future* (NCTAF, 1996). NCTAF proposed the goal: "within a decade – by the year 2006 – we will provide every student in America with what should be his or her educational birthright: access to a competent, caring, qualified teacher in schools organized for success." Two major recommendations of the commission to achieve this goal were (1) get serious about standards, for both students and teachers and (2) reinvent teacher preparation and professional development. These were to be enabled by a tripartite strategy of recommending that

every teacher in America would graduate from an accredited teacher education program, be licensed using performance-based standards, and work toward the accomplished teacher certification standards established by the National Board for Professional Teaching Standards. By the end of the century, there was growing optimism about the success of this strategy, but growing challenges as well (Yinger, 1999).

Challenges to the Professional Establishment

While the groups above sought to improve teaching and learning by means of consolidating professional jurisdiction for teaching and teacher education, critics outside of education were focusing on other aspects of professionalization. Their criticisms and recommendations for educational reform were based conceptually in the portrayal of the professional agenda as that of pursuing economic and political interests through exclusiveness, elitism, and protectionism. Their goal was to break up the public education establishment's market-shelters through deregulation, competition, privatization, and alternative choices. This applied not only to schooling, but also to teacher education and licensure (Hess *et al.*, 2004).

Alternative organizations such as the National Council on Teacher Quality and the Education Leaders Council were created to advocate opening up public education in the US to the invisible hand of the free-market system, which would allow student and parent choice to correct the problems of the system. With the change of the US Presidency in 2000, deregulation and choice, enforced by a national system of accountability for student and school academic performance did, in fact, become the backbone of federal educational policy. This policy has taken its most influential form in the 2002 reauthorization of the federal government's Elementary and Secondary Education Act referred to as the No Child Left Behind Act. At the state level, multiple programs were established to allow and promote alternative routes for teacher preparation and for teacher licensure for similar reasons.

Within teacher education, two further developments slowed the movement of the internal control professionalization agenda. In 2003, the federal agency that oversees accrediting organizations approved a second accreditor for teacher education, the Teacher Education Accreditation Council (TEAC). This new organization was formed as an alternative to what a number of university administrators and teacher educators regarded as a narrowly controlled, overly cumbersome, and expensive NCATE accreditation process. (It can also be described as an effort to assert the institutional form of governance for teacher education described earlier.) This event set in motion heated and continuing debates about the need for more than one national accreditor in teacher education, the most effective processes for accreditation review, and who should be the ultimate arbiter for teacher

education program standards and quality (Murray, 2005; Tamir and Wilson, 2005; Wise, 2005).

The second development to challenge the internal control strategy in recent years has been the publication of several high-profile reviews of the research literature related to teacher education. A key component of the notion of profession jurisdiction is to demonstrate a scientific knowledge base on which professional practice and preparation is founded. In spite of numerous studies of teaching and teacher education over the past 30 years, research reviews have been unable to substantiate a scientific research base for teacher education (Cochran-Smith and Zeichner, 2005). This situation has reinforced external criticisms that other factors, such as general intelligence and teacher commitments, have greater impact on effective teaching than learned knowledge, skill, and expertise (Walsh, 2001). In turn, this has also ignited calls for more rigorous, scientifically based research in education (Shavelson and Towne, 2002).

Standards-Based Accreditation: Current Challenges

Advocates of teacher education accreditation as a quality control and quality-improvement strategy assert that the strength of the current approaches is that these approaches are standards-based and focused on outcomes (Murray, 2005; Wise 2005). Yet, at same time, there are stakeholders outside of teacher education, as well as within, who continue to question the legitimacy and value of accreditation. Three underlying reasons can be attributed to this condition.

Weak Professional Consensus

The NCATE, the oldest and largest teacher education accreditor in the United States, prides itself on a standards-based approach built on a broad professional consensus built over many years. The difficulty with this stance is that to obtain consensus, NCATE has had to settle for broad, generalized standards that enable them to be met by institutions with differing missions, goals, and capacities. For instance, Standard 1 of the NCATE Unit Standards reads:

Candidates preparing to work in schools as teachers or other professional school personnel know and demonstrate the content, pedagogical, and professional knowledge, skills, and dispositions necessary to help all students learn. Assessments indicate that candidates meet professional, state, and institutional standards.

Though standards-assessment rubrics are provided for institutions and reviewers, there is little operationalization by way of behavioral specificity as to adequately demonstrate evidence of compliance. Underlying the need

to allow broad interpretation of standards is the felt need to accommodate the multiple goals, opinions, and ideologies held by faculty of education and others involved in professional coalitions. The approach can be presented as a professional consensus, but unlike other professional fields, the result is a divergent rather than convergent notion of professional education.

Weak Conceptions of Evidence

Both NCATE and the newer US accreditor, TEAC, state that they rely on evidence to make their judgments about quality. This is true, but both accrediting agencies have weak logics of evidence and therefore weak standards of what constitutes evidence. Again, the solution both have chosen to address the problem of institutional and ideological diversity in teacher education is to deliberately keep expectations broad and inclusive and allow institutions to determine and argue for what constitutes evidence. The TEAC self-study process is built upon institutional determination of what they choose to offer as evidence. Contributing to the difficulty of offering stronger conceptions of evidence is the paucity of valid measures of teacher candidate learning and performance. Also, the predominance of qualitative research as the preferred method for much of the research in teacher education creates difficulties of systematically aggregating, synthesizing, and interpreting research findings beyond local contexts (Cochran-Smith and Zeichner, 2005). Altogether, the lack of a professional logic of evidence prevents current accreditation frameworks from setting and holding professionals responsible for standards necessary to ground an evidence-based profession.

Mixed Professional Support for Accreditation

Teacher education is unique among professional education programs in the US in that nationally recognized accreditation is not universally accepted and supported. National accreditation is a requirement for professional schools in the established professions such as medicine, law, and engineering, and graduation from an accredited professional school is a prerequisite for taking licensure examinations in these fields.

To date, fewer than half of the 1300 education schools in the United States are currently accredited by either NCATE or TEAC. Studies have shown that those institutions who do not participate in national accreditation are not what the field would consider having the weakest programs. A number of highly regarded programs in prestigious universities choose not to participate. Nonparticipating education schools do so for a variety of reasons, but surveys by the American Association for Colleges of Teacher Education have indicated that these institutions believe that the accreditation process does not add value to

their own quality assurance and improvement efforts and is not essential to their demonstration of the effectiveness of their programs.

Additionally, research on the value of teacher education is limited and offers mixed conclusions (Tamir and Wilson, 2005). This fact combined with weak professional consensus and a weak logic of evidence to legitimize effective professional education practices have not surprisingly created a situation where there is limited regard for the impact of teacher education from many university administrators who make decisions about encouraging and financing accreditation processes. Mixed messages on the value added to teacher education accreditation within universities get communicated to students and parents, so that national accreditation is not regarded as a public symbol for quality in the minds of individuals making application decisions to teacher education programs. These same messages are heard by politicians at the state and federal levels, so that national accreditation has not become a required component of education policy, in spite of its advocacy by the professional teacher education organizations and accreditors.

A Future for Teacher Education Accreditation

Given the challenges to accreditation practices in teacher education cited above and the lack of success with the internal control strategies in other professions (Yinger, 2005a), it is unlikely that a continuation of current accreditation practices will reach the professionalization goals of teacher educators or increase the confidence and trust of teacher education stakeholders. Accomplishing these goals will require a systems intelligence strategy.

This strategy requires a two-pronged approach involving strengthening the jurisdictional claims for teacher education combined with a new professional orientation by teacher educators. This strategy has been successfully demonstrated in health-related fields, such as medicine and nursing, but does not currently exist in education. Realizing this strategy in teacher education will require additional institutional expertise and capacity and willingness to reexamine the professional orientation of teacher education faculty.

Systemic Intelligence for Teacher Education

Accreditation is designed to assure the public and other stakeholders that institutions and programs meet particular standards for educational quality.

Demonstrating this involves carefully making two prior decisions: (1) What are the standards for program effectiveness? (2) How should program effectiveness be operationalized?

As described above, current US teacher-education accreditation approaches address these decisions in order to maximize institutional and program freedom and flexibility. This approach reveals a professional logic that both decision makers and scholars employ: that the education system is so unique and its system characteristics so intractable that there is limited opportunity for continuous, substantive systemic improvements. These intractable characteristics include system complexity, unique organization, fragmentation, autonomy, lack of accountability, and the inability to agree on the ultimate goal of education. As a result of this logic, decisions about educational priorities are often being made *ad hoc*—from intuition, opinion, local preferences, and most dangerously, out of political self-interest.

The field of healthcare, facing similar dilemmas nearly two decades ago, pioneered a science of evidence which combined the key areas of systematic evidence synthesis of clinical research, cost analytics, and multicriteria decision making. This introduced an unprecedented form of systemic intelligence, which enabled leadership to enlarge their work to systemic problem solving (Elstein, 2004). Like leaders in healthcare, in marketing, and in environmental and space sciences before, education leaders must embrace these proven techniques to allow them to analyze multiple streams of disparate information and make decisions that are proven to have optimal impact.

These other fields have utilized a decision science that enables continuously getting systemically more intelligent: systemic intelligence. Proven methods have been demonstrated for transparently solving intractable system issues such as: resolving multiple system goals; determining the best data to measure system effect; handling community and political preferences; responding to a lack of rigorous professional evidence; and including expert judgment. These similarly complex systems overcame intractable system characteristics by executing a particular science which formalized the criteria for systemic effectiveness (Parmigiani, 2002). This enabled leaders of the profession to execute a deliberate, transparent, and rigorous evidence logic utilizing the tools of systematic evidence synthesis, multicriteria decision analysis, and enterprise technology infrastructure.

The ability, capacity, and will to accomplish this kind of system level of work in teacher education has recently been realized by one research group in the United States—the Teacher Quality Partnership, a teacher education research consortium in the state of Ohio (Yinger *et al.*, 2007). This science has not yet been applied to teacher education accreditation. To do so will require a commitment to evidence-based decision making and to capacity building in professional organizations and across teacher education programs.

Determining evidence-based program quality standards for teacher education first requires a professional evidence

logic that can identify and claim a professional expertise. To substantiate this particular expertise, research work must focus on: (1) the functional relation of student-learning outcomes and teaching practices and (2) the functional relation of teaching practices and professional learning practices (i.e., professional development and teacher education). To build an evidence-based accreditation system requires an immediate and long-term commitment to simultaneous research working on both these linkages, which fundamentally define our professional expertise. Necessary steps to be taken include:

- Developing a professional consensus on what constitutes evidence. Education researchers are often divided on ideological grounds, but other fields are successfully resolving these controversies.
- Identifying professional effectiveness criteria. There is growing consensus in the United States that the contribution to student academic achievement growth is an important indicator of teacher effectiveness.
- Developing a research knowledge base that demonstrates evidence-of-effect for particular teaching practices and particular professional learning activities. This will require more research designs and analyses that enable causal inference, such as controlled experimental trials.
- Establishing teacher education standards based on strong research evidence demonstrating causal relationships to teacher effectiveness, and where strong evidence is not yet available, incorporate rigorously applied expert judgment.

These are ambitious goals, but success in other complex professional systems demonstrates the possibilities and the means to achieve them. However, merely applying this science will not be sufficient. True evidence-based professional practice requires combining research evidence and professional judgment with client and public goals and preferences. This requires a new professional stance.

Teacher Education as a Public Profession

There is a growing body of theory that approaches professionalism as a cultural and political development focusing on social responsibility and the public good. Sullivan (2005) has proposed the reconstruction of professionalism from the dominance of scientific management practices shaped by corporate bureaucratic and technocratic ideals to a goal of responsive practices shaped by a commitment to public service. Yinger (2005a) has applied these ideas in a proposal to understand teachers as public professionals who have specialized knowledge and moral obligations to the common good. Professional capital depends on society for its legitimization, and part of this legitimacy (jurisdiction) is based on society's expectations that professional

capital will be used to address human problems and promote public purposes. Perkin (1989) described this professional social ideal as prizing mutual service, efficient use of resources, and the responsible use of knowledge for the larger good.

The stance of teachers as public professionals requires a new model of professional relationships with those they serve. Rather than seeing teaching as a knowledge transaction primarily controlled by educators, public professionals view interactions with clients and the community as work driven by mutual responsibility grounded in shared values and goals. May (2000) portrays this relationship as a professional covenant, where the focus of the professional relationship moves beyond expert service to incorporate the promissory integrity and trust necessary to make common work serve the common good.

Framing the work of teachers as public professionals creates a new form of professional accountability. Currently, educational accountability in the US is most often framed as a rating or grading scheme relying upon narrowly conceived performance outcomes. Many educators approach this process by seeking to limit public incursions on their work and by agreeing to fairly general and easily met accountability measures such as average passing rates on standardized academic tests. Public professional relations differ in that the commitment to mutual goals and shared responsibility yields increased involvement in goal setting by noneducators and increased transparency by professionals about their ability to successfully deliver results according to agreed-upon outcomes.

In the context of teacher education accreditation, a public professions commitment and stance by university teacher educators eschews the internal control jurisdictional agenda in favor of a more open and interactive relationship with teacher education's stakeholders – prospective and current teachers, school administrators, and parents and children. Accreditation would continue to be a peer-based activity, but the notion of qualified individuals would be expanded further to include teachers, parents, and the public.

Worries that this transparency and involvement would undermine and erode professional standards and quality can be countered by examples in medicine where patients and the public have been invited in to improve both clinical practice and to revise professional standards and accountability frameworks.

There is a growing movement in the United States to improve hospital practices and outcomes by public involvement strategies directed at evaluating specific clinical outcome results. The Institute for Healthcare Improvement has partnered with numerous American hospitals to create evidence-based medicine initiatives. These initiatives rely upon the application of research-based clinical practices combined with patient and community

engagement activities aimed at jointly setting health-outcome priorities and monitoring detailed data on clinical success rates.

In the United Kingdom, the General Council of Medicine and the National Health Service have for over a decade been involved in public engagement strategies to reform the standards and accountability frameworks for physician and hospital practice. This work has been built on asserting a new professionalism with the patient at the center of medical practice. This has manifested itself in professional preparation focusing on patient-centered medicine and formal public involvement in standard setting and the judgment of quality (Irvine, 2003). Both these examples demonstrate that established professions can create institution-level discourse with public stakeholders, which can produce a re-making of the profession and a re-building of public trust.

Summary

This article has located issues of teacher education standards and accreditation within the framework of professional goals, work, and societal relationships. Efforts for teacher professionalism in the past half-century have been described as a movement by educators to seek professional control of the work of teaching, its standards for practice and preparation, and its social jurisdiction. Political and social counterforces have been shown to have frustrated this work, but the root problems preventing a strong case for professional oversight and control of teaching and schooling processes have been described as weak professional consensus and weak evidence.

Establishing cognitive jurisdiction for teaching requires a professional knowledge base established on strong research evidence. Similarly, social jurisdiction for teaching requires renewed public trust established on evidence of effectiveness and shared education purposes. A professional strategy, shown to be successful in healthcare fields, built upon systemic intelligence and public engagement, has been described as a means to ground the future of teacher education on evidence-based standards and to enable the establishment of universally respected, evidence-based accreditation.

Determining Long Term Effects of Teacher Education

C N Brouwer, Radboud University Nijmegen, Nijmegen, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The existence of programs for preservice teacher education (TE) is not self-evident. The life and sustainability of such programs ultimately depend on the effects they have on teachers' in-service behavior. Effects of TE are defined here as durable consequences of the preservice acquisition of knowledge and skills and development of motives, as manifested in graduates' professional behavior. A stricter definition pertains to long-term effects of TE programs. Here, such effects are defined as durable consequences of participation in preservice programs which manifest themselves in professional behavior more than 1 year after the completion of preservice TE. It is the responsibility of educational research to demonstrate, describe, explain, and help optimize the relationship between preservice TE and the professional behavior which teachers exhibit and develop during their careers. The description and explanation of long-term effects of preservice programs lend greater credence to the utility of TE.

Relevance of TE Effect Research

Studying TE effects and especially long-term effects empirically is a relevant endeavor in several respects. Quantitative arguments in favor of TE effect studies deal with issues of recruitment, selection, and retention. Any country that wishes to sustain its educational system must know what contribution TE programs make to the availability and employability of its teacher workforce. Like no other component of a country's education system, TE possesses a multiplier function for the quality of schooling and learning throughout the system as a whole. TE programs deliver generations of teachers, who in turn educate generations of pupils and students, who on their part carry with them and transform the knowledge and skills acquired in school, college, or university during the rest of their lives and work. Indeed, the contributions that TE can make to the productivity of a country's educational system eminently justify research into the influence of TE programs on the teaching competence of their graduates.

Aim of TE Effect Research

The aim of TE effect research should be to explain the influence that specific features of preservice programs exert on teaching competence, especially in the longer run. If predictors of success in teaching can be found before

and during TE as well as during beginning teaching and the further career, this evidence could underpin guidelines and strategies for improving TE learning environments. Empirical evidence about long-term TE effects could not only help increase retention in the profession, but also lay a basis for developing teachers' professional practice and well-being during all stages of their careers. The relevance of long-term effect studies for policymaking in the domain of TE is clearly illustrated by the debate about what is an adequate or even the best architecture of TE programs, be they regular 4-year programs or alternative certification programs (e.g., Darling-Hammond and Youngs, 2002). Teacher shortages worldwide lend urgency to such questions. As yet, the empirical knowledge base for designing learning environments for teachers is growing, but seriously incomplete. There is a clear need for research which explains specifically how TE learning effects come about.

TE as a research field characterizes itself by an enormous complexity. Program effects are not exclusively influenced by program features, but these interact with the personal backgrounds of candidates and the varied contexts in which their schooling takes place. To explain the complex interplay between conditions, processes, and outcomes involved in teacher learning, an adequate research base is not yet available, the American Educational Research Association (AERA) Panel on Research and Teacher Education has concluded. However, improvements in research design are underway (Cochran-Smith and Zeichner, 2005, p. 704). This conclusion is even more applicable when long-term effects of TE are taken as criteria.

This article focuses on what we know about TE effects as well as how we know it. Coming to grips with the complexity of teacher learning is crucial to scientific progress in the field of TE. The empirical evidence about effects of TE programs are therefore referenced with special attention to the strengths and weaknesses of TE effect studies. On this basis, validity requirements for TE effect research are explicated and productive research strategies are presented. For this purpose, a number of pioneering and exemplary studies serve as illustrations.

Contested Ground. What We Know about TE Effects and How We Know Them

Empirical evidence about effects of TE programs has begun to emerge during the last decades of the twentieth century, both in Europe and in the English-speaking

world. Toward the end of the century, growing teacher shortages in the United States spurred survey research on a larger scale into the outcomes of alternative certification programs. These programs, developed initially in the US since the 1980s, were intended to attract new candidates to the teaching profession (Dill, 1996; Zeichner and Schulte, 2001) and often consisted of abbreviated or condensed versions of regular TE programs. The need to evaluate the adequacy of these programs has put effect research into TE programs, both alternative and regular programs, high on the agenda. However, long before that time, in fact since the formalization and institutionalization of TE programs began in the 1920s, qualitative research has been carried out representing the experiences of teacher educators in developing programs and of candidates while learning to teach.

The State of the Art

The state of the art in TE effect research becomes apparent from seminal studies and research reviews in this domain.

Seminal studies

Seminal research exploring how teachers become and develop as teachers was reported by Lortie in his well-known book *School Teacher*. In two case studies using survey questionnaires and retrospective interviews, Lortie vividly showed and persuasively argued how a web of social and psychological forces conditions the ways in which teachers are socialized by the existing school system (Lortie, 1975). Lortie's sociological angle reminds the reader of the risks of unreflective reproduction of craft traditions of teaching. In his wake, Lacey explored attitude change in aspiring teachers as they enter the school system and traced the various strategies of occupational socialization open to them. On the basis of five case studies, in which observations and questionnaires were used to follow prospective teachers as they moved from preservice TE through their first year of beginning teaching, Lacey (1977, 1995, p. 619) distinguishes among internalized adjustment, strategic compliance, and strategic redefinition as possible ways for beginning teachers to deal with existing traditions in schools.

Until the 1970s, large-scale empirical evidence about long-term TE effects was virtually nonexistent; in fact, even now, shortly after the turn of the century, it is scantily available. The project Teacher Attitudes, carried out at Konstanz University in the south of Germany, was the first in Europe to demonstrate by means of path analysis on national longitudinal survey data the influence of specific features of preservice programs on outcomes in graduates (Dann *et al.*, 1978, 1981). This project showed that program features encouraging the integration of theory and practice can delay and/or mitigate the occurrence of practice shock and the associated attitudinal adjustment to

existing teaching practices. Building on Kelman's (1974) work on types of attitude change, Dann *et al.* (1978, pp. 96–104) and Müller-Fohrbrodt *et al.* (1978) have identified as crucial in beginning teachers' socialization what they call discrepancy experiences; they experience a rift between idealistic notions developed during TE programs, on the one hand, and pressure from schools as institutions to rely on traditional patterns of behavior, on the other. These discrepancy experiences are strongest in situations where practical action is required (Dann *et al.*, 1981).

This phenomenon of conservative attitude shift was demonstrated repeatedly in the US by the Pupil Control Studies initiated by Hoy (Packard, 1988). It was also documented in early qualitative research by Corcoran (1981), who described entry into teaching in terms of transition shock.

Perhaps the most important contribution of the Konstanz research group is that program characteristics were shown to differ in how fast and in what respects they influenced the U-curve in prospective and beginning teachers' attitude development (Dann *et al.*, 1978, 1981). This evidence supports the conclusion that integrative approaches in TE, in which student teachers' practical experiences are closely linked to theoretical input, can strengthen graduates' innovative teaching competence (Dann *et al.*, 1978, 1981). Similar research and findings were reported from Hamburg by Hinsch (1979) and from the Netherlands by Brouwer and Korthagen (2005).

Research reviews

Both the European research referenced above and the comprehensive review undertaken by the AERA Panel on Research and Teacher Education in the US confirm that TE programs do influence graduates' learning outcomes. The AERA review contains indications that coursework can promote graduates' subject-matter knowledge and that methods courses combined with field work can have an impact on their professional behavior (Cochran-Smith and Zeichner, 2005). The beneficial influence of integrating theory and practice during teacher preparation on teachers' in-service performance was confirmed in the US by reviews and secondary analyses of partly cross-sectional, partly longitudinal survey data carried out by Darling-Hammond (1999, 2000). This synthetic work has yielded two important conclusions: (1) the amount and quality of teacher preparation are positively related to teachers' retention in the profession as well as their success in promoting student achievement and (2) teacher quality is the single most influential factor determining student achievement.

Taken together, these conclusions mean that preservice TE programs have a discernible and relevant influence on teaching and learning in schools, especially if they integrate practical and theoretical components. However, precisely how these effects come about and which specific

program features are responsible for which kinds of effects are questions which require further study of a sophisticated kind.

How to Research Long-Term Effects of Educating Teachers?

So far, much TE research lacks the qualities needed to refine and elaborate upon the available evidence. Wilson *et al.* (2002) reviewed 57 studies about the impact of TE programs published in peer-reviewed journals mostly during the 1990s. They concluded that this research was often small scale, allowed researcher bias, employed few direct measures, and often lacked in detail in reporting about methodology. Similar criticisms were voiced by Wideen *et al.* (1998) in their review of the research about learning to teach. In their judgment, the theoretical basis of such studies should be made more explicit. They also note a lack of longitudinal research and advocate a systemic and ecological approach in TE effect research. Considering this state of affairs, the AERA Panel on Research and Teacher Education calls for research taking into account the contexts of TE programs, participants' backgrounds and characteristics, and how these relate to the processes and outcomes of TE programs. Such research requires employing longitudinal designs more frequently and a theory-driven conceptualization of outcome measures, whose operationalization should go beyond indirect verbal data.

These reviews, with quite a some consensus, point in the same direction. The outcomes of TE programs probably never result from a limited number of social conditions and personal characteristics. They had better be conceived of as resulting from a complex interplay of factors which simultaneously create and constrain opportunities for learning. To understand how this complex interplay affects teacher learning, a type of relational knowledge is needed, as described by Apple (1979); in other words, a systems perspective which pays attention to the manifold relationships between the components of TE as a social system. If TE effect research is to answer its questions, it would benefit not only from stronger conceptualization generally, but also, especially from using ecological and developmental concepts to theorize about its research object.

Modeling the object of research

In order to explain how all the factors operating in TE programs work together to generate teacher learning, TE effect research should rest on more systematic theorizing. A suitable vehicle for achieving this is the decision-oriented evaluation model introduced by Stufflebeam and Webster (1988). This model distinguishes between different types of variables, designated as context, input, process, and

product (CIPP). When applied to preservice TE, context factors include the institutional and cultural constraints in schools, colleges, and universities within which TE programs are offered. Input factors include personal background characteristics of teacher candidates and the resources for training and guiding them on their way to beginning teaching. Process factors are the ways in which programs are implemented, including the degree to which and the ways in which practical exercise and theoretical study are adjusted to each other. These process factors are decisive mediators determining the nature of learning effects in graduates. These effects fall under the CIPP model component product. Models for TE effect research should take into account candidate, program, and context features and preferably include factors from each model component relevant for the study at hand. This kind of modeling encourages the researcher to examine the relationships and the balance of forces between influences emanating from TE programs and from school contexts in particular.

Ecological conceptions of the objects of social research go rather against the grain of mainstream educational psychology, but if the TE research community wants to develop a methodology that is congruent with theorizing about the complexity of teacher learning, it could consider a paradigm shift from a mechanistic toward an organicist worldview (cf. Baltes *et al.*, 1977). In developmental psychology, ecological conceptions have long been available, notably in the work of Bronfenbrenner (1979), who situates the individual as one of the driving forces in a nested structure of systems, that is, the micro-system, in which he or she directly participates, the mesosystem, which constitutes the institutional constraints within which human activity unfolds, and the macrosystem on national and world levels determining the material and cultural conditions of human development. Researching the individual as an entity developing in its social context, warns Bronfenbrenner, is seeking to understand his or her exosystem, that is, how the relationships between the three subsystems distinguished mediate personal development.

Methodology of exemplary studies

What we know about TE effects is determined to an important extent by how we know them. Empirical studies are inevitably shaped by the way in which researchers relate their theoretical perspectives to their choice and use of methods. It is from this angle that we now examine an illustrative selection of exemplary TE effect studies in order to try and cull from the researchers' experience suggestions for conducting ecological inquiry into the influence of TE programs on the teacher workforce and its professional competence. The studies presented below are all examples of longitudinal research.

Phenomenographic studies

Since the 1970s, especially, there has been a host of exploratory, phenomenographic case studies into prospective and beginning teachers' experiences in becoming a teacher (see the review by Wideen *et al.*, 1998). Most of this research is purely qualitative and involves small numbers of respondents, if only because the researchers lacked the resources to process large amounts of qualitative data. The result has been to describe in interpretive ways prospective teachers' experiences as they learned to teach. An advantage of this approach is that it can illuminate the processes and mechanisms involved in teacher learning, especially if the "inner workings" of the TE programs concerned are carefully described (Cochran-Smith and Zeichner, 2005: p. 700). However, studies which restrict themselves to using only qualitative methods in small samples may fail to identify and explain which program features significantly encourage later performance in teaching practice. Without larger numbers of respondents and strategic sampling, TE effect research cannot produce generalizable knowledge about productive learning environments for teachers.

Large-scale quantitative studies

At the other extreme is purely quantitative survey research capitalizing on the law of great numbers, which uncovers patterns and relationships, notably concerning issues of recruitment (cf. the pertinent entry), selection, and retention.

A persuasive example is Ingersoll's (2001) demonstration of a revolving-door effect in teacher turnover. By analyzing with regression techniques the national longitudinal data sets in the US spanning 7 years, Ingersoll showed that contrary to public and political opinion, there are sufficient numbers of teachers available who are willing to fulfill schools' staffing needs. However, too many of them grow dissatisfied too soon with the work conditions in education and therefore move to different schools or leave teaching profession altogether. Chin and Young (2007) reported how personal backgrounds of alternative-route candidates such as ethnic status, age, gender, family obligations, and career history interact with local and regional employment opportunities as well as attractive characteristics of teaching as a profession in determining recruitment patterns.

In the area of teacher selection and self-selection, various longitudinal studies were carried out tracing the backgrounds, employment, and work experience of graduates of alternative certification programs. A review of these studies makes it clear that rather than general measures, such as grade point averages based on standardized achievement tests, candidates' cognitive skills, and levels of cognitive complexity, their self-efficacy and previous experience in instructing and coaching people in group settings have some merit as predictors of retention or at

least success in teaching as rated by teacher educators and employers (Brouwer, *et al.* 2007).

Time-dependent patterns in retention have been uncovered by Shen (2003), using large-scale longitudinal data. Dropout of beginning teachers was shown to increase with time, often in leaps at the beginning of a new school year or semester. In the same research, a positive relation was found between the length of training and the length of time teachers remained in the profession. In addition, support for teachers after graduation can influence their commitment to schools. Various induction packages consisting of different types of support for teachers who were new to a school were shown to differ significantly in their influence on percentages of turnover after the first year of employment. Much of the turnover occurred among teachers without any type of support during induction. Turnover was reduced among teachers who had supportive communication with school leaders, and even more so when they were given opportunities to collaborate with colleagues and had access to teacher networks and extra resources (Smith and Ingersoll, 2004).

In the area of attitude development, Watzke (2007) analyzed the development of work-related concerns in 79 beginning teachers using six repeated measures with a concerns inventory. Fuller (1969) and others have posited a stage chronology, which has tended to portray beginning teachers' development as a series of subsequent steps proceeding from concerns about maintaining a desirable presentation of self through concerns about performing teaching tasks proficiently to concerns about the adequacy of one's own teaching in promoting student learning. In contrast to this self-task-impact-stage chronology, concerns about impact on learners were shown in Watzke's sample to rank consistently highest across time. Concerns about impact, whether academic or personal in orientation, were shown to recur over time instead of characterizing one specific phase of beginning teacher development.

Mixed-methods studies

A study based on ecological assumptions and relating processes and outcomes is the reconstruction of competence development in 357 teachers from the beginning of preservice training until the third year of in-service practice reported by Brouwer and Korthagen (2005). Building on the work of Dann *et al.* (1978) and using a conceptual model derived from the literature on teacher socialization, this study assessed the relative influences on competence development of preservice TE programs on the one hand, and school contexts before and after graduation on the other. The methods used in this study were questionnaires, document analysis, observations, and retrospective interviews with student teachers as they developed into beginning teachers, cooperating teachers, and teacher educators. Among the main findings were that a carefully planned alternation of student-teaching and college-based

periods, a gradual increase in the complexity of student-teaching activities, and the use of a clinical supervision model in cooperative small-group settings encouraged graduates' professional competence, notably their ability to activate learners.

Longitudinal mixed-methods approaches capable of addressing the complexity of teacher learning are also used on a larger scale in the Pathways into Teaching Project in New York City schools. In this project, comprehensive quantitative surveys are combined with detailed qualitative descriptions of an array of different TE programs and the learning experiences of the participants in them (Boyd *et al.*, 2006).

Validity requirements

Against this backdrop of examples and with due caution, the methodological strengths and weaknesses of studies of long-term TE effects can be assessed as follows. Explaining relationships between TE program features and outcomes in graduates is facilitated by combining quantitative and qualitative methods. Using quantitative data from sizeable samples enables the researcher to establish significant relationships and patterns and begin to generalize findings. Using qualitative data, preferably from direct observation, enables the researcher to reconstruct and infer from thick description (Geertz, 1973) in which settings and in which ways teachers acquire and transform professional teaching behaviors. TE effect research with explanatory power is further characterized by longitudinal rather than cross-sectional designs, repeated rather than one-shot measures, and multivariate correlational rather than experimental or quasi-experimental methods of analysis.

Given these experiences and trends in the conduct of TE effect research, it is appropriate to explicate what should count as valid causal explanations in an ecological conception of TE effect research. Therefore, two validity requirements are now presented for the benefit of explaining the complex whole of factors determining effects of TE programs. Conclusions about cause-effect relationships in TE effect research should be considered valid only, when:

- relationships are demonstrated on the basis of a research model incorporating context, input, process, and product factors and
- the processes responsible for these relationships are reconstructed.

The latter demand implies that explanations of human learning are incomplete, if only an experimentalist, black-box approach is taken. Such an approach would underestimate the role that subjective representations, such as perceptions, experiences, opinions, and attributions, play in human learning (cf. Maxwell, 2004). These two validity requirements embody a causal-genetic conception of

scientific explanation in educational research and share important assumptions about the object of research as put forward in Bronfenbrenner's ecological conception of human development.

Suggestions for Conducting TE Effect Studies

The validity requirements proposed above lay a basis for arriving at decisions about research design, instrumentation, data collection, and data analysis (cf. the criteria for research programs advocated by Bronfenbrenner and Lüscher, 1976).

Design

An ecological conception of TE programs and effects as an object of causal-genetic explanation would entail including in the design of an empirical study the main settings of the college-based curriculum, student teaching, and beginning teaching in schools. Prospective teachers should be followed longitudinally from the beginning of training until the second year of in-service teaching, preferably longer. The instruments and measures used should allow recording and understanding the backgrounds, actions, experiences, and motives of the persons studied.

Combining qualitative and quantitative methods helps solve the breadth-depth problem in investigating TE programs and effects. If one type of method is used exclusively, either many situations and persons are studied superficially, or a few are studied thoroughly (Berger, 1974). A solution to this problem is to select, from all the programs and respondents in a study, a smaller number to form a representative subset. These may be termed the whole sample and the subsample, respectively. The whole sample can then be studied using quantitative methods, so that generalizable relationships and patterns can be discovered. The subsample can be studied additionally by means of qualitative methods, so that mediating processes can be reconstructed and explained in sufficient detail.

Instrumentation

In order to arrive at a multifaceted representation of both the outcomes and processes of long-term teacher learning, it is advisable to use multiple instruments for data collection (cf. for the original idea of a multitrait-multimethod matrix in social research, Campbell and Fiske, 1959). Not only self-report methods should be used, but also direct observation, so that attributions by any respondent group can be recognized for what they are and reliable accounts of actual professional performance can be achieved.

The operationalization of observations and measures is crucial for validity. Three epistemological perspectives, that is, assumptions about the nature of TE programs and effects can serve as a guide for operationalization: the ecological, genetic, and activity perspectives. The ecological perspective assumes that the research object in the social sciences always consists of a social system, which is at the same time internally structured and embedded within a wider, often institutional context (cf. Maschewsky, 1979; Tabachnick, 1981). The genetic perspective recognizes all learning as a set of processes, whose unfolding influences learning. This perspective assumes that understanding learning outcomes requires understanding the processes which produce them (cf. Davydov, 1977). The activity perspective entails a focus on the actions of people as these express the continual tension between their personal motives on the one hand and contextual constraints on the other (cf. Zeichner and Tabachnick, 1985).

In quantitative inquiry, low-inference measures should be employed wherever possible. In qualitative inquiry, a balance should be sought between self-report and direct observation data. On-site visits, video recording of teaching, and retrospective and stimulated-recall interviews are therefore suitable methods.

Data Collection

In an ecological inquiry of TE programs and effects, minimally, the main respondent groups should be involved, that is, prospective, beginning and/or experienced teachers, cooperating teachers, teacher educators, and/or professional development facilitators (cf. Cochran-Smith and Zeichner, 2005, p. 331–334).

An important consideration in designing TE effect research is which time spans should be covered in longitudinal data collection. Decisions on this point are obviously made depending on the research questions and available resources, but it should be borne in mind that learning effects need time to come to fruition and to manifest themselves. To determine long-term effects of TE, it is advisable to cover time spans of at least 2 years. When following respondents over time, it is of course necessary to identify them, secure their consent with continued participation, inform them of the study's progress, and take all other measures useful for guarding against attrition generally (Mednick *et al.*, 1984).

Analysis Methods

Having based research design on ecological assumptions, TE researchers face strategic choices in analyzing pluriform data sets. Formulating and accounting for these choices with the help of a predetermined analysis plan can make or break a study's success. Evaluating any specific TE program in an ecological fashion confronts the researcher with social

constellations and processes of unique complexity. Tracing distal causes and mediating factors will be prominent challenges (cf. Baltes *et al.*, 1977). An analysis plan should therefore serve careful hypothesis generation and explicate the reasons why certain analysis techniques are selected and how their use is sequenced.

Given the validity requirement that the explanation of learning outcomes should rest on a reconstruction of the learning processes involved, it is logical to make qualitative analyses preceding quantitative ones, so that hypotheses can be generated and explored in a controlled way. If multivariate analyses yield clear indications of testable relations and/or differences, then experimental or quasi-experimental analyses can follow. This sequence conforms to the plea by Chatterji (2004, 2006) for extended-term mixed-method evaluation (ETMM) designs.

Finally, in analyzing quantitative longitudinal data, caution is needed in handling missing values. Attrition of respondents can easily cause individual data pairs to drop out of specific correlations and regressions. This risk increases to the degree that data pairs are collected further apart in time. To contain this risk, techniques can be used for estimating missing values (Peugh and Enders, 2004).

Conclusion

Qualifying and retaining teachers requires building an empirical knowledge base which can underpin program design in TE. Answering questions relevant for explaining and optimizing long-term effects of preservice TE programs can be achieved by means of carefully planned longitudinal studies combining quantitative and qualitative methods. TE researchers are well advised to conceptualize their questions using explicit, ecological models, which help them to theorize about the crucial role of mediating processes in generating learning effects in teachers. Research design, instrumentation, data collection, and analysis should fulfill validity requirements which are congruent with research models aiming at causal-genetic explanation.

If TE effect research were to succeed in mastering its challenges, evidence-based decision making could become possible in policymaking for TE. At the beginning of the twenty-first century, the greatest challenge for research into the long-term effects of TE is to help solve the dilemma of countering teacher shortages while simultaneously maintaining, enhancing, and assuring the quality of the teacher workforce worldwide.

TEACHER EDUCATION – EVALUATION OF THE PROSPECTIVE TEACHER

The Evaluation of Prospective Teachers in Teacher Education

D E H Tigelaar and J van Tartwijk, ICLON Leiden University School of Training, Leiden, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Teacher evaluation has been a major focus in literature on teacher education in the last few decades. Methodology for teacher evaluation has been described in special handbooks and many conceptual and research papers have been published about this subject.

In this article on the evaluation of prospective teachers, several aspects and issues are addressed that play an important role in evaluation in teacher education. We revisit the way that changing views on good teaching have influenced teacher evaluation and how evaluation has evolved into assessment, and we give a description of various assessment methods. We also focus on current trends in the assessment of prospective teachers. Finally, the quality of teacher assessments is discussed. Before that, there is a brief introduction to the different purposes of the evaluation of prospective teachers.

Purposes of the Evaluation of Prospective Teachers

The evaluation of prospective teachers can serve various purposes. First, it can be used as a selection method to determine whether individuals are qualified enough to be admitted into teacher education programs. Tests of basic skills in reading, writing, and mathematics; subject matter knowledge; and pedagogical knowledge can be part of such evaluations. Second, it can diagnose and influence the performance and professional growth of student teachers while they are involved in teacher education programs. Third, it can be used to determine whether student teachers should be given their initial teaching licensure. Finally, the results of the evaluation of prospective teachers can be used to monitor the effectiveness of teacher education programs and to account for the outcomes of these programs. These four purposes: selection, diagnosis, licensure, and accountability can be categorized into two main types of evaluation: (1) formative evaluation which is focused on diagnosing and monitoring progress and (2) summative evaluation which is focused on selection, licensure, and accountability.

Views on Good Teaching and Implications for Teacher Evaluation

From the 1960s to today, views on good teaching have evolved. Each of these views has influenced teacher evaluation and the influence of each view can be recognized in different traditions of research on teaching. At first, the ideal good teacher was supposed to be a warm and stable person. Research on teaching in this tradition mainly focused on analyzing teachers' personality characteristics and, from this, predicting the classroom climate that teachers created. In this research, teacher personality traits, such as warmth and indirectness, were related to students' responses in the classroom. However, it proved difficult to define and identify an effective teacher personality.

The most prominent foci in research from the mid-1960s till date have been teacher behavior and teacher cognitions and decision making. These research traditions and their inherent views on good teaching are described below, along with their implications for teacher evaluation.

Teacher Behavior

From the mid-1960s until the early 1970s, in line with the dominance of the behavioral psychology of learning at the time, educational researchers focused on teachers' instructional behaviors and how these related to student-learning outcomes. This implied that a good teacher was expected to possess a repertoire of effective behaviors for optimal student learning. In most studies, a process-product approach was applied in which systematic observation schedules were used to measure and evaluate a teacher's behavior or classroom interaction (the process) and to use these variables to predict student-learning outcomes (the product). Research in the teacher behavior tradition gradually resulted in long lists of effective teacher behaviors and observation schemes to score and evaluate these behaviors. When the implementation of these research findings did not actually lead to improvements in teaching practice, attention shifted to the teacher-thinking processes.

Teacher Cognitions and Decision Making

In the 1970s, influenced by the cognitive revolution in psychology, the focus of research on teaching shifted from teacher behavior to what actually goes on in the mind of the teacher. Examples of topics that were investigated were teachers' expectations, thought processes, decision making and planning, beliefs, practical knowledge, conceptions of subject matter and how subject matter should be taught to students, and differences in the cognitive orientations of novice and expert teachers.

From research on teacher cognitions and decision-making processes, it was increasingly recognized that for good teaching, thought processes are as equally important as behaviors, and that teaching is a complex activity which is heavily bound to the context (e.g., the subject taught, the conditions in the school, and the students' background). It was also acknowledged that teachers actively construct their own knowledge by interpreting events on the basis of existing knowledge, beliefs, and dispositions, and that teachers need a continuing capacity to learn from their experiences (Feiman-Nemser and Remillard, 1996). Although studies on teacher cognitions were not usually related to student outcomes, insights from this research have had implications on the way teaching is evaluated (Haertel, 1991; Darling-Hammond and Snyder, 2000; Uhlenbeck *et al.*, 2002). Teacher evaluation has developed from testing knowledge with paper-and-pencil tests, or using standardized observations, into a process aimed at gaining a comprehensive picture of the development of a teacher's knowledge and performance. Examples of this new type of evaluation, known as assessment, include: peer assessment, self-assessment, assessment in a simulated teaching environment, and the use of portfolios. These methods are described below.

Peer assessment

In peer assessment, colleagues or student teachers assess each other and provide each other with feedback (Boud *et al.*, 1999). Training in using peer-assessment procedures and providing effective feedback is necessary (Dierick and Dochy, 2001; Sluijsmans *et al.*, 2002). Usually, in peer assessment, groups of individuals are involved in defining criteria and procedures for their own assessments. In this way, they internalize assessment criteria and learn to provide useful feedback. Peer ratings tend to be fairer and more accurate in comparison to assessments by supervisors. However, peers often find it difficult to criticize their friends, and thus guidelines for evaluation need to be very clear.

Self-assessment

During self-assessment, student teachers make judgments about their own work and the extent to which they have met criteria and standards (Airasian *et al.*, 1995; Ross and Bruce, 2007). Mostly, student teachers are involved in

identifying the criteria and standards they have to apply to their own performance. Self-assessment may lead to new insights or an awareness of areas that need to be improved and may help prospective teachers to exert more control and responsibility for their own professional development. However, self-assessment needs to be combined with other assessment strategies, for example, peer assessment or observation by supervisors, to validate student teachers' own judgments.

Simulations

The use of simulations has its origin in the wish to assess the complex performances that many work situations require. In assessment centers, student teachers complete simulations – a coherent set of tasks and activities which represent the most important aspects of the work situation, such as planning a lesson or evaluating student work, and explaining and justifying their approach and decisions (Uhlenbeck *et al.*, 2002). The level of task performance and the student teachers' rationale for their approach are the basis for making judgments about a student teacher's knowledge and skills (Haertel, 1991; Shulman *et al.*, 1988). However, developing and carrying out simulations is expensive and time consuming (Uhlenbeck *et al.*, 2002).

Portfolios

When portfolios were first introduced, teachers gathered artifacts (i.e., work samples) that were illustrative of the quality of their own classroom teaching, and wrote captions in which they described what these artifacts were evidence of. Since their introduction in the early 1990s, increasing emphasis has been put on including materials from others, such as feedback from students and colleagues. In this way, a teaching portfolio integrates aspects of peer and self-assessment. In portfolio assessment, the burden of proof is the primary responsibility of the assessed student teachers, who need to convince assessors with the evidence in their portfolios that their level of competence meets the criteria. Since their introduction, more emphasis has also been put on the quality of reflections in the commentaries on the evidence in portfolios (van Tartwijk *et al.*, 2007). In these reflective commentaries, student teachers need to show that they have learned from their experiences and gained improved understanding of their own practice through critical analysis and the use of theory, and by building and reframing their own practical knowledge. However, composing portfolios is very time consuming and the quality of reflections in portfolios is often disappointing (Mansvelder-Longayroux *et al.*, 2007). Nevertheless, portfolios have become widely used in many teacher education programs.

Learning-Oriented Assessment

In the last few decades, the terms learning-centered or learning-oriented, with reference to teacher assessment,

have become common in teacher education (i.e., Carless, 2007). Learning-oriented assessment places more emphasis on the learning elements of assessment processes in teacher education: the purpose of the assessment being to monitor and evaluate student teachers' progress. An optimal integration of assessment and the learning process is important. This means that assessment programs need to be developed that are consistent with the goals for learning in teacher education curricula. In these assessment programs, various methods need to be used and many sources of information should be collected over a long period of time in order to measure the different aspects of student teachers' progress. In this way, a comprehensive picture of the student teacher's development and growth can be gained. The collected evidence can be related to standards and criteria which provide insight into the goals for student teacher learning and performance within the curriculum. Performance levels, which indicate levels of both performance and growth, can also be used to monitor a student teacher's progress.

Quality feedback is an essential ingredient in optimizing assessment for learning. This feedback not only should be focused on nonevaluative descriptions of the characteristics of a student teacher's performance, but should also involve evaluative comments linked to criteria that indicate the quality of a student teacher's work. Finally, it should promote setting goals for improvement (Sadler, 1989). Ultimately, monitoring progress on the basis of assessment information and providing feedback results in a summative judgment about the student teacher when finishing teacher education and gaining licensure. This means that formative and summative goals are related and the latter can be seen as a continuation of the former. The question of who is responsible for assessing different parts of a student teacher's progress and providing support and feedback until finishing teacher education and gaining licensure is a dilemma in this respect. There is a potential role conflict when the supervisor or

mentor takes on the double role of guide and judge of the learning process. This dilemma may be resolved by considering different assessment scenarios. In Table 1, examples of assessment scenarios in the context of portfolio assessment for both formative and summative evaluation of student teachers are outlined.

Standards-Based Teacher Assessments

From the mid-1980s, many efforts have been put into defining a knowledge base that describes what teachers should know and be able to do. Criteria and standards have been developed that specify what should be taught in teacher education programs and programs for teachers' further professional development. A well-known example of such criteria and standards are those that were introduced in 1987 by the Interstate New Teacher Assessment and Support Consortium (INTASC) (see section 'Relevant Websites'). These standards were developed over a long period by a committee consisting of members of the teaching profession, and they have been very influential. Based on these standards, which are discipline-specific, portfolio assessments for ongoing licensure were developed, which required teachers to include several portfolio entries, such as lesson plans, videotapes of and comments about two lessons, and samples of students' work. The INTASC standards are now being used by many teacher education institutes in the United States to define their curricula and to set their own standards for admission, licensure, and further professional development. In recent years, many other countries have also developed standards for teaching and teacher education, for example, the United Kingdom, Australia, New Zealand, and the Netherlands.

Primarily, teaching standards were developed to recognize teachers' professional status, improve their performance, and contribute to their professional learning. However, due to political debate about the presumed

Table 1 Scenarios for the role of the supervisor in portfolio assessment for both formative and summative purposes

The "job-application" scenario

Just as in a job application, student teachers themselves are responsible for a portfolio which proves to an assessment committee that they meet the criteria. The supervisor is not part of this committee. One of the criteria can be that the student teachers demonstrate growth in their portfolio.

The "driver exam" scenario

In this scenario, just like a driving instructor, supervisors help student teachers to prepare themselves for an assessment. Subsequently, an assessor uses information in the portfolio, such as video-recordings and student evaluations, to assess the level of competence, without consulting the supervisor. The situation resembles that of an assessment center, but the evidence is collected in "real" situations.

The "PhD supervisor" scenario

In this scenario, the supervisor helps the student teacher to reach the required level of competence. Once the supervisor decides that the portfolio shows that the student teacher meets the criteria, he or she can decide to ask an assessment committee to look at the portfolio (just like a professor does with the PhD thesis). Most of the time this committee will confirm the supervisor's decision. But if the supervisor does not do a proper job and is too lenient, the assessment committee might reach a negative conclusion.

decline in schools' and students' performances and failures in previous reform efforts to improve these performances, policymakers have placed more emphasis on researching teacher quality and the value of teacher education programs. As a result, the accountability function of standards has become more prominent, in the United States as well as in other countries. This has led to evidence-based studies on teacher quality in relation to student outcomes, and studies on the quality of teacher education programs.

The Quality of Assessments in Teacher Education

The introduction of new forms of teacher assessment, aimed at evaluating how teachers perform in their own practice, has led to discussion of what determines the quality of these evaluations (see, for example, Andrews and Barnes, 1990). Basically, this discussion comes down to the validity and reliability of assessments. We use the example of classroom management in this section to clarify some technical aspects of the quality of assessments.

Validity

The traditional definition of validity is the extent to which a measurement or test measures what it was designed to measure. From this perspective, three types of validity, that is, content, criterion, and construct validity, can be distinguished as intrinsic properties of a test or assessment. Construct validity refers to the test score as a measure of the assessed characteristic, which should be defined in a conceptual framework. This means that when a test is designed to assess classroom management, for instance, a clear and detailed definition of the construct of classroom management must be offered and the test scores must be related to that construct. Content validity focuses on the degree to which the content of the test and the response properties are representative of a defined domain. An example of such a domain is the extent to which the test of classroom management covers the skills required for good performance in classroom management. Criterion validity refers to the degree to which test scores predict future performance and correlate with the results on other tests measuring the same construct. This implies that when a student teacher is being assessed on his/her classroom management, the scores on the test are expected to depict how the teacher will perform in classroom management in the future, and the findings on the test should be comparable to those on other tests that are intended to measure the student teacher's classroom-management skills.

An expanded notion of validity

Cronbach and Messick use an extended notion of validity. As an alternative to regarding validity as a property of the test as such, they relate validity to the meaning of the test

scores. According to Cronbach and Messick, it is the meaning or the interpretation of the score that must be valid along with any implications of this meaning. The interpretations by assessors, as well as the consequences for the assessed student teacher that follow from these interpretations, are all part of what needs to be valid. This implies that both assessors' scores on a test of classroom management and assessors' suggestions of how to improve classroom management need to be valid. This concept of validity results in a proposal by Messick (1989) for an integrated validity framework, which combines issues related to content, criterion, and construct validity with considerations of value implications and social consequences. The acknowledgment that validity goes further than the properties of a test and is related to interpretations, value implications, and consequences of the use that is made of a test, is generally accepted today in teacher assessments.

Defining constructs and assessment tasks and criteria

As outlined above, in order to judge a student teacher's performance, that is, on classroom management, a well-defined conceptual framework is needed as a basis for the description of the construct to be assessed. Assessment tasks and scoring criteria which are used to evaluate a student teacher's performance should be relevant to and representative of the construct that is to be measured. Quality criteria for assessments should include content validity and content coverage, as introduced by Linn *et al.* (1991), and the extent to which results are representative, as suggested by Frederiksen and Collins (1989). Defining assessment frameworks can be done using a realist approach, in which the concepts in the assessment framework are supposed to reflect reality, or using a more constructivist approach, in which multiple perspectives are regarded as possible (Moss, 1992). In a realist approach, when an assessment framework is developed, the concepts and the assessment framework that are used to define the construct (i.e., classroom management) are classified and researched until a detailed assessment framework has been constructed. The assessment framework is then used as a basis for hypotheses about a student teachers' performance (for instance, in relation to pupils' outcomes), which can be tested in the assessment, and the findings from the assessment are then expected to be a true score of a student teacher's performance. By contrast, in more constructivist approaches to assessment, concepts are seen as aspects to consider in the assessment, which are instrumental and meaningful to their users, but do not necessarily reflect reality. The constructivist approach implies room for multiple perspectives on what is important in a certain teaching area, such as classroom management. The methodological advice for developing assessment frameworks is to focus on the opinions of different stakeholders and to gain an understanding of the cultural context in order to agree on

the construct to be assessed. This means that when an assessment framework is being developed for classroom management, various people who might have interest in the assessment, for example, pupils, teacher educators, school leaders, and the assessed student teachers themselves, are consulted on their opinions with regard to what is important for a teacher's classroom management.

In the literature on teacher assessment, we find elements of both realist and constructivist approaches to the definition of assessment frameworks. The Educational Testing Service in the United States (see section 'Relevant Websites'), for example, adopted a more realist approach by conducting job analyses, research interviews, and analyses of state licensing requirements in order to define an assessment framework. On the other hand, the INTASC assessment frameworks were developed in committees of different stakeholders in education, which is more representative of the constructivist approach.

Consequential validity

Assessments are not only useful in determining the level of teaching competence, but are also diagnostic and can therefore provide learning opportunities for the student teachers involved. When classroom management is assessed, the assessment should provide student teachers with suggestions for further development and improvement in this teaching area. With reference to the benefits of assessment for teaching and learning, educators often speak of the consequential validity of assessments in terms of their potential influence on teaching and learning. Messick included these consequential concerns in his characterization of validity. Messick's recommendation in this respect is to focus on evidence and rationales in evaluating the intended and unintended consequences of the interpretation and use of assessment scores, particularly those associated with scoring bias or unfairness in test use. Any negative impact on student teachers or groups of student teachers should not be attributable to construct underrepresentation or construct-irrelevant variance. When a student teacher has low scores on a classroom-management assessment, this should not be caused by exclusion from the assessment of an aspect of classroom management which is relevant to the assessment and which, if present, would have allowed the assessed student teacher to display competence. Nor should low scores on classroom management be caused by something irrelevant in the measurement which interferes with the assessed student teacher's demonstration of competence.

Additional validity criteria, such as fairness, meaningfulness, and transparency, have been proposed by Linn *et al.* (1991) and Frederiksen and Collins (1989) to enhance consequential validity. Fairness implies that the consequences of assessment should be similar for every student teacher and that there should be no bias toward any group of student teachers. Meaningfulness refers to the view that assessment tasks should be recognizable and considered

important by the student teachers who are assessed. Transparency implies that it should be clearly communicated to student teachers what they are expected to do regarding the problems and tasks included in the assessment. This means that student teachers should be told not only about which knowledge and skills will be assessed when their classroom-management performance is being evaluated, but also by which criteria and standards their performance will be judged and what steps they can take to improve their performance with regard to classroom management.

Studies into fairness have been part of the validity research agenda of high-stakes teacher assessments for many years. Studies into other aspects of consequential validity, such as the relevance and learning potential of teacher assessment, are rather new and limited because validity research is very time consuming, and therefore, many opt out of research into consequential validity (see Lustick and Sykes, 2006).

Reliability

Reliability refers to the extent to which assessment scores are variable when measurements are repeated under the same conditions or conducted by different independent assessors. Since multiple methods are involved in assessments, which are often collected over time, this form of measurement tends to be highly valid. However, studies into the reliability of teacher assessments reveal that there are serious problems with the consistency of assessment scores (Delandshere and Petrosky, 1994; Moss, 1994). This is due to the fact that teacher assessments contain a lot of qualitative, nonstandardized information, originating from a variety of contexts, which inevitably necessitates judges interpreting the meaning of the information as well as considering the context. Standardization of assessment sources, scoring procedures, and assessment criteria, as well as assessor training in using these criteria independently, are often applied to teacher assessments in order to improve consistency. However, these measures might compromise the validity of the measurement as well as the intended consequences from assessments (Moss, 1994). Nevertheless, in the assessment of prospective teachers, it is important that assessment results are both valid and reliable. This is especially important not only in assessments for summative purposes (i.e., for licensure) but it is also vital for formative purposes (i.e., to guarantee the quality of feedback in relation to assessment standards). In order to improve the validity and reliability of assessment results, it has been argued that assessors should follow an interpretist approach to assessment (Moss *et al.*, 1998). This means that assessors should discuss emerging hypotheses with a peer assessor and that hypotheses about an assessed student teacher should be challenged by the presentation of counter examples. When interpretations are being developed, it is recommended that they are continuously tested, challenged, and revised until they have accounted for all the available

evidence about a student teacher. It is also seen as important to carefully document the interpretation process in order to improve transparency. These principles have been researched in studies on INTASC portfolio ratings by Moss *et al.* (1998) and Schutz and Moss (2004). Their investigations reveal that assessors tend to seek confirmation of their initial interpretations, both when they work individually and when challenged by peers, and that they find it difficult to weigh all available evidence about a candidate into an overall judgment. Following these principles, however, places a heavy burden on assessors in terms of time and effort.

Conclusion

In this article, we have discussed several factors relating to the evaluation of student teachers. Standards have been developed for defining assessment criteria to evaluate prospective teachers, along with various methods and procedures for carrying out these assessments and guaranteeing their quality. It is a well-known fact that assessment determines students' learning activities, and therefore, programs for student teacher assessment, which are well embedded within the pedagogy in teacher education curricula, need to be developed. Procedures for establishing the quality of teacher assessments are quite complex and time consuming, which make them difficult to implement in teacher education institutes. Techniques to promote quality in teacher assessments need, therefore, to be developed further and converted into feasible strategies for all those involved in assessment in teacher education.

Diversity in Teacher Education

T Wubbels, Utrecht University, Utrecht, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In their review for the American Educational Research Association (AERA) panel on research and teacher education, Hollins and Guzman (2006), based on research in the US and Canada, cite an earlier conclusion on diversity in teacher education “. . . there has been remarkable consistency in the conclusions of previous reviews: Basic changes in teacher education for diversity are necessary, but have not occurred despite 25 years of attention.” This article looks at the validity of this conclusion reviewing international research available on diversity issues in teacher education, including the composition of the teaching workforce, student teachers’ attitudes and beliefs, teaching competence needed for multicultural classrooms, and the preparation in teacher education programs for this competence. Before turning to these topics we first define diversity.

Diversity

Diversity, generally, is a term stemming from biology and meaning the number and variety of different organisms in the environment in which they naturally occur. In education, Echols and Stader (2002) define diversity as “different racial and ethnic groups, cultures, traditions, and belief systems.” This is a somewhat limited definition because many more characteristics to describe different groups can be used. Menter *et al.* (2006), for example, discussing dimensions for inclusion of teachers in a representative teaching workforce, mention eight dimensions of diversity: social class/socioeconomic status, gender, ethnicity (including refugees, asylum seekers, and travelers), bilingualism, religion, disability, sexuality and sexual orientation, and age. Looking at grounds for discrimination shows that this list of eight characteristics is rather complete. Clarke and Drudy (2006), based on laws prohibiting discrimination in Ireland, mention two additional features: marital and family status,

but we feel it is not necessary to add this to the following list of diversity dimension that often are found in the educational literature: cultural, linguistic, ethnic, racial, social class, socioeconomic status, religion, gender, sexual orientation, age, and disability.

Searches since 2004 with Google Scholar for the adjunct presence of the terms teacher education and several types of diversity, produced the results in March 2009 as presented in **Table 1**.

From **Table 1**, it can be seen that the vast majority of hits concerns cultural, linguistic, and ethnic diversity in teacher education. Looking at the number of empirical studies, a similar distribution is found and often these studies combine issues of cultural, linguistic, ethnic, racial, social class, and socioeconomic diversity. The terms ethnic and cultural diversity have even been used frequently interchangeably and sometimes include even linguistic and racial diversity. The term culture refers to the perspectives (values, worldviews, etc.), practices, and products of a social group, that define how this group interprets and interacts with others. An ethnic group, therefore, is a group of people who identify with one another, or are so identified by others. Thus, ethnicity refers to social groups with a shared history, sense of identity, geography, and cultural roots. The narrowest way to think of ethnicity is by referring to people with origins from different parts of the world. The origin of the group identification, however, may take any of these forms: racial, cultural, linguistic, economic, religious, or political, making clear the overlap between ethnic, cultural, linguistic, social class, and socioeconomic diversity.

Some of the diversity features usually are left untreated in reports and studies on diversity of the (student) teacher candidate population, with the least attention being paid to age and disability. The main part of this article treats the combined racial, ethnic, socioeconomic and social class, cultural, and linguistic diversity. Whenever applicable, attention is paid to gender issues. Before that we discuss

Table 1 Number of hits in Google Scholar in March 2009 for various types of diversity in teacher education since 2004

Type of diversity	Number of hits
Cultural	2930
Linguistic	888
Ethnic	757
Racial	297
Religious	173
Gender	93
Sexual	80
Socio economic	21
Social class	12
Age	8
Disability	5

some aspects of the features of religion, sexual orientation, and disability. For age, no relevant studies have been found.

Disability

Research has shown that persons with disabilities can be successful educators who bring a unique perspective to the construction of pedagogies. Teachers with disabilities can also be valuable role models for students; however, they often face barriers in pursuing professional-level occupations. Gabel (2001), in a study of three student teachers with disabilities, concluded that their experiences with disabilities were an untapped resource with rich potential for the construction of pedagogical knowledge.

Religion

Religious diversity has hardly been studied in teacher education and, generally, it is not considered a problematic issue. Only eight out of 61 student teachers in the study by van Hook (2002) mentioned religion as a highly difficult topic to discuss in classrooms. In an Irish study by Clarke and Drudy (2006), of student teachers' beliefs on diversity, 96% showed openness to non-Christian religions. Another Irish study (Leavy, 2005) showed high levels of tolerance and support by student teachers toward religious diversity.

Sexual Diversity

A study by Sherwin and Jennings (2006) examined the coverage of sexual-orientation topics within 77 public university secondary teacher preparation programs across seven US states. They concluded that 40% of programs did not address sexual orientation as a diversity topic. Most programs that did address sexual orientation did not pay attention to the use of knowledge on sexual diversity in the student teaching practicum.

Composition of (Student) Teacher Body

Several reasons are mentioned in the literature for the need to draw the teaching workforce proportionately from all sections of society. The main reason is what Menter *et al.* (2006) call a commitment for universality in the society at large and in particular with politicians. Education therefore has to follow a public service ethic including the need to have a teaching workforce composed from the same broad range of cultural and social experiences as the students and families served by schools. Thus, schools can draw for the curriculum from the resources offered by all cultural groups. Further, many countries are facing a teacher shortage and therefore recruiting teachers from groups that until now did not contribute teachers is a way to get adequate teacher supply. Finally, Menter *et al.* (2006) claim that for countering the problem of lower school success of minority students than of mainstream students, it is necessary to have teachers from the same minorities in order to offer students adequate role models. This claim, however, is not empirically supported. Zumwalt and Craig (2006) conclude, from a review of studies in Northern America, that the evidence on what impact the match between teacher and student race and ethnicity has on student learning, is mixed. Similarly, the sometimes claimed negative influence of feminization in primary education on development of boys is hardly or not at all empirically justified.

Reviews on the composition of the teaching body usually reveal a mismatch between students' cultural and ethnic background in schools and the background of their teachers (Hollins and Guzman, 2006; Zumwalt and Craig, 2006). All over the world growing diversity of the student population is expected whereas the teaching force is expected to lag behind and stay longer predominantly white, middle class, and female. This, however, appears to be a Western stereotype because in many countries, the teaching force looks very different. In many African countries, for example, the teaching force is black and in some Islamic countries, teachers are predominantly male. **Table 2** gives an overview of the gender distribution in primary education in some countries to show how big the differences across countries are.

What probably is the case all over the world is that teachers come from a limited part of the countries' population and that changes in the student population are not immediately reflected in changes in the teacher population. To illustrate the selectiveness of the teaching force, we present data on the student teacher population in comparison to the country's population, for various countries.

Santoro and Reid (2006) report that while 25% of the Australians have a language background other than English, only 2% of the teachers in the state of Victoria were born outside Australia and for whom English was

Table 2 Percentage of female teachers in primary education in several countries from OECD, 2002 see www.oecd.org/dataoecd/36/56/33703261.XLS retrieved 28 July 2007; OECD, 2005 see www.oecd.org/dataoecd/36/36/35324994.pdf retrieved 28 July 2007; www.moedu.gov.bd/edu_statistics.php, retrieved 28 July 2007; www.statpak.gov.pk/depts/fbs/publications/nec2005/nec01.pdf, retrieved 28 July 2007; www.mceetya.edu.au/mceetya/demand_and_supply_2003,11940.html, retrieved 28 July 2007

Country	Percentage of female teachers
OECD average	80
Unites States	88
Bangladesh	36
Tunisia	50
Pakistan	47
India	37
The Netherlands	80
United Kingdom	82
Australia	78

a second language. Further, the ratio of indigenous to nonindigenous teachers is very imbalanced. While for every 73 indigenous students there is one indigenous teacher, there is, for every 13 nonindigenous students, one nonindigenous teacher.

In the Netherlands, the proportion of minority students in primary education is estimated to be about 19%, whereas the proportion of teachers from ethnic minorities is estimated to be between 1.5% and 3.0%. Based on a report on integration of ethnic minorities in the Dutch society, (SCP, 2005) it is clear this will change: in 2003, about 5% of mainstream Dutch secondary students entered teacher education whereas of ethnic minorities 3% did, thus approaching closer to the proportion in the population.

In Scotland, (Menter *et al.*, 2006) the proportion of teachers from ethnic minorities was estimated to be 0.7%, much lower than in the proportion of students in the population (4.6%).

In the United States, the situation is different. Although Zumwalt and Craig (2006) conclude that in schools in the United States teachers are predominantly white (84%), this is not very different from the country's population in 2000 consisting of about 75% whites, 12% blacks, and 12% others (Hobbs and Stoops, 2002).

We conclude that if one wants the teaching force to be a representation of the composition of the population, then in Western countries the feminization in education is a problem. Further, it appears that diversity in the teaching workforce in several countries lags behind the diversity in the society at large. We emphasize, however, that the wish for a representative teaching force cannot be based on solid evidence about the positive effects of such representativeness on student learning.

Student Teachers

For the match between students and teachers, not only are the formal background characteristics such as gender and race important, but also the attitudes and knowledge of (student) teachers about, for example, culture and diversity. Smith *et al.* (1997) identified four factors that help shape attitudes of entrants in teacher education: exposure to different cultural backgrounds (e.g., friendships, dating, sports), education (e.g., influences of teachers and colleges), travel (e.g., moving, vacationing, and military experience), and personal experience with discrimination as a child or as an adult. We now review what is known about diversity-related attitudes and knowledge of student teachers.

From their international review of the literature, Clarke and Drudy (2006) conclude that many student teachers enter teacher preparation programs with a thin base of knowledge relative to their own and other cultural histories and values systems. Many enter teacher education programs believing strongly in an optimistic individualism, the inevitability of triumph over any obstacle through hard work and individual efforts. The review by Hollins and Guzman (2006) concludes that most American teacher education candidates are white, female, middle class from suburbs or small towns and have limited experience with those from cultures different from their own. Many preservice teachers operate from a limited knowledge base about culture and identity, and have been to white schools in predominantly white neighborhoods. Many American candidates hold negative attitudes and beliefs about people different from themselves. Candidates do not feel adequately prepared for teaching in inner-city schools. These findings about attitudes generally are confirmed in other Western countries such as Ireland (Leavy, 2005; Clarke and Drudy, 2006), the United Kingdom (Holden, 2003), New Zealand (Waghorn and Stevens, 1996), and Australia (Santoro and Allard, 2005). Hagan and McGlynn (2004) found, in Northern Ireland, that 96% of student teachers in their study believed that the ability to address the question of diversity was an important dimension of a teacher's work, but that only 39% felt comfortable in diverse situations.

Lesar *et al.* (2006) report on Slovenian teachers' views on the Romanis and migrant children from former Yugoslavia. Teachers in their study seemed to assume that it is up to the child to adjust to the school system rather than vice versa, while the child's parents are required to prepare the child for the system as well as they can. These teachers did not see themselves as responsible either for the children's school results or their social inclusion. They were not searching for constructive solutions to help children overcome quite serious obstacles to knowledge acquisition. Teachers' views showed few signs of multicultural ideas and very little awareness of how important it is to develop

one's mother tongue and one's own culture. Lesar *et al.* (2006) also concluded that inclusive practices are not only nonexistent in teachers' minds, but also in their work.

One of the consequences of the monocultural experiences and the privileged racial and class status of many white college student teachers is their tendency to see themselves as noncultural and nonethnic beings who are colorblind (do not see or treat people of different color differently) and raceless. Research has indicated, however, that teachers who believe that they are colorblind and treat all students equally, actually privilege mainstream students (Schofield 2001).

Teacher Competence for Teaching Diverse Student Populations

After reviewing attitudes and knowledge of student teachers, we now turn to the teachers' competence to cater to the needs of a diverse student population. Most studies on teacher education candidates mention a lack of confidence in student teachers and even experienced teachers do not feel sufficiently competent in this respect (e.g., Clarke and Drudy, 2006; Holden, 2003). The often-mentioned barriers of student teachers toward a multicultural curriculum (e.g., van Hook 2002) could be a result of this lack of confidence in being equipped with the necessary skills.

Haberman (2004), based on his experiences in inner-city American primary and secondary schools, lists what characteristics of star teachers, in these schools, set them apart: their persistence, physical and emotional stamina, caring relationships with students, commitment to acknowledging and appreciating student effort, willingness to admit mistakes, focus on deep learning, commitment to inclusion, and organization skills. They also protect student learning, translate theory and research into practice, cope with the bureaucracy, create student ownership, engage parents and caregivers as partners in student learning, and support accountability for at-risk students. Undergirding these attributes is an ideology of being neither judgmental nor moralistic, not being easily shocked, recognizing their own weaknesses and compensating for it, viewing themselves as successful professionals rescuing students, and deriving energy and well-being from their interactions with students. These teachers combine attention toward children with attention toward content, recognize the imperative need of student success, and are learners themselves. These attributes predict the effectiveness and staying power of teachers serving diverse students in American low-income urban schools.

Many studies mention competencies teachers need for teaching diverse student populations. Humphrey *et al.* (2006), in a study in primary education in seven European countries, concluded that essential for responding to

diversity in the classroom are caring and inclusive attitudes, striving for inclusive values and solidarity in students, building networks with students and between students, and responsive teaching. Allard (2006) in Australia from a case study on one secondary math and physical education teacher concludes that relationships are critical: students who have experienced the trauma of being a refugee, or the bewilderment of being a migrant, or those whose first language differs from the mainstream, are deeply in need of teachers who will take the time to get to know them, appreciate their strengths, and find ways to instill a sense of hope and confidence through their relationships. Further, being able to critically assess the needs of diverse students – not as problems or as lacking in necessary skills, but as learners who might require different approaches to engage with new knowledge, means that new teachers need to have developed a wide repertoire of critical thinking and teaching skills to call upon.

With regard to promoting student learning, constructivist points of views led several researchers to claim that instruction should be organized so as to build on what students bring from home to school while stretching them beyond the familiar, and to stress the need to examine students' backgrounds. Another attribute very often mentioned, and that seems logically needed but has not been empirically corroborated, is a sense of student teacher's own identity (e.g., Banks, 1991; Zeichner *et al.*, 1998). Banks (2001) adds to this the importance of a balanced view of national and global identities.

Wubbels *et al.* (2006) reviewed literature on the interpersonal competence that teachers need for multicultural classes. They conclude that the following aspects of competence are found frequently:

- having high expectations of students, being interested in students perceptions, and being aware of own cognitions, and behavior;
- creating and maintaining a positive relationship and a safe environment through rewards, compliments, showing respect and confidence, and empathy and providing some freedom and responsibility for students; and
- promoting on-task behavior and creating and maintaining a productive, engaging, learning environment through clear structuring, strong leadership, setting, communicating, and enforcing rules, and probing for student problems and understanding.

They also conclude that many of these competencies are generic aspects of good teaching rather than being specific for multicultural classes. Considering the competencies mentioned earlier in this section, the conclusion of Wubbels *et al.* (2006) probably applies broadly to teacher competence for teaching diverse student populations.

Teacher Education Programs

Hollins and Guzman (2006) summarize results of evaluation studies on the preparation of teachers for diversity. They conclude that most universities in the United States have hardly begun to address issues of diversity. However, a few universities offer carefully crafted programs to prepare candidates to teach students from diverse populations. Studies show that when candidates deal with multicultural issues in the teacher education programs this does not always translate to changes in school practices once they leave these programs. After introducing commonly agreed-upon aims of teacher education for diverse student populations, we discuss several pedagogical approaches advocated.

Aims

In the literature, the aims of teacher education for diverse populations seem undisputed and these are consistent with the competencies mentioned in the previous section. By and large, aims that are often mentioned include (e.g., Hollins and Guzman, 2006; Zeichner *et al.*, 1998):

- reducing prejudice, that is, developing positive attitudes in candidates toward groups and individuals different from themselves;
- strengthening cultural sensitivity (including linguistic issues);
- strengthening multicultural competence including building relationships;
- promoting an attitude of openness to different backgrounds;
- equipping for pedagogy for equity and social justice, that is, developing and using curriculum materials and methods that support the achievement of students from diverse and minority groups;
- equipping for responsive teaching and adaptation to student backgrounds; and
- producing intercultural educational material.

It is also not disputed that these aims include a balanced mixture of knowledge, skills, and attitudes and it is considered important not just to focus on approaches and methodologies but also to establish how teachers' beliefs, attitudes, and dispositions are interwoven with their knowledge, skills, and behaviors in the classroom context.

Pedagogy

Several elements for pedagogical approaches in teacher education for diverse populations have been proposed. First, whatever is done, from a constructivist perspective and based on several empirical studies, it is required to take into account teacher candidates' prior beliefs upon

entry into teacher education programs. Prior beliefs are said to represent interpretive lenses through which student teachers attempt to focus, see, visualize, perceive, characterize, understand, and ultimately resolve their teaching concerns. We now list these approaches and provide data on its effectiveness when available.

Field experiences

Placing student teachers for student teaching in multicultural settings or settings different from the student teachers' background is an often-advocated approach (e.g., Zeichner *et al.*, 1998). It takes different forms depending on the student teachers' background: for some, getting acquainted with other cultures might imply going to a rural setting and for others, to an urban school. More extended field experiences can be created through community-based activities, intensive contacts with parents and pupils from other ethnic groups, and getting access to minority community resources. Hollins and Guzman (2006) conclude that there is some evidence for (short-time) positive effects, for example, on student teachers' beliefs. Combining these placements with community-based cross-cultural immersion experiences and having a structured reflection on experiences seem to be essential for effectiveness.

Critical self-reflection

As mentioned in the previous section, teachers need a clear sense of their own ethnic and cultural identities in order to be able to understand those of their students and their families. For teacher education, this implies offering opportunities to reflect on one's personal history and identity, and one's biases. Instruments used are, among others, writing autobiographies, family histories, and having discussions and confrontations with students from other backgrounds.

Analyses of diversity issues in society

Discourse on diversity issues in society can be analyzed with help of film, poetry, novels, scholarly literature, cases, discussions, role play, writing assignments, and e-mail exchanges. Focus of much of these activities is the reduction of prejudice and promoting awareness of diversity and inequality in society. Hollins and Guzman (2006), from studies on prejudice reduction, found more studies with positive than with no or negative effects; the latter, having in common, that they were all of a short time period or had an interrupted time interval.

Courses

A variety of specific courses are being offered in teacher education programs, for example, on diversity, on bilingual and multicultural education, and on equity pedagogy. Garmon (2004) reviewed empirical studies on the impact of diversity and multicultural courses on prospective teachers' attitudes toward, and beliefs about, different racial

groups. He concluded that the impact of such courses has been mixed. Some researchers have reported that student teachers' racial attitudes and beliefs have been changed in a positive direction by a course on diversity; however, others have reported little or no change in student teachers' attitudes and beliefs. Courses on equity pedagogy aim to equip student teachers for using pedagogies for equity and social justice. Hollins and Guzman (2006) report that generally the result of these courses is not impressive.

Modeling good practice

Providing teacher education in a way that caters to the needs of a diverse student teacher population, that is, showing good practice has been proposed as a powerful intervention. Such practice includes, among others, applying constructivist teaching approaches, being interested in student teachers' backgrounds and perceptions and taking these into account, using mixed student teacher groups, having high expectations of student teachers, creating and maintaining positive relationships and a safe environment, showing respect, confidence, and empathy. Most importantly, teacher educators should be aware of their own cognitions, values, prejudices, and behavior. In sum, the adage practice what you preach should be put into practice.

Methodological Remarks

Looking at the research methods used in the studies reviewed, we must conclude that several methodological limitations hinder general conclusions. Many studies use small samples, outcomes measures are not well developed (often only self-reported outcome data are used), there are few longitudinal studies, whereas there are many short-term and small-scale studies that have little general application, no random samples are used, no (randomized) controlled experiments are applied, and too little information on contexts is provided.

Conclusion and Prospects

The conclusion of Hollins and Guzman (2006) mentioned in the introduction still seems to hold: the student body in teacher education is not a reflection of the student body in schools. The plea for a diverse teaching force, however, is rather a political statement than a claim justified by empirical evidence for the usefulness of a diverse teaching force for improving student learning.

Further, student teachers are not well enough prepared for teaching in multicultural classrooms. No overwhelming success of the advocated pedagogic strategies in teacher education has been shown. Results of studies show mixed results at best. Although some studies suggest

a positive impact of teacher preparation approaches, the findings about preparing teachers for diversity are generally inconsistent and inconclusive. This state of affairs could originate from the interaction between program and student teacher characteristics. Effects may not only depend on program content and pedagogy, but also on types of student teachers participating and characteristics of schools in which they are placed for student teaching practice. For every student teacher type, different interventions might be needed. It is well known that student teachers' beliefs and attitudes serve as filters for subsequent learning. Garmon (2004) mentions a study that showed that student teachers with strong negative biases and stereotypes about diverse groups were less likely to develop beliefs and practices helpful for multicultural sensitivity and responsiveness. Garmon (2004) lists six key factors in student teachers for success in changing their attitudes on diversity: their openness, self-awareness/self-reflectiveness, commitment to social justice, intercultural, educational experiences, and experiences in their support group.

Just elaborating aims or pedagogies of teacher education probably will not be sufficient to strengthen the effects of teacher education programs. Using teacher education programs as tools for improving education for students from different cultural groups needs an institutional approach, including such elements as a clear institutional mission and policies reflecting the values of diversity, applying multicultural criteria for selection of entrants, personnel policies, and an entirely multicultural program content and pedagogy (see Zeichner *et al.*, 1998).

Social and Cultural Influences on Teacher Education

M Ben-Peretz, University of Haifa, Haifa, Israel

R Lotan, Stanford University, Stanford, CA, USA

Introduction

From admission requirements to granting certification and professional licensures and in-service professional development, teacher education is a complex and multi-dimensional process (Wang *et al.*, 2003). Local social and cultural elements, and global policies and economic fluctuations influence and shape the various stages of this process. To describe the relative contributions of these elements to pre-service teacher education programs, the article is organized as follows: program entry requirements and selectivity, description and analysis of some of the major components of teacher education programs, exit requirements, and the attractiveness of teaching as a career in different societies. It ends with a clarification of the tensions between global and local aspects of teacher education.

Conceptual Framework

Globalization, with the integration of multinational economic systems, the spread of technology and electronic networks, and the dissemination of information and knowledge across previously impenetrable national borders and iron curtains, has led to various degrees and forms of institutional and organizational isomorphism. However, in this increasingly global environment, many individuals and groups strive toward the preservation of traditional cultures, the maintenance of locally established social norms, and the continuation of accepted communal arrangements. The inherent tension between globalization and regionalism plays out in different arenas of social and cultural life, including education.

A depiction of the precarious balance and often outright conflict between globalization, on the one hand, and the traditional cultural and social forces of local contexts, on the other, guides our discussion of cultural and social influences on teacher education programs. Increasingly in many countries, the aims, the structures, and the processes of teacher education programs, like much of higher education, reflect mimetic institutional arrangements and comparable curricular content. These are brought about by widespread demand for, and consistent efforts toward, the professionalization of teaching. Common wisdom and tentative empirical evidence assert that the quality of teaching is a key predictor of student learning. In turn,

quality of teaching depends on initial preparation, continued professional development, and the structural conditions of teachers' work.

Since elementary and secondary schooling are becoming mandatory in almost all nations, teachers' work and careers are also subject to public concern worldwide. In response, many governmental agencies and educational programs struggle to find ways to recruit qualified candidates (often in short supply), to provide incentives for improved performance, to build attractive career ladders, and to persuade qualified teachers to stay in remote and poor areas, or in other difficult-to-staff locations. These are some of the global concerns related to teacher education that impact this process in diverse contexts.

Yet, teacher education programs also mirror the local cultural and social order and historical developments as they respond to the way a society defines the purpose of education and consequently the role of the teacher. Programs are influenced by contextual needs and constraints as well as political realities and pressures. They reflect ingrained relationships between community values and educational institutions, and dominant beliefs about the school's role in educating children. The following brief overviews serve to illustrate how historically conditioned social and cultural factors have influenced teacher education in two countries: the United States and Chile.

In the United States, the role of schools has changed with concurrent changes in the economic, social, and cultural circumstances of the nation. During the common school era, teachers (i.e., any individuals with minimal level of literacy and education) were primarily expected to be moral guides whose task was to instill values and civic responsibility in their students. A teacher's comportment and appearance were just as important as her knowledge of content and pedagogy. At that time, the public expressed a strong preference for female teachers who were perceived as better nurturers by nature and therefore better suited for working with children.

As industrialization and urbanization moved more and more workers into factories and masses of immigrants arrived in the country, employers and families realized that different skills were needed. Business leaders expressed their dissatisfaction with the poor quality of workers entering the workforce and began applying pressure on national and local government. Then, as now, corporate leaders became concerned that if children were not well prepared for work, the United States would be at a serious

disadvantage when competing with European or Asian manufacturers. Thus, schools were asked to educate workers as they became places that sorted individuals into future occupations and societal ranks (Cuban, 2003; Labaree, 2004). Schools and thus education became sites where people attended for social mobility and economic opportunity. These developments meant that teachers were valued less for their morals and more for the academic knowledge and vocational skills they could impart.

Historical and political upheavals and major societal transformations in Chile had profound impact on the educational system and its institutions, on teaching as a profession, and thus on the preparation of teachers. Cox describes this in part as follows.

As an authoritarian regime with sweeping powers, Chile's military government (1973–1990) profoundly transformed the administrative and financial model applied to the school system. The military regime decentralized school administration, introduced financing instruments based on subsidized demand, eliminated teachers' status as public employees, and used legal instruments and market incentives to stimulate the creation and growth of state-funded private schools – a “big-bang,” “regime-changing” sort of reform. (Cox, 2006: 3)

With the establishment of three successive democratic governments, a new reform-oriented educational agenda was introduced with “policies focused on the *quality and equity* of the school system, *processes*, and *learning outputs*. It also provided a new national-level statute for teachers” (Cox, 2006, p. 3). From the early 1990s, major ideological differences among majority and opposition parties play out over fundamental topics such as the “regulation of the teaching profession, autonomy versus state regulation of the private sector in education (expressed historically in the Chilean tradition as the opposition between the principles of *libertad de enseñanza*, freedom to educate, versus, *derecho a la educación*, or the right to be educated), the appropriate role of state and market mechanisms, and sexual education” (Cox, 2006, p. 4). As a result, in-service and pre-service teacher education in Chile have captured the attention of all major governmental agencies as well as that of the public. Remarkable monetary and human resources are dedicated to a sweeping reform agenda designed to bring about fundamental changes in the organization of schools and in classroom instruction.

The central argument of this article contends that, presently, globalization is reflected in two major aspects of teacher education programs in many national systems: in the characteristics of the student population that teacher candidates are required to support and to serve, and in the rhetoric of the proclaimed goals of these programs. The process of the realization of the proclaimed goals is a tenuous and at times contentious negotiation

influenced by historically and politically established social and cultural factors.

The greater than ever mobility of populations within and across national boundaries has produced significantly changed student demographics worldwide, causing ethnically, racially, often socioeconomically and linguistically, and therefore academically, heterogeneous classrooms and schools. Long-standing global issues, such as poverty, environment, conflict, and social justice, constantly take on new forms, whether as “war on terror,” or “going green.” Holden and Hicks (2007) state that “(t)hese issues affect the society that students live in now and in the future” (p. 13) and that “(t)he world of the early 21st century is complex and fast changing. Local and national issues, events and trends can only be understood if set in the wider global context” (p. 23).

The impact of global influences on teacher education in Scotland, for example, is treated by Hartley (2002). Hartley argues that globalization has three competing influences on teacher education: “those derived from economic globalization; those derived from the requirements of a new knowledge economy; and third, those emanating from the culture of difference (and inequality) which now typifies many developed societies” (p. 251). According to Hartley, the issues of cultural differences and inequality have to be treated in the local context.

Increasingly, in many globally connected countries, established rhetoric regarding the outcomes of teacher education converges around the view that teacher preparation institutions and programs need to produce professionals who can effectively educate heterogeneous student populations in ever-changing contexts while upholding high academic standards and rigorous curricula. As a direct outcome of the quality of teaching, students are expected to become global citizens, who value diversity across and within national borders. They are expected to become productive contributors to the twenty-first-century knowledge economy, successfully mastering vast bodies of information as well as being fluid, critical, and creative thinkers. Today, “teachers need to view themselves as public intellectuals who combine conception and implementation, thinking and practice, with a political project grounded in the struggle for a culture of liberation and justice” (Niemi, 2000: 16).

Entry Requirements and Standards

Globally, post-secondary education has been assuming an increased role in the preparation of teachers. Thus, a 4-year bachelor's or undergraduate degree is typically the standard entry requirement for most systems. In the United States, all teachers are required to hold a bachelor's degree. A 5-year program for both elementary

and secondary teachers is the standard in Thailand (Ingersoll, 2007) and Chile (Cox, 2004), among many other countries. Since 1971, all teacher education in Finland takes place in universities where programs last 4–5 years leading to an MA degree. Completion of these programs is considered the basic qualification for both elementary and secondary teachers in Finland, in order “to unify elementary and secondary school teacher education and to develop an academically high standard education. It was also necessary to answer the needs of a new comprehensive school system” (Niemi, 2000, p. 1).

Other systems, mainly in developing countries, vary both within and across the level and years of education required for teaching at the elementary or at the secondary level. In China and Singapore, the education required of elementary teachers is lower than that of secondary teachers, although in both these systems there is movement to bring elementary teachers on par with secondary teachers. For instance, in China a high school diploma is the minimum level necessary to enter elementary teaching, while upper secondary teachers must have a 4-year college degree. In Singapore, as in Hong Kong, an elementary-level teacher can gain entry with the equivalent of a 2-year sublevel or associate level, while at the secondary level, Singapore requires teachers to complete a 5-year program that includes a bachelor’s degree plus a year of further coursework (Ingersoll, 2007). Local cultural conditions may also determine the length of study required for a teaching certificate. For example, in Israel’s ultra-orthodox community, 2 years of study are sufficient for gaining a teaching certificate, compared to 3 or 4 years for other student teachers who are required to earn at least a BA or BEd. Teachers who do not have these qualifications are prevented from teaching in the secular school system. This is one of the ways in which the ultra-orthodox community upholds social and cultural boundaries closing itself off from mainstream Israeli society.

The mandate to higher education to contribute to and ultimately take responsibility for the preparation of the teaching force reflects progressive societal aspirations and demands for the professionalization of teaching and its elevation to parallel the preparation for the practice of law, medicine, or engineering. This relatively new development reflects a global tendency related to teacher education, as teachers used to lack university degrees in most countries.

The differences between teachers’ entry requirements for elementary and high schools may be related to local factors. In a vast country like China, requirements might be less stringent for elementary teachers because of the very high numbers of children attending elementary schools or lack of access to higher education institutions in geographically remote areas. The fact that Singapore, a small country, also requires less years of university studies in order to teach at the elementary level may be due to

how Singapore views the educational needs of very young children.

In the US, the requirements to become an elementary or secondary level teacher have never been considered especially rigorous. Those entering teaching in the US tend to be in the average to low range academically compared with other college graduates. To facilitate entry, the United States early in the last century created large numbers of low-cost, dispersed, and noncompetitive teacher-training institutions and colleges.

In Singapore and Korea, as in many other Asian countries, teacher-education students are of high academic achievement. These differences may be due to both social and cultural factors and are related to the status of teachers and teaching in the different contexts.

Structural Organization of Teacher Education Programs

Within national systems, there is variability in the sequencing and organization of professional preparation programs. In some programs, educational and professional preparations occur concurrently within a bachelor degree program. In other programs the degree is completed first, with subsequent professional preparation and certification. In the United States, the latter is often called a “fifth-year program” – a post-baccalaureate 1-year teacher preparation program leading to a teaching certificate and sometimes, a master’s degree. Several systems, including in the United States, also have alternative pathways into teaching. In these cases, candidates are not required to have completed professional preparation prior to employment and uncertified teachers can begin teaching before or during their preparation and training. Local shortages of teachers are one cause for such alternative routes into the profession; uncertainty concerning the added value of existing programs of teacher education might be another.

In England, recent changes in teacher education reflect the strong impact of society on the educational process

(The) changing view of education is clearly reflected in the changing name of the government department responsible: in 1992 the DES (Department of Education and Science) became the DFE (Department for Education); in 1995 that was transmitted into the DfEE (Department for Education and Skills). In these movements there is a significant shift, ideologically, from an intrinsic valuing of education as a good in itself to the extrinsic and instrument role it is now seen as playing. Its link, from 1995, with employment has inevitably meant a tighter focus on the training and skills essential for the world of work. (Halstead, 2003: 69).

The Curriculum of Teacher Education Programs

The curriculum of many teacher education programs includes well-established strands: method courses (that often assume mastery of subject matter content by the candidates), educational psychology that includes components of learning theory and child and adolescent development, philosophy of educational thought, history of educational systems and institutions, and sociology of education, evaluation, and policy studies. A separate strand deals with the clinical experiences of candidates in the field. Increasingly, however, teacher education courses aim at helping prospective teachers learn about local social and cultural conditions that impact students' learning and therefore need to be taken into account in teaching. An analysis of six teacher education programs in the USA and four in Israel found that in addition to obtaining a strong theoretical framework that incorporates knowledge of subject matter, educational philosophy, sociology, pedagogy, method courses and practicum, students of these programs are also introduced to the conditions in today's urban education with its diversity and dynamic change (Ben-Peretz and Landler-Pardo, 2007). For example, at Mills College in Oakland, California and at the University of Haifa in Israel (both cities with highly diverse populations), there is a strong emphasis on preparing teachers to understand the implications of social, cultural, and economic diversity and to teach toward equity. Courses, such as "Building structures for equity, excellence, and access," and dealing with the question of "how can we teach each child well in a racist society?" are being offered at Mills College. At the University of Haifa, awareness of the challenges of the rapidly changing conditions of modern societies is expressed in topics such as the "Multicultural curriculum" or "Acclimation problems." Other examples of courses dealing with the difficulties and challenges within teaching are: "Teaching linguistics and cultural minority students" at the University of California in Berkeley, California, "Principles of teaching exceptional individuals," at the University of Los Angeles, California, "Elements of diversity: English language learners" at Harvard University, Massachusetts, and "Teaching heterogeneous classes: adolescence – a challenge for the teacher" or "Management and discipline in heterogeneous classes" both at the Hebrew University, in Jerusalem, Israel. As a reflection of the program's mission and in response to state and national standards for teacher education programs, the Stanford Teacher Education Program, at Stanford University, in California offers courses entitled: "Teaching and learning in heterogeneous classrooms," "Language policies and practices," and "Supporting students with special needs." Syllabi of

some of these courses reveal that the local cultural and social conditions of children's and adolescents' lives are considered important factors in their academic development.

In England, as in South Africa, after apartheid, teacher education attempts to fulfill a role in relation to education for democratic citizenship (Harber and Serf, 2006). Several venues may lead to that goal. Student teachers may be provided with experiences of operating democratically in their courses. Harber and Serf (2006) claim that students in initial training "need to engage with key forms of inequality that challenge the development of a more democratic society – racism, sexism, homophobia, disability discrimination, etc" (p. 991). Moletsane (1998) found that in South Africa "racial and cultural tolerance was promoted on the course and teaching and learning methods encouraged and affirmed a plurality of opinions from the diverse group of students in the class. Classes provided an opportunity for self-expression and open debate by students that helped them to find their own voice in a safe and flexible classroom environment" (in Harber and Serf, 2006, p. 992).

In Germany a conference of ministers of education of the different German states published a special paper calling for an intercultural emphasis in teacher education. In order to prepare future teachers for cultural diversity, the paper recommends that issues of diversity be treated in all courses. These recommendations reflect the impact of global concerns in a local context (Beschluss der Kultusministerkonferenz, Germany, 1996).

At times, preparing student teachers for the social and cultural context of schools reflects elements of local religion, for instance, in the University of Madrid in Spain. At Acatlan University in Mexico, a number of courses in the teacher education program focus on social and cultural issues. Such is a course on problems in education in Mexico in relation to the economic, social, political, and cultural contexts, which is entitled "Problemas actuales de la educacion en Mexico."

A further example of the impact of social and cultural factors on teacher education programs concerns the power of Marxist ideology and implementation problems to inhibit the spread of a "new education movement" in the teacher education programs in the Soviet Union. The new education movement was "part of more general education reformism sweeping Europe and America in the first two decades of the twentieth century" (Partlett, 2007, p. 455). The leader of this movement in the first years of the communist regime in the Soviet Union was Shatskii, who relied on Western scholars like Dewey. Although Shatskii tried to integrate communist ideology with this movement, he was later marginalized within the Soviet educational system. When the Communist party asserted control over education in 1932, many of the new ideas

were rejected. This case reflects the tension between global ideas and local contexts.

Attractiveness of Careers

Compared with other professions, teaching has been considered a less attractive and less desirable line of work in the United States. In surveys of occupational prestige, teachers rank in the middle range. As other historically female-dominated occupations, teaching tends to have lower status and lower pay.

Many Asian nations, however, have a tradition of respect for teachers (Ingersoll, 2007). Relatively high salaries, comprehensive training, and full pay while undergoing training all make teaching an attractive career option in Singapore. In Hong Kong, teaching is ranked relatively high in occupational stature by senior-secondary school students – above accountants, engineers, doctors, and artists. Still, the quality of new entrants to teaching has been a matter of concern in Hong Kong.

In China too, teachers rank relatively high in surveys of occupational prestige. Yet, because teachers' salaries are low in China relative to other occupations, and especially low in rural areas, the occupation is not as attractive as some others (Gang and Meilu, 2007). In Korea, teaching is a relatively sought-after occupation because of its job security and its high social-status standing (Kim, 2007). The rate of teacher turnover is very low because most teachers remain in teaching until the point of retirement. In Japan, teaching profession is an attractive option for college students, is relatively well paid, enjoys respect, job autonomy, and a collaborative community with colleagues and affords chances to grow and develop as educators. Not surprisingly, turnover and quitting rates have traditionally been low (Fujita and Dawson, 2007). Thus, cultural and social differences in the career attractiveness of teaching are significantly related to entry conditions and teacher turnover.

Certification and Licensing

Most educational systems require candidates to obtain a government-issued certificate of license signifying that a candidate has completed required professional preparation and training. In most systems, professional preparation also includes a period of varying length in the field through supervised clinical practice or student teaching. Many systems require some kind of performance exam or paper-and-pencil test for prospective teachers. In some systems, these tests are administered as part of a teacher-preparation program; in others,

they are administered by the school upon employment or by the state. These commonalities reflect the global impact on the increased trend toward the professionalization of teaching.

Conclusion: The Tension between Global Concerns and Local Beliefs

Our analysis has shown the existence of several salient commonalities among teacher education programs in different countries, societies, and cultures. These commonalities include: the growing demand for academic degrees for teachers; the tendency to expand years of preparation; and the emphasis on professional competencies to be fostered in special institutions as well as through the practicum – the growing tendency to determine standards for qualifications of teachers as well as for the requirements to gain a teaching certificate. These commonalities may be interpreted as reflecting the effect of globalization, with its emphasis on the role of teachers in preparing citizens for the future workforce, and for living in a global world. Another factor leading to these common features is the growing view of teaching as one of the professions having a common core knowledge base, and modes of instruction. On the other hand, it seems that teacher education programs are also adapted to local contexts, be they political, economic, or cultural. Thus, teacher education in England reflects the pressure of greater central control, while teacher education in Spain, Mexico, or ultra-orthodox communities in Israel adapts itself to the religious context. It is important to note, however, that even global ideas and frameworks are not passively employed in local contexts. An editorial of *Teaching and Teacher Education* (vol. 15, 1999) deals specifically with global and local dimensions of reforms in teacher education (Elliott, 1999). This special edition brings accounts from developing countries in Africa, South America, and the Far East. Elliott argues that:

Teacher education reforms are not like machines which, providing operators follow instructions, can be made to work in exactly the same way regardless of context. Of course, the imperatives which stem from a world of markets will encourage the borrowing of concepts and models of teaching and teacher development, from those countries who appear to succeed in meeting such imperatives. Ideas are now globally mobilized and their trajectory tends to be from the north and the west to the south and the east. In the process they may be resisted, critiqued or reinterpreted/reconstructed as a basis for conceptualizing reforms in particular local/national contexts. (Elliott, 1999: 134).

The Townsend and Bates (2007) *Handbook of Teacher Education* devotes a whole section to “Globalization and Diversity: Promise or Problem?”. The section includes several chapters that focus on learning in a globalized world and the interplay between culture and teachers’ professional development. Certainly, the diversity of most communities in many parts of the world has made teaching and educating teachers much more difficult than it has ever before. Clearly, it is difficult to “establish a strong all-inclusive education system, based on the best ideas from other parts of the world but still maintaining the cultural integrity of the people.” (p. 8)

There is a growing awareness in developing countries that though it is important to introduce new ideas into teaching and teacher education programs, these have to be integrated with local beliefs and traditions. The fear that converging customs, norms, and ideas, will finally overrun diversity, and will serve to create a homogenous world society has brought about the formation of societies devoted to the preservation of local cultures, such as “Cultural Education and Cultural Sustainability: An International Network of Diaspora, Indigenous and Minority Education.” Moreover, it is not self-evident that the flow of educational ideas is necessarily only from west to east and from north to south. It may well be that in the future innovations in education will arise in diverse cultural contexts, and will spread from these in other countries like the strategy of “lesson study” from Japan to the United States. The potential tensions between global and local educational orientations may also yield new insights into global ideas implemented in local contexts.

The Role of Governance in Teacher Education

G E Karlsen, South Trondelag University College, Trondheim, Norway

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The phenomenon of governance and government is normally linked to the execution of power with a legal and legitimate basis. In social science literature, government is the traditional term for steering and control. Typically, the government refers to the state, understood as the political and administrative system at the national level and in particular the executive function of the state (Ball, 1990; Dale, 1989; Kuhlne *et al.*, 1999).

The Foucauldian concept of governmentality (Foucault, 2003) has been a guiding concept for recent education policy research with focus on mentalities and rationality of governing of the state and changes over time. Governance is a more versatile term in social sciences and research corresponding to the postmodern form of economics and political actors. In particular, there is a great deal of research about European governance related to the European Union (EU; Olsen, 2002; Kohler-Koch, 2005). In the EU's white paper *European Governance*, the concept of governance is defined as "rules, processes and behaviour that affect the way in which powers are exercised." Openness, participation, accountability, effectiveness, and coherence are considered as principles that should underpin what is called "good governance" (European Commission, 2001: 11, 17).

In this article, governance is used in a neutral meaning. Governance includes macro-actors and processes and relationships to and between states, regional, and local actors and markets in education policy (Lawn and Lingard, 2002). The governance in relation to teacher education also includes informal steering from nongovernmental bodies in the civil society and influence from the institutional culture in teacher education institutions (Lindblad and Popkewitz, 2001).

Teacher education has a high degree of complexity and a great variety in time length, content, organization, and the degree of specialization. In fact, there are more structures than countries if we consider, for instance, Europe (Eurydice, 2002; Garm and Karlsen, 2004). If teacher education is considered to be one educational system – as a unit distinct from others – with common, distinctive traits, it is a nonexistent phenomenon in the real world. What do exist, however, are the continuous political and professional discourses regarding knowledge, attitudes, behaviors, and skills necessary for the teacher profession and the institutions for teacher education.

Historically, the structure, content, and ideology of teacher education institutions mirror the present political

conditions. The governance of teacher education has normally been a national issue. National teacher education and the compulsory school system are normally interlinked (Karlsen and Kvalbein, 2003). They have been and still are key institutions for socialization into the modern state. The impressive research report of the AERA Panel on Research and Teacher Education (Cochran-Smith and Zeichner, 2005) summarize: "It is now widely agreed that teachers are among the most, if not the most, significant factors in children's learning and the linchpins in educational reforms of all kinds." Therefore, the importance of teacher education is obvious in many ways.

The education system and, in particular, teacher education has historically been closely connected with nation building (Vaage, 2001). Education is a part of rights and obligations in a complex relationship between the state and the individual citizen. This is still the normal situation; however, the traditional role of national governance is being challenged by new procedures and new global actors. The territorial representative parliamentary democracy, when limited to national state agents with agreements about rules within the structure of the national state, is being challenged by globalization. Bauman (1998) claims that this threatens to make national democracy irrelevant and powerless. With this background in mind, a simple model will function as an analytical framework for the further discussion of the role of governance in teacher education.

An Analytical Model – Levels and Systems

Although governance of teacher education primarily has a national mission, teacher education and its reforms are embedded in an increasingly global context. Therefore, the role of governance in teacher education has to be analyzed as an interactive process between supranational, national, and organizational (local) levels.

The model is a simplification of the complexity of educational governance. Teacher education includes both the professional education system at the national level and institutions at the local level. The model shows interrelations of main actors and forces affecting governance of teacher education at and within the national level and the globalization pressure from actors at the supranational level (Figure 1).

Traditionally, the nation-state has been associated with a specific geographical area, political entity, and, in addition, a cultural and ethnical unit. Political science

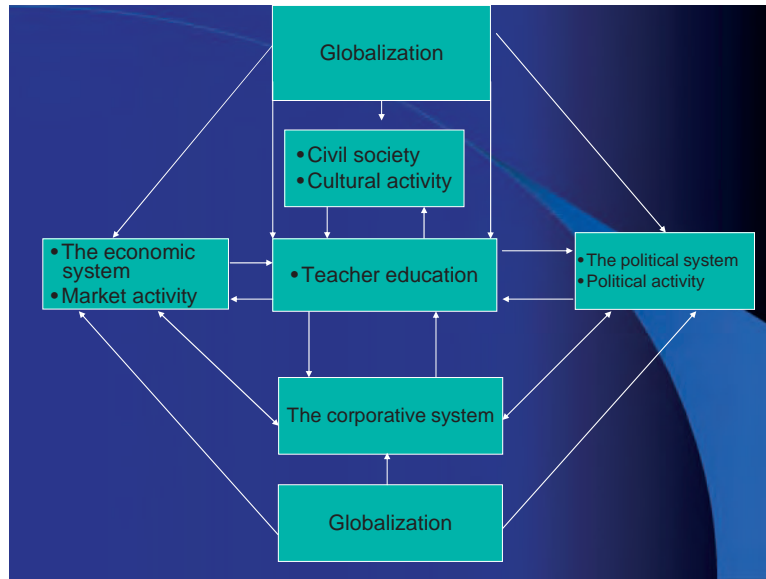

Figure 1 Governance of teacher education—actors and forces.

normally emphasizes the existence of a political and administrative system having internal and external sovereignty over a definite territory (Jones *et al.*, 2004). The central base for the national state is the legal framework accompanied by a set of related political, judicial, and administrative state institutions such as the parliament, state bureaucracy, courts, and police. The school system, and in particular the teacher education, is a key institution in the state.

The market, understood as rational decision making, is basically a social arrangement or a marketplace that allows buyers and sellers to discover information and carry out voluntary exchange of goods and services. Market activity within the economic system is primarily the arena of capital connected to economic transactions. The relation between the political and the civil system and the market will vary, but the move toward the market economy has been obvious (Lavigne, 1995). Although the free-market economy is prospering, the mixed economy is still common in most of the countries, with degrees of government influence in combination of state-owned and private enterprises.

The concept of civil society has had a renaissance both in political and comparative theory. Civil society normally refers to the arena of collective company and actions linked to shared interests, purposes, and values (Bron, 2001). The boundaries between state, civil society, and market are often complex and blurred. The civil society is composed of the totality of voluntary civic and social organizations and institutions that to a high degree form the basis of a functioning society (Hann and Dunn, 2006). The civil society provides rights connected to democracy, political consultation, and the development of life, within culture and religion, in or outside

institutional and organizational frames. The civil society can be understood as the glue of society. In this light, the formation of state and citizenship provides a framework for civil rights.

The growth of the organizational society, particularly in the nineteenth century, contributed to the development of new cooperative structures, creating new channels for influence. Labor unions promoted right to collective bargaining and tariff agreement between their members and the employers. Within the Nordic states system, for instance, negotiations between representatives of unions and employers' organizations gradually became a formalized decision-making channel in addition and, to some extent, as an alternative to the representative democracy (Dølvik and Engelstad, 2003). The political scientist Stein Rokkan (1987) has called this regime of governance "corporate pluralism" (p. 61). In relation to education, this became important because teachers created strong unions. The unions provided corporative power connected to participation in public committees, elected groups, public hearings, and, not the least, contracts about working conditions negotiated between the state and the unions. At the European level, the European Trade Union Confederation (ETUCE) is an influential teacher union with a total of 60 million members. The ETUCE is the only representative cross-sectoral trade union organization at a European level recognized by the EU (ETUCE, 2006).

The overall political neoliberal governance turn in the last 20 years has put both the political system and the civil society under pressure. New global ideologies, new strategies and new macro-actors are brought into force. Therefore, the governance in teacher education must be analyzed in this context starting with globalization and the driving forces behind it.

Globalization and Global Forces

Globalization is normally used as an umbrella term which refers to a complexity of economic, technological, cultural, social, and political interrelationships. The notion is frequently used both as a slogan in public debate and in scientific literature (Spybey, 1996; Held and McGrew, 2000). The term globalization term can be seen as a perception about a pluralistic, worldwide postmodern period after industrialism (Giddens, 1990). Although globalization is not completely a new phenomenon, it has become the dominating contemporary diagnosis in the last twentieth and the early twenty-first centuries.

There is considerable agreement among researchers that the economy is a driving force (Coulby and Zambeta, 2005). Globalization may primarily refer to a process through which national economies became increasingly open to supranational influence (Lundahl, 2005). At the core of globalization lays the new market economy with its market capitalism and worldwide economic activity. Globalization is further interpreted as a consequence of modern science and new technology, particularly in connection with information technology.

Globalization has led to a flood of influences economically, environmentally, politically, socially, and culturally, which are almost impossible to protect oneself against (Mishra, 1999; Martin and Schumann, 1996). The main hypothesis is that we are forced toward standardization not only economically, but also socially and culturally. A UNESCO report, led by the former EU President Jacques Delors, proclaimed a development for this century “towards a globalization of human activity” (Delors, 1996: 41).

Globalization is a phenomenon with consequences and influences – good and bad – also for teacher education. In particular, the themes of central control, the role of the state and teacher education as a cultural reproductive institution, create dilemmas and prospects (Thomas, 2002). The discussion surrounding globalization has essentially been linked to whether this is a desired or undesired development. On the one hand, it is claimed that globalization is necessary, inevitable, and the only possible way to get a larger degree of political and economic stability and predictability (Giddens, 2000). On the other hand, globalization is seen as a serious threat toward established order and common values. The development of antiglobalization forces has grown (Hill, 2006). The political left wing is the most obvious in alliance with environmentalists and labor unions, included teachers unions. The Education International (EI) is the world's largest, and probably the most important, teacher union with its 345 member organizations in 165 countries and territories. The union is critical of the impact of globalization on education and perceives the neoliberal globalization as a significant risk affecting public education, restricting the available policy space for national governments (Hill, 2006).

The acronym TINA (there is no alternative) refers to the slogan attributed to the former prime minister of Britain, Margaret Thatcher, who argued that globalization with its free trade and global economy was the only way for modern states. Others have argued that the global market economy, which is adopted in most of the states worldwide, is a neoliberal political agenda rather than an inevitable choice (Negreponi-Delivanis, 2001). Therefore, we need to examine this agenda in a governance perspective.

A Neoliberal Ideology and New Governance Strategy

The overall neoliberal turn can be perceived as a renewed ideology and a new governance strategy also for governance in teacher education. It appeared on the horizon in the 1980s and 1990s with its belief in the market as an agent for economic growth. The perception was that public sector, including education, was unproductive and unwilling to change. The new idea was that societies guided by the market would stimulate production, revitalize the civic society, and even strengthen democracy by individual choices and consumer power (OECD, 2000).

The governance turn was ideologically rooted in liberalization and, to some degree, conservatism as political ideologies with focus on less government regulations and greater participation of private actors (Beck, 2005). New public management (NPM) became the broad term used to describe the wave of public sector reforms. The main hypothesis was that institutions guided by market rules would reduce costs, be more efficient, and even lead to higher quality, without having negative side effects (Pollitt and Bouckaert, 2000). NPM, with its market orientation and its blithe acceptance of competition as a driving force, put public sector under pressure.

NPM emphasized individualism and freedom of choice. It also assumed that decentralization, deregulation, and restructuring would improve both utilization of resources and higher quality of service. In this perspective, education, and also teacher education, was perceived as a service sector among others. New governance reforms were needed. The Management by Objectives (MbO) model, known from legendary Peter F. Drucker (1964, 1977), and originally developed as a strategy for more cost-efficient production and leadership in industry and business, became a suitable answer also for governance of public education, including teacher education.

Decentralized Centralism – A New Dynamic in Educational Governance

The NPM ideology and the MbO governance strategy involved a new governance dynamic and changed use of

political tools. The relation between the market and the political system changed in favor of the market, however, at the same time, we can observe variation. States do not always passively adapt to the external, international constraints (Sassen, 1998). The earlier works have used the term decentralized centralism trying to catch the governance dynamic between centralization and decentralization processes (Karlsen, 2000).

As a governance strategy, the MbO combined centralization and decentralization in dynamic interplay at the same time. Setting central goals and standards for outcomes were tasks for the macro-level and therefore assigned to centralization, while choice of tools and the responsibility for implementation were duties at the microlevel and seen as decentralization. The MbO strategy was goal and outcome oriented, in which decentralization was fitted into a centralized strategy. The model gave local freedom and probably more acceptance to work under harder pressure. In fact, this was management by results, and the rise of what Fägerlind and Strömquist (2004) have called the evaluative state.

In teacher education, the trend to decentralize responsibility and deregulate state schooling was tied to a rhetoric of enhancing teacher autonomy and professionalism and stressed the importance of the teachers' expert knowledge (Karlsen and Kvalbein, 2003). An opposite centralized trend was the state's intensification of instruments for output control. Thus, increased output control might instead restrict teacher autonomy and contribute to deprofessionalization of teachers' work (Helgøy and Homme, 2004). Delandshere and Arens (2001) interpret new teacher education reforms in the US as decreasing teachers' degree of freedom to shape their own role as teachers. Teachers and teacher educators are perceived more as the object of policy rather than professional participants. However, good teacher education and good teachers have been politically seen as the backbone in any national education system (OECD, 2005). From the state perspective, teacher education is under double governance at the same time. Teacher education is perceived as a governance instrument for desirable educational change in the compulsory school system (Garm and Karlsen, 2004). At the same time, the authorities can use policy tools as governmental instruments for regulation of teacher education.

Changes in Use of Policy Tools

The globalization process and the new neoliberal governance strategy have affected the choice of policy tools and the balance between the state, market, and civil society. The frameworks of legislation and regulation are still important state authority tools, but they are weakened. National laws and regulations are adapted into an increasing supranational legislation (Shapiro and Sweet, 2002).

One example is the General Agreement on Trade in Services (GATS) agreement from 1995 inside the World Trade Organization (WTO), which created an extended multilateral trading merchandise system to services, inclusive of education (Jawara and Kwa, 2003). Knowledge has more and more emerged as a major trading commodity in the globalized economy (Coulby, 2005).

The economy is another tool and of high importance at the state level and is closely connected to the framing of funding systems. The MbO strategy with its focus on measurable outcomes has contributed to a change in allocation systems of state funding from earmarking to lump-sum systems. In public finance, earmarking is a specification of public expenditure, while lump sum is a total amount and one-time payment. Together with other resources, the economy is used as an incentive tool based on the assumption that institutional and individual behavior is motivated by maximizing utility (Eurydice, 1999).

School programs and curriculum as a state governance tool seem to be less important. Normally, the local teacher institution with the staff will have the obligation to elaborate local programs and curricula within a central framework (Klafki, 1999). However, the professional freedom is under pressure from the needs of the knowledge economy giving priority to basic skills and subject knowledge, particularly in science and technology.

While the importance of the above-mentioned tools all seem weakened in teacher education, the importance of evaluation and control have increased more or less worldwide (Wilson and Youngs, 2006). Agencies for quality assurance at the national level through evaluation, accreditation, and recognition have been established. Politically controversial standardized tests for pupils such as the Organization for Economic Cooperation and Development (OECD)-initiated Programme for International Student Assessment (PISA) and Trends in International Mathematics and Science Study (TIMSS) also effect teacher education even more indirectly. National and international agents for quality assurance, accreditation, and high standards are playing important roles within the new liberal turn serving powerful new actors.

New Supranational Actors – The New Institutionalism

The traditional studies of governance in political science have been based upon study of institutions, actors, and procedure, within the national state. However, over the last 20 years, studies of the new institutionalism have flourished (Rhodes, 1995; March and Olsen, 2005). New actors are playing new roles. The new institutionalism has roots tracing back to the early period after the Second World War. Supranational institutions such as UN (United Nations), WB (World Bank), WTO, and OECD

(Organisation for Economic Cooperation and Development) became increasingly involved in educational policy. In addition, regional institutions such as the EU in Europe, NAFTA (The North American Free Trade Area) in North America, and APEC (Asia–Pacific Economic Cooperation) in Southeast Asia are increasingly active in shaping education policy (Karlsen, 2002, 2006). Although the main agenda for these intergovernmental institutions was to develop policy for economic progress, they gradually included education in their policy actions. Institutions such as the WTO, WB, and OECD are mainly dominated and controlled by the world's richest countries. These institutions are backed by strong capital forces which have considerable influence, for instance, lobbying toward the political system. Molnar (2005) argues that education now is being swept in by global forces and actors and reoriented toward an integrated relationship with commercial interests.

A common ideological basis for the new international actors was, and is, liberalization emphasizing the importance of free trade and free capital movements. While classical liberalization, with roots tracing back to Adam Smith and John Stuart Mill as influential liberal thinkers, emphasized the value of human rationality and the protection of civil liberties, the new liberalism is closely connected to liberal market theory of economics. This new economic liberalism has occurred as a guarantee for efficiency and higher quality at the same time and implied a shift away from education as a universal citizenship rights to education as tradable commodities for the individual consumer. Alexiadou (2005) claims that the economic function of education has prioritized the creating of consumers and workers in the competitive capitalist economies, while the cultural and social role of education has been reduced.

What is relatively obvious is that concepts from the economic realm are being uncritically applied also to the discourse of teacher education. When knowledge and socialization are referred to as products and educational services, when students are users and the school has to adapt to the market and be competitive, it is not only a question of words, but an expression of thinking. When students are transformed into human capital and are perceived as increased advantage in a global competition economy, it affects educational values and reasoning of governance in a fundamental manner (Hill, 2006). The result is likely to be a more instrumental teacher education with diminished cultural and social relevance and weaker ties to the civil society.

The new global economy needs students with basic skills and high academic standards in central subjects, but at the same time flexible and innovative, motivated for quick and lifelong learning, and able to adapt to changes and the use of new technology (Rikowski, 2002). There is already a “global auction for jobs” (Brown *et al.*, 2007, p. 4), where the main

bidders are today's advanced economies. Greater workforce mobility has led to several governance actions for harmonization and a more standardized teacher education.

A More Standardized Teacher Education

One of the most influential policy actions is known as the Bologna process. The Bologna declaration was signed in 1999 by the ministers of education from 29 countries (Bologna declaration, 1999). The main objectives were the idea of establishing a European area of higher education by 2010, thus making academic degrees and quality assurance more comparable and compatible throughout Europe.

Although the Bologna process is not a formal EU process and now consists of 45 member-countries, the process can be perceived as a national implementation of central elements in EU's policy (Karlsen, 2005). The Bologna process is closely connected to the strategic goal in the EU's Lisbon strategy from 2000: making the EU the “the most competitive and dynamic knowledge-based economy in the world” (European Commission, 2002, p. 7). The aim of creating the European education area corresponds to the successful action of the internal market in the late 1980s and early 1990s. Higher education and knowledge are looked upon and treated more like economic commodities.

The Bologna process is in line with the neoliberal way of governing by setting central goals and encouraging the national states to find tools for implementation and, therefore receive feedback through regular stocktaking (Bergen Communiqué, 2005). It can be basically seen as a governance strategy for standardization of educational systems (Fejes, 2005). The reasoning is that the standardizing of higher education will create transnational employability and mobility within a system with quality assurance. The Berlin Communiqué (2003) called for an overarching framework and led to the EQF (Framework for Qualifications of the European Higher Education Area) (Bologna Working Group, 2005). The EQF consist of eight reference levels relating to learners outcomes, to which the national state has to relate the national qualifications frameworks (European Commission, 2004).

National and international agents for quality assurance, accreditation, and high standards are playing an important role, but the dependence of the policymakers varies. As an example, National Council for Accreditation of Teacher Education (NCATE) is recognized by the US Department of Education as an accrediting institution, while National Board for Professional Teachers Standards (NBPTS) is an independent, nonprofit, and nongovernmental organization formed in 1987 to improve quality by developing professional standards. There is also an ongoing work in OECD to create surveys for teachers and principals called Teacher and Learning International Survey (TALIS). Data from different countries regarding

teachers' competences and standards as defined in the survey tend to have a standardizing effect. In addition, professional efforts may have an unintended effect toward standardization, such as the impressive work edited by Linda Darling-Hammond and John Bransford (2005) with the subtitle 'What teachers should learn and be able to do'.

The European Commission initiative and work for common principles for teacher competences and qualifications demonstrate the importance of governance in teacher education. Teachers are called key players in the implementation of educational reforms to make EU the highest performing knowledge-driven economy in the world by 2010. Teachers should be well qualified; a profession based on partnership; important in the lifelong learning context; and a mobile profession (European Commission, 2005: 2,3). The Lisbon strategy and its related work programs, such as the Common Principles for Teachers, are all implemented according to the open method of coordination (OMC). The OMC includes identifying common objectives, agreeing on benchmarks indicators, exchange of good practice, and peer review (Gornitzka, 2006). Alexiadou (2005) describes OMC as a "new governance tool in the sphere of education" suitable to deal with sensitive areas (p. 13). Teacher education, traditionally closely linked to national sovereignty and issues such as national culture, nation building, and national identity, is a sensitive area in this OMC process.

Concluding Remarks

Teacher education has been and still is highly controversial, criticized, and politicized (Cochran-Smith and Zeichner, 2006). Social problems in the society and standards in schools are, in the political debate, seen as being directly correlated to the assumed quality of teacher education. In contrast to other higher education institutions with tradition for autonomy and self-governing, teacher education institutions historically have been used as important tools for state government purposes. Although teacher education still has a low academic status in traditional meaning, it has become more important politically.

Historically, teacher education has played an important role in maintaining a national culture and the vitality in the civil society. Teacher education has been an important political instrument for building a democratic system at the national level. Both at the national and the institutional level, there is increased tension between individual/institutional freedom and institutional/national control. The tension between individual freedom and institutional control can be related to the accountability outcomes ideology and use of policy tools.

Through the close connection to the compulsory school system, teacher education still forms the basis for

all higher education. However, the market is playing a more visible role in governance in teacher education. Globalization forces, new global actors, and a neoliberal governance strategy emphasize teacher education more instrumentally as a key institution in the new global knowledge economy. Now more than ever, teacher education is seen as a vital component in economic competition and growth. The governance discourse about teacher education is less cultural and social and more market oriented. However, the last years have presaged signs of de-globalization and the return of a new nationalism (Bello, 2002). The national state has played and still plays a key role in the governance of teacher education, but more on the demands from the market.

Introduction

Action research by teachers is often justified by the argument that the reality of educational practice is complex, changeable, and cannot always be accurately predicted in advance by general academic knowledge. Teachers constantly have to face the question: What in the given circumstances is the best way to act, in order to achieve what is important at this moment? Moreover, teachers who want to change their practice have to deal with issues related to how they or their pupils, colleagues, and others want to organize their lives and their work and so they always touch upon normative and ethical issues. That is why solving a problem or changing a situation is not only linked to empirical evidence but also to normative criteria. In social science this argument led to a plea for interpretative research focused on *verstehen*, that is, meaning construction (Gadamar, 1976). Interpretative research includes research from an insiders' perspective (action research with or by teachers) in addition to research from an outsiders' perspective (academic research on teachers) (Cochran-Smith and Lytle, 1993).

Ideas about the insiders' and outsiders' perspectives in social research parallel a changed view on teachers' learning in schools and in teacher education programs. With regard to teacher education, authors seem to agree about the limitations of the traditional transfer model, because general academic knowledge cannot simply be transferred in the expectation that teachers can apply this knowledge as intended by researchers. Empirical research has shown that teachers hardly ever use the knowledge they had to acquire on their teacher education

courses in their own practice (Gore and Gitlin, 2004). Similar doubts are being expressed about large-scale school reforms, where the professional development of the teachers who ultimately have to deliver the education tends to be neglected. Although brief one-shot workshops and similar activities are often offered, research has shown that these activities are not very effective (Cordingley *et al.*, 2007). Alternative approaches are often proposed which allow teachers to learn in and from their own practice through self-directed, research-based activities. These activities are based on ideas of action research as a tool for professional development, which is the focus of this article.

Action Research as a Tool for Professional Development

A great deal has been written about research by teachers as a tool for professional development and this has produced a range of interpretations. An idea that is common to the various interpretations of action research is that research strategies of the social sciences can be used to change social practice. Elliott (1991), for instance, defined action research as "the study of a social situation with a view to improving the quality of action within it" (p. 69). Carr and Kemmis (1986/1997) gave a more elaborate definition: "Action research is a form of self-reflective inquiry undertaken by participants in social situations in order to improve the rationality and justice of their own social or educational practices, their understanding of these practices, and the situation in which the practices

are carried out” (p. 162). Action research can be carried out by individual teachers, by a group of teachers, or by teachers in collaboration with academic researchers. Five key features can be identified from the literature (Ponte, 2002; Somekh, 2006):

- Action research is carried out by teachers (or other practitioners in the school) themselves. They study questions that emerge from their day-to-day experiences in their own practice and the situation in which they are practicing. The questions are supposed to arise from an experienced gap between what is intended and what actually takes place.
- In action research, teachers engage in reflection and change based on information they have systematically gathered and analyzed themselves. Teachers not only collect and analyze data about their pupils – or others who are involved in the issue under study – but also about their own teaching and learning. As in other forms of interpretative research triangulation, thick descriptions, peer debriefing, and member checks are among the main validation strategies to be used.
- Action research is carried out through dialog and collaboration with colleagues and others within and outside the school. Those others may function as a source of information, as co-researchers, and/or as critical friends who help each other to reflect critically on the design, execution, and results of the action research.
- In action research, those who are involved in the situation that needs to be changed are seen as partners in the research. In teaching, pupils are often, if not always, part of the situation that needs to be changed, and the pupils' voice, therefore, is seen as an essential source of learning for the teachers.

- The results of action research are published and are open to criticism from the wider community.

Teachers usually work with a model, traditionally consisting of complicated spirals and cycles of consecutive steps, such as: the formulation of a general idea; exploration of the general idea; drawing up of a general plan; planning, implementation, monitoring, and evaluation of concrete actions for improvement; and writing up of a case study or report on the teachers' own action research. It has gradually become clear, however, that teachers often struggle with these complex plans (Ebbutt, 1985), and the importance of a strict sequence of steps is now played down. Kemmis and Wilkinson (1998, p. 21) asserted that action research is a “fluid, open and responsive” process. In modern handbooks on action research (see, for instance, Altrichter *et al.*, 1993; Burnaford *et al.*, 2001; Somekh, 2006), research models are increasingly seen as heuristic tools instead of fixed sets of steps.

Box 1 contains a description of a school-based action research project carried out by McLaughlin *et al.* (1996).

History of Action Research

Action research has a long tradition, both in education and in other fields. As early as the beginning of the last century, action-research initiatives in education represented various attempts to bridge the gap between theory (academic knowledge) and teachers' practice. Action research started in the US and later spread to Australia, England, and other countries. A common feature of these early attempts was that they aimed to use research strategies to initiate and realize social (i.e., educational) change. Four important

Box 1

In the period before we started on the project, team members were more often engaged in one-to-one counseling and guidance of pupils. We had the idea that if pupils were better able to put their problems into words, the school would be able to respond more effectively. We assumed that problems related to confidentiality would play a part here. In terms of action research, this gave us our general idea.

This general idea led us to form a group which included members of the school management team, teachers, and school governors. We discussed the problem and invited Colleen – as the external researcher – to help us develop our ideas further. She gave a presentation on what can be learned about our problem from the professional literature. In terms of action research, this can be seen as a form of exploration.

We decided to extend our exploration by gathering factual data. To gather evidence in support of our assumptions on confidentiality, Pam was asked to interview pupils to get their views. Colleen interviewed teachers and Meryl explored school development by keeping a logbook and analyzing relevant documents. The insights gained were presented to the team. Members of the team were given the opportunity to respond by completing questionnaires and taking part in a team discussion. We saw this as additional evidence in support of our assumptions.

We discussed the findings and decided what we wanted to do. In action research terms, we drew up a general plan. Training the team was the first concrete step. This training was systematically analyzed and discussed (in action research terms, monitoring and evaluation). The feedback we obtained from this first step led us to reformulate our general idea and carry out a new explorative phase. The general plan was adapted to tackle problems to do with confidentiality that could not be resolved through training. This was our first action research cycle.

Subsequent cycles helped us to develop school policy on confidentiality. Guidelines were drawn up that were accepted by the whole school. Finally, we published our experiences.

(Summarized by McLaughlin, Clark and Chisholm in James and Ponte 1997, p. 25.)

theories deserve to be mentioned in this context: (1) the pragmatism of Dewey, (2) Lewin's theory on research in social change, (3) Corey's theory on curriculum development and research, and (4) the teacher as researcher approach of Stenhouse. These theories are discussed below in chronological order, leading on to some current interpretations of action research as a tool for professional development.

The foundations of action research were laid in the first place by the democratic reform movement and Dewey's pragmatism in the US at the beginning of the twentieth century. The interpretation of educational situations, according to Dewey (1929/1984), began with reflection on pupils' motives and problems – as they themselves experienced them. Teachers, therefore, were expected to think reflectively. Reflective thinking requires the continual evaluation of beliefs, assumptions, and hypotheses against existing data and against other plausible interpretations of data. The knowledge that teachers construct in this way helps them to change their teaching.

After Dewey's pragmatism, the social-psychological debate about the place of research in social change played a major role. It was Lewin (1947) who argued that communities that aspired to social change would have to study the impact of their own actions, and this meant that they would also have to explore their own norms and values. He was the first person to use the term action research, based on the assumption that methods of social-science research could be applied directly to solve social problems. The basic assumption was that each group that is involved in the situation to be changed would also be involved in planning and carrying out the research and in evaluating the research findings.

In the 1950s a debate emerged on the contribution of research to curriculum development. It was Corey who developed a collective form of action research, in which teachers and school principals worked together on curriculum development with external researchers. The purpose of this collaboration, according to Noffke (1997), was "(1) an increased commitment of teachers to change; (2) an increased probability that the actions proposed to teachers would be possible; (3) a greater range and variety of talent; (4) a reduction of individual risk; and (5) the prevention of feelings of manipulation" (p. 10).

In the 1960s ideas associated with action research faded into the background under the influence of positivist views on the relationship between educational research and educational development. The dominant curriculum model assumed a strategy in which research and development are separated: academics do research, experts design and disseminate, and teachers apply. The results from this approach proved to be disappointing and, partly because of this, action research experienced a revival in the 1970s. Stenhouse (1975) then introduced the teacher as researcher approach in England as an aspect of teacher-based curriculum reform. Like Corey, Stenhouse rejected the product approach to

the curriculum that was dominant at that time in favor of a process approach. In the process approach, the concept of curriculum is not conceived as planning but as realized teaching. The emphasis is no longer on the product but on the process of curriculum development (see, for instance, Grundy, 1987/1995). Like Dewey and Lewin, he associated action research with democratic views on education. These views were bound up with a commitment to human freedom, equality of educational opportunity, and freedom of belief. While Dewey, Lewin, and Corey were discussing action research mainly as a scientific method for social change, Stenhouse (1983) tended to also approach action research as a concept for the teachers' learning. He defined action research as: "a pattern of learning by a thoughtful study of problems; such study becomes research when it is made public by being published, at which point the student (read 'the teacher' for the purposes of this article) makes a claim intended to evoke a critical response" (p. 185).

Approaches That Emerged

The initiatives of Dewey, Lewin, Corey, and Stenhouse led to many different types of approach, for which the term action research is often used. Despite the many and varied interpretations of this concept and the overlaps between them, the following broad classification of action research can be made (see also, McKernan, 1996):

- approaches termed interactive research, development, and Dissemination;
- approaches termed teacher research; and
- approaches termed educational action research.

These approaches differ in a number of respects, in particular with respect to views on (1) the role of the different actors in action research, (2) the purpose of action research, and (3) the relationship between the development and application of insights by teachers. These differences are explained below.

Many interactive research, development, and dissemination projects involve field research that also aims to improve education in schools. This does not always necessarily progress to the actual implementation of methodically planned and evaluated actions for improvement by teachers. The basic assumption, according to McKernan (1996), is that: "each team shares in planning, implementation, analysis and reporting of the research and that team members contribute unique skills and expertise in a collective process. Often teams are made up of university faculty members, teachers, administrators, educational laboratory research and development personnel and funding body staff" (p. 12). Nowadays, this approach has evolved into many forms of collaborative action research in which teachers and researchers work together on a shared issue (McLaughlin *et al.*, 2005; McLaughlin, 2006).

Teacher research is defined by Lytle and Cochran-Smith (1994) as “systematic and intentional inquiry carried out by teachers in their own schools and classrooms, which has the potential to make accessible some of the expertise of teachers and to provide the university and the school communities with unique perspectives on teaching and learning” (p. 24). Various forms of narrative inquiry are also seen as teacher research. In this type of research the main emphasis is on teachers developing theories themselves and, as a logical progression from that, the professional development of teachers. Teacher research does not necessarily include methodically planned and evaluated actions for change (Zeichner and Noffke, 2001). Especially in the initial and post-initial teacher education courses in the US, teacher research is also often linked to Schön's (1987) ideas on reflection, which assume teachers' reflecting on their practices and integrating their observations into their emerging theories of teaching and learning. These forms of teacher research place more emphasis on the personal professional development of teachers than on theory development by teachers.

Both interactive research, development, and dissemination and teacher research seem to assume that teachers automatically change the way they act – or the situation in which they are acting – based on knowledge they develop. Experimenting with the insights obtained is not always seen as a necessary part of the research, whereas it is in the approaches termed educational action research. Stenhouse (1975), for instance, agreed with Lewin, in seeing real actions for change as an essential component of learning through action research. This was one of the reasons why Stenhouse's ideas have been further developed into a concept for professional development of teachers (see, for instance, Elliott, 1991; Tabachnick and Zeichner, 1991; Carr and Kemmis, 1986/1997).

Teachers' Learning through Action Research in Practice

It will be clear from the descriptions above that action research has endless variations. Teachers' learning depends not only on the differences discussed above, but also on the contextual and local conditions in which the research is conducted. Few comprehensive studies have been carried out on the effects of different forms of action research on teachers' learning, so it is difficult to generalize about teachers' learning through action research. Nevertheless, it is possible to offer some answers to the following questions:

- Who is carrying out action research?
- How do teachers learn through action research?
- What do teachers learn from action research?
- Under what conditions do teachers learn through action research?

Box 2

P was finding that his lessons were disorganized, unfocused, and not enjoyable. The pupils were not making much progress either. He asked himself the question: “How can I, in consultation with my pupils and colleagues, change the way I teach so that the class atmosphere improves and the pupils' performance improves?” He asked pupils to write down examples of what they considered to be good and bad teaching. From the long list of good teacher behavior he compiled a short list of 11 good qualities. He listed these in order of importance based on the pupils' opinions. Important good qualities included: “(1) explaining things well, (2) being patient, (3) explaining it until we understand it, ten times if necessary, (4) having a friendly chat at the beginning of a lesson, not starting on the work immediately, and (5) only giving an amount of homework that you can finish in the lesson.” P then asked the pupils to observe him and to score his lessons on the qualities that they themselves had identified as important. He then selected a number of areas where the pupils had given him rather low scores and started to experiment with them. This approach helped the pupils to feel that they were being taken seriously, as a result of which the atmosphere in the class improved (Ponte, 2002).

Box 3

Five experienced teachers in Ontario, Canada, joined a school-university partnership to study the student evaluation practices of 13 exemplary teachers selected for their expertise in using cooperative learning (Phase 1). Data were collected in two semi-structured interviews. Participation in phase 1 of the action research left the teacher-researchers in a state of positive dissonance: dissatisfied with their evaluation methods, aware of attractive new strategies, and confident of their ability to change their practice. In phase 2, the teacher-researchers conducted inquiries in which they developed and enacted strategies for teaching students how to self-evaluate. Data sources included student surveys of attitudes toward evaluation, student focus-group interviews, individual interviews with teacher-researchers, observations of team deliberations, action research reports, and storyboards created by the teacher-researchers. Each teacher-researcher used the phase 1 findings in different ways, with every teacher ignoring some results, modestly adapting others, and, most frequently, reconstructing the intent of the exemplary teachers without adopting their specific methods. The two-phase approach to action research contributed not only to the knowledge base of teaching (creation of a framework for teaching self-evaluation) but also to the personal practical knowledge of the teacher-researchers (how to enact the framework in their classroom) and enhanced teachers' expectations about their ability to bring about learning. These benefits might not accrue in action research projects without the involvement of teachers with average- or high-efficacy beliefs, collaboration in the design and analysis of the projects, or supportive university professors sharing research skills.

(Abstract by Ross *et al.*, 1999.)

Who Is Carrying Out Action Research?

Educational action research is carried out individually (by teachers in a school or by students on undergraduate and postgraduate courses) or collaboratively (by a team of teachers in a school or by university–school partnerships). The example in **Box 2** illustrates that an individual action research project may become a way of being for the teachers. However, its systematic and intentional nature, according to Zeichner (2007), is “what distinguishes it from the everyday thoughtful behaviour of good teachers. The evolving nature of action research is what distinguishes it from mere problem-solving” (p. 2). The example in **Box 3** is one of the many examples to be found on the Internet of collaborative action research in a school–university partnership in which a contribution to the knowledge base of teaching is claimed.

How Do Teachers Learn through Action Research?

Based on a variety of sources, including a review of action research reports in the *Educational Action Research Journal*, Ponte (2007) distinguished five strategies by which teachers learn through action research. These are briefly explained below.

Interaction between the application and construction of professional knowledge

Learning through action research can be characterized by the simultaneous construction and application of knowledge. By simultaneous it is meant that the development and application of knowledge are part of one cyclical process: teachers apply knowledge; they gather information on it; they interpret that information and, based on their interpretations, develop new knowledge, which they then apply again; and so on.

Interaction between academic and professional knowledge

Learning through action research takes place when teachers link their own professional knowledge to the general knowledge of academics. Without theory, without distance, and without abstractions, the knowledge of professionals can get stuck at the level of uncritical experience of everyday events, without consequences for future action. Not linking professional knowledge to academic knowledge may even lead to action research becoming counterproductive.

Interaction between educational knowledge and methodological knowledge

Learning through action research takes place at two levels. The first level concerns educational knowledge about course content, teaching strategy, the pupils, and

so on. To construct this educational knowledge, teachers also develop methodological knowledge or knowledge at the second level; in concrete terms this means knowledge about how to study their own practice.

Interaction between individual and collective knowledge

Teachers learn by constantly making connections between their personal knowledge and the collective knowledge of their peers. The first thing to note about collective knowledge is that it is knowledge which is described in such a way that it can be shared with others; for instance, by presenting reality in the form of a model, or by ordering and naming aspects of reality in a certain way. Shared knowledge is therefore necessarily abstracted knowledge which is open to debate.

Interaction between ideological, instrumental, and empirical knowledge

Teachers learn by linking the instrumental knowledge (What strategies do we normally have at our disposal and how can we apply them?) to ideological knowledge (What goals do we essentially want to achieve with our strategies and what are the moral–ethical pros and cons involved?). Both types of knowledge are still essentially concerned with plans. To fathom out the practical significance of this knowledge, teachers must constantly make a connection with empirical knowledge, that is, with knowledge about the actual teaching situations in which they are engaged in their daily practice.

What Do Teachers Learn from Action Research?

Many (mainly small-scale) studies have demonstrated the positive effects of action research on teachers’ learning (see Campbell *et al.*, 2007; Cordingley *et al.*, 2007; Dadds, 1995; McLaughlin *et al.*, 2005; McLaughlin, 2006; Zeichner and Noffke, 2001; see also, for instance, the *Educational Action Research Journal*, vols. 1–15). The main conclusion that can be drawn from these studies is that there are two different ways in which teachers find that doing action research helps them to develop a sense of empowerment. First, they report being able to influence their own practice and the situation in which they are practicing; and second, they report that they have more control over the process and that leads to even greater influence (knowing how they can realize that influence) (see also, Harris and Muijs, 2006). The latter is associated with the fact that teachers are acquiring habits and skills of inquiry that they continue to use after their first successful experience with action research. Research by, for instance, Caro-Bruce *et al.* (2007) into the effects of various action research projects in the US presents a similar picture.

These studies found that teachers feel encouraged to talk and collaborate with other teachers, and they concluded that teachers' learning through action research led to significant changes in their practice. Teachers become more learner-centered by talking and listening to their students more carefully and they develop higher expectations of what their students know and can do.

Finally, Zeichner (2007) claimed that "although there is very little evidence in the literature of improved student learning associated with action research as measured by standardised test scores, teachers who do action research have reported improvements in pupil attitudes, involvement in classroom activities, the analysis of students' work samples, and teacher-designed assessments." The findings presented here are consistent with studies such as these (Campbell *et al.* 2007; Cordingley *et al.*, 2007; McLaughlin *et al.*, 2005; McLaughlin, 2006; Zeichner and Noffke, 2001).

Under What Conditions Do Teachers Learn through Action Research?

Research findings also show that learning to do action research is more difficult for some teachers than for others, even when the participants are experienced teachers (see, for instance, the reviews of Campbell *et al.*, 2007; Cordingley *et al.*, 2007; Zeichner and Noffke, 2001; see also, Ponte, 2002). This is first to do with the fact that action research involves working on understanding and changing teachers' own practice over the long term, while the hectic everyday working life of teachers often invites them to do just the opposite, that is to seek short-term solutions to problems in an *ad hoc* way. Second, doing action research can force teachers to face up to hard facts, because it constantly requires them to reveal why they did what they did and to actually carry out what they planned. All this means that action research is sometimes difficult to sustain. Even teachers who are experienced with action research turn out to need colleagues to challenge and support them. Kemmis and McTaggart (1988) made the following recommendations based on their experience: "Start small, with a small group, negotiate meeting times, articulate a thematic concern and establish agreement that this concern is shared, establish a time-line for the action research cycle, arrange supportive work-in-progress discussions, work with 'critical friends', register progress not only with the participant group but also with the staff as a whole and other interested parties, make time to write, and be explicit about what has been achieved by reporting progress." (p. 25–26). In line with other studies (Campbell *et al.*, 2007; Cordingley *et al.*, 2007; Ponte, 2002; McLaughlin *et al.*, 2005; McLaughlin, 2006), Zeichner (2007) concluded that these conditions can only be realized when:

- Teachers work in a culture that respects their opinions and the knowledge that they bring to the research experience.
- Teachers have control over most aspects of the research process including defining a research focus, data collection, analysis strategies, and so on.
- Teachers are enabled to collaborate over time in a safe and supportive environment.
- The environment provides teachers with intellectual challenges and stimulation.

Final Remarks: Action Research in Initial Teacher Education

The findings outlined above present a general picture of action research as a tool for teachers' professional development. However, it is necessary to make allowance for differences between action research carried out by student teachers and the action research of experienced teachers. These differences can be made clear by looking at how the five strategies by which teachers learn when doing action research, as set out earlier, need to be modified when they are applied to student teachers.

Regarding interaction between the application and construction of professional knowledge, students are not blank canvasses when they embark on a course; also, what they bring with them is neither professional nor systematized knowledge based on experience in professional practice. Initial teacher education programs cannot therefore start with the application of professional knowledge as a basis from where to go on to develop new knowledge. The students do not have this knowledge when they start the course; they have to build it up gradually. This can be done by making connections with what they do have, namely general ideas about what teaching involves based on their own experiences. In this sense there appears to be a fundamental difference between action research by student teachers and experienced teachers. This also applies to the interaction between academic and professional knowledge. For both groups of teachers this is concerned with the question of how the knowledge component relates to the action component; however, student teachers will ask different kinds of questions from experienced teachers.

With regard to the interaction between educational knowledge and methodological knowledge, students come to the course with the expectation that they will learn how to teach and what their lessons should contain (educational knowledge). Only during the course will they learn to see and use action research as a way to continually develop their practice (methodological knowledge, see above). This focus on lifelong learning will be less obvious among student teachers than among experienced teachers.

As far as the interaction between individual and collective knowledge is concerned, students cannot be expected to have experience of teaching in an institutional, collective environment, let alone of sharing knowledge in such an environment, as envisaged by the ideal action research model. The challenge for the course, therefore, is to teach students to connect the action research they learn about on the course with the situation at the school where they carry out that research.

Finally, with regard to the interaction between ideological, instrumental, and empirical knowledge, student teachers can be expected to concentrate on the instrumental area of knowledge (What do I have to do?) and not yet on the ideological area of knowledge (Why do I want to do that?), or the empirical area of knowledge (Does what I am doing match the reasons why I am doing it?). The challenge for the course here is to stimulate students to use their research to develop knowledge in the different areas and to connect the different areas together.

Teacher education courses must, therefore, make allowance for the specific needs of student teachers, and research findings (Ponte *et al.*, 2004) suggest that courses are most successful in this when they slowly build up to grooming the students to carry out a fully fledged action research project. This means that reflective research-based activities should run right through all components of the curriculum from the start, but that a full-fledged action research project will only be appropriate at the end of the course. More and more action research is being done in projects in which teacher educators, mentors, or teachers in the school and the student teachers collaborate (Campbell *et al.*, 2007). Teachers who take a 1-year teacher education course after first graduating in a particular subject will only get the opportunity to get involved in a full-fledged action research project as part of in-service training activities after completing their initial training. Close cooperation between initial and post-initial activities is therefore essential. Finally, it is possible to conclude that learning to do action research can be classed as a form of professional socialization, that is, the gradual internalization of a set of professional norms and values. This socialization will not be achieved by carrying out an isolated block of action research within a curriculum based on traditional principles. Rather it is a total concept for the professionalism and professional development of teachers that pervades the whole curriculum.

Contemporary Approaches to Teacher Professional Development

What Does High-Quality Professional Development Look Like in Theory?

Teacher professional development (PD) has become very tightly connected to many school-improvement efforts around the world. In the past several years, there has been an increasingly urgent, perceived need for more PD opportunities, along with assurance that the programs are high quality and effective. Guskey (2000) argued, "Never before in the history of education has greater importance been attached to the professional development of educators" (p. 3). Indeed, as Feiman-Nemser (2001) and others have claimed, if we want schools to offer more powerful learning opportunities for students, we must offer more powerful learning opportunities for teachers – opportunities that are grounded in a conception of learning to teach as a lifelong endeavor and designed around a continuum of teacher learning. Adopting this expanded view of teacher learning and professional practice, educational reforms in all disciplines and across all grade levels stress the need for educators to take part in PD programs that increase their knowledge, improve their practice, and ultimately foster student learning and achievement gains.

Recent shifts in the prominence of ideas about the nature of cognition, learning, and teaching – from behavioral to cognitive to situative – are, by now, well known. These changes have been accompanied by parallel shifts in ideas about teacher learning and PD. Most experts in the field advocate moving away from an in-service training model, where teachers are expected to learn a clearly defined body of skills through a well-specified process, often delivered in one-shot workshops or courses taught away from the school premises. These traditional approaches are generally viewed as overly fragmented, not connected closely enough to classroom practice, and out of alignment with current theories of learning and school reform. They are being replaced by approaches that are more closely aligned with constructivist and situative theories and reform efforts; specifically they are grounded in classroom practice and involve the formation of professional learning communities.

Stein *et al.* (1999) provided a clear and concise overview of the contrasts between traditional in-service staff development and what they call the new model of PD. Regarding traditional in-service approaches, they wrote,

"These forms of professional development were designed to support a paradigm of teaching and learning in which students' roles consisted of practicing and memorizing straightforward facts and skills, and teachers' roles consisted of demonstrating procedures, assigning tasks, and grading students" (p. 238). By contrast, "The new paradigm for professional development represents a clear departure from the use of workshops to teach 'techniques' toward the use of multiple professional development strategies to build teacher capacity to understand subject matter, pedagogy, and student thinking" (p. 263). **Table 1** presents Stein, Smith, and Silver's summary of the traditional and new approaches along four dimensions and illustrates that there are extensive discontinuities in all of the areas considered.

Hargreaves (2000) provided a historical perspective on the nature of teaching and PD that complements Stein, Smith and Silver's analysis. He described the present state of affairs as follows:

In the still emerging age of the collegial professional, there are increasing efforts to build strong professional cultures of collaboration to develop common purpose, to cope with uncertainty and complexity, to respond effectively to rapid change and reform, to create a climate which values risk-taking and continuous improvement, to develop stronger senses of teacher efficacy, and to create ongoing professional learning cultures for teachers that replace patterns of staff development which are individualized, episodic and weakly connected to the priorities of the school. (Hargreaves, 2000, p. 166)

The focus in most of the current PD literature is on providing a long-term, inquiry or learner-centered structure that supports teachers as they collaboratively develop the professional knowledge they need to use in their own context. This new vision of professional learning communities as a structure for PD is closely connected to calls for instructional reform, both generally and in specific content areas. In fact, there is widespread agreement that standards for student learning, instructional practice, and teacher PD should be seen as interrelated components of broad-based educational reform.

Several educational scholars have produced lists of principles or features of high-quality PD, based on literature reviews and accounts of successful PD programs. A comparison of their lists suggests that there is a growing

Table 1 Characteristics of old versus new paradigms for professional development

<i>Inputs to design process</i>	<i>Traditional in-service staff development</i>	<i>New model of professional development</i>
Strategies	Focus on activities (techniques, ideas, and materials) Dominant formats are workshops, courses, and seminars Short duration with bounded personal commitments	Focus on building capacity to understand subject matter and guide students' development of concepts Uses a variety of formats including the provision of in-class support and scaffolding of teacher participation in practice-related efforts (e.g., grade-level meetings, after-school meetings) Longer duration with more open-ended personal commitments
Knowledge and beliefs	Teacher educator sets the agenda Theories of teacher learning based on the psychology of the individual Translation of new knowledge to classroom is a problem to be solved (usually by the teacher)	Iterative co-construction of agenda by teachers and professional developer over time Theories of learning that include social and organizational factors Challenge is to scaffold learning that is both immediately relevant to practice and builds a more generalized knowledge base
Context	Particularities of context not factored into staff development Takes place away from schools, classrooms, and students	Particularities of context play an important role in shaping professional development Takes place in a variety of locations, at least some of which occur in schools and classrooms
Critical issues	Focus is on developing the teacher (teachers participate as individuals) Leadership training not an issue	Focus is on developing the instructional program and the community in addition to the teacher (teachers participate as an organizationally cohesive unit) Leadership training is a big issue

consensus within the field regarding the central features of PD that are effective in improving teaching practice. Interestingly, this emerging consensus does not mean that the agreed-upon features are broadly defined or few in number. On the contrary, the lists of features are relatively extensive and include specific goals, activities, and practices. As the literature and research bases continue to grow over time, it is reasonable to expect even more specificity in this area. The next section highlights conclusions from several widely cited reports detailing the features of high-quality PD.

Features of High-Quality PD (in Theory and in Practice)

After reviewing the literature, six reports to focus on for a more extensive discussion and for comparative purposes were selected (Darling-Hammond and McLaughlin 1995; Hawley and Valli 2000; Knapp 2003; Putnam and Borko 1997, 2000; and Wilson and Berne 1999). Reports that considered PD in general, rather than in particular subject areas were selected. In addition, reports that collectively span a relatively long period of time, from early leaders in the field to recent publications that capture much of the current thinking were chosen. There are many other excellent reports in the literature that have been left out, either in the interest of space or because they did not meet

the selection criteria. It is also important to note that, for the most part, these reports do not provide evidence of student learning to support claims about effectiveness. This limitation is addressed later.

Table 2 presents a synthesis of the characteristics of high-quality PD that were noted in at least three of the six reports that were selected. The table is organized in two sections. The first section includes characteristics related to the content of high-quality PD; the second includes characteristics related to the process and structure of high-quality PD. These characteristics are discussed and elaborated in the following.

Content Characteristics of High-Quality PD

Two features stand out as content characteristics of high-quality PD: the content should be situated in practice and it should be focused (at least in part) on students' learning. Situating the PD content in the practice of teaching helps to ensure that what teachers are learning is relevant to their classroom practice. Specifically, high-quality PD engages teachers in inquiry about the concrete tasks of teaching, assessment, observation, and reflection, and provides them with the opportunity to make connections between their learning and their classroom instruction.

Three reports also noted the importance of focusing PD on students' thinking and learning. These reports indicate that PD activities should help teachers learn

how to elicit and interpret their students' ideas, examine student work, and use what they learn about students' ideas and work to inform their instructional decisions and actions. PD that involves teachers' close consideration of student reasoning opens up opportunities for collective inquiry about issues related to subject matter and pedagogy.

Process and Structure Characteristics of High-Quality PD

There is agreement among the reports that high-quality PD incorporates processes such as modeling preferred instructional strategies, engaging teachers in active learning, and building a professional learning community. When teacher educators model instructional strategies, PD participants have the opportunity to experience these strategies as learners, and then reflect on their learning and on the effectiveness of the strategies from the perspective of teachers. This type of approach is particularly important in times of reform, when teachers frequently are being asked to teach in ways that are substantially different from how they were taught or how they learned to teach.

All six reports included in **Table 2** reinforce the argument that the opportunity for teachers to participate actively and collaboratively in professional communities is an essential component of high-quality PD. By engaging teachers as active participants, PD providers acknowledge that learning is an active process wherein learners construct new understandings based on what they already know and believe. PD experiences are particularly effective when teachers participate in developing the learning opportunities, and work collaboratively to inquire and reflect on their practice. Respect and trust are important features of community development, enabling teachers to engage in discussions that are both supportive and challenging, and that maintain a balance between respecting individual community members and critically analyzing issues in their teaching.

Most of the reports specify that, to the extent possible, PD should be school based and integrated with other aspects of school change. High-quality PD experiences can be situated in multiple contexts, both in schools and offsite. Artifacts of practice, such as videotapes of lessons and student work, can be used to bring the classroom to the PD setting.

Finally, PD should consist of activities that are ongoing and sustainable over time, and that provide the opportunity for teachers to engage in cycles of experimentation and reflection. PD models with a cyclic approach might, for example, engage teachers in developing and enacting a lesson plan designed to meet the needs of all students, and then encourage them to individually and collaboratively reflect on their experiences. PD models that provide

teachers with the opportunity for such professional inquiry support their on-going learning and encourage change.

Research on Effective PD in Practice

Empirical evidence on the effectiveness of PD with these qualities is quite limited. Indeed, as Knapp (2003) cautioned, "The actual benefits of the asserted attributes of good professional development have rarely been examined systematically, either separately or in combination" (p. 120). Although few would argue with assertion of Hawley and Valli (2000) that evaluations of PD programs should incorporate multiple sources of information, both on the processes involved in implementing ideas learned through PD and on the outcomes for students, to date there are few evaluations of this sort. Despite the contemporary press for accountability for student outcomes, most of the research examines the relationship between PD and changes in teacher knowledge and instructional practices. Few research programs have explored the links between teacher learning, classroom practices, and student achievement.

Furthermore, as is true in the broader field of teacher education research, the research on teacher PD has been criticized for its limited scope and lack of scientific rigor. Scholars have run into difficulty when attempting to quantify the principles outlined in the more theoretically based literature. Most research to date consists either of intensive case studies on single programs or of self-report, survey data. In addition, the fields of mathematics and science are more heavily represented than other subject areas or other aspects of classroom practice. Nevertheless, this body of literature is widely read and cited, and it has been a motivating force as educational practitioners and policymakers push for increased PD opportunities.

At the same time, many educational scholars are committed to conducting research that will move the field forward. Borko (2004) suggested a three-phase research agenda for designing, implementing, and investigating scalable models of PD. This agenda provides a framework for guiding purposeful decisions about PD research. Phase 1 research projects take place at a single site and provide initial evidence that a PD program is feasible and can have positive impact on teacher learning. Typically, these proof-of-concept studies are relatively small; both qualitative and quantitative research methodologies are employed to document the design process and to study the impact on teachers' knowledge and practice. Phase 2 research projects build on and extend Phase 1 projects to determine whether a particular PD model is a scalable model. During Phase 2, researchers might study the implementation of a PD program in different settings or by different PD providers. They also might work with

Table 2 Characteristics of effective professional development^a

<i>Characteristics of effective PD</i>	<i>Darling-Hammond and McLaughlin (1995)</i>	<i>Hawley and Valli (2000)</i>	<i>Knapp (2003)</i>	<i>Putnam and Borko (1997, 2000^b)</i>	<i>Wilson and Berne (1999)</i>
<i>Content</i>					
PD content is situated in practice; addresses problems of practice.	PD engages teachers in concrete tasks of teaching, assessment, observation, and reflection that illuminate the processes of learning and development.		Content builds on teachers' pedagogical content knowledge (PCK).	Mantra: Situate teacher education in classroom practice. Ground teacher learning experiences in their own practice.	
Content of PD is focused on students' learning.	PD is connected to and derived from teachers' work with their students.	Content is focused on what students are to learn and how to support student learning; PD addresses impediments to and facilitators of student learning.	Specifically focused on high standards for students.		
<i>Process / structure</i>					
Preferred instructional practices modeled in PD.	Supported by modeling, coaching, and the collective solving of specific problems of practice.		Model preferred instructional practices (e.g., active learning), both in classrooms and in adult learning situations.	Mantra: Teacher educators should treat teachers as they expect teachers to treat students.	
Active teacher learning; teacher inquiry.	Grounded in inquiry, reflection, and experimentation that are participant-driven.	Teachers identify what they need to learn and, when possible, participate in the development of the learning opportunity and / or process to be used.		Mantra: Treat teachers as active learners who construct their own understandings. Empower teachers and treat them as professionals.	Teacher learning is activated, rather than bound and delivered; engage teachers as learners in areas their students will learn, but at a level more suitable to their learning.
Professional learning communities; collaborative learning environments.	PD is collaborative, involving sharing of knowledge among educators and a focus on communities of practice rather than on individual teachers.	PD provides learning opportunities that relate to individual needs but are, for the most part, organized around collaborative problem solving.	Collaborative and collegial learning environments.	Teachers need opportunities to participate in supportive professional learning / discourse communities in order to be successful in constructing new roles or changing their practice.	Communities of teacher learners who are redefining teaching practice; privilege teachers' interactions with one another, build trust and community while creating professional discourse that includes critique.

Table 2 Continued

<i>Characteristics of effective PD</i>	<i>Darling-Hammond and McLaughlin (1995)</i>	<i>Hawley and Valli (2000)</i>	<i>Knapp (2003)</i>	<i>Putnam and Borko (1997, 2000^b)</i>	<i>Wilson and Berne (1999)</i>
PD settings are appropriate to goals, often school based.	PD is connected to other aspects of school change.	PD is school based and integral to school-based operations. PD is integrated with a comprehensive change process.	School based when possible.	Mantra: Situate teacher education in classroom practice. PD experiences are situated in multiple contexts based on the goals of the PD.	
PD opportunities or models are ongoing and sustainable	PD is sustained, ongoing and intensive.	PD is continuous and ongoing, with follow-up and support for further learning. PD includes support from external sources to provide resources and outside perspectives	Rigorous cumulative opportunities for learning over time.		

^aWe use general terminology to describe characteristics of effective PD (i.e., cells in the first column), whereas we have attempted to use the language of the specific authors within the other cells to capture their voice and meaning.

^bThe 1997 chapter and 2000 journal article by Putnam and Borko both address teacher learning through professional development, but with somewhat different foci. Entries in this column represent a combination of ideas from the two papers.

nonvolunteer teachers or examine student achievement. Successful results from a Phase 2 program of research thus provide evidence that a full scale-up of the PD program would be useful to the field. Phase 3 research projects involve a comparison of multiple, well-defined PD programs, each enacted at multiple sites. Central research issues in these large-scale studies include comparing the resource requirements for the PD programs and their impact on teacher and student learning.

Below we provide examples of Phase 1 research on the PD of mathematics teachers, and of Phase 2 research on the PD of writing teachers. These examples illustrate key features of each research phase. To the best of our knowledge, no Phase 3, full-scale comparative studies of PD models have been conducted to date. However, there is another category of research that entails larger-scale analyses of multiple approaches to PD (but without detailed information about program characteristics or resource requirements); the literature in that area is discussed as well. Some emerging uses of technology in PD are also addressed.

An Example of Phase 1 Research on the PD of Mathematics Teachers

Early phases of development and research on PD models often use a design experiment approach to document the processes of the PD and the impacts on teacher learning. In general, these types of projects have focused

on implementation of a PD program by the designer at a single site, typically with motivated volunteers (Fishman *et al.*, 2003). Our own research – involving the development and implementation of a model of mathematics PD called the problem-solving cycle (PSC) – provides an example of Phase 1 activities.

The PSC model is an iterative, long-term approach to PD, with the goals of increasing teachers' knowledge of mathematics for teaching, improving their instructional practices, and fostering student achievement gains (Koellner *et al.*, 2007). Each iteration of the PSC consists of three interconnected workshops organized around a rich mathematical task. This common experience provides a structure within which the teachers can build a supportive community that encourages reflection on selected mathematical concepts, student thinking, and instructional practices. Central activities for participants include collaboratively solving the mathematical task; teaching it to their students; and exploring the teachers' instructional strategies and their students' mathematical reasoning. Video from the lessons and other artifacts of practice are used to situate the teachers' learning opportunities in the context of their work. The PSC is intended to be implemented by a knowledgeable facilitator, who helps to promote a professional community that supports the individual and collective growth of participating teachers.

Our research utilized a design experiment approach, with a group of eight to ten middle school teachers over

2.5 years. We documented the processes involved in developing and implementing the PSC model, as well as its substantial impact on teachers' knowledge and instructional practices. Our analyses revealed changes in patterns of participation in the workshops over time and suggested connections between teachers' experiences in the workshops and their professional learning. For example, analysis of workshop discussions revealed that over time, teachers talked in an increasingly focused, in-depth, and analytical manner about specific issues related to teaching and learning. On an assessment of algebra knowledge, significant increases in both the number of correct answers and the number of solution strategies used by each teacher were found. In addition, changes in classroom mathematics instruction over the duration of the project were observed. These changes reflected pedagogical topics, such as improving group dynamics and using more effective questioning strategies, emphasized in the PSC workshops. Thus, the findings indicate that, under ideal conditions (i.e., when implemented by the designer, with motivated volunteers), the PD model is feasible and can have a positive impact on teacher learning.

An Example of Phase 2 Research on the PD of Writing Teachers

After initial design research on a PD program many additional questions about the intervention must be answered before it is reasonable to allocate resources to a full scale-up evaluation. Such questions include: (1) What is the impact on student achievement? (2) Is it feasible on a larger scale (e.g., an entire school district) and with nonvolunteer teachers? (3) Can it be adapted to meet the needs and conditions of the local sites? (4) Are the PD materials and resources sufficient to ensure that multiple facilitators can implement the model while maintaining integrity with the designers' intentions? There is not one correct next-step in this phase of program development and research; rather there are multiple paths that can be explored in the ongoing study of a PD program.

Over the past three decades, various investigations of the National Writing Project (NWP) have explored several of these paths. Lieberman and Wood (2003) described the NWP as "arguably the most successful K-12 professional development project ever in the United States" (p. 187). The NWP has had a far-reaching influence on teachers and schools across the United States, where there is a steadily growing NWP network of nearly 200 university- and college-based sites. Initiated in the mid-1970s as the Bay Area Writing Project, as of 2003 the NWP had served approximately 3.5 million teachers. In partnership with schools or school districts, NWP sites host a 5-week summer institute for teachers in all grade levels and disciplines. During the following academic year, many of

these teachers become teacher consultants and facilitate workshops for their colleagues.

A core set of practices undergirds the NWP summer institutes. Designed to situate the teachers' learning in their own writing and classroom practices, these tasks guide teachers in demonstrating their writing instructional activities, studying theory and research about writing instruction, and immersing themselves in writing. However, by design, the focus of the institutes changes over time to meet the evolving needs of teachers and their students. Thus, a number of early institutes focused on prewriting; later ones addressed the use of rubrics; and more recent topics have included standardized assessments, writing with special populations, and technology. In addition, although the NWP sites share a national program model, their design and delivery vary according to local needs, reform priorities, school conditions, and research contexts. Thus, while there has been an ongoing, wide-ranging, and comprehensive evaluation effort, this effort is constrained by the intentionally flexible nature of the NWP.

A number of studies have investigated the impact of the NWP on teachers and students. In their review of this research, Pritchard and Honeycutt (2005) concluded that the positive effects on teachers' instructional practices have been well established. For example, several studies involving classroom observations of NWP-trained teachers indicate that the teachers gained new teaching strategies, used a greater variety of strategies, and devoted more time to writing instruction. Self-report data from teachers who participated in the NWP institutes suggest that they developed a valuable professional network, changed their philosophies about teaching writing, and acquired knowledge and skills related to teaching writing effectively. Of the published studies examining student work, central findings also favor the NWP approach over traditional approaches.

Larger-Scale Analyses of Effective PD

Although we are not aware of any studies that fit Borko's (2004) description of a Phase 3 project, a few researchers have looked across multiple PD programs to ascertain their effectiveness. As one example, Garet *et al.* (2001) surveyed a nationally representative sample of teachers who attended mathematics and science PD programs that received funding from the Eisenhower Professional Development Program. Although their survey covered a relatively large number and wide variety of PD programs, only a few teachers were sampled from each program; also, information about program effectiveness was based solely on teachers' self-reported increases in knowledge and skills and changes in classroom practice. Analyses examined three structural and three core features of the PD programs – features that the researchers identified through a literature review as best practices in teacher PD. The structural

features were form (e.g., study group, workshop), duration (e.g., number of hours, time span), and participation (e.g., collectively from the same school or grade, or individually). The core features were degree of content focus, active learning opportunities, and promotion of coherence (e.g., alignment with state standards).

The researchers found that all six features were related to teachers' self-reported changes in knowledge, skills, and classroom practices. These results support the notion that to be effective, PD models should take into account the array of features identified in the literature as best practices. However, the data revealed that many of the PD programs studied did not incorporate features of high-quality PD. Other analyses of the Eisenhower program have produced complementary findings.

Uses of New Technology in PD

Recent technological trends are having a strong impact on the field of teacher PD. Many new PD models are incorporating various technology-related components, including digital libraries, web-based virtual learning environments, and online and electronic conferencing features. Various forms of online discussion forums are particularly popular. In synchronous conversations, such as chat rooms, participants are present at the same time and respond electronically in real-time to one another. Virtual learning environments that feature asynchronous interactive tools, such as bulletin boards, enable teachers to participate in discussions anytime, anyplace.

Particularly as PD programs seek to scale-up or enter Borko's (2004) Phase 2 as described above, developers are increasingly turning to these contemporary, innovative technologies. As Goldman (2001) argued, "Many forms of electronic technology can overcome time and place constraints and provide the means to reach large numbers of individuals, potentially at costs lower than those associated with the physical presence of professional development personnel" (p. 21). PD that incorporates these technologies can draw upon resources not available locally, provide just-in-time work-embedded support, and accommodate individual teachers' busy schedules.

Currently, a broad array of online PD programs is serving large numbers of teachers. These programs are diverse in their purposes and goals, content areas, pedagogical approaches, and delivery methods. Many incorporate technology-related components that support content and process characteristics of high-quality PD—for example, collaborative virtual learning communities, interactive media to facilitate active teacher participation, video cases that address problems of practice, and digitized work samples to foster exploration of student thinking. Hybrid PD models that feature both online communication

(either asynchronous or synchronous) and face-to-face components are also gaining in popularity.

As one example, the PBS TeacherLine site offers over 100 online PD courses to preK-12 teachers in the fields of mathematics, reading/language arts, science, instructional technology, and instructional sciences. These relatively short courses (6–10 weeks) were developed with input from K-12 educational leaders and research experts and include online discussions with trained facilitators who have backgrounds in the subject matter. Designed to tie to classroom practice and link content to local and national standards, many of the courses feature streaming video of classrooms and digitized versions of student work. Research on TeacherLine includes formative and summative evaluations based on self-report data from participants and facilitators, expert-panel review of selected courses, and an assessment of the quality of online discussion board communications. Results indicate that facilitator quality related directly to participants' ability to apply course content to their classroom practice, and to their satisfaction with the course (Ramsdell *et al.*, 2006).

Another, quite different, example is Tapped In, an online environment for educational professionals that is designed to promote a community of practice. Drawing on rapidly expanding technological advances, Tapped In enables a professional online community that extends beyond local sites. Synchronous and asynchronous discussions, coupled with support tools, such as white boards, sticky notes, and web page viewers, allow teachers to work and learn with a diverse group of colleagues and experts. Schlager and Fusco (2003) argued, "Tapped In has been quite successful in achieving its original goal of bringing together and forging new relationships among education practitioners, providers, and researchers from around the world on a daily basis. Thousands of different people log in each month to engage in activities that include course and workshop sessions, group meetings, and public discussions spanning a wide range of K-12 topics" (p. 204). As of July 2006 there were 20 000 Tapped In members, and the monthly log-in rate was approximately 10–20% of the membership. The developers have documented their conceptual framework and design strategy in detail, and have begun to collect and analyze data on the impact of participants' Tapped In experiences on their professional lives.

Dede *et al.* (2006) reviewed nearly 400 empirical studies of online, face-to-face, and hybrid PD programs. Most of the literature reports program evaluations focused on the effects of program design, delivery, and use on the formation of teacher learning communities, discourse patterns, and levels of participation. Few studies examined changes in teachers' knowledge or skills, and even fewer addressed the impact on student learning. This conclusion supports Borko's (2004) premise that the research on contemporary PD (whether involving new technology or not)

falls mostly in the Phase 1 category. Dede and other leaders in the field have identified the need for more well-designed empirical research studies, and we expect to find a good deal of movement in this regard in the near future.

Conclusion

The field of PD is moving forward at a relatively fast pace. A majority of teachers in the United States are engaging in PD, and there is a push for more PD opportunities across the country. Similar increases in the level of interest and support for teacher PD can be seen throughout the world. Research in this field offers a relatively focused and agreed-upon direction for PD, which is consistent with prevailing theories about the nature of learning and cognition. At this point, much of the focus has shifted from creating theories of high-quality PD, to considering issues related to the design of PD programs based on current theories. Presently, a number of PD programs based on the current theories have been implemented, but few have been expanded beyond the proof-of-concept phase. Only a small research base exists on the impact of contemporary approaches to PD on teachers' learning and classroom practices, and the research base on student achievement is even smaller. However, with steady advances in the design, implementation, and evaluation of PD programs, and the expanding use of new technology, the research base in this field is likely to expand dramatically over the next several years.

School Development for Teacher Learning and Change

P Sleegers, University of Twente, Enschede, The Netherlands

K Leithwood, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

In the last decades, schools have been confronted with ongoing large-scale educational reform efforts and restructuring movements as strategies to improve the quality of education and to implement educational innovations. The educational reforms are, among other things, based on new forms of learning and aimed at the arrangement of learning environments intended to stimulate self-regulated, reflective, independent, authentic, and social-interactive learning. An important aim of these restructuring changes is to create opportunities for change at the local level and to enhance capacity building for learning in schools.

Research in educational organizations, however, indicates that changing teachers' practices is extremely difficult to accomplish. In their efforts to understand the complex nature of educational change, researchers have reconceptualized teacher change by using perspectives in which teacher learning embedded in the school is considered a key component of successful school improvement. As a consequence, the capacity of schools to enhance the professional learning of teachers and transform large-scale reform into accountable, learner-oriented, teaching practice has become a major focus in recent research in educational change (Fullan, 1999; Hopkins, 2001; Sleegers *et al.*, 2005; Smylie and Hart, 1999; Toole and Louis, 2002).

In this article, we examine research about the relationship between structural and cultural aspects of the school organization and teacher learning and change. We bring together two views of change that dominate the literature about school improvement and educational change. The first view, which we term the inside view, focuses on the capacity of schools to transform themselves into supportive environments for teacher learning and change. The second view concerns the implementation of externally developed reform designs into schools, the outside view. While one literature often informs the other, they view change through opposite ends of the telescope.

Underlying Assumptions

Insider and outsider approaches to change are premised on quite different assumptions. These assumptions are well captured in Chin and Benne's (1969) distinction between planned change, empirical-rational approaches to change, and normative-reeducative approaches. The empirical-rational strategy focuses on research-based models for change which assume that teachers, as rational

human beings, will implement changes in their classrooms which are demonstrated to improve student learning. The normative-reeducative conception of change, focusing on the professional growth of individuals who make up the system and on the problem-solving capacities of the system itself, assume that personal sense-making and collective learning are keys to improvement.

Empirical-rational and normative-reeducative approaches not only differ in their assumptions about change, but also in the direction for change (for a more elaborate description of these strategies, we refer to Richardson and Placier (2001) who have also used this framework for their thorough review of research into teacher change). While empirical-rational strategies view teachers as mere recipients and consumers of new behavior, beliefs, and programs of researchers, and as policymakers and educators outside the school, the assumption in the normative-reeducative approach is that change is part of a larger process of making sense of situations in which teachers work and live through individual and collective reflection on beliefs and practices. We were able to organize a number of studies about school development and teacher learning and change premised on Chin and Benne's (1969) normative-reeducative approach based on their underlying views on change. These included a wide range of studies about organizational learning, learning organization, and professional communities. The emphasis on organizational learning in schools, schools as learning organizations, and schools as professional communities can be regarded as an attempt to find alternatives for the disappointing results of restructuring schools and the school system. These studies often use a system theory on change that links structural, cultural, and political dimensions of school-workplace environments to professional learning. In these studies, organizational conditions (including leadership) are considered as the main levers of a school's capacity to change and as a prerequisite for linking teachers' professional development to school development. In this article we look at learning in schools and the school's capacity to change through the lens of organizational learning. We prefer the concept of organizational learning instead of the concept of learning organization, because the literature on learning organization is prescriptive, practitioner-oriented, and lacks scientific rigor (see Tsang, 1997). Therefore, we restrict our review to organizational learning in schools and conditions fostering this learning. We begin with a summary of this research.

There is also a considerable body of research premised on a rational–empirical conception of change. During the last 10 years, schools in US and other countries have been involved in implementing research-based school-reform designs that are developed by an organization external to the school or district, also known as comprehensive school-reform designs (e.g., Success for All, Comer School Development Program, Coalition for Essential Schools, Accelerated Schools, Modern Red School House, ATLAS Communities, Different Ways of Knowing and Core Knowledge). The use of these empirical–rational strategies for educational change and the scaling up of these designs can be explained by the current and growing pressure to change, including the push for strong terms of accountability and systematic reforms, and beliefs about the effectiveness of evidence-based decision making. Inspired by these developments, researchers have conducted studies of the effects and the transfer of these models to multiple settings (scaling up).

The Inside View: Organizational Learning in Schools

The concept of organizational learning in schools is used by researchers to gain more insights about the internal innovative capacity of schools to adapt to the dynamics of educational change. The idea that organizations can learn is hardly new. As early as the 1970s, organizational theorists were writing about how organizations could renew and improve their processes, products, and services; in other words, how they could learn (Argyris and Schön, 1974). Although interest in the concept of organizational learning originated in the corporate sector, it has attracted attention in the educational world as well (Leithwood *et al.*, 2001).

Schools are confronted with a continuous stream of changes in their environments (e.g., demographic changes, large-scale educational innovations, and sociocultural renewal). In addition, they face multidimensional restructuring demands to which they must respond. Furthermore, schools are under considerable external pressure because of tightened output controls introduced by accountability policies. Simultaneously, schools are expected to improve not only their internal change capacity but also their instruction through their professional development initiatives. Strengthening schools' internal conditions to promote organizational learning is considered an important prerequisite for addressing this onslaught of expected changes. Furthermore, learning is also expected to reduce the alienation and challenges to educators' motivations as the bureaucratic features of schools and their dysfunctional effects are reduced.

A common thread found in the many definitions of organizational learning is the focus on innovation and improvement through the acquisition of better knowledge and understanding about learning. Organizational learning can be defined as the activities through which organizational members construct new knowledge, or reconstruct existing knowledge in order to improve the functioning of individual organizational members and the organization as a whole (Leithwood *et al.*, 2001). Leithwood and Louis (1998) distinguish different levels of learning in schools, including the learning of individuals in organizational contexts; small group or team learning that occurs within subunits of the organization; and collective learning of the organization as a whole (e.g., new policies or procedures). Individual learning is considered to be necessary but insufficient for organizational learning; and organizational learning is more than the sum of all individual learning. Staff members share their knowledge and expertise by cooperating and exchanging information. These collaborative practices, for example, may focus on developing instructional material and curricula during which teachers exchange experiences, investigate each others' practices, develop new approaches, and learn from each other. The learning of staff within schools is considered to be good on the assumption that higher levels of individual and organizational learning contribute to better organizational functioning.

School improvement research indicates that teacher learning is crucial for improving instructional practices. Moreover, cooperation can contribute importantly to improving instructional quality and, hence, student achievement (Clement and Vandenberghe, 2000; Geijsel *et al.*, 2001; Louis *et al.*, 1996). Positive associations also have been found between teachers' learning and the innovative functioning of schools.

While there are good theoretical reasons to expect that individual and organizational learning will improve classroom practices and school performance, there is little on the empirical side to justify this expectation. Available evidence points to important preconditions associated with the individual, the task, and the school organization. With respect to the individual, Mitchell and Sackney (2000) point to the individual capacity of staff to learn, to actively (re)construct, and to apply knowledge. Such capacities seem to be influenced by psychological factors, such as personal teaching efficacy, autonomy or perceived control, and teachers' commitment, emotions, and sense-making (Coburn, 2001; Rosenholtz, 1991; Spillane *et al.*, 2002; Sleegers *et al.*, 2002; Van Veen *et al.*, 2005). The characteristics of the task to be carried out may also play a role in how motivated are the staff to learn (e.g., the degree of task control and the extent of task variation).

Among the organizational conditions that influence learning among staff, the role of school leaders is key,

especially as it is inspired by the concept of transformational leadership (Geijsel *et al.*, 2003; Leithwood *et al.*, 1999; Leithwood and Slegers, 2006). The role and forms of teacher collaboration aimed at improving instruction and education is also an important organizational condition. Such collaboration can be promoted by creating opportunities for it, by developing the collaborative skills of teachers, and by rewarding teacher collaboration. The intensity of cooperation and learning among staff, as well as the development of the school as a whole are dependent on the degree to which schools create opportunities for teachers' professional learning (Clement and Vandenberghe, 2000; Slegers *et al.*, 2002). Moreover, organizational learning also depends on both the availability of relevant data and agreed-upon standards to assist in interpreting such data. Learning is only possible if school staff are provided with information concerning important school issues (e.g., developments in student performance or the extent of parental participation) (Leithwood *et al.*, 2001; Earl and Katz, 2006).

Finally, Marks *et al.* (2000), among many others, have pointed to the importance of freeing one's organization from traditional structures, empowering teachers in decision-making processes, and developing cultures which value shared responsibilities and values.

The attention that organization learning receives in the literature is in contrast to the amount of empirical research that is available. The many explorative studies that have been carried out do not unequivocally verify or falsify the relationships between variables as hypothesized in the literature. There are some indications that schools, with the characteristics mentioned above, do indeed promote teacher learning, and educational change takes place more easily in those schools. Whether schools, in which collective learning takes place, promote higher levels of student performance has not been studied systematically. Nor has much empirical attention been devoted to the factors which trigger learning, although it is acknowledged, in general, that particular events (e.g., a decrease in student enrolments) may lead to learning.

Besides this system-oriented view of collective learning in schools, a key contribution to the study of school culture and change has been the concept of professional learning community (PLC) (Mitchell and Sackney, 2000; Stoll *et al.*, 2006; Toole and Louis, 2002). The term integrates three robust concepts: a school culture that emphasizes professionalism (is client oriented and knowledge based), stresses learning, and places a high value on teachers' inquiry and connection. Although researchers use different key indicators and variables to describe and measure PLCs, the central idea is about the existence of a social architecture in school organizations that helps shape teachers' attitudes toward new pedagogies. The key to learning, from this perspective, is not

adaptation but creation and the free choice of individuals to participate in a social reality called organization and, through such participation, to learn. Learning in PLCs is conceptualized as dynamic and cyclical. The strict distinction between conditions and effects disappears (Imants *et al.*, 2001). As a result, the links between conditions for learning, learning communities, and school improvement are described as recursive. Collaboration, participation, transformational leadership, reflective dialog, and the like can be an input, throughput, or outcome of learning processes. These potential stimulants to learning become productive insofar as they prompt both individual and social sense-making on the part of teachers. For a more detailed description of the scholarly work in this field, we refer to the article on PLC in this encyclopedia.

The Outside View: Implementation of Comprehensive School Designs

Since the No Child Left Behind (NCLB) legislation (US Congress, 2001), educational leaders and policymakers in the US have devoted much of their energy to creating systems and procedures for measuring school performance and improving the achievement of low-performing students. This policy initiative, with a dominant press for external accountability, has prompted the initiation of hundreds of school-reform efforts especially in failing schools. The NCLB-driven policymakers have stressed evidence-based decision making and the need for strong evidence of program effects to be eligible for federal funding. In order to meet these powerful incentives to improve, low-performing schools have been searching for blueprints, tools, and expertise, which make change possible and are able to demonstrate their effects in scientifically reputable ways. Starting with the comprehensive school reform demonstration (CSR) program in 1997, over 380 comprehensive school reform (CSR) models encompassing virtually all aspects of school operations, including instruction, assessment, classroom management, professional development, parental involvement, school management, and curriculum, have been developed in the US and also introduced in other countries. Many of these models are indeed grounded in scientific research and offer schools the solutions to their improvement problems (for an overview, see Borman *et al.*, 2004). To receive funding, a CSR model must:

1. offer proven methods and strategies;
2. integrate comprehensive designs for effective schools with aligned components;
3. provide high-quality and continuous teacher and staff professional development and training;

4. include measurable goals for student performance and benchmarks;
5. be supported by school faculty, administrators, and staff;
6. provide support for staff, school faculty, and administrators;
7. stimulate parental and community involvement;
8. use high-quality external support from a comprehensive school-reform design team with experience and expertise in school-wide reform;
9. plan to evaluate the implementation of school reforms and the students' results achieved;
10. identify resources (federal, state, local, or private) to support and sustain the school reform; and
11. show evidence of having significantly improved the academic achievement of students in the program as compared with students who have not participated in the program (The Coalition for Comprehensive School Improvement, 2005).

All the early funded reform designs were initially implemented in one location (Memphis, TN, USA), but have since transferred to multiple settings. The use of this empirical-rational strategy for educational change and the scaling up of these designs play a central role in the next stage of NCLB. Scaling up is mostly defined in a traditional way as the deliberate extension of an externally designed CSR design that has been successful in one school to more teachers, schools, and districts (Coburn, 2003).

Although the principles, methods, and strategies of the funded CSR models must be evidence-based, research to date indicates that most do not have strong effects on student achievements (Berends *et al.*, 2002; Desimone, 2002). In the first serious review of evidence on this issue, Borman *et al.* (2003) reviewed 232 studies for their meta-analysis of CSR effects. They found modest-to-positive effects on the achievement scores for the CSR models examined. Three models – the Direct Instruction, the Success for All, and the School Development model – were classified by the researchers as having the strongest effects (effects sizes ranging from +0.15 to +0.21), while 17 of the 24 models produced insufficiently reliable or generalizable results. Recently, some studies using defensible numbers of CSR schools, control schools, independent researchers, and extended time periods were conducted (Borman *et al.*, 2005; Sterbinsky *et al.*, 2006). Using a randomized field trial of 41 schools to evaluate the first-year results of Success for All, Borman *et al.* found effects on one (word attack) of four posttest measures. The magnitude of the school-level effect using the Success for All intervention relative to control schools was equal to an effect size of +0.22 (2 months of additional learning). Using a quasi-experimental design, Sterbinsky *et al.* examined the effects of five different CSR models in ten schools. Results showed

that CSR schools had significantly higher gain scores than control students on word identification, passage comprehension, and oral reading (effect sizes vary from +0.31 to +0.44). With regard to yearly cohorts, only effect sizes were found for passage comprehension (+0.27) in year 3.

Although some effects are apparent by now, the evidence remains very thin and most of the studies conducted have been small scale, often conducted by developers themselves and lacking well-selected designs and sophisticated statistical analyses. Additionally, these effect studies do not increase our knowledge of key issues of educational reform, such as how these models are adopted by teachers, the conditions under which these models can be implemented successfully, the possibilities and boundaries of scaling up CSR models, and the sustainability of educational reforms. There is a growing body of work that tries to shed more light on these issues by studying the CSR implementation processes in schools and the possibilities of scaling up these reforms (Borman *et al.*, 2004; Datnow *et al.*, 2002; Desimone, 2002; Klinger *et al.*, 2006; Sterbinsky *et al.*, 2006). Results of these studies show that most of the CSR reforms were actively shaped and reshaped (co-constructed) by teachers, school leaders, and other local educators to accommodate the various goals, materials, and demands of the program to local context. These processes of mutual adaptation were required to meet the practical demands of everyday school life and the needs of students.

Mutual adaptation also occurs when the content of CSR models differs from the pre-existing beliefs and practices of teachers. In this case, teachers focus on surface manifestations rather than underlying pedagogic principles. The way that different local actors interpret and enact these reforms thus plays a very important role in their implementation and influences program fidelity. Such mutual adaptation has mostly caused frictions with highly prescribed models and insensitive design teams. Most developers of CSR models recommend the exact implementation of the model (program fidelity) using a technical-rational approach that sees teachers as passive implementers instead of collaborators. But inattention to the cultural and political dimensions of change seems to hinder successful implementation. Results also show that strong principal leadership, teacher buy-in, sufficient resources and time, and district support for the reform are important for successful implementation of the model. Furthermore, findings also suggest that schools with a high innovative capacity, collaborated cultures, and highly committed teachers are more successful in implementing reform designs.

Although more research is needed to increase our understanding of conditions fostering the implementation of CSR models, the current findings suggest that for successful implementation of CSR models, attention

should be paid to the interrelations between the way teachers make sense of externally developed models, the structural, cultural, and leadership dimensions of the school and the local context in which the school is embedded (Datnow *et al.*, 2002). Surprisingly, these findings also concur with the results from research into conditions fostering organizational learning as described in the first section of this article. Despite the empirical–rational assumptions used in most of the CSR literature and research on educational change, normative–reeducative change strategies seem to be needed to foster real change within a school. Moreover, the findings also seem to suggest that schools which already have a high innovative capacity and are able to transform their organization into a rich learning environment for teachers can integrate externally developed reforms into their current practice far more easily than schools with a low innovative capacity. Therefore, it is far easier to seed new practices successfully in schools which have fertile soils (Slavin, 1998). Given the fact that CSR models are often thought to offer powerful incentives (tools, blueprints, and expertise) for low-performing schools to improve their performances, these findings present challenges for those wanting to scale up these designs.

Conclusions

In this article, we reviewed the growing body of research in the relationship between school development and teacher learning and change. By using Chin and Benne's classic distinction between empirical–rational and normative–reeducative change strategies, we brought two views of change that dominate the literature about school improvement together. From the system or insider view on teacher change, a normative–reeducative conception of the process focuses on the study of the professional growth of individuals who make up the system and on the change capacities of the system itself. From the implementation or outsider view an empirical–rational approach focuses reformers on research-based models for change, which teachers, as rational actors, are expected to implement in their classrooms. Although these two views use different assumptions about the nature and direction of change, results of research show that they inform each other. Successful educational reform needs to be context specific, integrated with the school's capacity for development, and stimulate collective learning in schools. In order to be effective, we agree with Hopkins (2001) that finding a balance between normative–reeducative and empirical–rational approaches seems to be a better way than using the so-called one-size-fits-all approaches. The challenge is to find change strategies and approaches that fit the best with the existing capacities of the school, or at least, capacities it can realistically acquire.

Future research should focus on the interaction between school internal capacities and external reform programs. Special attention should be paid to issues of sustainability and scaling up as fundamental to the successful implementation of educational reforms. To increase our understanding of key conditions in schools and effective change strategies that can support teacher learning and change, researchers should focus on issues such as the extent to which reforms can go beyond superficial indicators of change to alter teachers' beliefs, norms, and enacted practices (depth), how change can be sustained over time (duration), and how it can be extended to more teachers, schools, and districts (breadth) (Coburn, 2003; Hargreaves and Fink, 2006).

Glossary

Beginning teacher – Owing to local policies and cultures, the definition of a beginning teacher can vary, but is usually referred to as a new teacher starting to work as a teacher after having finished a teacher preparation program.

Induction – The process of initiating beginning teachers into their new role as both teacher and a member of the school organization.

Induction program – A more-or-less planned and formalized system to assist and support beginning teachers.

Induction standards – Standards required by beginning teachers for achieving the status as a qualified teacher during a period of induction (in some countries, new teachers can only become qualified teachers when they meet these standards).

Mentor – A more experienced teacher who gives support, assistance, guidance, and challenge to a teacher with little or no experience.

Teacher attrition – A term referring to teachers who voluntarily and prematurely leave the profession.

Teacher competency – Meeting standardized requirements in terms of knowledge, skills, and attitudes necessary for teachers to properly perform their work.

Teacher retention – A term referring to keeping teachers in the profession.

Introduction

The teacher induction period is generally referred to as the beginning teacher's first year or years of teaching after his or her qualification as a teacher. Induction is the process of initiating beginning teachers into their new role as both a teacher and a member of the school organization. Due to differences in local policies and cultures, the definition of a beginning teacher can vary. Nevertheless, it is increasingly acknowledged in many countries that even a very comprehensive teacher-training program cannot fully prepare the teacher for his or her first job; that is, when new teachers first start to work, they still have much to learn (Britton *et al.*, 2003). To support this additional learning, many schools have recently initiated

teacher induction programs and, in some countries, these programs have actually been made obligatory and now constitute part of the teacher qualification trajectory.

A teacher induction program can be defined as a more-or-less planned and formalized system to assist and support beginning teachers in becoming competent and effective professionals. Good teacher induction programs thus enable new teachers to not just survive but also prosper during their first years of teaching and thereby provide an impetus for continuous development (Cole, 1994). The first years of teaching represent a period (1) of rapid discovery with a steep learning curve and often intense emotions (Huberman, 1989) and (2) in which new teachers typically decide to stick with the profession or leave it.

In this article, an overview of the different research perspectives on teacher induction is first presented. As seen, changing times mean changing perspectives. Special attention is then paid to the current goals of teacher induction, the elements of teacher induction programs, and those program elements that appear to be most effective. In closing, some issues that challenge us to treat teacher induction as a phase in the more long-term professional development of teachers are addressed.

A Brief History of Teacher Induction

In the 1980s, researchers began to publish about the problems of beginning teachers, and teacher induction was introduced as a distinct stage in the training of teachers (e.g., Evans and Tribble, 1986; Veenman, 1984). In numerous studies, the sudden and sometimes traumatic transition from student to starting teacher was described. Based on this growing body of knowledge, teacher shortages, and the alarming numbers of beginning teachers leaving the profession, the notion of teacher induction emerged. It is now known, for example, that not only teaching-related problems and salary considerations but also an experienced lack of support, lack of influence within the school system, feelings of isolation, and overly heavy workloads may prompt beginning teachers to leave the field.

From a research perspective, three shifts of attention can be distinguished in the evolution of teacher induction.

1. From the mid-1980s until the mid-1990s, the focus of teacher induction efforts was on the provision of that instruction-related support considered necessary to

successfully function within the classroom (Gold, 1996). The mismatch between the ideals or expectations of beginning teachers and classroom reality was often found to lead to feelings of uncertainty and/or inadequacy, thus having a considerable impact on the self-efficacy and professionalism of beginning teachers (Flores, 2004). The support provided for beginning teachers during this period in the development of teacher induction was largely based on a deficit model of teaching in which the focus was on the organization and management of instruction and development of instructional routines.

2. Starting in the mid-1990s, teacher induction was increasingly shaped by the adoption of a more integrated approach to the provision of support, the professional development of teachers, and teacher assessment. High standards for teaching and learning that were built upon school/university partnerships and a strong mentoring component that involves not only the provision of support but also the offering of challenges became part of teacher induction programs (Feiman-Nemser, 2001). Given the attention paid to the learning of beginning teachers during their first years of teaching, induction was quickly assigned a position along the teaching continuum and came to serve as a bridge between the initial training of teachers and their later professional development.
3. It is currently agreed that a teacher induction program is most meaningful when embedded in the school context and is part of a more general policy regarding the professional development of teachers. From such a perspective, new teachers are also expected to actively contribute to the development of schools, assumed to have much to offer, and thus taken to be in a position to also contribute to both the teaching profession and the field of education in general (Tickle, 2000). Stated differently, the induction of new teachers is increasingly becoming a part of the school as a learning community. It can be argued that in a well-developed learning community, the content and nature of many existing induction programs need to be reconsidered.

The teacher induction period was initially considered the new teacher's first year of teaching following qualification. In line with the aforementioned changes of perspective on teacher induction, the idea of a clearly delimited, 1-year period of induction was abandoned, and the professional development of teachers throughout their entire careers was taken to be critical.

In sum, the research perspective on teacher induction shifted across a period of two decades from a view in which beginning teachers are assumed to be the passive consumers of the knowledge and experiences of others (a deficit model of teaching) to a view in which beginning teachers are assumed to actively contribute to both, their

own professional development and the professional development of others (a growth model of teaching). This shift was undoubtedly influenced by a more general shift in our thinking about the role of teachers and teaching in contemporary society as new developments in society are known to affect the missions and goals of schools and thus the work of teachers. Just as for professionals in other fields, lifelong learning has become increasingly important for teachers and therefore a more explicit part of school policy. Nonetheless, the initial perspective on teacher induction still predominates in many schools today where new teachers are placed in the same teaching situations as experienced teachers and thus treated as experienced teachers but with a number of deficits.

The Goals of Teacher Induction

In teacher training today, considerably more opportunities for student teachers to practice and work as teachers in schools are provided than in the past. Such practice opportunities are assumed to reduce the so-called practice shock experienced by most beginning teachers (Gold, 1996). Following graduation, however, many new teachers still find themselves in a situation in which: (1) knowledge and skills pertaining to subjects that are different than the ones that they grew comfortable with during their teacher-training period are being tested, (2) the new teacher is given sole teaching responsibility, and (3) the new teacher must juggle often contradictory views of teaching practice (views imposed by the specific school culture, views created by his or her own personal expectations, and views arising from general teaching norms) (Beijaard and Papanaoum, 2002; Kelchtermans and Ballet, 2002; Tickle, 2000). For many beginning teachers, this stressful situation can result in a decision to leave the profession altogether or move to another – presumably better – school. Against this background, most school-based induction programs today can be seen to have not only a professional development goal but also a clear policy goal: investment in the retention of teachers who – with some assistance and within a relatively brief time frame – can be made into more effective teachers as opposed to investment in the relatively expensive enterprise of teacher replacement.

The professional development goal underlying teacher induction may be concentrated on the following aspects of teacher induction: improved quality of teaching (e.g., instruction and relations with students), personal-psychological support (e.g., confidence building and handling of stress), and development as a teacher (e.g., enculturation into the profession, meeting of personal needs, and positioning oneself within the school as a teacher and a colleague). Such an encompassing

professional development goal goes far beyond the maintenance of order, which most people find to be the primary concern of beginning teachers (Feiman-Nemser, 2003). The induction mandates in many countries also “do not rest on an understanding of teacher learning, a vision of good teaching or a broad view of the role formal induction can play in new teacher development” (Feiman-Nemser, 2001: p. 1031). In reality, new teachers are often placed in a sink-or-swim position, alone in their classrooms with little or no support from colleagues, little or no decision-making power, and very few opportunities for additional professional development. In other words, most teacher induction programs today still strongly resemble the first teacher induction perspective (see previous section). Given the conditions and physical circumstances of schools today, new teachers are often left to simply hope that they will survive the first years of teaching (Tickle, 2000).

Many of the people responsible for today’s teacher induction mandates consider a policy goal more important than a professional development goal. In many countries, about 30% of beginning high school teachers and about 25% of beginning elementary school teachers leave the profession within a few years of their start; such teacher attrition is considered wasteful. Despite an advanced education and often extended student teaching experience, the initial years following qualification as a teacher can strongly influence the remainder of the individual’s teaching career (i.e., the decision to remain in the field or not). Thus, it is assumed that teacher induction programs should clearly address this issue of teacher retention.

The Elements of Teacher Induction Programs

Teacher induction programs usually vary with regard to the degree of formality, structure, and intensity; that is, the comprehensiveness (how many activities and people involved), the coherence (extent to which program activities are logically connected), and the longevity (duration) of the programs can widely vary (Breaux and Wong, 2003).

Britton *et al.* (2003) further found comprehensive induction programs, in particular, to typically involve one or more of the following elements.

1. Close contact with a more experienced teacher (a mentor). Generally speaking, one can learn from the experiences of others. Assigning a beginning teacher to a mentor can produce more effective teaching during the early years because the new teacher can learn from guided practice and not just trial and error. However, Feiman-Nemser (2003) suggests that the mentoring of new teachers must be trained because

good classroom teachers may find it difficult to formulate the thoughts underlying their teaching, explain the principles underlying their work, and so on. Teacher mentors must respond to the here-and-now concerns of beginning teachers and also create learning opportunities and establish more long-term goals with these teachers, which mean that mentors receive maximum support for their induction activities within the school.

2. Relations with other beginning teachers (peers). Contact with peers allows beginning teachers to share their here-and-now experiences. Regular peer-support sessions further allow teachers to interact, cooperate, and search for solutions to problems within a safe environment (Portner, 2001). Such support sessions have been found to be particularly helpful for beginning teachers. Positive peer relations can also let new teachers feel that they are part of a community of practice and not operating in isolation.
3. Reflection, inquiry, and examination of oneself and others. It is widely acknowledged that a reflective stance, both personally and professionally, is important for the development of a teaching identity. Along these lines, growing attention is being paid to new teachers enquiring their own teaching practices as a means to professionally develop themselves (Gold, 1996; Tickle, 2000). Inquiry-based approaches are also very promising as they require the active construction of knowledge within a learning community and the connection of experienced-based knowledge to knowledge from other sources (e.g., literature, experts).
4. Observation of and by others. Observation of peers and other colleagues can produce new insights. New teachers can learn from the observation of good teaching practices modeled by more experienced colleagues. Conversely, being observed – usually by the mentor – and receiving formative feedback can highlight strengths and weaknesses or areas in need of development. Adequate feedback can strongly influence the professional development of teachers and beginning teachers in particular.
5. Timing and sequencing of opportunities. It is important that the learning opportunities of new teachers be systematically organized in a professional development curriculum. This pertains to topics to be addressed, relevant literature, and learning activities. In such a curriculum, the roles of the mentors, peers, and other colleagues should also be made abundantly clear.

Other elements that are found to characterize teacher induction programs are: an orientation to and meetings devoted to aspects of school functioning, time to release, reduced teaching loads, no assignment to difficult classes, opportunities to interact with colleagues, and a school leader who facilitates and encourages new teacher learning. Beyond the elements mentioned here and

above, which are usually of a more general character, it has recently been argued to pay greater attention to the specific subject-matter needs of new teachers and the achievement of a better balance between general and specific teacher needs.

In several countries, specific criteria and standards have been recently formulated for competent teaching. From a professional growth perspective, these criteria and standards can further stimulate a meaningful dialog between peers and mentors with regard to the essence of good teaching, the development of personal learning plans, self-assessment, and feedback (Darling-Hammond and Snyder, 2000). For example, regular assessment using such criteria and standards provides new teachers and their mentors with feedback on how things are going, what areas need work, and how much progress has been made (Feiman-Nemser, 2003). In some countries, such as the United Kingdom, specific criteria and standards are also being used for additional qualification purposes; they indicate that a new teacher has met the relevant induction standards at the end of what is usually the first year of teaching.

Critical Elements for Effective Teacher Induction

Numerous studies have documented the value of teacher induction programs. It is generally agreed that such programs improve the capabilities of beginning teachers and reduce attrition rates among new teachers (Fideler and Haselkorn, 1999). Beginning teachers seem to prefer informal methods of professional development in combination with teacher networking. The dominant theme with regard to the induction of new teachers, however, is clearly the mentor. Smith and Ingersoll (2004) found packages containing a combination of mentoring and group induction activities to show the most positive effects in terms of new teachers not going to another school or leaving the profession. In addition to this, having a mentor from the same subject field appears to be critical for effective teacher induction, which means that the development of a framework for the role of the mentor in teacher induction programs may be an important direction for further research.

However, there is no agreement on exactly which elements of induction programs are responsible for their effectiveness. Which elements really make a difference and which elements appear to hinder the implementation of these programs are still not clear. This lack of clarity may be just as much due to some limitations on the existing empirical research on effects of induction programs (Ingersoll and Smith, 2004). Among the limitations on the research to date are the following.

1. Absence of control groups. Not working with control groups in research on the effects of teacher induction programs makes it difficult to attribute particular outcomes to the induction program itself. For example, to be sure that the detected effects can be attributed to being observed and the receipt of feedback, it is critical that such beginning teachers are compared to beginning teachers working in a similar context but without observation and feedback.
2. No control for program-external factors. Factors other than those inherent to the induction programs might explain certain effects or their magnitude and should therefore be considered. For example, the teaching culture that already exists within a school can mediate the effects of an induction program. More specifically, teaching culture characterized by structural cooperation may contribute more positive experiences than a teaching culture characterized by individualism (Williams *et al.*, 2001).
3. Small-scale nature of the studies. The small-scale nature of most of the research on the effects of teacher induction programs makes generalization impossible or difficult at best. Most studies document the value of a teacher induction program for the teachers in a particular school or district, while the effects found in one particular situation need not generalize necessarily to another specific situation.

Future Challenges for Teacher Induction

Many current teacher induction programs lack a clear view of what constitutes good teaching and a professional development perspective on teaching, which could provide some guiding principles for the learning of not only new teachers but also all teachers. It is generally agreed that a mentor plays a key role in the learning of a teacher even after the teacher's first year, but continued professional development calls for additional measures and learning opportunities. For example, learning from teacher networks and, more generally, from being part of a community of teachers with shared school responsibilities (Garet *et al.*, 2001). Nowadays, many schools are developing explicit policies for the professional development of their personnel. As part of such policy efforts, schools will have to challenge the prevailing survival perspective with a new perspective on the professional development of beginning teachers – a perspective that emphasizes both personal and professional growth and also an active role of these teachers themselves in their professional development.

To promote a new professional development perspective on teaching in general and the induction of new teachers in particular, it is important that schools and teacher-training institutes cooperate. First, a comprehensive induction

program places a considerable demand on the experienced teachers in a school, while the experienced teachers often have only limited resources and capabilities when it comes to this demand. Teacher educators can then step in to meet the specific needs of the teachers in a school and perhaps the entire school community. A second reason for cooperation between schools and training institutes is to ground teacher induction not only in practice but also in general principles and theories to be provided by teacher educators, including certain learning activities that are hard to organize in a school (Britton *et al.*, 2003). In addition, an ongoing collaboration between teacher-training institutes and schools can promote the continued development of teachers as professionals. An obvious prerequisite for such collaboration is, of course, that both the schools and teacher education institutes agree upon the goals of the professional development process and the means to be used to realize these goals.

The cooperation between schools and teacher-training institutes with regard to the professional development of beginning teachers, in particular, is now and in the near future seen as one of the most important challenges facing teacher education policy. The amount of time and experiences needed to become a fully competent and effective professional are very much open to question. Furthermore, the cooperation between schools and teacher-training institutes will lead to new insights into what can be learned at the workplace and what cannot. At this moment, very little is known about which characteristics of the teaching context promote the professional development of teachers. Beginning teachers are spending increasingly more time in schools, meanwhile it is good to know that working and learning may involve opposing if not conflicting processes!

Conclusion

It is obviously in the interest of students that their teachers ought to be competent professionals. Research shows that teacher competency can influence student learning gains and study results. High teacher turnover constitutes a threat to student learning, because high turnover rates can create an unstable and less effective learning environment. High teacher turnover rates also impose heavy demands on the remaining teachers and staff within a school and can require considerable time and money for the recruitment, hiring, and training of replacement personnel (Halford, 1999). Taken together, all of these suggest that the adoption of high-quality induction programs as part of a more general growth perspective on the professional development of teachers may help turn the current school situation around and that everyone stands to benefit from such an investment in the end.

On the basis of existing empirical research, it is difficult to draw conclusions about the impact of participation

in a teacher induction program. Do beginning teachers really change or develop their teaching behavior as a result of participation in such a program? Do the changes prompted by involvement in a teacher induction program also influence student learning? The search for the answers to these questions calls for carefully controlled experiments and cohort studies of, for example, teachers during their induction period and thereafter. Studies such as these are needed in addition to those studies that have already documented the value of specific teacher induction programs.

Finally and regardless of which induction program, the teachers in a school and school leaders have been found to shape a beginning teacher's decision to stay or not stay in the field of education the most. The key to retaining teachers is what Breaux and Wong (2003) call belonging, which is a basic human need. Most new teachers want more than just a job. As part of a team and part of a culture, beginning teachers also want to contribute and make a difference. Recognition of the potential of new teachers to contribute to the education of students and utilization of this potential are, however, necessary. Under such circumstances, which also involve mutual trust and respect, more academically talented and very capable teachers would decide to stay in the field.

Teacher Learning as Workplace Learning

J Imants, Radboud University, Nijmegen, The Netherlands

Introduction

A central notion in theories of workplace learning is the intrinsic and mutual relationship between working and learning. In teacher learning as workplace learning, two themes come together: the content and organization of teachers' work, and the content and process of teachers' learning in the context of their classrooms and schools.

During the last two decades, workplace learning has been an important item in discussions on vocational education and professional development in industrialized societies. These discussions cover the broad field of economic and cultural developments, technological and organizational innovations, knowledge economy and knowledge creation, and professional development and vocational learning in schools and work organizations. In discussions on teacher learning, workplace learning is a significant item for at least two reasons. Workplace learning is assumed to be a promising method for the development of productive learning contexts in teacher education and continuing professional development. Professional learning of aspiring and practicing teachers is expected to result in competences for the teaching of their students as productive workers and as productive learners in their future workplace contexts.

In this article, teachers' workplace learning is defined as changes in teaching practices in classrooms and schools that are mediated through individual teacher learning and problem-solving processes in the school (Ellström, 2001). In the field of education, professional development is the generic term under which teacher learning activities and programs are organized and discussed. Teachers' professional development can be defined as those processes and activities designed to enhance the professional knowledge, skills, and attitudes of educators so that they might, in turn, improve the learning of students (Guskey, 2000). Recently, these activities and programs often build on workplace learning insights. This article aims to explore the relatively new field of teachers' workplace learning in classrooms and schools, as it builds on, and adds new insights to teachers' professional development in schools. The question is how and in what directions teacher learning can be promoted in the context of work in classrooms and schools. First, the state of the art in teachers' professional development is briefly characterized. Next, recent general insights in workplace learning in combination with insights in teachers' workplace learning is discussed.

Teachers' Professional Development

Teachers' professional development literature shows a range of insights regarding views of learning (acquisition vs. constructivism), designs (fragmented vs. ongoing and systematic), and opportunities (formal and informal, mandatory and voluntary, serendipitous and planned). The lifelong curriculum of teachers' professional development seems fragmented and incoherent.

The rationales for professional development also diverge considerably. A first rationale argues that most educational reforms require a great deal of learning on the part of teachers. Teachers need support and advice to understand the reform and work according to the reform. A second rationale starts from the nature of teachers' work. Teachers play a crucial role in students' learning, and professional development of teachers is assumed to be in the interest of the students and teaching as a profession. The first rationale assumes that teachers show personal inadequacies in need of repair, while the second rationale assumes that teacher learning contributes to fulfillment as a practitioner in support of students' learning.

Attention is increasing for teacher learning and teacher professional development programs situated in the workplace in contrast to off-site programs. These off-site activities entail workshops, conference sessions, seminars, lectures, and other short-term training events on subject-matter issues and topics such as cooperative learning and classroom management. Design elements and conditions that can enhance the effectiveness of these activities are longer duration, connection with teachers' work context, focus on subject matter, and emphasis on analysis and reflection (Smith and Gillespie, 2007). By identifying these design elements and conditions, it is a small step toward recent on-site professional development methods that are embedded in daily work in classrooms and schools. These work-embedded methods include training within the school or local context, and creating ongoing professional communities, study circles, and inquiry groups. In addition to this, workplace learning has brought about a shift:

- from a focus on individual teacher knowledge, skills, and teaching competencies, including new instructional methods, to a focus on student learning and specific teacher problems;
- from off-site to on-site activities;

- from single sessions or a short series to long-term and ongoing sessions; and
- from a focus on change as something that is done to teachers, and programs that change teachers as passive participants, to change as a complex process that involves learning with teachers as active learners.

As far as research has been conducted regarding the effectiveness of learning activities that are embedded in daily work, it shows that teacher learning is promoted by a focus on subject-matter knowledge for teaching, understanding of students' thinking, and instructional practices. Further, the process of meaningful learning is slow and uncertain, and some elements of teacher knowledge are easier to change than others. It takes time to develop a community. Teachers have little experience engaging in a professional discourse that is public and critical of their work and the work of colleagues. Finally, it should be noted that combining features of off-site and on-site activities in professional development programs seems to be very effective (Little, 2006; Smith and Gillespie, 2007).

In general, several methods for workplace learning have been developed (coaching, supervision, and collegial consultation; mentoring and master–mate learning; development tasks and action research; and instruction and application in the workplace). These methods have been applied to (student) teachers' professional development in schools. Besides, new methods for the evaluation of (student) teachers' competences and learning are developed and applied (assessment instruments and portfolio). A recurring problem in teacher professional development is the gap between practice (school) and theory (university), and a central aim of these methods for workplace learning is to contribute toward bridging this gap. However, according to Eraut (2000), the problem of the theory–practice gap concerns the relationship between the codified professional knowledge (espoused theory) that is developed and taught at universities, and tacit teachers' knowledge (theory-in-use) that is developed and transmitted in classrooms and schools. Bridging the theory–practice gap cannot be reduced to mutual adaptation of these sources of knowledge. Sound application of one or more of the aforementioned methods is not sufficient to link espoused theory and theory-in-use, because the problematic relationship between these diverse bodies of knowledge has deep epistemological and (micro-)political roots. Besides, the effectiveness of these methods depends on the conditions of the workplaces in which they are applied, which is discussed in the next sections.

Despite an increasing body of knowledge on design elements and conditions, there is very scarce empirically tested knowledge about: (1) the effectiveness of teachers' professional development programs, and (2) more in

detail, about what teachers learn, how they learn, and how this knowledge improves their practice. The current state of practice and research of teachers' professional development is inadequate (Borko, 2004), and this constitutes a serious problem for policy, practice, and research. This does not mean that the design, learning principles, and beliefs of many programs are unreasonable or unsound (Wilson and Berne, 1999).

In summary, the literature on teacher professional development in schools shows a shift toward workplace learning, though at the same time a lack of theoretical and empirical understanding is observed. In the next sections the analysis of teachers' professional development is broadened by taking the mutual relationship between teachers' working and learning as the starting point.

Perspectives on Workplace Learning

The identification of professional development in workplace contexts depends on the perspective from which learning is analyzed. Generally, perspectives on workplace learning differ with regard to goals, outcomes, rationales, and managerial views. Workplace learning varies from adaptive to developmental, in terms of tasks, methods, and results, which are given or not given (Ellström, 2001). A broad range of possible learning outcomes for teachers in the workplace can be found, ranging from habitual reaction to reflective practice, and inquiry (Smylie, 1995). Four perspectives on teachers' workplace learning are distinguished (Nieuwenhuis and van Woerkom, 2006):

1. In teacher education settings, workplace learning primarily is regarded as preparation for working, and qualification is the goal. This perspective plays an important role in studies of on-the-job training in initial teacher education.
2. In ongoing work settings in schools, teachers' workplace learning is regarded as contributing to productivity of schools, often as nonformal learning and as an intrinsic quality of professional work. Development of routines is important in this perspective, besides development of improvements during the performance of work activities. This perspective can be helpful to understand the dynamics and outcomes of teacher induction and socialization.
3. In global market and knowledge economy settings, teachers' workplace learning is closely linked to the vitality of the school, school improvement, and to educational reform.
4. In the individual perspective, teachers' workplace learning is regarded as learning for life and individual professional development in community contexts.

Teachers' Workplace

Teacher learning is located in diverging contexts within the school. Three interrelated levels are distinguished:

1. individual or personal learning by teachers or school leaders within the context of the school;
2. social learning in small groups or teams of teachers; and
3. learning that occurs across the school organization as a whole.

According to Mitchell and Sackney (2000), it is the interrelatedness of conditions and processes at these three levels that explains successes and failures in school improvement and shared learning.

Formally, the school as a workplace consists of diverging units that are charged with diverging tasks and responsibilities. Informally, the school contains several spheres of influence and interaction. For teachers, the work with students, inside and outside the classroom, makes up the core of their work. Opportunities to enhance students' learning are the driving force for teachers to participate in professional development. For the large part of their working day, teachers work individually with (a) group(s) of students, rather isolated from their colleagues. The most meaningful work experiences that promote teachers' workplace learning is therefore gained in the work with students, in the student-related work with colleagues, and in the interactions with the workplace conditions that are closely linked to the work with students and colleagues – the community of practice in which teachers participate. Teachers' workplace learning is expected to be primarily located in the teachers' own sphere of influence and interaction, and in the units in which the work with students is organized. School conditions and processes that are located in the administrators' sphere can be assumed to affect teacher learning processes and results in an indirect way, more specifically, as mediated by processes of reinvention and reinterpretation by teachers in their own sphere. For example, an educational policy document of a school or district will not influence teachers' professional development directly. Depending on how teachers interpret the school's educational policy, this document will affect teacher learning indirectly in foreseen and unforeseen directions.

Workplace Conditions in Schools

The educational systems in industrialized countries are characterized by restructuring and standardization of work in schools, aimed at improved student learning and the promotion of a new professionalism in the teachers' profession. Simultaneously, tendencies of

bureaucratization and intensification in schools and teachers' work have been identified (Ballet *et al.*, 2006). It can be assumed that restructuring and standardization, combined with bureaucratization and intensification, will have significant and contradictory impact on the content, processes, and effects of teachers' workplace learning in schools. This actual impact can be opposed to the formal aims of reform. This complex relationship between working and learning is elaborated in this section.

In his review of general workplace learning research, Ellström (2001) distinguishes five groups of factors that can be assumed to be critical for facilitating or constraining the integration of learning and work: (1) the learning potential of the task; (2) opportunities for feedback, evaluation, and reflection on the outcomes of work actions; (3) formalization of work processes; (4) employee participation in handling problems and developing work processes; and (5) learning resources. These general factors reasonably summarize the results of overviews of workplace learning conditions in schools, with the exception of one group of factors. Schooling is a strongly moral and normative enterprise, and in overviews of workplace conditions for teacher learning, shared norms are often mentioned as a critical factor. Shared norms are added as a group of school factors to Ellström's general overview.

Learning Potential of the Task

Generally, task complexity, variety, autonomy, and control are regarded as important determinants of the learning potential of the workplace. Traditionally, teachers' work is viewed as complex, varied, and autonomous. Superficially, the school seems to be a favorable context for workplace learning. However, studies on intensification show tendencies of deprofessionalization in teachers' work, starting from a combination of narrowing and formalizing the traditional teaching tasks, and simultaneously adding new nonteaching tasks to teachers' work. These developments are accompanied by experiences of strong work pressure and negative emotions. Further, work redesign and task differentiation in schools only have weak links to aspired forms of teacher learning and student learning. To be an effective workplace learning strategy, redesign of work should focus attention on crucial problems of curriculum and instruction.

Teachers strongly depend on routines because they make an enormous amount of decisions each day they work (Eraut, 2000). Teachers' actions can be described as routinized when they no longer need to think about what they are doing because they have done it so many times before. In routinization, explicit knowledge is converted to tacit knowledge through repetition. Besides individual schemata, routines also are collective schemata for both understanding and acting: they supply teachers with shared understanding of who is doing what, and this

understanding allows teachers to correctly perform a practice. External and internal pressures can force teachers and schools to change their routines. Routines may restrict school's responses to change, but they can also help the school to survive changes in environmental demands and expectations (Hoeve *et al.*, 2006). Routines in teaching tasks have the potential to be impediments and opportunities for workplace learning.

Opportunities for Feedback, Evaluation, and Reflection on the Outcomes of Work Actions

Feedback on the results of work activities is considered to be necessary for learning to occur. Activities in which teachers reflect on student performance, work, and thinking can promote professional development. The effects of feedback can be cognitive as well as motivational. The function of feedback depends on the existence of clear goals. At the level of classrooms and schools, educational goals often are vague or inconsistent, and they can change during teaching. The problem of getting clear feedback on student performance because of unclear goals can be an obstacle for teacher learning in contexts where instructional tasks, methods, and results are given. However, inconsistent or unclear goals may promote analysis, evaluation, and reflection that are assumed to be important for innovative teacher learning.

In schools, much information is available that could serve as feedback and promote reflection on the quality of teaching and learning, for example, school self-evaluation reports, reports by the inspectorate, files of student assessment outcomes, aggregated student test results, and teachers' accounts of classroom experience (Little, 2006). Systematic use of this data on student performance, work, and thinking as sources for learning by individual teachers and teacher teams hardly occurs in schools.

Formalization of Work Processes

The daily educational and pedagogical practices in the school are important opportunities and constraints for teacher learning. This learning is focused on subject content, pedagogic and instructional methods, and classroom management (Scribner, 1999). Traditional forms of formalization (fixed regulations and procedures) of daily work processes in schools still tend to dominate instruction, classroom management, and organization in schools. For example, a persistent problem in education is the limited flexibility to deal with student diversity in schools and classrooms, notwithstanding inclusive aims. Moreover, images of how schools and classrooms should be structured and should function, as well as daily practices, build on traditional scientific management principles. A gap is existent between the innovative expectations on workplace learning in schools, and the highly

formalized instructional practices of aspiring and practicing teachers as contexts for learning.

However, starting from the observations that work in schools is routinized and that the daily knowledge base of teachers is strongly tacit, a process of formalizing instruction and guidance practices can also contribute to teacher learning. Formalization of instruction and guidance can serve as the starting point for questioning existing instructional routines and making the tacit explicit and open for discussion. In that case, the aim is teachers getting a better understanding of (1) what and how their students learn and think, and (2) how student learning is promoted by teachers' instruction and guidance. This learning by formalization should not be confused with simply replacing an old instructional method by a new one (Smith and Gillespie, 2007).

Teacher Participation in Handling Problems and Developing Work Processes

Learning is facilitated if teachers have access to and are able to successfully participate in problem handling and activities aimed at the development of improvements in instruction and guidance, both formally and informally. Teachers share positive perceptions of participation in decision making in schools with regard to instructional, pedagogical, and curricular topics, as opposed to administrative topics. Teacher participation in decision making can create frustration, anger, and distrust, when the implementation of decisions that were made is blocked or not promoted by school management. Teachers should be able to participate in all the steps of the cycles in which improvements are developed: planning, development, performance, and evaluation. When the majority of teachers is only expected to perform instructional tasks that are planned, developed, and evaluated by teacher leaders and managers, learning will decrease.

Teachers' collegial interactions vary in task interdependence and alignment (synergy in directions of aims and actions of different actors). High alignment and interdependence, for example, in the context of joint problem solving, are associated with richer and more stimulating learning environments for teachers. This collaboration can produce shared understanding and investment, thoughtful development, and a fair, rigorous test of selected ideas. Lower levels of interdependence and alignment occur when teachers exchange stories, tips, or materials. This can result in reinforcement of and emotional support for maintaining routines (Rosenholtz, 1989).

Shared Norms

Shared norms that affect teacher learning in the workplace can be distinguished in two types: norms regarding student learning and development, and norms

regarding teachers' work and relationships with colleagues. Collective focus on and shared responsibility for student learning are identified as important characteristics of teachers' professional communities in schools. The absence of a shared conceptual and technical language or a common technical culture in schools has been assumed to be a serious hindrance for the development of these shared norms. However, precise analysis of teacher professional conversations shows that too deep a skepticism on the opportunities in schools for developing shared norms oversimplifies and underestimates the potential of teachers' collegial practices for teacher learning (Little, 2006).

Isolation from colleagues has a negative effect on teacher learning by creating invisible walls between teachers and diminishing the valuable role of collaborative activities (Scribner, 1999). This individualism, in which personal experience plays a central role, is regarded as a defining feature of the teaching profession. Strong traditional cultures are based on teachers collectively defending this individualism and existing conceptions of appropriate curriculum and instruction, even in the face of student failure. Besides, strong innovative and professional cultures can contribute to norms of collegiality and experimentation.

Learning Resources

Three resources for workplace learning are teachers' prior knowledge, curricular and instructional materials, and time. Teacher learning by experience presupposes conceptual tools (e.g., pedagogical content knowledge) and explicit knowledge about student learning and how student learning is promoted by instruction and pedagogic methods. These conceptual tools and knowledge are used to identify and interpret relevant experiences while teaching, and they play an essential role in workplace learning.

Varied sources of instructional and curricular materials promote reinvention of instructional practices and lower barriers for experimentation. These practical materials provide opportunities for teachers to experience what works in daily classroom practice. However, when implemented superficially, the availability of the same sources bears the risk of counterproductive learning effects, because the anticipated student learning results are not realized in the case of superficial implementation.

Time is an important resource for participation in formal learning activities, as well as for reflection as part of the ongoing work process, especially in combination with related factors, for example, school schedules. Professional development activities should be conducted often and long enough to ensure gains in knowledge, skills, and confidence. Formal availability of time for professional development is necessary but not sufficient

as a resource for teachers to learn. Meaningful and time-consuming collaboration is often squeezed to margins of teachers' worklives (on Sunday afternoons or weekly evenings in teachers' houses). Daily work in schools should be scheduled and organized in such a way that teachers have a fair chance to take advantage of the time available for learning and development. Without these organizational protections, time for learning will disappear under the pressure of chains of incidents and daily routines. A complex trade-off occurs between time for production and time for learning in schools (Ellström, 2001).

Conclusions

Before presenting the conclusions, it should be noted that many of the insights presented in this article lack a solid base of research, although some research had been done on these topics. The field lacks an explicit shared conceptual language, and empirical research often is lacking the rigor that is needed for generalizations. Nevertheless, some tentative conclusions can be drawn from the previous analysis.

Summarizing the evidence, two perspectives on teachers' workplace learning and work-embedded professional development can be distinguished. These perspectives vary in assumptions on manageability and predictability of learning processes and outcomes in workplace contexts. In one view, teacher workplace learning is a specific activity that can be managed in the direction of formalized school outcomes and desired change. In the other view, teacher learning outcomes range from improvement in school performance to counterproductive effects on teaching and student learning. In this latter view, teacher learning is emergent, and steering opportunities for management to intervene effectively in this process are weak. An unanswered question is whether these perspectives are complementary or contradictory toward each other.

Several potentially effective methods for workplace learning have been identified. The effectiveness of these methods should be regarded within the specific workplace contexts in which they are applied, and keeping an eye open for the conflicting epistemological assumptions of the diverging bodies of knowledge (espoused theories and theories-in-use) that they try to unite.

Six factors have been identified for the integration of teachers' working and learning in schools. Usually, these factors are regarded as objective characteristics of the schools in which they emerge. However, it can be assumed that the impact of these factors mainly is located in how they are interpreted and reinvented by teachers, and how teachers make sense of these factors in their daily work. The relationships between these factors and teacher learning are complex and paradoxical. These factors

play a multidimensional role in teacher workplace learning: they potentially promote opposite directions of learning (reinforcing routines or promoting innovations) and they can have opposite side effects on teacher workplace learning (commitment or isolation, empowerment or alienation, etc.).

Traditionally, teachers have been regarded as passive participants in professional development and workplace learning programs, lacking knowledge and skills. Of late, teachers are more often regarded as active learners, and as agents in co-determining their working and learning goals, contents, processes, and outcomes. In this respect, the six factors for the integration of working and learning in schools also should be regarded as co-determined by the teachers themselves. Starting from insights in sense-making in organizations and schools, all aspects of working and learning in schools can be regarded as part of an ongoing process of reinvention and reinterpretation by teachers and other agents in and around the school.

Generally, high-commitment, flexible, and learning-intensive work systems are assumed to promote the integration of learning and working, but scientific management principles still tend to dominate the design of many workplaces (Ellström, 2001). The same phenomenon seems to hold for schools. Rosenholtz (1989) distinguished learning-enriched and learning-impovertished schools. Rosenholtz and other researchers found far more learning-impovertished schools than learning-enriched schools (Little, 2006). Workplace learning in schools has potential advantages, like facilitated transfer of learning, accommodation of different needs and learning styles, ability to tap collective knowledge, and the natural promotion of collaboration and school renewal. But there are also potential problems in workplace learning. Not all learning at work is good, as is shown by negative lessons learned by (student) teachers, reinforcement of existing biases, and refinement of poor practices (Bredeson, 2003). Moving all learning to the workplace might create too heavy a burden on the workplace. Effective professional development in schools implies the search for a productive balance and creative swing between adaptive and innovative varieties of individual and organizational learning, and on-site and off-site learning.

Teacher Learning with Lesson Study

A Murata, Stanford University School of Education, Stanford, CA, USA

Introduction

Lesson study is a collaboration-based teacher professional development approach that originated in Japan (Fernandez and Yoshida, 2004; Lewis and Tsuchida, 1998; Stigler and Hiebert, 1999). When it was first introduced in the United States in the late 1990s, it quickly gathered the attention of the US educators as it was thought to be an adoptable and effective innovation (Choksi and Fernandez, 2004; Lesson Study Research Group, 2007; Lewis *et al.*, 2004; National Research Council, 2002; North Regional Educational Laboratory, 2002; Richardson, 2004; Stepanek, 2001, 2003; Wilms, 2003). Lesson study incorporates effective characteristics of other professional development programs identified in prior research. It is site based, practice oriented, focused on student learning, collaboration based, and research oriented (Bell and Gilbert, 2004; Borko, 2004; Cochran-Smith and Lytle, 1999, 2001; Darling-Hammond, 1994; Wang and O'Dell, 2002; Little, 2001; Hawley and Valli, 1999; Wilson and Berne, 1999). Lesson study was also one of the foci for the International Congress on Mathematics Education (ICME) Ninth Conference in 2002 and has spread in many other countries (Fujita *et al.*, 2004; Lo, 2003; National College for School Leadership, 2004; Shimizu *et al.*, 2005). Despite the rapid rate of adoption, this form of professional development is still new in countries other than Japan, and thus schools and teachers in these countries are still at the early stage of adopting the innovation to their existing systems. There is an emerging body of lesson study literature, but we do not yet have a coherent and shared understanding and model of teacher learning with lesson study. The purpose of this article is to give an overview of lesson study with its structure (and variation), its history, and emerging lesson study research literature, in order to explicate teacher learning models in lesson study as well as to identify future research agenda with lesson study.

Lesson Study: History, Structure, and Variation

Lesson study is an instructional improvement approach that places teachers in the center of professional activity, with their interests and desire to better understand student learning. The idea is simple: teachers come together with a shared question regarding their students' learning, plan a lesson to make this student learning visible in

practice, and examine and discuss what they observe. Through the process, teachers have multiple opportunities to discuss student learning and how their teaching affects it. Lesson study typically follows the steps outlined in **Figure 1**, with a research lesson (live lesson observation) as a centerpiece of the study process (Fernandez and Yoshida, 2004; Lewis, 2002; Lewis and Tsuchida, 1998; Murata and Takahashi, 2002; Wang-Iverson and Yoshida, 2005).

After identifying a lesson goal, teachers plan a lesson. They will take a certain teaching approach to make student learning visible, keeping their lesson goal in mind. The main purpose of this step is not to design a perfect lesson but to test out a teaching approach in the lesson context to investigate how students learn. As they anticipate students' possible responses and craft the details of the lesson in a certain way, teachers learn the key aspects of the lesson, how students may possibly respond to these aspects, and the different thinking and reasoning behind the possible responses. Teachers will then focus on the particular student thinking in the lesson, take notes on different student approaches, and, after the lesson, discuss the data they have collected in a debriefing. While there are other professional development programs that incorporate many of the characteristics of lesson study (e.g., action research and teacher research), what sets it apart from others is the live research lesson. As discussed in the section below, research lessons create unique learning opportunities for teachers compared to other forms of professional development.

In Japan, lesson study has been widely used in schools for over a century, and many Japanese educators attribute success in changing their teaching practice to lesson study (Lewis *et al.*, 2006; Shimizu *et al.*, 2005). Any new educational approaches introduced in Japan are examined by teachers using lesson study as a foundational mechanism to support the improvement of teaching and better understand in practice. In many cases, teachers assume the main role in making the new approaches adoptable, and thus the approaches become more practical and understandable. Thus, lesson study works effectively to connect theory and practice in Japan. After the Third International Mathematics and Science Study, Stigler and Hiebert (1999) introduced lesson study to the US audience. Since then, lesson study has spread throughout the United States, and now over 400 schools are currently involved in lesson study (Lesson Study Research Group, 2007). It has also attracted the attention of an international audience, and there have been more than a dozen international

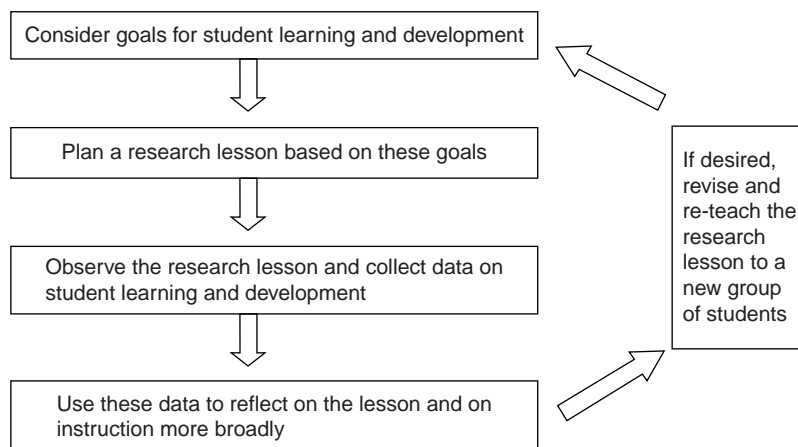

Figure 1 Lesson study cycle.

conferences and workshops around the world for people to share their experiences and progress with lesson study (Fujita *et al.*, 2004; Conference on Learning Study, 2006).

While lesson study is known in the United States (and other parts of the world) for a small, school-based collaboration typically in the subject area of mathematics, lesson study comes in many different shapes and sizes in Japan. There is a small, school-based lesson study as well as a larger-scale national-level lesson study (Murata and Takahashi, 2002; Lewis and Tsuchida, 1998; Shimizu *et al.*, 2005). For a large-scale and national-level lesson study in Japan, teachers often travel long distances to participate, and hundreds of people gather for one event. For a middle-scale and district-level lesson study, teachers may come together for a district's professional development day for which they have a list of choices of lessons with different grade levels, subject areas (Lesson study research conducted outside of Japan has primarily been focused on mathematics so far, therefore the chapter reports findings from these studies on mathematics instruction, however, lesson study may be used for all subject areas.), and topics to attend. These different kinds of lesson study meet different needs and interests of the teachers. While a small-scale and in-school lesson study is effective for teachers to improve their teaching for students of a particular community, where teachers share knowledge of the students and the community, a large-scale lesson study is important when a new educational approach (e.g., problem-based math instruction and collaborative learning) is introduced, and teachers across different schools are trying to make sense of what that means in their classrooms. Lesson study provides an opportunity to present a visible example of a new idea for teachers to discuss, ask questions, and come to construct a shared understanding of the new idea. Different forms of lesson study provide different learning opportunities for teachers.

Teacher Learning Models with Lesson Study

Teacher Learning

For decades, educational researchers have sought to understand what teachers learn and how teachers' learning translates into improvement of their teaching (e.g., Cohen, 1990; Franke *et al.*, 2001; Fuller, 1969; Fuller and Bown, 1975; Sherin, 2002; Shulman, 1987, 1996; Wood *et al.*, 1991). These questions are enormously challenging because of the intricate dynamics among teaching practices, beliefs, and knowledge (Sherin, 2002; Smith, 2000; Thompson, 1984), the many types of knowledge (of content, students, and curriculum, pedagogy) entailed in teaching (Shulman, 1987; Ball and Bass, 2000), and the limited transfer from many traditional forms of teacher education (e.g., lectures on content) to one's own practice (Ball and Bass, 2000; Ball and Cohen, 1996; Remillard, 2000). Teaching is a system, and changing one part of the system may not change the whole in the long run, since other parts will work to maintain the original function of the system (Stigler and Hiebert, 1999). Research and theory suggest that changes in teaching practice may be facilitated by opportunities for teachers to analyze familiar teaching practices in depth, make connections between familiar and new practices, and understand the changes needed in each part of the system of teaching in order to create an overall change (Franke *et al.*, 2001; Sherin, 2002; Smith, 2000). Professional development contexts that enable reexamination and reorganization of existing ideas – rather than simple acquisition of new ideas – may be most effective in changing teaching practice.

In considering the helpful context for learning of mathematics for teaching, Ball and Bass (2000) discuss a big challenge for which teachers are required to integrate across many kinds of knowledge, with this integration occurring in the context of particular teaching situations.

Since situations are classroom specific, the unpredictability makes it difficult for teachers to act on the spot. Focusing on student ideas in lessons and flexibly understanding what they mean, where they come from, and how to guide them to the goals set for the lesson requires the integration of the knowledge of students, content, and pedagogy. Curricular materials themselves do not readily present the richness of the mathematical ideas behind topics, nor do they help teachers gain the sufficient mathematical content knowledge necessary to teach the topic (Ball *et al.*, 2005; Remillard, 2000). Helping teachers learn the mathematics they need to know, and supporting them in understanding the connections between the particular knowledge with student learning and pedagogy, is key to teachers' learning and development. Lesson study allows teachers to focus on a specific topic and classroom context so that they can make sense of the meaning of the experience in their everyday teaching. However, their learning does not end there. What teachers learn in lesson study extends further than their immediate professional development context.

Teacher Learning with Lesson Study

Three-part teacher learning model

In examining the development and adaptation process of lesson study in the United States, Lewis *et al.* (2006) identified critical research needs, one being explication of the innovation mechanism. In order to understand how

lesson study supports instructional improvement, we need to better understand what happens with teachers in its process. Initially in the United States, people were interested in the curricular resources (e.g. lesson plans) teachers produce as results of lesson study to improve instruction. While that was a reasonable expectation, after several years of lesson study effort, we are now in a better position to understand that in the area of supporting instructional improvement, lesson study helps produce a lot more than mere lesson plans. Murata *et al.* (2004) suggest areas that develop and interact to support teacher learning in lesson study, and the modified model is shown in **Figure 2**. The three broad areas are teachers' knowledge, teachers' commitment and community, and learning resources (see also Lewis *et al.*, 2006).

As Fernandez (2005) also mentions in her study, lesson study provides opportunities for teachers to develop their pedagogical content knowledge. As different types of knowledge (e.g., knowledge of content, curricula, and student learning) essentially come together and interact with one another in the lesson study cycle (**Figure 1**), it creates an ideal context for which teachers combine these types of knowledge to make content accessible to their students. While different types of knowledge are typically learned in different settings by teachers in traditional professional development approaches (e.g., attending a lecture on math content and reading a book on classroom management), lesson study requires them to come together and work interdependently to support student learning in

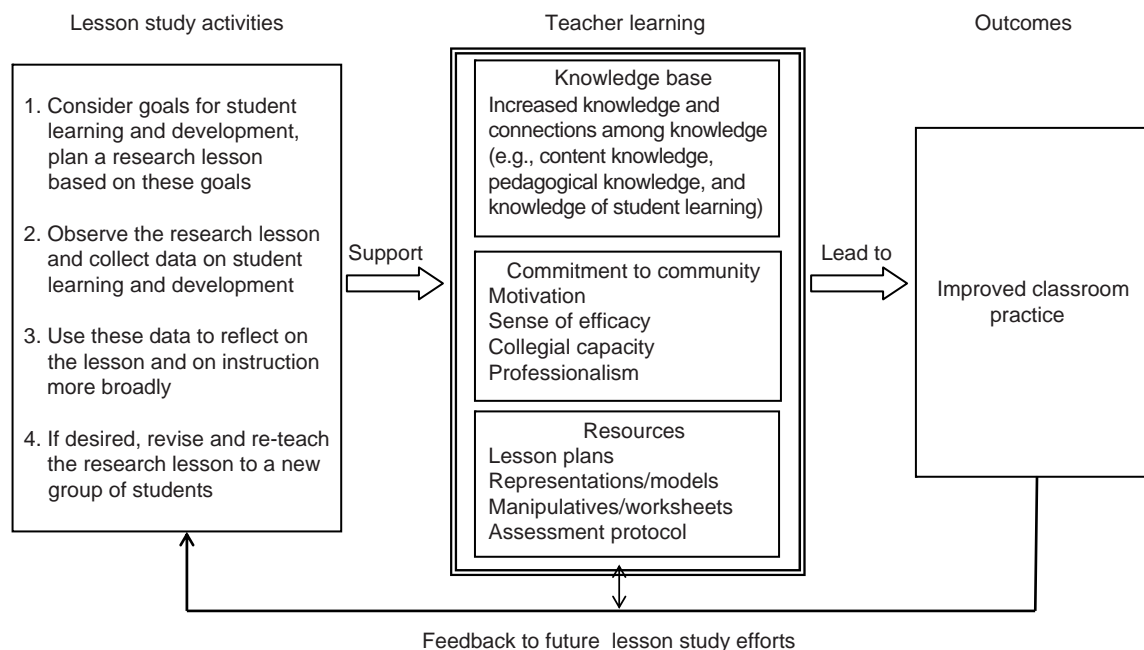

Figure 2 Lesson study activities, teacher learning, and outcomes. Modified from Murata, A., Lewis, C., and Perry, R. (2004). Teacher learning and lesson study: Developing efficacy through experiencing student learning. In McDougall, D. (ed.) *Proceedings of the Twenty-Sixth Annual Meeting of North American Chapter of the International Group of the Psychology of Mathematics Education*, pp. 985–992. Columbus, OH: ERIC Clearinghouse for Science, Mathematics, and Environmental Education.

the very practice of teaching, thus helping teachers experience different types of knowledge in a coherent and related whole.

Development of knowledge and connections among different types of knowledge support, and are supported by, the communities teachers create through lesson study. While teaching is considered as an independent practice in the United States and elsewhere, lesson study brings teachers who are otherwise isolated in their school structure to come together and work collaboratively. It is likely that teachers who teach similar content to similar students will have similar questions and issues about teaching. When these teachers gather and share their ideas and resources, a meaningful learning community is created, and the sense of belonging and professionalism developed in the community helps teachers to commit to their profession and motivates them to continually improve their practice (Grossman *et al.*, 2001). For the teachers who collaboratively plan a research lesson, the process helps to add purpose to their everyday work. Their everyday life is experienced as a part of the larger professional endeavor among colleagues and a purposeful activity for which different events in the process have reasons for happening.

Most obviously, the development and improvement of learning resources is a part of the lesson study process. Teachers' knowledge development and professional community growth interact with the development of resources (e.g., lesson plans), and as the resources are refined and improved, they provide a meaningful context for teachers to discuss student learning and to focus on the lesson. Just as young students find it helpful to have hands-on manipulatives to develop mathematical concepts, lesson plans become concrete scaffolds for teachers to focus their attention and learn about the specific content area in discussion.

The three areas (knowledge development, community development, and material development; **Figure 2**) are essential for instructional improvement with lesson study to support teacher learning. Many professional development programs aim only to help teachers develop knowledge for teaching. While the single-focus approach is effective in certain ways, when considering the sustainability of professional growth and teacher motivation, the three-part teacher-learning model identifies the interactive relationships among different areas of the model.

Focus on student learning

When it comes to mathematics teaching and learning, the new reform requires teachers, as they practice in classrooms, to balance and juggle existing knowledge of students, content, curriculum, and pedagogy while incorporating new ideas to make the practice more conceptually strong and student centered (National Council of Teachers of Mathematics, 2000). Teaching is viewed as an interactive process for which student learning and mathematics content

come together through effective teacher facilitation. The interactive teaching requires teachers to know how students typically think and express their understanding so that teachers can effectively facilitate their learning by weaving different ideas and providing experiences that encourage connection building among concepts and ideas. What binds different parts of the lesson study cycle is student learning, as teachers identify goals in terms of student learning of a topic, investigate curricular materials that teach the topic, plan a lesson to make student learning visible in the classroom with the topic, gather data in the lesson, and, afterward, discuss the student learning that occurred during the lesson. Teachers typically become increasingly knowledgeable about the particular topic (content) and student learning of the topic in the process, and learn to listen to their students' ideas.

One of the most important aspects of teacher learning that emerges from the lesson study process is the new way to see teaching as a series of activities of inquiry around student learning. It helps cultivate the new attitude toward teaching, that teaching is not a one-way and didactic path, but a two-way integration of student ideas and content in a meaningful manner facilitated by teachers, and that can be challenging. The strong focus on student learning in the lesson study process continually reminds teachers how important it is for them to understand students' ideas in good teaching and helps bring the visions of reform closer to their actual classroom practices.

Overcoming the challenges of adapting lesson study

The Columbia University Teachers College Lesson Study Group presented several US lesson study cases and identified central characteristics of the participation that limited teachers' learning. When working with Japanese colleagues, the US teachers were challenged to find a strong research focus and to stay with the research process with lesson study (Fernandez *et al.*, 2003). The US teachers also struggled with developing a meaningful research hypothesis, developing means to explore the hypothesis, using evidence to make claims, and generalizing the findings. In another study for which the US and Japanese teachers were interviewed about their lesson study experiences, the researchers found that the US teachers were more likely to describe content goals (e.g., learning how to add fractions) in disconnect to other goals (e.g., student disposition) and focused heavily on what teachers do in lessons and not on student discovery and autonomy (Fernandez and Cannon, 2005). Fernandez also investigated how teachers took advantage of learning opportunities that were created by lesson study (Fernandez, 2005), and, in the study, the lack of strong mathematics content knowledge and reasoning skills kept the teachers from taking full advantage of the opportunities to learn. However, the author also describes how the teachers in the

study collaboratively anticipated and discussed their students' thinking, revised and taught a lesson multiple times, and reflected on particular aspects of student thinking of mathematics that supported their learning as teachers.

One of the strengths of lesson study is that it places teachers in the middle of their learning process. In order for teachers to take full advantage of the opportunities, it requires them to have a research-oriented and inquisitive disposition. However, if the teachers do not have the prerequisite, the disposition can be gradually developed through participating in the lesson study process. Opportunities provided through lesson study support teachers to develop knowledge and research skills and engage in their future lesson study in more effective and meaningful ways. While it will take longer for beginning lesson study participants to learn to refine the critical research process, in most cases, these teachers will become familiar with the expectations by their second or third lesson study experiences. In the meantime, the sense of community and new professionalism will keep the teachers motivated. Thus, these challenges found in the case studies mentioned above should be considered the necessary learning steps for teachers who are beginning to see teaching as a research process for the first time.

Research Lesson: Centerpiece of Lesson Study

As mentioned previously, the research lesson is central to the lesson study process. In surveying 125 Japanese teachers, Murata and Takahashi (2002) found that teachers identified the research lesson as the most important element of lesson study that helped their professional development. Through research lessons, teachers could see models of teaching and make sense of how these models affected student learning. The research lesson works to improve classroom practice, spread new content and approaches, connect classroom practice to broader educational goals, and explore conflicting ideas, thus creating demand, shaping national policy, and honoring the role of classroom teaching (Lewis and Tsuchida, 1998).

Research lessons are observed live, and they provide a special learning opportunity that teachers would not find otherwise. Unlike watching a video segment of classroom teaching or reading teaching episodes in books, live lessons are experienced as a whole. Different events unfold as the lesson flows with interactions among people in the classroom. These events cannot be understood by the analysis of separate parts of the whole alone (Davis and Summitt, 2003; Herbst, 2003). Classrooms are complex, and teachers have their own unique expert knowledge to understand this complexity. With their knowledge, they notice aspects of classroom experiences in their own ways and understand them as parts of a complex whole. They

see relationships between small events that may be invisible for people who have not spent time in classrooms before as teachers. When experienced teachers come together and observe a live lesson, their expert knowledge comes to the surface as they interpret the effectiveness of the lesson and discuss it in the debriefing. The novice teachers who experience the lesson with experienced teachers are apprenticed into their knowledge through participation.

In research lessons, outside commentators are typically invited to share their ideas at the end of the debriefing sessions (Watanabe, 2002). These commentators can be university researchers who specialize in the very subject areas that are addressed in the research lessons, or other experienced teachers who are interested in the topics. The main expectation for these commentators is to bring out the characteristics of the observed research lesson, tie them to research or theories of teaching-learning and/or conceptual development of students, and present a bigger picture of what their observations mean in the field of education. Unlike typical school consultants who observe and give feedback on aspects of teaching, focusing on what teachers should do to make the particular lesson better, the research lesson commentators pull together the different ideas and data shared in the debriefing to present a coherent picture of student learning. It requires good knowledge of the addressed topic, experiences in classrooms, and certain personal communication styles to be an effective outside commentator, and with the short history of lesson study in countries other than Japan, this is an area that requires attention and development.

Summary and Future Research on Teacher Learning with Lesson Study

This article attempted to give an overview of lesson study and research conducted in terms of teacher learning with lesson study thus far. As mentioned, we are still at a very early stage of understanding how teachers learn with lesson study, and there are several key research possibilities for the future.

Since the lesson study process, especially the research lesson context, makes the teaching process and teachers' thinking visible, teachers' knowledge and its development can be studied in the settings. It is yet unclear what teachers' expert knowledge consists of and how different parts of this knowledge interact in effective teaching. Lesson study creates an ideal research setting for the investigation. Especially when experienced and novice teachers engage in lesson study together, the characteristics of the expert knowledge may surface in their work and discussions. Since lesson study activities focus primarily on student learning, we suspect that the expert knowledge includes a deep understanding of how students think

about particular topics or subjects at hand. The way teachers understand it and how teachers see their understanding as helpful for the planning and teaching of lessons will be important for educational researchers and teacher educators to know, so that we can effectively support all teachers' learning in lesson study as well as in other settings.

When schools and teachers face challenges in adopting lesson study to the existing school and classroom systems, these challenges should be carefully examined, explained, and understood locally. For any innovation, initial challenges are expected, and they provide a way for us to better understand the existing system as well as the innovation. If a challenge is due to a structural incompatibility (e.g., teachers do not have common planning time in their school day), administrative intervention may be sufficient to overcome the difficulty. If a challenge is due to societal difference (e.g., teachers are not familiar with the inquiry process), the lesson study structure may be modified to support teachers to learn about the research process to participate in meaningful ways for their own professional development and instructional improvement. As Lewis *et al.* (2006) discuss, we do not want lesson study to be considered ineffective after just a few years' implementation with mismatched program evaluations. In order to nurture lesson study in different contexts, we need to take time to understand the emerging challenges and carefully adjust and modify parts of the existing innovation while it continues to support teacher learning. Understanding various challenges with an innovation would illuminate aspects of teacher learning that would never come to light in original contexts alone.

In the twenty-first century, we have virtual and electronic means to connect lesson study groups across a nation or globally. There are virtual lesson study LIST-SERV that connect people across the United States, providing a context for them to ask questions, share progress they make with one another, and invite each other to research lesson events (e.g., Lesson Study Research Group, 2007). Some lesson study groups are connected electronically to collaborate together (e.g., Math Star, 2007). With lesson study being a new innovation, the regular flow of new information is essential for teachers' work and collaboration to be successful. This also provides an ideal research context for which we can investigate the challenges from teachers' points of view. We may also evaluate the effectiveness of electronic community and technology use for adopting innovation and understand the role they play in professional community development and learning. How well a certain virtual community is used and kinds of information exchanged will not only help identify the effectiveness of the virtual means of community but also aspects of lesson study, its challenges, and teacher learning in the process.

As we try to come to a shared model of teacher learning with lesson study, we need research that synergistically investigates different aspects of teacher learning as well as the aspects of lesson study to understand the learning process better. International collaboration may be the next step in establishing a research community, as we need to understand what we know at this point as a community that will inform what we need to know next.

Teachers Career Stages and Professional Development

R Fessler and E Rice, Johns Hopkins University, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The literature on teacher career stages over the years has provided useful frameworks for assessing teacher needs and planning appropriate professional development activities. Foundational work in this area can be traced to developmental psychologists. Teacher career stage conceptualizations that emerged in the 1970s were based primarily on observations and reflections of authors, resulting in models of sequential stages that mirrored the timeline of teachers' experiences. Later elaborations, often based on teacher interviews, provided greater differentiation within stages and acknowledged some individual differences. These models, however, were still fairly static, assuming that teachers progressed through stages in a linear, lock-step fashion. Finally, subsequent approaches have introduced more dynamic models that describe alternate pathways and variations brought on by organizational and personal environmental factors that impact careers.

Recent dramatic environmental changes require a reassessment of the way we view career stages and teacher development. These include organizational factors, such as teacher shortages and the concomitant creation of fast-track routes to teaching, and personal factors, such as the changing values brought to teaching by both career changers and new generations of young people entering the profession. By understanding how the changing terrain of teaching is impacting the stages of teacher career development, it may become possible to better address the needs of an evolving teaching population.

Approaches to Teacher Career Stages

Early Foundations

The knowledge base about teachers' development is rooted in a more general literature addressing the stages of human development. Indeed, the whole notion that teachers go through a set number of stages is traceable to Erikson's (1959) writings on the stages of adult development. Erikson's work on the development of identity also gave rise to seminal works on the development of cognitive complexity and moral development. Frances Fuller was the first to apply a similar model to teachers. Fuller (1969) linked categories of concerns to phases of teachers' careers, from early concerns for self to concerns for mastering the tasks of teaching, to eventual concerns

about the impact of one's practice on students. Fuller's theories led to a model of personalized teacher education designed to match the phases experienced by teachers, introducing the idea that professional development must be differentiated in accordance with teacher needs.

While the earliest models of teacher career stages built upon the work of Fuller, they generally derived their categories from common-sense observations and reflections on the careers of teachers (Unruh and Turner, 1970; Gregorc, 1973; Katz, 1972). These models, while espousing somewhat different sets of stages, all emphasized preservice, induction, and maturity. While Gregorc and Katz each offered a fourth stage, the general model was still one where the beginning teacher moves through one or two stages to become a mature, fully functioning professional. All these models were consistent with more general notions about how people progressed through careers: they are trained, they go through an initial introduction/learning period on the job, and finally they do their job. Little attention was paid to individual differences or variations in teachers' careers, and there was no analysis of environmental factors that might impact career development. Still, these descriptive models did provide an important foundation for further research, and they helped focus attention on the unique professional development needs of preservice and new teachers.

Research-Based Linear Models

In a series of studies at the Ohio State University in the United States, Kevin Ryan, along with Flora, Burden, Newman, and Patterson, began to examine the issue of the careers of teachers as a whole (Ryan *et al.*, 1979). Using personal interviews with teachers, these studies looked at first-year teachers, teachers with 4–20 years experience, teachers with 20–30 years experience, and retired teachers. The researchers documented the changing concerns of teachers as well as their implications for professional development, showing how experienced teachers' needs changed from technical skills to larger issues such as how to teach creatively. However, they still presented teacher development as a static and unidirectional process, with mature teachers treated as one homogeneous group. The later work by Burden (1982), while valuable for its use of a data-driven approach, continued to share many of the characteristics of earlier theorists. Given that his focus in the Ohio State studies was on teachers with 4–20 years of experience, it is interesting

that Burden's proposed stages of survival, adjustment, and maturity were very similar to the schemas of Unruh and Turner or Katz. A major limitation that Burden shared with earlier authors was his concentration on the first few years of teacher development, positing a mature or fully functioning teacher by the fourth or fifth year of a teacher's career. He, like many earlier theorists, had little to say about differentiated teacher development after the first few years.

Taken as a whole, though, the Ohio State studies did bring needed change to conceptualizations of teacher career stages. The focus on research, along with the description of individual differentiation within career phases and a sophisticated analysis of these individual differences, vastly expanded the descriptive knowledge about teacher careers. However, these studies still did not provide a conceptual framework for thinking about teacher careers other than as a linear model, and they paid little attention to either external or personal environmental factors that might differentially impact the careers of individual teachers.

Nonlinear Dynamic Models

Throughout the 1980s and into the 1990s, several researchers began to propose more complex, multidimensional analyses of teacher career stages. The two notable characteristics shared by these approaches were a dynamic, nonlinear view of teacher development and a focus on the role played by various environmental factors in the specific developmental paths taken by a given teacher. Huberman (1989) introduced the notion of career trajectories that describe a series of pathways, or options, that occur during teachers' careers. His themes/phases were derived from interviews with women and a more general population, resulting in the documentation of specific pathways for different groups. In his generic model, teachers begin with concerns about survival and discovery and move into a period of stabilization, followed by multiple pathways that differentiate based on their experiences and responses to their changing environment. He further suggested that professional development must respond to these differentiated experiences and trajectories.

Another nonlinear approach emerged in the early work on the Teacher Career Cycle Model (Burke *et al.*, 1984). These researchers observed teachers' career pathways through direct observations, teacher interviews, case studies, and literature reviews to develop a model that presented a social-systems orientation to teacher career stages. As most fully developed (Fessler and Christensen, 1992), the Teacher Career Cycle Model emphasized eight phases: preservice, induction, competency building, enthusiastic/growing, career frustration, career stability,

career wind-down, and career exit. Individual teachers' paths through these stages, though, were uniquely impacted by both organizational and personal environmental factors. Organizational factors included features such as school regulations, the management style of leaders, the atmosphere of public trust (or a lack of it), societal expectations, and the role of professional organizations and unions. Personal factors included considerations such as the family life of the teacher, positive events or crises in the teacher's life, individual dispositions, outside interests, and the life stage of the teacher. What differentiated this approach from earlier models was that it postulated a dynamic ebb and flow, with teachers moving in and out of stages in response to influences from both the personal and organizational environmental dimensions.

While these various approaches have served as useful methods of analysis for practitioners and researchers for several decades, recent dramatic environmental changes require a reassessment of career stages and their implications for teacher professional development.

Emerging Environmental Changes and Career Stage Theory

Virtually all earlier models of teacher development were based on several assumptions that may no longer hold true. One such assumption is the existence of well-defined, easily differentiated periods of preservice and in-service education. In addition, the more static models of career phases assumed a long-term commitment to a career in teaching, and even the developers of more environmentally sensitive models did not contemplate teaching careers of only 3–5 years. Environmental changes since the early 1990s have challenged these assumptions. These changes flow from both organizational and personal environmental factors.

Organizational and External Environmental Factors

While in 1992 Fessler and Christensen could still argue that teacher turnover was declining, by the end of that decade the teacher shortage had become perhaps the most written about problem in education. Many educational authorities have responded by experimenting with fast-track routes to the classroom. Although many of these efforts have resulted in high-quality programs, some allow new teachers to enter the profession with only a summer of training, and there have been increasing calls to allow individuals with specialized content knowledge to bypass traditional teacher preparation programs and move directly into the classroom based on their demonstrated

content knowledge. In addition, various alternative routes to teaching have attracted an increasing number of career changers to the teaching workforce. The existence of such programs blurs the distinction between pre- and in-service stages, and for many new teachers it may no longer make sense to separate preservice from induction and competency-building stages. This suggests that new models of teacher career stages must allow for the reality that current teachers simultaneously inhabit more than one career phase. Similarly, with programs such as Teach for America in the United States requiring only 2 years of service from their participants, the entire career cycle may be compressed and truncated for a growing number of teachers.

The teacher career cycle is currently impacted by a number of additional changing organizational environmental factors. Numerous calls for accountability in schools have resulted in an increased emphasis on high-stakes testing of students. Often the desire to enforce accountability and content-driven definitions of teacher quality has led to the marketing of curricula that are much more structured than past approaches. In their most extreme forms, these curricula change the role of teachers from that of creative professional decision makers to actors following a script. A concomitant shift to more top-down management styles in some school districts has led to less flexibility for creative teachers. Even those districts now moving back toward site-based management are empowering principals and other school leaders more than teachers. Finally, the challenges presented by urban, urbanizing, and poor rural school districts greatly impact the conditions under which teachers are asked to do their jobs. These teachers often face a dearth of resources, outdated textbooks, constantly changing leadership, and lack of goal clarity.

As described in the section titled 'Personal environmental factors', new generations of teachers may have difficulty functioning in these evolving working conditions. Indeed, it is likely that a combination of these changing environmental factors has resulted in an increase in teachers moving into the career exit stage. Many urban districts in the United States lose 50% of their new teachers within the first 5 years of teaching. For this reason, recent researchers have increasingly focused on the initial phases of teacher development as practitioners strove to deal with the demands for many thousands of new teachers. Post-initial phases of professional development have received much less attention during this era, and some of the more recent work has actually returned to less dynamic models, perhaps because of the stress on induction and mentoring of new teachers.

Some researchers studying the teacher shortage have argued that the problem is not actually one of teacher

recruitment, but of teacher retention (Ingersoll, 2001; NCTAF, 2003). This research has led to a variety of approaches meant to keep teachers in the classroom longer, including re-recruitment models to bring former teachers back to the classroom and providing classroom-embedded teacher leadership opportunities rather than requiring those with leadership aspirations to exit teaching to become administrators.

These changing organizational factors have had enormous impact upon teacher career stages. While there have been some positive developments, the overwhelming trend has been one of a decrease in teacher morale and a corresponding increase in career frustration leading to early career exit. Even those who stay in education for the long term are exiting the teaching profession earlier. Pressures to promote good teacher leaders to administrative positions (where many schools also face shortages) cause more good teachers to leave the classroom prematurely. This further points to a need to redefine the terms used to describe teacher career development.

Solving the twin crises of the teacher shortage and teacher retention will require new strategies. Teachers need professional development that provides them the necessary tools to make sense of the vast amounts of data provided by the accountability movement in ways that help them to improve their own instruction. The goal can be conceptualized as finding ways to continue to return mid- and late-career teachers to the enthusiastic and growing stage, perhaps through offering them the opportunities to build new competencies. This reinforces the need for classroom-embedded teacher leadership opportunities that do not lead to an administrative track. Some examples of this possibility are indeed being tried. Both professional-development schools and mentoring programs provide opportunities for mid- and late-career teachers to develop new competencies. There is at least some evidence that this helps teachers reenter the enthusiastic and growing stage of teacher professional development. For example, an unpublished survey of experienced teachers acting as peer mentors for beginning teachers in Baltimore, Maryland (USA) showed that the mentors felt reinvigorated in their own teaching by the opportunity to share their knowledge with their younger colleagues. There is also evidence that such mentoring helps to keep new teachers teaching longer, thus increasing the number of mid- and late-career teachers available for such leadership tasks (Smith and Ingersoll, 2004). Finally, whatever its other problems or virtues, the charter school movement in the United States often provides a place for teacher-leaders to guide their school's direction. These teachers are building new skills and are often re-engaged with questions of teaching and learning. All of these provide examples of what could be called a reinvigorating stage of teacher professional development.

Personal Environmental Factors

Teacher shortages in many countries have led to a variety of experiments in new ways to bring teachers into the classroom. These include efforts to attract career changers and young people. Each group brings new personal environmental factors with implications for professional development. Career changers bring their own unique traits to the teaching workforce. While their content knowledge is often wide and deep, they sometimes exhibit limited awareness of the characteristics of modern youth, especially in poor urban and rural areas (those areas in greatest need of teachers). This group of new teachers will thus need less professional development about rapidly changing content areas, but correspondingly more around pedagogical issues and approaches to teaching. They often enter teaching after careful reflection, suggesting that they may remain committed to teaching longer than some of their younger counterparts.

There is an emerging literature that addresses the values and characteristics of new generations of young adults that influence the way they look at the world of work and their career pathways (Howe and Strauss, 2000; Lancaster and Stillman, 2002; Raines, 2003). The Generation Xers, who were born between about 1970 and 1981, are generally described as being very skeptical of authority and bureaucracy, yet respectful of competence, and as individuals who work hard to advance their careers. They are oriented toward results, often very efficient and competent, and tend to be independent. Teachers in this category often see teaching as a steppingstone to advancing their careers – either within or outside of education. This group presents challenges and opportunities to school leadership, who are faced with the need to focus these talented individuals, while at the same time recognizing that many do not see teaching as a long-term career.

Millennials, who were born between about 1982 and 2000, are described as a generation that has been raised by parents who have been very nurturing and supportive. They have a great deal of confidence in themselves and high self-esteem. One of their defining characteristics is their heavy reliance on technology for personal and professional communications. As a group, they are described as wanting to make a difference, optimistic and hopeful about the future, but with little patience for bureaucracies that they do not agree with or understand. They expect a workplace that is challenging, collaborative, creative, and fun, with opportunities for both advancement and financial rewards. They demand inclusiveness, diversity in the workplace, and respect for all. New models of professional development may be needed for individuals demonstrating these characteristics, with a focus on their strengths, group work, efficiency, and increased involvement in their own growth plans (Raines, 2003). They are likely to be

receptive to setting goals for students that are fair and challenging and that reflect a sense of social justice.

These generalized characteristics of the emerging workforce seem to be in direct conflict with some of the organizational factors mentioned in the previous section. Further work is needed to create an organizational climate that is responsive to the personal needs of the generation Xers and millennials in order to tap their rich potential as effective teachers. Millennials' idealism and desire to contribute to social justice issues should be strong factors in recruiting them into teaching, but collaborative, nurturing, supportive environments and leadership styles will be needed to keep them in the classroom. Finally, expectations for financial rewards and career advancement might make these new-generation teachers more receptive than their predecessors to ideas such as merit pay and new versions of career ladders.

New Directions for Career Stage Connections to Professional Development

Based on the evolving environmental influences on teachers' careers discussed above, the following suggestions are offered for further development of career cycle research and applications:

1. There is a need to continue to examine changing environmental conditions and their impact on teacher career stages and professional development. The environmental changes outlined in this article reflect developments of the past 15–20 years, but they too will evolve as the profession faces new challenges and opportunities in the years ahead.
2. Researchers need to consider new conceptualizations of career stages and pathways that take into consideration emerging alternative teacher preparation models and subsequent professional development needs. Those prepared through alternative routes that include minimal professional education experiences will need support in building their competencies in pedagogy during their first few years of teaching.
3. Opportunities for teachers to be deeply involved in planning and decision making seem consistent with the needs and expectations of the generation Xers and millennials, but are often lacking in our top-down, accountability-driven, high stakes-testing environment. We will need to reconcile this conflict if we are to attract and keep a new generation of enthusiastic teachers committed to quality, diversity, and high achievement for all students.
4. A closer examination of generational differences (including newly evolving ones) is needed to determine the implications for professional development for early

career teachers, for collaboration among intergenerational school personnel, and for assisting senior leaders in understanding how to work with and tap the idealism of the millennials and the career-driven expectations of the generation Xers. As mentioned earlier, these new-era teachers may be receptive to merit pay and career-ladder models, but this might create conflict with their more senior colleagues.

5. Career state research should be further emphasized as a foundation for addressing teacher shortages as a retention issue by providing appropriate professional development and support to give early- and mid-career teachers more positive experiences and reasons to stay. This should include providing more opportunities for teachers to take on leadership roles that do not require them to leave the classroom, such as through mentoring and professional-development schools.
6. School leaders must address the potential disconnect between the increased emphasis on standardized teaching associated with testing and teaching for tests, on the one hand, and the need for creative teachers to be more involved in instructional planning and decision making, on the other. Can this be reconciled by more sensitivity to the needs of individuals at various stages of their careers? Can leaders keep teachers involved while still emphasizing accountability?

Further research and refinement of career stage models will be useful in addressing these and related issues facing educators in the coming generations and will move us forward in our understanding of post-initial stages of teacher professional development.

A Pedagogy of Teacher Education

J Loughran, Monash University, Clayton, VIC, Australia

Introduction

One way of understanding what a pedagogy of teacher education means is to think of it as comprising the processes and practices of teaching and learning about teaching, that is, a pedagogy of teacher education is an articulation of the knowledge of teaching and learning about teaching. Central to the idea of a pedagogy of teacher education is the use of the term pedagogy. Pedagogy is not meant as a synonym for teaching, rather pedagogy is about the relationship between teaching and learning. Therefore, a major purpose in articulating a pedagogy of teacher education is to ensure teacher educators' professional knowledge is translated into the practices of teacher education more generally.

The roots of a pedagogy of teacher education can be traced back to research in the 1980s where issues about pedagogy, in and for teacher education, initially gained currency. Liston and Zeichner (1988) worked with ideas about critical pedagogy and teacher education in an attempt to begin to pull together a number of the important structures and practices that they considered were at the heart of challenging the nature of teacher education. Berliner (1988) focused considerable attention on the pedagogy for teacher education as he advocated the need to better recognize and value the knowledge and skills essential to expert teaching and how that might impact teacher-education practices. However, a pedagogy of teacher education began to emerge as an area of interest in its own right as a consequence of the prevailing

approaches to researching teacher education and an interest in that which:

... happens behind the doors of those [teacher education] classes, about the ideas of teacher education, about the pedagogy of teacher education. ... discussions on a programmatic level are not fine grained enough to get at those ... What, I might ask, are students thinking, feeling, learning, believing (Wilson, 1990: 2)

The need to know more about teaching and learning about teaching also converged with concerns about the education of teacher educators. Therefore, the teaching and learning experiences of both teacher educators and student teachers became fundamental to a better understanding, that which comprises a pedagogy of teacher education.

A Growing Momentum

The shift in the research agenda, from studying teacher education from afar to something more upfront and personal, led to a conceptualization of teaching and learning about teaching through a pedagogy of teacher education.

Teacher educators must turn their attention to the content and pedagogy of teacher education. This includes considering the prior knowledge and beliefs that prospective teachers bring with them, as well as the models those novice teachers have to reflect upon and learn from.

(Ball and Wilson, 1990: 14)

In the early 1990s the ability of traditional teacher-education programs to positively impact, and therefore change, the nature of school teaching was increasingly questioned. Heaton and Lampert (1993) made clear the need for a “new language for talking about practice and new ways of interacting with learners” (p. 46). They argued that teacher educators themselves needed to be doing the same in their teaching about teaching, as they expected of their student teachers in their practice; so the notion of a pedagogy of teacher education became firmly established:

This means inventing not only a new approach to research but also a new pedagogy of teacher education: one where the actual problems of practice are central, where the question of what it means to know and learn . . . are integrated in ongoing work with students . . . [it] requires a new kind of discourse, new definitions, new rules of argument. (Heaton and Lampert, 1993: 46)

The Construct Takes Hold

Throughout the 1990s, ideas about a pedagogy of teacher education kept resurfacing through studies into teacher-education processes and practices as a stronger focus on teaching and learning about teaching took hold. However, when Korthagen *et al.* (2001) described the way in which a pedagogy of teacher education might be conceptualized, both philosophically and practically, in teacher educators’ practice, the construct resonated in new and powerful ways in the teacher education community.

Hamilton and Pinnegar (2000) viewed the development of a pedagogy of teacher education as being embedded in the work of self-study, or more so, as an outcome of self-study. Cochran-Smith (2000) viewed a pedagogy of teacher education as one way of better understanding the nature of learning in teacher education, such that more powerful professional development of teachers and teacher educators might be realized. Tigchelaar and Korthagen (2004) examined how to better link theory and student teachers’ experiences, in order to shed more light on what a pedagogy of teacher education might entail, while Doyle and Carter (2003) focused on a narrative perspective because they saw the knowledge base of teaching as residing in “the stories of experience as a teacher” (p. 134). Feiman-Nemser (2001) conceptualized a number of central tasks in learning to teach: (1) analyzing beliefs and forming new visions; (2) developing subject-matter knowledge for teaching; (3) developing an understanding of learners and learning; (4) developing a beginning repertoire (of teaching); and (5) developing the tools for studying teaching. These tasks gave a structure for ways of considering concrete aspects on what a pedagogy of teacher education might entail.

It is not difficult to see how this growing range of ideas and implications for better understanding the processes of teaching and learning about teaching and, in part, building on the shift from studying teacher education from afar to near by involving teacher educators themselves, helped to shape views of teacher preparation not as training but rather as a model for teacher learning, building on an approach based on practitioner inquiry. One important implication of a practitioner-inquiry approach is in the way that teaching itself becomes more deeply examined when the basis of research questions and methodological approaches are led by those involved in doing the teaching, and that is further exemplified when the practitioners are teacher educators.

Teaching as a Discipline: The Problematic Nature of Practice

Tillema and Kremer-Hayon (2005) drew attention to the dilemmas faced by teacher educators as they enact a pedagogy of teacher education. Their dilemmas (partnership with colleagues vs. individualism, conservatism vs. constructivism, guidance vs. mentorship, etc.) are not dissimilar to Berry’s (2007) exquisite articulation of tensions in teaching about teaching (the tension between: (1) telling and growth; (2) confidence and uncertainty; (3) action and intent; (4) safety and challenge; (5) planning and being responsive; and (6) valuing and reconstructing experience). These researchers’ knowledge outcomes (dilemmas and tensions) highlight ways in which a pedagogy of teacher education requires an ongoing responsiveness to the problematic nature of teaching about teaching.

By highlighting teaching as being problematic it makes clear the need for teacher educators to articulate and act upon a knowledge of practice which in itself becomes an *entrée* to new ways of seeing into the teaching and learning of both students of teaching and teacher educators. Holzer (2002) illustrated the difficulties created for learners when teaching is not viewed as being problematic and hinted at developing an understanding of teaching as a field of study (or discipline) in its own right. Therefore, if teaching is a discipline, an articulation of a pedagogy of teacher education is crucial for teaching about teaching to be more than the delivery of teaching information and to be embodied in the very act of teaching the practice of teaching:

the question to be raised concerns the pedagogy of learning to teach. . . . it is a significant and different entry point in conceptualizing teacher education. . . . central to this type of learning are the ways the teachers will be engaged in the work of learning to teach . . . teaching now becomes the “subject matter” of teacher education. (Holzer, 2002: 393–395)

A pedagogy of teacher education then requires teacher educators to be involved in investigating teaching and learning in ways that will lead them to learn from practice while being involved in practice. The issues, concerns, and dilemmas of practice become a major focus in explicating the problematic nature of teaching and therefore help to direct teaching of teaching.

Teaching about Teaching

Central to a pedagogy of teacher education is the point that the teaching of teaching is not about the simple delivery of information and ideas of teaching. Rather, it is the teaching about knowledge of practice through the careful and purposeful creation of episodes in which that knowledge is borne out in experiences of practice. Creating meaningful experiences of learning to teach for students of teaching requires the knowledge of teacher educators' practice to be made explicit so that that which is so often tacit might be made accessible, and therefore able to be examined in meaningful ways. To do so requires not only making the tacit explicit, but also developing and using a shared language of practice.

Making the Tacit Explicit

Polanyi (1966) highlighted the tacit nature of teaching and helped to make clear some of the difficulties associated with articulating a knowledge of practice. The ability to teach and to explain why particular approaches to teaching work, do not necessarily go hand in hand. Making the tacit explicit requires sophisticated skills and teacher educators need to be experts in such practice.

Inviting students of teaching to look into the tacit aspects of teaching includes: (1) thinking aloud in order to articulate problems, issues, and concerns of practice in practice; (2) journal writing by teacher educators for/to student teachers in order to share insights into a teacher educator's thinking about teaching episodes and events; and (3) openly challenging one's existing practices whereby taken-for-granted approaches to teaching and behaviors of teaching (of both teacher educators and students of teaching) are confronted, deconstructed, and reconstructed in order to make learning about teaching real and meaningful within a teaching and learning experience.

A Language of Practice

A language of practice is essential for creating new ways of considering and sharing knowledge of teaching and learning so that both, the generalizable and the specific,

are able to be captured, articulated, and portrayed. Many different ways of articulating a language of practice can be found in the literature including: (1) axioms; (2) assertions; (3) dilemmas; (4) paradoxes; (5) principles of practice; (6) program principles; and (7) summary statements.

In these examples of ways of articulating a language of practice, there are two forms of knowledge that are being drawn upon. First is a generalized form of knowledge more in line with the traditional research-knowledge outcomes (i.e., applicable across cases and derived from scientific approaches to research and knowledge claims). Second is knowledge derived from learning about practice through reflection on practice and is somewhat idiosyncratic and case based (i.e., developed by considering something which has been learnt through experience over time).

Understanding what it means to enact a pedagogy of teacher education depends, in some part, on acknowledging that one form of knowledge does not exist without the other. A knowledge of practice, somewhat paradoxically, needs to be conceptualized as being specific and context dependent as well as being abstract and generalizable. In that way, a pedagogy of teacher education is about making the knowledge of practice applicable, meaningful, and useful for teaching in teaching as well as being identifiable or applicable across teaching contexts. Therefore, how students of teaching are able to apprehend and respond to such views of teaching becomes crucial in translating teaching about teaching into meaningful learning about teaching.

Learning about Teaching

Being a student of teaching (Bullough and Gitlin, 2001) requires balancing dual agendas for learning. There is a need to learn about the subject matter of teacher education (i.e., knowledge of such things as questioning, classroom management, mixed ability teaching, etc.) as well as the way in which that subject matter is taught (i.e., the teaching that is employed to examine that subject matter). These two aspects were described by Russell (1997) as the content turn and the pedagogical turn and highlight that it is not only what is taught, but also how it is taught, that influences learning about teaching.

As noted earlier, because pedagogy is about the dynamic relationship between teaching and learning it stands to reason that a pedagogy of teacher education must therefore be overtly responsive to both teaching and learning about teaching. Hence, teacher educators need to be cognizant of the dual learning agenda of students of teaching as they construct and enact their pedagogy of teacher education. This dual learning agenda is also impacted by the way in which students of teaching experience the shift from student to teacher.

From Student to Teacher

Students of teaching enter teacher preparation programs with well-formed images of what they think teaching is and how it is performed. Their apprenticeship of observation (Lortie, 1975) can have a profound effect on what they expect of, and think they should do, in a teacher preparation program (i.e., commonly to be able to be told how to teach).

The transition from student to teacher highlights a variety of feelings, issues, and concerns for students of teaching that can further complicate their learning about teaching. Through a pedagogy of teacher education, this transition should be a time in which “the student perspective is valued and appropriately responded to as new understandings of the world of teachers and teaching expand and develop” (Loughran, 2006: 124).

Fuller highlighted how student teachers’ concerns shift over time (Fuller, 1969; Fuller and Bown, 1975). Although some have argued against such a developmental model, it is nonetheless important that both teacher educators and students of teaching are aware of, and sensitive to, the changes in concerns in learning about teaching and how they impact practice at different times during teacher preparation. This need to recognize shifts in concerns is one reason why a pedagogy of teacher education aligns so closely with notions of developing reflective practitioners through teacher-preparation programs.

Developing Reflective Practitioners

There has been a long tradition of developing student teachers as reflective practitioners (Grimmett and Erickson, 1988). Central to reflection is the need to be able to see a problem (e.g., curious/puzzling/engaging situation), and to do so from different perspectives. In learning about teaching, students of teaching need to learn how to recognize their own problems of practice in order to begin to direct their own professional learning of teaching. Therefore, a pedagogy of teacher education must be conceptualized and constructed in ways that helps students of teaching begin to see more deeply into the nature of practice so that they are able to recognize and respond to the problems of practice in positive ways.

Learning about teaching, like teaching about teaching, requires an inquiry stance in order for individuals to search for, and respond to, their own problems of practice so that their development of knowledge of, and actions in, teaching might develop and be extended in appropriate ways while still being responsive to their needs and concerns. One way of encouraging this to happen is through a student-teacher-as-researcher approach.

Seeing into Teaching through a Student-Teacher-as-Researcher Stance

There is a paucity of research in the student-teacher-as-researcher approach. Fundamentally, what a student-teacher-as-researcher approach requires, and is inherent in a pedagogy of teacher education, is the serious creation by teacher educators of possibilities for student teachers to “have opportunities to confront the abstract and unbounded complexity of teaching” (Cochran-Smith, 1991: 113) that is, to come to be challenged by the problematic nature of practice and to inquire into it.

By embedding learning about teaching in experience and by inquiring into those experiences through a student-teacher-as-researcher stance, more meaningful ways of learning about teaching are encouraged. Embedding learning about teaching in student teachers’ own experiences is important for supporting their attempts to build deeper understandings of knowledge of practice. A pedagogy of teacher education is enacted by supporting student teachers’ learning about teaching by going beyond the technical and inviting them to seek to become truly professional. That is catalyzed by inviting students of teaching to adopt a student-teacher-as-researcher stance in their learning about teaching.

Conclusion

A pedagogy of teacher education comprises principles, expectations, and practices that matter in shaping teaching and learning about teaching. Enacting a pedagogy of teacher education is about teacher educators better aligning their intentions and their practices so that the complex nature of teaching and learning can genuinely be unpacked and critiqued in teaching and learning about teaching. Teacher educators not only need to be able to teach, but they also need to be able to teach teaching, which means their practice should hold up for scrutiny the problematic nature of practice within the experiences of teaching and learning they create for their students of teaching.

A pedagogy of teacher education is, at one level, about the individual practice of teacher educators and how, through inquiry, that specialist knowledge of practice might be captured, articulated, shared, and critiqued. However, at another level, there is also a pressing need for such knowledge to impact teacher-education practices more generally

“first [at] the institutional level whereby . . . program organization and structure reflect the way in which a pedagogy of teacher education is inherently intended to

shape teacher education as a whole. . . . [and also within] the teacher education community [whereby] ideas, issues, concerns and conceptualizations might be developed, debated, articulated and portrayed in ways that will progress the field of teacher education”

(Loughran, 2006: 176).

Case Methods in Teacher Education

M Sato and C Rogers, University of Minnesota, Twin Cities, MN, USA

Introduction

Since the 1980s, case methods have gained traction in teacher education. Typically, cases are narratives drawn from real-life instances and used as teaching tools to catalyze group discussion and individual reflection. Published case books exist on a variety of topics (e.g., teaching in diverse contexts, classroom assessment practices, teaching particular subject matter concepts, and using group work) and some teacher education programs engage their candidates in the writing of cases, which are then selectively compiled into in-house casebooks for future classes to use. Case discussion as a pedagogical method is currently used in teacher education programs to support the development of beginning teachers as well as the mentoring and coaching practices of cooperating and mentor teachers (Shulman and Sato, 2006). Case writing by preservice teachers has also emerged as a pedagogy that has the potential of supporting the development of beginning teachers' understanding of instructional practices, professional development during their clinical experiences, the application of theoretical understandings to practice, and the development of their moral agency. Similarly, Loughran (2006) has argued for the use of anecdotes of difficult or unresolved situations constructed from the experiences of preservice teachers as a means of providing focus for their reflections on practice.

The construction and definition of what constitutes a case in teacher education varies widely. Cases can be constructed as exemplars of practice, as dilemmas faced in practice that can only be resolved through compromise, as historical documents that represent issues from the past that linger in the present, or as representations of everyday practice. In recent years, cases using multimedia representations of practice have become more common. Multimedia formats can provide classroom artifacts such as student work samples, classroom video, teacher narratives and reflections, and other classroom documents. These collections of artifacts are usually centered on a particular unit of instruction, instructional project, or issue of student learning rather than the traditional narrative construction of a written case. Akin to having preservice teachers write their own cases, one group of researchers has demonstrated the benefits of developing preservice teachers' abilities to identify, interpret, and analyze evidence of exemplary teaching by having them construct video cases of their mentor teachers during their student teaching experience (Beck *et al.*, 2002).

In her review of the literature on case methods in teacher education, Merseth (1996) suggested three purposes for the use of case methods. The first purpose describes cases as exemplars or models of best practices that depict theoretical or desired principles in action. The second purpose is to provide opportunities for analysis of a complex situation and to practice decision making vicariously. She states that "in this conception, cases are not used explicitly to exemplify theory but rather to present situations from which theory emerges" (p. 728). The third purpose of case methods is to stimulate reflection and potentially help the preservice teacher develop the habits and skills of reflective practice.

Merseth based this conceptual organization partially on the work of Lee Shulman (1986), who is widely recognized as catalyzing the emergence of case methods in teacher education. In his 1985 American Educational Research Association presidential address, Shulman provided a framework for the knowledge base for teaching and proposed three forms of teacher knowledge – propositional knowledge, case knowledge, and strategic knowledge. Case knowledge was described as "knowledge of specific, well-documented, and richly described events . . . [in which] the knowledge they represent is what makes them cases" (p. 11). Shulman speaks to both the substance of the cases and the pedagogical function that a case can serve by describing three types of cases:

Prototypes exemplify theoretical principles. *Precedents* capture and communicate principles of practice or maxims. *Parables* convey norms or values. Naturally, a given case can accomplish more than a single function. (p. 11, emphasis in original)

McAninch (1995) took a different approach in providing a conceptual framework for organizing the case methods literature in teacher education. She drew on Feiman-Nemser's (1990) five-part classification scheme for the orientation of teacher education programs: (1) academic, (2) practical, (3) technological, (4) personal, and (5) critical/social. In this analysis, McAninch attributed particular case books and some research efforts around case methods to one of these orientations. Using this programmatic or ideological approach to describe the purposes of cases and case methods seems problematic insofar as it assumes that case methods would be used by the instructors within a teacher education program the same way. It also does not account for the potential of using a

particular case toward different or multiple purposes as suggested by Shulman.

The rest of this article addresses both the empirical and theoretical bases for case methods in teacher education. We highlight some of the empirical research from the past decade to illustrate the kinds of research questions being pursued and the theoretical lenses that researchers use in framing their studies and analyzing their data. We point the reader to other compilations of the literature for summaries of earlier research (Merseeth, 1996; Sykes and Bird, 1992).

Empirical Base for Case Methods in Teacher Education

While many proponents of case methods have suggested the benefits of using this pedagogy, the call for more empirical research on case methods has been echoing since the early 1990s (Lundeberg, *et al.*, 1999; McAninch, 1995; Merseeth, 1996; Sykes and Bird, 1992).

Case methods research over the past decade has continued to focus on many of the issues that Merseeth identified in 1996: what preservice teachers learn from engaging in case methods, the influence of cases on how teachers think, and the influence of instructional contextual factors on how teachers learn through cases. As cases are increasingly constructed using multimedia formats, the contextual factors associated with learning from cases now account for differing electronic contexts and processes such as synchronous versus asynchronous participation in case discussions, supporting successful online dialog during case analysis, and differences between text-based and video formats of cases.

Lundeberg *et al.* (1999) compiled a research base for teaching and learning with cases. In their edited volume, they explore the fundamental questions raised in the title of the book: *Who Learns What from Cases and How?* They conclude that comparing case methods to other forms of pedagogy to determine comparative effectiveness would not be a fruitful direction for future research given the multiple issues related to isolating variables and conditions that might contribute to learning outcomes. Rather, they suggest that research should focus on what is it that students actually learn from case methods. For example, pedagogues and researchers often purport that case methods can help develop a teacher's reasoning ability, problem-framing skills, reflective mindsets, subject-matter knowledge, or pedagogical repertoires. Lundeberg *et al.* argue that teacher education as a field has not developed a shared meaning of these concepts and that the constructs are sometimes ill-defined in individual studies.

Researchers use a variety of data collection and analytical methods to determine effects of case methods on

preservice teachers' learning and development: analyzing transcripts of case discussions; interviewing and surveying participants about perceptions of learning and change; examining changes in coursework such as journals and writing samples; and asking participants to review their own writing and reflect on changes in their thinking and learning. Fewer studies have used quasi-experimental designs using pre/post measures of treatment and control groups.

In the past decade, the research on the pedagogical use of cases has examined how to structure case discussions, the role of the facilitator in case discussions, how expectations for case writing are communicated to students, and how case writing is scaffolded. Case books written for instructional purposes have also attended to pedagogical approaches in using cases by including discussion and reflection questions with cases or guidelines for facilitation and analysis of case discussions. Because of the episodic character of cases, some have argued that the pedagogical approach used with cases must make explicit efforts to help students use the particularities of the case to examine broader theoretical issues and principles for learning and teaching that the cases may represent (Shulman, 1992). Determining the quality of the case in relationship to the purpose for using the case is also essential to understanding the effectiveness of case pedagogies.

The long-term effect of learning from case methods and the transfer of what is learned to practice continues to be rare in the published literature. One study followed up with 31 teachers through mailed surveys to determine the impact of multimedia case-based instruction on their practice (Maloch and Kinzer, 2006). Telephone interviews with eight participants were also conducted to explore further the respondents' perceptions of the value of instructional methods courses, differences between traditional methods class procedures and case methods, and retention of case content over time. The authors report that the respondents found the use of multimedia cases to be influential on their learning, especially in helping them remember particular strategies they could use in their teaching and in providing high instructional engagement. Somewhat troubling, however, was the dominant perception among respondents that the cases used in their courses were meant to represent exemplars or models of practice. The instructors' intentions were that the cases represent the complexity of practice and the need for teachers to make contextually based decisions. The view of cases as models of practice seems to have limited the novice teachers' views about the applicability of the cases to their own teaching practice. Rather than seeing the substance of the cases as resting on underlying theoretical principles or as a tool to stimulate reflection, several respondents commented on not seeing direct applicability of the cases to their current teaching circumstances.

The appeal of case methods in teacher education has drawn international attention in the research literature. At the University of Twente in the Netherlands, Van Den Berg *et al.* (2004) examined whether exposure to a multimedia case of a teacher's exemplary science unit would transfer to student teachers' practice during their student teaching experience. After engaging with the online case, the novice teachers were asked to create new curricular experiences. The majority of students mirrored the curriculum presented in the case, following it like a script, while a few students used the case as a springboard for creating novel curriculum both within the subject-matter discipline represented in the case and to other subject-matter areas. Additionally, institutions in the Philippines and Singapore have been developing research around case-based pedagogies as a basis for reform in the teaching and learning of elementary school science and the adoption of constructivist instructional approaches for preservice teachers (Arellano *et al.*, 2001).

Theoretical Base for Case Methods in Teacher Education

While we agree with the need for more systematic development and continued research on case methods, we also emphasize that this research needs to be theoretically grounded in ways that allow the work to be useful within and across the diverse theoretical traditions of the field. Published research demonstrates several different perspectives on learning and teacher development. The degree to which research studies are positioned within a theoretical framework, however, varies from studies lacking identifiable theoretical perspectives to studies that use theories to guide their research questions, research designs, use of case methods, and analysis. In this section, we briefly explore the dominant theoretical perspectives currently used in research on case methods and describe a few studies that demonstrate strong theoretical grounding in pursuing research questions about case methods in teacher education.

Situated Cognition Theory

Situative theorists view learning as not only a process that occurs inside the mind of the individual, but also as being bound up in the physical and social contexts of activity as well as the activity itself (Brown *et al.*, 1989; Lave and Wenger, 1991). The situation in which one learns, including the interactions with others, the environment, and the physical and symbolic tools that one uses are all fundamental parts of the learning that takes place. The knowledge itself is distributed throughout the situation or the system and the learning is emergent and social. When

designing learning activities from the perspective of situated cognition theory, educators immerse learners in experiences and environments that are as-authentic-as-possible contexts in which their new ideas and behaviors will be applied. Putnam and Borko (2000) propose several approaches for engaging teachers in activities that map onto the tenets of situated learning: grounding teachers' learning in their own practice, using artifacts of practice in professional development activities, and using case-based learning experiences. They suggest that "rather than putting teachers *in* particular classroom settings, cases provide vicarious encounters with those settings" (p. 8, emphasis in original).

Using situated learning theory in their analysis, Yoon *et al.* (2006) investigated how case methods particularly influenced novice elementary school teachers' self-efficacy about teaching science. The researchers collected pre-case discussion questionnaires, transcripts of case discussion activities, and post-case online discussion board postings of 12 elementary school teaching candidates at the University of Toronto. The authors designed the case discussions to allow for multiple points of entry for participants with varying background knowledge and experiences to participate in the science-teacher community discourse. The structure of the case activities allowed the novice teachers to experience legitimate peripheral participation (Lave and Wenger, 1991) within the science teaching community by engaging in discussions about real classroom experiences. As the novice teachers gained self-confidence through their participation in the activities embedded in the case methods, they moved closer to the center of the community activity and discourse. The authors argue that the case served as a tool for the participants to make sense of a real classroom situation, test their knowledge, and to begin to align their discourse with the larger science-teaching community.

Through participation in the case activity and engagement with each other, we suggest that students were crossing boundaries by applying terminology and pedagogical activities learned in previous workshops, cross-referencing theoretical constructs from class readings, and relating personal experiences to the case scenario. The case itself represented an important boundary object around which meaning was constructed and shared, while the case method provided the necessary brokering mechanism (Yoon *et al.*, 2006, p. 25).

Cognitive Flexibility Theory

Among the approaches to learning that draw on cognitive theories, cognitive flexibility theory recognizes that some domains of knowledge are complex and ill-structured. In contrast to well-structured domains that may be organized in linear or hierarchical formats that translate into sequential instruction, ill-structured domains are

viewed as irregular and contextual (Spiro *et al.*, 1987). The theory suggests that instructional design for such domains should represent the complexity of the domain by creating webs of information (e.g., through the use of hyper-text), using multiple perspectives, and embedding the knowledge within multiple contexts. Students of ill-structured knowledge domains should engage in critical analysis, perspective taking, and problem framing to support the transfer of knowledge to new contexts. Thus, cognitive flexibility within such complex domains:

...includes the ability to represent knowledge from different conceptual and case perspectives and then, when the knowledge must later be used, the ability to construct from those different conceptual and case representations a knowledge ensemble tailored to the needs of the understanding or problem-solving situation at hand (Spiro *et al.*, 1991, 24).

While some aspects of learning to teach may reside in learning factual information and theoretical principles, many aspects of teaching can be considered a complex and uncertain endeavor. Many illustrations of teaching practice demonstrate the complexity of teachers' knowledge application, decision making, immediacy of response, and the overall management of dilemmas in daily practice. Based on this view of teaching, knowledge for teaching requires a flexibility of application and practiced decision making that would allow beginning teachers to respond flexibly to messy and context-dependent variation.

In a study from the University of Haifa in Israel, Eilam and Poyas (2006) used cognitive flexibility theory to study the efficacy of engaging with multimedia cases. They examined 21 responses of trainees in a university teacher education program using pre/post tests that emphasized implicit cognitive processes as central to teaching before and after a one-semester intervention. To address the development of cognitive flexibility in responding to messy classroom situations, a new teacher-training course was designed for future junior high and high school literature teachers and was offered via the Internet in the last semester of the teacher preparation program. The course comprised five video cases taken from real literature classrooms with accompanying written contextual information about the students, the teacher, the school, and the curriculum, as well as the materials used during the lessons. The participants also had access to the university library database, interview excerpts with the teacher on the video, external experts, and a web forum to engage in dialogue. In analyzing the web-based materials, the novice teachers were asked to describe the wide variety of contextual factors in complex classroom scenarios, interpret interrelations and interactions among those factors, and evaluate the possible effects on teaching and learning in the given situation. Based on content analysis of written responses to particular tasks prior to and after completion

of the course, the authors concluded that the novice teachers demonstrated an increased ability to survey and grasp the complexity of the whole classroom system including the implicit teaching-learning processes.

Social Cognitive Theory

One argument for the use of case methods suggests that cases can be used as a means of presenting exemplars of practice, allowing novices to see complex practices in action, thus providing a model of performance. This argument draws most strongly on social cognitive theory (Bandura, 1986) that posits that behaviors are learned by watching others' modeled behaviors. According to this theory, rather than mimicking the exemplar, the learner abstracts the structure and the underlying principles governing the behavior and then uses those principles to generate new versions of the behavior. It has been shown that the learner can produce innovative behaviors from observing multiple models and combining features from different models. The theory also suggests that cognitive skills can be verbally modeled through think-alouds that communicate reasoning while engaged in cognitive activities such as problem solving.

The Best Practices project at Arizona State University attempts to provide a collection of authentic technology-based teaching models by creating cases of real teachers who have been identified as exemplary by peers and university faculty and staff (Kurz *et al.*, 2005). The developers caution that the term "best practices" is not meant to imply that the teachers included in the database are the best, but the premise of their project rests on providing models of teaching and reflective practice behaviors to be used in teacher preparation.

Reasoning and Reflective Practice

In many ways, conceptions of teacher development grounded in theories of reasoning and reflective practice are distinct from one another; yet, their close association with the practical nature of teachers' work binds them together in this discussion and in much work associated with case methods. Reasoning can be viewed as a rational process of planned action. Practical activities, such as teaching, often demand on-the-spot action without the luxury of forethought. The Aristotelian concept of *phronesis*, often translated as practical reasoning or practical wisdom (Dunne, 1993), incorporates not only the action derived from thought but also suggests that one may come to know what one thinks through taking action. The knowledge of the practitioner is bound up in the action and can be further articulated or made explicit through reflection on that action. Schön (1987) similarly described knowledge-in-action as spontaneous and subtle, a taken-for-granted kind of knowing. Through reflection-in-action, one can

make adjustments and even perform on-the-spot experiments or engage in a “pattern of inquiry” (p. 27) that allows one to adapt action to the particulars of the situation. Reflection-on-practice allows for the postanalysis of the situation and a review of one’s performance, with the potential of evaluating the effectiveness and process of one’s choices.

Using a framework centered on reasoning to examine the potential outcomes of case methods is less concerned with knowledge structures and cognitive processes of transfer and places more emphasis on addressing the complexities of practice through action, including the moral means and ends of one’s choices. Harrington (1995) explored the development of preservice teachers’ reasoning by examining student’s written analyses of dilemma-based cases. She analyzed the responses according to the following framework for making reasoned decisions: problem identification, awareness of alternative perspectives, warranting of solution, consideration of consequences, and reflectiveness. She argued that case methods have the potential for preparing teachers to “make reasoned decisions—decisions incorporating and balancing theoretical, normative, practical, and consequential reasoning—foster[ing] the development of critically reflective practitioners” (p. 212).

Much has been written about the use of case methods to promote reflective practice and increase the reflective capacity of novice teachers. Many, however, have criticized the overused and underdefined concept of reflection in teacher education practice and research. Harrington *et al.* (1996) argued that “preparing teachers who are reflective requires a clear conception of what reflection is and the means to foster its development” (p. 25). In their study of 21 undergraduate students studying to be elementary school teachers, they analyzed a set of case analyses completed by the students to determine if students’ case analyses could be used to understand particular aspects of reflection exhibited by the preservice teachers. Drawing on Dewey’s (1933) definition of reflection, the authors examined the nature of open-mindedness (the ability to understand and take multiple perspectives), wholeheartedness (the ability to identify and address the limitations in one’s assumptions about authority and understand the complexity and ambiguity of issues), and responsibility (the ability to consider the moral and ethical consequences of choices and actions on self, others, and the broader society). The authors concluded that the students’ case analyses demonstrated evidence of these multiple dimensions of reflection.

Bridging Theory and Practice

Using case methods in teacher preparation is time intensive and may place limits on curriculum coverage in

teacher preparation programs. Yet, case methods have been lauded as a means by which the often-criticized gap between theory and practice can be bridged in the education of teachers. Traditional teacher preparation models often maintain distinctions and separations among theoretical knowledge emphasized in college and university classrooms, observation of expert teachers in classrooms, and the first-hand practice of the novices during clinical placements. The use of case methods allows prospective teachers to analyze an authentic situation critically, generate multiple theoretical and practical interpretations of it, and formulate plans of action for a particular situation.

In her reflections on 20 years of working with teachers developing and using case methods, Judith Shulman (2003) wrote about a “vision of teaching as a deeply professional and profoundly complex form of theoretically enriched *practice*. The practice may be informed by theory, but it can ultimately only be learned and understood through the study of practice” (p. 2). Shulman puts forth a theory of teacher learning grounded in the study of practice that is exemplified through activities such as case writing, case analysis, and portfolio analysis of practice. Thus, case methods have the potential to not only situate the learning of the teacher in a particular context but also to provide opportunities to theorize from practice while practicing theory.

Conceptions of Teacher Education

J A Whitcomb, University of Colorado at Boulder, Boulder, CO, USA

Introduction

Most individuals hold vivid memories of teachers who have touched their lives. Popular culture promotes stories of teachers as heroes who nurture the student's passion for learning. Large-scale studies using value-added modeling have demonstrated the teacher's impact on student achievement, as measured by standardized tests. The confluence of personal memories, popular culture images, and research findings places teaching at the center of educational reform efforts. Not surprisingly, interest in teaching draws attention to teacher preparation, a perennially contentious topic. For decades, teacher education has weathered criticism, for example, low entry standards, lack of intellectual rigor, overemphasis on theory, disconnect from the reality of schools, and programmatic incoherence. Both internal and external critics describe teacher education as a weak intervention.

Sustained critique reflects both the politicized nature of teacher education and distinct conceptualizations of good teaching and, by extension, teacher preparation. This article examines four conceptions of teacher education: (1) social justice, (2) teaching for understanding, (3) contemplative, and (4) clinician-professional. Each articulates a particular vision for the aims of teacher preparation that is grounded in an argument for educational purposes and features of good teaching. Each reflects an intellectual rationale that guides curricular goals and program design. The four approaches presented build upon and extend previous discussions of conceptions of teacher education; see Table 1 (Feiman-Nemser, 1990; Liston and Zeichner, 1991; Zeichner, 1987, 1993).

These conceptions are robust. Since the early 1990s, each approach has been elaborated and developed, with some approaches more than others, at the center of innovation and theory development in teacher education. No new conceptual approach has emerged to reframe conversations within the field about the aims of teacher education. This article emphasizes current understandings and instantiations.

Social Justice Approach

A social justice approach to teacher education begins with the idea that a central purpose of education is to redress social, economic, and political inequities. Its intellectual roots lie within a radical progressive tradition. In this

conception, a good teacher understands socioeconomic and political forces that maintain structural inequality and oppression, including how schools as institutions reinforce the *status quo* and further inequitable educational experiences. Given the centrality of race, ethnicity, and class in inequality, a social justice approach to teaching involves an ongoing commitment to grapple with these matters. A teacher for social justice enacts curriculum so that students develop both a critical social consciousness and the intellectual and practical tools to be agents of change. Students study the experiences of those who have been marginalized along with possibilities for liberation. The teacher also ensures that students learn skills and knowledge associated with the most powerful (cultural capital), thereby helping to promote access to all levels of society. Classrooms are democratic communities where the teacher helps construct an ethos of care and respect. Finally, a social justice teacher also embraces an identity as a community activist and sees this work as an extension of her teaching.

Social justice approaches to teacher education have been part of the teacher-education landscape since the 1930s. In the US, they emerged as part of a larger social movement to redress the ills of capitalism made evident in the Great Depression. Liston and Zeichner (1991) and Feiman-Nemser (1990) describe several well-regarded historical examples including the New College at Teachers College, Columbia University in the 1930s, the National Teacher Corps, and the elementary education program at the University of Wisconsin, Madison. Rodgers (2006) adds to our understanding of historical programs with her study of The Putney Graduate School (1950–64) which was known for turning the souls of its participants. The rise of social foundations courses as a core part of teacher preparation programs is also directly attributable to social reconstructionist or social justice conceptions of the purpose of schooling. While many of these early programs were small in scope, they offered compelling visions of this approach.

Since the late 1980s, reform conversations in teacher education highlight social justice. Several programs have demonstrated both intellectual willingness and practical approaches that illustrate the viability and vitality of this approach. These programs begin with the proposition that learning to teach is a transformative process. Though program structures (e.g., length of program, course sequences, and location and duration of field experiences) vary, most social justice programs have similar curricular aims.

Table 1 Comparative summary of conceptions, paradigms, conceptual orientations, and traditions of teacher education

<i>Conceptions of teacher education</i>	<i>Paradigms of teacher education (Zeichner, 1987)</i>	<i>Conceptual orientations (Feiman-Nemser, 1990)</i>	<i>Traditions of practice, traditions of reform (Liston and Zeichner, 1991; Zeichner, 1993)</i>
Social justice		Critical	Social-reconstructionist Teaching for understanding
Contemplative	Academic	Academic	
Clinician-professional	Personalistic	Personal	Developmentalist
	Behaviorist	Technological	Social-efficiency
	Traditional craft	Practical	
	Inquiry		

One aim is to help candidates develop conceptual tools to understand how the *status quo* marginalizes and oppresses some members of society. Teacher educators challenge and disrupt candidate's assumptions about how cultural diversity, race, class, gender, sexual orientation, and disabilities shape learner's experiences and opportunities in school and society. The aim is to foster candidate's critical consciousness. Through critical inquiry and reflection, candidates examine structural features of schools that promote inequality and, at the same time, analyze how their personal background might affect interactions with members of oppressed or marginalized groups. Such analyses guide candidates to grasp the political nature of teaching and inspire them to embrace the role of change agents.

While there is no one specific social justice pedagogical repertoire, most programs emphasize the following practices. Candidates learn to adapt and develop curriculum and assessments that reflect learner's lives and worlds and that foster learner's critical understanding of inequities. To promote access, candidates learn to build bridges from learner's worlds to school knowledge, to scaffold their thinking and learning of intellectually demanding academic tasks, and to provide appropriate linguistic supports for those whose primary language is not the language of instruction. Candidates develop abilities to establish and maintain safe, respectful classroom communities and to facilitate highly charged conversations, particularly ones that address race, class, language, and power. Many of the practical tools just described are consistent with culturally responsive approaches to teaching and thus are not the exclusive purview of a social justice conception of teacher education. One key distinction with social justice teacher education is the attempt to encourage candidates to take an activist role in standing up to unjust schooling practices. In recent years, this has involved taking a public stance on rigid accountability systems, creating places and spaces for parent voices to be heard, working on school or district committees to broaden the curriculum or to challenge tracking policies, and participating in community activist organizations.

Much scholarship on social justice conceptions of teacher education provides conceptual arguments for what capacities candidates need to develop along with

analytical descriptions of specific programs, courses, or learning experiences that foster this development. Rigorous studies examining evidence of effective social justice teacher-education programs are just emerging. McDonald (2005) found that programs explicitly committed to teach for social justice were more effective in helping candidates develop conceptual tools, rather than practical tools. Montano *et al.* (2002) also found that many of the typical structures in teacher education do not adequately prepare candidates to be change agents; thus, they recommend providing candidates with direct experiences in community-based activist organizations that allow them to identify with larger historical, social movements. In sum, since 1990, social justice conceptions of teacher education have been the center of research activity and program development. Much has taken place to give concrete shape to this conception of teacher education.

Teaching for Understanding Approach

Within a teaching for understanding approach, the central purpose of schools is to teach academic content. What comprises school subject matters has changed significantly over the last century, resulting in a rethinking of the teacher's role and the role of content in teacher preparation. In the early part of the twentieth century, academic content entailed mastering basic literacy, numeracy, and a defined body of content knowledge. Recitation was the most common teaching practice. The image of the teacher as a scholar-professional (Sokkett, 2008) prevailed. Essentially, the intellectual work of liberal arts study was the central feature of teacher preparation. Starting in the mid-twentieth century, reformers attempted to transform the content of the school curriculum from one based on factual recall to one where students grappled with substantive disciplinary questions and ideas, where students learned to evaluate claims and how new knowledge was constructed in academic fields, and where problem solving, dialog, and critical inquiry were normative. This notion of the curriculum synthesized and reflected Dewey's understanding that disciplinary content must be connected to learner's experiences, Bruner's argument for

teaching in intellectually honest ways, and Schwab's discussions of the substance and syntax of the disciplines. It is also consistent with constructivist and sociocultural theories of learning. Kennedy (2005) identifies three ideals that capture reform-minded views of teaching and learning academic content: (1) more rigorous and important content, (2) more intellectual engagement, and (3) universal access to knowledge.

Serious efforts to enact this approach to content in schools sparked a rethinking of the teacher's role in the classroom. Reformers often called this approach teaching for understanding. A good teacher in this approach acts as a facilitator. Essential to a teacher's pedagogical repertoire is the ability to structure engaging problems or essential questions that guide learners to construct understanding of disciplinary concepts rather than to receive finished knowledge. Teachers are keen perceivers of learner's thinking, attending to what is sensible in children's naive or novice ideas and guiding them to ways of thinking that are more accepted by scholars within the discipline. They facilitate dialog and manage an intellectually complex flow of information among learners. This is a significant reframing of the scholar-professional of the late nineteenth and early twentieth century, where imparting knowledge was the expectation. The emphasis on fostering the life of the mind and conceptual understanding of content provoked a renewed discussion of the role of content in teacher's preparation.

In 1986, Shulman (1986a) argued content was the missing paradigm in teacher education. He contended teachers must develop a pedagogical understanding of content, or pedagogical content knowledge, defined as

The most regularly taught topics in one's subject area, the most useful forms of representations of those ideas, the most powerful analogies, illustrations, examples, explanations, and demonstrations – in a word, ways of representing and formulating the subject that makes it comprehensible to others. Pedagogical content knowledge also includes an understanding of what makes the learning of specific topics easy or difficult; the conceptions and preconceptions that students of different ages and backgrounds bring with them to the learning of those most frequently taught topics and lessons. (Shulman, 1986b: 9, 10)

Shulman's conceptualization of pedagogical content knowledge both reflected and triggered a round of reforms centered on the role of content in teacher preparation. For example, one policy response in the United States was to reduce the number of required education courses and to increase courses in the academic major. However, the typical coursework within an academic major does not necessarily help teacher candidates develop pedagogical content knowledge, as that curriculum aims to prepare future scholars and researchers.

Yet, through content courses, teachers develop firmly held beliefs about the nature of the discipline and what content is most important, and these beliefs shape their classroom practice. As a result, starting in the mid-1980s, addressing teacher's beliefs about content became a primary site for teacher-education-program reform. Much of this activity occurred within content methods courses.

Distilling the research, Grossman *et al.* (2005) outline questions to guide curriculum and pedagogy in content methods courses. In addition to inquiry into the nature of the discipline, teacher candidates should examine how school knowledge is defined and elaborated, consider what student performances of understanding content matter look like, analyze primary curricula for teaching subject matter, investigate how teachers assess student's conceptual understanding, and gain familiarity with and appraise effective pedagogical practices in the content areas. Reformers who value teaching for understanding recognize that this kind of teaching is complex and ambitious and that it more likely to happen in workplace contexts that are organized to support teacher's collaboration. Teacher educators have developed or adopted practices to cultivate the candidate's pedagogical content knowledge and pedagogical repertoire to teach for understanding (e.g., lesson study, video clubs, case methods, and extended studies of student thinking about a particular topic). Overall, the emphasis on teaching for understanding as an approach to teacher education is most evident in content methods courses, rather than programmatic efforts; however, given the dominance of methods courses in many programs, teaching for understanding has come to occupy a featured space in the conceptual frameworks of many programs.

While teacher educators embraced the importance of pedagogical content knowledge and refined methods courses and programs around this aim, a vocal minority has persistently sought to return to a model where a deep exposure to disciplinary content is sufficient preparation to be an effective teacher. Despite challengers, teacher educators have moved substantially to conceptualize a vision of teaching and learning where both students and teachers engage in lively inquiry into the big ideas of the disciplines. In this conception, the teacher's active intellectual life is prominent.

Contemplative Approach

A contemplative approach to teacher preparation articulates with the most enduring of educational aims, the quest to know oneself, to connect with others, and to find one's place in the social and natural world. In this vision of education, learning occurs when individuals take up thoughtful explorations of meaning openly, critically, and even playfully. Together, teachers and students delve

into the mysteries and majesty of the human condition and the natural world. When compared to teaching for understanding, a contemplative approach offers a more transcendent vision of knowledge, one that, at its best, fosters wisdom along with understanding. Its roots are found in both humanist and spiritual traditions. To be a good teacher requires knowing one's subject and one's students, but most crucial is a teacher's knowledge of self. Palmer captures this view:

Teaching, like any truly human activity, emerges from one's inwardness, for better or worse. As I teach, I project the condition of my soul onto my students, my subject, and our way of being together. The entanglements I experience in the classroom are often no more or less than the convolutions of my inner life. Viewed from this angle, teaching holds a mirror to the soul. (Palmer, 1997: 15)

While the contemplative approach does not diminish the importance of craft and content knowledge, exploration of the inner landscape of a teacher's life is what anchors practice. The focus of teacher education thus turns to cultivating self-knowledge, developing an emotional and compassionate presence, and tapping into one's sense of vocation or mission. Teacher education is foremost about the development of identity and integrity rather than initial mastery of certain techniques or practical tools.

The contemplative bears a strong resemblance to approaches that others have described as personalistic, personal, and developmentalist (see **Table 1**), particularly in its commitment to developing and nurturing the self who teaches. Theoretical interest in self and identity that emerged in the 1990s gathers together studies of teacher beliefs and attitudes along with narrative studies of teacher's lives. This work provides new conceptual language and analytical tools to understand how teachers construct a sense of themselves. This theoretical lens on identity draws attention to the relationships between an individual's inner core or private self and one's situational and socially constructed identities. It also gives prime attention to the relational and emotional aspect of integrating one's evolving, and partially unknowable, inner landscape with one's external landscapes. It brings out the paradox that one must focus inward to turn outward. It affirms the central role of storytelling in the learning-to-teach process. Finally, it maps onto a larger developmental process of becoming a mature adult.

A related, but distinct, aspect of contemplative teacher education derives from a broader effort to introduce contemplative practices into schools and to characterize teaching as a contemplative practice. Drawing from contemplative traditions within several major religious traditions (e.g., Buddhism and Quaker), contemplation offers an antidote to the relentlessness and task orientation that seems to characterize contemporary schooling. Educators who turn to contemplation attend to the inner lives of

children and teachers. They speak about creating sacred space and time in the classroom, being mindful, and viewing students from a stance of wonder, receptivity, and acceptance (Miller, 1994). Contemplative teacher educators seek to introduce new teachers to contemplative practices enacted in k-12 settings and to model those practices within their own work.

Since contemplative teacher education is arguably the least mainstream of the four conceptions, programmatic examples are less abundant than the other approaches discussed in this article. Historical examples include the Bank Street College (in the 1930s), the Prospect School Teacher Education Program (1968–90), and the Humanistic Teacher Education Program at the University of Florida (Feiman-Nemser, 1990; Liston and Zeichner, 1991). These efforts reflect a progressive educational vision. Since the late 1990s, professional development, rather than initial teacher education, has been an active site for contemplative approaches, though these programs operate on the margins (see, e.g., the *Courage to Teach* program or the master's in Contemplative Education Program at Naropa University). It is premature to say that there is a pedagogy of contemplative teacher education. Distinctive features of courses and programs that fit within this approach include creating opportunities for candidates to draw meaning from their life histories, introducing candidates to meditative practices, giving attention to social-emotional dimensions of learning, and providing space for candidates to learn to listen and attend to children and youth.

Clinician-Professional Approach

A clinician-professional approach to teacher education aims to prepare teachers whose conceptual understandings and pedagogical repertoire reflect a consensually established professional knowledge base. (The term clinician-professional comes from Sockett's (2008) delineation of four moral and epistemic purposes for teacher education.) This approach implicitly compares teachers to medical doctors prepared in a Western context and views medical education as the model. A turning point in US medical education was the 1910 Flexner report, which resulted in a common curriculum grounded in the scientific basis for medical practice and the establishment of medical preparation in the university. Since the beginning of the twentieth century, teacher education, as a low-status profession, has struggled to gain credibility and respect. Invoking the Flexner report, one response to improve the quality and status of teacher education has been to establish a research-based, scientific approach to teaching and learning that informs teacher-education curriculum. In this sense, unlike the three conceptions discussed above, the clinician-professional

approach has a less distinctive normative vision for the broader aims of education and, by extension, good teaching.

The intellectual roots for a scientific approach to educational research extend back to Thorndike's argument (1910) in the first issue of the *Journal of Educational Psychology* where Thorndike asserted that experimental science and statistical analyses should guide all educational research. Within this approach, throughout the twentieth century, basic research in children's learning and development and scientific analyses of teaching practice shaped teacher-education curricula. Behavioral, cognitive, and sociocultural orientations within psychology played successive roles in defining conceptual content of the knowledge base for teaching, a good teacher's pedagogical repertoire, and how best to teach teachers. In this way, the clinician-professional approach is the latest and most sophisticated instantiation of the behavioral, technical, or social-efficiency traditions described by others (see **Table 1**).

Process-product research in the 1960s to the 1970s exemplifies a behaviorist inquiry into teaching. Process-product studies correlated specific, observable teaching behaviors (e.g., developing explicit objectives, time on task, wait time, or guided practice) with student achievement as measured on standardized tests. Subsequently, these discrete target teaching behaviors formed the basis for competency-based teacher-education programs. In the 1980s, the tight connection between behavioral psychology and teaching loosened as the field of psychology took a cognitive turn, and as educational research began to accept qualitative methods. Shulman's (1986a) critique of process-product research invited scholars to broaden research methods employed to examine teaching practice. His argument also spurred scholarly activity to define a research-based knowledge base for teaching. The cognitive turn gave greater attention to teacher's thinking, beliefs, and reflection. For this reason, teacher-education practices such as case methods or journals focused on fostering sound deliberation, decision making, and reflection.

Consistent in these evolving instantiations of a professional knowledge base is a commitment to social science research as the proper grounding for teacher's knowledge and practice. At the start of the twenty-first century, two distinct approaches to define the clinician-professional knowledge base and pedagogical repertoire are in play. The American Board for Certification of Teacher Excellence (ABCTE), in an effort to circumvent university-based teacher preparation, has developed a certification process based on passing multiple-choice exams that assess content and professional teaching knowledge. Exam content standards for the latter draw heavily from teaching behaviors identified in the process-product studies of the 1960s and 1970s. The multiple-choice exam format reinforces competency-based teacher education's emphasis on discrete, decontextualized practice. In contrast, the National Academy of Education's

Committee for Teaching Education publication *Preparing Teachers for a Changing World* (Darling-Hammond and Bransford, 2005) represents the most comprehensive attempt to codify the knowledge base and curriculum for teacher preparation. Research evidence that informs the National Academy report draws from studies conducted within different conceptual frameworks and methodologies (e.g., experimental, naturalistic observations).

The National Academy report envisions the teaching profession as serving democratic purposes. In this sense, it bears a resemblance to social justice conceptions of teacher education, as the aim is to foster children's learning and to enhance their life chances. The study organizes the knowledge base into three domains: (1) knowledge of learners and how they learn and develop, (2) conceptions of curriculum content and goals, and (3) understanding of teaching practices. While building upon previous articulations of a knowledge base, this report reflects recent scholarly activity emphasizing diversity, the role of language in learning, and the complexity of classroom worlds.

What distinguishes professional teachers is their knowledge and commitment to "practice based on what is known by the profession as a whole, rather than only one's own personal experience" (Darling-Hammond and Bransford, 2005: 15). Given the rapidly changing world of schools, the report positions teachers as adaptive experts, who are able to balance the dual aims of achieving efficiency in practice and engaging in innovation. The clinical-professional's pedagogical repertoire includes many of the research-based practices referenced in the three approaches described previously. Like a physician whose practice evolves as scientific studies refine or transform our understanding of the body and health/disease, the clinical-professional's repertoire evolves as understanding grows about how teachers support diverse students to learn complex subject matter.

Preparing to be a clinician-professional involves both carefully guided practice in evidence-based pedagogies and sustained inquiry into one's own practice. The contexts for teacher learning matter as learning will be most robust if it is both in and of practice. Overall, the clinician-professional approach tends to dominate teacher-education programs, in part because its comprehensiveness embraces aspects of other conceptions described in this article and in part because the knowledge base and pedagogical repertoire subsumed within this conception are codified in many national standards for program accreditation.

Conclusion

In closing, the four conceptions outlined in this article characterize the terrain of teacher education at the start of the twenty-first century. Each conception begins with an argument for a broad educational aim and its attendant

image of good teaching. By tracing back to each conception's intellectual roots and historical examples, current instantiations are located within an ongoing dialog of teacher-education practice. The influence of sociocultural learning theories, as it relates to both children/youth and teacher learning, is evident in all four approaches. Similarly, teacher educators who affiliate with each conception are grappling with how best to prepare teachers for increasingly heterogeneous classrooms. To educate teachers within a particular orientation involves creating opportunities for candidates to learn distinctive conceptual ideas and teaching practices. Yet, in all likelihood, most teacher-education programs reflect some blending of these conceptual approaches. The elaboration of each conception since the early 1990s (see **Table 1**) along with the dynamic interplay among them suggests a certain vitality and intellectual energy within the field of teacher education.

Inquiry-Oriented Teacher Education

R Schulz, University of Manitoba, Winnipeg, MB, Canada

The new scholarship of teaching and teacher education recognizes the enormous challenges of schooling in the twenty-first century, and emphasizes the importance of preparing teachers who understand the complexities of their role. Cochran-Smith (1999) contends that the most promising way of learning about such a complex role, so fraught with uncertainty, is based on inquiry within communities, rather than training for individuals.

In North America, the notion of inquiry was put forward over a century ago by Dewey (1904/1965), who criticized teacher education programs for placing too much emphasis on training and mastery or delivery of technical skills. He argued that, although first-hand practical experience in the schools is critical for the preparation of new teachers, the experience might well be miseducative if new teachers improved in the mechanics of teaching but failed to go on growing. Therefore, he advocated for teacher education programs which prepared new teachers to become critically thoughtful, ongoing students of education.

Some decades ago, in England, Lawrence Stenhouse (Rudduck and Hopkins, 1985) argued in a similar vein for the preparation of teachers to become extended professionals, proficient as problem solvers in their own schools, and knowledge generators for the profession. Stenhouse maintained that engaging in inquiry was essential to becoming an extended professional, and that systematic, self-critical inquiry was “linked to the strengthening of teacher judgement and consequently to the self-directed improvement of practice” (p. 3).

Inquiry can be defined as the systematic, intentional study of one’s own professional practice. (Cochran-Smith and Lytle, 1999). Inquiry is a stance, a way of knowing about teaching and learning from teaching. Inquiry is not a singular event – it is an integral part of teaching, a process that practitioners engage in consistently throughout their professional career as a way of learning from practice, even as they are engaged in the practice of teaching. Known by many names – teacher research, practitioner research, and insider research – teacher inquiry focuses on the concerns of teachers, as opposed to outside researchers, and involves classroom teachers in the disciplined and rigorous processes of researching their own questions in ways that can be scrutinized and verified by others as reliable and trustworthy. The term, as used in this article, therefore encompasses the various forms of research conducted by practitioners (individually and collaboratively) in their own schools and classrooms, for the purpose of increasing their own learning, enhancing

student learning, and contributing to school change. Key assumptions here are: (1) the knowledge needed to understand and improve teaching, and learning cannot be generated only by those outside; (2) teachers and teacher candidates who work in particular contexts are among those who have significant knowledge of both what the problems and questions are; and (3) through systematic data collection and analysis, how the problems within that context can be solved. Additionally, the knowledge generated by practitioners, and made public, is often also useful beyond the context in which it was generated. In this way inquiry becomes an important aspect of redefining teacher professionalism.

The conceptual scholarship on inquiry-oriented teacher education is extensive and rich, but the empirical research is not as robust. In her synthesis of the research on teacher education pedagogies, Grossman (2005) concluded that there were relatively few empirical studies about the impact of inquiry on teachers’ learning. Nevertheless, as we relinquish historically rooted notions of the teacher as “technician, consumer, receiver, transmitter, and implementer of other people’s knowledge” (Cochran-Smith and Lytle, 1999: 16) and shift to an expanded conception of the teacher as a knower, thinker, knowledge generator, and change agent, the understanding of what is required in teacher education programs has also changed, and an emphasis on inquiry is becoming more evident.

An inquiry orientation in teacher education constitutes a dramatic shift from traditionally organized programs, which disseminate a knowledge base constructed almost exclusively by outsiders. By contrast, inquiry-oriented teacher education programs present learning as a process of jointly creating knowledge. They see inquiry as an integral part of teaching, and focus on the processes of learning for teaching as well as learning from teaching. Teacher candidates learn about teaching by studying, in systematic and intentional ways, their own experiences both in the academic setting and in the field placement, at the same time they become critical consumers of the research of others. In a profession that usually strives for certainty and answers, inquiry-oriented teacher education programs prize questioning. Teaching is understood as a form of experience that is contextual, value-laden, intentional, as well as intuitive. As such, a different relationship between theory and practice is recognized. Methods, courses, and their historical preoccupation with technique are not the backbone of the program, and theoretical suppositions are not necessarily the starting point. Instead, the teacher candidates’ questions might be the

starting point, and as Smits (2007) suggests, active engagement with situations and in action is imperative with theoretical suppositions entering in a more dialogical fashion.

Different Understandings of Inquiry

Because of the widespread use of the term inquiry in teacher education, there is a need to discuss the many different understandings of what it means to be inquiry oriented. Definitions in practice and in the literature overlap, at times they pull in different directions and compete with each other. Various definitions of inquiry exist in science literature, and these may differ again from the way educators in humanities define inquiry and a pedagogy for inquiry. These different definitions and understandings include, among others: (1) inquiry as a process for co-constructing curriculum in the classroom; (2) inquiry as a process of questioning and knowledge building, and a means through which research is accomplished; (3) inquiry framed within concepts of construction and narration, in opposition to research, which comes from a tradition of discovery and revelation; (4) practical inquiry, where the aim is to generate or enhance practical knowledge; and (5) inquiry as a way of knowing in community, central to which is the idea that the work of inquiry communities is both social and political.

The point of inquiry, whether in the humanities or the sciences, is that there is always more to learn. As new knowledge is acquired in any discipline, the old, suddenly upended ideas seem quaintly uninformed. For children to be drawn into learning, educators know that they need to be with teachers who can engage them, immerse them in a current thought, entice them to pursue what is not known, and teach them the appropriate methods for this pursuit. If students are to become inquiry-minded critical thinkers and creative problem solvers, teachers can be no less so. The shared belief therefore, regardless of definition and discipline, is that if inquiry is to be a transformative force, what it is not, is merely technical tinkering.

While genuine inquiry might be conceptualized in the literature as a transformative force for teacher development and school change, it can also be reshaped to support a variety of educational or government agendas. Currently in England, where the standards movement holds sway, with its emphasis on accountability, inspection, regulation, centralized policy making, and nationally driven policy implementation, there is little encouragement for local meaning making, or constructing knowledge within the school community. Opportunities for defining one's own questions are reduced, and the inquiry teacher candidates engage in during their practicum placement often consists of helping the school make sense of new government initiatives or fine-tuning

strategies that make classroom routines or curriculum delivery more efficient (Schulz and Hall, 2004).

Inquiry is trivialized if it is understood only as a project, or if its purpose is primarily to tinker with and perfect certain skill sets.

As inquiry, with its breadth of definitions, becomes institutionalized in a greater variety of contexts, and co-opted by different political interests, there is a danger that it will become anything and everything, eventually devolving into nothing. However, in our efforts to reduce the plethora of definitions that surround inquiry, we want to be careful not to simplify the concept and the term to the extent that it can be contained within a single prescriptive, reductionist, and technical phrase. This would dilute its potency. The multiple definitions of inquiry need not be a liability. They can, in fact, be seen to enlarge and enrich the term, the process, and the possibilities, when those committed to the broader transformative goals of inquiry continue to debate and discuss among themselves their various understandings and practices. An ongoing conversation about what it means to inquire, best engaged in jointly by teacher educators, teacher candidates, and practicing teachers, if incorporated as a central component of a teacher education program, would create a second layer of inquiry, an inquiry into inquiry, whereby the practice of inquiry is modeled for teacher candidates, at the same time that the processes and outcomes of inquiry are being studied.

Inquiry is a stance, a way of being, and a habit of mind. It is a curiosity about one's own and other's learning, a wanting to know, being open to different possibilities and new ways of knowing, believing, that it is in wondering and questioning that learning begins, and then pursuing that learning in systematic and intentional ways. Taking an inquiry stance means becoming, as Dewey suggested, a "thoughtful and alert student of education." Alfred North Whitehead used the term "scholarly ignorance." If we recognize that there is much that we do not know, that there is something important to be gained by the process of inquiry, then it is our scholarly ignorance that can be generative of genuine inquiry.

Inquiry-Oriented Teacher Education Programs

Inquiry-oriented teacher education programs generally expect their candidates to be inquirers/researchers who have a breadth of knowledge and a variety of tools to ask questions about educational environments. Inquiry-oriented programs focus on learning for teaching as well as learning from teaching. They expect that teacher candidates will reflect on and continually evaluate the effects of their choices on students, their families, and other professionals in the learning community. Programs that

raise the awareness of teacher candidates to the larger issues of education, and encourage dispositions of inquiry, must also provide their teacher candidates with the skills and tools to confront the complexities and uncertainties of teaching. Different teacher education programs in different countries have approached this task differently.

For the last 30 years, teacher education in Finland has been research-based. Proceeding from the belief that effective teachers cannot only be consumers of research, that they must also be producers of research, teacher education programs in Finland require their teacher candidates to take both qualitative and quantitative research courses, as a way of preparing them for their extended professional teaching role. Currently, universities in Hungary are restructuring their teacher education programs. Recognizing Finland's success in international comparisons of education, Hungary is drawing on lessons about inquiry-oriented approaches from that country (Csapo, 2007).

Darling-Hammond (2006), in her work, identified a number of features common to seven exemplary US teacher education programs. All the programs she studied required that teacher candidates engage in inquiries or research about teaching, and Herr and Price (2007) estimate that approximately half the teacher education programs in the United States now require their teacher candidates to engage in action research, reflecting the current emphasis in that country of preparing teachers who see themselves as learners and inquirers into their own practice.

From within an inquiry-based literacy teacher education paradigm, teacher candidates learn to teach by observing children closely, being curious about children's wondering, supporting them in making their literacy learning visible, and collaboratively opening up worthwhile inquiry potentials. Curriculum development in the classroom is seen as a shared process, with learners and teachers collaborating together to make decisions based on the experiences and needs of a specific community of learners. There is a sense of negotiation and fine balance between what the children bring to the experience and the teacher's professional understandings of teaching, learning, and young children's development. Choice, decision making, and reflective practice inform and define the curriculum that develops. It is understood that there is not a single official learning path or end point. Teacher candidates develop their professional sense through reflecting in action, engaging in continued professional reading, and dialoguing with trusted others who are positioned differently within a professional inquiry community but who take teacher candidates' ideas seriously.

Another perspective on inquiry-oriented teacher education comes from the work of Korthagen *et al.* (2006). Drawing on their analysis of three teacher education programs in Australia, Canada, and the Netherlands, they outline some fundamental principles that they

believe make a difference. These include a belief about the importance of student teachers engaging in inquiry through researching their own practice and experiences as teacher candidates. They write that when teacher candidates create and share "their understanding of practice through results of their own research, perceived distinctions between theory, practice, transmission of knowledge and socialization into teaching may be confronted and their professional roles may be better recognized, defined and enhanced" (p. 1035). Because the contexts of the programs that these three researchers studied share similarities to many others around the world, they contend that this fundamental principle is also applicable to other contexts.

Consistent with international trends, an emergent interest in inquiry-based teaching and teacher education is also occurring in China, with movement away from traditional didactic teaching practices and a heavy emphasis on rote memorization, to an approach that incorporates inquiry methods. Stewart (2006), Zhou (2006), and Zhang (2005) report that while most teachers and teacher educators are still unfamiliar with inquiry-oriented approaches, many are showing interest in this new direction. At the same time, however, there is resistance to this call for change, and there are numerous systemic and cultural barriers to the immediate enactment of inquiry-oriented education.

The sole teacher-preparation provider in Singapore, the National Institute of Education, has also undertaken a major review of teacher preparation programs. Reconceptualizing the role of the teacher has become the focus of attention, and Tan *et al.* (2007) note that the emphasis is on developing "future-oriented teachers who are adaptable and flexible to meet the uncertain demands of a changing environment. The programs are designed to emphasize inquiry, innovation, reflection, mutual respect, personal connection, collaboration and community . . ." (p. 14).

If we think of inquiry as a way of knowing in communities, then taking an inquiry stance can mean, among other things, careful observation of what is happening in classrooms, documenting and analyzing practices, sharing and critiquing these with colleagues, as a way of learning from and with others, participating in study groups, going beyond discussions of "what works" to understanding "why" it works, and then extending the discussion to examine and question the values and assumptions that underpin our practices. In Japan, the practice of lesson planning (Stigler and Hiebert, 1999) is an example of one form of sustained, focused, and collaborative inquiry. Japanese math teachers work in groups, sometimes for months at a time, to plan a single math lesson, which is then taught, observed by fellow teachers, analyzed, modified, improved and retaught over and over again. The focus of this ongoing collaborative inquiry and refinement of practice is not on individual teachers and their teaching styles, but on

teaching methods, and how these might be improved in ways that support student learning. Japanese teachers who participate in this form of inquiry into their teaching see themselves as contributing to their own professional development, as well as to the more general development and dissemination of knowledge about teaching.

As Britzman *et al.* (1997) suggest, a great deal of the work of teacher education should be to “produce debate, multiple perspectives on events, practices, and effects, to move toward creative dialogue on practices. . .”(p. 20). In addition to a focus on research courses and participation in action research, collaborative lesson planning, and study groups, inquiry-oriented teacher education programs frequently utilize case studies, videotaping, critical incident methodology, and protocols to guide the way in which teacher educators and teacher candidates explore problems of practice together.

Other commonly used inquiry tools are reflective journals, essays, and portfolios. When these are used in very structured ways, their focus tends to be on a rational and logical analysis of experiences. A more comprehensive approach to reflection also pays attention to nonrational processes that might be accessed through visioning exercises, metaphor analysis, or the use of drawings, as Mitchell and Weber (1999) advocate, to help teacher candidates become aware of the often unarticulated beliefs and values that influence their actions in the classroom.

Self-study through various means, such as writing teacher stories, life stories, or autobiographies, provides another opportunity to explore the connections between our personal and professional lives (Loughran and Russell, 2002). Through self-study we can gain a better understanding of why we teach the way we do, how our teaching is connected to both our disciplinary backgrounds as well as to who we are, and how we might teach differently when faced with students who are very different from us. Autobiographical understanding is an important part of inquiring into what it means to practice as a teacher, and as such, it is foundational to change.

The practicum plays a critical role in every teacher education program. It has traditionally been the place where teacher candidates are evaluated on their performance or their delivery of newly learned techniques, a place where the focus is generally on technical knowledge, rather than a place where deep thinking is developed, where good learning – which involves inquiry – happens (Schulz, 2005). Certainly, teacher education programs must address the technical and procedural aspects of teaching, because planning for teaching and managing a classroom are of unarguable importance. However, the attainment of craft skills, while necessary, is not sufficient preparation for the professional role of teaching. If the practicum experience is to be educative, it must also provide opportunities for growth and learning, must help teacher candidates to understand the full scope of the

teacher’s role, and develop in them the capacity to learn from future experiences.

A promising format for inquiry within the practicum could begin with a question that the teacher candidate wants to pursue. The underlying assumption here is that if the inquiry is to lead to an instructional improvement, it needs to reflect the personal interest of the inquirer. After generating a question, the next step would be to gather evidence in the form of student and teacher work. The data could include the teacher candidate’s observational notes, notes from peer observations, students’ assignments, and videotapes of classroom interactions or students commenting on their work. Ideally, multiple perspectives are brought to the issue in order to understand the many dimensions embodied in the evidence from the classroom. To this end, the data are examined and discussed with the collaborating teacher, with other teacher candidates in the practicum setting, and with the university professor, who can also draw the group’s attention to sources in the research literature, relevant to the topic at hand.

Structures, such as protocols for discussion, can facilitate the goals of inquiry. They guide the discussants, deepen the conversation, help to surface thought-provoking questions, and open up other avenues of exploration. A common protocol practice is to have the presenting teacher candidate put forward the evidence he or she has collected in response to the original inquiry question, but without any elaborating commentary. The first opportunity to comment is given to the other group members who, individually, are asked to describe the evidence before them, making no judgments initially, but raising questions about the data, which can often lead to new insights about the issue. Only after the others at the table have completed their initial commentaries on the evidence, does the teacher candidate explain why he or she chose particular pieces of evidence to share with the group and why they seem to have significance. This is followed by a whole group discussion of what the evidence presented by the teacher candidate tells them about the inquiry question under consideration, what other evidence might be helpful in considering this question, suggestions for changes in practice based on new understandings, and what might be the focus for the next meeting.

Many teacher education programs are now also creating spaces and providing supports for their teacher candidates to engage in inquiry outside the more conventional courses and practicum sites. They incorporate into their programs opportunities for teacher candidates to work with children in hospitals, museums, or art galleries, to join activist groups focused on particular issues or school policies, to participate with parents in community initiatives, or to collaborate with faculty members in research projects. These alternative sites of learning become increasingly important as teacher candidates engage with diverse others to make meaning of their experiences, and question the status quo within schools.

In addition, a number of teacher education institutions are continuing their commitment to their teacher candidates beyond graduation, by supporting them in various ways through their early career experiences. This support often takes the form of regularly scheduled workshops for teacher candidates, where the preservice focus on inquiry is taken up again, but now within the context of the new teachers' classroom settings. Online circles of inquiry facilitate communication among new teachers and their former professors and provide additional electronic networking and support for the new teachers.

The importance of dialog to an inquiry stance is evident in the research currently being conducted in nine different countries, with teachers of English as a foreign language. The Brazilian component of this research (Jordao, 2007) involves the construction of open spaces in teacher education programs where teacher candidates and practicing teachers interact dialogically, to question and be questioned in their assumptions about their identities, their social roles, the role of English as a foreign language, their students' identities, the value of education, and the educational value of English as a foreign language in Brazil. The focus within these open spaces is not entirely on a rational and logical analysis of experiences. Equally important is intuitive and affective engagement with alternative perspectives, where multiple literacies in the form of images, film, caricatures, and narratives are used to illustrate to teachers that even our most reasoned and logical positions are ideological and localized in specific contexts. This can lead to an understanding that no position or theoretical stance is inherently better, and teacher candidates as well as teachers then begin to feel more at ease to construct and locate their own interpretations and value systems, and to engage with different perspectives more critically.

When teachers and teacher candidates are encouraged to pursue their personal wonderings, and their practical experiences are structured so that they can work together in an ongoing way with their peers, their professors, collaborating teachers, parents, and other professionals to share ideas, solve problems, and explore issues – not just at the technical level, but also at the deeper interpretive and critical levels – then they are experiencing effective collaborative inquiry.

Issues and Challenges to Inquiry-Oriented Teacher Education

Even as teacher education is moving toward a more complex notion of teaching, the political climate in many jurisdictions is moving toward a more technical stance. Given these tendencies, it becomes all the more important that teacher candidates are thoughtful and alert students of education who understand the political and ideological restructuring that is occurring, and who have the

knowledge, skills, and disposition to deconstruct and respond to the events around them.

Anderson and Herr (1999) believe that teacher research is presently marginalized, at least in part, because it is a potential threat to the hegemony of traditional forms of research, and if teachers wish to counter entrenched epistemologies, their contributions (through their inquiry practices) to a counter-discourse will have to be strong, intellectually rigorous, and useful. However, it is difficult for teacher candidates and teachers to act upon their commitment to inquiry when the culture of the school they find themselves in is not receptive to the concept.

Schulz and Hall (2004) found that genuine inquiry was seldom a priority in the English and Canadian schools they studied. Echoing the findings from many other studies, the teacher candidates in Schulz and Mandzuk's (2005) study expressed dismay at the disconnect between what they had been taught in their university classrooms, and what they were experiencing in their practicum settings. The exhausting dailiness of school demands seemed to suppress inclinations toward contemplation and inquiry, and the teacher candidates were concerned that what they were learning in their university classrooms would not be well received in the school classrooms. When the school learning community values more local and particular forms of learning and knowledge, it can provide the necessary support for teachers' emerging understandings as they inquire. Within a school community that values inquiry, where teachers and teacher candidates have administrative, collegial, and university support, they can find a space where taking risks and theorizing about teaching is encouraged. However, when the school setting does not support teachers' inquiry stance, the work of the university teacher education program is easily eroded.

Therefore, teacher educators have a responsibility to challenge school resistance to genuine inquiry, to work collaboratively with schools to promote ongoing teacher learning, and decrease the positional differences between the worldviews of school and university. A shared school/university commitment to teacher preparation and support holds much promise, but it also brings its own challenges. Working collaboratively across institutions that reflect the cultural divide between schools and universities is a complex undertaking in and of itself. Additionally, the institutional values of universities neither encourage nor adequately reward professors' practical work with teachers in the field, privileging instead, more traditional paths of research and publication. Similarly, state education officials seldom encourage teachers who want to be recognized as knowledge generators. Instead, they are more likely to become anxious when teachers find their voice as educators, question local policies, and propose alternative agendas. In Hungary, for example, educators involved in the reform of teacher education see the example of

Finland as a model to follow, but state restrictions will not allow them to implement all the educative reforms they propose (Csapo, 2007). In China, the cultural barriers to change are even more pronounced. These examples alert us to some of the broader systemic issues related to inquiry-oriented teaching and teacher education.

A large body of work currently exists that theorizes and describes the use of inquiry as a way to enhance both teacher and student learning. The scholarship in teacher education contends that inquiry-oriented approaches to teacher education disrupt the deskilling of teaching and encourage resistance to the implementation of ineffective teaching practices. Inquiry-oriented approaches in teacher education hold the promise of nurturing the intellectual leadership capacity of teacher candidates and supporting a disposition toward critical thoughtfulness and ongoing learning. Over the last 25 years, the growth of this body of literature has been accompanied by an ever-growing number of teacher education programs around the world that describe themselves as inquiry oriented. A next step in this development is for teacher educators to model and exhibit an inquiry stance themselves by producing sound, robust evidence of the impact of inquiry-oriented teacher education on the learning of students. Long-term programs of research, as part of the program of teacher preparation, should become the norm, with ties to student learning established wherever possible.

Narratives and Biography in Teacher Education

The Narrative Turn in Educational Research and Teacher Education

The 1980s showed a growing international interest among researchers in the field of human sciences in narrative and biographical approaches and methods. Since “narrative is the discourse structure in which human action receives its form and through which it is meaningful” (Polkinghorne, 1988, p. 135), narratives were considered as a powerful way to unravel and understand the complex processes of sense-making that constitute teaching.

Educational researchers quickly joined this theoretical, epistemological, and methodological development. The evolution came to be known as the narrative turn and it represented an important shift in the way teachers and their work were conceived of. Teachers’ talk about their professional lives and practices is very often spontaneously framed in narrative form. They use anecdotes, metaphors, images, and other types of storytelling to recall, share, exchange, or account for their experiences in classrooms and schools. Storytelling is the natural way through which people make sense of the events, situations, and encounters they find themselves in. “Humans are storytelling organisms who, individually and socially, lead storied lives. The study of narrative, therefore, is the study of the ways humans experience the world” (Connelly and Clandinin, 1990, p. 2).

Teaching is a complex social process, in which different people are interactively engaged. Teachers and students interact based on their interpretation of the situation, their own actions, as well as those of the others. Sense-making lies at the very heart of the teaching and learning process. Narrative accounts of these experienced interactions reveal the particular meaning they have or had for the people involved.

Using one exemplary illustration of how narrative techniques are being used in teacher education, the narrative turn will be further explained both in its practical applications and its theoretical grounding.

The Critical Incident Vignette: A Storied Example

The seminar room fills up with chatter as about 20 student teachers enter, move around, and find a seat in the circle of tables and chairs. Throughout the chatter, I pick up excited comments on experiences during their

recently ended practical training. After a brief welcome, I announce that the exercise I would want them to engage in will encompass three phases. An individual phase, a group phase, and finally a plenary phase that will take place during the next meeting in the seminar.

As a start I ask all of them to take paper and pen for an individual autobiographical reflection. They are asked to recall the best or worst teacher (the choice is theirs) they have ever experienced during their lives as a pupil or a student. The task is to focus on one typical event or experience with that former teacher and write a short narrative account of the event. A possible alternative assignment is to have them reflect back on their best or worst experience in their school lives as a pupil or a student. The assignment is most often reacted on by the student teachers with surprise, some hesitating smiles or raised eyebrows, but they all soon concentrate on the paper. After only a few minutes everyone is busy writing. Deep sighs, grim looks, and also amused smiles can be observed.

As most of them are about to end their writing, I ask them to find a catchy title for the piece. The title should both trigger the reader’s curiosity and summarize the key idea that is supposed to become clear from the vignette. Finally, I ask all the participants to turn the sheet and use the back to elaborate in a more systematic and explicit way what the experience has meant to them, what constituted its particular significance, and what possible relevance the story does have for their actual work as (student) teachers.

At the end of the meeting, instructions are given for the second phase of the exercise. The participants are being asked to meet in groups of three to perform a triangle discussion. They should themselves pick a time and place to meet and should allow for about one and a half hour for the discussion. During that discussion the participants are required to perform and strictly stick to one of the three prescribed roles: storyteller, soundboard, or listener. The first role is that of the storyteller: he/she starts with sharing the title and the story, followed by his/her reflective analysis of its actual significance. Once the storyteller has finished, the soundboard starts to play his/her role. The person in this role can ask clarifying questions about context, particular details, etc., which the storyteller then answers or explains. No comments or interpretations are to be made. This is the privilege of the listener, the third role. He/she can suggest different interpretations or open up alternative ways of viewing the experiences from the

story. However, all reflections or interpretations have to remain grounded in the story. No noncommittal speculations are allowed. Finally, the storyteller gets a chance to react with final comments.

Once this round is over, everyone changes roles and the cycle is repeated until every participant in the triangle has performed each of the three roles. The strict distinction between the role of soundboard and listener may have an artificial feel, but it is deliberately included to force the participants to suppress their spontaneous tendency to interpret the story against the background of their own experiences. Postponing this interpretation adds to the necessary active listening as well as to a growing awareness about one's temptation to engage in overhasty commenting.

The third and last phase in the exercise is a plenary discussion during the next seminar meeting and concentrates on the insights that were revealed through the structured storytelling and analysis. The discussion is guided and directed in such a way that the focus is on the participants' actual thinking about teaching and about themselves as teachers. Furthermore, the public reflection should also include relevant elements of the professional context and the relationship between that context and the narrator. A climate of trust and safety is established for the discussion and all stories and reflections are, in principle, being accepted and valued. At the same time, however, critical questions are being asked, alternative interpretations provided, different types of arguments juxtaposed and commented on. Throughout the discussion, links are made to relevant theoretical perspectives and concepts to (re)frame issues, or to deepen the reflective analysis.

This brief account of the critical incident vignette, as I developed and used in both preservice and in-service training (Kelchtermans, 2007), is meant as an example of how narratives can be purposefully used in teacher education. It allows the participants to experience how a personal anecdote reveals not only its significance while it happened, but also its relation with the present. The stories from the past reveal a lot about the way the storyteller thinks about him/herself in the present, especially when used with experienced teachers or with student teachers in the final phase of their training (after internship experiences). The context (for e.g., other people in the scene, the organizational conditions, the social and cultural environment in and around the school, etc.) is also included and its particular meaning and impact on the storyteller become evident in the emerging picture. Taking up the different roles contributes to an increased awareness of the social, interactive character of the shared sense-making that takes place. Furthermore, the interactions entail the possibility of breaking up taken-for-granted interpretations, providing alternative understanding of that past experience and – as a consequence – of one's actual situation.

Narrative Practices with Student Teachers

The actual practices of using narratives and biographical accounts in teacher education are quite diverse, yet they very often reflect a common underlying rationale. This can be illustrated by the example of the critical incident vignette.

Both research and common experiences show that life stories most often contain events that appear to have had a very significant meaning for the narrator. Often these events are all but extraordinary or spectacular. Sometimes they may even look trivial to others. But for the storyteller these events, encounters, experiences are their turning points, which made them reflect and reconsider their taken-for-granted views. These so-called critical incidents are "key events in an individual's life, and around which pivotal decisions revolve. They provoke the individual into selecting particular kinds of actions, which lead in particular directions. (...) Critical incidents are a useful area to study, because they reveal, like a flashbulb, the major choice and change times in people's lives" (Sikes *et al.*, 1985, p. 57).

The critical incident vignette is one exercise that takes up this idea. The assignment to reflectively recall, narratively share and analyze a particularly meaningful event can take different forms. Yet it always, more or less, includes the three steps: (1) description of the event, (2) identification of the issue that is raised in or by it, and (3) a statement of the sense the student made of it with respect to his/her process of learning to teach (Carter, 1993).

It thus always aims at triggering a reflective move from the storied event to an analysis of its particular meaning and relevance to the narrator's actual thinking and actions.

Another group of narrative techniques or exercises draws on metaphorical thinking: (student) teachers are invited to come up with a metaphor to typify themselves as teachers or to define what, in their opinion, constitutes the core of good teaching. These personal teaching metaphors (Bullough, 1991) thus represent, in a condensed, narrative way, their key ideas about themselves as (student) teachers. They may also reveal how these ideas can change over time. As such it makes sense to engage (student) teachers in exercises with personal teaching metaphors or accounts of critical events at different moments during the process of learning to teach (e.g., as an element in a reflective portfolio which they compose during their teacher education or as part of a professional diary). Comparing the differences between that actual metaphor and the ones developed at earlier stages helps to explore and understand one's personal learning process as well as the experiences that triggered the changes.

Narrative methods also allow student teachers' reflections to move beyond the technical issues of appropriately

using knowledge and skills to achieve effective teaching performances (Kelchtermans, 2007). Very often the student teachers' reflections as well as the teacher educator's feedback on practical teaching activities concentrate merely on these technical issues of how to improve one's actions. Although the importance of this technical dimension in teacher professionalism goes undisputed, there is more to good teaching than skilful performance and efficiently dealing with the "how to" questions. Teaching and being a teacher inevitably also involves deciding on moral dilemmas, living through emotional experiences, and dealing with political issues of power and influence. Coping with these moral, emotional, and political dimensions of teaching constitutes an equally important agenda for teacher education as do the issues of teaching skills and (content) knowledge. Through narrative accounts of teaching experiences, student teachers can reflectively address their moral puzzlements (e.g., conflicting norms about good teaching), emotional concerns (e.g., the experience of powerlessness or self-doubt when pupils do not show the learning outcomes that one had aimed for), or political actions (e.g., conflicts with colleagues or principals about the most appropriate content or methodology in teaching). Sharing and discussing on these dimensions help student teachers to accept these dimensions as inherent to the teaching profession and thus essential to their identity as teachers.

In order to achieve this, a common underlying pattern composed of two complementary elements can be found in the different narrative techniques in teacher education. First, the techniques constitute a vehicle for helping the narrators express through different narrative forms their deeply held ideas about themselves as a teacher, their values, and beliefs about (good) teaching, motivation, etc. Second, this individual, personal storytelling however, always needs to be complemented by particular interventions and reactions by the audience, that is, peers and/or teacher educators. Their comments and questions on the publicly shared narrative accounts aim at questioning, probing, challenging, and deepening the reflective analysis. The storytelling in itself is not enough. Many authors stress the need to link story-telling with forms of narrative inquiry, in which the stories and the beliefs they reveal are critically analyzed, questioned, re-storied. Interpersonal dialog, narrative accounts, and the critical use of theoretical knowledge thus have to go hand in hand.

The striving for authenticity as well as the critical probing of the accounts constitute two essential and necessary principles for the guidance of narrative practices. The guidance must avoid the practice wherein the sharing of the narratives does not simply affirm or strengthen student teachers' personal ideas and actions. Critical and public examination may result either in a more informed conviction and awareness of one's ideas, or in a thoughtful

reconsideration and rethinking of what was until then taken for granted.

Although an environment that is supportive, trusting, and positive is a necessary condition to allow the sharing of and learning from narratives to take place, it remains a continuous task for the users of narratives to avoid the trap of uncritical self-satisfaction. The way to achieve this is to create and maintain a productive level of discomfort that helps the critical reflection to move beyond the story as such.

In order to properly balance safety and challenge in these activities, the sharing of autobiographical anecdotes by teacher educators with their students is often used to lay the ground and build the necessary trust to engage the student teachers in narrative accounts about themselves and their lives.

Narrative Language, Context, and Voice

Although teachers' professional actions are, to an important degree, determined by the structural conditions of policy regulations, institutional environments, and organizational settings, the narrative turn explicitly reminds that teaching and learning to teach cannot be properly understood or conceived without acknowledging the obvious role of agency and sense-making. Teachers are competent social agents engaged in educating children. Teaching thus involves planning, deliberation, intentional and purposeful intervention, and action. Yet, its actual evolvement in the work with students can never be fully predicted or controlled. Therefore, technical and scientific language is too limited to capture the full experience of teaching and learning to teach.

Narrative language offers possibilities to get beyond these limits, because of a series of particular characteristics. First, a core process in narratives is the emplotment: by situating experiences in a narrative, the narrator organizes them in a particular linguistic frame and order (beginning–middle–end) through which the particular meaning of his/her experiences emerges (plot).

Narrative language further performs at the same time a referential and an evaluative function. The referential function describes events and experiences from the past in a temporal order. The evaluative function links the events with the moment of narrating by revealing what the experiences meant for the people involved in the present (Labov and Waletzky, 1973).

Third, narratives thus always link past experiences to the actual social context. They even constitute that context, because they reflect a need to communicate, to share a meaningful experience with others (Hoepfel, 1983). Through storytelling a particular social setting emerges with different actors and roles. On the one hand, there is the narrator or storyteller who provides the narrative. His/her narrative account allows for the personal, subjective

voice to be spoken and heard. Yet, on the other hand, in the telling of the story there is always an audience already implied. Narratives are told or written by someone, who always by that time has an explicit or implicit idea of possible audiences. As such, the narratives are fundamentally intersubjective or interpersonal in nature. This applies to the direct act of storytelling as well as to different forms of written narrative accounts.

Fourth, the contextualizing characteristic of stories, however, not only includes its spatial dimension, but also the temporal dimension. Stories situate experiences both in space and time. This is most obvious in (auto)biographical stories where experiences from one's personal life are being recalled (life stories) – thus (auto)biographical stories reveal how the narrator's understanding of the present is influenced by experiences from the past as well as his/her expectations about the future.

The use of stories and narratives is finally also valued for its emancipatory power. Narratives allow for the practitioner's voice to be heard and taken seriously in educational research and theory development. Yet, although acknowledging the emancipatory potential, several authors have warned for the trap of subjectivism or a romantic misconception of that emancipation. Creating a space for the voices that are often silenced in educational research is important, but it is equally crucial that these voices are always interpreted and understood as situated in and thus influenced by political, ideological, institutional, and structural contexts (Goodson, 1992).

Narratives, Teacher Thinking and Professional Identity

Within the overall interest in narratives and biography, several particular elements and evolutions have contributed to their appeal and relevance for teacher education.

First, right from 1980s, the developments in cognitive psychology have had an important influence on educational research. In line with these developments, educational researchers became convinced that in studying teaching as well as the training of future teachers, attention needs to be paid not only to performance skills, but also to the beliefs that guide (student) teachers' actions (Clark and Peterson, 1986). This so-called teacher thinking research stresses the importance of studying teachers' cognitions and the particular form, content, and development of the know-how they use in their work. This knowledge can partly be characterized as formal or systematic knowledge. This knowledge is based on research, for example, explicitly organized in, and provided by, the teacher education curricula. But apart from this formal knowledge, teaching involves other forms of knowing or understanding that are more informal, experiential, idiosyncratic in nature, and as such closely linked to the

individual's experiences during his/her life. The acknowledgment of both formal and informal types of professional knowledge, and forms of understanding in teacher professionalism, as well as the need for every student-teacher to integrate them in a personal way, have had far-reaching consequences for the pedagogy of teacher education and, more in particular, stimulated the use of narratives in teacher education.

Second, the acknowledgment of the experiential nature of (student) teachers' informal knowledge inevitably leads to a biographical perspective on learning to teach. Student teachers do not enter teacher education as blank sheets, but rather bring with them about 15 years of personal experiences in schools. They have lived and worked in many classrooms, experienced dozens of different teachers, and thus inevitably have built a very personal set of ideas and beliefs about what it means to be a teacher, to be teaching, and to be a student. This personal interpretative framework (Kelchtermans, 2007) is thus embedded in one's biography as a (student) teacher. At the same time, the framework is influenced by and develops through the learning that takes place during the teacher education program. But in its turn it also influences that learning process. It acts as an interpretative lens, mediates and filters the way student-teachers deal with and make sense of the curriculum of their teacher education program, interpret experiences during practical training, etc. It thus is both an outcome of and a condition for this learning.

Yet, because of its biographical, experiential, and largely idiosyncratic nature, this framework and the understandings it constructs may be one-sided, limited, or simply wrong. As such it may negatively bias student teachers' learning and sense-making of the formal curriculum and especially of the experiences during practical training (internships). Several authors have argued that, the often observed washing out effect of teacher education programs once teachers have started their career, is due to the fact that the implicit personal, interpretative lenses of the student teachers were not deliberately made explicit or discussed. In order to control possible biases and ensure a sustainable, in-depth integration of the curriculum by the student teachers, the curricula of teacher education programs have to aim at making this implicit knowledge explicit and bringing it up for critical scrutiny and discussion. Only this way the validity of student teachers' personal professional knowledge, as the basis for their professional decisions and actions, can become more valid and justified.

Narratives and storytelling can play a part in this process of making the implicit knowledge explicit. In order to do so, however, it is of crucial importance that work with narratives in teacher education goes beyond the telling and sharing of stories as such. Storytelling, therefore, has to be linked with forms of narrative inquiry,

in which the stories and the beliefs they reveal are critically analyzed, questioned, and re-storied (as is illustrated for example by the exercise on the critical incident vignette).

Third, the use of narratives in teacher education *per se* is also in line with and contributes to the emphasis on teachers' reflectivity. Reflection, both as an attitude and skill refers to people's capacity to look back on and think about themselves, their actions, and the situation they find themselves in. Because of the dynamic, highly unpredictable, and complex character of teaching and learning processes, reflectivity is a crucial tool for teachers to properly understand professional situations, choose appropriate actions, and learn from these experiences. Through reflection, teachers thoughtfully examine and integrate new knowledge and practical experiences, with deeply held beliefs and opinions. Narratives and different forms of storytelling have proven to be powerful tools to engage student teachers in reflection. As argued before, narratives are particularly powerful as triggers for reflection on the nontechnical aspects of teaching and learning to teach such as the emotional, ethical, and political aspects.

A final reason for the importance of narrative and biography in teacher education is the recognition that the person or the teacher is a constitutive part of the educational situation. Therefore, teachers' idea of themselves as teachers, their sense of identity is of much greater importance to them as practitioners than in occupations where the person can easily be separated from the craft. When speaking about their job, teachers demonstrate "persistent self-referentialism" (Nias, 1989): their self as a person is always implicated. Developing a sense of professional identity as a teacher constitutes a red thread for student-teachers' learning and development throughout their teacher education. (Auto)biographical reflection or narrative accounts allow for this self to be explicitly addressed.

Supervision in Teacher Education

Supervision in Teacher Education

Supervision in teacher education is meant to assist teacher education candidates preparing to enter the profession for the first time and to assist practicing teachers in the development of the skills necessary for effective teaching. Supervision is usually carried out through three separate processes: (1) observation, (2) analysis, and (3) discussion or sharing information collected and organized by the supervisor with the teacher education candidate or teacher. Teachers in the field often comment that they learned how to teach by practicing the act of teaching in actual classroom situations with a skillful supervisor to guide them and that student teaching is often viewed as the most useful part of the teacher education process (Roth, 1983). John Dewey (1963) speaks of experiences that are educative, and says that the direction in which growth takes place must be specified and indicated. Experience alone is not always a good teacher and teacher education programs around the world have implemented some form of supervision as a part of teacher preparation.

Approaches to supervision have been described through various terms (some philosophical and some practical) as: essentialism, experimentalism, and existentialism (Glickman, 1990); positivism, phenomenology, and critical theory (May and Zimpher, 1986); and learner-centered (Paris and Gespass, 2001). Whatever the name given to supervision, observing, analyzing, and discussing the act of teaching is viewed as an effective way to improve teaching performance. Additionally, government departments of education exert a strong influence on supervision in teacher education by setting requirements for the amount of clinical practice a teacher must complete in order to be licensed.

Historical Perspectives on Supervision in Teacher Education

Supervision in teacher education is not a new component of preparing teachers or providing professional development opportunities for teachers already in the field. While reform efforts to improve the conditions of teacher education have proliferated in the past 40 years, the importance of a well-trained supervisor to facilitate the growth of a novice or an experienced teacher remains as central to the process today as it did nearly a century ago. Bulletin #14, *The professional preparation of teachers for American public schools*, a report issued by the Carnegie

Foundation for the Advancement of Teaching in 1920, recommended that teacher education programs be clinically based, with ongoing opportunities for observation and supervised practice in real world settings (Imig and Imig, 2006).

A little more than 50 years after the Bulletin #14 report, the AACTE Commission on Education for the Profession of Teaching determined that educators must develop teaching skills through practice in a controlled training environment accompanied by effective direction and supervision. The effective use of both laboratory and field-centered approaches has long been viewed as crucial to the development of the complex competencies of teaching.

Early schools were often staffed by low-paid individuals with little formal education. The profession of teaching had yet to develop and supervising teachers was often left to local officials whose task was to visit schools and make recommendations for their improvement (Fuller, 1982). Supervisors may also appear in the form of educated individuals or a visiting committee whose mission was to see that the teaching was competent and the learning adequate. Even in the early stages of supervision in teacher education, it was understood that supervisors would be objective, draw conclusions based on the evidence, and give balanced feedback. An increase in the number of teachers required to meet the needs of the ever-growing number of students and schools resulted in more emphasis being placed on teacher preparation and supervision.

Normal schools of the nineteenth century in the United States (US) gave detailed attention to supervised practice that followed a significant amount of time spent observing in classrooms (Clifford and Guthrie, 1988). Feiman-Nemser (1990) reports that James Earl Russell, dean of Teachers College (1894–1927), described a model laboratory school where exemplary teachers would oversee the training of novices. In the mid-1960s, the Harvard University Masters in Teaching Program initiated a clinical supervision process in which the teacher education candidates and teachers helped determine the focus of their own supervision (Goldhammer, 1969).

We find similar stages of development in teacher preparation programs with regard to supervision practices around the world. There are numerous efforts underway at this time to standardize teacher education programs. The Bologna Accord (1999) in Europe and the Report of the House of Representatives Standing Committee

(www.gmacbolognaproject.com/docs/BolognaCheatSheet-2005) on Education and Vocational Training in Australia (Hartsuyker, 2007), as well as several national committees and commissions in the US (including a commission sponsored by the National Academy of Education) bear testament to this movement. The European Commission (2007) has also recently put forth proposals aimed at improving the quality of teacher education in member states and standardizing the guidelines. All of these reports and commissions have implications for the future supervision of teacher candidates.

Supervision in Constructing a Professional Identity

The practice of teaching and learning to teach are so inextricably connected that attempting to help someone learn to teach without actually critiquing their attempts at teaching seems pointless. Interactions between experts and novices in teacher education that focus on instruction have been the subject of numerous research studies. When the emphasis in supervision is on helping teachers develop skills in delivering instruction, helping the same teachers construct a professional identity may become secondary. Recent research on supervision has focused on teacher participation in their own development as teachers through collaboration with colleagues, peer feedback, reflective practice, and action research (Glickman, 1990; Holland *et al.*, 1992; Yusko, 2004; Shin *et al.*, 2006). One view of supervision as described by Glickman (1990) sees “the focus of supervision as a process of eliciting the teacher’s own thinking and planning.” (p. 550).

Constructing a professional identity cannot occur in a vacuum. This process requires that quality leaders assist novice teachers in their journey towards a professional identity. The complex act of the construction of a professional identity by teacher education candidates during the transition from university setting to a school context is examined through a collaborative partnership utilizing Internet discourse among all participants (Dauvisis *et al.*, 2005; The Association of Teacher Educators’ Commission on Quality Leaders for Novice Teachers, 2006). Dubar’s (1996) description of professional identity development as the simultaneously stable and provisional; individual and collective; subjective and objective; and biographic and structural result of different processes of socialization that build individuals and define institutions encompasses the many variables associated with learning to teach in a social environment.

Research on Supervision

Research on supervision in teacher education has demonstrated that supervisory observations alone are not sufficient to fully interpret and critique the experiences of

teacher education candidates and teachers. With this in mind, institutions of higher education around the world plan and implement strategies for improving supervisory practices in teacher education. In the University of Montreal’s 4-year teacher preparation program, at least 700 hours in a school setting are required. Supervisors and teacher education candidates in this program are taught the processes of practical argument (Fenstermacher, 1987), shared reflective practice (Tochon, 1996), and use of videotapes to gain a greater awareness of the relationship between feedback and action in the supervisory process (Gervais, 2005). The benefits of paired-placements and the power of communication within particular contexts to improve teacher education practice in collaborative settings are examined in detail by Sorensen (2005) at the University of Nottingham.

The use of specific tasks to help preservice teachers in Santiago, Chile identify, interpret, and analyze professional performance within a specific institutional culture is discussed by Rittershaussen *et al.* (2005). This study examines the knowledge constructed by preservice teachers regarding professional performance and the challenges they perceive in becoming members of a professional context through dialog with supervisors. A study by Chan *et al.* (2007) looked at the preconceptions of teaching and learning held by preservice teachers in Singapore. Another study by de Leon-Carillo looked at the preconceptions of teacher roles held by preservice teachers in the Philippines. The preconceptions that students bring with them to the teacher preparation program can serve as guides for the field experiences they need to have in order to become effective professionals. Other studies, including one conducted by Ballard (2002), have shown that student teacher beliefs are greatly influenced by those of the cooperating teachers with whom they work. These findings indicate the need for careful selection and training of cooperating teachers.

Supervision and Induction

Supervision is a natural by-product of induction programs. Induction programs are designed to give new or experienced teachers support and assistance rather than simply assessing their work. As part of induction programs, mentors, that is, teachers with a record of success in their own classrooms, are assigned to guide other teachers in the acquisition of the skills of teaching and the professional tools necessary for a teaching career. Induction programs often include a form of clinical supervision for teachers who face trouble in the classroom.

The school administrator plays an important role in establishing an environment that facilitates the supervision and the work of mentors. Experienced teachers are asked by their administrators to serve as mentors or cooperating teachers. Some teachers assume the mentor role eagerly as another step in their own professional

development. Others may be less than enthusiastic. Whichever way teachers approach the task of supervision, they have firm opinions about what conditions must be present for teachers to be successful. Many perceive the school administrator to be responsible for establishing an environment that supports both supervision and the mentoring process and that assists experienced teachers in their role as a professional guide. The support that cooperating teachers and mentors are able to offer teachers is strongly influenced by physical considerations such as the proximity of classrooms, the schedules, and the teaching assignments, all of which are ultimately controlled by the administrators (Quinn, 1994).

The availability of such induction support and mentoring varies greatly among teacher education contexts, ranging from nonexistent to outstanding. There is a growing body of research to draw on regarding the value of such support for the beginning teacher. Darling-Hammond (2006) cites numerous studies that show that teachers who participate in a supervised student teaching experience are more likely to stay in the profession, as are those who participate in mentoring programs during their first 2 years of teaching (p.339).

The Supervision Triad

The activities and processes of supervision in teacher education normally occur in a triad (teacher education candidate or practicing teacher; cooperating teacher or mentor; and university supervisor or administrator). While variations on the degree of involvement and classification of members of the triad do exist, the teacher education candidate or teacher is the purpose for the supervision, while another, more experienced teacher takes responsibility for observing and critiquing the necessary teaching activities. A university or college supervisor, whose responsibility is to guarantee that requirements of the institution are fulfilled, works closely with all other members of the triad as well as the school administrator to ensure that the supervision is being conducted in a purposeful and supportive manner. This triad formation is common to most, if not all, existing teacher education programs.

It is expected that the supervision triad will create an effective learning environment for the development of practical knowledge, skills, and dispositions relevant to the professional growth of teachers. Through completion of specific assignments such as writing and implementing lessons for small groups or an entire class of students during field-based experiences, the teacher education candidate observes the complexities of classroom life and is able to analyze these observations through discussion with an experienced cooperating teacher and a university supervisor. Supervisory discussions encourage teacher education candidates and teachers seeking

professional growth to reflect upon their instructional practices. Such discussions help them recognize the elements necessary to prepare their own classroom learning environments to accommodate the individual needs of learners.

The purpose of supervision, whether it is to improve teaching behaviors, to increase teacher reflection and critical analysis, to increase skill in using a particular teaching strategy, or to improve general satisfaction with teaching, must be clear among all members of the supervisory triad for its greatest effect to be achieved.

Participants in a supervision triad

Teacher education candidate

The teacher education candidate or teacher seeking professional support is the purpose for supervision. Their role is to demonstrate knowledge, skills, and performance that meet expected standards in the areas of planning; instruction and management of the classroom environment; and management of the activities and behavior of students. In addition, candidates and teachers are expected to comply with all school and district policies.

The cooperating teacher

The cooperating teacher is often viewed as the single most important influence by teacher education candidates in the process of learning to teach. Costa and Garmston (1987) list three contributions that a cooperating teacher or mentor can offer to others. They model best practices, they pass along the tools of the trade, and they encourage development of the intellectual process of teaching in others by articulating their actions and thought processes. Effective cooperating teachers and mentors become what Costa and Garmston (1994) refer to as cognitive coaches.

At some point in the interaction with a practicum student, student teacher, intern, or beginning teacher, the cooperating teacher or mentor will have to give criticism or offer advice. Henry and Beasley (1989) offer suggestions for interactive practices by cooperating teachers and mentors that lead to effective supervisory experiences. Among these suggestions, clear and specific communication and feedback, modeling espoused behaviors, consistency, offering rationale for actions and suggestions, and using problem-solving strategies to guide professional growth are considered as most supportive of supervisory interactions.

The university supervisor

The main role of the university supervisor in the supervision triad is to see that institutional requirements are completed by the teacher education candidate. The university supervisor must often assume roles other than that of observing teaching practices and providing constructive analysis of said practices. The university supervisor may find it necessary to facilitate relationships among

teachers, to serve as a personal confidant when necessary, to provide individualized instruction, and to provide guidance in areas that may have been overlooked by other participants in the triad (Zimpher, 1980). The university supervisor may also serve as a seminar leader and a placement consultant.

All participants in the supervision triad need to possess certain personal characteristics that help to prevent disharmony and discord. The characteristics most relevant to the supervision triad focus on interpersonal and communication skills. Before supervision in teacher education takes place, agreements must be established and guidelines set. It is imperative that all members of the triad become familiar with the supervisory process to be followed and be aware of the potential outcomes of the process. Supervision styles should accommodate differing stages of teacher development. Seminal development of frameworks for classifying supervisory behaviors and conferences were offered by Amidon and Flanders (1967) and Spaulding (1967). Variations on these frameworks have produced a variety of ways to conduct and assess supervision in teacher education.

Changing Perspectives on Supervision in Teacher Education

Supervision for social justice

Diversity in the school-age population is a major concern for educators in many nations. Changing demographics and increasing diversity have presented challenges for the majority of teacher education programs. Many nations have expressed concern that the needs of all students are not being met in schools as they are currently staffed with teachers who are not knowledgeable on working with diverse student populations. Some programs are trying hard to provide preservice teachers with the knowledge, skills, and experiences they need in order to provide all the students with quality education. The challenges are many.

Han and Singh (2007) report on the difficulties in the recruitment and retention of student teachers and teachers from minority and immigrant groups in Australia. There is a mismatch between the type and length of the field experiences needed by immigrant education students who have had no experience with the culture of Australian schools and the generic model of field experiences offered by teacher preparation programs. The minority preservice teachers believe that their supervisors do not understand their needs. As a result, the increasing diversity of Australian students is not being met with an increase in teacher candidates from other ethnic or linguistic groups.

Teacher education programs are currently seeking answers to questions related to preparing high-quality teachers for all student populations. Some of these questions are: (1) How can preservice teachers learn to

work with the strengths that diverse students bring with them to school rather than searching for reasons why they are deficient according to the teacher's values and expectations? (2) How can supervisors facilitate the development of teachers who can be effective with all types of learners in a diverse classroom?, and (3) How can clinical supervision help preservice teachers provide a level playing field for all members of the classroom group? The answers to these dilemmas are critical at this time of increasing globalization.

One elementary school in the southwestern US has more than 80 flags hanging in the lunchroom representing the homelands of the students in the school. The minority has become the majority in the Clark County School District. Yet the teaching force is predominantly Anglo and female. Teacher educators in many nations, such as England, Ireland, and the US to name a few, are grappling with these issues. Given the current political realities, supervisors and teachers alone cannot alter the reality of poverty, class, and language. What they are trying to do is equip preservice teachers with experiences that allow them to work in culturally diverse classrooms and begin to reflect on what skills and knowledge they will need to provide equitable learning experiences for all (Jacobs, 2006).

Alternative routes to licensure

There appear to be differences in the types and models of supervision provided for students in university-based teacher education programs and for those who come in through an alternative program or the normal school route. This seems to hold true globally. Some alternative programs shorten the field experience segment of the program. Some students do not have clinical experience until their last semester, or student teaching experience. The person actually supervising may differ as well. In some alternative teacher education programs there are no university supervisors, only cooperating teachers.

Some programs in the US put college graduates immediately into a classroom before they have any pedagogy coursework. These novice teachers take classes while on the job and are assigned mentor teachers to work with them while they are teaching in their own K-12 classrooms. If the quality of the mentoring is good, many of these new teachers can do quite well.

Other licensure programs that consist mainly of online coursework have only limited fieldwork. Their students have no preliminary practice or observations in classrooms, but hit the ground running during their student teaching experience. Again, the quality of the supervision and mentoring plays a big role in the success or failure of these teachers. We can expect to see more alternative routes to licensure developing around the world as large numbers of existing teachers retire and the populations in many countries continue to grow.

School university partnerships

A unique response to the challenge of university-based teacher education programs working closely with public schools has been that of the professional development school (PDS). In some places, these are called partner schools. In the US, PDSs were initiated in response to a recommendation of the Holmes Group, an organization of College of Education deans (Darling-Hammond, 2006). The purpose of the PDSs was to create partner schools that worked closely with teacher education faculty to create an environment conducive to learning to teach all children. Public school teachers were viewed as teacher educators and provided supervision of clinical experiences. Sometimes, the experience of the teacher education candidates in PDSs is modeled on medical education and preservice teachers actually do rounds similar to the practices of medical students in hospital rotations. Such arrangements require expert supervision. Teachers at PDSs often engage in graduate coursework in supervisory practices.

Variations on a Traditional Model of Supervision in Teacher Education

Teacher education programs around the world are experimenting with new models of supervision. These models are sometimes driven by contextual variables and sometimes by sound pedagogical theory. For example, one program in the US is trying paired student teacher placements similar to other experiments. They have grounded their program in Vygotsky's zone of proximal development and are trying to provide the teacher education candidates with peer support as they progress through the developmental levels of learning to teach (Baker and Milner, 2006). The newly adopted teacher education guidelines in Ethiopia call for five consecutive practicum courses in partner schools from the beginning of the program (Degago, 2007). One program in rural Australia has facilitated the placement of future teachers in remote rural schools by implementing a support system that incorporates face-to-face mentoring with innovative use of communication technology (see more about technology in the next section.). Some programs in European nations require 1 or 2 full years of clinical experience before licensure (Cobb, 1999). Others in some developing countries still rely on the normal school license rather than a degree program. Students in these programs rely on the teachers in the schools for supervision and mentoring.

Supervisory Assessment of Field Experiences

This is an age of teacher accountability for student learning. Thus, many supervisors look for evidence that learning is taking place in the classroom of preservice

teachers. Some programs use formalized data such as pre- and post-test scores. Others have students reflect, in their portfolios, on the effectiveness of the lessons they taught and an analysis of what worked and what did not work and why. Many accreditation bodies are demanding this sort of evidence before licensure of new teachers and many state and national legislatures are also demanding this type of evidence of teacher effectiveness at the preservice level.

The Use of Technology in Supervision

The age of technology has influenced methods of supervision in teacher education. A variety of technological tools exist that can support supervision and student self-assessment in teacher education. Some teacher preparation programs provide preservice teachers with laptops to use for journaling their daily experiences in the classroom. Students can also utilize their laptops to communicate with their supervisors and peers on a regular basis, thus creating a community of learners. Electronic communication is especially helpful for students doing field work in remote or rural areas, but can be used by all preservice teachers. Some forms of supervision make use of videocams and electronic recording devices for students to utilize in the reflection and analysis of their teaching efforts. Technology can be seen as a tool to improve the quality of student practice and teacher mentoring. In the information age driven by technology, supervision in teacher education may become more self-directed than that in the past, as novices and experienced teachers alike turn to the Internet for advice and examples.

Techniques for using technology in reflection/self-analysis

Technology has also provided preservice teachers with greater opportunity than ever before for self-analysis and reflection of their work. Students can even download demonstration teaching classes and watch expert teachers teach in real classrooms. They then can analyze their own teaching based on what they saw. Many teacher preparation programs are teaching their students the evaluation systems that will be used to assess their performance when they are teaching full time. Some programs are even using these systems to assess candidate skill and expertise, so as to better prepare the teacher for the expectations of the workplace. Many of these assessments are online and students can get immediate feedback from their supervisors.

Portfolios have been used in teacher preparation programs for some time. Now, however, students are preparing electronic portfolios of their culminating field experiences and are including videoclips of their teaching. Not only are these portfolios used by supervisors to

mentor future teachers, but they can also be used as part of an application package when the candidate applies for professional employment.

Online supervision in teacher education

Online supervision in teacher education programs does exist, but even with online teacher education programs there is normally a full-time, supervised, in-classroom experience with a clinical supervisor to observe and evaluate performance based on acceptable professional standards. However, the use of webcams and other digital imaging in computers makes it easy to demonstrate teaching practice for someone not present in a specific classroom. Teacher education programs have long used videotape recordings of teaching practice as a form of self-analysis and discourse between supervisors and teachers. While the face-to-face interactions between supervisors and teachers have been the norm, it is possible that technologies to aid online interactions will influence changes in supervision in teacher education.

The Future of Supervision in Teacher Education

It is likely that supervision in teacher education will continue to be a critical element in learning to teach and to improve teaching skills. Presentations at international and national conferences attest the interest of individuals in creating meaningful supervisory practices that result in effective teaching. At the 2007 meeting of the Association of Teacher Educators held in San Diego, California, Dr. Fedotova, Director of the International Information Center in Russia, discussed the challenges of Russian education under the process of globalization and the world educational community. At the 2007 Annual Meeting of the American Educational Research Association, Dr. Ping Deters, from the University of Toronto, presented a paper on internationally educated teachers. As research is shared among members of the global community of teacher educators, knowledge of what works in supervision will traverse international boundaries, become refined and adapted to individualistic contexts, and will continue to expand in concept and practice.

Summary

Supervision in teacher education is an issue that is of major concern to educators all over the world. The articles discussed elsewhere in this encyclopedia will further refine and define the major issues raised in this article. In this age of teacher accountability, teacher educators are searching for effective and efficient ways to provide experiences that will prepare teachers to facilitate equitable opportunities for all students to learn and achieve success. While individual national contexts will

influence practice, there are many commonalities with regard to the challenges and implementation of effective supervision.

Glossary

Beliefs – Beliefs are psychological understandings, premises, or propositions that are felt to be true.

Educational beliefs – These refer to beliefs about the role of the teacher and/or student in instructional processes. In the literature, a bipolar distinction is made between teacher-centered traditionalistic and more progressive or student-centered educational beliefs.

Expectancy value theory – According to this motivation theory, beliefs are a central construct that influences what teachers value and expect, and how this influences their actual teaching behavior.

Mathematics beliefs – Beliefs that refer to conceptions about the nature of mathematics, the nature of mathematics teaching, and the process of learning mathematics.

Teacher beliefs – These are psychological understandings, premises, or propositions about processes, variables, and actors that are central to learning and instruction settings, such as educational beliefs, epistemological beliefs, beliefs about inclusive education, etc.

Introduction

Teachers' beliefs have become a crucial variable in studying teaching behavior and teacher education. From the 1980s to the present, researchers have investigated both explicit and implicit knowledge and beliefs of preservice, novice, and experienced teachers to identify these beliefs and to examine how knowledge and beliefs affect learning to teach. Teacher beliefs are central to recent theories about teachers' identity. In their review about teachers' professional identity, Beijaard *et al.* (2004) state that beliefs are conceived as important constituents of teachers' professional identity formation. This implies that beliefs are of vital importance for teacher education since it determines the way the student teachers develop their meaning making and decision making. This suggests that beliefs are part of a complex set of variables and processes that determine teaching

behavior. The complex nature of teachers' beliefs implies that teacher education is critical to consider the development of a consistent belief system in teachers and student teachers.

Defining Teacher Beliefs

The concept of beliefs has a long history and has been defined in a variety of ways. Consequently, a conceptual confusion can be observed since authors easily adopt alternative terms. In addition, "some researchers refer instead to teachers' 'principles of practice', 'personal epistemologies', 'perspectives', 'practical knowledge', or 'orientations'" (Kagan, 1992, p. 66). It is therefore not surprising that Pajares (1992, p. 307) considered teacher beliefs as being a: "messy construct," noting that "the difficulty in studying teachers' beliefs has been caused by definitional problems, poor conceptualizations, and differing understandings of beliefs and belief structures."

Richardson (1996) defines beliefs as psychological understandings, premises, or propositions that are felt to be true. As such, beliefs can be represented as estimates of the likelihood that the knowledge someone has about a proposition or a subjective experience is correct. Alternatively, beliefs also refer to the likelihood that an event or state of affairs will occur (Wyer and Albarracín, 2005). Furthermore, as beliefs are clustered as a set of interrelated beliefs in a broader, general belief structure or system, they can vary in strength. The more a belief is interrelated with others in this structure, the more difficult it is to alter the belief in question (Pajares, 1992).

Since we focus on beliefs in the context of preservice teachers, the question is often raised with reference to the relationship between beliefs, attitudes, and knowledge. With reference to the relationship with attitudes, a distinction is made between an affective, a cognitive, and a conative component (behavioral or action part). Presently, beliefs are considered as representing the cognitive part of attitudes. The difference between beliefs and knowledge is presently also clearer. A differentiation commonly made is that beliefs are based on judgments and evaluations (subjective probability), whereas knowledge refers to objective verifiable facts.

Teacher Beliefs in Interaction with Other Processes and Variables

In the literature, the attention paid to teachers' beliefs cannot be isolated from the attention paid to other and clearly related constructs. From the mid-1980s, educational researchers began to focus on nonbehavioral components of teaching behavior, such as: (1) teachers' beliefs about classroom, students, school, and learning; (2) teachers' decisions for designing and presenting a teaching activity; (3) teachers' perceptions on classroom-teaching affairs; and (4) teachers' roles and their self-images (Kagan, 1995). This observation is important since it positions beliefs in the complex overall setting of teachers and their context. It is helpful to study the central position of beliefs as a motivational construct. In this context, it is most useful to reiterate the expectancy-value perspective on motivation as it has been expanded by Wigfield and Eccles (2000) and to rephrase it in terms of teacher-related processes. We stress the importance of this broader orientation toward beliefs in view of the consequences that can be derived for teacher-education practices. The model implies that beliefs consist of affective components, goal orientations, competency judgments, and perceptions about the teaching tasks to be carried out. In addition, the model points out that beliefs influence what students or teachers value. It helps to understand how beliefs are related to teaching expectations and how this results in choices, persistence, duration, and engagement in teaching activities. In addition, the model also stresses the fact that beliefs are influenced by cognitive processes, such as perceptions of the social context and interpretations of attributions related to earlier teaching experiences and

incidents. Moreover, the model stresses the impact of the external context. The relationships depicted in the model help to understand how the outcomes of teaching performance affect the extent to which future behavior will be valued, how beliefs are affected, and what expectations do result from these experiences. The model helps to understand why teacher's beliefs tend to be associated with a congruent style of teaching. The feedback loop in the model is of critical importance. The feedback loop gives teacher educators and trainers the opportunity to influence beliefs. **Figure 1** illustrates how the beliefs are part of this complex interplay with other variables and processes.

Positioning teachers' beliefs in this wider setting of mechanisms that influence actual teaching behavior also helps to make clear that beliefs and belief systems serve as personal guides in helping individuals to define and understand the world and themselves (Pajares, 1992). Teachers' educational beliefs are understandings, premises, or propositions about education, established through multitudinous experiences (Pajares, 1992). Teachers' beliefs are considered as relatively stable and act as a filter through which new knowledge and experiences are screened for meaning (Kagan, 1992) and that underlie teachers' planning, decision making, and behavior in the classroom.

Beliefs about What?

In addition, the model presented above makes it clear that the focus on the beliefs could be as varied as the teaching profession itself and therefore reflects on the issues

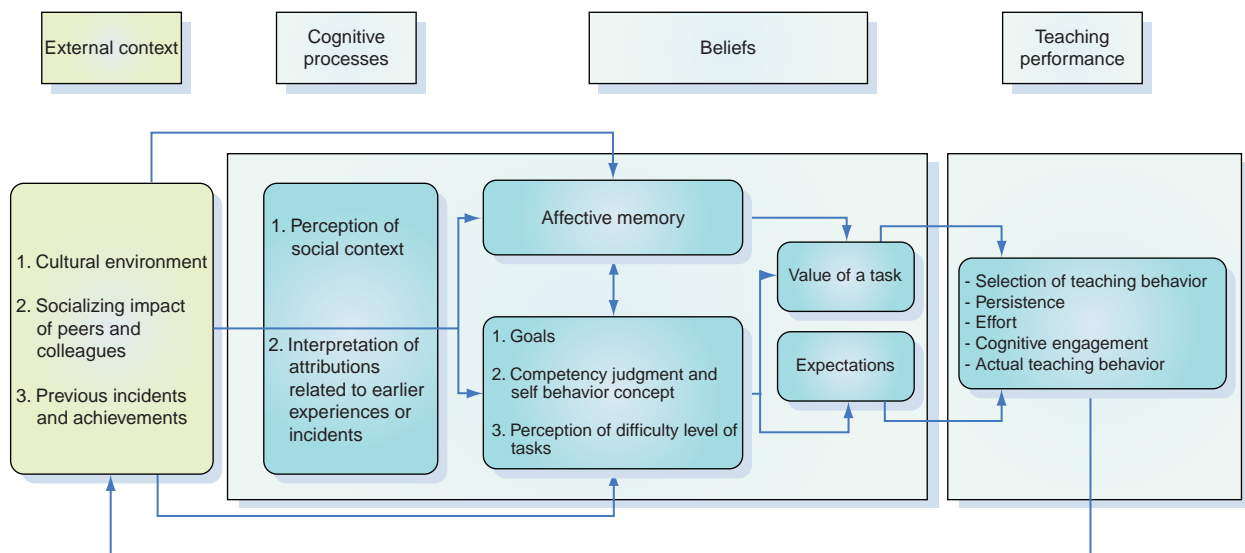

Figure 1 Beliefs in relation to motivational variables and processes. From Wigfield, A. and Eccles, J. S. (2000). Expectancy-value theory of achievement motivation. *Contemporary Educational Psychology* 25, 68–81.

related to learners (e.g., beliefs about inclusion and about diversity), knowledge (epistemological beliefs), teaching components (beliefs about the curriculum, beliefs about what learning content is important, beliefs about media (information and communication technology (ICT)), teaching strategies, evaluation, etc.), parents, instructional context, and organizational dimensions. The literature reflects this varied nature of the focus of teachers' beliefs. For example, He and Zhao (2006) state that teachers' beliefs include beliefs about learners, teaching, disciplines, teaching efficiency, and teacher themselves. This is in line with distinctions made by Kagan (1992) who indicates that beliefs are a particularly provocative form of personal knowledge that is generally defined as pre- or in-service teachers' implicit assumptions about student learning, classrooms, and the subject matter to be taught. A major problem in research of teacher beliefs is the wide-ranging nature of beliefs. Often research about educational beliefs is too context-free. Hence, almost 15 years ago, Pajares (1992) considered restricting the object of research study to a particular educational belief or a limited belief system and to clearly define the object under investigation.

Measuring Teachers' Beliefs

The nature of beliefs makes it difficult to measure them straightforwardly. Since beliefs cannot be observed directly, they are measured indirectly. Shavelson *et al.* (1986) presented the first overview of available methods to study beliefs. They refer to analysis of policies, repertory grid technique, and process tracing (e.g., think-aloud, stimulated recall, and journal keeping). Kagan (1992) presents a systematic description of techniques that is still viable. She refers to (1) experimental tasks that ask teachers to think aloud when analyzing classroom vignettes or when viewing their videotaped performances (stimulated recall); (2) semi-structured interviews, during which teachers are asked to recall specific classroom events and decisions; (3) concept maps that teachers draw to depict their understandings of pedagogical issues; (4) a close analysis of the language that teachers use to describe their thoughts and actions; and (5) traditional Likert-type attitude scales. Other approaches embrace case study methodologies, analysis of teachers' concerns, and in-depth interviews.

Beliefs as Entry Qualifications of Prospective Teachers

A result of the growing interest in teachers' beliefs is the conviction that preservice teachers already enter teacher education with a clearly established belief system about

teaching, learning, and themselves as teachers developed over years of life experience and exposure to a wide variety of teaching–learning situations and contexts. It is well documented that these preconceived ideas remain quite stable during teacher training (e.g., Pajares, 1992; Wideen *et al.*, 1998) and have a strong influence on student teachers' understandings of and experiences in their classroom placements (e.g., Kagan, 1992; Richardson, 1996).

Old beliefs must be challenged and proven unsatisfactory in order to assimilate new beliefs into existing conceptions. This is in line with the general findings of Quillen (unpublished PhD thesis) that: "Teacher education researchers have long been aware of the power of beliefs and the resistant-to-change beliefs of many preservice teachers as well as experienced teachers." This puts teacher educators in a difficult situation since the beliefs:

- are well established by the time student teachers enter their preservice training;
- are already formed at an early stage;
- develop into a belief system that is difficult to change; and
- act as a selective filter to develop new knowledge.

This explains, in part, why student teachers tend to reiterate their personal classroom experiences and also explains why some authors stress the predictive value of beliefs for a successful entry into the teaching profession. The latter explains why it might be important to unlearn and discard some beliefs.

The results of the research about the beliefs of incoming student teachers also clearly point out that, next to stability, in the initial beliefs, changes also could be observed, but this depended largely on the beliefs held by the supervising teachers. The former is not only critical in view of developing sound professional teaching competences, but also to reconsider the nature of the teacher education experience itself. Teacher educators should be aware of the fact that student teachers enter the teacher-education setting with a set of beliefs about teacher education. Preservice teachers tend to think of teaching primarily as a task involving affective, interpersonal relationships rather than a profession requiring a skilled and knowledgeable practitioner. Generally, preservice teachers do not expect to receive much from their education classes and appear to be less interested in what they perceive to be theory and more interested in practical approaches. They feel that they would be good teachers without any preparation, because they believe that the majority of their knowledge about teaching would come from practice in the field or through trial and error when they eventually enter the classroom.

It appears from the findings of these studies that preservice teachers underestimate the complexity of teaching. Yet, student teachers who are guided by these

kind of naïve, idealistic, and unrealistic teaching beliefs have been found to feel overwhelmed, shocked, and disillusioned when confronted with the complexities and responsibilities of a classroom (e.g., Wideen *et al.*, 1998). Student teachers who fail to reconstruct their images of self as teachers appropriately may encounter frustrations sufficiently severe to terminate their teaching career before they really had a chance to begin (Kagan, 1992). Therefore, in order to improve professional preparation and teaching practices, teacher educators cannot neglect the role of beliefs and need to develop specific strategies and approaches to cater to belief systems as an integrated part of the teacher education system. Moreover, teacher educators need to be explicit about their own beliefs about teacher education and training.

Changing Teachers' Beliefs in Teacher Education

Given the established nature of beliefs, and the fact that the beliefs work as a selective filter in developing professional teaching competences, teacher-education approaches are challenged to consider the pervasive influence of teachers' beliefs. This could result in the implementation of a series of specific activities or teacher-education strategies. However, the processes by which beliefs can be changed are not well understood. In addition, research overall is rather dour about the prospects of changing candidates' beliefs. The simple adoption of a number of strategies, tricks, etc., is insufficient. Teacher educators themselves should, first of all, adopt an updated conception as to how student teachers evolve and how teacher education should take this into consideration. There is clear empirical evidence that shows how teacher education programs are too focused on transmitting pedagogical knowledge that hardly gives consideration to modifying beliefs. In their review, Wideen *et al.* (1998) conclude that successful teacher education programs not only merely change but also build upon student teachers' beliefs by making use of a systematic and consistent support of teacher educators during institutional meetings, as well as of cooperating teachers during teaching-practice periods. Hence, these teacher education programs are characterized by the integration of practical experiences and theoretical study.

The approach of the pedagogy of realistic teacher education (Korthagen *et al.*, 2001) is exemplary in this context. This approach starts from concrete practical problems and the concerns experienced by student teachers in real contexts. It aims at the promotion of systematic reflection of student teachers on their own and their students' wanting, feeling, thinking, and acting on the role of context, and on the relationships between those aspects. Furthermore, this realistic approach states that

teacher education should respect the three consecutive levels along which professional learning develops (gestalt, schema, and theory). Teacher education should help student teachers become aware of their needs, find useful experiences, and reflect on these experiences. At the gestalt level, actions are typically based on unconsciously triggered needs, values, meanings, feelings, and behavioral inclinations. Gestalts refer to the personal conglomerates of needs, concerns, values, meanings, feelings, and behavioral inclinations united into one inseparable whole, which often unconsciously (or only partly consciously) plays a role in shaping teacher behavior. During the process of professional learning, the student teacher may reflect on his or her gestalts and develop a conscious schema of concepts, characteristics, and principles that are helpful in describing practice. The theory level is reached when a logical order is constructed in and between schemata, resulting in a coherent theory.

The above paragraph not only implies a number of potentially successful strategies to influence teachers' beliefs, but also reconsiders the model presented earlier about how beliefs as part of a complex interplay of variables and processes might be helpful when considering the antecedents and consequences of the adoption of specific beliefs. Considering the importance of the external context, the model suggests that teacher education approaches should:

- Present a richer and more varied cultural context where a multitude of beliefs and related teaching and learning approaches are being adopted. Changes in teachers' beliefs are generally not effected by reading and applying the findings of educational research, but, instead, student teachers appear to obtain most of their ideas from actual practice. Therefore, it seems important to put preservice teachers in a sufficient number of real-life situations and oblige them to reappraise their existing beliefs, attitudes, and knowledge. Select a rich variety of learning situations that provides opportunities to reflect on and reconceptualize beliefs about teaching and learning.
- There is plenty of research evidence that points at the critical role of sharing and discussing instructional practices with peers. Hence, we recommend bringing student teachers in contact with peers and cooperating teachers who have adopted a wide variety of beliefs and related instructional approaches. In the context of educational innovations based on the use of ICT, grass-roots projects and good practices have, for example, proven to be successful teacher education projects. However, mere observation of personal practices and instructional models of peers and cooperating teachers is insufficient. Reflection on these experiences and practices should be fostered in order to result in more sophisticated epistemological beliefs.

- Develop a feedback approach that accepts and stimulates varying, dissimilar, and divergent thinking about and the adoption of teaching and learning approaches; and giving the critical impact of cognitive processes that underlie teachers' beliefs, student teachers should be invited to reconsider their perception of the social context and their attributions related to earlier instructional success or failure.
- Rath (2001) presents a list of concrete and more general approaches that are more or less in line with the former statements about changing (student) teachers' beliefs:
- Confronting student teachers with dissonance. Dissonance theory suggests that if we engage teacher candidates in activities that arouse dissonance, beliefs might change. This implies that we arrange for conflicts between new experiences and past experiences. In this context, it is important to raise conflicting beliefs to the surface, and to foster discussion, comparison, examination, and challenge.
- Apprenticeship experiences. This implies that apprenticeship experiences are critical at the start of a teacher education program. This is in sharp contrast to earlier approaches where internships were rather a part of the later phases in teacher education. Of course, the teacher educator should carefully select settings that are helpful in activating specific beliefs.
- – Values clarification involves asking student teachers to reconsider the beliefs they hold. After examination, reacceptance, considering alternatives, anticipating consequences, and trying their implications, the values are expected to develop.
- Case study. In this instructional strategy, student teachers are invited to study cases of instruction through different lenses: the lens of their own beliefs, belief systems derived from constructivism, or direct instruction or the project method. It is hypothesized that this could invoke changes in the belief systems.

Changing Particular Preservice Teachers' Beliefs: Mathematics and Educational Innovations

To exemplify some of the approaches described earlier to change teacher beliefs, we focus on practices and related research that tried to change teacher beliefs related to mathematics and educational innovations (e.g., ICT).

Based on a literature review in relation to teachers' beliefs on mathematics, Ernest (1989) concludes that three components of beliefs have a significant impact on teachers' instructional practices:

- his/her view or conception of the nature of mathematics,
- his/her model or view of the nature of mathematics teaching, and
- his/her model or view of the process of learning mathematics.

This belief structure can be partly related to the earlier general description of beliefs and points at epistemic issues, beliefs about how peoples learn, and how we teach. Quillen (unpublished PhD thesis) reviewed the literature about mathematics beliefs of preservice teachers. She studied in detail the way the student teachers adopted relational beliefs or instrumental beliefs. Relational beliefs about teaching and learning mathematics refer to the inclination to provide opportunities for students to explore, investigate, use a variety of problem-solving strategies, and use prior knowledge to solve problems involving concepts that have not been previously taught. Instrumental beliefs about teaching and learning mathematics mirrors direct instruction, teaching by telling, and using memorization of rules, formulas, and procedures to solve problems.

There is abundant literature about attempts to change teacher beliefs related to mathematics. Most attempts share the basic characteristic that challenging these beliefs is done in an explicit way in order to transform the beliefs from nonevidential to evidential (Green, 1971) and exposing them to the individual preservice teacher in view of a critical analysis and discussion with student peers. Strategies to make beliefs explicit build on involving preservice teachers in doing mathematics and learning through talking mathematics. Making beliefs explicit is also the basis of intervention studies that research the extent to which preservice teachers adopt the constructivist base of the new mathematics curriculum, introduced by the National Council of Teachers of Mathematics (NCTM) in the USA in 2000. Researchers have pointed out that most teachers' past experiences with mathematics are/were rather in conflict with the NCTM model that embraces constructivist pedagogical beliefs. Most teachers reflect beliefs that build on their experiences with traditional, behaviorist methods of mathematics instruction that mainly build on transmission and absorption. This creates a tension between teachers' beliefs and the ambitions of the mathematics curriculum innovation. The study of Swars *et al.* (2006) is an attempt to influence the related teachers' beliefs. The study clearly shows that it required a long-lasting intervention (2 years) and a wide variety of instructional strategies to successfully change the teachers' beliefs about the teaching of mathematics. Strategies comprised: thorough reading of the basic assumptions of the new curriculum, classroom discussions and learning activities focused on social-constructivist pedagogy, analytical viewing of

classroom videotapes of classrooms, clinical interviews with children (e.g., about the children's understandings of number and operations), report writing about field experiences using the new type of mathematics pedagogy, and analysis of NCTM-based lessons (check of coherence between practices and principles).

Another extensively studied field where attempts to change and influence teacher beliefs is that of educational innovations in general and the implementation of ICTs in particular. In the literature, there is a general agreement that the adoption of an educational innovation can only be explained when the teachers' beliefs are also taken into account. In the research literature, it is, for example, acknowledged that teachers' beliefs tend to be associated with a particular use of ICT in the classroom (e.g., Ertmer, 2005). Studies explain this by hypothesizing that teachers who use computers do so because their conceptions of ICT use fit into their existing teaching belief system. If teachers perceive that computers address important instructional and learning needs, the perceived value will be higher. There is growing evidence that teachers, for example, adopting constructivist beliefs, are more dynamic computer users. Research that focuses on changing teacher beliefs about ICT builds on a variety of strategies. Typical studies stress on the importance of setting up of long-term initiatives. Furthermore, they also build on critical reflection by student teachers on their own video-taped science lessons culminating in a focus group session. This strategy seems to make preservice teachers able to differentiate between their own beliefs and teaching practices that are not or in line with critical assumptions. Research also indicates that changes in beliefs do not imply that earlier beliefs have to disappear. Whereas in the past, authors centered on bipolar and contrasting dimensions in belief structures, for example, the bipolar distinction between teacher-centered traditionalistic and more progressive or student-centered educational beliefs, researchers have shifted their attention toward a multidimensional approach of the structure in belief systems. In newer approaches to influencing and changing preservice teachers' beliefs, teacher educators rather try to promote that student teachers hold both traditionalistic and progressive educational beliefs. Recent research points out that teachers adopting both strong constructivist beliefs and strong traditional beliefs reflect a higher adoption of and more integrated use of ICT.

Conclusions

Wrapping up the conceptual, theoretical, and empirical base in relation to teachers' beliefs results in a complex and especially challenging agenda for teacher educators. Though current conceptions about teachers' belief are

rooted in a strong research tradition, it is not yet clear how teacher educators can cater to teachers' beliefs in an adequate way. Promising directions for future research and educational practice adopt a comprehensive view toward the education of student teachers and in-service teachers. They consider teachers as active agents with a central personal responsibility in the development of their professional competences.

Teacher Education and Models of Teacher Reflection

Defining Reflection

One would be hard-pressed to locate a teacher education program in the world today that does not somehow express interest in the promotion of teacher reflection. Indeed, the notion has become so deeply embedded in conceptualizations of teaching and learning to teach that many no longer see the need to make such an orientation explicit in the descriptions of their programs. On the one hand, this could be perceived as a good thing – the inherent value of reflective practice is no longer in question. On the other hand, it can mean that educators are not paying enough attention to the meaning or effectiveness of its definition, intent, implementation, or outcome. Furthermore, consistency of use can too often be assumed and significant differences overlooked; this failure to problematize teacher reflection can diminish its potential and undermine progress.

The aim of this article is to draw attention to the similarities and differences in current understandings and applications of reflection in teacher education and offer a conceptual framework for refocusing and reinvigorating the work in this arena. It begins with an articulation of common definitions of teacher reflection, looking first at the roots of this notion in the scholarship of John Dewey and Donald Schön. The aspects of these long-standing formulations that seem to persist, crossing temporal and contextual boundaries, are identified. The fine-tuning that has occurred over time, as well as the most widespread shifts in emphasis, are then portrayed. Employing this generalized definition as a lens, a framework for identifying and differentiating the most prevalent models of reflection now existing in teacher education is presented. The framework consists of three interrelated continua: purpose, content, and means. This discussion concludes with a consideration of the implications of these variations, along with recommendations for how the continua might be utilized to inform and enhance subsequent steps with regard to the research and practice of reflective teacher education.

Historical Roots

Rodgers (2002), one of the many scholars concerned with the role of reflective thinking in both teachers' and students' learning, worries that "reflection has suffered from a loss of meaning. In becoming everything to everybody, it has lost its ability to be seen" (p. 843). In order to

prevent that from happening, she revisits four of the main criteria that characterized Dewey's original conceptualization of the term:

1. Reflection is a meaning-making process that moves a learner from one experience into the next with deeper understanding of its relationships with and connections to other experiences and ideas. It is the thread that makes continuity of learning possible, and ensures the progress of the individual and, ultimately, society. It is a means to essentially moral ends.
2. Reflection is a systematic, rigorous, disciplined way of thinking, with its roots in scientific inquiry.
3. Reflection needs to happen in community, in interaction with others.
4. Reflection requires attitudes that value the personal and intellectual growth of oneself and of others. (Rodgers, 2002: 845).

The result of Rodgers' subsequent analysis is a reminder that, if engaged as Dewey intended, reflection is the means by which human beings learn from their experiences so as to improve themselves and their society. It is the only way for making meaning that is justified – empirically, theoretically, morally – and thus educators ignore its systematic articulation and development at their peril, particularly with regard to teacher education, where the learning of both the novice teachers and their future students is the essence of the endeavor.

The field of teacher education would do well, in other words, to revisit Dewey's (1938) definition of reflection: "Active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusions to which it tends" (p. 9). It needs, therefore, to be both the means of reflective teacher education and the end toward which it aims – the preparation of teachers who both embrace this process of making meaning from experience for themselves and conceptualize and facilitate their students' learning in the same way. Certainly, these two core ideas are fairly universal in the field and seldom contested. Teacher educators agree that reflection is a means for candidates to learn from practice, which can subsequently be employed to improve that practice. But the details of the why, what, and how of this process can vary greatly.

Many in the field concur that one of the main reasons reflection has become so widely embraced in recent years and so well integrated into teacher education is the work

of Donald Schön (1983). The magnitude of his impact is in part due to the fact that he considered reflective practice to be synonymous with professional thinking. Reflection is not merely contemplation or recollection, and not only for the purpose of learning; it is problem based and action directed. It is the means by which professionals can solve their problems of practice in meaningful and ever more effective ways. The terms he used to identify the two ways of engaging the process – reflection-on-action and reflection-in-action – make that connection explicit. By suggesting that the latter is even a possibility, he helped shift attention to the enactment and outcome of reflective deliberation.

Key to successful problem solving, in Schön's view, is the ability to frame – and reframe – a problem of practice appropriately, since that determines and delimits the solutions sought and generated. In general, teacher education embraced these notions and over the last several years has given particular attention to making better connections between theory and practice and to helping novices learn the skills and dispositions necessary to reflection on and in action. But ironically, this widespread acceptance may have contributed to the loss of meaning and the invisibility to which Rodgers (2002) referred. Consequently, those who encourage another resurgence of interest in teacher reflection are doing so by fine-tuning its definition and by emphasizing particular aims and expectations for both the process and its results.

Recent Developments

Many of the characterizations of reflective teacher education that emerged just prior to or during the Schön revitalization included categorizations of various types of reflection. Van Manen (1977), for instance, identified three levels of reflectivity: practical/technical, social/political, and moral/ethical. Though he, and many others, suggested that the practical/technical was of a lower level and thus not the ultimate aim, it was nonetheless viable as a focus or form of reflection. One of the widespread changes occurring in the field in recent years is the elimination of the practical/technical as a stand-alone category, which was actually advocated by both Dewey and Schön. Donahue (2005), for instance, in discussing the meaning of reflection in the teacher education program at Mills College states: "While some policymakers, textbook publishers, parents, and perhaps even teachers think of teaching as merely a technical activity of implementing curriculum according to established criteria, most teachers appreciate that teaching is intellectual work and reflection is a vital means of nurturing the intellectual dimension of teaching" (p. 40). Apparent in this statement is the assumption that reflective teaching is different from technical teaching.

Most teacher education programs engaged with reflective teaching at present accept that, at the very least, they

need to be attentive to the substantive learning and the transformed thinking of their student teachers. Feiman-Nemser (2001), when writing about how to strengthen and sustain teaching for the future, makes the following claim: "After decades of school reform, a consensus is building that the quality of our nation's schools depends on the quality of our nation's teachers. . . . This paper rests on a single premise with far-reaching consequences—if we want schools to produce more powerful learning on the part of students, we have to offer more powerful learning opportunities to teachers" (pp. 1013–1014). In their preservice programs, then, student teachers need to engage in cycles of reflective inquiry in order to "begin forming the habits and skills necessary for the ongoing study of teaching in the company of colleagues" (p. 1019).

Korthagen and Vasalos (2005) articulate a comparable recommendation in greater detail. They advocate for a structured support process aimed at the promotion of core reflection, that which is focused on the deepest levels of a student teacher's personality – mission and identity. The means for facilitating this type of reflection is through their ALACT model, which consists of five phases: action, looking back on the action, awareness of essential aspects, creating alternative methods of action, and trial. It bears much resemblance to the typical action research cycle, but gives greater emphasis to the affective dimension of the learning to teach process and to the need for surfacing and exploring contradictions between a candidate's identity and mission and her beliefs and behaviors.

Several in the field at present, while applauding this insistence on deeper learning and transformed beliefs, consider it to be a necessary but not sufficient effort. Also essential is greater specification of the ends toward which reflective teaching is directed. Those in this camp are reemphasizing the moral imperative inherent in Dewey's original definition: "I will argue that efforts to prepare teachers who are reflective must both foster genuine teacher development and support the realization of greater equity and social justice in schooling and the larger society" (Zeichner, 1996, p. 201). This implies that a certain set of criteria be applied in determining whether the solutions teachers develop for their problems of practice are meaningful and effective – the aim of professional reflection, according to Schön. What is more, the nature of the problems that are detected and the ways in which they are framed are challenged by this orientation, thus calling into question the terminology itself and its accompanying protocols: "This involves framing certain educational issues as dilemmas rather than problems with clear solutions and deliberating thoughtfully about decisions that involve competing claims to justice" (Cochran-Smith, 2004, p. 15).

In essence, these teacher educators are stressing the fact that reflection in teaching and teacher education is a means to other ends and not an end in itself. The two,

however, are necessarily linked; learning to teach for social justice requires taking what Cochran-Smith refers to as an inquiry stance toward practice. The candidates must, therefore, reflect on their ideas and actions in critical inquiry communities where issues of equity are raised and fundamental assumptions, prejudices, and even values are interrogated. Others who stress similar types of political and ethical outcomes employ the idea of reflection in a comparable way. Kumashiro (2002), who engages with what he calls antioppressive teacher education, argues that typical forms of self-reflection are not enough unless they include the exposure and interruption of the harmful repetitions embedded in both intentional and unintentional teaching activity.

What is noticeable in these representative descriptions of the purpose and facilitation of reflection in contemporary teacher education programs is the frequency with which terms like inquiry and teacher research are utilized. In many instances, they are considered to be synonymous with reflective teaching – the expressions are used interchangeably. For many teacher educators, taking an inquiry orientation to practice is the same as reflective teaching. Thus, various forms of teacher inquiry are considered to be the means by which student teachers engage in and learn about reflection on and in practice. In surveying 12 European preservice and in-service programs about their conceptions of reflective practice, Clarke and Chambers (1999) found that many equated it with action research. In fact, several who favored such approaches never used the term reflection with regard to their programs at all, which tends to validate Rodgers' previously mentioned concerns. Others consider inquiry and reflection to be somewhat different endeavors; in this volume, for instance, there are separate articles on models of reflection in teacher education and inquiry-oriented preparation programs. In either case, more explicit exploration of the relationship between the two is needed. The following section presents a framework for differentiating models of teacher reflection that might be useful in that regard.

Models of Reflective Teacher Education

The literature on reflection in teacher education can be categorized according to the foci suggested by Donahue (2005): "In defining reflection, theorists have wrestled with questions of why teachers reflect, what they reflect about, and how they reflect" (p. 39). In part, this selectivity is an artifact of the research and reporting process – the circumscription necessary to a meaningful and manageable investigation or essay. But in many instances, these delimitations also represent a differentiation in the philosophies and priorities guiding the design and implementation of particular reflective teacher education programs. Consequently, these categories should be useful for

making distinctions among the programs. In addition, there is considerable within-category variation that might best be characterized by three nondevelopmental continua – purpose, content, and means. These continua are interrelated, meaning that where a model of teacher reflection placed on one continuum tends to suggest where it would or should be placed on the others. These three continua, therefore, have the potential to be utilized as a framework for identifying, differentiating, and ultimately constructing and evaluating models of reflection in teacher education.

In the next section, each continuum is described in more detail, drawing upon examples from the literature and the generalized definitions previously summarized for illustration and explanation. Then the ways in which the three seem to interrelate in theory and practice are discussed, thereby demonstrating the conceptual integrity of the conglomerate and its potential as an analytical framework for the design, critique, and transformation of reflective teacher education.

Purpose

This continuum is concerned with the aim of the reflective process – why student teachers engage in reflection and what should be gained from that endeavor. On one end of the continuum (let us say the left end to facilitate comparison with the other continua) is a focus on the development of the lifelong learning and problem-solving capacities of individual candidates. On the other end (let us say the right end) the focus is on the transformation of social institutions and systems in ways more consistent with democracy, equity, and social justice. What is important to clarify here, especially in this first discussion, is that this is not a developmental continuum. It is not meant to imply that attention to student teacher learning is at a lower level or a less important area of concern than attention to social transformation. Nor should it suggest that the intention is to move a student teacher or a teacher education program through a series of stages that culminate in an exclusive focus on changing society.

What the continuum does convey is a viable range of options. Any purpose not inclusive of at least one end of the continuum would not be consistent with the current and long-standing definitions of reflection described above. For instance, a technical orientation intended simply to aid novices in applying preexisting curricular packages would not be considered reflective teacher education because it is outside the range; it could not be placed anywhere on this continuum. Furthermore, programs and interventions that do not attend at all to an articulation of its ultimate goals would not qualify as a model of teacher reflection. What the continuum also embodies are the multiple possibilities for combining both aims. Anywhere on the continuum, aside from the extreme ends, represents some combination of the two.

The middle point, therefore, signifies a full and balanced integration of both aims.

In applying this analytical tool to the literature review, several programs and projects that could be located near the left end of the continuum were discovered. They were concerned with the meaningful learning of individual student teachers and with the development of the attitudes and skills of reflection on and in action that would ensure lifelong growth and ever-improving practice. Feiman-Nemser (2001), for instance, argued for the need to place “serious and sustained teacher learning at the center of school reform” (p. 1014). Though this perspective may be closer to the middle of the continuum, she characterizes improvement primarily in terms of more powerful student learning. Though this is a critical component of institutional and social transformation, it does not include the interrogation and undoing of embedded inequitable and oppressive structures so fundamental to the social-justice end of this continuum.

In contrast, programs or practices near the right end of the continuum were difficult to locate. To be sure, the number of reflective teacher education programs that consider more equitable institutions and just societies to be their ultimate aim is increasing. But these also embrace the goal of individual growth, which would situate them closer to the center of the continuum. In fact, most would consider one to be impossible without the other. On the one hand, social transformation is not achievable without individual teacher transformation and, on the other, improvement in teaching is meaningless in the absence of excellent and equitable outcomes for all learners both within school and beyond. Such a finding might suggest a need to refine the continuum in the future, but at any rate, it does not seem to interfere with its analytical potential, or that of the other continua.

Content

This continuum is concerned with the content of reflection – what it is that student teachers are reflecting on and about. It constitutes the target and the source for the issues and dilemmas addressed by the reflective process. At the left end of the continuum, attention is directed toward the student teacher – his/her internal processing and external actions, and often, the relationship between the two. At the right end, novices interrogate the inequities embedded in educational institutions and systems and the societal structures, norms, and discourses they represent and validate.

As in the previous instance, more examples could be found for the left side of the continuum. Many teacher education programs consider the primary impetus for teacher reflection to be the problems of practice that they encounter: “I define reflection as the deliberate and purposeful act of thinking which centers on ways of

responding to problem situations in teaching and learning” (Loughran, 1996, p. 14). Like Loughran, most teacher education programs that direct reflection toward problems of practice insist on attention to the relationship between teaching and learning. A teacher’s beliefs, knowledge, or behavior cannot be understood, evaluated, or improved irrespective of an assessment of student learning. But again, only a few raise questions about whether or not those student outcomes represent greater equity or improved social justice. Those who do refer to social justice seldom incorporate explicit deliberations about the larger context or include challenges to the ways in which typical modes of educational problem solving may reify those structures.

Also as above, few programs seemed to situate themselves at the far right end of the content continuum. Those who insist that student teachers reflect about systemic inequities, also emphasize the need for individuals to interrogate their own beliefs and practices in that regard, which would be at the center of the continuum. Gitlin (2005), for instance, proposes the following: “what needs to occur at a fundamental level to confront oppression and move toward any form of social justice is to make everyday politics the object of inquiry” (p. 15). This requires reflection on oneself and one’s cultural community as well as that of the other, and to determine what traditions of interaction between the two protect the repressive *status quo* so that those conventions can be disrupted. Noteworthy here is that such models of teacher reflection do not simply represent a straightforward combination of the two ends of the continuum. In these exemplars, the nature of self-reflection is different; it reframes the problems of practice using the equity lens. The means for promoting such reflection, though similarly variable, seem to be somewhat less transfigurative.

Means

This continuum is concerned with how student teachers engage in the reflective process and how they learn to do so. At the left end of this continuum are means for facilitating and encouraging the interrogation and improvement of personal assumptions, knowledge, and pedagogy. At the right end are means for fostering the capacities and propensities necessary for political activism. The vast majority of current research into reflective teacher education seems to be concerned with this continuum – figuring out how to teach and support student teacher reflection, as well as ensure that candidates incorporate it into their practice for the long term. In these instances, the purpose and content, though not the direct objects of attention, are often mentioned in the course of process description or implied by the evaluative structures used to interpret the effects. Thus, an approximate placement on all three continua is usually possible.

As with the others, most programmatic efforts for fostering reflection would be placed on the left half of the continuum. They are directed toward helping individual student teachers learn the skills and dispositions necessary for engaging in reflection on and in practice both during the program and throughout their careers. They represent efforts to help student teachers take an inquiry orientation to practice – to frame and reframe their practical problems, design and implement powerful pedagogies, and analyze and evaluate student learning outcomes – so that they can learn from their actions, develop their professional knowledge base, and engage in more effective teaching. These studies explore the potential benefits of a whole range of very specific strategies, for example, journals, seminars, mentoring, coaching, metaphor production, action research, reading groups, autobiography, mural-making, dramatic enactment, and so on. Other investigations consider more holistic interventions, such as Korthagen's ALACT model for reflection (Korthagen and Vasalos, 2005). There is a growing body of literature, referred to as self-study, where the teacher educator researchers are equally concerned with their own learning and development through various forms of investigative research that include similar varieties of reflective deliberation (Loughran *et al.*, 2004).

Some of these studies that address the hows of reflection also examine means for helping student teachers, and often their teacher educators, to interrogate and transform their deeply held beliefs, assumptions, and understandings using the lens of equity and social justice. They endeavor to undo existing prejudices and help develop a critical stance toward the processes of teaching and learning, again through particular interventions or through a more pervasive structure, such as the principled-practice approach utilized at Mills College (Kroll *et al.*, 2005). These models would be located nearer to the center of the continuum, especially if, as in the latter case, they also advocate for instruction that will prepare novice teachers and their students for civic engagement and encourage them to “join with others in larger movements for educational and social equity” (Cochran-Smith, 2004, p. 159). Again, it means that there are no models on the far right end of this continuum. Instead, those who attempt to include strategies for nurturing political activism also engage means for the development of the social-reconstructionist dimension of teaching. The center position is, in that sense, more additive than transformative; it adds large-scale involvement to the already-reframed critical pedagogies.

Implications

As noted above, most of the readings in this domain were targeted at just one of the continua, especially individual articles or chapters, in part due to the limitations of time

and space. But even in those instances, placements on the other dimensions could often be inferred. If a study was investigating the impact of a strategy for promoting critical reflection, for instance, the goal of greater social justice was either stated or implied and the content for reflection tended to incorporate systemic traditions. But, the framework was also useful in detecting potential contradictions. If a model claimed to have the aim of promoting social justice, but did not include structural inequities in their investigatory content, that purpose might be called into question. At any rate, it was clear that the three continua are and should be consistent with one another in a coherent model of reflection in teacher education and thus together can serve as a framework for future analysis and development.

Purpose, content, and means are, therefore, three foci to which all teacher education programs concerned with the promotion of teacher reflection need to give serious attention in both their deliberations and enactments. Even though all research studies cannot focus on all three at once and there can be great benefit from isolated attention to programmatic details, the other dimensions must always be considered in both the framing and interpretation of those investigations.

To be considered a viable model for teacher reflection in teacher education, the purpose, content, and means of these models must be articulated and there needs to be consistency among them with regard to placement on the continua. If the fundamental purpose of education is considered to be greater democracy, equity, and social justice for children and for the world, reflective teacher education programs must be designed and enacted so that they could be situated at the center of all three continua.

Teacher Education as Teaching for Understanding with New Technologies

M S Wiske and D E Spicer, Harvard Graduate School of Education, Cambridge, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Activity theory – A developmental conception of ways that technologies, practical action in the world, individuals, and communities shape and are shaped by the process of learning.

Collaborative curriculum design tool – An online environment that supports collaboration on the design of curriculum structured by the Teaching for Understanding framework. It includes examples, supportive prompts and resources, an integrated message board to facilitate communication with colleagues whom the designer adds to a design team, tools for supporting alignment of goals with instruction and assessment, and means for attaching related files and websites, and publishing the final design.

Teaching for Understanding (TfU) – An educational model, based on collaborative research conducted at the Harvard Graduate School of Education, including five elements: generative topics, understanding goals, performances of understanding, ongoing assessment, and collaborative reflective communities.

Understanding as performance – A concept of understanding as a capability to think with what one knows and apply it flexibly in varied situations.

WIDE World (Wide-scale Interactive Development for Educators) – An innovative professional development program developed and based at the Harvard Graduate School of Education. Its mission is to engage and support large numbers of educators across multiple levels of school systems in aligning their efforts to form professional networks that promote excellent instruction and improved performance by students, teachers, coaches, and leaders. It supports the application of research-based frameworks, such as Teaching for Understanding, by providing interactive online professional development courses and face-to-face support services to K-12 educators in the US and around the world.

Introduction

The proliferation of knowledge with new information and communication technologies, coupled with a clear

consensus from recent research on learning, dictate that education goes beyond simply transmitting information and procedures to focus on cultivating continuing learners. This requirement is certainly true for teacher education. A recent AERA Panel on Research and Teacher Education (2005) emphasized that teacher education must be an ongoing process of inquiry that does not end with certification but continues throughout the professional career, and across diverse educational settings. In this article, we examine the synergistic contributions of an explicit educational framework, called Teaching for Understanding (TfU), and networked technologies in helping teachers support the active learning that they and their students require in the twenty-first century. We use activity theory to conceptualize the roles of the TfU framework, networked technologies, and professional communities in continuous teacher education. Three examples illustrate how this approach can be applied to varied, interconnected stages and contexts of teachers' learning.

Mastery Teaching to Promote Understanding

Before analyzing the process of teacher education, we must consider the kind of learning that teachers need to promote. Public schools spread throughout industrializing democracies during the nineteenth century partly to prepare a broad range of citizens as contributors in increasingly hierarchical and mechanized workplaces and pluralistic societies. Teachers aimed to transmit basic skills through drill and rote recitation to groups of pupils who varied widely in age and experience. By the turn of the twentieth century, progressive educators criticized such rote learning and advocated more inquiry-based approaches that took account of students' varied interests. Despite a century of efforts, didactic instruction that Goodlad (1984) calls "frontal teaching," still prevails in most public schools around the world.

Recently, progressive reforms have gained new allies among some policymakers seeking to foster students' capability to think creatively, analyze and critique knowledge, reason systematically, apply knowledge flexibly, formulate and solve new problems, collaborate effectively in teams, and develop skills and habits of mind that promote continuous learning. While the dominant political discourse remains one of accountability, some leaders

in business and government have embraced an expanded conception of accountability that no longer views mastery teaching as primarily transmitting a canon of facts, theories, and accepted procedures. Enlightened leaders have come to view teaching as a process of helping students construct their own understanding and apply their knowledge through interaction using varied means, among diverse people, and within authentic contexts. In many countries, an emerging collective goal for education emphasizes deep and flexible student understanding.

What do we mean by understanding? The TfU project, a 6-year collaborative action research study convened at the Harvard Graduate School of Education during the 1990s, began with this same question. University-based researchers working with teacher researchers in schools came to define understanding as a flexible performance capability – being able to think with one’s knowledge and apply it creatively and appropriately in a range of circumstances. They conceived dimensions of understanding that encompass not only conceptual knowledge in one or more domains, but also methods of inquiry and reasoning, forms for presenting one’s ideas effectively with multiple symbol systems in varied situations, and appreciation of the purposes and limitations of learning in various disciplines.

Developing a flexible performance capability is as important for educators as it is for their students. Conceptual knowledge and familiarity with techniques are of limited use to a professional who also is not able to retrieve, synthesize, generate, and apply such knowledge effectively in practice and in interaction with others. Eraut (1994) whose research focuses on the nature and development of professional knowledge writes, “. . . learning knowledge and using knowledge are not separate processes but the same process.” Therefore, teaching for understanding is both a goal and an appropriate means for educating teachers.

TfU as Goal and Means

Harvard’s TfU project identified features of curriculum, pedagogy, and assessment that were common across examples of lessons that successfully developed learners’ understanding. As described by Blythe (1998) and Wiske (1998) researchers and teachers distilled these features into a coherent framework that crystallizes responses to core educational questions that are explained below.

What Topics Are Worth Teaching for Understanding? (Generative Topics)

Topics relate to important ideas in subjects, domains, or disciplines that are central to the required curriculum, connect both to learners’ experience and the teacher’s passions, can be approached through multiple entry points and/or media, and generate continuous inquiry.

What Should Learners Come to Understand? (Understanding Goals)

Goals focus on understanding key concepts, methods of inquiry and reasoning, purposes for learning, and disciplined forms of expressing understanding. Understanding goals aim beyond remembering information or practicing routine skills to target creative applications of knowledge. Effective teachers publicize explicit understanding goals that define the purpose of learning and serve as a basis for assessing progress.

How do Learners Develop and Demonstrate Understanding? (Performances of Understanding)

Effective teachers require students to stretch their minds as they develop and demonstrate understanding of target goals. Teachers sequence accessible yet challenging learning activities that engage students’ initial ideas and interests. Through guided inquiry, teachers progressively coach students toward more sophisticated, synthetic, and independent levels of performance. A rich range of learning activities allows students to work with varied media, through multiple intelligences, and in different participation structures so that all students are engaged and appropriately challenged.

How can the Students and Teachers Assess Achievements in Ways that Promote Further Learning? (Ongoing Assessment)

Teachers and others frequently analyze student performances in relation to public criteria that align precisely with understanding goals. Students may even help define the criteria for high-quality work. Frequent assessments include generating pertinent suggestions for improving both students’ work and the teacher’s planning. Multiple authentic audiences, including students themselves, parents, subject matter experts, and interested community members, may participate in assessment and feedback.

How can We Work Together Most Effectively within and beyond the Classroom? (Collaborative, Reflective Communities)

Teachers who promote understanding develop a culture of respect, reciprocity, and reflection with learners. Students build capacity to learn from and with one another by identifying common goals, developing a shared language and routines for reflective dialogue, and celebrating diversity and shared accomplishments.

The TfU framework shares many features with various formulations of twenty-first century learning, other syntheses of educational research, and characteristics

that most teachers recognize in their own good ideas and practices. These similarities underscore the generic applicability of this framework as a common, comprehensive language and structure for designing, conducting, and explicitly modeling effective pedagogy. In the examples presented later, we highlight the elements of TfU as mediators of teacher education activities whose goal is mastery of teaching that promotes students' deep and flexible understanding.

Networked Technology as a Mediator of Teacher Education

Education of preservice teachers often occurs far away from classrooms where teachers work, which hampers learning through authentic performances. Academic institutions, where most teacher preparation is based, are usually distant from the schools and other authentic settings where novice teachers might practice teaching. Skilled teacher mentors are scarce and travel is expensive, which limits opportunities for teachers to benefit from expert coaching.

Learning through reflective performance is equally difficult for in-service teachers. Finding time to analyze their work with colleagues and coaches is difficult. In hurried meetings, teachers are hard-pressed to reflect deliberately about lesson plans, teaching, and assessment. Corridor conversations and disorganized bits of paper are not easily captured in a form that promotes ongoing assessments or sustained collegial collaboration among teachers.

Networked digital technologies provide numerous advantages for overcoming these difficulties of teacher education and promoting the elements of effective TfU. Potential contributions of new technologies include:

Providing accessible templates and tools that structure work around common concepts, for example, interactive online environments for developing lesson plans. Enabling teacher learners and mentors to capture, store, and revise documents, videos, audio files, and images digitally in forms that can easily be shared, annotated, reviewed, analyzed, and co-constructed.

Rapidly transmitting written, as well as spoken, communication across distance and time, thereby encouraging more deliberative dialog and easing the limitations of synchronous meetings.

Making the work of students, teachers, and coaches visible to many so that individual insights benefit large groups.

Facilitating ongoing assessment with feedback from multiple sources. For example, teachers post work in the online environment where it can be reviewed, in relation to criteria, by teachers themselves as well as peers/coaches, and then easily revised.

In these ways, online technologies provide support for the use of a shared framework, collaborative exchange of materials and ideas, and sustained coaching, and enable ladders of professional development that stimulate educators to stay in the profession as they seek ways of contributing to and benefiting from contact with a professional community without abandoning direct work with students.

Teacher Education Viewed with Activity Theory

Activity theory offers a developmental view of the ways that conceptual frameworks and technologies, practical actions in the world, individuals, and social institutions shape and are shaped by one another in the learning process. This makes it particularly suitable for analyzing the roles of the TfU framework, networked technologies, and professional communities in teacher learning.

Building on the ideas of Vygotsky (1981) activity theory portrays activities such as teacher preparation and in-service professional development as continually changing, complex, self-organizing systems. It regards activity as a potential generator of both individual and organizational learning.

Engeström (1987) and more recently Roth and Lee (2007) used activity theory to describe how several distinct elements play crucial parts in mediating – literally being in the middle of – individual and group learning processes, as diagramed in the paradigmatic triangle of cultural–historical activity theory shown in **Figure 1**. The activity of developing expertise as a teacher is mediated by the division of labor and social rules that structure interaction within a particular community, such as the institutional setting of a school. The division of labor and rules are established and shift over long periods of time, serving collective motives that constitute the object or goal of activity. Of particular importance to our discussion of teacher learning are the mediating instruments in use within such communities. These instruments may encompass concepts (e.g., the components of a specific educational framework) as well as material tools (e.g., interactive digital tools and websites). Instruments and elements of community shape how the subject(s) or learner(s) orient, think, and perform in and for a particular activity.

Activity systems are in continual flux as participants negotiate tensions among different elements. Learning can be viewed as the resolution of contradictions among elements allowing the subject to take advantage of an expanded range of actions, including access to a wider repertoire of mediational means, taking on new roles, and forging robust ways of working within existing constraints.

Figure 1 Engeström's model of the socially distributed activity system. Reproduced from Engeström, Y. (1987). *Learning by Expanding: An Activity-Theory Approach to Developmental Research*, p. 78. Helsinki: Orienta-Konsultit.

Consequently, as Engeström (1987) emphasizes, new objects or goals come into view and the system of activity as a whole is capable of evolving.

We use activity theory to examine teacher education within various systems of activity that orient subjects toward a goal or object, broadly characterized as mastery of teaching or pedagogical expertise. We highlight ways that two kinds of instruments – networked digital technologies and the TfU framework – expand the range of possible action for those pursuing mastery of teaching that promotes students' deep and flexible understanding. Activity theory illuminates the influence of these instruments in three different settings of teacher education: a graduate-level university course, an online course for practicing educators, and a school district.

Teacher Education in Varied Contexts

Teacher education involves continuous learning throughout an educator's career, including preservice teacher preparation, in-service professional development, and ongoing learning through inquiry and interaction within and among multiple levels of educational practice (e.g., relationships with administrators, researchers, and professional networks). Consequently, we chose examples that illustrate how TfU and new technologies promote mastery teaching aimed toward students' understanding in various phases and situations of teacher education.

Formal Teacher Education Course

One of the authors uses TfU as an implicit and progressively explicit mediating instrument in her course at the

Harvard Graduate School of Education called Designing Curriculum for Deep Learning. This one-semester course is for graduate students whose prior teaching experience varies considerably. Some are veteran teachers, some are professionals in other fields without prior teaching experience, and some are completing a teacher preparation program. The course applies and models the elements of TfU and the instructor emphasizes these parallels as the course progresses.

The generative topic of the course is designing curriculum that applies research-based principles to promote teaching and learning for understanding. Understanding goals for the course include understanding how to: (1) apply principles of effective teaching, learning, and curriculum design; (2) use technology to improve teaching and learning; and (3) participate effectively in a collaborative, reflective professional community. The core performance of understanding in this course is the design of a small unit of curriculum (1–3 weeks of lessons), developed in collaboration with a practicing educator, which explicitly exemplifies principles learned in the course. Students in the course are helped to identify a teacher partner whose setting, subject matter, and learners align with the student's own interests. Prior graduates of the course often volunteer to serve as a teacher partner, thereby enriching and extending the professional community of course participants. Designing a unit with and for the teacher partner adds to the generativity of the topic by anchoring the project in an authentic context of each student's choice and by enabling students to make a significant contribution in the world while benefiting from the consultation of an experienced teacher.

Students use an online collaborative curriculum design tool which is structured with elements of the TfU

framework to scaffold the design and refinement of a curriculum plan in collaboration with their teacher and other members of the class. This online tool includes specific support for designing each element of the framework and a message board where students exchange ideas with their collaborators. The teaching staff use the message board to provide ongoing assessment and feedback. As members of the class become more familiar with design criteria based on the theories from their reading, including TfU, and more skilled in contributing to a collaborative, reflective community, they are taught how to become effective self- and peer-evaluators.

The course is an activity system in which the concepts of TfU and the online curriculum design tool are mediating instruments that orient subjects (the students) toward the object of expertise in the design of curricula that promote understanding. This system includes a community that encompasses course members and collaborating teachers and the broader institutional setting of a graduate, professional school. The rules in this community include active application of theories to practice through design, reflection, and revision. The division of labor encourages a collaborative, reflective community whose members, including the instructor, contribute knowledge and provide feedback on colleagues' curriculum designs to improve learning.

Online Professional Development Program: Overlapping Systems of Activity

WIDE World at the Harvard Graduate School of Education offers online professional development courses that both model and teach participants how to apply research-based pedagogies. Several of the courses support designing and teaching with the TfU framework; some use the online collaborative curriculum design tool. During six biweekly sessions, participants learn to apply each of the four core elements of the TfU framework while engaging in participation structures that build the fifth element, a reflective learning community, both within the course and in on-site teams. Teachers may enroll in the online courses with two to three colleagues who work on the course assignments together. On-site teams in WIDE World courses are clustered into online study groups organized by subject area with approximately ten other teams or individuals who interact regularly with an online coach.

WIDE World online courses use the TfU language and networked technology to mediate in-service professional education for teachers:

1. The design of the courses models the same educational principles (TfU) that teachers are taught to use in their classrooms with their students.
2. Course assignments focus on trying out TfU ideas with students while the course is underway, thereby

building participants' capacity to think flexibly with what they learn and apply it in a range of contexts.

3. Experienced study group coaches offer tailored support and suggestions to help participants actively apply what they are learning in their own situation. Coaches also promote systematic exchanges and dialog among participants using the language of TfU to encourage development of a collaborative, reflective professional community within and across the online study groups.
4. By recruiting online coaches from graduates of its courses and by offering online courses for school leaders, WIDE World seeks to develop local capacity to sustain and extend the work initiated by participants in WIDE World courses.

In this setting of teacher education, activity in the online course occurs at the overlap of two other activity systems that exist on a longer time horizon – the institutional setting of the course participants' schools, on the one hand, and the institutional setting of the WIDE World project and the graduate school of education that serves as its home, on the other. The transient activity setting of the online course can be viewed as what Senge (1994) terms a practice field where participants work toward the object of mastery teaching. Networked technology provides ways of supporting experimentation with new mediational means (e.g., concepts of TfU and novel participation structures in both online and on-site teams) in ways that expand the possibilities for action within the participants' own classrooms. In this way, the activity setting of the course attempts to bring into view the object of mastery teaching for understanding within participants' schools.

Learning at Work through Continuous Inquiry: Embedded Systems of Activity

Researchers including Guskey (2002) and Little (1999) have shown that instantiating teachers' learning in new teaching practice hinges not just on individual learning but, most important, also on organizational learning. WIDE World's programs aim to stimulate continuous inquiry to strengthen practice in educational systems by providing related online courses for teachers, coaches, and leaders. In terms of activity theory, the subjects of this more-encompassing activity system includes people at all levels of educational practice that constitute schooling. In this example, the object on which we have focused in earlier examples – mastery teaching for student understanding – expands to encompass the practice and learning of all involved in promoting this goal. Such an object might be labeled mastery educational practice for students' deep and flexible understanding as the collective motive encompassing students, teachers, and leaders as subjects.

WIDE World uses TfU as a consistent model and common language across programs for educators working at all levels. Networked technologies provide flexible environments to support reflective, collaborative professional communities within and across role groups and innovating school systems. In this way, the activity system of a particular classroom can be viewed as part of the larger activity system of an entire school, which is in turn part of the more encompassing activity system of a larger organization – a school district or educational authority.

The Binghamton, New York, public schools have participated in a range of WIDE World programs over 3 years to promote ongoing learning for teachers, coaches, and leaders. District-level instructional leaders in Binghamton initially took WIDE World's TfU course. As they experienced learning with and applying the framework principles, they envisioned using online courses as a means of developing a shared language of teaching across the district. They focused especially on the comprehensive high school, which was under pressure to improve student performance. The administrators recruited teacher teams to enroll in WIDE World's online courses. Some teachers took additional online courses and were trained as WIDE World coaches. Administrators worked with two teams in the high school – a Math team and a team of English teachers – to develop a reference cohort that is expected to encourage other teachers to experiment with the framework and move toward greater coherence across the district.

During the past year, the Binghamton administrators have participated in an online action research seminar that WIDE World hosts. The seminar aims to develop local capacity in school systems to assess the impact of professional development as part of evidence-based continuous improvement in teaching and learning. Participants in the seminar collaborate on refining research questions, developing instruments and methods, analyzing the work of leaders, teachers, and students, and sharing results of this research. As the administrators collaborate with teachers to support and assess the impact of online professional development, they strengthen a local community whose language, roles, and interactions are shaped by the TfU framework.

Implications and Future Directions

The importance of schools as learning organizations and the ascendance of distributed professional networks as a mediator of professional learning is a consequence of shifts in work practices accelerated by information and communication technologies. New technologies serve as both stimulants of and means for restructuring schools

as complex, data-rich environments and making increasing demands professional teachers, new entrants, and established veterans alike, for higher quality and greater equity in their practices. The examples we have presented suggest an expansive view of possible settings for teacher education, ones that promote continuous learning aimed toward mastery teaching for students' deep and flexible understanding. The examples include the a traditional classroom in a graduate school of education linked to various school settings, the overlapping activity systems of school and university connected by networked technologies, and the embedded activity systems of organizational learning within a school system supported by online professional development.

One cross-cutting theme throughout this discussion is the importance of viewing professional learning as extending across the professional life span. Another theme is the use of the TfU framework as a specific, yet flexible, mediating instrument that conveys research on effective teaching in a usable form. It also provides a common language for educators as they continue to study, share, and improve practice.

Our experience with WIDE World, since its inception in 1999, suggests several trajectories of development in teacher education in the near future:

Global: Professional networks will become more global, enabling educators to learn from a wider range of colleagues as they develop, debate, and apply conceptual frameworks, technologies, and examples of practice across geographic and cultural distances.

Personal: Educators will be able to blend and extend opportunities for teaching and learning across their professional life span, connecting formal and informal learning through onsite experiences at university, conferences, and the workplace with online learning opportunities. Networked technologies will enable educators to play multiple roles in varied professional communities throughout their careers.

Organizational: Interweaving work across different settings of educational praxis will support more fluid collaboration among teacher educators in universities, schools, research organizations, policymaking agencies, and other places.

Technological: Continued developments in multimedia and online technologies will enable participants in teacher education to capture and share a wider range of artifacts both synchronously and asynchronously across distances, thereby evolving methods and resources for ongoing inquiry and improvement.

Conclusion

We analyzed how the TfU framework, networked technologies, and multiple layers of professional communities

can support connected, continuous teacher education in varied contexts. Activity theory gave us a lens to discern elements in an array of activity systems aiming toward a common goal of mastery teaching and learning to foster students' deep and flexible understanding. We portrayed three settings in which the TfU framework and networked technologies serve as mediating instruments to support this goal for educators. The examples of a graduate-level university course, an online course bridging school and university, and a district-wide initiative aimed at increasing educators' opportunities for learning illustrate ways in which teaching for understanding and new technologies support coherent, sustained teacher education at multiple levels across overlapping systems of activity. Such a panorama requires teacher education to be viewed in an expansive frame, one that entails organizational as well as individual learning, extends across the professional life span, and encompasses the wide variety of settings where the activity of learning occurs.

Glossary

Knowledge base of teaching – It refers to all profession-related insights that are potentially relevant to the teacher's activities.

Stimulated recall – Interview in which teachers explicate what they were thinking in response to a videotape of a lesson they have just given, aimed at retrieving teachers' knowing-in-action.

Teachers' craft knowledge – The accumulated wisdom and know-how teachers construct through experience, and which is the basis for dealing with everyday teaching situations.

Craft Knowledge and the Teacher Education Knowledge Base

Many established theories about teaching do not seem to correspond to what teachers know and do in practice. Past experiments with curricular and educational reforms often failed because they did not match teachers' ideas about what works in practice. These reforms were usually descriptions of what a teacher had to do in order to implement the reform successfully. In other words, they prescribed teacher behavior. There seems to be a lack of correspondence between ideas about what teachers should know and what they do know. In the field of teacher education, teacher educators are regularly confronted with student teachers who indicate that they see little congruence between the theories taught in the teacher education institute – described, for example, in the book by Reynolds (1989) *Knowledge Base for the Beginning*

Teacher – and what experienced teachers do and say in practice, the latter seeming to be of far more use for teaching.

Scholars, who emphasize the importance of what experienced teachers know for use in teacher education (e.g., Grimmer and MacKinnon, 1992; Loewenberg Ball and Cohen, 1999), suppose that experienced teachers are professionals. An important feature of professionals is that they share a common knowledge base (cf. Schön, 1983). Based on this feature, it is assumed that at least a part of experienced teachers' knowledge is shared by many teachers. However, no general agreement exists about the specifics of this type of knowledge. One question addressed in this article is whether there is an agreed-upon knowledge base that can – at least partly – be derived from the content of what experienced teachers know, and which can contribute to the enhancement of beginning teachers' teaching practice. Another question is how this might be done.

The knowledge base of teaching is described as all profession-related insights that are potentially relevant to the teacher's activities. The main function of such a knowledge base is to improve the practical arguments in the teacher's thinking process. Fenstermacher (1986) stated that the criterion of benefit of educational research in general should be "the improvement of practical arguments in the minds of teachers and other practitioners" (p. 44). These practical arguments refer to the beliefs and moral convictions that underlie a teacher's actions and eventually account for student learning. However, teachers' thinking processes and the practical arguments they use are highly complex, reflecting the nature of their work. For beginning teachers, the challenge is to develop their own practical arguments and craft knowledge in a well-considered way. It is important for them to

be acquainted with the knowledge of experienced teachers, how they draw upon this knowledge when teaching, and how this knowledge relates to more theoretical insights about teaching. This might help the development of their own craft knowledge and, as such, the development of their teaching practice.

Teachers' knowledge has been an object of study for several years. In most of these studies, the importance of this type of knowledge – also described as teachers' craft knowledge – for the education of new teachers is emphasized. Feiman-Nemser and Remillard (1996) indicated that research on teachers' craft knowledge "...further reveals the complexities and uncertainties of interactive teaching and the need for considerable thinking in action" (p. 76).

Loewenberg Ball and Cohen (1999) stated that, in order to help student teachers to develop into professional practitioners, teacher education programs should include attention to the kinds of knowledge, skill, and other qualities necessary for professional teaching. According to Lottero-Perdue and Brickhouse (2002), learning a vocation is only possible when learners have access to the expertise of old-timers. This allows beginners to eventually participate fully in the activities of the communities of practice. In their study, an important conclusion was that adequate social access to knowledge is an important factor for acquiring competence in the workplace. Adequate social access to knowledge was linked in their study to an organizational expectation that information can and should be shared, through interaction and direct communication, and through the use of written sources.

The concept of teachers' craft knowledge is to a certain extent trivial in the literature. From the beginning, research into this type of knowledge has been grounded in a high degree of regard for teachers. Research into teachers' personal practical knowledge resulted from dissatisfaction with the way teachers were viewed in most research on teaching that was done until then, in which teachers' knowledge was given little credit. Many researchers followed by taking teachers seriously as holders of (practical) knowledge, and aimed at giving teachers a voice in research on teachers. However, other authors point to the problematic character of investigating this type of knowledge, and sometimes even warn against taking this knowledge seriously. They claim, for example, that teachers' craft knowledge also contains fragmentary and inaccurate opinions. It is also highly subjective in nature, and its relationship to what teachers actually do in practice is doubtful. They prefer to focus on situation-independent claims about teacher knowledge and behavior. Most teacher education programs, however, contain a mixture of general and situation-independent knowledge about teaching, on the one hand, and teachers' craft knowledge, on the other – the latter pertaining to, at minimum, a mentoring program of some kind.

The question of the contents and nature of the knowledge underlying teachers' professional behavior is essential. In this article we elaborate upon these questions: What are the content and nature of this type of knowledge? Why is it essential to incorporate it in the teacher education knowledge base? How might this be done? Research findings show that experienced teachers' craft knowledge provides information about the types or categories of knowledge needed to teach well, and about how experienced teachers use and integrate this knowledge while teaching. More specifically, teachers' craft knowledge provides information about the way research-based knowledge and teaching practice are related and combined.

Teachers' Craft knowledge: Nature and Content

The term craft knowledge refers to the accumulated wisdom and know-how teachers construct through experience, and which is the basis for dealing with everyday teaching situations. Grimmer and MacKinnon (1992) labeled this type of knowledge as a form of professional expertise and, in line with Schön (1983), found it to be embedded in reflection-in-action. Reflection-in-action plays a central role in professional performance and its development. It refers to a mental process in which practitioners combine elements of their own knowledge in order to deal with uncertain, unique, or complex situations. In teaching, such situations are ongoing and require an immediate response. This is also an important reason for the difficulties beginning teachers report when they try to act upon theories they encounter in teacher education. Teaching situations are complex and multifaceted. Dealing with such situations requires multiple kinds of knowledge to be brought together in an integrated way. However, such situations require split second responses. Integration of knowledge in such a short period of time requires routinization that beginning teachers do not have. This explains why beginning teachers can analyze such situations afterward (i.e., reflection-on-action), but find it difficult to do so while teaching (i.e., reflection-in-action, based on craft knowledge). Although student teachers acquire knowledge in teacher education, using that knowledge in action is an old problem in learning to teach.

Teacher education programs often have separate courses about various knowledge bases, such as subject matter or child psychology; however, the task of teaching requires that these knowledge bases, or categories of knowledge, be integrated and simultaneously accessible. Observing how experienced teachers behave, sitting in the back of the classroom, does not automatically help student teachers develop a deeper understanding of how the various knowledge bases are integrated in teaching.

Figure 1 Relationship between teachers' craft knowledge, and research-generated knowledge and teaching practice.

Furthermore, simply copying the behavior of experienced teachers will most probably result in conservatism. An important use of research on teachers' practical knowledge is that it can provide student teachers "with a realistically complex picture of the cognitive aspects of teaching" (Clark and Lampert, 1986) that goes beyond the "how" of teaching and provides insight into the "why" underlying teaching.

An essential feature of teachers' craft knowledge is that it involves research-generated knowledge and specific knowledge about teachers' own teaching practice, and, most interesting, knowledge of how these two are related. Grimmer and MacKinnon (1992) stated that teachers' knowledge is derived "...from a considered response to experience in the practice setting, and, though related to knowledge that can be taught in the lecture hall, it is formed over time in the minds of teachers through reflection" (p. 387).

Figure 1 shows the general view on this issue: teachers' craft knowledge provides information about how experienced teachers relate research-generated knowledge to their teaching practice, and vice versa. The arrow in **Figure 1** represents this relationship.

Teacher education programs were criticized in the past for leaving a gap between theory (i.e., research-generated knowledge) and practice, because they were not able to link the two. Teacher education programs consisted of two parts: an institutional part concerned with research-generated knowledge, and a student practice part. Attempts to link the two were superficial, and mostly the student teachers' responsibility. Experienced teachers' craft knowledge provides information about just that relationship, and is valuable as such. What is known about what teachers know is described through an exploration of the nature and content of teachers' craft knowledge in the next two subsections.

Nature

In the literature on teachers' knowledge, a host of names are used: craft knowledge, case knowledge, situated

knowledge, (personal) practical knowledge, and tacit knowledge, to name but a few. As Fenstermacher (1994) remarked, these names do not necessarily refer to different types of knowledge, but to the fact that the contexts in which they are used differ. A great deal of the variety in conceptualizations of teachers' craft knowledge can be explained when underlying assumptions about the nature of this type of knowledge are identified. Several characteristics of teachers' craft knowledge can be identified that have been emphasized in studies of this concept:

1. it is personal, which means that each teacher's knowledge is to some extent unique;
2. it is contextual, meaning that it is defined in, and adapted to, the classroom situation;
3. it is based on (reflection on) experience, indicating that it originates in, and develops through, experiences in practice;
4. it underlies teaching practice;
5. it is mainly tacit, indicating that many teachers are not used to articulating their knowledge;
6. it is related to teaching practice, on the one hand, and to research-generated knowledge, on the other; and
7. it is content related, meaning that it is connected with the subject taught.

The last aspect, the content-relatedness of teachers' craft knowledge, has a number of serious implications for the discussion about the inclusion of this type of knowledge in the teacher education knowledge base. This becomes even more evident when what is known about the content of teachers' craft knowledge is taken into account.

Content

In many studies of teachers' craft knowledge, researchers have focused on its content, generating insights into categories which make up teachers' knowledge and beliefs. Shulman (1987) was one of the first to investigate the kinds of knowledge that teachers possess and that underlie their actions; he developed a number of domains and categories of teacher knowledge, which other researchers have used, expanded, and refined. These categories are:

- content knowledge;
- general pedagogical knowledge, with special reference to those broad principles and strategies of classroom management and organization that appear to transcend subject matter;
- curriculum knowledge, with a particular emphasis on the materials and programs that serve as tools of the trade for teachers;
- pedagogical content knowledge, that special amalgam of content and pedagogy that is uniquely the province of teachers, their own special form of professional understanding;

- knowledge of learners and their characteristics;
- knowledge of educational contexts, ranging from the workings of the group or classroom, the governance and financing of school districts, to the character of communities and cultures; and
- knowledge of educational ends, purposes, and values, and their philosophical and historical grounds (Shulman, 1987: 8).

Studies in this area of research are usually conducted in a specific subject-matter context, such as English, social studies, mathematics, and science. Particularly in secondary science education, the concept of pedagogical content knowledge remains topical, and seems to refer mostly to the type of knowledge that is directly related to teachers' actual practice when teaching their subject. What is striking in most of these studies is that the content of teachers' craft knowledge is seen as an integration of several categories of knowledge. This is in line with Grimmer and MacKinnon's (1992) definition of craft knowledge, in which it is clear that this kind of knowledge encompasses several elements of the kinds of knowledge distinguished by Shulman and his followers. Craft knowledge in teaching, they stated, is essentially teachers' accumulated wisdom, derived from their understandings of the many dilemmas inherent in teaching. It represents intelligent and sensible know-how in the action setting. It is "...a particular form of morally appropriate and sensible know-how that is constructed by teachers...in the context of their lived experiences and work around issues of content-related and learner-focused pedagogy" (p. 396).

Part of teachers' craft knowledge, therefore, is knowledge about the various knowledge areas. All teachers have knowledge about learners, the content, the curriculum, etc. The differences found in the various studies concern what teachers know about these areas and how they integrate their knowledge about these different areas. Many researchers describe these differences in a classification of types of knowledge, in which teachers' craft knowledge is described along similar categories (often based on the categories that Shulman developed and that were described above). The content of these categories and the way the categories are related is quite uniform within the types distinguished, but shows substantial differences across the types. To illustrate such differences, **Table 1** shows descriptions of three teachers' craft knowledge about a category described as student learning and understanding. The descriptions are from a qualitative study on experienced teachers' craft knowledge about teaching reading comprehension to 16- to 18-year-old students (Meijer, 1999). The right column contains citations of the three teachers that illustrate the differences found. Other qualitative studies show similar patterns in teachers' craft knowledge (or practical knowledge, pedagogical content knowledge, etc.).

In sum, the results of studies on teachers' craft knowledge show not only common features in this type of knowledge, but also substantive differences, reflecting that this type of knowledge is idiosyncratic by nature. This variety and idiosyncrasy may pose problems as well as challenges in the search for craft knowledge underlying teaching, particularly when the aim is to incorporate this type of knowledge in teacher education. There is no one straightforward way to do so when the idiosyncratic nature of teachers' craft knowledge is taken into account. The next section contains some strategies to involve this type of knowledge in the teacher education knowledge base that are described in the literature.

How Can Teachers' Craft Knowledge be Involved in the Teacher Education Knowledge Base? – Eliciting Teachers' Knowing-In-Action

Leinhardt (1990) described craft knowledge as encompassing the wealth of teaching information that very skilled practitioners have about their own practice. She argued that this type of knowledge needs to be merged with theory in order to design a complete, valid assessment of teachers. Also beyond the field of teacher assessment, the need to combine the craft knowledge of (expert) teachers with research-based theories is felt, especially in the field of teacher education. The question is how such knowledge can be accessed and processed in order to aid student teachers' professional development. In a recent attempt to capture what beginning teachers should learn, Hammerness *et al.* (2005) stated first that "wisdom can't be told" (p. 371). Expert teachers cannot simply tell what they know in a way that is ready to be used by beginning teachers, mainly because of the tacit nature of this type of knowledge. Second, Hammerness *et al.* described the issue of knowing but failing to have this knowledge guide one's actions. Teachers do not automatically draw on knowledge acquired during, for example, coursework to help them solve problems in practice. Taking these two issues into account, the focus needs to be not on the knowledge that teachers have about their teaching, but on the knowledge that is embedded in their teaching, and that directly guides their actions. This is a crucial assumption behind research on teachers' craft knowledge: teachers' knowing is expressed in their teaching. Schön (1983) argued that to understand the practice of professionals, we need to understand their knowing-in-action. This is comparable to Leinhardt's (1988) idea that teachers' knowledge should also be examined in use in order to enable understanding of the complex process of teaching. Leinhardt stated that teachers' cognitions and actions should be investigated while they are teaching, because,

Table 1 Descriptions of three teachers' craft knowledge about the category "Student learning and understanding"

Teacher	Description of category "Student learning and understanding"	Some citations from semi-structured interviews and stimulated recall interviews
Subject-oriented teacher (Craft knowledge type A)	The knowledge and skills that are needed in reading comprehension are present in students in rudimentary form. However, they do not see what is important in a text, so they definitely need the teacher to help them. Reading comprehension is very difficult for students; some will never learn it because they do not see the main idea in texts, they just see "words, words, words" and they lack vocabulary. Furthermore, students have difficulties reading texts that do not fit in with their environment. Not all students have the same working style: some use the teacher's own method (as they should), but others, for reasons of their own, have their own way of working. During the lesson, the teacher was often wrong about what the students did or did not understand. Quite often he expressed surprise if students did not show understanding where he had expected it.	<p>...if you let them work for themselves, they often don't understand at all what it [i.e., the text] is about...they pick up a few things, but they don't see what's important and what's not, so they just pick up what amuses them.</p> <p>...I was thinking about the problems you have to deal with as a teacher. You can choose the wrong subject, you can have children in the classroom who don't do their best, are neither motivated nor interested, or children who are too stupid to understand a certain text, or children who are motivated, but lack vocabulary. How can you deal with all this? I thought, well, that's disappointing, that one student thinks it [i.e., the text] is about football, and another thinks something else. But no one was aware of what it was really about, no one, no one understood anything at this moment... [and at a later moment:] They still didn't understand what it was about... and it bothered me, I thought, I don't want to hear the same wrong answers again.</p>
Student-oriented teacher (Craft knowledge type B)	Students barely master the necessary skills for reading comprehension: their reading level is low. Able students are intelligent and gifted, whereas students who have difficulties with reading comprehension are always asking the wrong questions and read incorrectly. The teacher thinks it is lack of talent that causes this. On the other hand, he also referred to the students' environment when assessing their abilities.	<p>[Why a student has difficulties understanding texts]...I don't know, different science, I can't tell, I don't understand. It's like a fiddler, how come not everyone is able to play the violin in the same way?</p> <p>In general, the students' reading level is low. But that's not their fault...one does notice that there is a cultural decrease, I think that societal influences are important here...And that pushes young children not to take an interest in non-material matters...And it leads to the fact that they are not capable of concentrating long, and because of that are not able to read for long periods of time.</p>
Student-learning-oriented teacher (Craft knowledge type C)	Students at this age and level have a reasonable vocabulary and read fairly well, but lack general knowledge. If the level of difficulty of the texts is increased gradually and students use (some of) the strategies the teacher gives them, every student can learn to comprehend texts. However, students who are poor in reading comprehension tend to be chaotic in their approach to a text, which interferes with their acquisition of reading strategies. During the lesson, this teacher appeared to be focused on student learning and understanding, and tried to anticipate problems they might run into.	<p>They are chaotic. This becomes manifest, for example, in a summary that isn't a summary: Too many words, difficulty in capturing the essence in a text, difficulty in finding key sentences. You might say that, for such a student, it's very difficult to separate essentials and side-issues.</p> <p>When a student is reading out loud like this, I just read along with him...and here I pay attention to: does he read well, does he read as if he understands what he is reading? Here, at this moment, I knew when I was preparing this lesson that this would cause them problems, this 'pluralism in linguistic usage'...so here I thought, yes, yes, I knew this was going to happen.</p> <p>At that moment, when they were working for themselves, I had the opportunity to read the text for myself again. And I tried to read it through their eyes, and tried to picture what problems they would run into.</p>

at that moment, knowing and acting are inseparable. Brown *et al.* (1989) argued that all knowledge is produced in activities and situations. Knowledge is, therefore, situated in actions or, as Leinhardt defined it, it is "embedded in the artifacts of a context" (Leinhardt, 1988: 148). This implies, according to Brown *et al.*, that knowledge should be investigated in the situation in which it is being used. They stated that the examination of knowledge can be inappropriate, or even invalid, if this knowledge is stripped from the way it is used.

To involve teachers' craft knowledge needs in teacher education might imply two strategies. First, student teachers can gain access to experienced teachers' craft knowledge that has been examined by others and, for example, written down in (multiple) case studies or typologies, such as illustrated in **Table 1**. Second, student teachers might investigate experienced teachers' craft knowledge themselves. Some examples of how experienced teachers' craft knowledge might be involved in teacher education and the conditions that have to be met in order to do so are described below.

Cases

The findings of several studies indicate that detailed descriptions of the contents of teachers' craft knowledge are relevant to student teachers. Researchers and teacher educators have suggested ways of incorporating such descriptions, often as cases, narratives, or stories, in teacher education. Related to this, Hammerness *et al.* (2005) describe "analysis of teaching" as a crucial factor in teacher education. Cases not only concern written cases, but also include videos of teaching practices. Databases with videotapes of classroom teaching exist at many teacher education institutes, for example, at the University of Michigan, at the Carnegie Foundation's Knowledge Media Lab, and at the New Teacher Center at the University of California, Santa Cruz, and there is a national database of teaching practice in the Netherlands. A related initiative is a website, which has a digital exhibition of the Teachers College Record highlighting websites on which multimedia are used to document teaching and learning in classrooms in California, Philadelphia, and New York City, from elementary and high schools, and in math, language arts/English, and social studies. All these databases include interviews with the teachers, who comment on their videos by giving arguments for choices they made. Finally, links to relevant theories are provided. In this way, student teachers can easily access many teaching practices and are provided with information about the knowledge behind what is shown in the teaching fragments and how this relates to relevant theories (i.e., research-generated knowledge).

Stimulated Recall

Research on teachers' craft knowledge has also resulted in a range of creative methods to elicit this type of knowledge, such as various interview techniques, mind-mapping assignments, and responses to videos. One instrument of particular interest is the stimulated recall interview, in which, teachers explicate what they were thinking in response to a videotape of a lesson they have just given. The information retrieved in this way closely relates to Schön's idea of knowing-in-action, and to Leinhardt's plea for investigating teacher knowledge in use. The instrument has its origin in studies by Bloom (1953) and has been used by several researchers since then.

Using this instrument allows student teachers to analyze the craft knowledge of an experienced teacher. The stimulated recall interview is in fact a substitute for the thinking-aloud technique. However interesting a thinking-aloud technique would be in capturing a teachers' thinking while he or she is teaching, this technique is clearly not suitable as it would interfere with lessons. In a stimulated recall interview, a videotape of a lesson a teacher has just given is used to aid the teacher's recall of interactive thoughts during the lesson and to stimulate him or her to relive the lesson. The stimulated recall interview can be used to make much of teachers' tacit thinking explicit and to elicit cognitions underlying their observable actions. Such cognitions are characterized by the following:

1. split-second thoughts;
2. tied to the specific context (i.e., the lesson);
3. closely connected to teachers' knowledge and beliefs, on the one hand, and
4. closely connected to classroom practice, on the other; and
5. integrative in nature.

These characteristics might be problematic when the aim is to generate objective statements about the cognitions teachers in general have while teaching, but they make such cognitions all the more interesting for student teachers who are in the process of trying to understand what is going on in the classroom.

There are several ways to use the stimulated recall technique in teacher education. For example, Ethell and McMeniman (2000) described a way in which the technique can be systematically planned in a teacher education context. They developed the intervention "making explicit and gaining access to the thinking underlying expert teaching," which involved a series of workshops with student teachers structured in four steps:

- Step 1: observation and inference.
- Step 2: making explicit personal theories.
- Step 3: expert teacher's reflection on action (i.e., responses in the stimulated recall interview).
- Step 4: contrasting novice and expert reflections.

Meijer *et al.* (2002) also described the stimulated recall interview as a tool for student teachers to elicit their experienced mentor teachers' craft knowledge. They described the value of systematic examination of experienced teachers' practical knowledge by student teachers as, among other things, the window it provides on the thoughts behind teachers' observable teaching. In addition, it gives opportunities to relate these underlying thoughts to the theoretical and more abstract notions student teachers are confronted with in teacher education.

Conclusion

Examining experienced teachers' craft knowledge provides student teachers with opportunities to better understand other teachers' teaching and their own teaching by (1) experiencing the relationship between a teacher's craft knowledge and his or her teaching, (2) learning about the relationship between other teachers' craft knowledge and their own (developing) craft knowledge, and (3) exploring the relationship between (experienced) teachers' craft knowledge and more theoretical notions they learn about in teacher education. This understanding can help student teachers develop their own teaching in a more conscious way, as they can underpin the choices they make in their teaching more thoughtfully.

In sum, the conditions for incorporating teachers' craft knowledge in the teacher education knowledge base in a sensible way are the following:

1. the knowledge has to pertain to teachers' knowing-in-action;
2. this knowledge needs to be related to the student teachers' own (developing) craft knowledge;
3. it also needs to be related to research-generated knowledge and theories; and
4. it then needs to be related to student teachers' future actions and practical arguments.

Final Remarks

Teachers' craft knowledge is one of the sources of the teacher education knowledge base. It can provide valuable insights into the complexities of teaching and contribute to the professional development of beginning teachers, as we have described in this article. It is necessary, however, to take into account the principle of the conservatism of practice as described by, for example, Loewenberg Ball and Cohen (1999) and the process described by Zeichner and Tabachnick (1981), who found that liberal and progressive insights student teachers encountered in teacher education were washed out by daily school experiences

and conversations with their experienced colleagues. One of the most essential components of the process of learning to teach is learning how to learn in and from practice. Linking theory and practice is vital. Student teachers need to learn various strategies for linking theory and practice. Experienced teachers' craft knowledge is just one valuable source in this process.

Moral Values in Teacher Education

W Veugelers, University for Humanistics, Utrecht, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Values are embedded in the curriculum, the school culture, and the behavior of the teacher. The question is not whether teachers display values in education, but rather which values they display, and how the teachers work with values in their teaching. Values are embedded in educational practices, in curriculum materials, and in discourses in school. Values are the ideological flavor of teaching. Values can be taught explicitly, but values are always interwoven in regular teaching practices. Sometimes these hidden values become conscious when teachers reflect on their educational practice. But generally, the values remain hidden and do their work and influence the identity development of students.

Moral values are values that express ideas about the good life. There is constant debate about which values constitute the good life. Aristotle introduced the idea in his *Nicomachean ethics*, and there is continuous debate in philosophy and social science about which values are important, and about what exactly is meant by a certain value. Based on their ideas about living together in society, Rawls and Kohlberg advocated the value of justice. Gilligan and Noddings criticized the cognitive emphasis in justice, and stressed the affective side of living together and argued for the value of care. From a multicultural perspective, Banks espoused the value of diversity – the appreciation of difference. Moral values are quite abstract but become meaningful in concrete practices and narratives. Stressing the same abstract moral value can still result in different concrete interpretations of the value and in distinct practices. Moral values should therefore be studied in their context.

The development of people's values is conceptualized in different ways in both academic work and in practice, and is embedded in more extended concepts about human development. For example, the development of values is part of personal and social development, moral development, identity development, and citizenship development. What these concepts have in common is that the focus is on the development of the individual. Values are expressed in attitudes that become visible in opinions and concrete behavior. Attitudes based on moral values refer to being in society, being with others, and the reflective view on one's own identity.

Adding value to development implies that human development is seen not as a natural biological process, but as a process of giving meaning to the world. It is a process of growing into cultural practices and positioning oneself by articulating what is valuable; it is a personal reconstruction of cultural practices and narratives. It is making sense of your life.

Different Concepts of Moral Development

People differ on the pedagogical and moral goals of education, on how educational institutes can work with values. In educational policy, both in research and in practice, there are different ideas about the desired outcomes of education in the personal, social, and moral domains; about how to work with values in education; and about the role of schools. As in the character education movement, the focus can be on teaching the right values, or as in the Kohlberg tradition of moral development, the focus can be on developing skills to reflect on values and behavior. Youngsters in the Kohlberg tradition are supported in developing cognitive skills to articulate their own values. In this tradition, analyzing and communicating values are important tools for moral judgment. Despite Kohlberg's emphasis on the value of justice and on the educational concept of just community schools, Kohlberg has been criticized by the character education movement for stimulating value relativism. According to these critics, Kohlberg and his followers were not clear about the moral goals they wanted to attain.

In turn, the character education movement stressed the importance of good behavior and virtues. This was criticized by the Kohlbergians because the character education movement disregards the critical autonomy that people as human beings can have in making moral judgments. A second criticism was that they saw moral values not as situated but as fixed values. For the character education movement, living the good values is more important than reflective and communicative competences in the moral domain. There was strong polarization in the early 1990s between the proponents of a value approach and a more developmental approach. Nowadays, many scholars are aware of the importance of both values and competences to reflect and communicate, and they attempt to integrate both values and competences (Solomon *et al.*, 2001; Veugelers and Vedder, 2003). Values are not seen as purely abstract and fixed, but as situated, and analytical and communicative skills are necessary in order to work reflectively. As an educator, you may express your values because displaying the values you find important is unavoidable. However, what is important is the room you leave for others to articulate their own values.

Moral development is linked with many aspects of the individual, such as the social being and citizenship. Moral development can be seen as more fundamental, as driving the concrete attitudes and behavior. Moral values tend to

be rather abstract, but they become concrete in narratives and practices. Because moral values are so abstract and fundamental, they are difficult to teach and to change. Given the fact that moral values are important for human development, education cannot fail to pay attention to them. Even if education does not wish to give explicit attention to moral values, the values do their work through the hidden curriculum. In, for example, the work of Durkheim, Bourdieu, and Willis, the sociology of education has shown that values always do their work. If a teacher opts to keep the values hidden in educational practice, the teacher is, in fact, also making a moral choice. When values remain hidden and are not the subject of reflection, the emphasis is more on adaptation than on a critical moral judgment, and students are not then challenged toward a more self-regulated personal moral development.

Moral Education in Contemporary Education

The task of moral education has, in recent years, been reinvented in many countries. Currently, the most used concept is that of citizenship development. The concept of citizenship has moved beyond the political level to the social, the interpersonal level, and even the intrapersonal level – it is about how you live your life. Citizenship development is linked to identity development. Processes of nation building and citizens' identification with civil society and political structures are arguments in favor of citizenship education on the political level. Social cohesion and public behavior are arguments on the social level. Self-regulation on the interpersonal and intrapersonal level is a necessary condition for both the social and the political levels. The political, the social, the interpersonal, and the intrapersonal levels are linked by values, narratives, competences, and practices. Education could choose to say that we only work on the political level, and that we leave the social and the interpersonal level to the private world of the students, but this would then mean that the linkage of the four levels remains unreflective. The political level then continues to influence the social and interpersonal levels, but only in a hidden way.

Citizenship development can aim at different social, cultural, and political practices: at adapting to society by emphasizing obedience and social behavior in an unreflective way; on a more individualistic type of citizenship that stresses autonomy and disregards social concern; or on a more critical-democratic type of citizenship that considers both autonomy and social concern to be important (Veugelers, 2007). The idea of educating for democracy has been strongly advocated by Dewey. He spoke of a democratic way of life, democracy as lifestyle. Citizenship development is about knowledge, skills, and attitudes

(values), and the combination of these elements is often referred to as competences. Knowledge and skills are important. For a democratic society to flourish, it is necessary to know about democracy, to have the competences to act democratically. However, what is crucial are the values, the will to behave democratically. Willing to live a democratic way of life is seen as the pedagogical aim of contemporary citizenship education in democratic societies (Banks, 2004). A link between citizenship development and moral development is necessary to give citizenship a moral foundation, in order to make the linkage of the political, the social, and the interpersonal meaningful.

Values are interwoven in all aspects of teaching: in the curriculum, in the school culture, and as moral examples in teachers' behavior. Working with values is an essential part of teaching. Educating students to become teachers requires the teachers to learn how values are embedded in education; how they themselves, as reflective practitioners, can consciously create moral-based practices in education; and what different philosophical, pedagogical, and political theories and religious and cultural traditions say about moral development and the role of education.

The Moral in Teacher Education

Many scholars mention the important role teachers play in moral education, and there is a growing body of work that focuses on the education and professional development of teachers themselves. There are publications about the moral task of education that extends the research to the field of teacher education (see, e.g., Buzzelli and Johnston, 2002), and there is also research on teacher education that now includes a moral perspective (e.g., Russell and Loughran, 2007). In their book *The Moral Dimensions of Teaching*, Buzzelli and Johnston (2002, p. 132) present a moral perspective on teacher education. It includes redefining the teacher–student relationship, examining the personal beliefs and philosophies of students, re-contextualizing course methods and content knowledge, and ensuring authentic field experience and student activities. For them “morality constitutes that set of a person's beliefs and understanding which are evaluative in nature: that is, which distinguish, whether consciously or unconsciously, between what is right or wrong, good and bad.” (Buzzelli and Johnston, 2002, p. 3). Redefining the teacher–student perspective means sharing power and authority and becoming co-learners and inquirers with students. It is moral reflection because it entails the careful observation of, thinking about, and criticism of how we build relationships with our students. This requires moral courage and moral imagination.

Students should, according to Buzzelli and Johnston, be invited into an apprenticeship in these moral sensibilities

and to examine, test, and reformulate their beliefs and personal philosophies. When it comes to methods, students should learn how methods and content influence the growth and development of individuals in a moral sense, in what they learn about themselves and their relationship with the world, and in the differences between learners in this process of meaning making. When students enter classrooms during their field experience or their teaching practice, they become moral agents in the lives of the children in those classrooms. They need to develop an awareness of the moral significance and moral meanings of policies, practices, routines, and of the rituals of the classroom and the school.

More details about the moral dimension in teacher education can be found in the work of Johnson and Reiman (2007). In their research with students in teacher education they developed a matrix of indicators for the moral/ethical domain by using a neo-Kohlbergian framework. The post-conventional schema includes the following indicators:

- realizes the curriculum can be viewed from multiple perspectives;
- considers the benefits and consequences of instructional choices;
- takes into account a variety of learning styles when planning activities;
- holds a humanistic–democratic view of learner discipline;
- views rules as being designed to safeguard certain rights;
- considers rules as alterable and relative;
- is sensitive to students' rights;
- makes decisions based on the context of situations; and
- self-concept is organized around moral principles.

There is no strong empirical base for moral education in teacher education. Most of the work that has been conducted has focused on pedagogical goals and on formulating the consequences of research for educating prospective teachers in teacher education. We think it is necessary to develop a multiperspective view on moral values in teacher education. It can help make both the theory and the practice more suitable to support students in their transition toward becoming teachers.

Different Perspectives on Moral Values in Teacher Education

This section presents an overview of research and practices of different perspectives on working with moral values in teacher education. We speak of perspectives because the various approaches differ in philosophical background, pedagogical goals, and in suggested methodology. It is important to articulate different ways of thinking

about moral education, not to decide what is really moral but to stimulate dialogs about possible pedagogical goals and practices. The distinction made between the different perspectives is inspired by the work on teacher education by Liston and Zeichner, Aloni's philosophical foundations of humanistic education, and on our own work on different ways of teaching values.

The five perspectives are presented in a sequence that can be seen as different stages in the educating of teachers. Each stage adds a new element to its predecessor. The various perspectives are embedded in different ideas about the teaching and learning of moral values, the kind of citizenship society needs, and the very task of education. The perspectives articulate different educational practices that assume different types of methodology and goals of teachers, and therefore of teacher education. When presenting the five perspectives, we articulate what makes this approach unique.

We distinguish the following perspectives:

- value transfer;
- reflective practitioner;
- moral sensitivity;
- participation and dialog; and
- moral politics

In describing and analyzing these perspectives we refer to the way these perspectives work with values, skills, praxis, and social action.

Value Transfer

This approach focuses on the transfer of moral values in education. In this view, morality consists of virtues, of traits that support good behavior. As a teacher, being a good moral example and teaching students about good moral people are important methods in this approach. Student reflectivity is not really strengthened. The value transfer method is part of a pedagogical vision that has well-defined ideas about the good life and about important cultural traditions. The focus is more on getting youngsters involved in existing cultural practices rather than on challenging them to position themselves in an open, multicultural, and changing society. This approach can be situated in a national educational system that is concerned about its cultural heritage, or in a tradition that is based on a religious worldview that perceives its worldview to be more static than dynamic.

The emphasis in teacher education based on this perspective is on creating strong moral characters in student teachers, on learning about good people in the national and one's own cultural history, on telling stories in which the good moral life of concrete historical or contemporary examples are expressed, and on methods for correcting antisocial and antimoral behavior (Sockett, 1993). The main focus is behavior, not reflection or action.

Reflective Practitioner

According to many sociological analyses, modern society needs citizens who are flexible and reflective. Many professions require professionalism based on what Schön referred to as reflection-in-action. In education, this calls for a practice in which youngsters reflect on their behavior, take responsibility for their actions, and try out new behavior in an experimental and reflective manner. The reflective paradigm has had considerable influence on the thinking about teacher education. Prospective teachers in reflection-oriented teacher education practice are continuously challenged to question their beliefs and their teaching behavior. The emphasis in the reflective-practitioner approach to teacher education is on reflection on one's own professional behavior (Korthagen, 2004). The assumption is that one's personal beliefs influence one's pedagogical-didactic behavior.

Teachers should learn to consciously handle their methods and actions. Trying to make teachers and prospective teachers aware of their hidden beliefs, to further develop their pedagogical identity, and to expand their competences are part of this paradigm. Moral values can be part of the reflection process. Research shows that it is not easy to reach the moral level in reflection-oriented teacher education (Lunenberg *et al.*, 2006).

Moral Sensitivity

Moral values are abstract and are normative because they say something about the good life, about good and bad. Moral values are embedded in all narratives and practices, but how does one detect them? Following the reflection perspective, we can ask questions about why one chooses a certain alternative. We can do it critically and ask on which values the statement or behavior is based; we can ask what drives the action. In dialogs, we can challenge students to explain why they chose these ideas and practices. For moral reasoning, you must not only know cognitively that moral values are involved, but you must also have the sensitivity to feel and be aware of when moral values are at stake. The third perspective is therefore moral sensitivity (Campbell, 2003; Tirri, 1999). Knowing about moral values and moral dilemmas is not enough. Teachers should have the awareness to detect when moral values are involved.

Teachers should develop the sensitivity to see when moral values are at stake and how meaning is given to them. Not only is knowledge about teachers' behavior, as in the reflective-practitioner perspective, necessary, but what is even more important is an insight into the identity development of students; and this implies, seeing how students position themselves, give meaning to their experiences and the world around them, and how they work with the values involved. Teachers should incorporate this moral sensitivity in the art of their teaching.

Analyzing processes of meaning making by students and teachers in many situations and comparing different constructions for the same situation can stimulate the development of moral sensitivity. Students should learn to speak in moral language. Engaging theories and practices that focus on moral dilemmas and on moral concerns of participants can enhance the development of moral sensitivity.

Participation and Dialog

More culturally oriented sociological analyses of society argue that youngsters need to develop dialogic competences and an active action-oriented participation in society. Education should therefore pay more attention to dialogical learning, learning by experience, and activity-oriented learning. Dewey's pragmatism and Vygotsky's cultural activity theory have influenced the development of this perspective. From a Deweyan perspective, participation is not enough; experiences should lead to the transformation of knowledge and active processes of knowledge construction and competence development. A dialogic approach, based on the discourse theory of Habermas, has always been an important element in Kohlberg-oriented moral education (Oser, 1994). Students should be involved in communication actions that challenge their ideas and deconstruct the values interwoven in them – this can help them reconstruct their own personal beliefs.

Students in teacher education should learn to use these dialogic and action-oriented activities in a learning environment that supports this kind of professional development. Gaining practical experience is a crucial element in many teacher education programs (Ten Dam and Blom, 2006). Action research and networking should be added to this learning. A perspective aimed at participation and dialog, as mentioned above, can create dialogic learning and change. Teaching, for Dewey, is a moral endeavor because its constituent acts have moral meanings in their own right and genuine intellectual work always implies moral development (Hansen, 2003). Hansen shows how moral assumptions are manifest in rituals, such as classroom beginnings, in teachers' style, and in the curriculum. Hansen argues for more attention toward moral knowledge and moral judgment in education and in teacher education. Participation, action, and reflection should include concern about moral values.

Moral Politics

We refer to the fifth perspective as moral politics. Morality, in this view, is seen as embedded in a political context, and the aim of education is formulated as political action for social change. Teacher education and social action are linked in this perspective. Beyer (1996) speaks of democratic education, Oakes and Rogers (2006) use the concepts of teaching for changing the world, and teaching for social justice. Empowerment of people and working on structural

changes that enhance humanity and change at grassroots level are considered to be pedagogical goals. The work of Dewey and Freire, and critical theory and critical pedagogy have influenced the development of this perspective.

Teacher education in this perspective is linked with social activist groups in and outside schools, and students learn by trying to bring about change in schools and in the community. In their teaching practice, prospective teachers attempt to create democratic classrooms, to include minorities' perspectives in the curriculum, and organize participatory social inquiry in and outside the school. Teaching is seen as social and moral engagement and as creating a better and more just world. Reflection and action are linked and aimed at realizing these moral goals. Teacher educators are clear in their critical emancipatory view, and their particular choice for schools that serve disadvantaged children. They hope prospective teachers opt to enter this kind of education.

We have placed the five perspectives in **Table 1** that shows the differences between the different perspectives.

We can argue that all the five perspectives have their particular strengths depending on the goals they have in education and the corresponding teacher education method. If one wants to focus in education on character building and on making clear the values one finds important, then the value-transfer perspective is the most useful one. When education is seen as very flexible in its content, structure, and teaching methods, and is one in which teachers are autonomous and considered to be professionals, then a more reflective perspective is necessary. If this kind of education considers the development of morality as crucial and important, then the moral-sensitivity perspective is desired. If learning is seen as transforming practices and learning by doing and dialog, then the participation and dialog perspective is needed. And if this transforming practice is seen as part of a struggle for social justice and democracy, then the moral-politics perspective is useful. We are aware of the fact that concrete practices often show a unique combination of elements of these perspectives.

It is easy to say that teacher education should pay more attention to moral values. As we have shown in this article, moral values can be incorporated in numerous different ways in education in general, and in teacher education

in particular. Teacher educators can choose how they include moral values in their teaching education program.

Pedagogical Content Knowledge

J H Van Driel, ICLON–Leiden University Graduate School of Teaching, Leiden, The Netherlands

Introduction

The term pedagogical content knowledge (PCK) was introduced by Lee Shulman in his presidential address to the American Educational Research Association (Shulman, 1986). Shulman argued that, for a long time, research on teaching and teacher education had undeservedly ignored questions dealing with the content of the lessons taught. Shulman presented a strong case for PCK as a specific form of knowledge for teaching which refers to the transformation of subject-matter knowledge in the context of facilitating student understanding. Teachers need this type of knowledge to structure the content of their lessons, to choose or develop specific representations or analogies, to understand and anticipate particular preconceptions or learning difficulties of their students, and so on. Shulman asserted that teachers had a unique way of looking at practice and his intrigue with the manner in which they did so encouraged an examination of teachers' pedagogical thinking in ways that, it was anticipated, would reveal what teachers must know to best teach their content to their students.

Shulman's introduction of PCK, that is, his call for attention to the knowledge that teachers use and need to teach specific content, connects with a well-established tradition in the European literature on teaching and teacher education. The German word *Fachdidaktik* is often used to refer to this tradition, which is more philosophical than empirical. *Fachdidaktik* may be translated as the pedagogy of subject matter.

In preparation programs for secondary teachers within this European tradition, a relatively large amount of time is usually reserved for coursework on *Fachdidaktik*. In this context, preservice teachers are required to address questions concerning the significance of the content for their students' future, the structure and the exemplary value of the content, and the ways in which the content may be represented to make it interesting and comprehensible for students. However, the *Fachdidaktik* tradition has not provided detailed insights into the ways in which teachers transform subject-matter knowledge, and how they relate their transformations to student understanding during classroom communication in order to overcome student misconceptions, thus contributing to meaningful learning. Such issues lie at the heart of the concept of PCK, which explains why empirical research on PCK adds a new perspective to the *Fachdidaktik* tradition.

In the past 20 years, a plethora of publications studying and integrating PCK into teacher education have been published in the research literature. Publications have addressed various subject areas, including English, mathematics, science, physical education, and social studies (Grossman *et al.*, 2005). Although researchers have thus begun to push to find ways of examining what teachers know, still few concrete examples of PCK in subject areas have emerged. Hence, the construct itself has not yet positively impacted the valuing of teachers' professional knowledge and practice.

Van Driel *et al.* (1998) highlighted this concern when they noted that although the research community embraced the notion of PCK, few topic-specific examples existed in the literature to illuminate this important aspect of teachers' professional knowledge. Suggestions to account for this paucity of concrete examples include the tacit nature of teachers' knowledge and the absence of a shared language or structure to adequately discuss that knowledge. Related to this is the problem that teachers are often unaware of the knowledge they possess, which is often contextualized and associated with particular students, events, and classrooms.

In this article, we begin with a brief review of the ways in which PCK has been conceptualized in the research literature, followed by an overview of research that has focused on the way PCK develops, and the factors influencing this development. Concluding this article, we discuss research on PCK in relation to the practice of teaching and teacher education.

Conceptualizing Pedagogical Content Knowledge

One of the preeminent issues in the research literature is the ongoing discussion on the nature of PCK: What is it, and how can it be represented? The key elements in Shulman's original conception of PCK include knowledge of representations of subject matter, on the one hand, and understanding of specific learning difficulties and student conceptions, on the other. Shulman suggested that the more representations and strategies teachers have at their disposal within a certain subject domain, and the better they understand their students' learning processes in the same domain, the more effectively can they teach in that domain.

In a later article, Shulman (1987) included PCK in what he called “the knowledge base for teaching.” This knowledge base consisted of seven categories, three of which were content related (i.e., content knowledge, PCK, and curriculum knowledge). The other four categories referred to general pedagogy, learners and their characteristics, educational contexts, and educational purposes. In the subsequent years, many scholars have used Shulman’s knowledge base for teaching as a starting point, and have conceptualized PCK in other ways. Although almost all scholars adopted the two key elements of PCK mentioned above (i.e., knowledge of comprehensible representations of subject matter and understanding of content-related learning difficulties), they have extended the concept by including other categories of knowledge in PCK from Shulman’s knowledge base for teaching, such as knowledge of curriculum, or assessment.

In an often-cited paper, Magnusson *et al.* (1999) presented PCK as a separate domain of teacher knowledge which exists alongside other domains, such as pedagogical knowledge and beliefs. In their discussion of the nature of PCK, they presented a model in which PCK for science teaching consists of five aspects or components: (1) orientations toward teaching science, (2) knowledge of science curricula, (3) knowledge of students’ understanding of science, (4) knowledge of assessment in science, and (5) knowledge of subject-specific and topic-specific strategies. Acknowledging that these components may interact in very complex ways, these authors claim that effective teachers need to develop expertise in all aspects of PCK, and with respect to all topics they teach. Orientations toward teaching science, in particular, have been identified as a critical component within this PCK model (Friedrichsen and Dana, 2005). Sources that shape teachers’ orientations toward teaching science include: prior work experiences, professional development choices, beliefs about students and about learning, as well as time constraints.

Several scholars have addressed problems associated with investigating PCK in terms of specific components or categories. This may lead to a segmented and simplistic representation of teachers’ knowledge. To acknowledge its constantly evolving nature, Cochran *et al.* (1993) preferred to speak of pedagogical content knowing (PCKg). Similarly, Mason (1999) emphasized the dynamic nature of PCK in research and teaching, respectively. Rather than representing PCK as a fixed or static body of knowledge, Mason perceived PCK as an ability to combine content knowledge of a discipline with the teaching of that discipline. Adding to this, Hashweh (2005) proposed to consider PCK as a collection or repertoire of pedagogical constructions, which teachers acquire when repeatedly teaching a certain topic.

Loughran and colleagues argued that researchers often fail to acknowledge the complex relationships and

interactions existing within a teacher’s personal professional knowledge base (Loughran *et al.*, 2001, 2004). Attempting to portray PCK in a way that is valid and useful from a teacher’s point of view, these authors constructed a series of resource folios for various (science) topics consisting of a content representation (CoRe) in combination with the so-called pedagogical and professional-experience repertoires (PaP-eRs). For example, a resource folio for the topic of force includes a CoRe and PaP-eRs about teaching and learning this topic. A CoRe is structured around questions related to some of the elements of Shulman’s knowledge base, in particular, knowledge of the main content ideas associated with a specific topic, teaching procedures and purposes, and knowledge about students’ thinking.

Each CoRe is connected to a collection of PaP-eRs, which illustrate aspects of PCK in action of the topic under consideration. PaP-eRs are short narratives based on teachers’ accounts of teaching a specific topic and are intended to make explicit teachers’ pedagogical reasoning, that is, the thinking and actions of a capable teacher in teaching a specific aspect of the content. PaP-eRs include a variety of narrative representations, for example: a dialog between two teachers exploring their approach to the teaching of particular content and student responses to it; a teacher’s annotated curriculum document, or a student’s perspective of a teaching/learning situation. The function of PaP-eRs is to elaborate and give insight into the various interacting elements that comprise a teacher’s PCK.

To conclude this section, it is clear that PCK has attracted considerable attention in the research literature, but there is no universally accepted conceptualization of PCK. The general fuzziness around the concept of PCK has meant that that which is searched for, and that which is uncovered is variable indeed. In fact, the literature on PCK reveals several dilemmas:

- Since various scholars have included different elements within their conceptualization, it is unclear whether PCK should be seen as knowledge which is very specific for each topic that teachers teach, or one should think in terms of general or subject-specific PCK? The former implies that teachers need specific PCK for each particular topic they teach, whereas the latter suggests that there are ideas, for example, about teaching strategies, which are useful across topics within a subject area (e.g., algebra, or even mathematics).
- Given the discussion about the complex, dynamic, and holistic nature of PCK, there are obvious challenges for researchers investigating PCK in analytical, empirical studies, to avoid breaking down PCK into segmented and static entities, resulting in a simplistic and hence misleading picture of teachers’ knowledge.
- Related to the previous issue is the problem of how research into PCK can become more relevant for the

practice of teaching and teacher education, so that PCK becomes an important concept, not only for researchers, but also for teachers and educators.

The Development of PCK

Marks (1990) perceived the development of PCK as an integrative process revolving round the interpretation of subject-matter knowledge and the specification of general pedagogical knowledge. Since this process is rooted in classroom practice, the implication is that preservice or beginning teachers usually have little or no PCK at their disposal. Magnusson *et al.* (1999) argued that development of PCK is a complex and nonlinear process. These authors stated that a teacher education program can never completely address all the components of PCK that a teacher needs. Research reported by Van Driel *et al.* (1998) concluded that while subject-matter knowledge is prerequisite, the major source of a teacher's PCK is teaching experience. Hence, the development of PCK should also be an important element of the continuing education of teachers.

How PCK develops is discussed in the following section. This discussion is organized according to the following themes relevant to PCK development: (1) the role of subject-matter knowledge, (2) teaching experience, (3) a focus on student learning, and (4) the design of teacher education.

The Role of Subject-Matter Knowledge

Several authors have pointed at the problematic nature of preservice teachers' content knowledge, both substantive and syntactical, when they enter teacher education (e.g., Halim and Meerah, 2002). When their subject-matter knowledge is very limited and contains many misconceptions, preservice secondary teachers hardly develop PCK during their teacher education program. Working with beginning elementary science teachers, Appleton (2003) tried to compensate for these teachers' lack of content knowledge and PCK by providing them with what he called activities that work that included, for instance, hands-on activities intended to raise interest among young children around particular science content. Using these activities apparently helped these teachers to start teaching science with some success, and consequently stimulated the beginning of the development of their PCK.

From studies on experienced teachers, however, it appears that a strong and well-integrated subject-matter knowledge does not guarantee the smooth development of an individual's PCK. In particular, when teaching unfamiliar topics, it appears that experienced teachers drew from their general pedagogical knowledge, which can

constitute a supporting framework for the development of their PCK (Hashweh, 1987).

Teaching Experience

Preservice teachers' lack of teaching experience explains why they usually express little to no PCK. Added to this, the concerns of many preservice teachers related to self-confidence and an ability to teach may also, at least initially, hinder the development of their PCK. This means, until a teacher has gained sufficient confidence and experience and mastered basic classroom skills, that the development of PCK as a readily accessible and useful translation of subject-matter knowledge into classroom practice may be delayed. However, while teaching experience may promote the development of PCK, the provision of structured opportunities for reflection on the relationship between subject-matter knowledge and classroom practice is also important for facilitating the development of preservice teachers' PCK. Without such opportunities PCK development is at best, haphazard and at worst, barely apparent.

The role of teaching experience was highlighted in a longitudinal study of 10 years of one elementary science teacher (Mulholland and Wallace, 2005). These authors found that all the various knowledge bases that comprise PCK grew over time, although in different ways. In particular, general teaching knowledge bases and interactive knowledge bases, such as knowledge about learners, developed substantially, whereas subject knowledge bases remained relatively stable. Moreover, this study illustrated the development of PCK as a complex pattern of interactions between these various components, which is situated in the teacher's classroom. In this particular study, new curriculum materials appeared to be an important source for this development.

A Focus on Student Learning

Central to the notion of PCK is the idea that instruction can only be effective if it is attuned to the ways in which students learn specific content. Preservice teachers usually have limited ability to relate students' prior knowledge to instruction and to adequately anticipate student conceptions. Consequently, it has appeared to be important to provide preservice elementary teachers with opportunities to observe student learning in practice and, in connection to this, to study the research literature (e.g., on misconceptions regarding specific topics). Applying these ideas, Zembal-Saul *et al.* (2002) found that preservice teachers were able to focus on student learning, while maintaining a strong subject-matter emphasis, thus contributing to the development of their PCK. Similarly, De Jong and Van Driel used a workshop format in which preservice teachers were asked to prepare and teach a

series of lessons on an important theme from the chemistry curriculum. As a result, these preservice teachers demonstrated a growing awareness of specific instructional strategies in relation to a better understanding of student thinking about the topic of their lesson series. Reflecting on and discussing teaching experiences appeared to be crucial for this development (De Jong *et al.*, 2005; Van Driel *et al.*, 2002).

The Design of Teacher Education

Various studies have been conducted on ways of structuring and organizing preservice teacher education programs to promote the development of PCK (De Jong *et al.*, 2005; Loughran *et al.*, 2006; Zembal-Saul *et al.*, 1999). However, the reported impact of such programs on the development of preservice teachers' PCK is varied. It would appear that the preservice teachers experience difficulty merging subject-matter courses and education courses that are not integrated by design. In programs that were not deliberately structured to help promote integration of different types of knowledge, preservice teachers appeared to retain separate views of subject matter and pedagogy as opposed to the integrated knowledge base advocated by PCK. In the context of such nonintegrated programs, it has been demonstrated that knowledge development appears most strongly influenced by individual and contextual factors, resulting, among other outcomes, in the adoption by preservice teachers of conventional instructional strategies, stressing procedures instead of student understanding.

Some significant gains in the growth of PCK through short-term, intensive, skill-oriented workshops or via specific activities have been reported. Justi and Van Driel (2005) incorporated the design of a lesson series in an action research project that was a requirement for preservice secondary teachers as part of their teacher education program. It was found that, in particular, reflective activities (such as writing reports and sharing experiences in collective meetings) stimulated the development of subject-matter knowledge and PCK of these preservice teachers. Sperandio-Mineo *et al.* (2005), working with a group of 28 preservice teachers of physics, found similar results, concluding that the development of PCK is a complex process which is connected with deepening of subject-matter knowledge and improved awareness of pedagogical issues. Loughran *et al.* (2006) employed a modified version of their aforementioned CoRe and PaPeRs framework in a preservice science teacher education program, whereby preservice teachers developed their own CoRes and PaPeRs based on their learning about PCK at university and from their experiences of teaching in schools. In this case, the structured framework together with ongoing opportunities for reflection about the process of their knowledge development supported deeper

subject-matter understandings of these preservice teachers and a growing awareness of the value of PCK for teaching.

Conclusion

We conclude that research on the development of PCK presents an ambiguous picture. Obviously, teaching experience and subject-matter knowledge are important, but contextual and personal factors apparently may lead to quite different processes of knowledge development. The development of PCK is perhaps then best viewed as a complex interplay between knowledge of subject matter, teaching and learning, and context, and the way in which teachers combine and use this knowledge to express their expertise. In the context of preservice teacher education, PCK can be promoted by addressing both preservice teachers' subject-matter knowledge and their educational beliefs, in combination with providing them with opportunities to gain teaching experience, and in particular, to reflect on these experiences. Specific workshops may serve as an intermediate measure, helping to initialize and frame subsequent teaching experiences.

At the level of specific topics, however, there is little research to inform us about the ways in which teachers transform subject-matter knowledge and how they relate their transformations to student understanding. Neither has there been specific input for teacher education in this respect. Instead, most recommendations regarding PCK development for preservice and in-service teacher education are of a rather general nature.

In our view, PCK implies a transformation of subject-matter knowledge so that it can be used effectively and flexibly in the communication process between teachers and learners during classroom practice. From this perspective, the main aim in studying teachers' PCK is to understand how and why teachers teach a certain topic the way they do and, in particular, how their teaching approach is related to, or focused on, student learning. Achieving such an understanding is vital to the development of effective preservice and in-service programs.

However, much of the research on PCK so far has not served this purpose very well. This can be explained partly by the tacit nature of teachers' personal professional knowledge, which has urged scholars to develop instruments and procedures that help to make this knowledge explicit and measure PCK in a valid manner, rather than exploring what the construct might offer to the practice of teaching and teacher education. In addition, it must be noted that PCK is quite sensitive to personal characteristics of teachers and their working contexts. Several studies (e.g., Henze, 2006) have reported substantial differences between the PCK of experienced teachers around the same topic area, even when their

subject-matter knowledge is similar and when they teach the same curriculum. These differences appear to stem from a range of factors including different orientations toward teaching, different purposes and practices.

Nevertheless, it seems possible to capture and portray PCK in such a way that key notions of teaching and learning a specific topic are made explicit (Van Driel *et al.*, 1998). In addition, discussing and sharing such key notions among teachers may contribute to the establishment of a collective PCK, that is, a shared or common form of teachers' professional practical knowledge about teaching certain subject matter. At the same time, there should, of course, be room for individual teachers to adapt or complement this shared knowledge to their own situations (cf. the above-mentioned resource folios of Loughran and colleagues).

By introducing the construct of PCK, examining, analyzing, and modeling it in preservice teacher education practice (both at university and in school-based practicum), it is more likely that teaching will be seen as a specialized and sophisticated practice. In this way, PCK may emerge as a way of thinking about teaching subject matter that encourages learning about teaching that goes beyond the acquisition of instructional strategies and techniques to include an understanding of how learners develop an insight in specific school subjects.

Teacher Education and the Educational Foundations Knowledge Base

F B Murray, University of Delaware, Newark, DE, USA

Teacher educators are doubly interested in teaching as it is both their subject matter and their method. Like all teachers, it is important for them to know how much of the subject matter their students have already mastered so that they can build on their students' prior knowledge of the field. Long before there were teacher educators and teacher education programs, there was effective teaching because we are after all a teaching species, a species whose young cannot, and do not, survive unless they are taught, invariably and historically, by persons with no formal schooling in teaching, let alone in the disciplines of the foundations of education (psychology, philosophy, history, and sociology).

Some have argued (e.g., Gilbert and Borish, 1997) that teaching is so basic to life that it can be found at the cellular level, but most researchers find that teaching requires (1) an intention to teach, (2) a belief that the pupil does not know something, and (3) the teacher's implicit understanding of the pupil's mind (Strauss and Ziv, 2004; Premack and Premack, 1996). Even if teaching was as simple as requiring the presence of a teacher when an activity was performed repeatedly, there are few documented cases of new learning in nonhumans in these instances (Visalberghi and Frigaszy, 1996, p. 286).

Children as young as 3 years have been shown to teach (Ashley and Tomasello, 1998) and Strauss *et al.* (2002) found that children's style of teaching a new board game (or building something) changed from demonstration and modeling at 3–4 years to predominately verbal explaining at 5 and 6 years (i.e., from show to tell). Seven-year-olds can adapt their teaching on occasion to their perception of what their pupils already know and can do. They sometimes ask their pupils if they have understood and tailor their teaching to the learners' mistakes. The way children teach is also influenced by schooling itself. Maynard (2004) found that older Mayan children (6–11 years) who had been to school were also able to adopt school-like teaching with their younger siblings (didactic teaching at a distance) in place of indigenous teaching practices used in families for cooking and weaving (close-up interactive demonstrations).

Teacher education students come to attend teacher education programs, as Olson and Bruner (1996) also argued in their account of folk pedagogy, with two natural strategies already in place – showing and telling. Before they begin their teacher education programs, teacher

education students have also acquired a naïve, but serviceable, theory of the human mind (see Heider, 1958; Baldwin, 1980 on naïve psychology). In this naïve or common sense psychology, they see the pupil's school achievement as tied to only four factors – the pupil's ability, effort, task difficulty, and luck. With these four factors, they think they can explain completely the pupil's success or failure by attributing the level of the pupil's work to his/her ability, effort, to the difficulty of the school task, or to plain luck. The problem with this naïve account is that it is unduly limiting insofar as ability is concerned, to take only one example, which is not fixed or stable but varies from moment to moment interactively with many other mental factors, not just the few in the naïve theory (Baldwin, 1980; Murray, 1991).

Regrettably, even after the completion of a teacher education program, many experienced teachers' reasoning about teaching is still fairly limited and constrained by views of teaching that the prospective teacher had before beginning a teacher education program. Strauss and Shilony (1994) interviewed both experienced and novice science and humanities' teachers about how they would teach a topic of their choice to children of various ages (7–17 years). Both novice and experienced teachers in both disciplines conceptualized teaching only as the flow of information from their heads to their pupils' heads, acknowledging that their own role was only to devise manageable and interesting ways of entry into the students' mind so that the information could be stored and anchored appropriately. The student is passive, a receptacle waiting to be filled, and if the information fails to flow to its destination, the receptacle was taken to be too small and/or the student was inattentive. The novices and experienced teachers were indistinguishable in their responses and therefore, Strauss and Shilony attributed their responses to their preteacher education training and pre-existing common sense naïve views of teaching. There is also some clear evidence that experienced teachers perform differently from novices (Berliner, 1988). They are able, for example, to read highly contextualized cues in the classroom that allow them to spot trouble and also contribute to the smooth functioning of the class. These skills, however, were seemingly learned on the job and not in their teacher education program.

Astington and Pelletier (1996) cataloged the following tenets of prospective teachers' beliefs about teaching:

(1) children are born with abilities and capacities that unfold linearly in time, (2) instructional sequences should match developmental sequences, (3) learning occurs sequentially within a hierarchy of skills, and (4) student errors are attributable to incomplete learning or inattention. When the pupil is to learn to do something, the teacher need only demonstrate or model it, and when the pupil is to know something, the teacher need only tell the pupils what they need to know.

Teachers' reasoning about their pupil's accomplishments, in fact, proves to be surprisingly indistinguishable from the layperson's explanations. Kuhn (1991) found, for example, when she asked teachers, "What causes children to fail in school?" the teachers' reasoning was that the pupil "shows no superiority over reasoning regarding the other topics. . . performance for the school topic is in fact somewhat inferior to their performance for the other topics. . ." (p. 249). Their reasoning, like about half the other subjects in her study, tends to be absolutist, that is, they believe it is possible with sufficient study to know with certainty the causes of a phenomenon, often through a personal commitment to a theory or assertion.

On the whole, the prospective teacher's prior knowledge and beliefs make it difficult to have teachers learn some of the newer teaching techniques such as dialectic, discovery, invention, cooperative learning, and collaboration, because the prior techniques are often the opposite of the newer strategies. They may, for example, require the prospective teacher to refrain entirely from showing or telling. They are also at variance with the Astington and Pelletier (1996) prior tenets because developmental pathways, for example, are rarely linear, but often show fits and starts, oscillations, and even reversals, particularly when performance is at an optimal level or when a new skill is being developed (Fischer and Bidell, 1998).

The teacher education program, particularly the foundations disciplines, are meant to shore up the mental life of the teacher, especially their states of mind when they explain to themselves their student's behavior, when they insist on certain classroom practices, and establish schoolwork requirements. It gives them a basis for deciding, for example, whether to prohibit handheld calculators in arithmetic lessons, to group students by ability, to require memorization of certain facts and not others, to socially promote some students to the next grade, to allow some students to skip a grade level, or to adopt new teaching methods. In other words, the knowledge base of the educational foundation disciplines refers to that body of opinion, information, and knowledge that the professional teacher relies on to justify her professional decisions.

This knowledge is important if only because teachers attempt only what they believe is possible. The judgment that an aspect of education is impossible, or impossibly difficult, usually flows from the prior misconceptions held by prospective teachers because they tend to be firm and

absolute tenets. The core knowledge of educational foundations typically promotes more flexible forms of pupil accomplishment that go beyond what can be simply given to the pupil by showing and telling.

Having said that, it is important to note the limitations of what can be had from the educational foundations disciplines. On logical grounds alone, sound practices can be derived from both true and false theoretical propositions. The soundness of an educational practice is simply not guaranteed by whether it fits with what is taught in teacher education courses, even when the builders of the theory, who have created the educational technique, think it stems from their theories. Although a proven effective teaching technique, programmed instruction does not tend to lose that effectiveness when the various theoretical requirements Skinner (its inventor) placed on it are violated (e.g., programs that scramble frames randomly, delay or omit reinforcement, and require only covert responding are as effective as their theoretically sanctioned opposites). While the Montessori practices are compatible with Piaget's theory, they were developed independent of it and succeeded quite distinctly from the truth or falsity of Piaget's propositions. Both Piaget and Skinner, for example, have different but adequate explanations for Montessori teaching. This should not be surprising because there are many instances in science and other disciplines where different theoretical positions yield the same practical recommendations. For example, both the Ptolemaic view in astronomy, which holds that the Earth is at the center of the Universe, and the Copernican view of astronomy, which holds that the sun is at the center, yield the same navigational practices for traveling on Earth.

There is still another problem for teacher educators when they try to connect propositions in their educational foundations courses with practices in the schools. What teachers are able to do and what they actually do are often quite different. Even if they have a competence that would be sufficient to accomplish a teaching task, they may accomplish the task in a way that bypasses the competence altogether as can be seen in the following example. Virtually all adults, and most preschoolers, can give the plural of the following nonsense nouns – *wug*, *wot*, and *gutch*; in fact, they could even give the past tense if these same words were presented to them as verbs (e.g., Today A is *wugging* B, but yesterday A *wugged* B, and so on). Yet, almost no one knows the linguistic rule for the assignment of the plural (/z/, /s/, /ez/) or past tense (/d/, /ed/, /t/) allomorphs (*wugs*, *wots*, *gutches*), but everyone acts as if they knew the rule for the pluralizing these nonsense words even though it is obvious that they do not. They base their flawless plural and past tense performance on some factors of language competence apart from their formal knowledge of linguistics even though their formal knowledge of linguistics, if they had it, would have been sufficient for them

to pluralize the nonsense nouns and form the past tense of the nonsense verbs.

Thus, even when teacher educators succeed and the prospective teacher learns the content of the teacher education curriculum, there is still no guarantee that the teacher based his or her teaching practice on some knowledge of educational psychology, history, philosophy, or some body of research literature acquired in the teacher education program and its foundations courses. The fact that they could have, might have, or even should have, is no evidence that they did, or would ever, base their practice on the knowledge they acquired in their teacher education program.

Consequently, any effort to enhance the teacher's knowledge of the educational foundations could ultimately be pointless because the expert teacher, like the fluent speaker, could very well have based his or her performance on some other area of competence (Peterson, 1946). Even if prospective teachers have acquired a competence based on their study of the educational foundations, there is still the question of whether they would be disposed to use that competence in the classroom (Murray, 2007).

Having said this, however, we know that how the teacher does theorize or speculate about school events is a powerful determiner of the events. Prospective teachers, and unfortunately some experienced teachers, make a number of teaching errors that one day may be viewed as malpractice. These seem to stem from a naïve representation of teaching and schooling (Brophy and Good, 1986; Evertson *et al.*, 1985). For example, novices, especially those with the best and most decent intentions, blunder when they teach pupils who are very different from themselves. They treat pupils from whom they have low expectations in the following ways: they seat them outside the zone of frequent interaction; they treat them as a group rather than as individuals; and they look at them and call on them less often. When they do call on them, they ask them lower-level questions and give them less time to respond and fewer hints than they give their more able pupils. They give them less praise, even when they are correct, and more blame when they are wrong than they give pupils from whom they have higher expectations. They may do all this not only out of a mistaken sense of kindness, but also an impoverished view of the nature of teaching and the factors that figure in it (Hawley and Rosenholtz, 1984; Murray, 1996). There is hardly a better example of how the teacher's prior beliefs and implicit theory of classroom events influences practices than this example of how teaching practices flow from the teacher's expectations and predictions about his or her pupils' ability and effort.

Even if the teacher had acquired the information about the diverse groups of pupils in the classroom from the teacher education program, and was disposed to act in

sympathy with it, the teacher, even an experienced teacher, might still fail to act on the information in an appropriate manner (Murray, 2007). Cohen (1990), for example, reports a case of one enthusiastic teacher, Mrs. O, who believed she had adopted an innovative teaching approach only to have it shown that her innovative teaching was stubbornly hobbled with traditional and natural techniques which undermined her good intentions.

Given that so much rests upon teachers' expectations, predictions, and the way they think about schooling, the role of the foundations courses is to insure that teachers can evaluate evidence, can spot a fad or an unsound proposal for innovation, have an educated view of how the pupil's mind develops, have a reasoned and informed position on the major public policy issues that affect schooling, and the intellectual resources to face novel and unexpected classroom problems and opportunities. Amateurs often make bad guesses and predictions and they have few defenses against destructive educational fads because common sense and folk wisdom are often inadequate for the analysis of genuinely new and novel events.

Had the US and the UK teachers and administrators in the 1960–70s known more educational history, for example, they might not have required, as they did, one-quarter of USA and nearly all the UK pupils to learn to read in a special alphabet (*ita*, the initial teaching alphabet) that had a separate letter or symbol for each of the 45 sounds (phonemes) of English (e.g., *wuns* in *ita* would be once in traditional orthography). Had they known the history of spelling-reform efforts, they would have known that *ita* was but a version of *phonataby*, another alphabet used to the same end in the 1860s and the reasons why it was discarded. Had they known more educational psychology (in particular, the Osgood learning transfer surface), they could have predicted that the shift from *ita* to the regular alphabet would harm the pupil's spelling (negative transfer) even though it would actually help reading (positive transfer). Had they known more about educational research, they would have evaluated the claims for the benefits of *ita* more carefully than they did, quite differently from their knowledge of the history of spelling reforms or positive and negative transfer in learning psychology.

The study of the foundations disciplines seeks to give teachers a representation of schooling that allows them to ask for and search out the information that would be needed to evaluate the claims of any innovator. While they may have no information about *phonataby*, *per se*, they would know what kind of information they should have before implementing the innovation.

Prospective, novice, and experienced teachers are constantly presented with educational happenings or phenomena (girls on the whole do better on language problems, boys do better on spatial relations problems; the words in the middle of any list take longer to learn than the words at the beginning or end; pupils can recognize more words than

they can produce; some pupils learn their lessons faster than other pupils; some pupils conform to the rules of the classroom and some resist them; and so on). Teachers will inevitably speculate on the reasons for these and other phenomena they find in their classrooms. The complete account of an educational phenomenon entails the search for answers to a number of questions about a phenomenon that are informed by the foundations disciplines: what kind of phenomenon is it (was it a learning issue, motivational, social class, or genetic?); how did it get that way (was it always that way, only recently, only that way for certain groups, or does it come and go?); how does it work (was it produced through learning, maturation, or culture?); and how can it work better, and what is the point of it (fitting pupils for the economy, increased social justice, self-actualization)? The preponderance of recent scholarship in education has centered on the question, "How does it work," that is, the mechanisms that make schooling work. However, at least four aspects of any educational event – whether at the pupil or school system level – also need to be specified before it can be said that the event is completely intelligible, understood, or explained. The complete account treats:

1. the substance of the event: the relevant biology of the behavior in the case of the pupil or in the case of a classroom, school, or system, the various tangible agents, laws, policies, and structures that make it up.
2. the antecedent conditions that are necessary and sufficient for the event: those which elicit, trigger, and maintain the event. These are the causes of the event, in the usual sense of the term cause. In the case of pupil accomplishment, it is thought to have something to do with what the teacher did and knew.
3. the form or structure of the event or that which makes the event one phenomenon rather than another. If a child finally comes to say $2 + 2$ always equals 4 and never any other number, is this a change in language, logic, learning, teaching effectiveness, personality, memory, or what? What is the change a change of and how could we know? If a school begins to group pupils according to their standardized test scores, what kind of change has occurred in the school and community? When can historical events be said to coalesce as one historical period or era rather than another?
4. the purpose or point of the event, what it leads to, how it fits in with everything else, and how other events in the pupil's life, for example, makes the event intelligible and vice versa. Does the event mean anything? What is the point, significance, or meaning of the event?

Consider the curious fact that some young pupils, even those who know how to count correctly, think that spreading out a row of five marbles makes the row have more than five marbles while other pupils know that the number in the row is still five. How could the teacher

figure out how is it that some children know that the number of objects is independent of their spatial array while other children act as if the array also changed the number of objects (concepts of this sort are found at all levels of the curriculum)? Some teachers see the issue as a matter of a logical deduction, the child's ability to deduce the correct answer, and others see it merely as a matter of memory – being able to recognize and give the right answer. We will return to this example later.

Many issues in education are really debates about whether the explanation for a phenomenon is to be found solely in the antecedent conditions for it or in its form or structure as well. The debate is not so much about the student's accomplishment, but about what it means. For example, in one view there is alarm when a pupil who had used mice as the plural for mouse begins to say *mouses*, while in the other view, the reintroduction of *mouses*, wrong as it is, is a sign of linguistic progress because it shows a newly found sensitivity to a new class of linguistic rule. Along similar lines, in one view the pupil who argues that Churchill was right to firebomb Dresden gives exactly the opposite answer from the pupil who argues Churchill's act was wrong. Yet, the two arguments, while contradictory on the surface, may be structurally identical and signify that the two pupils have achieved precisely the same level of moral and logical development. On a larger scale, some see the function of the schools as the liberating transmission of the culture from one generation to the next, while others see the very same events as the imposition of a class structure that represses individual freedom and reduces opportunities.

The attempt to explain educational change totally in terms of antecedent events, the necessary and sufficient conditions, carries with it a determinism that many think precludes the possibility of spontaneous events, of emergent events, of discontinuities, of stages in the pupil's grasp of a subject matter insofar as spontaneity can exist only when events cannot be reduced to, or linked strictly and solely to, those events that come before them. Thus, it could be said that theories that allow for educational changes that are inherently unpredictable from their antecedents introduce a more sophisticated or advanced view of education.

If all there is to know about an earlier educational period is known, it still may not allow the teacher to predict the nature of the pupil's subsequent educational accomplishments. The point here is that so much depends upon the teacher's view of the issue and the way in which he or she thinks about whether the pupil's behavior is determined or open-ended and whether the object of instruction is the correct response or the underlying structure of the response, and so on.

Consequently, because teachers, like every reflective person, invent theories and explanations, teacher educators need some criteria for evaluating the available

theories in the educational foundations before including them in the teacher education curriculum. There simply are differences in the power and adequacy of various educational theories that must be acknowledged and respected.

What must we have from a good theory? What questions must it answer about the classroom phenomena it attempts to explain? What problems must it resolve or eliminate? All educational phenomena have more or less the same basic form – there is some change, or difference, in the student (or teacher, class, school, district, etc.) that is found over a relatively long period of time (weeks, months, years) in the case of development, or in a relatively short time (seconds, minutes, hours, and days) in the case of learning. What must a good theory tell us about these changes and differences? What should prospective teachers be thinking about, or considering, to shift their theorizing from those of an amateur to those of a professional?

Contemporary scholarship points to ten categories that a good theory should address and that the teacher should consider:

1. the form or pattern of the change – a way to identify, name, or define the phenomenon, a way to distinguish it from other phenomena. There must be a way to measure it and perhaps produce it. The act of naming or defining carries the risk that more may be thought to be known and understood than really is, but it is an essential part of any theory to name the phenomenon and the criteria for the naming. Thus, we call the child's incorrect response to the spatial array of the number of marbles, nonconservation, and thereby mark it off from other phenomena and begin the act of knowing and making sense of it.
2. cause – the causes of the phenomenon, the necessary and sufficient conditions for it – the eliciting conditions. This is not to say that the specifications of the necessary and sufficient conditions constitute the whole account or explanation, but only that they are a part of the story, so to speak, and without their specification, a theory would not be satisfying. Thus, we want to know under what conditions the child will assert that there are as many marbles as there were before the row of marbles was spread out, and under what conditions the child will claim there are more or fewer marbles.
3. mechanisms – what cognitive device produces the phenomenon. How do these devices function, and how, over the time span during which the change takes place, do they actually produce the change? In the number of marbles in the row example, what roles do learning, social interaction, imitation, cognitive dissonance, mediation, maturation, perception, and so on play in the child's exhibition of the

phenomenon? How do they lead the student who was wrong to be right?

4. the educational end point – the educational goal for the changes. Later events cannot cause earlier events, but they can help us make sense of the earlier events by showing what the earlier events lead to – nonconservation leads to conservation and not the other way around. The child's error that the number of marbles changed as they were spread out would make more sense if we had a way to see it as an instance of the child's newly acquired notion of logical necessity and not merely as an episodic peculiarity of the young child's thought (Murray, 1990). It is helpful to know why the earlier periods fail to hold the developing mind at some point or stage for a longer time even without knowing the character of the next stage or period. Because of the open-ended character of education and the potential for inherently unpredictable outcomes of mental functioning and accomplishment, it may be inevitable that theorists will always understand more of where the mind has been, so to speak, than where it is going.

Moreover the good theory may provide a way to think about better educational outcomes. Given that many educational outcomes are possible, and that just as many evolutionary solutions are possible for species development, the good theory could be asked to account for, identify, explain, and clarify the better of the available outcomes – outcomes that maximize what it means to be human. We ask that the good theory critically examines the educational outcomes that appear to be necessary and unalterable to determine whether they are really just one of a range of possible educational outcomes.

5. the meaning of the phenomenon – the attribute of intentionality and the question of what the student meant or intended when he/she said the row now had more than five marbles. The question of the meaning or significance of the phenomenon is a micro-version of the question of the goal of education. It is an inquiry into the purpose and significance of some aspect of mental life.

Just as there is no single interpretation of a text, apart from a framework of interpretation, one would not expect that there could be a single meaning of a behavioral phenomenon that was unrelated to a theory or an interpretative framework that could give meaning to the event.

6. unity of knowledge – the good theory must have the potential for coherence with the other disciplines. Thus, we would expect not to be surprised that the onset of conservation (knowing the number of marbles remained the same), for example, is linked to increases in brain lateralization, brain surface, the completion of myelination, increases in EEG alpha activity, and increases in working memory.

7. deductive formalism – while the logic of discovery and the logic of justification are different, the good theory should eventually have a form such that phenomena are explained by virtue of their being implications of general propositions of a theory. The appeal for a deductive formalism in the good theory does not mean that theory building needs to proceed by that route, but only that eventually there would be a version of the theory that can be expressed in the fashion of the hypothetico-deductive system (e.g., conservation makes sense within a developmental theory that explains many other phenomena like conservation and some others that are very different like seriation, transitivity, class inclusion, and egocentrism, but all derivable from a hypothetical device – concrete operational thought).
8. cohort specification – it is now understood that generational and historical effects compromise the generality of many findings, like the shape of the growth of intelligence function (Baltes *et al.* 1977). Such effects should now be seen as an integral part of the phenomenon. Of course, cohort, or time of the subject's birth, is merely a proxy for some yet-to-be-discovered historical and cultural factors that operated during a particular period, and that these factors would significantly alter research findings that are reported in research paradigms that were not sensitive to generational factors.
9. cultural and social determinants – the identification of factors and mechanisms that operate uniquely in particular historical periods, and not in other periods, has led researchers to consider wider ranges of these contextual and interactive factors (Rogoff and Lave, 1984).
Native Americans in the southwest, are not fooled as much by conservation problems about the clay ball's weight as other children appear to be, and Bedouin children are not fooled as much as others about conservation of liquid amount (see Murray, 1981). In virtually every domain of psychology, substantial effects can be attributed to factors that appear to be features of a particular context, social or cultural group, geographic location, historical time period, and so on. Obviously the successful theory will find a way to make sense of this – at the moment – bewildering array of context-specific influential factors.
10. the theorist – the interdependence of fact and theory or text and interpretation leads to an examination of the theorist as a person and thinker. The interpretive framework that allows events to be facts in a science is shaped presumably by personal features of the theorist that heretofore were considered irrelevant when science was viewed exclusively as objective and self-correcting. At the moment we can only

speculate how Piaget's account of moral development would differ had it been formulated outside Protestant Geneva, or how Skinner's account of learning would differ had it not been formulated by an American and so forth. However, as theories are invariably written and otherwise promulgated, their meaning is also subject to all the hermeneutic issues implicated in the attempt to specify the meaning and significance of an educational change in mental functioning in the first place.

In summary, a good theory of schooling is what will eventually be found in the educational foundations disciplines of the teacher education curriculum, and it will be a key ingredient in what the teacher relies upon in professional decision making.

The Relationship Between Theory and Practice in Teacher Education

A Perennial Problem of Teacher Education

In 1904, John Dewey noted a gap between theory and practice in teacher education (Dewey, 1904), and he discussed possible approaches to bridging this gap (see also Shulman, 1998). Nevertheless, during the whole of the twentieth century, it has remained the central problem of teacher education worldwide (Lanier and Little, 1986). In various analyses of this problem, the focus has often been on the question of how practice can be better linked to theory. Only relatively recently, has attention focused on the possibility that theory can be better linked to practice.

Below, the theory–practice relationship will be analyzed, as well as the nature of knowledge relevant to practice. We will also discuss different approaches to improve the link between practice and theory, which leads to the conclusion that no single trick will solve the perennial issue.

The Sacred Story about Theory and Practice

During the late nineteenth and early twentieth century as psychological and pedagogical knowledge developed, academics wanted to offer this knowledge to teachers in order to change education and adapt it to scientific insights. This is how the idea of the professionalization of teachers began. Indeed, as Hoyle and John (1995) point out, the availability of a recognized body of knowledge is one of the most important criteria for categorizing an occupational group as professional (see also McCullough, 1987). It seemed only logical to teach important theories to preservice and in-service teachers, who could then apply this knowledge base in their teaching. Clandinin (1995) calls this “the sacred theory–practice story”, and Carlson (1999) speaks about the “theory-to–practice approach”. Wideen, *et al.* (1998) put it like this:

... the implicit theory underlying traditional teacher education was based on a training model in which the university provides the theory, methods and skills; the schools provide the setting in which that knowledge is practiced; and the beginning teacher provides the individual effort to apply such knowledge. In this model, propositional

knowledge has formed the basis of university input. (Wideen, *et al.*, 1998: 167)

In many places, this has led to a system in which experts in certain domains teach this knowledge to prospective teachers. As Barone *et al.* (1996) argue, the result is often that a teacher program consists of a collection of isolated courses in which theory is presented with hardly any connection to practice. Ben-Peretz says:

The hidden curriculum of teacher education tends to communicate a fragmented view of knowledge, both in coursework and in field experiences. Moreover, knowledge is “given” and unproblematic. (Ben-Peretz, 1995)

Schön (1983, p. 21) speaks about the technical-rationality model, which is based on the notion that “professional activity consists in instrumental problem solving made rigorous by the application of scientific theory and technique.” In fact, three basic assumptions are hidden in this view (cf. Hoyle, 1980):

1. theories help teachers perform better in their profession;
2. these theories must be based on scientific research; and
3. teacher educators should make a choice concerning the theories to be included in teacher education programs.

The technical-rationality model has been dominant for many decades (Sprinthall, *et al.*, 1996; Imig and Switzer, 1996, p. 223), although many studies have shown its failure in strongly influencing the practices of the graduates of teacher education programs, which is discussed in the next section.

Meager Impact of Teacher Education

Many researchers have shown that the traditional technical-rationality model does not function well. Zeichner and Tabachnick (1981), for example, discussed that many notions and educational conceptions, developed during preservice teacher education, were washed out during field experiences. Comparable findings were reported by Cole and Knowles (1993) and Veenman (1984). Veenman also points toward the severe problems teachers experience once they have left preservice teacher education, a phenomenon named the transition shock. It is interesting to note that this transition shock is described in studies from many different countries.

For example, at Konstanz University in Germany, large-scale research has been carried out into this phenomenon (Müller-Fohrbrodt, *et al.*, 1978; Dann, *et al.*, 1981; Hinsch, 1979). It showed that teachers pass through a quite distinct attitude shift during their first year of teaching, in general creating an adjustment to practices current in the schools, and not to recent scientific insights into learning and teaching. Building on the work of the Konstanz research group, Brouwer and Korthagen (2005) did an extensive quantitative and qualitative study in the Netherlands among 357 student teachers, 128 cooperating teachers, and 31 teacher educators, which again showed the dominant influence of the school on teacher development (see also an early study by Lortie, 1975).

In their well-known overview of the literature on teacher socialization, Zeichner and Gore (1990) put forward that researchers differ in the degree to which they consider teacher socialization to be a passive or an active process. However, all studies on teacher development emphasize that it is very difficult for an individual to really influence established patterns in schools. Educational change appears to be a beautiful ideal of teacher educators, but generally indeed not much more than an ideal. Bullough (1989) emphasizes that in this respect there is a severe problem in teacher education. As Zeichner and Gore (1990, p. 343) put it:

Studies that have focused on the institutional and cultural levels of analysis have clearly shown, for example, that various ideological and material conditions within teacher education institutions, schools, and societies serve to establish limits on the range of options available to both teacher education students and teacher educators.

As a result, the impact of teacher education on the practice of their students is very limited, as Wideen, *et al.* (1998) conclude in a thorough and extensive review of the international research into the outcomes of teacher education, a conclusion that was also drawn by the AERA Research Panel on Teacher Education in a meta-analysis of North-American research (Cochran-Smith and Zeichner, 2005). Several studies show that beginning teachers struggle for control, and experience feelings of frustration, anger, and bewilderment. The process they go through is more one of survival than of learning from experiences. Novice teachers do not feel sufficiently prepared by their teacher educators, and come to view colleagues in the schools as realistic role models, as the people who do know how one should go about teaching.

Apart from the fact that the traditional technical-rationality approach to teacher education creates little transfer from theory to practice, this approach creates another fundamental problem. Elliot (1991, p. 45) states that teachers who realize that they are not able to use the theory presented to them by experts, often feel threatened by theory. These feelings of threat are further enhanced

by the generalized form in which experts tend to formulate their knowledge and by the ideal views of society or individuals behind their claims. Often the result is a dislike of theoretical deepening in teachers (Cole, 1997).

Causes for the Gap between Theory and Practice

As Robinson (1998, p. 17) reminds us, “narrowing the research-practice gap is not just a matter of disseminating research more effectively or of using more powerful influence strategies.” The causes for the gap lie deeper and a variety of these causes have been put forward in the literature. First, we have already seen that from a sociological perspective one can frame the problem as one of socialization toward patterns existing in the schools.

A second cause often mentioned in the literature is the complexity of teaching (e.g., Hoban, 2002, p. 35–40). Hoban (2005, p. 9) states: “(. . .) what a teacher does in a classroom is influenced by the interaction of many elements such as the curriculum, the context, and how students respond to instruction at one particular time.” Hoban continues by saying that this view of the nature of teaching necessitates holistic judgment (cf. Day, 1999) about what, when, and how to teach in relation to a particular class, and this is something for which it is hard to prepare teachers. Moreover, practice is generally ambiguous and value-laden (Schön, 1983). Robinson (1998), states that in specific educational situations, even experts have different opinions of what is the best way to use theory. Different theories may each have their value in explaining a certain aspect of the situation, and lead to different perspectives.

A third cause for the theory–practice divide often mentioned has to do with the learning process within teacher education itself, even before the stage in which theory can be applied to practice. According to many researchers, teachers’ prior knowledge plays a powerful role in their learning (Wubbels, 1992). Their preconceptions show a remarkable resistance to change (Joram and Gabriele, 1998). This can in part be explained by their firm roots in the many years of experiences that student teachers themselves have had as students within the educational system (Lortie, 1975). Preconceptions also shape the way new knowledge is being understood. Stofflett and Stoddart (1994), for example, argue that teachers’ conceptions of how subject matter should be taught are strongly influenced by how they themselves learned the subject content. These authors showed that student teachers who themselves experienced learning in an active way, are more inclined to plan lessons that facilitate students’ active knowledge construction. Huibregtse *et al.* (1994), showed that, even with experienced teachers, there is a strong relation between their preferred way of teaching

and the way they themselves are used to learning: they have a limited view of the learning styles of their students, and tend to project their own way of learning onto the learning of their students.

A fourth cause has been named as the feed-forward problem: “resistance from the student teacher at the time of exposure to given learnings and, later, protestations that the same learning had not been provided in stronger doses” (Katz *et al.*, 1981, p. 21; see also Bullough *et al.*, 1991, p. 79). This problem can also be stated as follows: in order to learn anything during teacher education, student teachers must have personal concerns about teaching or they must have encountered concrete problems. Otherwise, the usefulness of the theory is not clear to them, and they are not motivated to study it. Later, when they do come across problems, there is often no opportunity to acquire the relevant theoretical insights.

Other authors add that teacher development cannot be fully understood if it is considered merely from a cognitive perspective. Teaching is a profession in which feelings and emotions play an essential role (Nias, 1996; Hargreaves, 1998a), but “the more unpredictable passionate aspects of learning, teaching and leading (...) are usually left out of the change picture” (Hargreaves, 1998b, p. 558). The problem of promoting fundamental professional change is first of all a problem of dealing with the natural emotional reactions of human beings to the threat of losing certainty, predictability, or stability. This affective dimension is neglected very often in the technical-rationality approach, which is another cause for the transfer problem.

The human aspect can be elaborated even further. Many authors emphasize that learning to teach cannot be separated from the person of the learner (see for an overview Korthagen, 2004). Bullough (1997, p. 21) states that “teacher identity-what beginning teachers believe about teaching and learning and self-as-a-teacher-is of vital concern to teacher education; it is the basis for meaning making and decision making.” He adds that the most important learning outcomes will thus be personal, idiosyncratic, and probably immeasurable. This concurs with Day (1999, p. 94) who talks about the “unpredictable, personalized nature of teaching.”

Finally, there is a cause for the transfer problem that has drawn so much scholarly attention that the entire next section is devoted to it.

Practical versus Formal Knowledge

Clark and Lampert (1986, p. 28) argue that once inside school, teachers “are expected to accomplish complex and even conflicting goals. Under these circumstances, a priori knowledge identified by researchers about the relationship between particular decisions or actions and their

outcomes, is of limited worth.” Teachers often have little time to think and thus need prompt and concrete answers to situations (Eraut, 1995). Action-guiding knowledge is rather different from the more abstract, systematized, and general expert knowledge teacher educators often present to student teachers (Tom, 1997). Various terms are used to name this difference, but generally used are the concepts of practical knowledge and formal knowledge. According to Fenstermacher (1994), the former type of knowledge develops in teachers by participating in and reflecting on their own actions and experiences; it is situated knowledge (Brown, *et al.*, 1989). This practical knowledge enables teachers to deal effectively with practical problems. The validity of this knowledge is confined to the type of contexts or situations within which the events occur, and teachers often have difficulty in putting it into words. This lack of explicitness may also limit student teachers’ learning from the practical knowledge of their mentor teachers if no additional measures are taken (Zanting, *et al.*, 2001).

Formal knowledge, or propositional knowledge, is the knowledge produced by conventional research in order to answer a question such as: What is known about effective education? It meets criteria for reliability, validity, and has the potential for generalization. Fenstermacher refers to Aristotle, who already made a similar distinction between two types of knowledge, which he called *phronesis* and *episteme*.

Kessels and Korthagen (1996) emphasize that formal knowledge or *episteme* (which they also refer to as theory with a capital T) should certainly not be absent from teacher education programs, as, now and then, student teachers should be helped to see the larger picture of educational knowledge. On the other hand, they add that:

More often, however, they need knowledge that is situation-specific and related to the context in which they meet a problem or develop a need or concern, knowledge that brings their already existing, subjective perception of personally relevant classroom situations one step further. This type of knowledge is called *phronesis*. We could also call it ‘theory with a small t’.

The character of *phronesis* is more perceptual than conceptual: it focuses the attention of the actor in the situation on certain situational characteristics important to the question as to how to act in that situation. To put it concisely, *episteme* aims most of all at knowing more about many situations, while the emphasis of *phronesis* is on perceiving more in a particular situation and finding a helpful course of action on the basis of strengthened awareness. The best translation of *phronesis* may be practical wisdom.

An important cause for the limited impact of many teacher education programs may be that they focus too much on formal knowledge (*episteme*) and do not support

their students sufficiently in developing their perceptual awareness or *phronesis* (Loughran, 2006, p. 8–9). This could mean that teacher educators themselves create the gap between theory and practice. Of course, the conditions under which teacher education takes place are generally not very supportive of a change in old habits: large enrolments and limited time for teacher educators to visit student teachers during their teaching practice are some of the most significant inhibiting factors (Barone *et al.*, 1996, p. 1117).

Directions for Bridging the Gap between Theory and Practice

During the recent decades, several strategies have been introduced into teacher education with the aim of bridging the gap between theory and practice. It is difficult to present a complete overview of all of them, but in this section some productive strategies will be described.

First, several attempts have been made to improve the theory-into-practice approach through pedagogical strategies, such as the promotion of reflection (e.g., Clift *et al.*, 1990; Schön, 1987), or through tools like (video) cases, portfolios, etc. Each of these has its merits in helping teachers develop useful action-guiding theory with a small *t*, or in supporting them to make connections between existing theory and their own implicit thinking about education. However, a fundamental solution to the theory–practice divide may require more radical changes in program structure, in which “greater continuity exists between teacher preparation and the schools where beginning teachers begin their teaching careers” (Wideen *et al.*, 1998, p. 159). Before discussing this promising development, a warning has to be given regarding an extreme elaboration of this idea. In many programs, the traditional approach of theory first, practice later has been replaced by the adage practice first, theory later (Sandlin, *et al.*, 1992). Alternative certification programs have been created in which novice teachers sometimes receive very little theoretical background, and teacher education becomes more of a process of guided induction into the tricks of the trade. In many places in the world, this trend is also influenced by the need to solve the problem of teacher shortages. Although this development may satisfy teachers, politicians, and parents, there is a great risk involved. The balance seems to shift completely from an emphasis on theory to reliance on practical experience. Such an approach to teacher education does, however, not guarantee success. Long ago, Dewey (1938, p. 25) already stated that “the belief that all genuine education comes about through experience does not mean that all experiences are genuinely or equally educative.” (cf. Loughran, 2006, p. 22) As already discussed above, teaching experience can be a process of socialization rather than an

opportunity for professional development (cf. Wideen, *et al.*, 1998). Hence, there is a risk that in a practice-first approach, the basic question, namely how to integrate theory and practice, is still not solved.

Nevertheless, promising developments are visible under the umbrella of professional development schools (PDSs) (Bullough and Kauchak, 1997; Darling-Hammond, 1994). The idea is to develop collaborative partnerships between institute-based teacher educators and school-based teachers, sharing the responsibility for the preparation of prospective teachers. In this context, there is a focus on developing new teaching methods, and an emphasis on an ongoing professional development for all involved in such projects (Abdal-Haqq, 1997).

Both in the PDS movement and in the more general trend to move teacher education to the schools, there are two significant aspects: on the one hand, these developments mirror a wish to ground teacher education more strongly within practical contexts, but on the other hand, teacher education faculty involved tries to avoid the risk of early socialization toward traditional educational patterns. That is why these attempts at strengthening the practical relevance of teacher education are characterized by an emphasis on critical reflection on current practices, and attempts to adapt formal knowledge to practice. This requires strong and long-term partnerships between university faculty and teachers in the schools, which in certain places have been very effective (see e.g., the Oxford Internship Model described by McIntyre and Hagger, 1992).

Referring to publications by authors supporting collaboration structures between schools and universities, Furlong *et al.* (1996) conclude that the PDS approach may finally allow for a real integration of theory and practice. However, case studies also illustrate many problems associated with the PDS approach (see Darling-Hammond, 1994). Castle (1997, p. 221) concludes that “many of the problems stem from the reality that change of this nature involves individuals and relationships.” An important problem is that when a leading person moves to another job, the whole collaboration structure may collapse.

Other strategies of which their advocates claim that they really bridge the gap between theory and practice are those putting teacher research in the forefront of professional development. (Cochran-Smith and Lytle, 1993; Stenhouse, 1975). Ponte (2005) observes that the idea that teachers themselves can do research, goes back as far as the beginning of the twentieth century, and has led to a variety of slightly different approaches to teacher research. Lewin (1946), for example, introduced the term action research and emphasized its role in promoting social change. Other common terms are reflective inquiry, practitioner research, and self-study research (see for an overview McKernan, 1996). One of the challenges of teacher research is that “it is in danger of becoming

anything and everything" (Cochran-Smith and Lytle, 1999, p. 21). This has led to attempts to develop explicit methodologies for this kind of research (e.g., Bullough and Pinnegar, 2001), and pleas to put more effort into connecting the outcomes of individual studies to the broader research community (Zeichner, 2007).

Another fruitful strategy for linking theory and practice focuses on the concerns students develop in practice, and tries to build teacher education on these concerns and student teachers' preconceptions that these concerns bring to light. Korthagen *et al.* (2001) describe how this can be done in a so-called realistic approach, and present evidence that this does indeed bridge the theory–practice gap. Others focus on the importance of making student teachers' preconceptions explicit through their narratives about practice (e.g., Kelchtermans, 1993). However, enacting such approaches requires a strong investment in staff development, as they build on specific pedagogical interventions.

More recently, social constructivist views and the notion of communities of practice (Wenger, 1999) have led to approaches that no longer focus on the individual practitioner, but consider professional development as being strongly intertwined with professional cultures. Although the strength of such social constructivist approaches is that they start from the reality of professional development, which is always embedded in a certain social context, one does have to find ways to circumvent narrow-mindedness and undesirable socialization. In other words, the fundamental tension between what happens in a community of practice and the wish to deepen practice with existing theory is still there to be taken care of. According to Husu (2002) a key element is not to strive for unanimous agreement, but to focus on discourse and the testing of plural meanings.

Darling-Hammond (1999, 2006) identified a number of additional components of teacher education curricula that appear to be beneficial, such as a shared, clear vision of good teaching apparent in all coursework and clinical experiences; well-defined standards of practice; a rigorous core curriculum taught in the context of practice; and intensively supervised, extended clinical experiences (at least 30 weeks), carefully chosen to support what students have learned in their courses. The importance of this latter component is emphasized in a vast amount of literature claiming that the most important factor in promoting the relationship between theory and practice is individual coaching or supervision (e.g., Korthagen *et al.*, 2001; Showers and Joyce, 1996). The idea is that a strong supervisor may be able to effectively connect the student's personal experiences in educational settings and his/her present concerns to theory – both theory with a small t and theory with a big T. However, Franke and Dahlgren (1996) show that not all supervisors do so.

Toward an Integrated View

As Lanier and Little (1986) argue, all teacher education programs have to confront the problem of the gap between theory and practice. It is now more than a century since Dewey expressed his concern about this gap. Has the solution been found? Each of the approaches discussed in the previous section has its own merits and seems to solve part of the problem. Similar to teaching, learning to teach is also too multifaceted to be dealt with in a simple way. As Wideen *et al.* (1998) suggest, what is needed is an integrated view, in which all the aspects influencing teacher development are taken into account, and which combines several of the approaches mentioned above (compare Hoban, 2005).

The Research Needed

Finally, an additional issue has to be mentioned explaining why it has remained so difficult to bridge the theory–practice gap. For many decades, there has also been a gap between the research carried out on teacher education and the work of teacher educators in teacher education programs. Research on teacher education did reveal the meager impact of programs, but what actually goes on inside teacher education all over the world has remained obscure (Zeichner, 1999). As a result, research has generally been of little practical help to those teacher educators wishing to promote the integration of theory and practice, as Cochran-Smith and Zeichner (2005) observe. Only relatively of late has research into teacher education been carried out from an insider perspective (cf. Anderson and Herr, 1999). Especially, the growth of so-called self-study research by teacher educators (see e.g., Loughran *et al.*, 2004) has helped us learn more about the details of approaches that teacher educators use – which of these are effective and which are not. The educational community can benefit from studies describing what is really happening in preservice and in-service programs in different countries, especially from studies linking program goals with careful analyses of the behavior of teacher educators or cooperative teachers, and the effects on student teachers' learning processes. In such studies, it is important to pay special attention to the contextual influences of practicum schools. Day (1999) is an excellent example of this kind of perspective in in-service contexts. Such studies may clarify that it is possible to link theory and practice in teacher education in such a way that positive effects on graduates can be demonstrated, as Brouwer and Korthagen (2005) have shown. Through such research, chances may increase that teacher education can make a difference, and therefore that in the long run its success may counterbalance the criticism from politicians, school principals, parents, and even the teachers themselves.

Characteristics of Teacher Educators

Teacher educators have diverse backgrounds and working circumstances.

Many teacher educators have been primary or secondary school teachers before becoming teacher educators. They have a bachelor's or master's degree in education or in the subject they teach. There are, however, also subject specialists and specialists in social studies with a master's or PhD degree, without previous teaching experiences, who become teacher educators.

Teacher educators work in schools (school-based teacher educators), colleges and universities. For some it is their primary occupation, while others combine teaching at schools with being a teacher educator, or are professors in a subject area who hold an additional job in teacher education.

The scope of tasks and responsibilities of teacher educators is broad. Teacher educators teach a variety of subjects. They are responsible for the education of future teachers at both the undergraduate and the graduate level. However, that is not their only responsibility. Those who teach the teachers are the linchpins in educational reforms of all kinds, which include taking diversity into account, ensuring that students pass high-stakes tests, developing the documentation required by professional accrediting agencies, complying with stringent new regulations, building genuine partnerships with schools or universities, parents, and other stakeholders, and developing curricula (see Cochran-Smith (2003)). In other words, new developments in education almost always affect teacher education and teacher educators. Beyond that, teacher educators are expected to set a good example for future teachers with regard to implementing these new developments in practice.

Moreover, the shortage of teachers in many countries (Moon, 2007) has led to a variety of teacher education programs that offer shorter and/or more intensive routes

to a diploma. In combination with the growing amount of public attention paid to the quality of teaching and teachers this affects the work of teacher educators and increases the pressure put on them.

In spite of the considerable amount of attention that has been paid to the preparation of teachers in the last decade, scant attention has been directed to the preparation of teacher educators (Cochran-Smith, 2003). Mueller (2003) states that one is simply stamped teacher educator upon accepting a job with that title. The development of expertise and an identity as a teacher educator is a process most teacher educators go through alone (Lunenberg and Hamilton, 2008). There is hardly any educational support for the transition to what is, for almost all novice teacher educators, a second profession. Whether formal education for teacher educators is the solution is the question. Cochran-Smith (2003) states that although a curriculum for becoming a teacher educator is conceivable, it is not likely that it would constitute the major entry point or means of role definition for a majority of teacher educators. Thus, she continues, we need to think of the education of teacher educators as a continuous process, one that is forever. Working together in communities, teacher educators should explore and reconsider assumptions, try to understand the values and practices of families and cultures that are different from their own, and construct a pedagogy that take these differences into account in locally appropriate and culturally sensitive ways. Smith's contribution to this encyclopedia describes the state of the professional development of teacher educators.

With regard to the content of the professional development of teacher educators, Murray (2005) concludes that the priorities for teacher educator induction are: acquiring the pedagogical knowledge and experience appropriate to teaching teachers, enhancing the scholarship teachers acquire through school teaching and developing it through published research outcomes, and becoming research-active. As far as acquiring the pedagogical knowledge and

experience for teaching teachers is concerned, Murray's research shows that most former teachers have to discover in practice what it means to teach adults who are preparing to become teachers. In the following, we focus on the other priorities of becoming a teacher educator: enhancing scholarship and becoming research-active.

Scholarship of Teacher Educators

Traditionally, teacher educators' research has had a low status within the educational research community, a reflection of the low status of teacher educators in colleges and universities around the world. This is due in part to the diversity of teacher educators, their knowledge of and skills for research, and their level of involvement in teacher education. Most teachers do not carry out research as part of their job. Therefore, their research knowledge and skills are often either rusty or at the level of an undergraduate student. A substantial number of them become teacher educators without research being part of their job description. Professors of teacher education often situate their teaching in teacher education and their research in another (subject) field, not in teacher education. Knowles and Cole (1995) described a vivid example, explaining how they almost developed split personalities. In their teacher education practices, they worked with views of knowledge as being context-bound, personal, and dynamic. In their research work, however, they had to show their faith in the traditional means of knowledge growth, which almost always implied a certain degree of distance between the author and the object of research, a distance that could be well accounted for with the aid of the then-dominant research methodology. Beyond this, Cochran-Smith (2003) warns that many teacher educators (like other teachers) simply do not have sufficient time to act as researchers in their own practice because they are often part-time, temporary, or school-based personnel, and so on.

This situation, however, is changing. Katz and Coleman (2005) found that there is a global trend toward academization in teacher education. More often, teacher educators are expected to be both excellent teachers of teachers and respected researchers. As a consequence, more and more novice teacher educators are expected to conduct and publish research to get tenure.

The growing emphasis on teacher educators' research is in line with the growing emphasis on having students and student teachers perform research in schools and in teacher education institutions, respectively. Thus, teacher educators must not only become experts in conducting research, but are also expected to guide their student teachers' research and to teach their student teachers how, in turn, they can guide research by their pupils. This is no small challenge, as the support and coaching the novice teacher

educators receive as they strive to become researchers is, generally speaking, still minimal to nonexistent.

Nevertheless, there is a significant growth in teacher educators' research. The birth of self-study research at the beginning of the 1990s was an enormous stimulant. Zeichner (1999) states that it was probably the single most significant development ever in the field of teacher education research. The self-studies of teacher educators' own practices offer a way to address the contradictions between teaching and research that professors experience (Loughran *et al.*, 2004). As previously mentioned, traditionally the teacher educator's main task was teaching and if research was involved, the focus was almost always outside teacher education. Without question, the idea that teacher educators' own practices could be the object of research has been an important factor in promoting self-study research. Self-study research carried out by teacher educators focuses on their own teaching and academic practices.

Zeichner (1999) emphasizes that self-study appears to be a productive way for teacher educators to connect the academic task of conducting research with their own professional development and the development of the profession as a whole. In this way, self-study research contributes to further development of the scholarship of teacher educators and fits into the trend of the academization of teacher education. Self-study research also offers novice teacher educators the opportunity to start with small-scale research, focused on questions and problems they encounter in their new teaching education practice. A detailed information about self-study research is discussed elsewhere in this encyclopedia.

Research by Teacher Educators

The emergence of teacher educators' research is embedded in three trends, which in turn are connected with the shortage of teachers and the pressure to improve teacher quality. The first trend is academization, as described above.

The second trend concerns changes in ideas about teaching and teacher education, such as the paradigm shift to the constructivist approach and the increasing school-based education of teachers. The constructivist approach gave rise to the view that knowledge cannot simply be transmitted, but that people construct their own knowledge on the basis of their experiences and that novice teachers, therefore, should be treated as active learners who construct their own understandings. Consequently, it means that the role of the teacher educator had to change congruently with the role of the teacher. In practice this change gave rise to questions and problems to be studied. An interesting example is given by MacKinnon and Scarff-Seater (1997) in their self-study.

The authors agreed that teacher education students needed opportunities for testing, discussing, and comparing various perspectives on teaching. However, in studying their practice they discovered that this point of departure could lead to misunderstandings about theory among students. For example, one of their students wrote that constructivism had taught him that he need not require any knowledge in science in order to teach it, because he could simply allow his students to figure things out for themselves. Based on this study of their own practice, MacKinnon and Scarff-Seater concluded that attention must be paid to the manner in which students learn about constructivism and the way a constructivist perspective is used in teacher education programs.

Because of the shortage of teachers, among other reasons, the amount of learning time student teachers spend at school than at teacher education institutes is increasing. The increasing school-based nature of teacher education has also evoked new research questions; for example, the division of tasks between teacher educators in teacher education institutes and teacher educators who are school-based, and the consequences of this division of tasks for the relationship between theory and practice.

The third trend is the political pressure for standardization in teaching and teacher education. Moon (2007) even states that more policy attention has been given to teacher education in the 1990s than in the 100 years that preceded it. Policymakers want research that provides clear and final answers (Cochran-Smith and Zeichner, 2005). Teacher educators' research counterbalances this trend. Teacher educators realize that a main characteristic of many of their studies is that the problem under investigation develops, shifts, and changes in response to the continual shifts in education. Berry (2004) concludes that teacher educators' efforts to tackle problems of practice rarely result in tidy solutions. Knowledge that is developed through investigations of practice reflects the indeterminate swampy zone of practice described by Schon (1983). In line with Bullough and Pinnegar (2003) one can state that the aim of teacher educators' research is "to provoke, challenge and illuminate rather than confirm and settle" (p. 20).

The currently available research by teacher educators is rooted mainly in North America, Australia/New Zealand, and Western Europe. Israel too has a sound history of research by teacher educators. In Asian and Latin American countries there is a growing recognition for teacher education; however, academic studies by teacher educators are still an exception rather than a rule. In Africa there is still a general scarcity of publications on teacher education and of teacher educators (UNESCO, 2005).

Within the broad range of subjects studied by teacher educators as well as by academics, governmental institutes and educational organizations, some common themes on

which teacher educators' research seems to focus can be identified. These are:

- Learning by students and teachers, such as studies on the perceptions, beliefs, and perspectives of learners, their learning strategies and learning styles, and the role of reflection. Collaborative learning and learning in communities are also studied within this theme. In many studies on new manners of assessment, such as the use of portfolios, teacher educators also focus on students' learning. The studies within this theme are often related to the constructivist approach, as mentioned above.
- The relationship between theory and practice, and between schools and teacher education institutes. Studies on theory and practice focus on the question of how to link theory and practice, and on the role of reflection in this process. Studies on professional development schools and on the role of mentors can also be situated within this theme. With the shift toward school-based teacher education this theme has had even more attention from teacher educators than before.
- Subject-related research. Subject studies are a classic research theme for teacher educators, because these studies can be linked relatively easily with research in other departments. In mathematics especially there is a solid, still-growing knowledge base on learning and teaching mathematics. For this growth, Ball *et al.* (2001) give credit primarily to studies on pedagogical content knowledge that have been carried out since the 1990s. Recently there has been an increase in ethnographic and qualitative studies on learning and teaching languages (Hancock, 2001). This increase seems to be connected, at least in part, with internationalization and the migration of people all over the world. Teachers at all levels confront these changes, and consequently teacher educators have to prepare teachers for them.
- Diversity and ethics. Studies on the influence of gender, race, and socioeconomic background on learning and teaching are on the increase especially in Western countries. Differences in gender, race, and socioeconomic background have an impact on the canonical knowledge about multicultural education (among other topics) that exists and is used in teacher education and teaching. They also affect relationships in education and its hierarchy. There is an increase in teacher educators' autobiographical research on the diversity theme. In contrast, studies by teacher educators on moral issues in their own teacher education classes are still scarce; most studies focus on the role of values in primary or secondary education.
- Pedagogy of teacher education and the role of the teacher educator. These studies focus on how and why to use knowledge in a specific context, on being able to adapt and change, that is, to be responsive to the teaching and learning environment. Self-study research by teacher educators has also increased the number of studies on the

relationship between the teacher educator and the novice teacher, both in terms of personal histories and backgrounds and the consequences for learning and teaching. These studies focus on the crucial role of teacher educators in teacher education and its influence on multicultural education, among other areas. Studies in this field are often based on the European *Bildungs* tradition, in which the link between teaching and learning is the focus point (Van Manen, 1999).

- With the increase in research by teacher educators, the attention given to methods and methodology used in teachers' and teacher educators' research has also grown, especially with regard to inquiry, case studies, action research, narrative studies, and self-study research. One can conclude that the main focus of these studies is on qualitative methods.

Since the past decade, information and communication technology seems no longer to be a theme *an sich* in teacher educators' research. Computers have become a tool, used for example in collaboration, and are studied in this context. In the same sense, the use of video has become a part of studies on pedagogical approaches.

More information about the findings of studies on the fields mentioned here can be found in the diverse entries on teacher education.

Challenges for the Future

As described above, western countries have the lead in teacher educators' research. An overview of teacher educators' research, however, is not available. A systematic overview of research in teacher education is available only in North America. The American Educational Research Association (AERA) panel for studying teacher education, which wrote the overview, explored the contents and boundaries of research on teacher education. In its official summary it stated that education and teacher education pose many kinds of questions, including some that are grounded in moral, ethical, social, philosophical, and ideological concerns. The panel continued by saying that, although these questions can be shaped and understood more fully on the basis of evidence, they cannot be settled by empirical evidence alone (Cochran-Smith and Zeichner, 2005). Therefore, research on teacher education and teacher educators' research is, or should be, aimed at gathering empirical evidence, not only to increase the knowledge base for teaching and teacher education, but also to stimulate the growth of practical wisdom by novice teachers and by teacher educators themselves.

Research on teacher education and especially research by teacher educators is a relatively young field. Most studies conducted by teacher educators are small-scale and predominantly based on qualitative data, such as

narrative data from course assignments, field notes, and transcriptions of classroom observations (Cochran-Smith and Zeichner, 2005). As a result, the growing number of available studies is often not looking at the same thing, or when they are, different methodologies are used. More coherent and longitudinal research on all above-mentioned themes is needed.

There are exceptions, however: the longitudinal study by Furlong *et al.* (2006), for example, on the development of teacher education in the United Kingdom from the early 1990s onward. In the UK, teacher education institutes within higher education are obliged to cooperate with schools, unlike elsewhere in the world. Schools offer teacher education programs without involving teacher education institutes. Furlong and his colleagues concluded that after a period in which schools and teacher education institutes looked for creative ways to work together, national policies and the pressure to solve the shortage of teachers led to a technical, rationalistic approach that flattens complexity and suppresses the epistemological and pedagogical dimensions of teacher education.

Another important finding by the AERA panel is that, until recently, the three layers involved in teacher education (teaching of teacher educators, student teachers learning to teach, and learning by the students of novice teachers) have hardly been studied in connection with each other. However, the first initiatives to do so have now been taken by teacher education institutes in the US. The Teacher Pathways Project, carried out by Stanford University and the University of Albany, is a multiyear study of teachers and teacher preparation programs that follows New York City teachers through their teacher education and careers. It studies – Who they are?, Whether or not they stay in teaching?, and What factors affect the learning of the students they teach? (Boyd *et al.*, 2007). This study is a multidisciplinary project in which well-known teacher educators as well as other specialists have participated. The project explicitly states that one of its important goals is to evaluate current education politics and to provide education policymakers with current, useful data to inform their policy decisions.

The Teachers for a New Era Project is another example of a collaborative study on the three layers of teacher educator impact. It is carried out by 11 partners in the US. The project's starting point is that the quality of the teacher has a profound influence on pupil learning and might even be considered the single-most important factor in student achievement in schools. The focus is on the development of evidence-based programs; the evidence includes attention to gains in pupil learning accomplished under the tutelage of teachers who are graduates of the programs conducted by the participating projects. Like the Pathways Project, this project also aims to have political influence.

An important aspect of both these projects is the attempt to carry out large-scale, multimethod studies without losing

sight of the shifts and changes in the daily practice of education, and by avoiding unproductive standardization.

On a smaller scale, comparable initiatives have been undertaken elsewhere. For example, the program council for educational research of the Netherlands Organization for Scientific Research (NWO/PROO) provides grants for top-level research. It has made one of its main objectives in which the learning and teaching of teaching, and learning by students will be integrated. This offers teacher educators the opportunity to apply for research grants that could make it possible to include their own practice in large-scale studies.

In summary, the development of coherent research programs by teacher educators on diverse themes is the most important challenge for future teacher educators' research. Small-scale studies can progress if theoretical backgrounds and methodological approaches are shared from the beginning of these studies. In addition, larger and more experimental studies are also needed. As Zeichner (2007) states, in order to meet the challenge of developing coherent research programs, collaboration between teacher educators from different institutes and from different countries is necessary. Fortunately, there is a growing international community of teacher educators, one that is building a tradition of working together.

Professional Development of Teacher Educators

P K Smith, University of Bergen, Bergen, Norway

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The purpose of this article is to provide an overview of issues related to professional development of teacher educators. Professional development, as defined in this article, is an internal process in which professionals engage within a formal or informal framework. The process is rooted in critical self-analysis of professional practice, and steps taken to improve current practice are called professional development activities.

Professional development occurs when beliefs and assumptions about the profession change, and as a result, professional practice changes. The latter is related to professional decisions taken prior to action.

This model of action (Figure 1), which is contextually dependent, presents the idea that professional decisions take place not only based on theoretical and practical knowledge, but also based on analysis of the immediate context within a space of professional autonomy, a core value of higher education (Altbach and Lewis, 1995). The volume of space varies with the context, with the personality of the teacher, stage in career, and most of all, with teacher educators' professional confidence. Professional growth takes place when autonomous actions within the autonomous space are improved as a product of learning processes, theoretical as well as experiential.

Koster *et al.* (1996) made the distinction between school- and institution-based teacher educators. School-based teacher educators are experienced teachers who accept students of teaching into their classes during the practicum, whereas institution-based teacher educators are teacher educators teaching in higher education institutions. This article is limited to discussing professional development of institution-based teacher educators.

The first part of the article deals with purposes for teacher educators' professional development activities, the context in which activities take place, including level of formality, if engagement is on an individual basis or within communities of practice and learning. Next, examples of professional development activities are briefly discussed in light of expected constraints.

Purposes of Professional Development

Improving Teacher Education

From the profession's point of view, the main purpose of teacher educators' development is to improve teacher

education at a local and at a national and international level. Loughran (2006) advocates the urgency of developing a pedagogy of teacher education, a shared understanding of teaching teachers from a situational and broader perspective. Creating a pedagogy of teacher education depends on teacher educators being "conscious not only of what they are teaching, but also the manner in which teaching is conducted" (p. 11). Critical reflection is a prerequisite for professional development; however, it is not sufficient if it is carried out in isolation. Professional knowledge needs to be articulated to make it accessible to students of teaching and to other teacher educators. In this manner, a pedagogy of teacher education is developed.

The urgency of relevant and high-quality teacher education is highlighted in the OECD (2005) report titled 'Teachers matter'. The report informs about an aging teaching force in many countries, and teacher education needs to attract competent candidates who, as qualified teachers, will know how to meet the multiple challenges faced in schools undergoing constant change. Teacher educators not only need to stay updated, but they are also expected to be involved in forming educational change. Current and future school teachers take on different roles than the teaching roles they were exposed to as pupils. Currently, they are asked to support pupils in becoming independent and self-directed lifelong learners (OECD, 2005). Students of teaching need to personally experience self-directed learning during teacher education, and teacher educators serve as models (Lunenberg, *et al.*, 2007) for ongoing learning and professional development for students of teaching.

Meeting External Standards

External standards for teacher educators are being developed in various countries, often as a reaction to the wide criticism of teacher education (Apple, 2001; Berliner, 2000; Turley and Nakai, 2000; Nieme, 2002; Koster and Korthagen, 2001). Engaging in and documentation of professional development are among the several standards for teacher educators. The American Association for Teacher Educators (ATE) has developed a set of seven standards, and standard 3 reads as follows: "Master teacher educators inquire into, and reflect on, their own practice and demonstrate commitment to lifelong professional development."

In the list of indicators which elaborate on this standard, teacher educators are required to systematically

Figure 1 Professional decision making. From Smith, K. (2007). Empowering school and university-based teacher educators in their role as assessors of student teachers' teaching practice – a school–university cooperation. *Educational Research and Evaluation* 13(3), 279–293.

plan their professional development, stay updated in terms of theory and practical experiences, and document the process of professional growth for self- and external assessment purposes.

Five competencies are listed as professional standards for Dutch teacher educators, of which the fifth is called “development and personal growth competence” (Koster and Dengerink, 2001, p. 350). As with the American example, Dutch teacher educators are also required to “make their own learning process visible to colleagues and students” (Koster and Dengerink, 2001, p. 350). Smith (2005), in her study of how novice teachers and teacher educators define a “good teacher educator,” found that novice teachers value teacher educators practicing a meta-cognitive approach to teaching by explaining why and how they teach as they do, and teacher educators themselves were found to highly value self-awareness and engagement in professional development as characteristics of “the good teacher educator” (p. 184).

Internal Drive to Learn and Improve

Koster *et al.* (2005) examined what teacher educators themselves thought should be included in the professional profile for teacher educators in various teacher-education settings in the Netherlands. Out of six task areas that teacher educators are expected to master, three are considered necessary for all, the first one reads: “the teacher educator working on his/her own development and that of colleagues (professionalism and well-being)” (p. 165). In terms of competencies, teacher educators are expected to have a “very necessary” competence which was found to be the “communicative and reflective competence” which was broken down into subcompetences; one of which is worded: “being able to evaluate one’s own teaching and make changes accordingly” (Koster *et al.*, 2005, p. 167).

Smith (2003) argues that engaging in professional-development activities and updating professional knowledge is essential not only to ensure the quality of teacher education, but also to maintain enthusiasm and interest in the profession. She refers to the work of Day (1999) who found that teachers, who are professionally challenged, are less likely to leave the profession as result of professional

fatigue, and they seem to be happier in their jobs. Smith claims that there is little reason to believe that teacher educators feel differently.

Strengthening the Professional Status within Higher Education

In the previous section, personal intrinsic motivation for professional development has been briefly discussed; however, there is, to a large extent, also personal extrinsic motivation for professional development of teacher educators.

Documentation of engagement in professional-development activities is frequently required by institutions for tenure, promotion, and to gain a stronger professional status. Nixon (2001) points at a global trend toward academization of teacher education of which formal professional learning outcomes are required in the form of advanced academic degrees and publication of research. In Israel, new teacher education faculty are required to hold a PhD to be given tenure, and experienced teacher educators are requested to obtain a PhD or to go for early retirement (Katz and Coleman, 2005). In the current trend of standardization and academization, there is external pressure on teacher educators who want to strengthen their academic position within the institution by becoming visible researchers, program designers, and holders of PhD degrees to be seen as being actively involved with professional-development activities. The higher the academic rank aspired for, the heavier the focus on research and publication, which seems to lessen the importance of excellence in teaching (Katz and Coleman, 2002; Smith, 2005).

Novice Teacher Educators

Recent research documents the frustrating transition the novice teacher educators go through in the process of shifting from being expert teachers to being novice teacher educators and inexperienced researchers in a context which values research more than teaching (Murray and Male, 2005; Zeichner, 2005; Dinkelman, *et al.*, 2006; Ritter, 2007). Most novice teacher educators lack formal training as teacher educators, they are chosen for the position because they are successful school teachers and school-based teacher educators. The shift from being what Murray and Male (2005) calls first-order practitioners in school to second-order practitioner in an academic institution is often done by accepting the position as teacher educators (Dinkelman *et al.*, 2006) without any special preparation (Zeichner, 2005). The new academic context causes a transformation of professional identity, from being a teacher relating to children to being a teacher educator relating to adults and becoming involved with unfamiliar academic activities (Dinkelman *et al.*, 2006; Ritter, 2007), research

being perceived as most demanding (Murray and Male, 2005; Dinkelman *et al.*, 2006; Zeichner, 2005).

Zeichner (2005) discusses four main professional activities that novice teacher educators are recommended to be involved with: self-study of own practice, active involvement in developing curricula and courses, learning about new school reforms, and constantly keeping updated with professional literature. Engaging in research and publication is a new requirement which causes anxiety and stress to many (Murray and Male, 2005). Systematic self-study and action research are modes of research which support new teacher educators in the unavoidable professional development processes (Zeichner, 2005).

Contexts for Professional Development

Professional development of teacher educators takes place in different contexts, which also dictates the level of formality. Eraut (1994) introduced the terms off-job and on-job learning in professional development processes.

Off-Job Learning

Off-job learning is formal learning which takes place in contexts other than the regular workplace, for example, enrolment in formal studies for advanced degrees.

Another type of off-job professional development activities are formal in-service courses for teacher educators; however, these are, in most settings, rare: "there is often little or no professional development provided for faculty to help them learn how to continually improve their work with novice teachers" (Zeichner, 2005, p. 119).

An exception to this is the Mofet Institute in Israel (Korthagen, 2001; Smith, 2003, 2005), a government-funded independent institution which serves as the center for development activities for the country's teacher educators, novice as well as experienced teacher educators. The Mofet Institute has five main focuses:

- In-service courses of various length and degrees of formality, the longest of which goes over 2 years and certifies teacher educators.
- One-day courses and seminars with well-known professionals in the field, national and international conferences, face-to-face as well as virtual events.
- Research support unit which provides financial support, research guidance, statistical support, and initiates research projects.
- Publication center which is the major publication house for teacher education material in Israel. The center supports authors of books financially and with expert counseling. The only peer-reviewed journal in Hebrew in the field of teacher education is published by Mofet's publishing house.

- Resource and information communication technology (ICT) center which holds a wide range of international literature in paper as well as in electronic form. Many publications are translated into Hebrew.

The Mofet institute provides opportunities for off-job learning which cover a wide range of professional-development activities for teacher educators.

On-Job Learning

On-job learning is learning from practice through reflection, self-study, informal meetings, and networks with colleagues, and in more formal communities of learning. An example of the latter can be found at the University of Bergen, Norway, where all staff members at the Faculty of Psychology are members of research groups, and those involved with teacher education meet regularly to share research ideas, getting feedback on projects with which they are involved, supporting each other when preparing for conference presentations, and reviewing each others' papers before they are sent to professional journals. Teacher educators meet regularly to discuss the university's teacher education program, and recently members of staff have started video-recording their teaching and present the recordings to the staff inviting suggestions for improvement (Smith and Krumsvik, 2007). Time is set off for working and supporting each other research-wise as well as teaching-wise. This is how these teacher educators have interpreted Lave and Wenger's (1991) concept of communities of learning and Wenger's (1998) idea of communities of practice.

A more recent development of on-job learning is work-based learning (WBL). WBL is based on a socioconstructivist view of learning. Learners construct meanings from experiences in a particular context in dialogs with others (Brodie and Irving, 2007). Van Eekelen *et al.* (2005), in their study of teacher learning, revealed that learning in interaction and learning by doing was reported to be the most important factor in professional development. Billett (2001) defines three key factors in workplace learning: (1) engagement in everyday work tasks, (2) direct guidance from co-workers, and (3) indirect guidance provided by the workplace itself and others in the workplace.

Currently, professional learning is not viewed as an isolated individual journey, but an ongoing process which involves other members of the professional community. Personal growth is still perceived as an individual process; it is the personal beliefs, assumptions, and performances that change. The process, however, is embedded in professional learning within a community of practice.

Professional Development Activities

In this section, some common professional activities for teacher educators are discussed.

Formal Studies for Advanced Academic Degrees

A number of countries have initiated steps to improve the quality of teacher education, example of which is the requirement that teacher educators hold advanced academic degrees, at least master degrees, and in many contexts, also PhDs. Teacher educators also undertake formal studies because they want to do a better job as professionals. However, in many settings, formal studies are traditional and not directly related to teacher educators' work. The studies are theoretically based within a specific discipline or in psychology and do not directly link to the work of teacher educators as practitioners (Zeichner, 2005). Alternative PhD programs or EdD programs with a practitioner focus are introduced in the UK (e.g., University of Bath) as well as in the US (e.g., University of Arizona).

Universities need to offer more programs of a similar kind if teacher educators are required to hold advanced academic degrees relevant to the profession. Lunenberg and Willemse (2006) claim that teacher educators enter the profession for two reasons: "1) they have been good teachers or 2) they were experts in some particular area" (p. 82). The first group is large, and the motivation to engage in further studies is enhanced by offering practically oriented study programs.

Short Courses and Sporadic Lectures

A frequent professional development opportunity is attending lectures of well-known experts. Even though invited experts might provide new insights and trigger reflective processes, the impact of such activities in terms of changing beliefs, attitudes, and practice have been found to be meager (Darling-Hammond, 2006). Dochy (2004) carried out a study with graduate students, which looked at what effect various teaching approaches had on the students' long-term memory, and the results are not surprising:

- lectures: 4.5%,
- reading: 11%,
- audiovisual media: 22%,
- demonstration: 32%,
- group discussion: 56%,
- practical: 75%, and
- teaching the subject to others (peers): 82%.

One might assume that the impact of teacher educators does not differ much to that of graduate students.

Participation in Professional and Conferences

Part of conference participation is indeed listening to lectures, thus getting new insights into current trends within the professional field; however, conference participation

offers additional professional-development opportunities. If teacher educators present papers, a major part of professional learning precedes the conference itself. The research, preparing the presentation, and writing the paper is an intense professional-development activity whose product is presented to a wide audience for comments and feedback. The viability of the outcome of the learning process, the personal knowledge, is tested, and the received feedback feeds into the professional development process and takes it forward. Moreover, the opportunity to create professional networks beyond one's own institution is an important professional-development activity in itself.

Research

Research and scholarship of teacher educators is discussed in depth in another article in this volume; it is therefore discussed in brief in the current article. Research is a basic requirement of higher education faculty. It is also viewed as one of the most stressful professional-development activities that teacher educators undertake (Murray and Male, 2005; Yogeve and Yogeve, 2006).

Cochran-Smith (2005) argues that research is part of teacher educators' responsibility, and it complements practical aspects of the job. Being consumers of research is essential to being updated with new development in the field. As producers of research by systematically enquiring into the local context, teacher educators are involved with improving practice and contributing to an emerging pedagogy of teacher education (Cochran-Smith, 2005; Loughran, 2006). There is a close link between teacher educators' research activities and practice to the extent that "the boundaries between research and practice often blur, creating opportunities for reflection on and improvement of the practice of teacher education" (Borko *et al.*, 2007, p. 6). Yogeve and Yogeve (2006) examined differences between the research carried out in Israeli teacher education colleges and that carried out in education departments at the universities. They noticed that there is an emerging distinction of practitioners' research content-wise and that college-based teacher educators conduct more practically oriented research, yet there were no significant differences in terms of research methodology applied. There is a trend "toward action research and other qualitative studies, it nonetheless does not largely depart from the traditional types and methods of research on which university schools of education focus" (Yogeve and Yogeve, 2006, p. 40). The authors explain this by claiming that college teacher educators depend on university supervision, and that there is not yet a solid research foundation and culture within colleges of teacher education.

The positive professional-development opportunities related to research enjoy a wide consensus in the literature on teacher education (Yogeve and Yogeve, 2003;

Zeichner, 2007; Cochran-Smith, 2005; Borko *et al.*, 2007); however, there is also sharp criticism of the quality of research carried out by teacher educators. Cochran-Smith (2005) argues that teacher-education research needs to go beyond local practice and link to general research issues in teacher education (Zeichner, 2007) if the impact of teacher-educator research is to be noticed.

Self-Study

Self-study has become a frequent type of research for teacher educators. "Self-study as a formal approach to research seeks to increase understanding of oneself; teaching; learning; and the development of knowledge about these" (Loughran, 2004, p. 9). It is closely linked to critical self-analysis of professional practice, which is the core of professional development as defined in this article.

Recent publication of self-studies is wide and much of it is published in the journal *Studying Teacher Education* edited by John Loughran and Tom Russell. Self-study has been identified as an individual research journey into personal practice of teacher education today, however, with an increasing pressure of going beyond the self (Cochran-Smith, 2005; Zeichner, 2007; Borko *et al.*, 2007). Loughran, in a recent paper, states that, "the reality is that self-studies are dramatically strengthened by drawing on alternative perspectives and reframing situations, thus data, ideas, and input that necessitate moving beyond oneself" (Loughran, 2007, p. 12). Various egocentric models of reflection were met with similar criticism by supporters of sociocultural learning theories, and the reflective dialog (Kolb, 1998) with a wider audience is today seen as essential for professional development.

Feedback on Teaching

Another dialectical form for professional development essential to teacher educators is feedback on teaching from superiors, colleagues, and students.

Feedback from superiors

Feedback from superiors is usually based on observation followed by a feedback session or an annual appraisal meeting. An additional source of information about the quality of teaching is student responses to formal feedback questionnaires. Feedback meetings with superiors have the potentiality to be forceful triggers for professional development; however, this is not always the case. Poyas and Smith (2007) found that teacher educators are unhappy with the way their work is being assessed. There is a lack of transparency and documentation of how superiors are informed about the quality of the teacher educators' work, a fact to which deans of faculties and heads of departments admitted. If this is the case, there is little substance in superior feedback, and it is not

very useful for professional development purposes, and even less for assessment purposes.

Feedback from colleagues

Peer feedback is found to have a positive impact on learning, and especially research by Filip Dochy and his colleagues on peer feedback in higher education is encouraging (Dochy *et al.*, 1999; Struyven, *et al.*, 2003; among others). The approach of peer feedback as a professional-development activity for teacher educators is less common, yet Smith (2003) strongly advocates it, and it was found to be conducive to professional learning in a self-study of two teacher educators at the University of Bergen reported by Smith and Krumsvik (2007). The main obstacle to collegial feedback is that it is not common and requires a supportive and safe atmosphere within the staff, which removes reluctance to invite colleagues to observe one's teaching and to share critical incidents (Tripp, 1993). Reflective dialogs with peers who share knowledge about the local context provide valuable opportunities for teacher educators' professional development.

Feedback from students

A major problem in evaluating teaching in teacher education is the lack of clarity regarding what tools to use when evaluating quality teaching.

The most common evaluation instrument is student feedback in the form of standardized questionnaires, and whereas such questionnaires collect opinions on certain aspects of teaching, other, not less important, aspects of teacher educators' responsibilities, such as creating knowledge, involvement in educational issues in general, and pursuing professional development, are rarely included. It has been claimed that student questionnaires lack validity due to narrow documentation of teacher educators' responsibilities and work (McKeachie, 1997). Many teacher educators are doubtful as to whether students are capable of evaluating teaching in teacher education and worry that students misuse the trust and the power they have been given (Seldin, 1993).

Thus, formal student feedback based on a standardized questionnaire, according to Smith and Welitzker-Polak (2007), is not found to support teacher educators' professional development. The lack of trust put in formal standardized feedback questionnaires is not only related to the tool itself, but also just as much to the way the collected information is handled. If student feedback is the main source on which managerial decisions are made, the feedback is perceived as stressful and does not encourage professional development. Smith and Welitzker-Polak's study (2007) suggests that teacher educators are not against formal student feedback in itself as long as they are the owners of the information and draw upon it in discussions with colleagues and superiors in a nonthreatening and

supportive atmosphere. Informal student feedback collected by the individual teacher educators has proven to be more conducive to professional growth, mainly because it reduces a commonly held defensive attitude to standardized student feedback (Smith and Welitzker-Polak, 2007).

Portfolios and Professional Development

Portfolio has recently become a widely used tool for documenting professional development (Klenowski *et al.*, 2006; Smith and Tillema, 2006; among others), and there is evidence that it enhances professional development mainly by enabling the professional to take responsibility of and monitor personal professional development, and not leaving it to others. Professional development cannot be forced; the professional has to be open to engage in development activities and to change (Day, 1999). The portfolio is useful in documenting professional growth reflected in learning activities and personal critical analysis (reflection). It is found to be contributing to professional development and be of sustained use when the portfolio is compiled voluntarily and not viewed as compulsory for assessment purposes. However, advantages inherited in voluntary portfolio use are, to a certain extent, reduced by the fact that portfolios are less likely to be maintained when not made compulsory within a formal framework (Smith and Tillema, 2001). Compiling a professional portfolio is time consuming, and time is a major constraint when teacher educators' professional development is concerned.

Constraints

The necessity of professional development of teacher educators is, today, not disputed, yet there are several constraints that reduce the range of development and its impact on teacher educators' professional growth.

Time and Resources

Time availability is, perhaps, the main constraint on professional development. Even though some research reports that new teacher educators feel they have more time for reflection as teacher educators than as school teachers (Dinkelman *et al.*, 2006), other research reveals that a frequent complaint by teacher educators is being short of time (Smith and Tillema, 2006). Korthagen (2000) reports that some American teacher educators work 45 h per week, and the lower the academic rank of the teacher educators, the higher the teaching load becomes, a fact which reduces professional-development opportunities. Professional development time needs to be integrated in the job responsibilities including meeting time for staff development. This is a question of resources, as more

people are needed to share the total workload of teaching, administration, and professional development (research, networking, community learning, etc.).

Support

Lack of support from the immediate workplace environment has also been found to be a constraint to professional development (Smith and Polak-Welitzker, 2007). In a competitive environment, people keep quiet about professional questions and challenges, trying to manage alone for the fear of losing the job, or for missing out on tenure and promotion opportunities. Professional growth lies in critical analysis of successful as well as less successful practice, and it is hampered if the environment is not perceived as supportive and opportunities for reflective dialog are few (Day, 2007).

Confidence and Motivation

Confidence in one's ability to learn, grow, and achieve is closely linked to support from significant others as well as to the motivation to pay the price in terms of time, effort, and frustration inherited in learning (Smith, 2006). There are, as discussed previously in this article, personal and external reasons to engage in professional development, and similarly the motivation is of intrinsic and extrinsic nature. Motivation lies in the personal need to grow and learn; however, external incentives found in a goal-oriented, self-chosen, professional-development plan with clear milestones and increased appreciation by the professional community is likely to affect the process positively. Thus, teacher educators as a profession move from a level of professional expertise to a level of professional scholarship. "To be scholarly is to engage in intellectual inquiry and to bring it to scrutiny for the public arena" (Trigwell, 2007).

Conclusions

The view adopted in this article is that professional development is an integrated part of teacher educators' responsibilities as is made apparent in emerging standards for teacher educators. Reasons for engaging in professional development vary; there are intrinsic, personal drives for improvement and continuous learning, as well as external demands by institutions and by policy- and decision-making bodies.

Professional development causes changes in personal beliefs, assumptions, and performance within an autonomous professional space where decisions are taken. It is the individual person that grows. However, the activities are fertilized by dialogs with the immediate and wider professional community, the underlying theory is socio-cultural in which communities of learning and of practice

enhance the individual as well as the collective learning process and contribute to improved outcomes of learning.

Strategies for professional development reflect the personality of the individual, the context, and external goals. They all require, however, resources such as time, effort, and support by colleagues and management, all of which also form constraints on teacher educators' professional learning. Developing regional and national resourceful professional development centers for teacher educators might be a future way to challenge some of the constraints.

This topic – professional development of teacher educators – is wide and enjoys an increasing attention of researchers and educators. The intention of the current article has been to discuss the most salient characteristics of the topic in brief with a humble acknowledgment that relevant issues and informative research have not been included.

Self-Study by Teacher Educators

T Russell, Queen's University, Kingston, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Self-study by teacher educators is a relatively recent research activity, becoming a named area within the field of teacher education research in 1993 when a special interest group was formed within the American Educational Research Association (AERA). The group's name, Self-Study of Teacher Education Practices (S-STEP), does little to reveal what self-study is, and the goal of this article is to describe self-study, explain why it is significant within teacher education research, illustrate how self-study is carried out, and summarize some of the influence that self-study can generate. A growing self-study literature of conference proceedings, edited book collections, and refereed journal papers led to publication, in 2004, of the *International Handbook of Self-Study of Teaching and Teacher Education Practices* (Loughran *et al.*, 2004), which is now the most definitive reference on self-study by teacher educators. To introduce the context in which self-study research is situated, it is helpful to begin with a recent perspective on the fundamental problems faced by those who work in teacher education.

Self-Study as a Response to the Challenges of Learning to Teach

The significance of self-study as a relatively recent development in teaching and teacher education becomes clearer against the backdrop of the broad context in which teacher educators work. Darling-Hammond (2006) describes three fundamental problems that represent significant challenges to the work done by teacher educators in preservice programs of teacher preparation. These problems have been faced by teacher educators for decades, implicitly if not explicitly.

1. The problem of the apprenticeship of observation: "Learning to teach requires new teachers to understand teaching in ways quite different from their own experience as students" (p. 35).
2. The problem of enactment: "Learning to teach requires that new teachers not only learn to 'think like a teacher' but also to 'act like a teacher'" (p. 35).
3. The problem of complexity: "Learning to teach requires new teachers to understand and respond to the dense and multifaceted nature of the classroom" (p. 35).

The first problem, concerning the apprenticeship of observation, is not just intriguing; it is rarely addressed explicitly in planning and enacting a preservice teacher education program. "A significant challenge teachers face is that they enter teaching having already had years of experience in schools" (p. 35). Darling-Hammond quotes from a classic sociological analysis of teaching in which Lortie observes that all students, including those in preservice teacher education programs, typically lack a great deal of information about why teachers act as they do:

They are not privy to the teacher's private intentions and personal reflections on classroom events. Students rarely participate in selecting goals, making preparations or postmortem analysis. Thus they are not pressed to place the teacher's actions in a pedagogically oriented framework. (Lortie, 1975, p. 62)

Even when pressed, many teacher candidates find it difficult to describe how and why they went about selecting goals and making preparations for their teaching, and then analyzing the effects of their teaching. As a case in point, preservice candidates may seem to understand what we refer to as reflection, but they are often challenged when trying to analyze and develop new frames for what they are doing in the practicum classroom.

The innovative teaching approaches that teacher educators urge prospective teachers to consider and that they believe could improve what happens in schools have emerged from and are supported by the extensive research over the last 40 years on how people learn. Research tells us that people learn best when they are active, challenged, and engaged. Research reminds us that all students come to us with prior knowledge in the subject area. The largely invisible apprenticeship of observation generates the prior knowledge and beliefs that our candidates bring with them, but teacher educators are not necessarily adept at recognizing, exposing, and responding to those beliefs and adapting their teaching accordingly.

If prospective teachers consider themselves to be blank slates or if they are treated as such, they are unlikely to see teaching in new ways that help them to understand and cope with the first years of teaching. They may also be less likely to go on to become the teachers that they and their teacher educators hope they will become. The problem of the apprenticeship of observation spills over into the problem of enactment. "Learning how to think and act in

ways that achieve one's intentions is difficult, particularly if knowledge is embedded in the practice itself." Much information "best emerges in the actual work of teaching—and guides the planning and instruction that follows" (Darling-Hammond, 2006, p. 37). "Novices bring their own frames of reference to the ideas they encounter in teacher education; these may be incompatible with the approaches they are learning about in their coursework and clinical work" (p. 38).

To illustrate the problem of complexity, Darling-Hammond cites the work of Lampert (2001) and extracts these four elements of the problem (Darling-Hammond, 2006, p. 39, emphasis in original):

1. *Teaching is never routine.*
2. *Teaching has multiple goals* that must be addressed simultaneously.
3. *Teaching is done in relationship to diverse groups of students.*
4. *Teaching requires multiple kinds of knowledge to be integrated.*

Although teacher educators might feel that they understand the meaning of these propositions, it is quite another issue to describe how teacher education courses can help candidates to appreciate the problem of complexity as their teacher educators work to help them prepare for practicum experiences and the first year of teaching. Teacher candidates often expect that they will wear the teaching mantle with ease. Unwittingly, preservice programs may suggest that putting on the teaching mantle is relatively straightforward. Until candidates acknowledge and confront their educational histories as well as the diversity of learners in every classroom and the challenges of creating contexts of productive learning, teacher education will continue to be the poor cousin of university disciplines.

The problems of preservice preparation, induction, and professional development have been documented. The charge of fragmentation and conceptual impoverishment applies across the board. There is no connective tissue holding things together within or across the different phases of learning to teach.

The typical preservice program is a collection of unrelated courses and field experiences. Most induction programs have no curriculum, and mentoring is a highly individualistic process. Professional development consists of discrete and disconnected events. Nor do we have anything that resembles a coordinated system. Universities regard preservice preparation as their purview. Schools take responsibility for new teacher induction. Professional development is everybody's and nobody's responsibility. (Feiman-Nemser, 2001, p. 1049)

One broad conclusion that can be drawn from these researchers is that teacher education is far more complex than it has commonly been taken to be, if we consider the

short period of professional preparation relative to other professions and if we consider the lack of explicit attention to the problems of apprenticeship of observation, enactment, and complexity. When self-study of teacher education practices arrived on the landscape of teacher education, it was with a strong sense that teacher educators themselves must look within. We learned from the apprenticeship of observation: "we teach as we were taught" tends to be just as true for teacher educators as it is for teachers. We also must confront the problems of enactment and complexity. One of the very first observations that teacher candidates may make in their education courses involves the teacher educator who uses one teaching method (often transmission-based) to advocate another (often inquiry-based). If teacher educators cannot practice what they preach and enact their own values and understandings, what incentive is present for teacher candidates to attempt to do so? Similarly, Darling-Hammond's four statements about the problem of complexity are just as true for teaching done in preservice programs as they are for teaching done in primary and secondary schools. If teacher educators wish to address the problems of apprenticeship of observation, enactment, and complexity with those they wish to help to learn to teach, they are very unlikely to succeed if they have not considered their own development and current practices from the perspectives provided by those same problems.

What is Self-Study and How Does One Begin?

In the context of teacher education, self-study is research in one's own setting of practice to understand and reduce the gap between the good intentions of teacher educators and the actual learning of preservice teacher candidates. Two related steps are essential:

1. Self-study requires making what Schön (1992) described as a reflective turn, a fundamental change in one's perspective on personal teaching practices.

When we attend to what we know already, appreciating the artistry and wisdom implicit in competent practice, believing that by reflection on that practice we can make some of our tacit knowledge explicit, we take a "reflective turn" that leads us to see students and teachers . . . as participants in a kind of reflective practice, a communicative and self-reflective practice of reciprocal inquiry. (Schön, 1992, p. 123)

2. Self-study requires viewing those learning to teach not as empty vessels to be filled with knowledge they lack but as experienced students with extensive but incomplete and potentially misleading knowledge of

teaching that must be explored and reinterpreted as part of becoming a teacher.

Broadly speaking, self-study begins with discomfort and dissatisfaction with the view that learning to teach is a straightforward matter of learning how to teach by being told and then moving to practicum settings to practice what one has already learned. Self-study becomes a powerful research strategy when a teacher educator is willing to explore the complexities of learning by those who wish to become teachers in the context of exploring simultaneously the complexities of one's own learning to teach. Self-study begins by attending to events, experiences, and interactions that had previously been ignored, not because they were irrelevant but because they were taken for granted and accepted as familiar and unproblematic.

To illustrate the nature of self-study, consider the following personal accounts provided by four teacher educators who contribute regularly to the literature of self-study of teacher education practices (Hamilton *et al.*, 1998). Five years into their self-study research, these individuals each responded to the question of whether self-study research is changing teacher education.

John Loughran focused his early self-study on identifying principles of his own practice as a teacher educator:

I believe that one of the most important shifts in my teaching practice is bound up in the ability . . . to articulate the principles of practice that underpin my teaching. Student-teachers do not learn about teaching by being told about it, nor do they learn about teaching simply by experiencing it. They learn about teaching by being involved in a range of activities and possibilities, through reflection on experience and by being able to question that which they experience and those with whom that experience is associated. (p. 1)

He lists six elements that he has identified by attending closely to the learning of the student teachers he teaches: relationships, trust, independence, purpose, engagement/challenge, and modeling (pp. 1–2).

Mary Lynn Hamilton began her report with the event that triggered her self-study:

Within the first few minutes of my new career . . . , I overheard a young woman say quite passionately that her professors never enacted their beliefs. From her perspective, the university classroom was riddled with inconsistencies. That unknown student inadvertently triggered my deliberate inquiry into my own teaching—in what ways do my actions in the classroom conflict with [my] beliefs? . . . Early in my career as a teacher educator I recognized the importance of aligning beliefs and actions in the classroom. As I did that I saw that teacher evaluations and my own comfort level in the classroom improved. . . . I noticed shifts in my language about teaching and in my students' language about teaching and learning. (p. 2)

Tom Russell's entry into self-study was driven in part by returning to the secondary school classroom after an absence of more than 20 years:

Self-study has enabled me to understand my teaching and my students as never before. When the term "self-study" was gaining attention and interest, I had taken myself back to the secondary school physics classroom to better understand the work I was helping people learn. Now I had a better conceptual framework for viewing both my own development as a teacher and the development of those learning to teach. I also began teaching an M.Ed. course in action research, and through successes and failures, self-study became the key to better understanding. . . .

I can now credit self-study with enabling me to develop the following pedagogical principles that were present in my teaching in 1997–98 but very absent in 1992–93.

- Build on and trust in their extensive early teaching experiences.
- Build a community in my classroom.
- Every class includes a significant experience, with implications for how we teach.
- Gather backtalk [students' comments about the quality of their learning] often and distribute it freely.
- Identify a few central themes, post visual cues to each, and link to them as often as possible.
- Replace lectures with notes on a website; use classroom time for experiences and discussions.
- Encourage and reward self-directed learning.
- At the end of the course, ask students what they think you learned from them. (p. 3)

Vicki LaBoskey wrote that virtually all her research since beginning self-study "has been designed to help me learn about my own teaching. The driving force behind my work has been an effort to improve the ways in which I teach about teaching to prospective and inservice teachers" (p. 4). She gives four examples, and the third illustrates how self-study can influence one's work with colleagues:

The third instance is on a larger scale; it involves a change in program philosophy that resulted from self-studies my colleagues and I did of our individual and combined efforts with regard to our guiding principles. During the 1996–97 academic year, our teacher credential program had been structured around five fundamental principles. Throughout that year we engaged our student teachers in a number of evaluative activities in order to help us determine how well we were doing with regard to these goals. We learned that, despite our emphasis on constructivist learning theory, our student teachers were not as strong as we wanted them to be in the teaching of powerful subject matter knowledge to their students. As a result, we added a sixth guiding principle this year

which had a direct impact on both what we taught and how we taught it. (p. 4)

Additionally, even though self-study is the study of oneself, it is not an activity done on one's own. Loughran and Northfield (1998) explained the rationale for collaboration during self-study:

The learning in self-study is intensely personal, but self-study itself requires collaboration. . . . In this approach, the intensely personal aspects of the study that might otherwise be simply accepted without challenge or scrutiny are able to be professionally and constructively challenged from within the study itself. (p. 14)

There is always a danger that individuals will interpret situations in ways that reinforce existing perceptions. Genuine study of classrooms is associated with a willingness to consider alternate frames of reference, and colleagues are an important source of ideas and support as the teaching and learning are reviewed. (p. 16)

Thus, it is typically both important and highly productive to identify a collaborator for ongoing analysis of one's questions, perspectives, and data during self-study research.

Focal Points of Self-Study Research

The preceding examples illustrate the early efforts of four teacher educators who hold strong commitments to self-study research. In each instance, the trigger was an experience that required better understanding of personal teaching practices in order to improve the quality of learning by those preparing to become teachers. Identifying principles of pedagogical practice is a significant theme in much self-study inquiry. Two of the main focal points for self-study researchers are the improvement of teacher education programs (e.g., Loughran and Russell, 2002) and the fostering of social justice (e.g., Tidwell and Fitzgerald, 2006).

As previously noted, the enterprise of preservice teacher education is unique in several significant respects. No other profession works with individuals who already know so much, strictly by observation, about what experienced teachers do. No other profession works with individuals who have spent so much time talking, usually superficially, about the quality of teaching and their own school learning experiences. Because this knowledge of what teachers do is inferred but never checked, preservice teachers know very little about how teachers think about their work. Perhaps more significantly, teacher education is the only profession that must practice the profession of teaching as it tries to help others develop propositional and experiential knowledge of the profession. When a teacher educator teaches preservice candidates, it is only

too easy to fall into contradictions such as lecturing about the importance of not lecturing. In teacher education, it is impossible to separate how one teaches from what one teaches. It is the high probability of unintended but significant gaps between what we say and what we do as teacher educators that drives many teacher educators to self-study.

Just as when teaching is thought of as transmission of curriculum content to students, when preservice teacher education is conceptualized as transmission of knowledge about teaching from an experienced individual to a beginner, there is little need to listen to what students have to say about their learning experiences. Self-study by teacher educators challenges this perspective directly, and self-study often includes finding ways to listen to and include the voices of those being taught. Cook-Sather (2002) argued well for the importance of listening to students, and breaking out of old assumptions and patterns is an important element of self-study:

Most power relationships have no place for listening and actively do not tolerate it because it is very inconvenient: to really listen means to have to respond. Listening does not always mean doing exactly what we are told, but it does mean being open to the possibility of revision, both of thought and action. At a minimum, it means being willing to negotiate. Old assumptions and patterns of interaction are so well established that even those trying to break out of them must continue to struggle. And understanding that is part of what it means to listen. (p. 8)

Methodology of Self-Study Research

From the perspective of self-study methodology, two documents are particularly significant. The first is Bullough and Pinnegar's (2001) paper on 'Guidelines for quality in autobiographical forms of self-study research'. The prominence of this journal and the arguments set forth by Bullough and Pinnegar added important legitimacy to self-study methodology. Most self-study research is qualitative rather than quantitative; statistical information can be relevant and helpful, but self-study tends to focus on improving the quality of teaching and that of students' learning, both in individual teacher education classrooms and in teacher education programs.

The second document is LaBoskey's (2004) chapter in the *International Handbook of Self-study of Teaching and Teacher Education Practices* (Loughran *et al.*, 2004). Her chapter summarizes "the epistemological, pedagogical, and moral/ethical/political underpinnings of self-study, which serve as the conceptual framework for the field" (LaBoskey, 2004, p. 817). As such, it is an essential reference and excellent entry point for anyone new to self-study. LaBoskey identifies four central features of self-study research methodology:

“improvement-aimed,” “interactive,” employing “multiple, primarily qualitative methods,” and demanding “that we formalize our work and make it available to our professional community for deliberation, further testing, and judgment” (pp 859–860). LaBoskey’s conclusion offers insights that link the methodology of self-study to its purposes:

The methodology of self-study is well conceptualized, well grounded in epistemological and pedagogical theory, and well justified by interconnected moral, ethical, and political values and ideals. It has clear features that . . . will allow us to proceed with integrity and evaluate with confidence. . . . Those of us in the field need to continue the process by incorporating into our teaching and research practice the understandings and procedures we deem trustworthy enough to risk trying, with appropriate adaptation and assessment, in our own programs with our own students. (p. 860)

Zeichner (2007, p. 37) has argued that self-study has found its place in teacher education research by adding “dignity to the important yet universally undervalued work of those faculty and staff who educate a nation’s teachers.” He has also issued an important challenge to those who engage in self-study research, urging them to focus on how their learning from self-study can contribute to the questions asked generally by teacher educators and policymakers:

The political realities . . . in many countries . . . require that self-study researchers become more engaged with the mainstream of research in teacher education and insert the perspectives and voices of practicing teacher educators more centrally into the policy debates that frame teacher education practice at the local level. (p. 43)

Now that self-study research by teacher educators has developed a significant body of literature and a generally accepted research methodology, it is certainly appropriate for self-study researchers to add their research findings to the broader body of educational research.

Summary

Self-study by teacher educators addresses the long-standing gap between what preservice teacher education programs set out to accomplish and the professional learning actually perceived by those who complete these programs and begin to teach. Those who engage in self-study recognize that learning to teach is more complex than those who enter teacher education programs might imagine. Self-study begins with a willingness to address the familiar gap between goals and realities by gathering data that can challenge and promote rethinking of long-standing assumptions. Principles of pedagogical practice

are often an important issue in self-study research. Improving teacher education practices, at both personal and program levels, and fostering social justice have been significant focal points in much self-study research by teacher educators. The methodology of self-study is now well documented and the field is ready to more directly make contributions to our knowledge and understanding of major issues in preservice teacher education

Arts Teacher Education

L Beudert, University of Arizona, Tucson, AZ, USA

© 2010 Elsevier Ltd. All rights reserved.

This article examines arts teacher education in relation to the following arts disciplines: dance education, drama/theater education (drama and theater are used interchangeably herein), music education, and visual art education, given that it is these art forms that are mostly taught within schools. Our focus is primarily on the preparation of preservice teachers who will eventually work as specialists in a specific arts discipline in primary and secondary schools; however, the preparation of nonspecialist primary teachers, who are required to teach one, or more, of the arts disciplines, are also addressed.

An International Arts Education Landscape

The arts are culturally diverse and relate to humans all over the world. They are fundamental forms of understanding and are part of our lived experiences. Educating about and within the arts involves introducing learners to a range of traditional and innovative forms, such as classical and popular music, film, dance, plays, sculpture, crafts, singing, photography, digital arts, and folk art and dances. The arts not only sustain and reflect cultural traditions and customs, but they also engage and confront sociocultural issues (e.g., sexuality, gender, race, ethnicity, politics, economics, oppression, social justice, the environment, and spirituality) within contemporary societies. In addition, educators, artists, musicians, performers, actors, and dancers respond to the rapid development of the Internet,

and new media and technologies within their artworks, dances, plays, musical compositions, and performances. Furthermore, traditional borders between the various arts are becoming blurred and less distinct, as artists pursue interdisciplinary connections and associations across and within the arts. Alternatively, however, trends toward globalization can lead to the trivialization of the cultural aspects of local arts and customs (e.g., in India, Africa, and Latin America), since many art forms are passed on via cultural traditions and apprenticeships within many indigenous groups.

An education in the arts is a vital component within our lives, and it is central to the human and equal rights of all (Mason, 1999). Nevertheless, how diverse peoples, cultures, societies, and governments view the arts vary, and these viewpoints, in turn, affect the nature and availability of arts education and arts teacher education worldwide.

Unfortunately, the arts in schools do not fare as well as other school subject disciplines. The arts are often perceived as nonacademic, or are considered too costly in terms of resources and time within school curricula; thus, they frequently reside on the peripheries of formal primary, secondary, and even tertiary schooling, despite appeals, worldwide, for their inclusion in education. In some countries (e.g., the Netherlands, Germany, Israel, England, Australia, Canada, New Zealand, Japan, and the United States), children and youth participate in at least one of the arts disciplines, at some point, during their primary and secondary school education. Regrettably

though, in parts of Europe, Africa, the Middle East, Latin America, and Asia, fewer possibilities exist, if at all, for children to be formally educated within the arts.

In many countries (an exception is the United States), specialist arts teachers tend to teach only in secondary schools as primary classroom teachers, with little or no background in the arts, are assigned to teach arts education. In some nations (e.g., the United States) where music and visual art specialists teach at the primary level, foci on testing in the so-called academic subjects (e.g., mathematics, language arts, and science) are a factor in the gradual decline in the number of arts courses taught in schools; and in some countries (e.g., Australia and Norway), interdisciplinary or integrated arts education courses are taught in primary schools, rather than separate courses in one or more of the arts disciplines. Besides, there are fewer dance and drama/theater education programs within primary and secondary schools and tertiary education compared to arts educational programs in music and visual art.

Given the aforesaid, the task of the arts educator within schools is both broad and multifaceted. Thus, arts teacher educators are charged with training arts teachers, primary- and secondary-level arts specialists, and nonspecialist primary teachers, who can (1) understand, negotiate, and manage the complexities of teaching the arts within today's changing and diverse societies; (2) develop curricular, pedagogical, and inquiry approaches and strategies that will allow them to teach their respective arts disciplines authentically, ethically, and meaningfully within schools; (3) maintain and advocate for the inclusion of the arts within curricula and schools; and (4) confront and tackle societal and global indifference to the arts themselves. In addition, arts teacher educators themselves must strive by necessity to be knowledgeable about, and up-to-date within, their particular arts specialty.

Navigating the Arts Teacher Education Landscape

In order to find our way around this vast arts teacher education landscape more clearly, this article focuses on four specific themes within arts teacher education; each of which has its own set of challenges, dilemmas, and strengths. These themes are: (1) the changing nature of arts content knowledge, (2) emerging pedagogical practices within arts teacher education, (3) professional and institutional issues, and (4) what teacher education can learn from arts teacher education. Examples from each of the individual arts education disciplines are interwoven within each theme.

The Changing Nature of Arts Education Content Knowledge

Content knowledge within arts education

In most countries, arts specialists are required to have a strong background (at least a baccalaureate degree) in an arts discipline and/or related subject matter; nonetheless, not all countries (e.g., Greece, Italy, Spain, and Belgium) provide opportunities for preservice professional training. Obviously, the nature of these degrees and the coursework options within them will vary; there is no one single degree or set of mandated courses that future arts teachers are required to complete in their subject disciplines. Some may have studied within traditional universities and colleges that offer distinct arts education degrees in dance, drama/theater, music, or visual art education. Others may have earned a degree primarily in dance, theater, music, or visual art from either a traditional university or college or from a specialized, professional arts institution, such as a college of art or conservatory of music or drama. This latter group of prospective teachers will enter some form of postbaccalaureate or graduate-level teacher education program in order to become qualified to teach. In some nations, preservice arts teachers do hold baccalaureate degrees, but they must take competitive exams before being accepted into teaching (e.g., France) or they must have earned master's degrees before taking teacher education coursework (e.g., Finland).

Given the aforementioned, prospective arts teachers bring to their teacher education coursework a range of differing dance, theatrical, musical or artistic abilities, understandings, and skills. Nonetheless, merely being knowledgeable within an art form or being competent as a musician or dancer does not automatically mean that all artists or performers have the requisite knowledge base to teach others about the arts. For example, prospective dance teachers must not only be experts at dancing, but they must also develop an understanding of choreography, improvisation, dance history, dance criticism, dance forms, esthetics, and issues related to cultural diversity within dance, if they are to be successful dance educators in primary and secondary classrooms. Moreover, in some countries (e.g., in Hong Kong, Finland, and Taiwan), preservice dance teachers are prepared within physical education teacher education programs rather than in programs that specialize in dance education.

In contrast, drama/theater education preservice teachers, who have been introduced to the academic aspects of theater (e.g., plays, playwrights, and theater history) in their tertiary degree studies, will enter preservice drama/theater education programs in which they will be introduced to aspects of creative dramatics, drama in education, educational drama, process drama, or theater in education. Drama/theater education in many primary

and secondary schools is viewed as child-centered and as a means of helping learners develop social skills, such as empathy and caring, although some contemporary drama/theater teacher educators are beginning to argue that both practical and theoretical frameworks must be tackled within drama/theater education programs.

The dichotomy within drama/theater education implies that, at times, the art forms that are taught within primary and secondary schools may not resemble those that are promoted within tertiary degree programs or reflected in contemporary arts practices. In visual art education, for example, many teacher educators are concerned that preservice teachers are able to develop primary and secondary school curricula that enable children and youth to explore contemporary and multicultural issues, themes, and contexts, such as those related to gender, identity, social justice, design, contemporary crafts, community, the environment, and today's media-infused and visual world. All too often, however, the artworks created in schools, particularly primary schools, are devoid of these qualities, and resemble what can be termed child art or school art.

Arts teacher educators must ensure that today's preservice teachers, once they start their teaching careers, do not always replicate the types of arts education practices that they themselves experienced in their own primary and secondary schooling, and so fail to implement contemporary ideas within the field. Furthermore, primary classroom teachers who teach visual art, and the other arts disciplines, do not often have the necessary content background to teach the arts successfully; thus, they must be helped to develop and teach arts curricula that move learners' understandings beyond simplistic concepts and practices.

Balancing local and global knowledge in arts education

Today's arts teacher educators must successfully prepare teachers to work within their local communities, honor the differences of their students, and acknowledge the traditions of local artists and, simultaneously, recognize the sociocultural aspects of the arts in a changing world. Immediate quandaries surface when making decisions about what content knowledge should preservice teachers know within their respective arts disciplines, whose knowledge should they teach, and what roles should new media and technologies play in preservice arts teacher education. These three major tensions are briefly highlighted further:

First, there is the concern that preservice arts teacher education programs in non-Western nations are often associated with Eurocentric practices and colonial models of education. Preservice teachers leave these programs with little preparation and expertise in arts subject matter that reflects the ethnicities, cultures, and identities of their future students. Dance teacher education practices

in Brazil serve as an example. Dance has only become a serious area of study since the 1990s, despite Brazil's long history of dance traditions, which originate from the cultural practices of indigenous peoples, black African slaves, and Portuguese colonizers. Nevertheless, dance education is still mostly taught from Eurocentric, classical, and academic perspectives. Such foci on Western practices are also evident in the other arts education disciplines; thus, many Brazilian teacher educators strongly advocate that preservice arts teachers must be taught about local arts traditions, coupled with knowledge about the informal arts cultures of Brazilian children and youth.

Second, local communities are changing in many parts of the world, especially in the West, partly due to immigration patterns and shifting demographics. For example, within some European countries, arts teacher educators are faced with the challenge of preparing teachers to teach students from families of recent immigrants and refugees. In many European countries, this challenge is exacerbated further when national educational policies and school curricula frequently emphasize teaching about a country's own specific culture, rather than curricula that relate to the multicultural backgrounds of these displaced children and youth.

Third, in today's world of mP3 players, iPods, mobile phones, podcasting, and Internet sites, such as YouTube, the retrieval of music, videos, performances, and visual data from the Internet is accessible in many continents. Thus, arts teacher educators must help preservice teachers understand the curricular and pedagogical benefits and problems associated with these technologies within arts education. In visual art education, for instance, inquiries into digital technology, advertising, cyberspace, and mass media are becoming prominent, because some teacher educators recognize the potential of these technologies for promoting intercultural understanding, along with exploring contemporary and ethical issues related to analyzing, exploring, and deconstructing media and visual culture.

The issues outlined above suggest that arts teacher education faculty members face serious challenges in terms of what they should teach and advocate within their courses and research. Fundamentally, arts teacher educators cannot help future arts teachers learn all there is to know, for as African music teacher educator, Oponelo (2000) argues, teachers cannot adequately be prepared in both Western and local African musical traditions. Mason (1999) points out that the traditional arts should not succumb to the trends, unpredictability, and uniformity of globalization, whereas other arts teacher educators believe that the integration of new technologies are inevitable within primary, secondary, and tertiary arts education. Tensions clearly exist in balancing local and global knowledge within arts teacher education.

Emerging Pedagogical Practices and Inquiries in Arts Teacher Education

Arts teacher education: Pedagogy and practice

Preservice arts teachers must develop an understanding of the interrelationships of arts-based content with successful and authentic pedagogical methods that can transform this content meaningfully within classroom contexts. For example, performance is central to music, yet preservice music teachers must not just perform music, instead they are obliged to identify with appropriate pedagogical methods intrinsic to helping their students learn to play, understand, and appreciate music.

Preservice teacher education coursework and field and practicum experiences within school settings introduce teacher candidates to various pedagogical methods within their respective arts disciplines. An array of teaching and learning practices is threaded throughout arts teacher education. Most teacher educators adopt approaches such as traditional lecturing and demonstrations, cooperative and group learning, and one-on-one tutoring. Others teach (1) using various technologies, such as television and online distance learning; and (2) employing feminist pedagogical approaches, which they believe serve as models for facilitating collaborative learning and student construction of knowledge within the preservice classroom. Still others advocate for the development and modeling of pedagogies intrinsic to the arts that they teach.

Refashioning preservice arts teachers' beliefs

Preservice teachers must not only perceive themselves as change-agents for the arts within schools, thereby transforming, enriching, and expanding the lives of their students through the arts, but they must also acknowledge that, as life educators (Nieto, 2007), they must seek change within themselves and so question their own assumptions and beliefs about teaching the arts and their students. How then do arts teacher educators help prospective teachers acknowledge the many ways in which learners learn and so teach for deeper understanding, yet at the same time, confront, question, and reflect upon their own pedagogical beliefs? For example, how are preservice teachers encouraged to examine their beliefs about arts content, pedagogy, and learners, together with their assumptions about the arts and others in terms of gender, race, class, culture, sexual orientation, and disabilities? How can they reflect on their own arts background and education, so as not to merely imitate experiences and curricula grounded in their own primary and secondary schooling? For example, preservice teachers' beliefs about the nature of visual art education are important indicators of how capable they will be as future visual art teachers; merely having a strong visual art background does not necessarily mean that preservice teachers will be successful teachers. The following

pedagogical strategies are examples of how some arts teacher educators address these issues in their courses.

In drama/theater teacher education, teacher educators use performance methods that enable preservice teachers to enact their pedagogical, social, and political beliefs in forms of role-playing. As a case in point, Greenwood (2002) drew upon interactive drama/theater education as a cross-cultural tool with preservice Maori educators in remote northern New Zealand. A participatory drama workshop encouraged preservice teachers and instructors to inquire into their educational goals and philosophies, as well as to question their deep-rooted assumptions about the Maori culture. Future teachers experimented with role-playing and acted out scenes. Interactive drama/theater techniques are successful pedagogical strategies that allow for the examination of preservice teachers' beliefs and self-knowledge.

Within dance, drama/theater, and visual art education, the body is viewed as a performing, sensory, and pedagogical tool for exploring cultural constructions of identity, gender, race, social justice, and sexual orientation. Such interactive strategies facilitate preservice teachers' own interrogations of their assumptions about others, which in turn, allow them to take steps toward acknowledging and dispelling issues related to gender-bias, sexism, homophobia, and racism, as well as to reflect upon their future roles within classrooms.

Visual journals (comprising, e.g., drawings, paintings, text, and collages) are constructed in visual art education preservice classrooms. The images within the journals serve as reflective commentaries on preservice teachers' professional development. For instance, the creation of visual or performance metaphors (e.g., works of art, texts, installations, musical compositions, and performance pieces) engages preservice teachers in conceptualizing and representing their teaching beliefs. Preservice teachers in the arts construct traditional portfolios of their experiences within student teaching and courses, or create electronic portfolios (comprising artworks, photographs, videos, performances, curriculum vitae, and teaching statements) that are often placed on Internet websites.

Arts teacher educators encourage the use of autobiographical life histories and the writing of educational memoirs with preservice arts teachers. For instance, teacher educators are responsible for not only helping nonspecialist primary teachers become more confident in teaching the arts, but they must also provide ways in which they can contemplate their reluctance to teach the arts. If primary classroom teachers, for instance, write and reflect on stories about their own prior arts experiences and their own art teachers, they are often more likely to acknowledge the value of teaching and integrating the arts in their classrooms in authentic ways, even if they find teaching them difficult.

Some arts teacher educators utilize reflective journaling practices in order to foster the growth of preservice teachers as caring, ethical, and committed professionals. Reflective journaling allows preservice teachers to intentionally evaluate their beliefs about the arts, as well their attitudes and beliefs about learners. Additionally, arts teacher educators ask preservice teachers to examine written case studies about arts teaching. By reading and analyzing these case studies, preservice teachers can explore and recognize sociocultural issues related to teaching within the arts. In addition, preservice teachers write their own narratives and case studies about teaching, especially after observing and working within actual primary- and secondary-school settings. Online blogs and Internet chat rooms can also facilitate ongoing discussions about classroom theories and practices and the nature of arts education.

Professional and Institutional Concerns

An extensive literature review conducted for this article found that arts teacher education programs and practices unfortunately remain underresearched, although several comprehensive syntheses of international arts education research exist. Teacher education research is not central to the research carried out within each of the distinctive arts education fields. Large-scale and worldwide studies have not been completed on this topic. In particular, demographic information and data on arts teacher education programs are notably absent. The following professional and institutional concerns are now briefly examined.

Developing a familiarity with arts teacher educators

As the arts education disciplines shift philosophically and are continually being redefined, it is important to understand whether arts teacher educators themselves are able to accept and adapt to such changes. Today's arts teacher educators face many pressures to prepare preservice arts teachers for a lifetime of work in a very different world to that in which they themselves were educated. Surprisingly, few details exist about their professional and working lives, as they are silent and missing persons in the arts education literature.

In the United States, for example, many arts teacher educators work in small teaching-oriented tertiary institutions, where, because of heavy teaching loads and institutional pressures and commitments, they are not required to, or have insufficient time to conduct research; thus, they contribute little to the published scholarship within arts education. Their intellectual work frequently comprises designing courses, presenting in-service workshops, or working within their own arts disciplines as studio

artists, dancers, performers, and musicians. Those faculty members, who do conduct research, are less inclined to study teacher-education issues, even if they are involved in teacher training, and many seem reluctant to self-identify as arts teacher educators. Moreover, many faculty members responsible for teaching teachers are either employed part-time or are graduate students. In the United Kingdom, teachers in schools take on a large part of arts teacher education.

This lack of research on faculty teacher educators and their programs is worrisome and perplexing because it is difficult to ascertain how current and knowledgeable teacher educators are within their particular disciplines. For instance, what do arts teacher educators teach, and does this content reflect the changes that are taking place within their disciplines? Are they knowledgeable about and/or willing to inquire into and tackle such issues as balancing local and global knowledge, or incorporating advances in new media and technology within their courses? What are their beliefs about the arts and teaching? And how are their beliefs reflected in their pedagogical and intellectual practices? To add to these queries and uncertainties is the notion that a number of arts teacher educators are raising questions about the professional concerns of faculty members (and preservice teachers) who are culturally and/or racially diverse, gay or lesbian, and/or experience disabilities.

Recruiting preservice arts teachers

There is a need to recruit and prepare diverse arts teachers to meet the needs of the changing composition of schools. Teaching within the individual arts disciplines is obviously not an attractive profession to many within the younger generation. In the United States, for instance, there is not only a shortage of arts teachers of color, especially African-American teachers, but there is also a shortage of arts teachers, in general. What is more, there is an increase in the number of teachers who are retiring, and newer teachers are leaving the profession after teaching for only a few years. This state of affairs is exacerbated by the shortage of tertiary arts teacher education programs, especially in Latin America, parts of Europe, and on the African continent.

Given diminishing resources and changing priorities in education, some primary and secondary schools, especially within Canada and the United States, employ visual artists, musicians, dancers, and actors to teach children and youth, rather than qualified arts teachers. These artists usually have little or no pedagogical background or expertise in teaching their art forms, and are often called artists-in-residence or teaching artists. Basically, these artists have not taken any tertiary teacher-education coursework. It is clear that arts teacher education must become involved in preparing these artists in the future.

International alliances

At the 2006 UNESCO World Conference on Arts Education in Portugal, the International Drama/Theater and Education Association (IDEA), the International Society for Music Education (ISME), and the International Society for Education through Art (InSEA) created an alliance within which, they were determined to enlist support for the inclusion of arts education in schools and communities across the globe. This alliance draws on members from 90 countries, and illustrates how international organizations are pivotal forces in advocating for, as well as promoting, arts education and arts teacher education worldwide.

Learning from Arts Teacher Education

Teacher education is about the sharing of a collective body of knowledge about teaching and learning. What then can non-arts teacher educators learn from the arts and arts education? Dance, drama/theater, music, and visual art are fundamental forms of understanding (Eisner, 2002), since they embrace aural, visual, and kinesthetic traditions. Furthermore, knowledge within the arts contributes to the intellectual, emotional, imaginative, moral, sensory, and spiritual development of persons. Critical to a person's development and education as a dancer, musician, performer, or artist is an ability and willingness to take risks, improvise, solve pictorial and spatial problems, communicate, make judgments, collaborate, and work independently.

Exemplars from teaching and learning within arts teacher education can inspire teaching and learning practices within teacher education, in general. Bresler (2005) observes how aspects of musicianship, such as empathy, perceiving, interpreting, and communicating, are present in the intricacy, nuances, and unpredictability of teaching-learning relationships. Marques (2004) suggests that teaching is like choreographing a dance as arts teachers spend time researching and selecting content; these actions require rehearsals, discipline, and patience as an ongoing dialog between theory and practice takes place. Schonman (2005) proposes that teaching is about enactment and is a performing art; as a result, the theatrical provides an alternative means of reconceptualizing and analyzing teaching. Furthermore, arts-based pedagogical and research strategies such as visual portfolios, photographic and video documentation, performances, and visual and autobiographical narratives can assist in revealing the contextual nature of primary, secondary, and tertiary classrooms more fully.

Goodson (2007) notes that increasing globalization and knowledge-based economies place additional demands on schools, as well as adversely affect the "hearts and minds" (p. 137) of teachers as human beings. The qualities truly

needed in today's teachers resemble those qualities embraced, shared, and communicated within and across the arts (Eisner, 2002; Nieto, 2007). Future teachers need to possess many skills in order to be prepared for their multidimensional roles in today's multicultural and complex schools; therefore, preservice arts teachers, on account of their knowledge of the arts and their arts education preparation, may be at a distinct advantage compared to peers in other subject areas.

Conclusion

After reviewing sources for this article, it is clear that challenges and questions linger within the textures and sounds that lace together the fabric of international teacher education within dance, music, drama/theater, and visual art education. This extraordinary fabric is interconnected with copious threads and is simultaneously crafted with diverse multicultural lineages, which, at times, remain invisible within the arts education literature and teacher education as a whole. International arts teacher education must be more vividly portrayed and distinctly heard as teacher educators, practitioners, and preservice teachers advocate for, research, and grapple with the complexities of teaching and learning the arts within and across national borders.

Mathematics Teacher Education

K Krainer, Universität Klagenfurt, Klagenfurt, Austria

S Llinares, Universidad de Alicante, Alicante, Spain

© 2010 Elsevier Ltd. All rights reserved.

Student teachers, teachers, and teacher educators are all regarded as teachers and as lifelong learners. Teachers are seen as active constructors of their knowledge, embedded in a variety of social environments that influence and shape them and, at the same time, are influenced and shaped by them. Therefore, teachers are expected to continuously reflect on their practice and to change it where appropriate. Teacher education is understood as a goal-directed intervention in order to promote teachers' learning, including all formal kinds of teacher preparation and professional development as well as informal (self-organized) activities. Mathematics teacher education (MTE) aims at improving teachers' beliefs, knowledge, and practice and contributes to affective and cognitive growth of the students. It is a challenge to find answers to the questions of where, under what conditions, how, and why mathematics teachers learn, and how important the domain-specific character of mathematics is. The major sources of this article are recent analyses on research in the field of MTE.

Mathematics Teacher Education: A Practical and Emerging Field of Research

In the last 20 years, researchers in mathematics education have increased attention on mathematics teacher education (MTE). This shift is reflected in the emergence of international handbooks. In 1996, the first *International Handbook of Mathematics Education* (Bishop *et al.*, 1996) was published. The first *International Handbook of Mathematics Teacher Education* (Wood *et al.*, 2008) has been published in 2008. Till about 1990, MTE was mainly a field of practice (mostly presenting success stories, more or less grounded on the basis of theory and evidence.). Since then it also increasingly became a field of research. In 1998, the *Journal of Mathematics Teacher Education* (JMTE) was launched. This journal marked the beginning of a new era since this was the first international journal focusing genuinely on research in MTE. It was only 4 years earlier that the founding editor of JMTE stressed that "as a profession we had just begun to recognize the significance of conceptual orientations for guiding research on teacher education (Cooney, 1994)." Simultaneously, numerous books and articles on the problems and progress in describing and interpreting learning processes by mathematics

teachers were also published (see e.g., Jaworski *et al.*, 1999; Krainer *et al.*, 1999; Lin and Cooney, 2001; Peter-Koop *et al.*, 2003; Sowder, 2007).

Common Trends in MTE and Related Research

There are three common trends that can be sifted out of the literature on learning in mathematics of student teachers, teachers, and teacher educators over the last 20 years (see Llinares and Krainer, 2006). These three trends refer to the intervention, goals and designs of teacher-education activities, as well as to the research focus on the processes and results of these activities. With regard to two trends, namely (1) teacher educators' and researchers' increasing attention to the social dimension and (2) attention to teachers' reflections, there is sufficient evidence including examples that indicate the variety of corresponding activities. The third trend, namely the increasing attention to the general conditions of teacher education (e.g., time, structure, institutional settings, and human resources), is newer and can be seen as an influence of work done on the practice and research in MTE in other fields, for example, organizational development.

Social Dimension

For a long time, MTE has been seen as the training of individual student teachers and teachers. They were basically regarded as receivers of mathematical and other kinds of knowledge. Teacher education was seen as an intervention process predominated by teacher educators, the (student) teachers were expected to listen and to put the learned into practice. Research was mainly investigating individual teachers' beliefs, knowledge, and practice, in many cases assessing whether these beliefs, knowledge, and practices were regarded as sufficient. When research on mathematics teaching increasingly showed the complexity of this process, at first the role ascribed to mathematics teachers changed. They were, for example, expected to put more emphasis on supporting students' joint construction of meaning and to reflect the didactic contract between the teacher and the students. Teacher educators' reflections on their own practice and voices of experienced teachers increased the demand that

teacher educators themselves should represent a new role model for teachers. Indicators for that movement were the emergence and usage of new theories that go beyond cognitive views on learning. In MTE, several steps toward explaining teachers' learning in theoretical models have been taken. Since teachers' learning is a complex process in which multiple factors intervene, a diversity of models focusing on particular aspects of teachers' learning is more likely to achieve than an overarching theory. Early models were mainly taken or modified from psychology, and later from sociology (e.g., Wenger's communities of practice). On the other hand, various approaches from mathematics educators have been developed (e.g., teaching triad; four dimensions of teachers' professional practice; four analytic domains and mediating processes; epistemic approach to teaching-learning process; and three-layer model). All these models take advantage of approaches and theories developed in other contexts and disciplines, like constructivist theories, organizational theory, or system theory.

Overall, this caused a qualitative shift of attention in practice and research toward putting a greater emphasis on the social dimension in teacher education. Increasingly, papers in teacher education began to refer to school development and some sorts of communities, for example, teacher-inquiry groups, study groups, communities of practice, or networks of critical friends. All these social systems are intended to be a good basis for facilitating joint reflection and to lead to an improvement of practice. For example, a study shows that the formation of site-based professional communities worked well in one school but poorly in the other. The decisive factors, among others, were teachers' (pedagogical content) knowledge and their expectations about students' learning.

The shift to the social dimension is mirrored in research literature. In the conference proceedings of the *Psychology of Mathematics Education* (PME) between the periods 1990–95 and 1996–2001 the percentage of studies that refer to the sociological and sociocultural theories increased from 3% to 10% (see Lerman and Tsatsaroni, 2004). This trend is similar in mathematics education journals. Notions like collaborative learning, organizational learning, sharing knowledge, designing didactic contracts, negotiating norms, systemic thinking, etc., influenced the thinking and writing of mathematics (teacher) educators. To some extent, the focus on collaborative learning, sharing knowledge, etc., has been built both on a certain trust in the ability of teachers to reflect, observe, and argue, and on the conviction that these competencies are central to the development of teachers. Based on these principles, the view of teacher education cannot be confined to activities that aim at individual teacher's growth, it has also be linked to a kind of learning in communities, including more formal kinds of

school development as well as participation in informal networks.

In this context, new information and communication technologies are being used to support both the social interaction among mathematics (student) teachers and the emergence of communities. New technological tools (e.g., video papers and blogs) make it possible to extend the boundaries of the class and can remove the boundaries between preservice education and professional development. New questions arise, for both teacher education as a field of practice and research: How are new forms of discourse and new forms of participation operated? How do they mediate the construction of meaning? How can communities be created and sustained? And how can socialcultural perspectives in teacher education be combined with other approaches?

Teachers' Reflections

Partially connected with the social shift mentioned above, we can see a stronger emphasis on the reflection of teachers as a second trend in MTE. Reflection is increasingly considered a key element in the development of processes required for ongoing learning, since it is a means by which teachers continue learning about teaching and about themselves as professionals. Often teachers are involved in teacher-education activities where they reflect on the mathematical thinking processes of students or on the reflections of their own learning (e.g., in contexts where they do mathematical activities themselves or in discussions about their practice and beliefs). Here, it is assumed that the attitudes, skills, and knowledge (student) teachers need are generated when they treat the knowledge and theory produced by others as generative material (points of reference) for interpretation of mathematics teaching, students' mathematical thinking, and the contextual conditions of teaching.

In addition, teachers' reflection can be used as a key element in investigating the growth of the teachers. For example, a focus in this type of research examines what teachers notice when observing their classes, the interpretations they give of events and the changes they propose in their practice. The findings from these studies reveal that differences in the beginning teachers' reflection were linked to changes in practice.

Other studies investigate the changing views of teachers on the students' learning processes and outcomes. For example, a researcher studied teachers' expectations on how secondary students verify conjectures in geometry. The mathematics teachers tended to underestimate students' reasoning on a four-level scale. However, when the same teachers were demonstrated typical examples of the reasoning of students (thus getting a better feeling for students' reasoning levels), their assessment improved. This shows that theory-based models (here for levels of

students' thinking) can not only be used as research instruments but also as a means to involve teachers in meaningful reflections and discussions.

In general, research reports show that teachers' learning is not only promoted by meaningful activities, but also by reflections on these activities. In many cases, teachers' reflections play a double role: they aim at increasing the teachers' understanding (of mathematics, of students' mathematical thinking, of institutional constraints on teaching, etc.), and at the same time they are used by researchers as means to describe and interpret teachers' learning.

Since about 10 years, increasingly interactive multimedia learning environments were used to support (student) teachers' learning about teaching mathematics and to study their growth when analyzing teaching events. Research instruments influence practice, and practice itself is the place where new instruments are generated. In particular, supporting teachers to write down experiences in a systematic and self-critical way is an intervention toward an investigative attitude which is the entrance card to participation in a research community and culture. Nowadays, the new forms of discourse generated by the currently available communication tools such as video paper, blogs, bulletin boards, and so on, use writing as an instrument for collaborative reflection and as a tool for inquiry. The new type of text generated by these communication tools can be used as an improvable object that favors the generation of a progressive discourse and as one that acts as the focus of collaborative knowledge building. For example, the process of creating a video paper – as a multimedia document that integrates and synchronizes different forms of representation, including text, video, and images, in one single nonlinear cohesive document – supports teacher reflection. The same is true for writing in order to participate in online discussions as a means to notice mathematics teaching. These processes of writing are qualitatively different from simply watching a video from a whole lesson to reflect on one's practice: when mathematics (student) teachers' have to select relevant clips or particular events from a videotaped lesson to discuss, their reflection is fostered by initiating a more analytical process that might not necessarily happen if they had just watched a whole lesson without needing to produce a written text. In this sense, for example, the multimodal character of video papers (combining video and text) enriches reflection and thus also the process of meaning-making and knowledge construction.

In combination with the assumption that teachers are key persons of educational change, it makes sense to regard them as reflective practitioners, researchers, and experts. Recently papers on teacher educators' growth have been written indicating that mathematics teacher educators' learning and their self-reflection is an important issue as well.

General Conditions

In particular, with regard to practicing teachers' learning, a third trend in the research on MTE can be recently observed, namely a stronger awareness of the general conditions on which teachers work (and thus also teacher educators' interventions) is based. Presumably, influenced by the closer look at the social context of teachers' learning and the particular focus on their reflections, researchers get more evidence and thus also look more deeply at the resources and the support that teachers get (or do not get) when they participate in teacher-education activities. Some studies indicate factors concerning mathematics teachers' working conditions that supported or constrained teachers' work. In particular, relationships of mathematics teachers with the school administration and other teachers or the presence of a teacher leader were decisive factors that influenced the development of teachers' professional communities at the school sites. At best, general conditions at the school and at the district level support the formation of teacher communities, and expert teachers out of these initiatives (communities) are respected as teacher leaders and eventually earn official roles in the district. However, in many cases, informal teacher communities are not interconnected with formally appointed groups, committees, and task forces: there exists a gap between a school or district as a designed organization (consisting of formally designated roles and divisions of labor together with official policies, procedures, routines, management systems, organizational units, etc.) and as a lived organization (comprising the groups within which work is actually accomplished together with the interconnections between them).

Consequences for the Field

It is worth taking the three trends seriously and regarding them as the challenges for the future. First, looking at MTE as a field of practice, it makes sense to critically reflect the balances of the individual and the social (dimensions of teaching and learning), of action and reflection (in and on practice), and of internal and external (resources and support); it is equally important to concentrate on the specific challenges of mathematics education, for example, the insufficient image of mathematics and mathematics teaching or the change that new means (e.g., technology) bring to it.

Second, more research is needed in MTE. Many studies on these phenomena so far used qualitative research methods, and it makes sense to go further there in order to generate new explanations and assumptions. It is desirable to use the synergy of teachers' expertise and therefore to engage them in research activities and to support research action, among others, with the goal that some of them might develop deeper interest in research and will enlarge

the scientific community. Most teachers do not read research papers; however, being involved in such projects as mentioned above, bridges the gaps for some teachers. This might be the starting point for cooperative intervention research balancing the development interest (achieving an improvement through the intervention) and the research interest (gaining understanding with regard to the specific case, eventually generating more general scientific knowledge). However, also more external and quantitative research are needed, in particular, looking at the outcomes of different types of teacher education or at longitudinal studies of mathematics teachers' learning and career. In all these cases, large populations are necessary to test relevant hypotheses. International comparative studies such as IEA teacher education and development study in mathematics (TEDS-M; see e.g., Tatto *et al.*, 2007) will certainly bring interesting results and new challenges for teacher education. Similar to studies on student assessment, researchers began to create competence models in order to describe different kinds of knowledge of teachers and to use it in research in mathematics (and science) teacher education. Overall, there is a future challenge to combine qualitative and quantitative research methods and to integrate systematic reflections of teachers into research projects (see Adler *et al.*, 2005).

Third, the fact that mathematics is a major subject at schools and in comparative studies can be taken as a chance to see MTE as a collaborative endeavor of researchers, practitioners, and educational policymakers. For example, as a reaction to weak results in comparative studies like TIMSS and PISA, some countries started nationwide teacher-education initiatives in order to improve the situation. Since teachers and teacher educators are important change-agents of this kind of reform, these initiatives are well advised to take into account the ideas, needs, and wishes of the scientific community and the educational policy, and equally those of teachers and teacher educators, which are nearest to the place where the steps of change are taken and given its concrete form.

Teacher education is best done in safe environments where it is possible for teachers to speak out their fears and problems. Laying blame on teachers' wrong beliefs, insufficient knowledge, and bad practice is not promising until teacher educators and researchers know the general solutions to all particular problems. This is an unreachable and undesirable vision since all sciences including mathematics are socially constructed and principally fallible. However, researchers (in mathematics education) can and should make suggestions that are grounded in theoretical considerations and based on evidence. They should aim at presenting (written, oral, video-based, etc.) starting points for discussions which serve not only new scientific insights, but also new steering knowledge for educational policies and new practice-relevant proposals for teachers and teacher educators.

Music Teacher Education

M W-y Wong, Hong Kong Baptist University, Hong Kong, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

This article introduces various systems of music teacher education in some selected countries and discusses the current challenges for music teacher education.

Music Teachers and Music Teacher Education Systems

There are diverse types of music teachers in the field of music education. Some are employed by schools to teach as specialist music teachers, generalist music teachers, band directors, choir masters, and instrumental teachers; some are employed by music companies or music studios; and some are self-employed as instrumental or music theory teachers for individual students or small groups.

As there are diversities in the types of music teachers, economic development, and social and cultural contexts around the world, there are diverse types of institutionalized music teacher education programs that developed in different parts of the world, ranging from those with no specific preparation at all to postgraduate education at universities. Music teachers who teach in private music studios or music companies usually are proficient musicians, but they are not required to have formal music teacher education or pedagogical training. There are usually some government regulations on the basic requirements of the qualifications of school music teachers. In some countries, basic education for all tends to include completion of high school, and teachers are required to have a university education. In some countries, only senior high school teachers are required to hold university degrees, while primary and junior high school teachers usually hold subdegree qualifications. The following sections describe the formal music teacher education for school music teachers available in selected countries. Further information about music teacher education of these countries can be found in the websites of teacher education institutions and government organizations provided at the end of this article.

Africa

In Africa, structures of music teacher education systems vary from country to country. In South Africa, music teacher education programs are offered by universities and colleges of education. Various kinds of qualifications, such as diplomas, bachelor degrees, and postgraduate degrees are granted to graduates of teacher education

programs with duration ranging from 1–3 years. In the Republic of Botswana, a music teacher education course is only offered at subdegree diploma level by one of the six government-operated colleges of education that trains teachers for schools. Information about music teacher education is lacking in the official websites of governments and universities of other African countries.

Asia

In Asia, music teacher education programs are provided by various education institutions and universities. In Malaysia and some places of the Peoples' Republic of China, music teacher education programs are offered as 3-year nondegree programs for secondary school graduates by colleges of education, normal schools, and conservatories. In Japan, Korea, Philippines, Singapore, and some places of the People's Republic of China, music teacher education programs are offered as 4-year degree programs and 1-year postdegree diplomas by colleges of education, normal universities, and comprehensive universities with music education as specialization. Prospective teachers of these programs have to complete practice teaching in schools. The duration of practice teaching differs between countries, and lasts from 1 month to 1 year.

In some countries, such as Korea, Malaysia, and Singapore, music teacher candidates are selected by their government. The music teacher trainees of Malaysia and Singapore are sponsored by their governments and receive a monthly salary throughout their period of music teacher training, and are assigned to serve in government schools upon completion of the music teacher education programs. In the Philippines, graduates of professional education diploma programs specializing in music education are eligible to take the Licensure Examination for Teachers, which qualifies them to teach in schools.

Europe

According to the European Forum for Music Education and Training (2005), there are various institutions providing music teacher education in the countries of the European Union. These institutions include conservatoires, *musikbochschulen*, *académies de musique*, music departments and education departments in general universities, and teacher training colleges that train music teachers for schools and instrumental teachers and vocal

teachers at undergraduate and postgraduate level. Due to the reforms in European higher education, music teacher education programs have been undergoing changes since 2000. The duration of these programs ranges from 3 to 6 years. Pedagogical subjects are offered to performing music students as well as music teacher education students because most music graduates may teach. Teacher candidates have to complete teaching practice in school. Continuing professional development programs, with the duration ranging from 4 months to 3 years for music teachers, are offered by higher education institutions. At the postgraduate level, higher degrees in music teacher education are also available.

North America

In Canada, music teacher education courses are offered as part of initial teacher education programs which are offered by universities. Professional development programs for in-service teachers are offered by universities as graduate studies, or sponsored by provincial and territorial governments, teacher associations, and school boards when new curriculum or policies are implemented (Connelly and Clandinin, 2004). Teacher re-certification programs are also available for teachers who are new to the province or have left the profession for a period of time and do not have recent teaching experience. The required qualification for music teachers in different provinces varies.

In the United States, colleges and universities offer different models of music teacher education programs. There are 4-year undergraduate degree programs, 5-year integrated degree programs, and 1-year postgraduate degree programs that lead to teacher certification. The requirements of teacher certification for music teachers vary from state to state. In-service professional development programs and higher degrees in music teacher education are also available in some universities (Nierman *et al.*, 2002).

Southern Hemisphere

In Australia, music teacher education programs are offered by universities and colleges at undergraduate and postgraduate level. Teacher candidates have to complete 45–80 days of teaching practice in schools. Three-year and 4-year full-time undergraduate degree programs, 4-year and 5-year full-time double degree programs, and 1-year full-time postgraduate degree programs are available. Graduates of these courses are qualified for registration as specialist music teachers in schools. In-service professional development courses are offered by universities and private institutions.

In New Zealand, music teacher education programs are offered by universities at undergraduate level. Graduates

who study a 4-year full-time bachelor degree in music education with teaching practice in schools are qualified to teach music in schools.

Music Teacher Education Curricula

The components of music teacher education curriculum can be categorized under the headings of methodology and pedagogy of music teaching. According to traditional trends of music teacher training, some music educators regard subject-matter knowledge of music and practical skills of instrumental playing as the most important knowledge and skills that music teachers should possess; while some educators believe that pedagogical skills are more important. However, there is an increasing emphasis on inquiry-based learning and expecting music teachers to develop the ability to conduct classroom research and practice reflective instruction (Leglar and Collay, 2002). Research methods and microteaching have become essential elements in music teacher education programs.

Challenges of Music Teacher Education

Education Reforms

Following the trends of education reforms around the world, the development of teacher education has become a concern in terms of policy and practice. There is a need to restructure teacher education systems, arrange provision required for facilitating teachers to implement change in curriculum, and provide opportunities for professional development of teachers. These concerns apply to music teacher education as well.

Connecting music education with arts education is one of the current trends in curriculum reform. In some countries, music has been submerged in the arts learning area. Music teachers may need to broaden their knowledge in other art forms. Therefore, preservice and in-service music education students should be nurtured with cross-curricular attitude to help them succeed in the music curriculum of the new century (Kimpton, 2005). Music teacher education programs may have to provide more general knowledge on arts subjects to cater to the changes in school music curriculum. Some music teacher educators indicate that music teachers may lack sufficient musical knowledge and skills to teach music if the time allocated for music education is reduced because of adding more arts subjects into music teacher programs (Pascoe *et al.*, 2005). In order to support cross-disciplinary studies and curriculum integration, music teacher education programs have to take the lead to support collaborative works with teachers and teacher educators of other disciplines in widening the worldview of music teacher education candidates, and provide opportunities for students to

experience holistic learning beyond the traditional framework of subject-based curriculum.

Reform in assessment has been coupled with education reform in many countries of the world in recent decades. Many educators have advocated the use of outcome-based assessment which measures learners' success by their individual achievement (Boschee and Baron, 1994), alternative assessment, formative assessment, or assessment for learning that could better reflect students' learning process (Wiggins, 1998; Black *et al.*, 2004). Music educators also advocate the use of diverse types of assessment, and hold positive views about using nontraditional assessment, such as teacher-created assessment rubrics, student-created assessment rubrics, self-assessment, peer assessment, portfolio assessment, and assessment of listening activities to facilitate learning to help students learn better and to assess students' learning processes and learning outcomes (Asmus, 1999; Cantwell and Jeanneret, 2004; Cavner and Gould, 2003; Chiodo, 2001; Eppink, 2002). These changes in music assessment rely more on teacher-constructed assessment. However, the concept of formative assessment or assessment for learning may be rather new to music educators as well as music teacher educators. Therefore, equipping music teacher education students with the knowledge and ability to design and implement assessment reform in music education is going to be one of the major challenges for music teacher education programs (Colwell, 2002).

To foster student's creativity through creative music making in classroom instruction is another common advocacy in curriculum reform. Many music teachers are performers instead of composers. They may not be familiar with creative work in classroom and express hesitation in implementing music-composing activities (Orman, 2002). Therefore, music teacher education programs may need to provide knowledge and skills to help music education students and in-service music teachers to develop their interests, enthusiasm, and confidence in implementing creative music work in the classroom.

Curriculum reform has caused great frustrations to music teachers because of the heavy workload required and the enormous change of curriculum and assessment (Cox, 1999; Fallis, 1999). Since most music teachers are trained musicians before they enter the teaching profession, they may not be aware of the issues in school education and music education. In addition to developing music teachers with an open and innovative mindset to cope with the challenge of dealing with educational changes, it is necessary for music teacher education programs to provide music teacher education students with the opportunities to familiarize and socialize themselves with the reality and expectations of the workplace, and enhance their understanding of the position of music among various disciplines in school education, as well as

strike a healthy balance between their identities as musicians and music teachers.

Professional Partnership

Collaborative professional development partnership is considered to bring about benefit to all parties that are involved: it provides valuable experience for (1) collaborating music teachers to learn about new techniques and materials; (2) music teacher educators to have the opportunity to keep up with the current practice in music classrooms; and (3) music teacher candidates to relate theory and practice in classroom music teaching (Morin, 2000; Conkling and Henry, 2002).

There are various forms of partnerships, such as integrating academic and professional preparation for beginning teachers with professional development schools and partnership programs (Henry, 2001). Collaboration among teachers to offer beginning-teacher induction and mentor programs could provide more support for preservice teachers and beginning teachers so that they feel more confident and prepared (Conway, 2001; Burton, 2004). Building partnership networks for in-service teachers could benefit novice and expert teachers as well as music teacher educators through professional-development workshops and site-based collaborative research (Robbins and Stein, 2005). Artists in residence programs have been a common strategy of partnership program for schools and artistic agencies. Such programs could help music teachers provide a wide range of musical experiences for students because they may not be expert in all kinds of music. Interdisciplinary curriculum is another common strategy for building professional partnerships. Planning and implementing of interdisciplinary curriculum requires music teachers and teachers of other subjects to work collaboratively. However, music teachers may not have the knowledge and experience to administer these collaborative learning programs or work with experts in other disciplines. Therefore, it would be another challenge for music teacher education programs to equip music teacher education students with the necessary experiences in developing collaborative professional partnerships.

Diverse Musical Cultures and World Music

Due to colonialism in the nineteenth century, music of Western cultures has been dominating the school music curriculum in many countries. The advocacies of teaching music with a multicultural approach, a pan-cultural approach, and global perspectives have been discussed among music educators of all levels since the mid-twentieth century (Campbell, 2004; Walker, 1990; Leith-Phillipp, 1995; Reimer, 2002). In the ever-increasingly global society with music of Western culture as the major stream in music

programs and music teacher education programs, music teachers are facing the challenge of broadening students' musical and cultural perspectives through appreciation of non-Western musical styles on the one hand, and the lack of relevant knowledge and resources about non-Western musical styles on the other. Since appreciating music of a culture includes the experiences of listening to the sound and understanding music as one of the ingredients that contribute to culture, it is necessary for music teacher education programs to provide music teacher education students with the experience, knowledge, and skills in guiding students to appreciate different musical cultures around the world.

Mass Media

The younger generations around the world are brought up in an environment with much stimulation from mass media. Developing students' competencies with new media forms could be seen as a way for them to express themselves (Buckingham, 2003) and also a challenge for music educators. Students are more easily attracted by computerized audio-visual equipments such as mobile phones with all kinds of audio-visual recording functions, Wi-fi, iPod, Karaoke, etc. that play popular music promoted by the mass media. Making use of the music from mass media may attract more attention from students and fill up certain culture and generation gaps between music teachers and their students. Music teachers who are educated through traditional music teacher education programs may need to equip themselves with the necessary knowledge and skills so as to guide students to apply musical knowledge and skills in producing creative works in new media forms. It would be a challenge for music teacher education programs to develop music teacher education students' sense of lifelong learning and provide professional development programs for in-service teachers to refresh their knowledge and skills in making use of mass media in music teaching.

Computer Technology

Computer technology has become an indispensable part of peoples' lives in the twenty-first century. The younger generations are increasingly familiar with the application of computer technology, which has been advocated in the school music curriculum under the current education reforms around the world. Computer technology has become a valuable resource for music teachers who wish to broaden the musical experience of students.

The Internet offers a library of references for students to experience a wide variety of music on many websites. Music teachers may use the Internet as an additional method of enhancing and supplementing classroom

music activities (Bauer and Daugherty, 2001). The musical functions of computer technology include the opportunities for exploring and creating music. Music technology could be a way to lower barriers for students to notate musical compositions with traditional notation skills and the need for performing skills (Reese, 1995), and computer-assisted music composition could facilitate students develop their music creativity (Reese and Hickey, 1999). With the use of computer technology, music teachers could apply computer technology to facilitate lesson planning and daily classroom instruction, such as music printing, music sequencing, multimedia authoring, and creating personal homepages with sound files (Walls, 2000), as well as producing interesting audio-visual aids to facilitate students in appreciating music with holistic experiences of human senses. However, research studies found that music teachers might encounter difficulties and change in pedagogical practice when using computer technology in classroom teaching (John, 2005). As computer technology is developing at a speedy pace, incorporating technology training as a part of teacher education curriculum is becoming essential. In order to help music teachers better equip themselves with adequate knowledge and skills in the application of computer technology in music teaching and learning, music teacher education programs should consider providing preservice and in-service music teachers with the knowledge and skills for processing and editing computerized audio and visual files for promoting music appreciation; performing as well as composing activities; developing music teacher education students' interests and ability to explore music resources that are available from the Internet; and applying computer technology in all phases of music production, such as, music creating, recording, editing, mixing, and sharing.

Supply of Music Teachers

Music education in school relies on quantity and quality of teacher supply. Though parents usually have high expectations of music education for their children, the *status quo* of music teacher education may not satisfy their expectation. Comparatively speaking, the monetary returns and the workplace conditions of school music teachers are not as attractive as that of teachers who run private music studios; the poorer living conditions of school music teachers can hardly attract able and talented students to pursue music teacher education and this results in a shortage of music teachers (Asmus, 1999; Wang, 2004; Lee, 2004; Kim, 2001). Many new music teachers never enter the profession after their student-teaching experience and many of them drop out of the profession during their first few years of teaching (Kimpton, 2005). There are many reasons why capable

music students do not enter the teaching profession. Difficult working conditions, low salary, low priority of music education within the school curriculum, and the conflict of dual identities of being a musician and a music teacher could cause job dissatisfaction and occupational stress that result in music teacher attrition (Scheib, 2004; Scheib, 2006). In order to help music teachers lessen their job dissatisfaction and occupational stress, there is a need for preservice music teachers to foster their identity of being a teacher during their university-level education and to convince school administrators to support the professional development of music teachers as musicians as well.

Implications for Music Teacher Education

In response to the challenges mentioned above, music teacher education should develop in the direction of facilitating music education students pursue lifelong learning in the following areas:

- apply computer technology in classroom music instruction;
- reflect on the structures of music education in schools and socialize according to the reality and expectation of the workplace, so as to balance the identities between musician and music teacher;
- develop reform-mindedness to cope with the challenge of educational change in the movement of school curriculum reform;
- design a well-balanced curriculum to develop the musical abilities of students and cater to students' learning needs as well as their holistic growth;
- develop the ability to employ a variety of strategies to evaluate students' learning processes and learning outcomes so as to find directions for future development of a music curriculum; and
- support innovative and collaborative endeavors, such as, collaborating with teachers of other disciplines in providing opportunities for students to experience holistic learning beyond the traditional framework of subject-based curriculum.

Introduction

Research findings from the last 30 years indicate that students, regardless of nationality, have difficulties learning science (Osborne and Dillon, 2008). They harbor misconceptions about science concepts that are resistant to change by traditional teaching methods. They often fail to develop scientific thinking processes and habits of mind. Even worse, it has often been reported that students have a low appreciation of, and negative attitudes toward science. In many countries, they score poorly on standardized tests and choose not to enter pathways to scientific careers. The development and implementation of science education standards, new curriculum materials, and inquiry-based instructional strategies are often regarded as solutions to the problem of poor learning in science. However, the negative trends outlined above continue despite repeated attempts at science curriculum reform in countries around the globe.

At the same time, numerous studies have shown that the science teacher is the most important factor in improving student achievement (Hattie, 2003). Thus, the preparation of new science teachers is crucial to the future of science education. How to prepare high-quality science teachers who can help achieve the goals of science education reform is the topic of this article. The nature of science education has specific implications for the preparation of prospective science teachers. Science teachers need to learn to address students' preconceptions and misconceptions and to use specific conceptual-change strategies. Also, the experimental nature of science urges the use of laboratory work in science classes, which implies the need to develop specific teacher competences related to instructional strategies (e.g., guided inquiry teaching), as well as in the domain of safety issues.

We start this article by discussing what we know about the future teachers of science who enter science teacher preparation programs. Next, we discuss what the literature says about curriculum, instruction, and assessment in science teacher education. We conclude with implications for the continuing education of teachers of science.

A number of important constructs from the teacher education literature frame our thinking about science teacher preparation. First, Shulman's notion of pedagogical content knowledge (PCK) helps us think about what we want prospective science teachers to learn and what we as science teacher educators need to know to effectively

instruct them (Shulman, 1986). Second, a conceptual-change framework helps us attend to the knowledge and beliefs that students have when they enter science teacher preparation programs, and find ways in which science teacher educators can challenge and help students of teaching modify their ideas (Russell and Martin, 2007). Third, and related to the previous point, experiences in classrooms provide the basis for reflection, which drives the professional development of teachers (Schön, 1983).

Prospective Science Teachers' Knowledge and Beliefs

Teacher education programs, which focus exclusively on the preparation of science teachers, almost always aim at teaching science at the secondary level (students aged 12–18). For primary education, the preparation to teach science is normally a relatively small part within a broad curriculum aimed at learning to teach all subjects in the primary grades. In higher education, little, if any, preparation to teach is included in science doctoral programs. Recent views of science teacher education recognize the importance of diagnosing teachers' prior knowledge and beliefs about science teaching and learning as they enter teacher preparation programs and courses. Therefore, in this section, we summarize primarily what we know from research about students in secondary science teacher preparation programs, focusing on their knowledge of science content and the nature of science, their orientations to teaching science, and their emerging knowledge for teaching science (i.e., PCK).

Subject-Matter Knowledge

Research in science teacher education has identified problems concerning the subject-matter knowledge of future teachers, including their understanding of science concepts as well as their views of the nature of science as a discipline. In particular, it appears that prospective secondary science teachers, even those with a more extensive science background, have serious weaknesses in their science content knowledge (e.g., misconceptions about science topics which in many cases are very similar to those of younger students). Although the relationship between science teachers' content knowledge and their teaching practice is contested, there is ample evidence in the

research literature that science teachers with a weak content background tend to avoid certain topics, or apply mainly didactic approaches when teaching these topics, sticking closely to their textbooks and asking lower-level questions (e.g., Hashweh, 1987).

Science teacher educators believe that prospective teachers need to know something about the epistemology of science, or what is called the nature of science. Abd-El-Khalick *et al.* (1998) proposed five aspects of the nature of science that should be addressed in science teacher preparation, namely, that scientific knowledge is: (1) tentative and subject to change; (2) empirically based on and/or derived from observations of the natural world; (3) subjective and/or theory-laden; (4) partly the product of human inference, imagination, and creativity involving the invention of explanations; and (5) embedded in social, cultural, and historical practices. The research on prospective teachers' knowledge of the nature of science has demonstrated inadequate nature of science conceptions and practices. Many researchers have pointed out that prospective science teachers hold naive and positivist conceptions of what science is, and how scientific knowledge is developed, for instance, believing that the substantive content of science is fixed and unchangeable rather than tentative (e.g., Lederman, 1992). This view seems related to the belief that scientific knowledge can be transmitted to learners in a straightforward and nonproblematic way, thus conflicting with the well-accepted constructivist idea that learners actively construct knowledge themselves, based on their previous ideas and experiences.

Orientations toward Teaching Science

Orientations toward teaching science refer to teachers' knowledge and beliefs about the purposes and goals of science education for a specific target group. According to Magnusson *et al.* (1999), these orientations inform teachers' instructional decisions, and therefore, to a large extent, determine teachers' choices of textbooks, instructional strategies, and ways of evaluation. This is probably also true for teachers of other subjects.

Research has pointed out repeatedly that students enter science teacher preparation with specific ideas about teaching and learning science (e.g., Loughran, 2007). These orientations have been developed over many years of experiencing science teaching as learners, from primary school through higher education. Being successful learners of science themselves, they often tend to teach science in the way they were taught. This starting point implies various problems:

- The belief that the way they were taught science should be used as a model for their own teaching, since it worked quite well for them, may stimulate the use of traditional approaches to teaching science (e.g., didactic

or activity-driven; Magnusson *et al.*, 1999), which are problematic when science for all or science for public understanding is an important goal of the curriculum.

- The belief that teaching science is straightforward, and that learning to teach science merely requires to follow a script, conflicts with the notion of teaching as a complex activity (Loughran, 2007), and may seriously hinder the consideration of alternative perspectives (such as conceptual change or guided inquiry).
- Being based on, and intertwined with, experiences over many years, prospective teachers' beliefs appear to be quite stable and do not change easily (Davis, 2004).

Pedagogical Content Knowledge

Following the model of Magnusson *et al.* (1999), we briefly discuss the following elements of PCK from the perspective of future science teachers: (1) knowledge of student learning of science, (2) knowledge of science instructional strategies, (3) knowledge of science curricula, and (4) knowledge of science assessment.

Knowledge of student learning of science

Studies on science teachers' knowledge of students' alternative meanings of science (misconceptions) and their approaches to learning science demonstrate that, not surprisingly, experienced teachers usually have more knowledge in this area than future and beginning teachers. In particular, studies contrasting the knowledge of expert teachers with that of beginning teachers emphasized that the latter are normally unaware of students' learning difficulties, and ignorant of their alternative conceptions (e.g., Akerson *et al.*, 2000).

Knowledge of science instructional strategies

Science instructional strategies, such as inquiry-based, conceptual change, context-based, and problem-based approaches are not very well known to beginning teachers. Moreover, it appears that beginning teachers do not easily adopt these strategies partly because: they conflict with their orientations toward teaching science; partly because they have rarely experienced good models of these strategies; and partly because they are in conflict with the school culture (Adams and Krockover, 1997). Topic-specific strategies, aimed at promoting students' understanding of certain science concepts (e.g., Ohm's law, chemical equilibrium, and homeostasis) can be used effectively only if a science teacher is knowledgeable about the ways students learn and come to understand the respective topics. Since prospective teachers cannot be expected to have this sort of knowledge at the start of their preparation, they tend to follow the strategies available for them (i.e., in science textbooks) in a strict manner (Hashweh, 1987).

Knowledge of science curricula

Few studies have been published on future and beginning science teachers' curricular knowledge. Southerland and Gess-Newsome (1999) found that student teachers of elementary science took their science curriculum as given, without questioning the topics to be taught. In addition, a study by Geddis *et al.* (1993) showed that student teachers in a secondary science program tended to focus on nonessential concepts because they did not know which topics in their curriculum were critical, and how deeply to cover such topics.

Knowledge of science assessment

There is a dearth of studies on future and beginning teachers' knowledge of science assessment. According to our experience, the challenge of science teacher education is to broaden the knowledge of assessment from traditional assessment for grading (e.g., tests and lab reports) to assessment for learning through formative and summative authentic methods. Such methods aim to monitor and assess students' conceptual understanding; students' laboratory, inquiry and modeling skills; and their epistemological beliefs (cf. nature of science).

The above discussion shows that, in the context of science teacher education, many students have knowledge and beliefs that need to be challenged, extended, and elaborated (Loughran, 2007; Russell and Martin, 2007). How this can be done in the course of a science teacher education program is discussed in the following sections.

The Curriculum for Science Teacher Education

The design of curricula for science teacher preparation (both the overall teacher preparation program and science-specific pedagogy courses) is based in large part on values and purposes for science teaching and science teacher education held by science teacher educators. Most programs for science teacher preparation around the world (see Abell, 2000) recognize the importance of subject-matter knowledge, general pedagogical knowledge, and PCK in preparing high-quality science teachers. Thus, these programs include recognizable and common components to build these knowledge bases: liberal arts courses, science content courses, general pedagogy courses (e.g., educational psychology, classroom management, educational history and philosophy), and subject-specific teaching and learning courses (called methods courses in the US and something similar to subject matter for teaching in Europe, e.g., *Fachdidaktik* in Germany). Most programs also value the authority of learning from experience (Russell and Martin, 2007) and thus include significant supervised field experiences in school classrooms. The programs vary widely in terms of the relative

emphasis placed on these components, on program length, and on academic level. In some countries, for example, science teacher education takes place in 2-year colleges, in some places it requires a 4-year university program, and in other places teacher preparation is a fifth year or master's program. Recently, countries suffering from science teacher shortages, such as the US, the UK, and the Netherlands, have seen the advent of postbaccalaureate alternative certification programs that attract mid-career individuals into the teaching profession.

The enactment of these components is influenced by the philosophical orientation of the teacher preparation program. Researchers have proposed different ways to categorize the purposes and goals for science education. For example, Roberts (1988) defined various curriculum emphases in science educations, including providing a solid foundation in science, preparing students for the next grade level, science skills development, and helping students generate everyday explanations. Such classification schemes can help us think about the curriculum of science teacher education as well. For example, science teacher preparation programs of the past focused on preparing teachers as technicians capable of implementing specific strategies (e.g., wait time, cooperative groups). Recent views of science teacher education recognize the importance of challenging future teachers' prior knowledge and beliefs, and helping them see viable alternatives to transmission-oriented science teaching. Russell and Martin (2007) called this orientation to science teacher education "teaching for conceptual change." Science teacher education curricula that follow a conceptual-change orientation are aimed at helping future teachers to reflect on practice and make decisions that are grounded in student learning. Whereas the technical approach to science teacher education, referred to above, often resulted in teachers who strictly followed their textbooks and focused on teaching for the test, recent curricula for science teacher education often aim at preparing science teachers to design and test curricular materials (e.g., Justi and Van Driel, 2005).

Most programs meant to prepare future science teachers include subject-specific pedagogical coursework focused on the teaching and learning of science at particular grade levels. Dependent on the teacher educator's orientation to teaching science teachers (see Abell and Bryan, 1997), these courses may include topics such as:

- how students learn science, including common misconceptions and conceptual change approaches;
- state and national standards and curriculum for teaching science (including the nature of science, personal and societal goals, science habits of mind, and science concepts and principles);
- science instructional strategies and representations for teaching specific science topics (e.g., use of models in

- science, laboratories and laboratory safety, context-based instruction, demonstrations, computer simulations, analogies, science talk, and science writing); and
- assessment in science classrooms.

We conclude that curriculum design for science teacher preparation programs should be deliberate and based on accepted goals and purposes for science teacher education. To accomplish the goals and purposes of science teacher preparation, science teacher educators must have a repertoire of effective instructional strategies. We address this topic in the next section.

Instructional Strategies in Science Teacher Education Programs

Given the gap between the beliefs about science teaching and learning held by individuals who enter science teacher preparation programs and those who design such programs, science teacher educators need strategies to identify and address prospective science teacher beliefs. Davis (2004) reviewed several instructional strategies that might be effective for identifying science teachers' initial knowledge and beliefs, which include the use of narratives, pictorial representations, descriptions of ideal science lessons, metaphors, and concept maps. Science teacher educators also need strategies to promote changes to these ideas. For this purpose, strategies such as discussing cases, engaging in action research or lesson study, and promoting reflection have been successful (Abell *et al.*, 1998; Russell and Martin, 2007). In any case, it is crucial that science teacher educators monitor the extent to which the strategies they apply promote conceptual change and knowledge integration among prospective teachers. Science teacher educators use different strategies depending on their learning goals for prospective teachers. To develop prospective teachers' knowledge of students' learning difficulties and of their alternative conceptions, researchers have demonstrated that effective strategies include (1) observing student learning in classroom situations (both in real classrooms, as with the use of video-vignettes), (2) interviewing students and experienced teachers, (3) analyzing data related to student learning (e.g., transcriptions of classroom discussions, think-aloud protocols, and student paperwork; Geddis, 1993), and (4) studying and discussing relevant research literature in relation to prospective teachers' observations and practical experiences (Van Driel *et al.*, 2002).

Some studies have shown that a better understanding of student misconceptions (e.g., by studying authentic student responses to test questions) may help prospective teachers understand the importance of specific instructional strategies, such as the use of analogies (Geddis, 1993). Veal advocated the use of content-specific vignettes,

consisting of written descriptions of teaching and learning episodes, as an effective strategy to help prospective teachers develop ideas about teaching a specific topic (Veal, 2002). In the context of elementary science teacher education, Appleton (2003) suggested providing prospective teachers with so-called activities that work as a means to increase both their science content knowledge and their confidence to teach science, and also function as a source for developing science PCK.

However, only a few studies report successful attempts to promote science teachers' knowledge and the use of instructional strategies in practice. All these attempts revolve around gaining practical experiences with the instructional strategies under consideration, in particular, the planning and teaching of science lessons incorporating such strategies, followed by reflection by the prospective teachers to make sense of their experiences (Zemba-Saul *et al.*, 2002). De Jong *et al.* (2005) conducted a project with prospective chemistry teachers on the teaching of particle models. First, the participants analyzed their own experiences as learners, followed by going through some chemistry textbooks. The core of the project consisted of planning and teaching a series of lessons aimed at promoting student understanding of particle models, followed by sharing reflections within the group of prospective teachers and their educators. The researchers found that whereas all participants became more aware of student learning difficulties in this area, about half of the sample also gained a better understanding of the possibilities and limitations of the use of specific teaching strategies, focusing on particle models. In the same domain, Justi and Van Driel (2005) took this approach further by providing prospective teachers with examples of potentially useful instructional strategies, and then asking them to conduct an action-research project on the design and teaching of a lesson series focusing on the use of teaching models. This approach, which involved studying the research literature, collecting and analyzing data from their students, contributed to prospective teachers' understanding of the potential and pitfalls of the instructional strategies they had tried out in their project.

In the domain of laboratory work, Clermont *et al.* (1993) focused on the use of chemical demonstrations, applying a workshop format which enabled the participants (i.e., novice chemical demonstrators) with opportunities to practice demonstrations, both with colleagues who gave feedback and with school students. They found that the participants became more aware of the complexities of several demonstrations, how these complexities could hinder student learning, and how to adapt and simplify demonstrations to avoid these problems. The authors concluded that intensive, short-term, skill-oriented workshops may improve teachers' PCK of demonstrations. In a similar design, combining microteaching and field-based practical experiences, Niess (2005) stimulated prospective

science teachers to integrate technology (i.e., real-time data collection devices) in the design of their lessons, leading to the development of what she labeled technology-enhanced PCK.

Concluding this section, we have seen that approaches which promote prospective science teachers' knowledge and beliefs about the teaching and learning of science combine the following characteristics: (1) explicating initial ideas about teaching and learning; (2) analyzing student learning of science; (3) planning and conducting science lessons, either in workshops, or, preferably, in real classrooms; and (4) reflecting and discussing experiences, thus relating activities (1), (2), and (3).

Assessment of Science Teacher Preparation

Assessment of science teacher preparation can take place at various levels. Program-level assessment of science teacher education programs in some countries is governed by program accreditation processes. In the US, for example, the National Science Teachers Association in cooperation with National Council for the Accreditation of Teacher Education (NCATE) specifies standards and benchmarks for programs that outside reviewers use to judge program quality (Gilbert, 1994). Most recently, in order to comply with outside policy agencies and to provide a summative assessment of prospective teacher learning, science teacher education programs often require graduating teachers to synthesize their learning through portfolios or action research projects, including evidence of student performance.

Assessment of science teachers in specific courses can also be accomplished via multiple measures. A plethora of assessment methods can be found in the science teacher knowledge research literature (Abell, 2007). To assess science teacher subject-matter knowledge, researchers have used concept maps, interviews, diagrams, and tests. Similar types of measurements would be applicable to the college science course to assess prospective teachers. To assess PCK, researchers have devised a number of tasks, such as lesson preparation, reflection on video cases, the development of content representations and pedagogical experience repertoires (Loughran *et al.*, 2004), and the use of rubrics to distinguish among different levels of PCK (Taylor and Gess-Newsome, 2007). Each of these types of assessments is designed to both document teacher knowledge development and to help them learn from the assessment itself.

Programs of science teacher preparation also assess prospective teacher learning during field experiences, including student teaching internships. For example, supervisors use observation rating scales to provide formative feedback to prospective teachers as well as

summative evaluations of their performance. Prospective teachers often track their performance through reflective journals and analysis of classroom videos. In these cases, the goal is to help prospective teachers think about student learning and their own practice, and make changes in their practice based on feedback from the assessment.

Assessment in science teacher preparation thus serves several purposes. It can be used to diagnose prospective teachers' initial ideas, to provide formative feedback to guiding learning and instruction, and to provide summative evaluation for grades, program accreditation, and teacher licensure. Very similar to assessment in science classrooms, the best assessment provides a learning experience as well as data on knowledge and performance.

Conclusions and Further Professional Development

Science education, whether it aims at introducing all learners to the main ideas and principles of science or at the training of future scientists, calls for teachers with specific qualifications. To teach science effectively, that is, in a way that promotes students' understanding and abilities, science teachers need a thorough understanding of the ways their students learn science content and skills, and what sort of learning difficulties may occur, and why. Moreover, it is important that science teachers understand what and how science can be interesting or challenging for their students. Closely connected to this understanding, science teachers need to develop a large repertoire of instructional strategies and representations of science content, which they can use in classroom practice in a flexible way so as to accommodate student learning, stimulate interest in science, and anticipate differences between students. Moreover, similar to teachers of other subjects, they need to know and use a repertoire of formative and summative assessment techniques, which goes beyond the traditional and familiar ways of testing. In this article we have demonstrated how science teacher education can contribute to the initial development of the professional knowledge needed to teach science. For a more lengthy discussion, the reader is referred to the 'Further Reading' section. We conclude this article with some remarks about science teachers' further professional development.

Preparing science teachers during initial teacher education is only the first step in their professional development. As newly qualified and beginning teachers, they continue to work toward gaining expertise. In particular, since science knowledge is dynamic, science education is constantly evolving, thus requiring science teachers to be continuously critical of what and how they teach. The challenge for science teacher educators is to help teachers develop into adaptive experts (Bransford *et al.*, 1999), that

is, professionals who have developed a set of important routines, but at the same time, keep looking for new possibilities to improve and adapt their practice, experimenting with new approaches, and so on. In any case, it is important that science educators help science teachers move beyond copying the models from their own education that worked well for them in the past, because those methods likely will not work with many of their students.

Science teacher education is facing a critical time when the need to prepare high-quality science teachers is at a peak. Although we recognize that learning to teach science is a career-long endeavor, we believe that a strong foundation must be laid during the science teacher preparation program. In order to improve science teacher preparation, the field must attend to the preparation of future science teacher educators. Our doctoral programs must develop, in addition to adept researchers, informed and skilled science teacher educators who understand who their students are, how to develop meaningful curriculum and effective instruction, and how to assess the development of science teacher knowledge.

Glossary

Authentic pedagogy – An instructional model that highlights the authenticity of student learning and achievement; it stimulates students to form deep understandings of a topic or discipline and develop new understandings by adopting various inquiry methods, collaborating with others, and addressing real-world public problems.

Citizenship education – A broad field of study with goals to help students respect different cultures, develop the willingness and capability to participate in politics at different levels, cultivate skills to work with others, and examine and address environmental and human right issues in a global context.

Content knowledge – The facts and organizing principles of subject areas.

Culturally relevant pedagogy – An educational perspective with the goal of meeting the academic and social needs of culturally diverse students; it seeks to make school learning meaningful and relevant to children's lives beyond school.

Global citizenship education – A field of study that seeks to balance unity and diversity of peoples and cultures worldwide; it concentrates on the education of students to understand and appreciate different cultures, to think and address problems with global consciousness and compassion, and to collaborate for the common good.

Multicultural education – An area of study with the goals of helping all students to develop knowledge, skills, and attitudes to participate effectively in democratic society and of creating equal educational opportunities for students from diverse racial, ethnic, social-class, and cultural groups.

Pedagogical content knowledge (PCK) – A theoretical perspective for understanding teaching and learning proposed by Lee Shulman and colleagues as part of the Knowledge Growth in Teaching project; PCK is the knowledge formed by subject matter knowledge, pedagogical knowledge, and context knowledge.

General Challenges in Social Studies Teacher Education

As context for understanding the state of current challenges roiling the field, we begin with a very brief tour of some enduring and contemporary problems (e.g., purpose and content of social studies teacher education; competing notions of citizenship; the lack of research in social studies teacher education; and the content versus method debate for preparation courses) faced by social studies educators and teacher educators. Because the problems inherent in social studies teacher education are linked to social studies education in general, our discussion draws upon both fields.

Purpose and Content

First is the issue of purpose. Social studies and history education have historically suffered from multiple goals. Often, social studies is earmarked as the curricular domain responsible for the educating of citizens (although one might argue that educating good citizens is the responsibility of all educators, no matter what is the focus of their subject area). Others have suggested that social studies concerns the teaching of a set of subject areas, which can be narrowly conceived or broad. In the US, for example, there are some who argue for the teaching of history, economics, and geography alone. Others argue for a broader view. For example, the National Council for the Social Studies (NCSS), the leading US organization in the field, lists anthropology, archeology, economics, geography, history, law, philosophy, political science, psychology, religion, and sociology as the core areas of social studies focus, complemented by appropriate content from the humanities, mathematics, and natural sciences. Thus, social studies teacher education similarly faces the challenge of purpose, goals, and objectives. Should the preparation focus on preparing teachers to teach skills for citizenship, disciplinary content, disciplinary skills, an integrated approach, and/or community service? These goals, often competing, complicate the role of the social studies teacher educator.

A related issue is how to teach these disciplines collectively, integrating them as a coherent field of study, while simultaneously preserving the integrity of the various domains. The enormity of this challenge – providing

both breadth and depth in numerous disciplines – can be intimidating and discouraging. The social studies teacher educator faces a related challenge: What liberal and specialized education prepares future teachers to teach a broad sweep of topics that they cannot possibly master in deep ways?

Moreover, the inherently controversial nature of many topics and concepts related to the social studies – for instance, equality, liberty, diversity, war, human rights, racism, or terrorism – can be a lightening rod for often heated debates. Whose history gets told, who benefits from what economic trend, who has what kinds of rights, where boundaries are located, and who has jurisdiction over whom – these are a handful of issues that social studies teachers confront on a regular basis. There are two related special challenges for the social studies teacher educator: First, teacher educators need to recognize that their own students – prospective teachers – will have diverse opinions and views on such topics. Second, those teacher educators need to help prospective teachers become educators who can respect the multiple perspectives of their own students (no matter what the teacher's own perspectives may be), as well as create educational opportunities that might involve surfacing and confronting those differences.

Content Knowledge versus Method/Pedagogy

Second, a contentious area in social studies teacher education is the debate on disciplinary content versus method, or pedagogy. Disciplinary content refers to the facts and organizing principles of subject areas. For the social studies subjects, such as history, geography, and civics, disciplinary content may include significant people, historical events, the Earth and its peoples, and forms of government. Furthermore, disciplinary content also refers to the disciplinary processes or thinking skills. Such processes involve thinking chronologically, interpreting primary documents, creating and reading maps, and making collective decisions. Generally, education students study such content in their prerequisite courses in the individual disciplines prior to their enrollment in education courses. However, research has shown that preservice teachers are often not well prepared in these disciplines. This is not surprising given the fact that most prospective teachers never get too deeply into any one subject area given the breadth of topics they need some familiarity with. As a result, teacher educators in social studies frequently teach content as well. The problem that may arise for the teacher educator is twofold: insufficient course time to teach subject content and insufficient in-depth expertise in all the various disciplines.

Methods courses address the means teachers use to convey knowledge, skills, and values to their students. They may use general strategies, following the guidelines

of authentic pedagogy; complex instruction; controversial public issues; or understanding by design. In their methods courses, preservice teachers are introduced to these general strategies that focus on content standards, assessments, and instructional approaches; or teacher educators may focus on teaching preservice teachers specific instructional strategies, such as inquiry, simulation, concept formation, discussion, and case-based methods. In such methods courses, there is the assumption that preservice teachers have acquired content knowledge in the various disciplines.

Social studies teacher educators in methods courses are directly involved in the content versus method debate when they are confronted with the reality of whether to teach content, method, or a combination of the two. Many social studies teacher educators argue it is impossible to teach one in the absence of the other – that the dichotomy is actually invalid. However, questions remain about the optimal mix of content and method, as well as the proper extent and nature of the content taught. These questions are further complicated by the problem that, as Lee Shulman suggests, in addition to knowing subject-matter content, teacher educators must also know pedagogical content knowledge (PCK), which is the content of competent instruction.

Competing Notions of Citizenship

Third, while many social studies education scholars and organizations consider citizenship training the cornerstone of social studies instruction, they often have competing notions of what citizenship is. One list of the defining characteristics of citizenship was provided by a multinational panel of 182 scholars, practitioners, and policy leaders from 26 countries of the Citizenship Education Policy Study (CEPS). The panel identified what citizenship should mean in the twenty-first century:

- ability to understand, accept, appreciate, and tolerate cultural differences;
- capacity to think in a critical and systematic way;
- willingness and ability to participate in politics at the local, national, and international levels;
- ability to work with others in a cooperative way and to take responsibility for one's roles/duties within society;
- willingness to resolve conflict in a nonviolent manner;
- ability to look at and approach problems as a member of a global society;
- willingness to change one's lifestyle and consumption habits to protect the environment; and
- ability to be sensitive toward and to defend human rights (e.g., rights of women, ethnic minorities).

Although the CEPS panel's list is laudable in intent, the citizenship characteristics it identifies are, nevertheless, very broad and open to multiple (often competing)

interpretations. For example, interpretation of the fourth bullet, the ability to work with others in a cooperative way and to take responsibility for one's roles/duties within society, is vague enough to describe both the passive, law-abiding citizen and the radical, reformer citizen. It is also possible that the CEPS citizenship characteristics may be too idealistic. Depending on geographic, political, and social circumstances, the seventh bullet, the willingness to change one's lifestyle and consumption habits to protect the environment, may be interpreted by many societies as an unrealistic, if not unattainable, virtue.

For teacher educators in social studies, finding an agreed-upon conception of citizenship, at either the national or global level, presents a challenge. Unlike mathematics where the Pythagorean theorem, for example, is the same, context to context, a key goal of social studies education – education for citizenship – varies not only between nations, but also within nations. Some countries refer to the term citizenship as the judicial relationship between citizen and state, whereas in other countries, the term refers to the way citizens interact and coexist with one another.

In recent years, education researchers have focused on citizenship as commitment to community action. Marilynne Boyle-Baise and Carl Grant have traced the evolution of teaching citizenship in the US from the 1970s to the present and have shown how citizenship, which had once been thought of as community participation education, currently is considered service learning. In the earlier understanding, citizenship meant the participation of society in community decision making, but more recently citizenship has adopted the Rawlsian ideals of justice that focus on collective participation in the distribution of community resources as a way of promoting the common good. Both of these notions of citizenship, past and present, are concerned more with societal action than with the acquisition of knowledge.

Other organizations have offered competing interpretations of citizenship that, by contrast, stress knowledge as the key component of citizenship. For example, in 2003, the Fordham Foundation, a Washington, DC research organization influential in educational circles, published *Where Did Social Studies Go Wrong?* This book, in its back-to-the-basics approach to teaching social studies, argues that citizenship studies should focus on the history and civic knowledge and values of Western traditions. Furthermore, the book argues that social studies education (including teacher education) has been hijacked by the so-called forces of political correctness with the result that history study has been watered down, replaced by topics such as multiculturalism, environmental studies, peace studies, and social justice.

However citizenship study in social studies education is defined, research shows that preservice teachers generally have only a vague understanding of the notion of

citizenship. Their struggle with defining and teaching citizenship in their classes may be because of the multiple definitions of citizenship they have learned and because their own experience as participating citizens has been rather limited. For teacher educators in social studies, the challenge to find a responsible and neutral way to instruct preservice teachers in citizenship pedagogy is one of their most difficult challenges.

Moreover, standards concerning the good citizen say nothing about the fact that many citizens of many nations do not want their children to think critically, consider themselves global citizens, protect the environment, or defend human rights. Citizenries are conflicted, and social studies teachers are not well prepared when they enter schools ignorant of the mismatch between the variety of assumptions the public might hold about good citizenship and these normative values. Thus, social studies teacher educators also face the challenge of preparing new teachers to sensitively navigate the idealized norms of schooling and the larger public and community in which that schooling takes place.

Lack of Research on Social Studies Teacher Education

Research on teacher education more generally is limited in scope and method. Research on social studies teacher education suffers from similar problems. A common research model in social studies teacher education at present is the self-study: an investigation of the researcher's own practice undertaken to better understand and improve her/his own teaching. Such case studies on teacher educators' reflective practice are interesting for their description and analysis of the problems, challenges, and successes of the individual teacher educators. However, this research is not easily generalized since it provides no macro-level findings on best practices in teacher education, and there is considerable variability in the quality of that research.

Another area of research on social studies teacher education focuses on the influence of methods courses and field experiences on preservice teachers' beliefs and values, rather than on their acquisition of skills and knowledge. Some studies have found that while there were important connections between students' learning in methods courses and their development of beliefs, preservice teachers still had difficulty implementing the practices learned in the methods courses. Again, this research is similar to much other research concerning teacher education. Samples tend to be modest, instruments tend to be locally developed and not validated, and outcome measures tend to be far removed from measures of student learning.

In summary, contemporary research into social studies teacher education is primarily concerned with

understanding the predispositions of preservice teachers and the effect of methods courses on these beliefs. The research tends to be done by teacher educators who are studying their own programs or practices, and there is very little large-scale or comparative work to draw upon. One argument against this stream of research is that an understanding of preservice teachers' beliefs has little relevance for understanding their teaching approaches; another argument points out that, without evidence of improvement in teachers' practices or student learning, it is difficult to know what insights can be gleaned from the current research.

Trends in Social Studies Teacher Education

Social studies teacher education, like all teacher education, is not a static activity, but changes constantly in response to new trends developed from new research findings and policy mandates concerning schooling and teacher certification or licensure. An awareness and understanding of the current trends in the field is useful in envisioning the development of the field. Three of the most influential trends in social studies teacher education are authentic pedagogy, global citizenship education, and multicultural education/culturally relevant pedagogy (CRP).

Authentic Pedagogy

Authentic pedagogy is an instructional model that sets out three guidelines for curriculum design, instruction, and assessment: (1) construction of knowledge; (2) disciplined inquiry; and (3) value beyond school. In construction of knowledge, students should produce or construct new knowledge (as opposed to reproducing knowledge). In disciplined inquiry, learning should be rooted deeply in a field of knowledge. In value beyond school, learning should have utilitarian or personal value beyond classroom application. Many scholars of social studies teacher education believe strongly in the value of authentic pedagogy as a way to improve learning. Since many disciplines included in social studies are associated with boring pedagogy (e.g., memorizing countries and capitals and dates of wars), proponents of authentic pedagogy work toward teaching social studies in ways that allow students to probe content thoroughly and with application to their lives outside school. This pedagogy is also known as authentic academic achievement.

The NCSS has also taken an active role in advancing more authentic instruction in social studies. The NCSS has identified five key criteria of powerful social studies education: meaningful, integrative, value-based, challenging, and

active. The goal of social studies education that meets these criteria is to help students build a social understanding of the human condition and of their civic responsibility. One professional development program for social studies teachers, produced in partnership with the NCSS, is *Powerful and Authentic Social Studies (PASS)*. This program defines social studies education standards based on both the authentic academic achievement and powerful social studies models. These criteria and standards for social studies teaching and learning reflect educators' commitment in making social studies relevant and intellectually rigorous for students. Many teacher educators in social studies methods courses use these models to evaluate preservice teachers' lesson plans.

However, research shows that generally preservice teachers and in-service teachers do not follow such criteria and standards in their instruction and assessments. Instead, they follow teacher-centered practices that mix lecture with textbook readings and close-ended questioning. Some researchers argue that such traditional social studies teaching, that de-emphasizes standards, denies students instruction that is intellectually rigorous and relevant.

Global Citizenship Education

Global citizenship education (GCE) is the trend that promotes a global dimension to education by seeking to balance unity and diversity of peoples and cultures worldwide. As the world becomes increasingly interconnected through technology, international relations, and human rights projects, educators have begun defining the criteria of a participatory, global citizen. Elizabeth Heilman identifies seven capacities of GCE, including a focus on combining talents to work toward the common good, compassion for others' situations and concern for human rights, and the ability to examine policies and issues critically and ethically. Social studies education, which includes instruction in citizenship, history, and geography, is well positioned to advance this trend.

For the social studies teacher educator, instruction in GCE presents special concerns. Many preservice teachers, as well as in-service teachers (especially those at the elementary level), are often nervous about social and political issues. Some may not feel prepared for, or comfortable with, issues of public concern that are of a controversial or complex nature. They also worry about adverse parental reaction if they make war, religion, race, and so forth the topics of classroom study. In addition, there is a concern that preservice teachers lack the necessary, in-depth knowledge of world geography and history, and of foreign political and economic systems. Furthermore, the global experiences of new social studies teachers are often limited, and that background knowledge and experience might limit their capacity to be the

kinds of teachers GCE needs. Currently, the sensitivity of the issues and the complexity of the instruction make GCE more of an aspiration than an implemented educational trend in social studies teacher education.

Multicultural Education/CRP

Multicultural education is a field of study that generally seeks equality of educational opportunity. CRP seeks teaching strategies that advance this goal. The current trend in multicultural education and CRP is especially significant in social studies education that features culture, human rights, ethnic and social relationships, and issues of race, class, and gender. Thus, social studies teacher educators are concerned with teaching the presentation of multicultural subject content in the classroom and with sensitizing preservice teachers to the needs, interests, and skills of students from diverse backgrounds.

Several scholars of social studies education and multicultural education have set content and practice standards for teachers in this area. Gloria Ladson-Billings, has led critically important research on classroom implementation of relevant teaching strategies based on five criteria of CRP:

1. when students are treated as competent they are likely to demonstrate competence;
2. when teachers provide instructional scaffolding, students can move from what they know to what they need to know;
3. the focus of the classroom must be instructional;
4. real education is about extending students' thinking and abilities; and
5. effective teaching involves in-depth knowledge of both the students and the subject matter.

These criteria not only reflect praiseworthy pedagogical practices, but also reflect the idea that culturally relevant teaching means expecting high-quality work from all students. No distinction is made between the standards set for students from lower socioeconomic backgrounds and those set for students from more privileged backgrounds.

One of the issues of greatest concern in CRP is the importance of recognizing racial and cultural diversity in students. Various scholars and organizations have frequently addressed this issue as it relates to classroom teachers. Teacher educators continually emphasize the importance of connecting school learning to children's lives beyond the school setting, which often means making the curriculum more inclusive of the beliefs and traditions of various cultures and ethnicities. The Multicultural Education Consensus Panel, comprised of eight US scholars of teacher education, proposed 12 essential principles for education and diversity, one of which addresses teacher learning. This principle emphasizes the importance of

professional development programs that instruct teachers in the relationships among ethnic groups and in the ways students' background (race, ethnicity, language, and social class) influence their behavior in schools.

A second issue in multicultural education and CRP is the generally acknowledged cultural divide that often exists between students and their teachers. For example, in the US, many K-12 teachers, especially at the elementary level, are white females from mid- to upper-level socioeconomic backgrounds. Similarly, countries such as France and Sweden, with increasing numbers of ethnic minority immigrants, experience the same separation between teacher and student. Scholars argue that this cultural disjuncture between students and teachers has critical consequences for students' attitudes toward and interest in social studies education. The argument is not that minority teachers are superior as social studies teachers, but that minority children may be more open to learning if taught by people of more similar background.

Summary

Owing, in large part, to the controversy in education around social studies as a course of study that replaces the individual academic disciplines of history and the social sciences, social studies teacher education is also a controversial area. Therefore, the social studies teacher educator faces numerous challenges in preparing preservice teachers for their work in the classroom. Broadly, these challenges relate to the general questions of what and how social studies should be taught. Among the specific challenges that the social studies teacher educator faces are the content versus method debate, the issue of how to define and teach citizenship, and the lack of education research on the pedagogic experiences and problems of teaching social studies.

Social studies teacher education is an evolving field, and today many educational trends influence its development. Standards and criteria for instruction in citizenship and multiculturalism have been proposed; more relevant pedagogy is recommended to replace traditional methods of instruction; and more educational technology in the classroom is available, and its use is encouraged. Each of these trends creates both opportunities and difficulties for social studies teacher education, especially as one considers them together. Meanwhile, there remains a dearth of comprehensive research on social studies teacher education that could inform how and what we teach new teachers in their professional education programs.

With continued experimentation, discussion, and research, social studies teacher education will continue to develop. There are societal and educational issues, challenges, and trends that schools of education and professional development programs will have to deal with as the

practice and theory of teaching teachers to teach evolves. Social studies teacher educators, as much, if not more than other teacher educators, will have to be adaptable, innovative, and committed as they educate preservice teachers for their teaching assignments.

Teacher Education for Elementary Education

K D Brown and G N Carnes, University of South Carolina, Columbia, SC, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Accountability – It denotes efforts to cultivate and control for high-quality instruction, including accreditation, high stakes testing, and credentials.

Accreditation – An evaluation process in which a group of evaluators examines an elementary-teacher preparation program to ensure that it is meeting established standards of quality.

Candidate – An individual admitted to, or enrolled in a teacher-education program to earn his/her first credentials to teach.

Education for all (EFA) – Commitment originally made in Jomtien, Thailand (1990) and renewed in Dakar, Senegal (2000) by over one hundred and fifty governments and an equal number of organizations to provide education for all by 2015.

Effective teacher – Teacher impacts to motivate students to learn specified dispositions, skills, and/or knowledge.

In-service teacher – Educator who has earned certification from a teacher preparation program.

Millennium development goals (MDGs) – Eight goals agreed to by the world's governments and major development organizations. Goal #2 is to achieve universal primary education.

Pedagogical knowledge – General concepts, theoretical insights, and research about effective ways in which one teaches.

Preservice teacher – Designation synonymous with candidate.

Primary – Level of education synonymous with elementary education in some countries.

Universal elementary education (UPE) – Access and completion for both boys and girls of a full course of primary schooling.

The international push to introduce qualified teachers into classrooms and the high frequency of teacher shortages around the world shape the way individual countries and international organizations structure and experiment with the preparation of elementary teachers. Many stakeholders view education, particularly the education of young children, as an important avenue for national development. In developing countries in particular, economic growth, development, and improved living standards often result from the provision of quality education to a country's youngest children. While many

factors influence the quality of education, teacher preparation is arguably the central component. Therefore, the preservice preparation of elementary teachers and the ongoing professional development of in-service teachers merit special attention. The commitment of industrialized countries to education for all (EFA) and the approaching millennium development goal (MDG) of universal primary education (UPE) in every country by 2015 brings renewed global interest and concerns about the appropriate training, quality, and availability of elementary-school teachers.

Elementary education varies around the world. Generally, students in elementary education range between the ages of 6 and 14, encompassing grades 1–8. Estonia certifies elementary teachers to teach in grades 1–6, while Kenya certifies its graduates to teach grades 1–8. Within the US, elementary education often spans grades 1 through 5 or 6, overlapping the grade bands for early childhood and middle school. In some countries, the grade band is more limited, focusing on students whose ages may range from 7 to 12. Just as Cobb found in her international comparison of teacher certifications, diversity in certification bands is not limited to national boundaries. Within a country or region, elementary grade levels vary. For example, some teacher preparation programs within the United States offer a Middle Child certification for individuals who wish to teach in grades 4–8. Other US states certify their graduates to teach grades 2–5, K–8, or preschool through 6th grade.

While great diversity in age and grade range continues to define elementary education, the twenty-first century is marked by an emerging global convergence in the definition and government commitment to elementary education. In 2007, the joint expert group (JEG) of the United Nations Educational, Scientific and Cultural Organization (UNESCO) attempted to establish universal parameters that would define the length of elementary education. One possibility linked the duration of compulsory basic education to the minimum age for admission to employment, which was 15 years, under Article 2(3) of ILO Convention No. 138 (1973). Another viewpoint suggested that the first 5 years, subsequent to pre-school education, might be a more suitable minimum requirement. The JEG decided that more conceptual work was necessary to harmonize and clearly define the parameters and nature for elementary and basic education. Although universal parameters have yet to be defined, the global commitment to elementary education has been well-established through the commitment of the vast majority

of the world's governments to EFA and the achievement of the MDG to provide universal elementary education by 2015.

Despite this global commitment to defining and supporting elementary education, the conditions of elementary schools for which teacher education institutes prepare candidates vary tremendously among industrialized and developing countries. UNESCO data indicate that these differences include the pupil–teacher ratio (ranging from 43:1 in sub-Saharan Africa, to 17:1 in Eastern Europe and Central Asia) and the percentage of trained teachers in the classroom (69% in sub-Saharan Africa and 96% in East Asia). Despite the notable increase in elementary-school enrollments from 1999 to 2005 totaling 41 million children, with 36% increase reported in sub-Saharan Africa and 22% in South and West Asia, the Education for All Global Monitoring Report projects that of the 86 countries that have not yet reached universal elementary enrollment, 58 will not be able to achieve this by 2015. Of additional importance to the general context of global elementary education is the significant proportion of uncertified elementary-school teachers common to sub-Saharan Africa and East Asia.

System of Elementary-Education Programs

Teacher candidates for the elementary level have traditionally been educated in stand-alone special teacher training institutes/institutions, also called normal schools. In many parts of the world, the training of preservice elementary teachers has shifted to public or private tertiary-level institutions of higher learning, including universities and nonuniversity, postsecondary institutions. In the United States, majority of elementary-teacher candidates are trained in large state universities, although alternate-route teacher preparation programs based outside the university system have grown in the last decade. In Hong Kong, however, preservice elementary teachers continue to be trained in a specialist institution. In most developing countries and some industrializing countries in Central and South America, prospective elementary-school teachers are given the option of specialized secondary-level programs leading to certification. Conditions for entry into an elementary-teacher education program vary considerably. With the exception of the People's Republic of China, most of the industrialized countries now require applicants to complete secondary education. Individuals who enroll in elementary-teacher education programs in the People's Republic of China typically have completed junior high (secondary) school before enrolling in a 3- or 4-year teacher preparation program.

States play a significant role in the regulation and funding of teacher training programs. Control over the teacher-education institution is typically held by a national-level Ministry of Education (at times with a role for university representatives), a regional or state-level body or by the institution itself. Certification requirements typically are determined by Ministries of Education or, in more decentralized education systems, by a state government. In the US, states are considered gatekeepers since they decide which institutions are permitted to train teachers and determine the standards for a teaching license. The teacher-education system in Germany is similarly designed to the decentralized, state-based system in the US allowing each federal state control over the teacher examination, which is the formal certificate required to teach in a state public school. National regulatory boards have developed in the case of the US, as evidenced by the National Council for the Accreditation of Teacher Education (NCATE) and the Teacher Education Accreditation Council (TEAC), but these bodies lack the authority to regulate and standardize teacher education programs. Despite the absence of these organizations' formal authority over teacher-education programs, most initial teachers in the US will be expected to have graduated from an accredited teacher education program.

General Components of Preservice Teacher Education Programs

Quality teacher preparation provides new teachers with the skills, dispositions, and competence they need to begin their teaching careers and remain in the profession. Darling-Hammond identified several features of exemplary teacher preparation programs, including:

- a common, clear vision of high-quality teaching that is apparent in all coursework and clinical experiences;
- a curriculum grounded in substantial knowledge of child and adolescent development, learning theory, cognition, motivation, and subject-matter pedagogy, taught in the context of practice;
- extended connected clinical experiences (at least 30 weeks) which are carefully chosen to support the ideas and practices presented in simultaneous, closely interwoven coursework;
- well-defined standards of practice and performance that are used to guide and evaluate coursework and clinical work;
- strong relationships, common knowledge, and shared beliefs among school- and university-based faculty; and
- extensive use of case study methods, teacher research, performance assessments, and portfolio evaluation to ensure that learning is applied to real problems of practice.

While the specific aspects of elementary-teacher education programs vary considerably around the world, four components are commonplace: qualifying exams, a tertiary degree requirement, academic and professional coursework, and a teaching practicum. The structure of elementary-teacher education varies greatly and a broad discussion exists around the globe concerning the appropriate balance of these curricular and experiential components of teacher education. Williamson and Morris have found that in countries influenced by the craft-oriented British model of teacher education (e.g., Hong Kong, Australia, and New Zealand), there is a greater emphasis on the practicum component of the program. In countries that have programs with a more academic emphasis (e.g., China and Japan), a greater proportion of time is earmarked for the study of subject matter. An additional model of teacher education common in many African countries is what Avalos identifies as a behavioral skills-training approach, which prepares candidates to act in particular ways rather than exercise judgment.

The twenty-first century is bringing a more systematic restructuring and redesigning of elementary-teacher education programs. For member countries of the European Union, the Bologna Declaration strove to create a uniform bachelor- and master-degree system across Europe by 2009. For countries like Germany, Blömeke has observed that the Declaration has meant a major shift in the way elementary candidates are educated; taking the place of the traditional two-phase system (described below) will be a three-phase system involving a 3-year bachelor degree program, a 1-year master's phase and a 2-year practical training phase. A second common reform is the shift in teacher preparation to the increased role of schools in the initial teacher-education process typically through partnerships. The following section reviews these four components in details and provides specific examples from elementary-teacher education programs.

Exams

While many programs require teacher candidates to demonstrate their ability to apply pedagogical knowledge in an elementary classroom, teacher candidates must complete one or more teacher examinations to show how they are able to synthesize knowledge that resulted from coursework and field experiences. Examinations that are used to determine candidates' academic promise and levels of literacy are increasingly common. In some countries, elementary-teacher applicants must successfully pass a national exam. In Germany, candidates must complete oral and written exams at two points in their preservice education. A two-phase system of education constitutes German elementary-teacher preparation. The first period, an academic focus on subject and pedagogical

courses lasting 3.5 years, concludes with the First State Examination. Successful completion of this exam allows the student to graduate to the second phase of his/her education, which emphasizes learning and developing teaching skills through a mix of student teaching and studying general and subject-specific pedagogy. The Second State Examination concludes the preservice teacher's formal initial education. In the US, the mix of these four components is arranged differently. Many states use one exam, typically the PRAXIS I, as an entry exam into the elementary-teacher education program. After approximately 3 years of coursework, including a practicum, preservice teachers take their final exam, PRAXIS II, as part of their final certification process.

Tertiary Degree Requirement

International organizations such as UNESCO support a global standard requiring tertiary qualifications for teaching at the elementary level. A significant range exists among states, even within a geographic region, to achieve this international ideal. For example, almost all of Jordan's elementary-school teachers have this tertiary qualification, whereas only 14% of Tunisia's elementary teachers meet this requirement. UNESCO data reflect the low percentage of China's elementary teachers with this qualification – 13% – which contrasts sharply with the high percentage – 97% – of Peruvian elementary teachers. Some countries, like Vietnam, do not require a tertiary degree as a requirement for elementary-school teaching. The length of the tertiary qualification also varies by country. Most Organization for Economic Cooperation and Development (OECD) countries require 3–4 years of tertiary training, but Russia only requires 2 years and Germany mandates 5.5 years. The extent of this tertiary requirement has an impact on the academic foundation of the elementary teachers and the future need for in-service education.

Academic and Professional Coursework

Teacher-education programs typically require a general and professional education with an area of specialization. The purpose of the academic core courses in an elementary-teacher education program is to provide the candidate with a sound general education. In most US institutions, elementary-teacher candidates must complete liberal arts courses, increasing their level of literacy in several disciplines. This general course work aligns with common courses required for other university students in humanities, social science, natural science, mathematics, and physical science disciplines. The pedagogical or professional courses that include pedagogical studies, teaching methods, and strategies aim to acquaint preservice teachers with instructional strategies and issues specific to elementary education. In many industrialized countries,

this component of the teacher-education program includes general exposure to the curricular content concentrating on broad frameworks to facilitate the understanding of the individual and social context of learning and teaching (i.e., psychology, social foundations, etc.).

Practice/Practicum

A fourth component of teacher-education programs is the practicum or teaching practice. The practicum, also called practical training, provides opportunities to develop teaching skills and experience on the ground, in elementary classrooms. The education of elementary candidates typically includes some degree of actual classroom experience under the guidance of an experienced teacher, using an apprentice-oriented approach. The practicum component of the preservice program can last from a couple of weeks (i.e., in Taiwan) to almost 4 months (i.e., in New Zealand).

A vigorous, international, and multi-decade debate has been ongoing concerning the design and efficacy of the practicum. Schulz finds critics of the traditionally designed practicum, which emphasizes the mentoring teacher's evaluation of the preservice teacher's demonstrated technical skill in the classroom, argue for a practicum with a broader educative purpose that provides candidates with opportunities for inquiry, for trying and testing new ideas within supportive environments, and for engaging in new conversations about teaching and learning.

In-Service Education

In-service education, also called in-service training (IST), in-service training, education, and practice (ISTEP), teacher professional development (TPD), and continuing education, refers to the professional development of teachers who are already in the classroom. Governments worldwide rely on in-service education to improve and update the skills of current teachers as well as to introduce and implement educational reform. For example, in the 1990s, state governments in countries, including Vietnam and Namibia, have depended on IST to promote child-centered curricular reform. ISTEP sessions for elementary teachers range in length from a couple of hours (e.g., Estonia) to at least a month (e.g., Mongolia before voucher reform) during the academic year or breaks; IST may be mandatory, a requirement for continued certification, or voluntary. The financing and administration of ISTEP varies worldwide. In industrialized countries like New Zealand, groups associated with national or teacher-education programs, such as the Advisory Service, operate in-service teacher education, whereas in many developing countries, organizations based outside of

the country, such as international nongovernmental organizations (NGOs) and bilateral- and multilateral organizations dominate ISTEP.

International organizations (e.g., UNESCO) have found existing in-service education programs to be inadequate and ineffective. Although participation rates in in-service programs may be high, the transfer of the skills learned in these IST sessions and a significant change in teacher action is restricted by, at least, four factors: (1) a disjuncture between the assumed nature and the reality of classroom conditions; (2) the lack of follow-up support by skilled mentors; (3) the continued dominance and demands of exams, whose role and content may be out of line with the proposed reform; and (4) outdated teaching methods used in in-service sessions.

Quality Control of Elementary-Teacher Education Programs: Accreditation

While governments historically had some accountability measures, the increased prevalence of international studies of pupil performance (e.g., PISA and TIMSS) and growth of domestic comparative examinations have given rise to greater accountability measures and mechanisms for teacher preparation programs. Increased interest in and concern about teacher quality worldwide is related to evidence that an effective elementary teacher is the strongest determinant for student achievement. Many countries identify effective teachers as an important factor for student achievement.

Accreditation of elementary-teacher education programs varies considerably, as revealed by the following discussion of the situation in US, Canada, and China. Given the differences in the manner in which elementary/elementary-teacher preparation programs are accredited throughout the world, commonalities are few. The teacher-education programs are judged by a defined set of expectations that serve as a rubric for approval. These guidelines establish coherence to the assessment of the quality of teacher education. In many cases, the evaluation team consists of individuals within and outside of the institution. This configuration adds to the level of credibility to the accreditation process.

In some countries and provinces (i.e., US and Ontario, Canada), the quality of the teacher-education program is based on qualities that teacher candidates demonstrate. In another instance, accreditation is based on opportunities that candidates have to demonstrate competencies. In the US, several elementary-teacher preparation programs submit folios to the National Council for Accreditation of Teacher Education (NCATE), which accredits almost 98% of teacher-education programs, or the Teacher Education Accreditation Council (TEAC). In doing so, they must provide summaries of candidates know and

can do in light of 19 standards that the Association for Childhood Education International (ACEI) and other professional organizations have identified for elementary-teacher candidates through the use of six to eight assessments. In addition to reviewing the submitted report, the evaluation team visits the institution to interview faculties and teacher candidates to gain additional insights into the evidence under consideration. On the other hand, TEAC accredits elementary-teacher education programs on the basis of an internal audit conducted by education faculty in light of TEAC principles that focus on the program's claims regarding candidates' subject-matter and pedagogical knowledge and teaching skills. Regardless of the accreditation body that a teacher-education program chooses, accreditation is voluntary. Canadian teacher-education programs submit their applications for accreditation to evaluation teams within their respective territories, followed by visits from those evaluators.

The quality of teacher education in the People's Republic of China falls directly under the purview of the State Education Commission (SEC). One of 23 of its subdivisions, the Teacher Education Bureau (TEB), formulates policy on teacher education. The SEC outlines the curricular framework for all normal institutions that are directly under the supervision of the SEC. The framework consists of foundation courses (i.e., politics, moral education, a second language, and physical education), professional education courses that include pedagogy, psychology, philosophy, history of education, and sociology; subject-matter specialization, replicating knowledge of a secondary teacher; and optional courses that may include art appreciation and extracurricular activities. The elementary-teacher education programs within the normal schools are accredited on the basis that their curricula are strictly aligned with policies set forth.

Universal Concerns and Problems with the Education of Elementary-School Teachers

Relationship between Educational Reform and Teacher Education

One of the central conversations in the field of elementary-teacher training, and teacher education more broadly, is the relationship between educational reform and teacher education. Scholars in the field of teacher preparation note the general trend of developing reform policies without the input or initial involvement of teachers at the preservice or in-service levels. Zeichner and Tabachnik find this reform approach common in Africa, where teacher education focuses on preparing teachers to exhibit the skills needed to implement reform that others have conceptualized, perpetuating authoritarian classroom patterns that many African teachers experienced

in their own education. In some rare cases, attempts to restructure or revamp teacher education are made before the introduction of a significant educational reform. Countries such as Papua New Guinea lengthened elementary-teacher education in the 1980s and 1990s, before instituting broad reform.

Professionalism

High-quality teacher preparation strongly predicts teacher retention and good teaching practice. Given this association, concern about the quality of teacher-education programs and the graduates of these institutions is common worldwide. In developing countries, especially in sub-Saharan Africa, where it is common for elementary-school teachers to start teaching without formal training, governments seek to increase teacher professionalism as part of the broader EFA reform agenda. In the United States, a major component of the No Child Left Behind (NCLB) legislation is the development and definition of a highly qualified teacher at every level including elementary.

Industrialized and developing countries face key challenges regarding the cultivation of quality primary-school educators, including cost, lack of institutional infrastructure, and the tension between increasing the number of teachers while maintaining (or improving) the quality of their preservice and in-service instruction. Inventive solutions have developed over the last 20 years to improve the quality of teacher education. Distance education or information and communication technology (ICT) has developed as one strategy to assist in preservice and in-service teacher training. India, for example, relies on distance-learning technology via EDUSAT, the world's first education satellite, to enhance the quality of primary teacher education.

Shortages

An additional problem facing countries around the globe is a persistent shortage of teachers at the elementary level; a dilemma that is particularly acute in developing regions experiencing a sharp increase in student enrollment, attempting to train millions of teachers to serve these students and trying to meet commitments to EFA. In many African countries, elementary-school enrollments have swollen beyond structural capacity due to the dropping of past mandatory school fees. For example, in Chad the number of students in school has doubled between 1995 and 2005. Schools located in less-desirable geographic locations, which include both rural and urban areas, or serving less-privileged populations (i.e., ethnic minorities, indigenous populations, and lower-income students) face the greatest teacher shortages, in terms of adequate training and supply, worldwide. In industrialized countries, such as the United States and the United

Kingdom, shortages align with specific subject areas and specializations, especially special education, foreign language, mathematics, and science.

These shortages have shaped the structure of PRETEP and INSTEP teacher-education and certification programs. In the hopes of attracting teachers, governments have shortened the initial teacher training cycle (e.g., Uganda, Tanzania, and Malawi) and lowered the admission requirements for the training (e.g., Mozambique). Lewin and Stuart highlight one example of a program designed to increase the number of elementary-school teachers is the Malawi Integrated In-service Teacher Education Program (MIITEP), which connects college-based education to school-based training and supplemental local and distance education sessions. In the United States, teacher shortages have spurred the development of alternative teacher certification programs and led to the recruitment of international teachers.

Conclusions

One of the central concerns of societies around the world is the availability and quality of their children's first years of school. In some countries, primary education constitutes the maximum schooling for a child. As we see in the goal of universal primary education, access to primary education, especially for girls, in many regions of the world remains a distant goal. In other countries, the elementary level becomes the foundation for future years of secondary and tertiary education. In both cases, the primary school teacher is of critical importance in the child's basic social, academic, and emotional development. This review of teacher education for elementary teachers examines the many ways that societies have agreed to prepare teachers for this central role. While the context of teacher education varies significantly around the world, broad agreement exists that, as future professionals, candidates need some specialized professional training in an institution that more frequently is housed in a university or other tertiary learning program. Another point of global convergence is that some system of quality control both for the candidate and the institute of teacher education should exist. Typically, state-controlled certification and institutional accreditation perform this function. Finally, a global look at teacher education for elementary teacher underscores the common problems and issues facing states concerning the development and improvement of public schools. Among the most pronounced of these problems are the persistent issue of how to best involve teacher education in system-wide school reform, the most effective and cost-effective ways to cultivate high-quality teachers, and the critical shortages of primary school teachers. At the start of twenty-first century,

we find cooperation between states, NGOs, and multinational organizations aimed at improving primary schools and elementary-teacher education around the world.

Teacher Education for Teaching the Gifted

A Y Baldwin, University of Connecticut, Storrs, CT, USA

© 2010 Elsevier Ltd. All rights reserved.

Teacher Education for Teaching the Gifted

The international community has often taken its ideas regarding the gifted from the activities of those universities and persons actively involved in Education of the Gifted. The differences in the philosophies of the different nations have often made the US model the most difficult one to follow. Adjustments, realignments, and specific criteria for the quality or characteristics deemed necessary for teachers of the gifted are made; however, the evaluation of the criteria established is sorely lacking. Do we dare move forward in this century without a full understanding of the importance of the necessary attributes of teachers of the gifted within the context of the global environment? Attention must be paid to the emerging efforts to clarify these attributes. Although the context of this article is designed to focus on the teacher of the gifted, it is important to note that defining what we mean by the use of the term gifted is important.

Although the use of the term gifted and its definition have varied throughout the last three decades, the movement toward a more inclusive use of the term has begun to emerge. Previously, giftedness was inextricably tied to the IQ score and also judged by the academic achievements of the individual. Research and experiential examples have brought to the attention of proponents in this field that gifted characteristic can be exemplified in many different ways (Baldwin, 1984; Baldwin and Vialle, 1999; Renzulli, 1978; Ford, 1994; and Frasier, 1987). The observant teacher is often the person who recognizes this quality and advocates for inclusion of this student in programs for the gifted. However, too many students are not recognized because teachers who have not had training in this field are often tied to the notion that giftedness is synonymous with achievement and good behavior; therefore, they are led to believe that the absence of these qualities means that giftedness does not exist.

The field of Education of the Gifted has entered a new era where the qualities of teachers of the gifted are becoming the focus of attention. Although this change of focus is not limited to teachers of the gifted, it means that the qualities of teachers selected for teaching the gifted are dependent, in large part, on the quality of the training these teachers acquired during their preservice years or in-service and graduate programs.

Evaluation of the quality of training that preservice teachers have received is too often missing. For teachers of

the gifted, adjustments and realignments are often made in specific criteria for the quality or characteristics deemed necessary. Baldwin (1993) outlined the research and findings by Bishop (1968). Although this study was done quite some time ago, it is still referenced in contemporary research studies on teachers of the gifted. He reported on those characteristics which the subjects of his study said were present in successful teachers of the gifted. He determined that these teachers were experienced, of superior intellect, mature individuals, creative, had high personal achievement needs, and tended to be student oriented. This early determination of the characteristics of teachers of the gifted has been repeatedly found in subsequent studies of these characteristics.

Teacher Training

Concern about the issue of teacher training was highlighted in the winter 2007 issue of *Educational Horizons*. Each article was related to the experiences and training of teachers for this generation and contemporary times. Darling-Hammond and Baratz-Snowden (2007) in their summary of the National Academy of Education Committee on Teacher Education's report referred to the inequality of the training of teachers and posed the question of concern which is, "How is it that we permit so many ill-prepared individuals to assume such an important role in society?" (p. 111). Some of the answers to these questions were proposed as follows (p. 112):

- As a society, we do not invest seriously in the lives of children, most especially poor children and children of color who receive the least-prepared teachers.
- The conventional view of teaching is simplistic: teaching is viewed merely as proceeding through a set curriculum in a manner that transmits information from the teacher to the child.
- Many people do not understand what successful teaching requires, and do not see teaching as a difficult job that requires rigorous training.
- Others believe that there is not much more to teaching than knowing the subject matter that children should learn.
- Many state licensing systems reflect these attitudes and have entry requirements that lack demanding standards, especially for teachers who teach poor and minority students.

- Researchers and teacher educators have only recently come to consensus about what is necessary basic knowledge for entering the classroom and how and when such knowledge and skill should be acquired.

As editors of this research, Darling-Hammond and Baratz-Snoden commented, "Thus beginning teachers need consistent opportunities to apply what they are learning, to analyze what happens, and to adjust their efforts accordingly. They need to engage in inquiry and reflection about learning, teaching, and curriculum as well as direct instruction in specific areas of content" (p. 115). For teachers of the gifted, each of these answers is important. The inclusion of students of color in programs for the gifted, in large part, depends upon the type of instruction the student has had; therefore, well-defined criteria for excellence are needed.

Teacher Education Standards for Teaching the Gifted

The field of Education of the Gifted has grown to the point where the preservice training of teachers in understanding the characteristics of gifted students has become as essential as in-service training and advanced degrees in education of the gifted student.

Although standards-based programs have been successful in keeping teachers on track with skill development, in the field of education of the gifted it has denied the process of creative planning and development which is crucial in the effective educational experiences of gifted students.

The National Association for Gifted Children (NAGC) and the Council for Exceptional Children (CEC) cooperatively developed over a period of 3 years, teacher preparation standards for teachers of the gifted. These standards were approved by NCATE. The ten standards are listed under the title *NAGC-CEC Teacher Knowledge & Skill Standards for Gifted and Talented Education*. Each of the standards has subcategories that define what is expected in each standard. These standards are listed below with a short explanation of how each should be reflected in planning and teaching for gifted students (see NAGC report (2006) for listings of each subcategory and procedures for assessing each).

Standard 1: Foundations

Issues that deal with philosophies, theories, diverse and historical points of view, and human issues are the basis for this standard. The field of Education of the Gifted is fraught with divergent thinking about who is gifted and how to best provide for these needs. Each teacher needs to have a good foundation upon which to make decisions about the appropriate approach to teaching the gifted child in his or her class.

Standard 2: Development and Characteristics of Learners

Understanding the differences in the various learning capabilities of children is an expectation of all teachers but a crucial factor with teachers of the gifted. The range of differences within the classroom of gifted students requires knowledge of these learning differences and how they can be accommodated.

Standard 3: Individual Learning Differences

Culture and experiences play an important role in the learning differences of students. The role of nurture versus nature is significant in establishing the basic expectations of potential giftedness in a student.

Standard 4: Instructional Strategies

Having a repertoire of teaching strategies is crucial in differentiating lessons for gifted students. There is a need to engage all students in challenging, multicultural curricula.

Standard 5: Learning Environments and Social Interactions

The encouragement of independence of thought and the ability to live harmoniously with others of different cultures is an important role for teachers of the gifted.

Standard 6: Language and Communication

The teacher of the gifted should provide opportunities for oral and written communication that provide effective ways in which students can interact with their peer groups and show understanding and appreciation of the cultures of various groups.

Standard 7: Instructional Planning

The adaptation of materials that suit the learning requirements of the gifted child is important for the teacher of the gifted. The goals that are provided in the curriculum could be long range as well as short range but must be adapted to meet the needs of the learner.

Standard 8: Assessment

Assessment strategies are important in the general and specific analysis of the needs of the particular student. Identification of abilities is varied and teachers need to know the advantages or disadvantages of the various assessment strategies.

Standard 9: Professional and Ethical Practice

Teachers of the gifted respect the laws and regulations that refer to the teaching of students. They also maintain ethical behaviors when dealing and teaching students.

Standard 10: Collaboration

Working with professionals in the field helps teachers to share experiences and techniques that have been successful. This sharing and collaboration should be extended to parents and communities.

The training (related to methods), education (extension of knowledge), and evaluation (the quality of teachers' effectiveness with students) are all important concerns in a teacher's effectiveness in the classroom. The movement by NAGC and CEC toward designing a set of standards for teachers of the gifted recognizes those qualities that indicate effectiveness.

Among the many things of the legacy of Lee Shulman, until recently the president of the Carnegie Foundation for the advancement of teacher education, is the advanced study of teacher education programs, to bring out the richness, beauty, and complexity of teaching by making it visible as is done in other professions (Carnegie Foundation News, 2007). It is important that programs to train teachers of the gifted design the teacher education programs so that this richness, beauty, and complexity can be recognized.

Research Available on Qualities and Training of Teachers of the Gifted

Questions still remain regarding the characteristics that are specific for teachers of the gifted. Baldwin (1993) expressed at that time that there was a need for answers to the continuing flow of questions regarding the desired abilities of teachers of the gifted. Were these characteristics any different from ones desired for all children? These questions that still need empirical answers are (p. 621):

- Should the teacher of the gifted be highly gifted, if so what should the IQ score be?
- How extensive should the knowledge of the teacher of the gifted be?
- Should the basic characteristics required to teach gifted elementary grade students be the same for gifted students at all levels?
- What type of educational background should the teacher of the gifted have?
- What is the difference between a teacher of the gifted and a good teacher of all the other students?
- What specialized training should teachers of the gifted have?

The data cited by Baldwin (1993) and Baldwin *et al.* (2000) contain nomenclature that provides a continuing

perception of what the teacher of the gifted should be. These perceptions are solid enough to give institutions of higher education a good road map for developing appropriate selection strategies, courses, and evaluation of the students at the conclusion of this coursework.

Research Methods and Findings

The methodologies used to find teacher characteristics have mainly been qualitative. Methods, such as case studies, narrative studies, surveys, correlational studies, and causal/experimental studies, have been used and are still being represented in the most recent studies mentioned here. Gentry (submitted) emphasized in her study that “with qualitative research, the intent is not to generalize but to inform” (p. 28). She has proposed that the research from her study, that included 400 teachers out of which a group of 18 were said to be exemplary teachers, should give future researchers and persons concerned about qualities of teachers of the gifted basic data from which to conduct further study. This would also be a starting point for preservice and postservice training program design. Gentry's research was designed to determine the perceptions of students about those teachers that students considered exemplary.

Four themes emerged from her research as follows:

- Theme 1: These teachers know and take a personal interest in their students.
- Theme 2: These teachers set high expectations for themselves and for their students.
- Theme 3: These teachers make content and learning meaningful and relevant to the future and respect students' choices.
- Theme 4: These teachers have a clear passion for their students, teaching, and for their content.

These themes that reflected student's perceptions of exemplary behaviors of teachers of the gifted mirrored the behaviors that other researchers (e.g., Bishop, 1980; Baldwin *et al.*, 2000; Whitlock and DuCette, 1989) have also indicated in their research.

In Gentry's research, high expectations of teachers and their students were ranked highest among the most desirable traits listed in the themes above.

Findings from this study raise several questions for future research and planning on behalf of Teacher Education Universities. Can teachers be taught how to develop positive relationships with students? What role does humor play in teaching and learning in a broader context? What might Career and Technical Education and teachers who have professional experiences offer education in general? Can the attributes of the exemplary teachers be used to develop better pre-service and in-service

teachers? How can passion for content, students, and teaching be assessed and used to recruit and retain quality teachers? Gentry (submitted)

In an effort to pinpoint qualities that reflect teachers of the gifted, Vialle and Quigley (2002) found in their research ($n = 377$) regarding the perceptions of children toward their teachers, that personal and social characteristics of teachers were highly regarded. The perceptions of students in both of these studies give teacher education faculty information that must be considered in the process of training teachers of the gifted.

Another study was undertaken to determine the effectiveness of two experiences: one of a specific practicum within a Saturday Program for gifted students and the other an online course to provide this knowledge base of giftedness to undergraduate preservice teachers (Bangel *et al.*, 2006). In their study of two different methods of preparing preservice teachers in education of the gifted, they concluded that the standard teacher education practicums do not include the necessary experiences with gifted students. "Teacher education programs strive to prepare novices to become high-quality teachers for our youth. Among those youth will be a number of gifted students who desire to have appropriate education opportunities but have not had them, due to lack of training for their teachers" (p. 356–357).

Desired Traits for Teachers of the Gifted

Over and over again, scholars in the field have listed those characteristics they think are important for teachers of the gifted. Although empirical research is limited in this area, observations and modified studies have indicated similar theories about the needs of the gifted teacher. In **Table 1**, many of these theories are listed under the suggestion of Maker (1982) of three areas that she felt were the important ones to be used in analyzing a teacher's preparedness to teach the gifted as well as a means of addressing training for teachers of the gifted. These areas are:

- *Philosophical* which focuses on the teacher's feelings about education of the gifted. What are the ideals and beliefs about education of the gifted to be considered in this area?
- *Professional* which focuses on the type of training necessary for the teacher of the gifted. What type of courses, professor's knowledge, and practicum experiences are needed?
- *Personal/innate quality/personality* what qualities are present that would make an individual a good prospect for teaching the gifted student?

Listing of themes by Vialle and Quigley (2002) coincided with Maker's ideas closely and described their three

Table 1 Classification of behaviors for teachers of the gifted in three basic areas

Basic area	Behaviors
Philosophical	Positive attitudes toward the concept of giftedness Accurate concept of giftedness Personal beliefs regarding education of the gifted Willing to advocate for the gifted Dedicated to help students reach their potential
Professional	In-depth knowledge of subject matter Knowledge of varying learning styles Works with students to reach their goals Uses creative methods to find solutions to problems Remains alert to educational tools and use of them Able to stimulate students Professional training in education of gifted IQ score of 128 or above Flexible with use of time Provides proper environmental support Well organized in planning Culturally responsive in planning curricula Displays gifted behaviors
Personal/innate quality/personality	Willing to take risks Self confident Perceives emotion and accepts students emotion Warm and friendly with support of students Sense of humor Fair in making decision with students Enthusiastic High verbal skills Introspective

areas as personal–social characteristics; teaching strategies/approach; and intellectual–cognitive characteristics. Their listing of numerous sources indicate that there is great consensus about those characteristics deemed necessary for the teacher of the gifted in each of these three areas. These characteristics are needed for all teachers; however, following model revision and caution for models of teacher training by Dall'Alba and Sanberg (2006), the additional qualities of flexibility, willingness to take risks, acceptance of ambiguity, respect for student ideas, out-of-the-box thinking, acceptance of differences of opinions, and encouragement of students to pursue different trajectories of learning are difficult to define but necessary additional characteristics for teachers of the gifted.

Teacher Education Programs Challenges

In selecting and training teachers, personal practical knowledge is crucial because in spite of the planned

curriculum, he or she will need to bring to the classroom their way “of reconstructing the past and the intentions of the future to deal with the exigencies of the present situation” Connelly and Clandinin (as cited in Craig (2006)).

Meeting the Needs of Gifted Children from Various Ethnic Groups

Giftedness can be expressed in many ways. There are many faces of the gifted and we should lift the masks as suggested by Baldwin and Vialle (1999). Defining giftedness and identification of giftedness have become the Achilles heel of efforts to show that giftedness can be exhibited in many ways. Inclusion in programs of children from different cultures is presently a great concern for professionals in this field. Scott *et al.* (1996) reported that, “in the United States of America, children from culturally different and/or low socioeconomic environments constitute a growing percentage of all students, yet assessment tools that effectively evaluate their academic potential are lacking” (p. 147). Little has changed since that time; therefore, advocacy from teachers plays a large role in recognizing the latent abilities of these children. More than three decades ago, the problem of gifted black students in gifted classes (the term black is now referred to as African-American) was addressed when several students were to be selected for the first class for black gifted students in this segregated school system. The identification process used at that time would have eliminated all but three of the students of this class. Advocacy and a different approach to identifying these students were used. A challenging curriculum, exposure to new ideas, and an opportunity to engage in exciting and stimulating activities showed on subsequent achievement tests, that effective experiences within the classroom had allowed the latent abilities to bloom. These students were diamonds in the rough (Baldwin, 1977).

As Baldwin and Vialle (1999) have stated, giftedness can be evident among students of different cultures, physical impairments, language differences, and socioeconomic circumstances. These imaginary masks have often kept students from being recognized as gifted. Teachers of tomorrow must have the training and experience needed to lift these masks.

Summary and Recommendations

The proper education of the gifted requires that teacher training programs for the preservice teachers become an important goal for teacher education programs in higher education institutions and local educational centers and school districts. The present focus on teacher training mirrors the previous focus that was on the gifted students

and their needs. There has always been a need for gifted students to have the opportunity to explore new ideas and to work with students of similar ability. For teachers, it is also important that they be given the necessary training that will free them to explore new ideas with the understanding of the myriad of differences in the interests and needs of these students. Meeting their needs is not an elitist concept but one that is egalitarian meaning that all children should have the opportunity to develop his or her abilities as far as possible.

The new standards for teachers of the gifted are guidelines within which programs and teachers are assessed; however, these guidelines are only the beginning for the teacher of the gifted. Teaching is an art which mirrors the same color, drama, and excellence of achievement that is felt by the conductor of a symphony, the producer of a play, or the display of a graphic artist. The qualities inherent in these achievements are difficult to quantify but must be there in successful teachers of the gifted.

We are moving toward improving the training of teachers of the gifted but we have miles to go in the process. The tools for this process are available and must be put into action in order to capture the great potential for the future.

Teacher Preparation in Mother Tongue Education

M Kooy, University of Toronto, Toronto, ON, Canada

H Hulshof, ICLON, Leiden University Graduate School of Teaching, Leiden, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

The article offers an overview of the evolving state of teacher education in mother tongue (L1), the home language of nations (e.g., Greek in Greece and English in Australia). Mother tongue education's focus on language, which reflects a nation's culture and identity (as expression and medium of communication), lies at the heart of schooling. Unlike other subject areas, it functions as both the medium and object of study. Not surprisingly, differences that exist on the place and purpose of mother tongue education remains the most debated and contested school subject. Little agreement on the specific subject matter content and definitions makes it persistently difficult to define a shared understanding of the core concepts and skills of the school subject. Understandably, this affects and even shapes how teacher education in mother tongue occurs in the university programs (Luke, 2000). The complex, often parallel, and even competing views and practices of mother tongue education affect the ability to clearly spell out the state of a field that is itself multiple, varied, and rapidly changing.

The conventional theory/practice divide between the university and the school results in differences between academic content of mother tongue in university programs and mother tongue subject content in schools. Hence, what preservice teachers learn before entry into mother tongue subject teaching in their field experiences in schools may not transition smoothly into schools but become a parallel body of knowledge (O'Neill, 2000). The knowledge of linguistics and literature acquired at the university, therefore, may differ significantly from the content knowledge required in the mother tongue as school subject.

Developments in educational theory regarding the relations between the what (subject content) and the how (teaching abilities) matter to mother tongue education in that they provide guidelines for this pedagogical translation. Global efforts in mother tongue teacher education, then, share the goal of approaching academic study of mother tongue in order to socially relevant educational practice (Darling-Hammond and Bransford, 2005).

Not surprisingly, university-based teacher education in mother tongue varies in programs and practices within and between nations. Nevertheless, most programs share three consistent features: (1) subject-matter knowledge background; (2) professional and pedagogical knowledge development; and (3) field-based (student teaching) experience(s) in mother tongue education. The transition from content knowledge to pedagogical knowledge

predominates in teacher education since it strives to bridge academic content knowledge with knowledge of mother tongue as school subject and its pedagogical practices.

Mother Tongue Subject-Matter Knowledge

Content and background knowledge in mother tongue required for admission to teacher education ranges from a few undergraduate university courses in literature and language (such as at the University of Toronto) to a master's degree (such as in the Netherlands). Generally, evidence of mother tongue competence comes in the form of university records (unlike some programs requiring a competency test such as in second-language education). The assumption that mother tongue content knowledge translates into the knowledge required for creating mother tongue teaching strategies in the school subject matter often fails to materialize. Some research is beginning to identify specific, translatable subject-matter content knowledge specifically directed to mother tongue school subject matter. Nevertheless, determining specifically what background content knowledge applies most directly to mother tongue teaching in schools remains underinvestigated and requires further inquiry and research (Lucas and Grinberg, 2008).

The subject mother tongue in schools (and by association, preservice teacher education) remains particularly contentious in many national contexts, and becomes the site for ongoing (often political) debate. The conflict occurs around what constitutes mother tongue subject matter and what competencies and skills students are expected to achieve. These debates affect all stakeholders in the educational process (e.g., from preservice teachers to students and policymakers). Periodic shifts and trends in economies and ruling political parties call for increased competence in mother tongue to bolster the edge of competitiveness in the world. These competencies are often measured in test results (a particularly pointed example of this is the current no-child-left-behind policies in the United States).

Mother tongue as subject remains contested because of its central place in education; that is, expression and reflection of a national culture occurs through language. Since all subject-matter teaching and learning in schools (and elsewhere) occurs through language, mother tongue serves both as the source of communication and as an

object of study. In addition, given the recognition that literacy represents a level of power not available to all, access becomes an issue (e.g., Freire's work in South America and denial of literacy for girls in Afghanistan under the Taliban). The complicated network of variables that influence and shape what counts as subject-matter knowledge remains a major issue for mother tongue subject in preservice teacher education.

Professional and Pedagogical Knowledge Development

Professional education for preservice teachers in mother tongue education explores how background knowledge and content translates into teaching subject matter. Indeed, translating disciplinary content knowledge into pedagogy remains the singularly most important purpose of mother tongue methods courses.

"Knowing the subject matter terrain is the foundation for pedagogical content knowledge" (Grossman and Schoenfield, 2005: 204, 205) and a teacher's "content knowledge organized for teaching" is a better predictor of successful teaching than content knowledge alone (Grossman and Schoenfield, 2005: 206). Grossman (1989) compared the effect of subject-specific coursework in pedagogical content knowledge (PCK) by contrasting six beginning English teachers, only three of whom graduated from teacher education. She demonstrates that subject-specific coursework can be a powerful influence on how teachers think about and teach their subjects. Given this, it remains critical to identify the specific mother tongue content knowledge required for developing sound pedagogical knowledge for mother tongue teaching (Hulshof and Verloop, 2002, 2005), although precisely what knowledge remains to be determined.

Shulman's conception of PCK (in 1986), remains a key feature in understanding the nature of practices in mother tongue teaching. This understanding moves beyond subject knowledge to specific subject knowledge that matters for teaching. Shulman (2004) understands this knowledge as "ways of representing and formulating the subject that make it comprehensible to others" (p. 203). The European tradition of didactics (pedagogy) has always been associated with the why and what questions of teaching. Neither purely an academic discipline nor an educational theory, it represents a conversation or a bridge between the two (Freire calls this praxis). Hence, content in teaching has always played a significant role in thinking about pedagogical reasoning. This undoubtedly influences the European perception and view of PCK related to mother tongue education (Hulshof and Verloop, 1996).

What students are expected to achieve in skill and competence in mother tongue education undergoes

periodic shifts. The common recurring belief (often political) that students lag behind their counterparts in other parts of the world in language and literacy skills brings a surge of remedial new policies, programs, and practices targeted to raise student scores and make them more globally competitive.

Decisions by policymakers reflect conceptions of purposes, practices, and models of mother tongue education. Responding to the call to upgrade and improve student performance frequently leads to imposing a skill-and-drill model of mother tongue education (e.g., traditional, canonical texts such as Shakespeare, the study of grammar, and a focus on language skills). Frequently, high-stakes testing drives the curriculum and the test results provide evidence for improvement (the US no-child-left-behind policy provides an example). University teacher educators and researchers often offer models of mother tongue reflecting a sociocultural, critical literacy perspective (e.g., texts represented in technology, media, and graphic novels; writing for understanding (process rather than product orientation); and language and meaning as socially constructed). The two orientations reflect distinctively different practices and pedagogies. This tends to perpetuate the divide existing between university mother tongue teacher-preparation courses and the realities of practices in the schools.

A current exception to this gap appears to be Finland. Its top international ranking in mother tongue language (Linnaky, 1993; Valijarvi *et al.*, 2002) begs the question: How does the Finnish school system determine subject-matter content and pedagogical practices? Who makes such decisions? How does this affect mother tongue teacher education? Perhaps Finland's decentralized school system and its considerable autonomy given to teachers make collaborative decision making and agreement about shared practices and subject-matter content more realistic and possible. Perhaps the relationship between the schools and universities minimizes the traditional gap. A close examination of its mother tongue preservice teacher programs is warranted. As mother tongue is both medium of communication and object of study, comprehending the implications of PCK for mother tongue education is very complex.

A robust understanding of PCK takes into account the intersection of subject content, cognition, and students and includes, among other things, the ability to anticipate and respond to typical student patterns of understanding and misunderstanding by generating multiple examples and representations of challenging topics that make content accessible to a wide range of learners. For mother tongue language education, this suggests learning multiple and alternative approaches and strategies to literacy and language (primarily reading and writing).

Three significant issues affect how L1 coursework is structured and practiced in teacher education: (1) content

of methods courses; (2) increasing diversity and languages in L1 classrooms; and (3) movement from literacy to literacies.

Mother Tongue Education Methods Courses

Methods courses vary among nations and within mother tongue education methods courses. The inconsistency is particularly noteworthy because mother tongue education is central to schooling; mother tongue education courses often represent the core requirement for every year of secondary schooling (e.g., in Canada, mother tongue English or French represents the only mandatory subject in every secondary grade). The importance of understanding how to create links and transitions to pedagogical practices in preparing teachers for mother tongue education in the schools cannot be understated.

In Europe, mother tongue methods courses tend to use similar content structures: (1) objectives, content, and examination of the school subject; (2) nature and history of the school subject; (3) innovations in subject-specific pedagogy; (4) curriculum development; (5) lesson preparation; (6) educational psychology; (7) textbook analysis; (8) relationship between academic discipline and school subject; and (9) research in the school subject and preliminary research skills.

Decisions on course content and practices for mother tongue education are particularly complicated because of a lack of common and shared standards and a number of versions of mother tongue education that continue to exist. Barnes (1984) summarized these as: (1) basic skills; (2) personal growth (Dixon's (1967) model); (3) disciplinary; and (4) critical literacy. Each model reflects a particular theoretical framework and the resulting values, priorities, practices, and expectations particular to it. Questions arise for mother tongue education courses: What model is privileged? Which one(s) is ignored or undermined? Does the university program aim to prepare preservice mother tongue teachers for the realities of the classroom (reflecting what happens in schools) or is it required to expose students to the four models cited above, or should it be responsible for advancing the most recent research that includes a postmodern perspective and realities of a changing world and cultures (such as the increasing diversity and languages represented in many urban classrooms)? The conundrum captured in the persistent lack of agreement about what constitutes viable and defensible mother tongue subject and practices fuels ongoing debates on the course content and practices in the university program.

School realities and university ideologies often clash and, in doing so, perpetuate the existing chasm separating the two. Teachers in preparation programs are vulnerable, apt to accept (at least in the abstract) models proposed in university methods courses. A lack of applied and

practical experience (e.g., reading about critical literacy as a sufficient condition for understanding and transforming the knowledge into pedagogy) prevents drawing from earlier experience and knowledge to make decisions based on extensive teacher knowledge. Mother tongue methods courses, then, precariously balance the decisions about what to include and exclude in the preparation of teachers.

To make the transformation of content knowledge a reality requires participating in the practices and pedagogies of mother tongue education. When complemented by readings of current perspectives and discussions in the class, the methods course draws on the intellectual and practical elements of learning to teach (Smagorinsky *et al.*, 2003). Through personal engagement and reflection, it becomes possible for preservice teachers in mother tongue to imagine and transform their content knowledge (Mansvelder-Longayroux, 2006).

Mother Tongue Teacher Education in/for a Changing World

The changing demographics in many urban contexts make an already-complex subject area even more unwieldy (Beavis and O'Mara, 2006; Green, 2006). Toronto, the world's most multicultural city, has classrooms with many, even no children born in Canada. This also increasingly becomes the case and even the norm in some (particularly urban) schools in many other nations (Darling-Hammond and Bransford, 2005). Preparing teachers for these new realities is often neglected, even ignored, at the preservice level. Preservice mother tongue education teachers are often struck by how unprepared they are for teaching in diverse classrooms (Kooy, 2006).

The shifting classroom demographics raise critical questions: How are mother tongue teachers being prepared to teach for this ever-changing world? What approaches, perspectives, and practices reflect what "prospective teachers need to [do to] reorganize their subject matter knowledge into knowledge about how to teach subject matter to diverse students" (Bransford *et al.*, 2005: 15; Lucas and Grinberg, 2008)? How will teacher-education programs attract a more diverse teaching population (which remains primarily white and female, at least in Canada and the United States) that more clearly reflects the student populations?

The growth of transnational movements requires remaking mother tongue education courses to meet the changing demographics of classrooms and its implications for teaching and learning. Cochran-Smith (2004) recommends transforming teacher preparation "informed by the large bodies of work that now exist about . . . the preparation of teachers for a diverse society, which come from critical and multicultural perspectives intended to interrupt the norms

of conventional teacher education” (p. 212). Inevitably, this focuses on (mother tongue) language.

From Literacy to Literacies in Mother Tongue Education

Conventionally defined and practiced in mother tongue education, literacy involved reading and writing – that is, developing skills in learning how to read and the study of reading and writing (reception and production) of school texts. Current social and technology trends are redefining and reshaping traditional understanding of school literacy from the singular to plural literacies. Socially, this takes into account transnational movements and immigration that continue to change the demographics of classrooms. Diverse multilingual student populations bring multiple literacies into mother tongue classrooms. Parallel to this reality is a growing sense that *literacy* continues to move into *literacies* with the advent of technology requiring skills, such as computer literacy, and becoming literate in multiple new ways such as newer text forms (e.g., video games, film, and modern graphic novels). Green (2006) argues that recent questions concerning literacy and technology “represent quite critical, crucial challenges . . . reaching to the very heart of English [sic] teaching and English studies in education” (p. 371). Beavis and O’Mara (2006) add that, “literacy and technology are perhaps the central matters of concern for English teaching today” (p. 253). In such changing realities, understanding how to engage students in multiple literacies (Luke, 2000; Comber and Reid, 2006) that more clearly reflect the social and textual realities of student and teacher lives is becoming increasingly important.

Incorporating new knowledge to more adequately prepare mother tongue teachers includes such possibilities as adding a minor or supplemental certificate, a course specifically dealing with multiple languages and cultures of diverse classrooms, or requiring a foreign language credit prior to admission to teacher preparation (particularly mother tongue teacher courses) for diverse student populations (Lucas and Grinberg, 2008: 625). The need to adjust mother tongue education in the universities for effective and meaningful teacher preparation must include the recognition that globalization, changing classrooms, and the accompanying social and technological changes require new ways of approaching mother tongue education in schools.

Field-Based Experiences

Preservice mother tongue education teachers shape their teacher knowledge through the intersection of three lenses: background content knowledge, university methods courses, and field experiences. Field experiences often constitute the highlight of the teacher-preparation

experience since here opportunities to learn in and from practice occur. In the classroom, preservice teachers experience the subject in action. Examples of subject matter used in the interaction of theory and practice include: working with different levels of literacy competences, application of new strategies for reading comprehension instruction, and introducing poetry and linguistic subjects in the classroom. Mother tongue teacher education in the Netherlands, for instance, begins at the university with discussions about the subjects in methods courses. Field experiences in the schools follow where mother tongue education teachers, with guided application, apply the principles and practices of these related and relevant mother tongue subject areas at school. Finally, the preservice teachers use a portfolio to reflect on their performance (Mansvelder-Longayroux, 2006). Since field experiences affect and, to varying degrees, shape perceptions and perspectives of mother tongue as school subject, they play a significant role in mother tongue teacher preparation.

Competing models of mother tongue education (see above) and to the significant gap existing between university programs and the choices of schools and supervising teachers for field experiences. Preservice mother tongue teachers often enter schools and teachers that differ from the idealized versions of mother tongue in the university. School realities often reflect the incredible pressures of mother tongue teachers to demonstrate student competence and improvement in literacy and language (e.g., through test results). The preservice teachers witness mother tongue education practiced with an “ethic more geared toward coverage and control” and a “diminishing value placed on student-centered teaching methods” (Smagorinsky *et al.*, 2003: 22). Preservice teachers can feel caught between competing models of mother tongue education and are challenged to make sense and meaning of the field. Nevertheless, the knowledge of the tensions between the two institutional cultures and ideologies remains; some work on reconciling and collaborating is beginning to emerge (Clark, 2001; Kooy, 2006).

The call is out for more collaborative negotiations to align mother tongue education as a methods course at the university and mother tongue as school subject in the schools. The lack of adequate supervisory teachers for effective field experiences complicates the issue further. Unless such connections occur, the mother tongue teaching preparation can be parallel rather than integrated experiences to build teacher learning.

Concluding Remarks

Mother tongue education is in a state of flux, even turmoil as it struggles to find its way and map out its place. The paradigm wars and the changing social and technological advances seriously challenge conventional ways

of teaching mother tongue. The duel between traditional and postmodern conceptions of mother tongue education persists (Mitchell *et al.*, 2006). This leaves a conundrum that presently has little solution or agreement among those interested in mother tongue education in schools. What effect does this tension have on successful and meaningful mother tongue education? Can we agree on the kind of professional content knowledge in mother tongue education that offers a pedagogical translation into the profession and practices that prepares for authentic teaching and learning?

The tensions, in part, arise from political and neo-conservative movements in many nations and schools that continue to alter the face of mother tongue education (see Doecke *et al.* (2007) for an example in Australia). Public and political calls for increasing competence in literacy (assessed through high-stakes testing) and the pervasive lack of agreement on the nature and purposes of mother tongue education contribute to the uncertainty of the field. Nevertheless, global attention to literacy implies a need for university–school collaborations to cultivate stronger ties and work together to responsibly and effectively prepare preservice teachers of mother tongue for diverse languages and cultures, texts, and contexts, in light of the new and changing social realities of their classrooms (Lucas and Grinberg, 2008).

In many national contexts, preparing mother tongue teaching remains problematic. Since mother tongue/language is central within school curricula – the heart of any given culture – its purposes, practices, and ideologies significantly impact meaningful participation in society. Clearly, this shared issue calls for large-scale comparative, international studies. Currently, the field is characterized by many small-scale, one-off, and often (though not necessarily) qualitative studies. A lack of research funding results in a fragmented research field without the mechanisms for cumulative or comparative building of knowledge, or a strong theory of teacher education. Looking across institutional, multinational contexts offers more possibilities for cohesion and general research conclusions (Wilson *et al.*, 2001). Such research knowledge would provide opportunities to discuss intersections and differences in mother tongue education that, in turn, could affect mother tongue methods courses. Larger-scale, multinational research studies have the potential to build a repertoire of rigorous research that can inform policy debates, government inquiries, and curriculum designers across varied contexts (Mitchell *et al.*, 2006). The critical nature and centrality of mother tongue education requires finding defensible and shared ways to prepare teachers that reflect the changing nature, knowledge, and practices of mother tongue education in which teacher knowledge and skill make translation from teacher knowledge to effective and transformational student learning experiences possible.

Vocational Teacher Education

S Johansson, University of Umeå, Umeå, Sweden

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In this article, vocational teacher education is explored and distinguished from other forms of teacher education. The notion of vocational teacher includes a person who teaches youth or adults skills leading to competency in a specific vocation, trade, or profession. Examples would be a teacher preparing students for careers as a mechanical engineer, carpenter, baker, auto mechanic, hairdresser, chef, restaurateur, backhoe operator, store clerk, welder, electrician, nursing assistant, plumber, painter, etc.

Issues considered below are all related to vocational teacher education. However, since vocational education and vocational teacher education are complex activities, necessarily intertwined with each other, one cannot be treated without the other. Furthermore, in order to ascertain what distinguishes vocational teacher education, one must, to some degree, compare it with other forms of teacher education. However, since pedagogy, didactics, sociology, and psychology are common subjects relevant in most teacher education, they are deliberately avoided.

Today vocational education (hence vocational teacher education as well) is becoming increasingly important on the international, national, regional, and local political arenas. A well-educated and well-trained work force is universally considered a key factor in the competitive global marketplaces, an attraction to capital investment and to the development and sustainability of a prosperous society. The large number of recent concepts that have appeared in research on vocational education and work-based learning indicates the rapidly increasing value accorded to the subject. Such concepts include reflective practitioner (Schön, 1991), life-long learning, and tacit knowledge (Polanyi, 1966), situated learning (Lave and Wenger, 1991), activity learning (Engeström, 1987, 1994, 1999), and master-learning (Nielsen and Kvale, 2000). All those concepts indicate that learning is something more than theoretical issues relating to formal education at schools or in universities. Thoughts about the nature of learning influence both vocational education and the training of vocational teacher's education since they introduce new assumptions and alternative ways of thinking what vocational education really is and how it should be carried out. At the same time, old views on what type of knowledge is valuable are being challenged, and this in turn has a strong impact on which issues are to be treated in vocational teacher education and how it should be conducted. New concern can also be noted at

international research conferences where special interest groups devoted to vocational education and vocational teacher training are rapidly growing.

Many Different Models

Societies have developed vocational systems where specific competencies and skills needed by its work force are reproduced and transferred to its youth. Depending on historical and cultural circumstances, these systems have taken many different forms. In some places state authorities regulate education, while in others trade-specific agents, employer organizations, or labor unions struggle for control. The cost of this education may be paid by taxes or may be market based with student fees. There are places where training is customarily offered in evening classes, although the full-time model predominates. Training can take the form of an apprentice program or take place in school workshops, or in a combination of both. In some regions, traditionally handicraft is well established; elsewhere industrial mass production is emphasized. Despite the differences, an issue that appears to be universal is the stability of the traditional division between male and female. Since vocational education is deeply intertwined with historical, cultural, and traditional factors, when changes are contemplated, a number of stakeholders attempt to influence them to suit their own ends. Embedded in this Gordian knot of traditions and stakeholders is the vocational teacher training itself. Because of the wide variety of vocational education models, there are equally many different models of vocational teacher education. Some programs simply ask for college education, while others require a university degree. The requisite vocational competence for such teachers may be in the vocational teacher training. Alternately, teacher training may be limited to pedagogical issues. There is a model in which two types of vocational teachers work in pairs: one teaching theoretical issues in the classroom and the other providing hands-on-training in a workshop setting. In many cases models vary within a national system, depending on the vocation at stake. Thus, there seem to be as many forms of vocational teacher education as there are vocational education models. Nevertheless, although this wide variety of models makes vocational teacher education difficult to characterize, it makes us focus on the least common denominator found in diverse models in order to come up with an adequate description.

Differences between Vocational- and Subject-Oriented Teacher Education

To clarify the issues that distinguish vocational teacher education from other forms of teacher education, regardless of the model or where it is applied, some aspects are explored in what follows. Our aim is to point out what is essential to vocational teacher education and does not affect other categories of teacher education to the same extent.

When introducing the notion of vocational education, a dividing line seems to emerge between it and subject-oriented education (e.g., mathematics, language instruction, natural science, social science, etc.). It is noticeable that subject-oriented education has a knowledge area corresponding to a university scientific discipline. This knowledge area originates in the academy and slowly trickles down into course syllabi at the schools. A teacher wanting to specialize in an academic subject thus looks to a university's departments when deciding what their own education should focus on. Contrary to this, when a prospective vocational teacher plans a course of study, there is no academic base to imitate; instead, one must look at areas of activity in working life. These activity areas require specific competencies for carrying out tasks in a given vocation, trade, or profession. The different points of departure, a knowledge area for subject specialist teachers and an activity area for vocational teachers, distinguish between and shape those two teacher categories.

Steering Systems in Vocational- and Vocational Teacher Education

School systems may be looked upon as containing a number of arenas, in which each has its own task (Lindensjö and Lundgren, 2000). In the policy arena, political agents formulate a comprehensive curriculum, generally on a national level, that besides containing laws and regulations, directs teachers work within the school system. With respect to vocational education, representatives from the various branch organizations, unions, and employer committees establish syllabi for each specific vocation. Often vocational teachers are involved in such work. Course syllabi are also constructed for other competencies judged important on regional and local levels. Here vocational teachers play a major role. In the transformation arena, curricula and syllabi are transformed in a shape that approaches actual training. The job of planning for actual training, taking numerous specific issues in a profession into account, is an essential part of what has to be mastered by all vocational teachers and, therefore, integrated into teacher education. Finally, in the realization arena,

the actual training of students takes place. It forms the essential core of teacher training.

The main guide of the vocational teacher education is the curriculum. Here the teacher educator finds the answers to the question of what education should focus on. A curriculum may be more or less detailed. It may be divided up into a number of smaller parts with fixed content and strict time limits, or it may be more broadly descriptive, with fewer details. The former would result in a course of instruction directed by strict control and discipline. The latter curriculum would be conducive to a higher degree of freedom and allow more problem-oriented and individualized teacher training and give student teachers the opportunity of participating in the design of their own training.

The arenas described above are common to formal education, but in both vocational education and vocational teacher education there are additional arenas formed by branch, employer labor, and trade unions whose opinions have to be considered. Whatever mode of procedure is adopted, insight into the arenas mentioned above is an essential part of all vocational teacher education. However, an institution must not only plan and carry out an existing syllabus, but also possess the ability to construct syllabi suitable for training in competencies important for the local work force.

Admission Requirements

One of the most critical aspects in models of vocational teacher education is the admissions process. Besides its function of determining who may enter the vocational teacher profession, it also expresses prevailing assumptions about the best way to carry out vocational training. In some places academic qualifications are considered a necessity and work experience is given less importance, while elsewhere the opposite is true. Two major standpoints can be found, although a combination would be preferred – either considerable practical work experience is demanded, with knowledge, skills, and competencies acquired during a certain length of time in the profession at stake; or theoretical knowledge, as evidenced by academic credits, is asked for, in the form of a master degree. A third standpoint holds that the ability to motivate students and cooperate with stakeholders is the most important qualification. In practice, what is sought in a potential vocational teacher is closely related to the existing vocational education model.

Laws and Regulations

Vocational teacher education emphasizes on awareness of the rules and regulations that apply to each specific trade

or vocation. These may be safety precautions for electrical installations in bathrooms or environmental regulations concerning the disposal of old carpets. The knowledge of such laws and regulations is essential for a vocational teacher to know, so that they can be conscientiously included in the training of students.

Promoting Aspects of Vocational Education

Vocational education, as with other types of education, has a hidden curriculum behind the official one (Jackson, 1968). Many studies point out that vocational training involves skills and knowledge for a particular vocation; equally important is the invisible transfer of the prevailing work culture with its embedded values (Willis, 1977). This factor distinguishes vocational education from general education. Something hidden is transferred in the way training is carried out, whether it takes place in a school workshop or on the job. Students will unconsciously be induced into accepting hierarchical order and division of work at their future workplace (Johansson, 1999). For example, working in a restaurant in Hanoi is very different from doing the same work in a restaurant in New York or in Monrovia. In some places, work is organized according to a strict hierarchy and with a strong division of work. In other places, work is organized in a more relaxed way, affording a higher degree of freedom to workers. How vocational education is carried out will greatly depend on how work is organized by the local work culture and tradition. The issue of the degree of freedom will, in turn, strongly affect how vocational teacher education needs to be conducted. Vocational teacher education must clarify these unseen aspects in training future teachers. In addition, a vocational teacher often serves as a model for students and may therefore have a strong impact on their values and behavior.

Learning Material

As mentioned earlier, the ability to prepare for vocational training is an important part of vocational teacher education. Textbooks are generally only available for the larger trades. The reason is that the demand is so low and the useful life of such books so short that publishers hesitate to enter the field. Another reason is that equipment and machinery used in vocational training are often of different manufacture and specific teaching material has to be written accordingly. Consequently, vocational teachers must be capable of preparing their own teaching materials, and the necessity of doing so should be stressed as a part of their education.

Place of Training

If training is carried out in a school workshop, the vocational teacher must have the ability to select suitable equipment and maintain all types of machinery. Another responsibility is to keep an adequate supply of consumable material on hand because in most mechanical, electrical, and wood shops, as well as in places such as kitchens, vehicle-repair shops, and hair-dressing salons, the amount of consumable material is overwhelming. A well-developed management system is needed to purchase, store, and inventory all items. The selection, maintenance of equipment, and consumables are specific issues that have to be addressed in vocational teacher education.

When training is carried out in the form of an apprenticeship program or as on-the-job training, a problem emerges of structuring and controlling the student's education. In addition to issues of responsibility decisions about what training should include must be made, depending on what issue is at stake at the moment. No matter what is contained in the syllabus, the training must proceed along the lines of what is currently going on at the job site. However, uncertainty develops as to work quality and grading, since the work is done in the absence of the teacher. This is again a unique issue that distinguishes vocational teachers from other kind of teachers.

Multidisciplinary, Activity- and Problem-Oriented Tasks

Vocational education has a strongly multidisciplinary aspect. For example, a bricklayer must know something about physics when deciding how to build a brick wall, some knowledge of chemistry to choose the right kind of cement, practical psychology when dealing with customers and superiors, and accounting when calculating prices. Thus, in planning training, instruction in diverse areas of knowledge must be included.

Another factor the vocational teacher needs to consider is that all tasks within a vocation are both activity and problem oriented. Every task in every job involves one problem or another to be solved. The objective may be clear, but neither the method nor the means can be taken for granted. Although many problems are routine based, others are complex and require technical equipment and special skills. Operations can be reduced to a number of more or less well-defined tasks, each consisting of a problem to be solved using specific tools. For example, when a baker makes bread, questions arise concerning the type of flour, the amount of spices, the tools that are necessary, and the choice of oven temperature, in addition to where flour, spices, and yeast should be bought. Other decisions must be made with regard to how ingredients

should be transported, where they should be stored, and how much to sell the baked goods for. The task of a vocational teacher is to simulate situations like these in order to conduct training as close to actual conditions as possible.

Grading Students and Quality Control

Grading in vocational training classes is another area that distinguishes vocational teacher education from other types of teacher training. To judge the level of a student's competence to perform a work-related task differs considerably from measuring knowledge in other science areas. Work-related tasks include invisible elements of knowledge and skills. Furthermore, such tasks mostly have to be made more or less independently and in complex social contexts. Judgments involved include such matters as responsibility, creativity, accuracy, speed, sustainability, and the ability to reflect upon the quality of one's work. In technical vocations the work is often concrete and thereby more easy to measure. Nevertheless, awarding grades will be even more complicated when the task to be judged is in a service or care-giving profession where competency in cooperation and communication are very important. Thus, the ability to judge behavior is a competence that has to be cultivated in vocational teacher education.

The work context students will enter should be considered when vocational teacher training is planned and carried out. Vocations are embedded in complex social contexts that include others in that vocation, adjacent vocational areas, and customers. For example, a long-distance truck driver has to cooperate with storage company workers, both when loading and unloading, truck inspectors at weigh stations, customers, superiors, and toll collectors when driving on international routes, not to mention the responsibility of driving a heavy-duty, 64-wheel vehicle.

Vocational Student Teacher

In a situation where the entire course of vocational teacher training is conducted at a college or university and the future teachers will have limited practical experience when hired for their first teaching job, they will suffer from a lack of credibility, both with their students and from local business representatives, making it difficult to arrange on-the-job training for their students in local business.

On the other hand, in a model where the students are admitted to teacher education programs due to their work experience, they will suffer from lack of previous formal education in areas such as reading and writing

skills. Conflicts might also develop when middle-aged workers enter university classrooms. Studies indicate that some of the latter do not fully accept the school's focus on academics, preferring to stress their own vocational competence.

Recent Trends in Vocational Teacher Education

Two major trends are visible in contemporary vocational education. One is an increasing academization, that is, traditional vocations are finding their way into universities. The other is an increasing tendency for basic vocational education to be carried out in an apprentice form. These two trends are seemingly incongruous, although they, in fact, complement each other. In almost every work place, there are those who carry out routine tasks with little competence demanded of them, and those who handle the more complicated tasks. This division of work was formerly negotiated at the workplaces, but with the increase of educational differences, the division will be drawn at the university. Today subordinate status depends mostly on the length of one's experience, seniority principle. In the future, as theoretical education increases, a position might not depend on seniority but on educational achievement. Another aspect to take into account is that simple and routine tasks are disappearing with the increasing automation and computerization. As a result, there are fewer and fewer jobs that demand low competence today.

The first trend has resulted in the greater part of vocational teacher education today being conducted at the university level or it is on its way there. This has put considerable pressure on vocational teacher education, especially where work experience was formerly considered a valuable admission requirement. Thus, those engaged at the vocational teacher education have a double role. On the one hand, vocational teacher education should prepare a student for a teaching career as envisaged; on the other hand, the same student should be qualified to enter a research program at the university level. This equation is not easy to balance and causes problems, especially when admission requirements are based on long-term work.

The mentor phenomenon (Little, 1990) has achieved a meteoric rise in teacher education internationally over the past couple of decades. While mentoring is now a major feature in various phases of teachers' professional development worldwide, the present article focuses on the mentoring of beginning teachers during their initial teacher preparation (ITP) courses and subsequent early induction into teaching.

Teacher mentoring is characterized by multiplicity in a range of aspects, from variations in meaning carried explicitly or implicitly by the term itself, through the emphases and strategies characterizing alternative approaches, to different ways of implementing and organizing mentoring in practice – all of these variously informed in turn by a range of ideas and theories relating directly or indirectly to professional learning. As background to the current research picture regarding beginning teacher mentoring, we briefly sketch the nature of its recent advent, the theories and perspectives potentially informing it, and the varying relations of such theoretical resources to practical mentoring.

Mentoring in Context: Advent, Theory, Versions

The Advent of Teacher Mentoring

The modern rise of mentoring in teacher education can be traced in large part to two relatively distinct origins in the 1980s. On the one hand, mentoring arrangements were introduced by educational policymakers at various levels, particularly in the USA, to contribute to teacher professional development, not least by way of mitigating the reality shock encountered by beginning teachers, but also as a means of rewarding and retaining the capable teachers who might take up the mentoring role (Little, 1990).

Mentoring also featured as part of alternative certification programs designed to increase the supply of teachers at points of need (Feiman-Nemser, 1990). At this point, the approach tended to derive from business management, where mentoring involved a one-to-one relationship with the protégé or mentee in which the more senior and experienced mentor was expected to combine a variety of functions, including teacher, sponsor, role model, and confidant.

On the other hand, the 1980s also saw a more intellectually grounded development by teacher education institutions of new forms of teacher preparation centrally involving field-based mentoring. A prime example among several in the UK was the Oxford University Internship Scheme, a radical attempt to tackle what its developers saw as major problems endemic in the traditionally dominant pattern of teacher education. The new scheme placed central emphasis on the role of the mentor, a subject teacher who took primary responsibility for the professional education in classroom teaching of one or two intern students, within a systematic partnership arrangement negotiated between the university education department and the schools involved. Comparable higher education-based initiatives were also seen in North America during this period (Feiman-Nemser, 1990), with policy groups and educationists calling for a more substantial involvement of schools in teacher preparation.

Since then, there have been moves in many countries toward beginning teacher mentoring. Perhaps the most clear-cut of these occurred in the UK, where in 1992–93 the government mandated that student teachers in England and Wales should henceforth spend at least two-thirds of their courses in schools, where practicing teachers should play a major role in supporting their attainment of government-specified teaching competences (now standards).

Table 1 Recent perspectives on teacher professional knowledge and its acquisition

<i>Perspective</i>	<i>Central features</i>
1. Reflective practice	Emphasis, associated particularly with Dewey, on the importance of conscious problem-solving for effective practical action; Schön's extension to include thinking within the course of action as well as outside it, plus his rejection of the traditional idea that professional capability is simply the application of abstract knowledge
2. Craft knowledge	(Teaching) craft as situated intelligent know-how involving intuitive sensitivities, awarenesses, and action capabilities; anchored in personal experience and educable through reflection, but not reducible to explicit rules, principles, or routines. Associated particularly with Grimmer, who draws on aspects of 1, 7, 11, and 12
3. Personal practical knowledge	Associated particularly with Elbaz; strong overlap with 2, but recognition of explicit theory as well as theory embedded in action. Connelly and Clandinin emphasize the embedding of knowledge in teachers' personal narratives and metaphors
4. Practical reasoning	Emphasis mainly by philosophers on role of explicit critical thinking and argument in deciding on and justifying educational actions
5. Explicit teacher knowledge	Focus on what types and content of declarative knowledge are required as a basis for effective teaching. Associated particularly with L.S.Shulman's emphasis on integration of subject knowledge with pedagogical insight
6. Values and personal engagement	Teaching seen as a craft that is inherently moral by way both of affecting persons and requiring commitment and motivation from persons, which are thus integral aspects of teacher professional capability
7. Constructivism	Originally a psychological theory that human awareness, knowledge, and capability are formed not just passively by the impact of external reality, but also by an interplay between this and what the person brings to the encounter with it and how they actively think about issues. Disagreements among proponents as to how far the influence of such individual preconceptions and processes can be modified by outside/social agents, and as to the epistemological consequences of a constructivist psychology
8. Study of expertise	Recently developed psychological investigation of characteristically complex human forms of capability and their development, typically by means of expert–novice comparisons
9. Cognitive psychology of skill	Post World War II psychological study of skill and skill acquisition, originally using information-processing models and focusing on simple manual activities, later extending to more complex capacities, including social skills
10. Situated cognition and learning	Psychological–anthropological stance arguing that knowledge and capability are gained within and relate to particular social and historical situations, as opposed to dealing to abstract generality. Cognitive capacities are seen as typically distributed across and involving coordination among members of social groups, and inherently involving use of tools, whether physical or conceptual
11. Implicit cognition and learning	Philosophical tradition, mainly associated with Ryle, emphasizing that intelligent action capability or knowing how does not necessarily involve explicit declarative knowledge or knowing that. Recent experimental psychological research confirming not only that cognitive processes involved in action may occur unconsciously, but that acquisition of some kinds of capability may occur without conscious deliberation

Theories and Research on Teacher Professional Knowledge and Learning

Concurrent with the above developments, the same period also saw substantial growth in theorizing and research on the nature and development of teaching capability, under the label of teacher (professional) knowledge. Munby *et al.* (2001) and Tsui (2003) provide useful reviews of this now extensive work, which has yielded a range of perspectives, derived from various analytical, theoretical, and empirical bases. **Table 1** briefly characterizes the major representatives, which are covered more substantially by various other entries in this encyclopedia.

Drawing implications from such sources for teacher mentoring and development requires recognition, on the one hand, that these perspectives are not only distinguishable, but that, as Munby and his co-authors emphasize, there are various kinds of issues and tensions among

several of them. To this can be added that even in their own terms, some positions are themselves subject to critiques and alternative versions. Nevertheless, it is equally important, on the other hand, to make clear that, in various ways and to varying degrees, these perspectives overlap and combine to support a number of general themes of relevance to teacher education, including school-based mentoring. **Table 2** indicates these themes and their degree of support from different sets of perspectives.

The most notable theme concerns the centrality of practical experience for the development of professional know-how (**Table 2**, theme A), which is supported in differing respects by the great majority of the perspectives cited. However, any tendency to replace the traditional privileging of theory in teacher education by exclusive experientialism would, for example, be countered by a range of support for the importance of conscious reasoning

Table 2 Professional learning themes and their supporting perspectives

<i>Theme</i>	<i>Source/perspective</i>
A Professional learning requires practical action and experience	Emphasized by: Reflective practice; craft knowledge; personal practical knowledge; study of expertise; cognitive psychology of skill; implicit cognition and learning; situated cognition and learning. Included in: Values and personal engagement; constructivism; practical reasoning; explicit teacher knowledge.
B Importance of explicit knowledge and conscious reasoning/reflection	Emphasized by: Explicit teacher knowledge; reflective practice; practical reasoning; cognitive psychology of skill. Included in: Constructivism; study of expertise; values and personal engagement; personal practical knowledge.
C Intuitive character of developed know-how	Emphasized by: Craft knowledge; reflective practice; personal practical knowledge; study of expertise; cognitive psychology of skill; implicit cognition and learning; Included in: Situated cognition and learning
D Power of learner-teachers' pre-conceptions	Emphasized by: Constructivism; cognitive psychology of skill Included in: Reflective practice; practical reasoning; explicit teacher knowledge; values and personal engagement; study of expertise
E Developmentally staged nature of professional learning	Emphasized by: Study of expertise; cognitive psychology of skill Included in: Constructivism
F Promotion of responsible autonomy	Emphasized by: Values and personal engagement; Included in: Reflective practice; personal practical knowledge; craft knowledge.

and declarative knowledge (theme B). Purposefulness and explicit problem solving are also important aspects of a somewhat neglected precursor of the modern study of expertise, the cognitive psychology of skill (Table 1, perspective 9), which also provides a corrective to the behaviorist associations still characterizing much usage of this term (cf. Tomlinson, 1999). Thus differential emphases among these well-grounded perspectives may signal the complementary, combined importance of several themes, rather than competition between them as mutually exclusive alternatives.

Tensions do nevertheless remain. Widespread indication that well-established components of skilled action and cognition tend to be deployed intuitively and unconsciously (theme C) does, for example, imply problems for potential communication of and reflection on teachers' professional know-how, even if at the same time it helps explain the strength of the teaching and learning preconceptions (theme D) student teachers typically arrive with from their own lengthy experiences as school pupils. On the other hand, changing relationships between explicit and implicit processes in teaching development (Tomlinson, 1999) are illuminated by a further theme (E), the claim that progress toward relatively full professional capability tends to proceed through a series of developmental stages. While this would imply the need for different forms of learning assistance at these different stages, differences of detail among development models (e.g., Dunne, 1994; Furlong and Maynard, 1995) do raise further issues.

Finally, the value-led personal engagement aspect of teaching (theme F) has received increasingly explicit consideration in recent decades, as well as being part

and parcel of the reflective, craft knowledge and personal practical knowledge approaches. Together with traditional humanistic psychological concerns, these sources make it clear that cognitive, emotional, and motivational support for the development of responsible professional autonomy must feature as a further basic strand in promoting teacher professional development.

Versions of Mentoring

From the now considerable range of literature, it is noteworthy that the term mentoring is used with varied meanings, that is, to convey what are actually a range of somewhat differing concepts, that are typically complex and multifaceted. Such meanings of the term show the family resemblances typical of linguistic usage, in that different sets of mentoring conceptions have different common strands as well as differing contrasts. Important kinds of defining features at stake here include mentoring functions or purposes, strategies or ways of going about achieving such purposes, and contexts in which the activity is to be set.

Thus, on the one hand, it seems clear that in teacher education over the last couple of decades, mentoring has moved on from the career-advancement focus of its early business model and come largely to mean assisting teacher professional development/learning (function aspect) on a one-to-one basis (context/strategy aspect) in the professional activity setting (context aspect). On the other hand, nevertheless, such a claim requires qualification at least in that: (1) some usages involve a more specific concept, for example, adding strategy criteria such as that by definition

mentoring must include promotion of reflection or exclude explicit mentor evaluation of the mentee (e.g., Wang and Odell, 2002) and (2) the above conception is itself relatively general, admitting of considerable further differences of detail.

Given these often subtle differences among mentoring conceptions, it is important not to take the meaning of the term for granted, but to establish the facets specifically defining any particular usage, whether explicitly or implicitly, conceptually or operationally. When one does this, it becomes apparent that existing versions of mentoring show considerable variation and idiosyncrasy (Wang and Odell, 2002).

The relationship of practical developments in mentoring to theoretical ideas and research is difficult to track, but appears to have been both complex and evolving. School-based mentoring could itself be seen as an obvious embodiment of the practical experience theme noted above, and although its arrival in 1980s teacher education appears to have been prompted more substantially by policymakers or practitioner reaction to the traditional separation of intellectual learning and practical experience, Schön's ideas about reflective practice do seem to have acted as a particularly influential catalyst, judging by the speed and extent to which reflective vocabulary entered the discourse and espoused theory of teacher educators (Furlong and Maynard, 1995).

However, the take-up of other perspectives listed in **Table 1** has been less clear-cut and apparently more sporadic. In their extensive 2002 review of mentoring research, Wang and Odell did classify predominant assumptions underlying mentoring programs under three theoretical paradigms. However, this was a *post hoc* analysis and the authors made clear their view that none of these paradigms suffices alone, particularly for the mentoring of progressive reform-minded teaching. When we turn to the growing number of practical books on mentoring, we often find little reference to formal theoretical ideas, even if there is frequently linkage with research, often the authors' own. Those that do make explicit reference to theoretical frameworks tend to do so within a paradigmatic pluralism which seems appropriate to the challenging nature of the practical field. Currently, such explicit usage of theoretical approaches in the context of educational research findings seems to be on the increase, at least as far as academic journal publications are concerned.

Research on Mentoring

The last two or three decades have witnessed an explosion in the number of research studies and publications dealing with various aspects of mentoring. However, this work is decidedly disparate and few comprehensive studies are available. Furthermore, the evidence base relating to the

effectiveness of mentoring remains limited, doubtless partly because of the inevitable difficulties of disentangling the effects of mentoring from other kinds of process and influence. Nevertheless, a number of common and useful findings have begun to emerge with respect to the mentoring of beginning teachers.

Effectiveness and Benefits

From its modern outset, teacher mentoring has been seen as holding the promise of professional motivation and development not only for beginning teacher mentees, but also for teachers providing the mentoring, and thence benefiting schools and educational systems more broadly.

Benefits for mentees

Research suggests that one-to-one mentoring is an important, if not the single most effective, method of supporting and facilitating the professional development of trainee and neophyte teachers. A wide range of benefits of mentoring for beginning teachers have been documented, including reduced feelings of isolation, increased confidence and self-esteem, professional growth, increased self-reflection and problem-solving capacities, and the assimilation of their mentors' practices. The benefits of mentoring featuring most commonly among research findings on this issue relate to mentors' provision of emotional and psychological support, important because mentees' emotional condition is argued to have wide consequences for their progress. A number of studies (e.g., Bullough, 2005; Moor *et al.*, 2005) have reported evidence of mentors boosting the confidence and increasing the morale and job satisfaction of beginning teachers.

Research also points to the impact of mentoring on different aspects of the developing capabilities of beginning teachers, most notably their behavior and classroom management skills, and their ability to manage their time and workloads (e.g., Moor *et al.*, 2005). More generally, mentors have also been found to play an important role in the socialization of beginning teachers, in helping them to learn and adapt to the norms, standards, and expectations associated with being a teacher in a given context (Wang and Odell, 2002).

Benefits for mentors

A wealth of evidence coming predominantly from mentors' own accounts indicates that mentoring beginning teachers tends to have a positive impact on the professional lives of mentors themselves. First, with respect to motivation and commitment, research has found that many mentors derive satisfaction from undertaking the mentor role, especially through seeing their mentees progress and noticing evidence of their own impact on mentees' teaching development. Through the responsibility involved, through mentors feeling reassured when

their ideas are validated by university tutors, feeling less isolated as teachers and enjoying increased collaboration and enhanced professional recognition, mentoring is thus found to consolidate mentors' teacher identity and to increase their sense of self-worth. Studies report mentors claiming increased confidence in their own teaching, improved relationships with pupils and colleagues, and a generally revitalized or reenergized engagement with teaching.

In a study typical of many others in its outcomes, Lopez-Real and Kwan (2005) found that 70% of mentors in a school–university ITP partnership program in Hong Kong claimed to have benefited professionally from their mentoring role. Reported gains included new and improved teaching strategies, enhanced knowledge and use of information and communication technology (ICT), improved communication skills, greater self-reflection, and increased knowledge and support capability with respect to the professional development needs of beginner teachers and others.

There are multiple sources of potential impact upon mentors' own learning via their involvement in mentoring beginning teachers. Perhaps the largest body of research evidence in this area relates to mentors' learning through self-reflection or critical reflection on their own practice. Most mentors in Lopez-Real and Kwan's (2005) study thus suggested that the mentoring process forced them to reflect on their own teaching, for example, because they "felt compelled . . . to account for and explain the reasons for their [teaching] methods" (p. 19), while many of the mentors involved in research conducted by Hagger and McIntyre (2006) were also said to have welcomed the experience because "it made them think about their own teaching". Mentors have also reported learning from their beginning teacher mentees, from their participation in mentor training courses, from university tutors in university–school partnership ITP programs and, more generally, from increased opportunities to talk to others about teaching and learning.

Benefits for schools and educational systems

It might be expected that some of the above-reported benefits of mentoring would produce consequent gains for these teachers' pupils and schools. The evidence on this particular outcome is limited, however, again partly because of the complexity of researching it. However, there is growing indication, largely from the United States, that mentoring programs for teachers in their first years in the profession can under certain conditions increase retention and stability, in that teachers who are mentored are both less likely to leave teaching and less likely to move schools within the profession (e.g., Johnson *et al.*, 2005). It is also possible that schools and educational systems may benefit from the enhanced retention of those teacher-mentors who become more confident, committed, and capable as a result of their participation in

mentoring. There is limited direct evidence of this to date, though in the UK Moor *et al.* (2005) noted a number of additional benefits for schools involved in this kind of mentoring program.

We now turn to what research tells us about the conditions under which the benefits of mentoring are most likely to be realized.

The Conditions for Effective Mentoring

Contextual support for mentoring

The success of mentoring programs in general and of particular mentoring relationships is influenced by a variety of contextual factors. The most consistent finding in this area is that mentoring is more likely to be effective where teacher-mentors are provided with additional release or noncontact time in which to prepare for and undertake the mentoring role, while successful mentoring is further facilitated where timetabling allows mentors and mentees to meet together during the working day. There is some evidence that mentoring is more likely to lead to positive outcomes where mentors receive financial reward and/or some other form of incentive or recognition for their work; where it is carried out in contexts which are relatively free from excessive emphases on externally determined goals and agendas; where mentors are committed to and involved in the design and evaluation of the broader programs of which mentoring is a part; and where such programs are coherently integrated and not characterized by fragmentation among the contributing school- and higher education-based teacher educators.

Mentoring is also more likely to be successful where it takes place within schools which are characterized by collegial and learning cultures and which value learning teachers (Edwards, 1998), where both mentors and mentees have access to support outside of the mentoring relationship and where there are mechanisms in place for both mentee and mentor to initiate without blame the establishment of an alternative pairing.

Mentor selection and pairing with mentees

Research confirms that the success of beginning teacher mentoring is at least a partial function of the ways mentors are selected and paired with mentees: not all good or experienced teachers make good mentors, and not all good mentors make good mentors of all beginning teachers. Mentors should be effective practitioners who can model good professional practice and be professionally respected by their mentees, but perhaps most importantly of all, they should want to do the job and be committed to the work of mentoring. They need to be supportive, non-judgmental and trustworthy, have a positive demeanor, possess good listening skills and the ability to empathize, as well as the willingness and ability to take an interest in beginning teachers' work and lives.

Mentoring has been found more likely to be successful where decisions about mentor–mentee pairings take account of mentees' strengths and limitations, and where the mentor and mentee get along both personally and professionally. Mentoring also tends to be more effective, other things being equal, when mentors teach the same subject specialism as their mentees, but becomes less effective when the mentors are the mentees' head teacher or deputy head teacher, the latter being explained in terms of more senior colleagues finding less time for mentoring and beginning teachers tending to be more inhibited by the high status of the mentor within the school staff structure (Hobson *et al.*, 2007; Johnson *et al.*, 2005).

Mentoring strategies

Like all forms of teaching, mentoring is most effective where it addresses and responds to the needs of the learner/mentee. This means that mentors of beginner teachers should respect the individuality of their adult learner mentees, taking account of mentees' particular learning styles and concerns by way of strategies that are appropriate to the stage of development they are at. However, as Wang and Odell's (2002) review in the context of reform-oriented teaching reminds us, mentoring must keep sight of its particular goals. Thus, there are indications that early in the mentoring relationship, mentors should help mentees identify and engage in critical interrogation of their conceptions of teaching, learning to teach, and mentoring, including discussion of the nature and advantages of different forms of reflection, since these can otherwise present barriers to mentees' professional learning and development. Mentors should also seek to agree with mentees the individual goals of the mentee and the objectives of the mentoring relationship, and should revisit and review these objectives and goals periodically and, where appropriate, revise them.

While the extent to which mentors are able to address mentees' individual needs can be pivotal to the success or otherwise of mentoring, research has also found a number of general approaches, strategies, and tactics to be effective and likely to be valued by beginning teacher mentees.

First, effective mentors provide their mentees with emotional and psychological support, make them feel welcome, accepted and included, and are approachable. Second, effective mentors are those who not only dispose of sufficient time and do spend time with their mentees, but also do so on a regular basis. Third, effective mentors allow their mentees an appropriate degree of autonomy to make decisions and to develop their own teaching styles, while not being too *laissez-faire* or hands off. Fourth, a considerable number of studies have found that one of the most valued aspects of the work undertaken by mentors with beginning teachers is lesson observation (both of and by the mentee) which involves analysis of the processes involved. Mentors' observation of the lessons of their

mentees tends to be valued most where the objectives of the observation are agreed upon in a preobservation conference, and where the postobservation conference focuses on specific aspects of mentees' teaching and includes constructive comments from the mentor. It should be conducted in a sensitive, nonthreatening way, providing an opportunity for genuine dialog in which there is joint explanation and exploration of perceptions leading to agreement on the strengths and weaknesses of the mentee's teaching. The latter deserves some emphasis in the light of indications of teacher mentors failing to challenge their mentees' assumptions sufficiently (e.g., Edwards, 1998). The dialog should also include discussion of the likely impacts of observed teaching actions and leave the mentee with clear ideas on how he/she might overcome any problems and work toward improving weaknesses. Such discussions would also hopefully be located within attempts to scaffold mentees into deeper levels of thinking and reflecting about teaching and learning.

Finally, a number of writers have argued from a variety of perspectives that collaborative teaching, including planning and reflection, by teacher mentors and their mentees offers a mentoring strategy with strong potential for realization of many of the themes listed earlier in **Table 2**. Apart from a small number of exceptions (e.g., Burn, 1997), however, research on such a strategy is so far notable by its absence.

Mentor preparation and support

Many have argued that since even excellent school teachers may not be effective facilitators of adult professional learning and because the mentoring role is a relatively new one that can clash with traditional norms and structures of teaching (Little, 1990), it is important to provide mentors with preparation and support. This should be practical and specific, including strategies for functions such as observation and discussion of mentee teaching, promoting mentee reflection, and discussing pedagogical issues with them. But on the basis of research findings (e.g., Bullough, 2005) and the kinds of modern perspectives on professional knowledge and learning mentioned earlier, it is equally conclusive that such preparation must go beyond the behavioral inculcation traditionally associated with training and include the cognitive resources and supported participatory opportunities needed to develop intelligent mentoring capability and identity. Writers such as Bullough (2005) suggest the utility of mentors engaging in discussion of mentoring with other teacher-mentors and university-based teacher educators. However, while Graham (1997) provides evidence that such forms of collaborative inquiry are effective in overcoming mentor isolation, the evidence base regarding the effects of different kinds of mentor preparation is generally still rather sparse.

The Dark Side of Mentoring

A number of commentators (e.g., Sundli, 2007) have castigated what they see as an uncritical optimism widely characterizing literature on mentoring in education. Warnings concerning what Long (1997) termed “the dark side of mentoring” are nevertheless equally long-standing and in recent years, such possibilities have been considered by several published studies. The overall pattern of evidence indicates that rather than being inevitable consequences inherent in mentoring *per se*, such downsides are functions of failure at various levels to ensure the sorts of conditions for effective mentoring considered above. This is nevertheless not to suggest that all conditions for effective mentoring are always achievable or, conversely, that their nemesis, the obstacles or sources of collateral damage to mentoring (Kilburg and Hancock, 2006), are always possible to overcome.

Disadvantages of mentoring for mentors

Some studies attest failures to realize the sorts of potential benefits to mentors referred to above, but others indicate that mentoring can actually be disadvantageous or harmful to them. Three main problems are documented.

First, many studies (e.g., Hobson *et al.*, 2007; Moor *et al.*, 2005) have reported mentors experiencing difficulties relating to increased and competing demands on their time as a result of their involvement in mentoring in addition to normal teaching roles. As well as impacting on mentors’ work–life balance and stress, this can also contribute to difficulties in accommodating the needs of their mentees. There seems to be no evidence of any related, negative impact on the learning of such mentor teachers’ own pupils, though this may be due to the lack of research or publication.

Second, research has found that mentors sometimes experience feelings of insecurity, nervousness, threat, and even inadequacy at the prospect of their lessons being observed by mentees or by their mentees presenting new and challenging ideas (e.g., Bullough, 2005). Third, some studies have indicated that mentors can feel isolated in the role (e.g., Graham, 1997).

There are indications in the research of such problems being caused or exacerbated by mentors being given insufficient or no additional time in which to carry out their mentoring duties, by a lack of preparation for the role, or by inadequate training that deals substantially only with its administrative aspects.

Disadvantages for beginning teachers and educational systems: Limitations of mentoring in practice

Research on beginning teacher mentoring has also uncovered variation in the nature and quality of mentoring support provided and has documented evidence of poor

mentoring practice, which has negative consequences for mentees, their schools, and wider education systems. There appear to be four main kinds of failings.

First, some studies have found mentors failing to provide sufficient support for beginner teachers’ emotional and psychological well-being, characterized in many instances by general unavailability. In some cases the situation can be worse, with student teachers being overloaded or even feeling bullied (Maguire, 2001) by their school-based mentors.

Second, and as noted, considerable research has suggested that some beginning teachers are not sufficiently challenged by their mentors – in some cases, by not being given sufficient responsibility or autonomy and freedom to innovate. Edwards (1998), for example, argued that partly due to the assessment framework of ITP in England and partly to protect their own pupils and their learning, primary phase teacher-mentors in their study tended to guide their student teacher-mentees into low-risk activities.

Third, numerous studies have shown mentors tending to see their role primarily in terms of the provision of safe sites for trial and error learning, focusing in their interactions with mentees on technicalities or performance issues such as classroom management and subject content, devoting little or insufficient attention to pedagogical issues and in particular to reform-minded teaching, to the promotion of reflection incorporating an examination of principles behind the practice, or to issues of social reform and social justice. Indeed, some studies (e.g., Sundli, 2007) have shown that some teacher-mentors hold a transmission perspective on teaching and learning, have a limited understanding of concepts such as critical reflection, continue to hold dualist notions of theory and practice, and lack the confidence to incorporate theoretical insights into their work with mentees.

One outcome of such failings is that, in spite of the explicit aim of some mentoring programs being to reduce teacher attrition, they have actually contributed to trainee and beginning teachers withdrawing from their courses or dropping out of teaching (e.g., Hobson *et al.*, 2007). A further potential consequence is that this restricted quality of mentoring serves to restrict mentees’ learning and development in a variety of ways. One finds little evidence, for example, of school-based mentoring achieving its often-stated aim of reducing theory–practice dualism among beginning teachers and helping them to recognize and utilize the theoretical work covered in their ITP programs (Bullough, 2005). Not surprisingly, a number of studies have suggested that such restricted kinds of mentoring result in the reproduction of conventional norms and practices, rendering beginning teachers less likely to develop reform-minded and learning-centered approaches to teaching or to advance social reform and social justice agendas (Wang and Odell, 2002).

Conclusion and Prospect

Beginning teacher mentoring continues to establish itself evermore firmly worldwide and can draw on an increasing range of theory informing professional learning and useful findings from a burgeoning research effort in teacher mentoring. Nevertheless, while the multilayered complexity of teaching teachers ensures no fewer challenges to mentoring research than those facing pedagogy and pedagogical research generally, we must note, for example, that very few indeed of the studies informing this article went beyond accounts of mentoring by mentors and mentees themselves, or involved any meaningful comparison between the professional learning outcomes of persons receiving and not receiving mentoring support. It is to be hoped that while firmly retaining their methodological and philosophical criticality, future researchers in this field may also be somewhat more adventurous in their investigation of the effects, including both potential benefits and costs, of particular versions and strategies of beginning teacher mentoring.

Partnerships Between Schools and Higher Education

C Day and L Smethem, University of Nottingham, Nottingham, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article examines the nature of partnerships across different education systems, presenting a selection of those which, available research suggests, hold most relevance to the advancement of teaching and learning in all countries in this century. In the international arena, all governments are focusing their attention on high-quality teaching in the drive to raise standards and improve education for all pupils, regardless of their background or circumstances. In these contexts, the importance of partnerships between agencies, which serve the needs of children and young people, has been realized by governments. This is especially the case in education. Pre-service teacher education, for example, has long been criticized in many countries as being too theory driven and dominated by higher education. Thus, many governments in Europe, North America, and Australia have moved away from supporting teacher education programs, which separate the learning about being a teacher function (the province of universities) from the learning to teach function (the province of schools). At the same time, there has been a widespread acknowledgment that the continuing education and training of teachers is essential in a rapidly changing world as governments intervene more frequently in all aspects of the life of schools with new policies designed to improve standards.

This article identifies and discusses key purposes, forms, processes, and outcomes of contemporary pre- and in-service partnerships between schools and higher education. Such partnerships have been acknowledged internationally as being an important strand in strategies to reduce inequalities, raise the quality of education for all teachers, and enhance the quality and relevance of school education in the twenty-first century. Although the concept of partnerships for educational improvement is not new, there is a growing body of literature across initial teacher education, teacher professional development, and educational research, which acknowledges school–higher education institution (HEI) partnerships as being powerful ways for educators to form collaborations that can result in improved practice and results for students. The literature also points to the need for time, trust, and mutual respect as conditions for success in partnerships (e.g., Sachs, 2003).

Partnerships have been defined as consisting of “two or more parties that share common goals that cannot be reached by either party independently” (Barnett *et al.*, 1999).

Several writers highlight mutuality within partnerships, including the importance of mutual respect, common goals, and interests. However, simply sharing the same set of goals does not guarantee that these will be achieved successfully:

for partnerships are not always benevolent and pressure groups outside the school frequently have more than the children’s interests at heart. (Hargreaves and Fullan, 1998: 5)

Success depends upon whether and how the leadership is distributed in the system, how the partnership is conducted, and on what basis. It is important, therefore, to separate out organizational arrangements for partnerships from the individual and organizational learning that may take place within them. School–HEI partnerships may take a number of different forms which include:

- postgraduate programs, generally for midcareer teachers and nonaccredited in-service programs; both may involve classroom-based research;
- several schools working together with an HEI in one district or country (perhaps working with schools in another district or country);
- a school working with consultants in a local authority/school district and/or HEI;
- research consortia (funded, for example, by education ministries or unfunded);
- action research projects (funded or unfunded); and
- collaborative research networks (formal or informal).

These forms of partnership share three assumptions: (1) critical reflection is a necessary part of being a professional in schools and universities; (2) learning only from one’s own experience will ultimately limit learning; and (3) change is more likely to occur if those who lead change in schools and classrooms are active participants in shaping change agendas. At face value, partnerships champion knowledge which is produced by the user community rather than that which is usually produced by knowledge experts who are far removed from the context in which knowledge will be applied. In effect, partnerships create a variety of opportunities for teacher professional development, including learning from colleagues, which some regard as highly influential. However, partnerships are neither always emancipatory nor do they necessarily promote models of professionalism that may appeal to teachers themselves and to those working in HEIs, especially when they become vehicles for the implementation of

centralized or localized policies, which are not seen by teachers to be beneficial to the students with whom they work. We now examine six innovative school–university partnerships from different parts of the world.

School–Higher Education Partnerships Involving Preservice and Experienced Teachers

Preservice Teacher Education

Teacher educators based in the HEI often lack credibility with pre- and in-service teachers as they are perceived as being out of touch with schools and educational practice. Preservice teachers therefore tend to value more highly their interactions with practicing teachers. The OECD's survey (OECD, Organisation for Economic Cooperation and Development) of initial teacher education notes international concern about the "limited cooperation between teacher education institutions and schools" (OECD, 2005: 134) and resultant lack of "coherence and alignment" (OECD, 2005: 108); it highlights a need for greater sharing of expertise that would enable trainee teachers to make connections between theory and practice. The aim is to guard both against the apprenticeship or tips-for-teachers model of learning to teach, which entirely school-based training might produce, and the irrelevance of theory to practice, which university-dominated training models may be perceived to produce. In England and Wales, since 1992, the government has required schools to be full partners in initial teacher education for secondary school teachers, with trainee teachers spending 24 weeks out of a 36-week course in schools working with teachers and pupils (Department for Education, 1992). Yet in this partnership model, although there is shared responsibility for the assessment of practical teaching, in most instances the leadership largely remains in the control of the HEI, with the partnership characterized as an unequal expert–client relationship (Brisard *et al.*, 2005). Thus, in themselves, partnership models do not always represent equality of roles or decision-making processes, or production of shared knowledge.

Professional Development Schools

In many parts of North America, professional development schools (PDSs) have been established which combine preservice, in-service, and collaborative research and development, drawing on the influential work by Holmes Group (1986) in reforming the national teacher education system in the United States. PDSs embody the principles of collaborative partnerships between schools, school districts (local authorities), and university faculties of education, but go beyond those established in preservice teacher

education in engaging university and school staff in research and development directed at improving practice and enhancing student learning. In PDSs, then, collaboration is the norm for teachers, most of whom otherwise spend most of their working lives isolated in their classrooms. Learning Consortia in Canada perform a similar function. Beginning teachers who have been trained in a PDS are, according to Darling-Hammond (2006: 163), generally more positively viewed by employers than new teachers who have been trained elsewhere. To a large extent, he/she attributes this to the powerful connections between theory and practice in both the school and the HEI, which result in a capacity for constant improvement (2006: 185). Working with beginning teachers has also been shown to benefit experienced teachers who, by reflecting on and articulating their own practice, enhance their own teaching. Indeed, it is claimed that PDSs lead to change in practice for preservice teachers, experienced teachers, and university teachers.

School-Level Development: Improving the Quality of Education for All

Hopkins *et al.* (1998) created Improving the Quality of Education for All (IQEA) in the 1990s, primarily in the United Kingdom. Key concepts in the IQEA approach to authentic school improvement are reflection and collaborative action inquiry led by School Improvement Groups whose work is closely allied to whole-school improvement planning and is supported by senior teachers. Partnerships between school, university, and local authority (district) are premised upon a commitment to working with rather than on schools (Hopkins *et al.*, 1998: 5). The model aims to develop an inquiry-based professional learning community through staff development, with whole-school in-service training events focused on teaching and learning, interdepartmental discussion of and workshops on teaching and learning, at times drawing on expertise within the school, at times working with HEI colleagues. The underpinning framework is one of collaborative inquiry as a means of generating shared knowledge and sustaining improvement.

The National Schools Network and Innovative Links Project Between Schools and Universities

The National Schools Network and Innovative Links Project are school-based research partnerships in Australia with HEIs that focus on improving the work practices and conditions of teachers and students and enhancing student learning (Sachs, 2003: 23). Both projects engage teachers and academics in collaborative research projects for which they jointly identify a focus. The projects are based on the formation of learning communities. Like PDS and IQEA, they actively acknowledge that teacher learning is central

to reform and the impact that teachers' engagement in their own learning may have upon student learning outcomes. The Innovative Links Project was a nationwide initiative which represented formal and explicit partnerships between schools and universities, which engaged teachers in learning which challenged their conceptions of schooling, teacher education, and teacher professionalism. Fundamental to the project was teacher inquiry, which was directly focused on enhancing student learning. The success of this project can be judged by the fact that some partnerships continued their work beyond the end of external funding.

Sachs (2000: 85) maintains that both projects are underpinned by core principles of learning which comprise the basis for "rethinking the practice of teacher professionalism – learning, participation, collaboration, cooperation and activism." She asserts that these principles are fundamental values for the socially responsible and active professional (Sachs, 2000: 83). These projects also enable academics to redress the perception that they are out of touch with the real world of teaching. There is, then, an important difference between these and the PDS movement emanating from America and the IQEA project emanating from England, in that the Australian projects more overtly address and interrogate the nature of teacher professionalism, and, within this, the emancipation of teachers as being critical to educational reform.

Networked Learning Communities

Networked learning communities (NLCs) are groups of schools, usually though not always closely connected geographically, which come together for a lengthy period of time (usually more than 2 years) in order to design and conduct classroom and school-centered inquiries together, which they believe will be of collective benefit. They almost always involve, also, partnership(s) with one or more external agencies. As with other partnerships in this article, they are underpinned by principles of user-produced knowledge, learning, collaboration, trust, and practical inquiry. NLCs exist in many countries (e.g., through European Community-funded projects).

The nature of relationships in NLCs is one of the key challenges to the growth in network learning, which involves partnerships between schools and higher education. It seems to have been assumed in these initiatives that the peer pressure exerted implicitly or explicitly by those involved in active participation will somehow, of itself, move the school, teachers, and universities further in the desired direction of change. In all cases of partnership, however, it seems that the quality of leadership is key to successful change. In the case of networks, it is network leaders whose role is to mediate between the ownership of activities at the school level and the broader interests and needs of the network.

The creation of NLCs takes time and is not always easy (there will always be individuals and groups whose individual or collected vested self-interest may not be served by this). In the process, new knowledge, skills, and dispositions will need to be developed and tentative steps to change supported.

Collaborative Action Research

For many years, teachers from higher education in different parts of the world have promoted and supported systematic practical school and classroom inquiry among teachers. Indeed, this form of inquiry, often referred to as participatory action research and teacher research, is a fundamental part of the work of PDSs, IQEA, and NLCs. However, its origins lie in principles of teacher empowerment, emancipation, and change, the belief that it is teachers themselves who should take decisions about classroom improvements and that these should be based upon the collection and analysis of data. Many universities now provide masters-level qualifications in action research, and supporting non-accredited work of this kind and specialist international journals contain accounts of teachers' work (e.g., *The International Educational Action Research Journal*). Unlike the examples used previously in this article, action research may be carried out by individual or groups of teachers at school level with minimal financial support. However, it is usually supported by a critical friend from higher education. This was the case in the Best Practice Research Scholarship Scheme, a UK Department for Education and Skills initiative to support teachers' continuing professional development. Approximately, 1000 small grants were awarded each year (2000–2003) to serving classroom teachers to support school- and classroom-focused research projects, supported by partnership colleagues in HEIs. In their evaluation, Furlong and Salisbury (2005) reported considerable strengths in this initiative, which was popular with schools and HEIs, with significant impact on teachers' learning, on practice, and on pupils' learning. Collaborative action–research partnerships may focus upon investigating aspects of classroom practice by the systematic collection and analysis of data from one's own classroom and the emphasis is always on improvement through reflection and self-confrontation within an ethical framework of justice, critique, and professionalism (Campbell and Groundwater-Smith, 2007). Alongside these, there are also examples of larger-scale collaborations and even systems that have adopted action research as a means to improvement. For example, Walker (2002) reports on the use of this in teacher education reforms in Namibia and Brazil where policymakers do adopt this approach to partnership learning, however, Cochran-Smith and Lytle (1999) warn that their motives can be prioritized over those of the teachers.

Discussion

Sachs (2003) highlights the potential of school–HEI partnerships for improving teacher professionalism and professional development. She also warns that:

In order to develop collaborative partnerships we must not underestimate the high level of trust and mutual respect that this entails. Without trust and respect, partnerships are on very shaky ground. (Sachs, 2003: 75)

The examples of partnerships which are provided in this article are not intended to be comprehensive or representative of the huge range of partnership configurations that exist, often informally, in and between different teachers, schools, schools and districts, universities, and other agencies. They have been selected, however, as examples of systemic and institutional trends which, in themselves, illustrate an acknowledgment that if schools are to serve the increasingly complex needs of economic success and the well-being of societies in the twenty-first century, then learning alone is no longer sufficient. In the knowledge society, interdependence and connectedness are the new watchwords.

In theory, then, partnerships, where each partner contributes equally to knowledge production and improvement in practice, can create important learning opportunities for the
