With this design, both groups receive treatment but at different time points. The experiment is replicated in two phases with the role of group switching as experimental or control group (i.e., switching replications). Note, however, that the first phase and the second phase do not provide the same experimental condition. Treatments are rendered to two groups at different time points – with the first group receiving treatment following one pretest, whereas the second group receives treatment following two pretests. Likewise, the first group is administered the posttest twice, whereas one posttest is used for the second group. These different conditions create contextual differences for the two groups for both treatment and testing conditions. However, this modified replication still helps the evaluation of threats to validity. Potential threats include history and compensatory rivalry when the treatment is removed from the group that the treatment was first introduced to.

Pretest–posttest control group design using a reversed-treatment control group or groups

$E O_1 X_+ O_2 \quad E O_1 X_- O_2$

$C O_1 X_- O_2 \quad C_A O_{A1} X_- O_{A2}$

$C_B O_{B1} O_{B2}$

In both diagrams, X_- represents a conceptually opposite treatment expected to reverse the effect from the original treatment (X_+) predicted by the research to produce an effect in a direction (Shadish *et al.*, 2002) – that is, a treatment effect is supported by a statistical interaction, with posttest scores of the two groups pointing at different directions. With this design, the causal construct should be defined and manipulated carefully to develop a test that captures the outcomes that run opposite ways. As the control group receives a reversed treatment, some plausible threats to validity can be ruled out. For example, a pretest–posttest difference can be attributed to the treatment and not to participants' reactivity to the experimental situation (i.e., participants' perceptions of the experimental situation are part of the treatment tested) or novelty effects (participants respond well to a novel experiment). A reversed treatment is not feasible for situations where such treatment causes ethical and practical concerns.

The second design (the diagram on the right-hand side) that includes an untreated control group is useful when X_+ and X_- do produce differential outcomes in two groups but in the same direction. Inclusion of an untreated control group will shed more light on the direction of the outcomes.

Conclusions

Quasi-experimentation is an important research approach – especially when randomization is not reasonable. Thus, experimental research conducted in field settings (classrooms, schools, or districts) employs mostly quasi-experimental design. Due to the nonrandomization in quasi-experimentation, threats to the validity of causal inferences are numerous. Apparently, for quasi-experimental research to be meaningful and useful for improving educational practices and providing support for various educational theories, substantial improvements of the commonly used quasi-experimental design are necessary. This article illustrates only two basic

designs for two-group situations and provides improved designs that may help researchers assess various threats involved in quasi-experimentation.

Regression Discontinuity Designs

A Kelava and S Rohrmann, Technical University Darmstadt, Darmstadt, Germany
V Hodapp, Goethe University Frankfurt am Main, Frankfurt, Germany

© 2010 Elsevier Ltd. All rights reserved.

Sometimes there are research situations when the realization of a randomized experiment is practically impossible or ethically not justifiable. For example, in educational research, a reading training program should be given to children who have lower scores in a reading achievement test instead of giving the training program to those children who do not need it. Therefore, programs are given to children below a cutoff score and not given to children above the cutoff score.

In such research situations, regression discontinuity (RD) designs allow for an unbiased estimation of treatment effects when participants of a quasi-experimental study are assigned to conditions on the basis of a cutoff score (for an excellent introduction see Shadish *et al.*, 2002).

The Principle of RD Designs

The key idea of the RD design is that the experimenter controls the assignment of participants to two or more conditions. The experimenter assigns participants to conditions on the basis of a cutoff score of an assignment variable that was measured before the treatment. Participants scoring below a given cutoff score are assigned to one condition and participants scoring equal or greater than the cutoff score are assigned to another condition. In contrast, in a randomized experiment, the assignment is determined by a coin toss or another random drawing which is uncontrolled by the experimenter.

The basic RD design can be summarized as a simple pre-post design (see **Table 1**).

In the RD design, the assignment variable (pretest) and the outcome variable (posttest) need not be the same measure. They can be completely different and independent measures. However, the assignment variable O_{assign} has to be at least an ordinal measure. Nominal variables, for example, dichotomous variables, cannot be used as assignment variables.

Figures 1 and **2** illustrate a hypothetical RD study. The assignment variable could be a pretest on a fictive outcome, for example, a reading test. Children scoring less than a cutoff score, here set at 50, are assigned to the treatment group and children scoring equal or greater than the cutoff are assigned to the control group. In **Figures 1** and **2**, the assignment variable (pretest) is given as the abscissa and the outcome variable (posttest) is given as the ordinate. These two figures graph a scatter

plot of the assignment variable against the outcome variable. A vertical line separates the treatment group from the control group.

Suppose that the training was not effective (see **Figure 1**). In this case, the assignment variable scores (pretest) and outcome scores (posttest) would be linearly related across both conditions with a given amount of correlation, here set at 0.90. There would be no substantive change of the scores except for differences that are due to unreliable measures (changes due to maturation, etc. are excluded).

However, if there is a (constant) effect of the treatment, participants in the treatment condition show increased outcome scores. In **Figure 2**, the treatment effect is set to ten score points. This means that the children's reading achievement improves by ten points. This change is equivalent to a ten-point score shift and results in a vertical displacement (discontinuity) at the cutoff. The slopes of the two regression lines are identical (parallel). The discontinuity (the vertical displacement) gives the RD design its name.

A true treatment effect will cause an upward or downward displacement in the regression line of the treatment group that relates the assignment to outcome. The displacement can be either a change in mean or a change in the slope of the treatment group's regression line. A change in mean indicates a constant change of the outcome score for all participants in the treatment group. A change in the slope indicates that the treatment is more effective for some values of the assignment variable than for others. **Figure 3** shows a change of slope in the context of the reading training program example presented above. As can be seen, there are two effects. First, there is a treatment effect that shifts the outcome score values. This means that children receiving the training program improve in reading ability, regardless of their pretest score. Second, there is an interaction between the assignment variable and treatment. This means that the effect of the training is stronger for the children who had higher assignment scores.

Model Specification within the RD Design

In order to estimate the treatment effect within the RD design, an ANCOVA-like regression model has to be specified. In the simplest (linear) case, when a constant treatment effect is expected, eqn [1] can be estimated (see **Figures 1** and **2**):

$$O_{\text{post}} = \beta_0 + \beta_1 \text{Condition} + \beta_2(O_{\text{assign}} - O_{\text{cutoff}}) + \varepsilon \quad [1]$$

where β_0 is an intercept, β_1 is the treatment effect of the binary variable Condition that records which treatment the participant received (0 = control, 1 = treatment), β_2 is the effect of the assignment variable O_{assign} (centered at the cutoff O_{cutoff}), and ε is the error of prediction.

As can be seen in eqn [1], the selection bias, which is due to the nonrandom assignment to conditions, is controlled by specifying the effect of the assignment variable O_{assign} .

In **Figure 1**, there is no treatment effect, which is equivalent to $\beta_1 = 0$. In **Figure 2**, there is a ten score points treatment effect, which corresponds to $\beta_1 = 10$ in eqn [1]. The intercept and the effect of the assignment variable are $\beta_0 = 50$ and $\beta_2 = 1$, respectively.

In the nonlinear case (see **Figure 3**), when an interaction between treatment variable and assignment variable is expected, eqn (2) can be estimated:

$$O_{\text{post}} = \beta_0 + \beta_1 \text{Condition} + \beta_2(O_{\text{assign}} - O_{\text{cutoff}}) + \beta_3 \text{Condition}(O_{\text{assign}} - O_{\text{cutoff}}) + \varepsilon \quad [2]$$

where β_3 is the coefficient of the interaction term. In **Figure 3**, the interaction effect corresponds to $\beta_3 = 0.5$. The intercept is $\beta_0 = 50$, the treatment effect is $\beta_1 = 35$, and the effect of the assignment variable is $\beta_2 = 1$.

Requirements for the RD Design

Assignment Variable

The RD design requires that the assignment to the conditions is based only on the cutoff score and not on any other variables or influences. The assignment rule (based on the cutoff) must not be overridden by removing a participant from one condition and assigning him to another. Otherwise, the validity of the experiment is impaired.

In order to have a valid design, the assignment variable must not be caused by treatment. Therefore, the assignment variable has to be measured before the start of the treatment. The assignment can be a pretest of the outcome variable, but does not have to be. It can even be totally unrelated to the outcome and have no substantive meaning within the research situation. For example, the assignment could be based on the date of application to a program (e.g., Cain, 1975). In this case, the RD design functions like a randomized experiment in which the assignment process is unrelated to the outcome (like a coin toss). Therefore, the RD design works whether the assignment variable is related or not to the outcome variable.

The assignment variable has to be a continuous variable or at least a (monotonically increasing) ordinal variable,

Table 1 Basic RD design

Pretest	Cutoff	Conditions	Posttest
O_{assign}	X	T	O_{post}
O_{assign}	X	C	O_{post}

O_{assign} = pretest measure of the assignment variable.

X = participants are assigned to conditions T or C based on a cutoff score.

T = treatment condition; C second treatment (e.g., control condition).

O_{post} = posttest measure of the outcome variable.

Figure 1 Regression discontinuity study with no treatment effect; no effect of the training program.

Figure 2 Regression discontinuity study with treatment effect; effective training program.

Figure 3 Regression discontinuity study with treatment and interaction effect.

such as income or test achievement scores. Dichotomous variables, such as gender, are not allowed, because they do not permit the estimation of a regression (line) within each group. There would be no variation within each group which makes the estimation of a regression line impossible. Therefore, the assignment variable should be continuously distributed with sufficient variance.

Cutoff Point and Additional Requirements

The selection of a cutoff point depends on several considerations. It should be chosen on substantive consideration,

such as professional opinion about who needs a medical treatment or which children need compensatory education. As shown by Cohen (1983), the statistical power and the estimation of interaction effects are both facilitated if the cutoff is set at the mean of the distribution of the assignment variable scores. However, there can be difficulties locating the cutoff at the mean when participants are arriving one after the other in the study so that the mean cannot be computed until all participants have arrived. Difficulties also arise when cost or need limits treatment to those participants who have higher scores on the assignment variable. In each case, placement of

the cutoff at extreme values reduces the power to detect a treatment effect.

If several assignment variables are available with different metrics, a total score can be formed by z-transforming the variables and averaging them (Judd and Kenny, 1981). By this strategy, unreliable assignment variables and variables with poor distributional properties can be summarized to assignment variables with desirable properties.

It is important to know the overall functional form that relates the assignment and outcome variable (i.e., whether it is linear, curvilinear, logistic, etc.). If the functional form is misspecified in the analysis, biased treatment effect estimates will result.

All participants must belong to one population prior to being assigned to the conditions, such that prior to assignment, it must have been possible for all participants in the study to receive the treatment if the cutoff had been set differently. For example, suppose a reading training (treatment) was implemented in school A for children scoring below a cutoff and that the control group contained children in school B who scored above that cutoff. As the treatment was not implemented in school B, it would not have been possible for school B children to receive the training even if their scores were lower than the cutoff score. Therefore, this selection bias would also lead to biased inferences on the treatment effect in the RD design.

Like in a randomized experiment, the participants in the treatment group should all receive the same amount of treatment, and those in the control group no treatment at all. When some treatment group participants receive less treatment than others, the validity of the study will be impaired. Treatment crossover participants also weaken the integrity of assignment. Therefore, it is important to retain all participants in the conditions to which they were originally assigned.

Extension of the Simple Basic RD Design

The basic RD design can be extended in several ways. Instead of comparing a treatment condition with a control condition, two treatment conditions could be compared with each other. The analysis remains the same.

The design can be extended for more than two groups, namely three or more conditions. For example, there could be two different treatment conditions and one control condition. Then, the assignment variable score has to be divided into three intervals by defining two cutoffs.

Treatments can be administered at different doses to different treatment groups so that those participants with higher addiction scores receive higher doses. For example, Fagerstrom (1978) applied an RD design in a study using nicotine gums to prevent relapse among participants who quit smoking. Participants with higher addiction scores

received doses of 4 mg nicotine and participants with lower addiction scores received 2 mg nicotine.

By using two cutoff scores the participants could be separated into three groups. The two outer groups would receive exactly the same treatments, say a training program, and the inner group would be the control group. If the treatment is effective and the control group shows no effect, the relationship between the outcome, on the one side, and the assignment variable and the dichotomous variable representing receiving of treatment, on the other side, would be quadratic. This design has an increased power by a reduced multicollinearity between these two predictors of the outcome variable in a linear model (Kelava *et al.*, 2008).

Theory of the RD Design

In order to show that the RD design yields unbiased estimates of treatment effects that are comparable to a randomized experiment, we will explain that the randomized experiment also uses RDs to estimate effects and that RDs serve as complete models of the selection process.

Link to Randomized Experiments

Suppose that in a reading achievement study a randomized experiment with a pre-post design is applied. Participants are pretested with a reading achievement measure, randomly assigned to training or no training (treatment vs. control condition), and then posttested with the outcome measure reading achievement again. If the treatment has no effect, the experiment would show a scatter plot of the pretest against posttest scores as shown in **Figure 4**. This figure would have a positive slope of the regression line, but no cutoff, because the assignment to groups was random across all pretest scores. The participants are randomly intermixed because random assignment ensures that there is no systematic relationship between treatment group membership and any pretest scores.

Figure 5 shows a scatter plot that would result if the treatment in the randomized experiment had the same 10 score points effect on the reading achievement as the RD design in **Figure 2**. For each group, a separate regression line is graphed. If we add a vertical line at a pretest score measure of 50, the displacement of the two parallel regression lines at this score would be an unbiased estimate of the treatment effect; and if we delete all treatment participants to the right and all control condition participants to the left, the resulting graph would be identical to the RD design in **Figure 2**.

Figure 5 illustrates another important difference between the RD design and a randomized experiment.

Figure 4 Randomized experiment with no effect of the treatment.

Figure 5 Randomized experiment with a ten-point treatment effect.

In the randomized experiment, the pretest means of the groups are identical at about 50 score points by random assignment. In the RD design, the cutoff-based assignment creates groups with maximally different pretest means and with nonoverlapping distributions. Nevertheless, the RD design yields unbiased estimates of the treatment effect.

In randomized experiments, the treatment effect is inferred by comparing the treatment group posttest mean with the control group posttest mean. In RD, the comparison is not between means but between regression lines. Their intercepts and slopes are compared with each other.

RD as a Complete Model of the Selection Process

In contrast to other quasi-experiments in which assignment to conditions is less controlled, the selection process in RD and in randomized experiments is completely known and perfectly measured. In a randomized experiment, the assignment mechanism is perfectly known, because it is the result of a perfectly measured coin toss. The experimenter can record the result of the coin toss and the assignment that follows from the coin toss. In an RD design, the assignment mechanism is also completely

known and depends on whether the score on the assignment variable is above or below the cutoff. Therefore, the RD design can adjust for the differences at pretest (which is in fact the perfect modeling of the selection bias) and obtain an unbiased estimate of treatment effect. In both cases, in the random experiment and in the RD design, there are no unknown variables that determine to which condition participants are assigned, whereas in quasi-experimental studies, we do not know what the selection process into conditions is and cannot measure it perfectly (Lord, 1967). Therefore, we are not able to correct for selection bias.

Problems that May Arise

The biggest problem in the implementation of the RD design is the adherence to the cutoff. In RD, the treatment assignment must follow the cutoff, but this can be violated by the expectations of treatment professionals that their personal judgment should decide whether a participant gets a treatment. If their judgment is not quantified, recorded, and made part of the assignment variable, the use of such judgmental strategies violates the assumptions of the RD design and the statistical modeling process will lead to false inferences. Cases that are admitted to a treatment, although their scores indicate an assignment to another condition, should be eliminated prior to the treatment and the data analysis.

Another problem complicates the adherence to the cutoff. If participants trickle in too slowly or too quickly, the cutoff score has to be adjusted to keep the program filled. However, if sample sizes are large enough, one can adjust the cutoff successively and analyze each group admitted using a different cutoff in separate RD designs.

Severe problems can result when cutoffs are public. This can foster manipulations by those participants who want to be assigned to the treatment condition. For example, in Berk and Rauma's (1983) RD study, prisoners were provided with unemployment compensation if they had worked more than 652 h over the previous 12 months while in prison, if they had not, no compensation was paid at all. However, those prisoners that were close to the cutoff might work more hours so they can get into treatment, whereas others do not try if they know they have already made it or have little chance of doing so. This affects the distribution of the assignment variable. In the worst case, leaving a gap at the cutoff can result in bimodal data.

Treatment crossovers and attrition are also problems that may arise. Biased treatment effect estimates result when those assigned to treatment do not take it or those assigned to control end up in treatment. Attrition is a problem when it is not random at all. If attrition is related to assignment, biased estimates result again. For example, if students who are on the dean's list are admitted to a

program and subsequently change to a better college due to the good results, the estimates of the treatment effect will be biased (Seaver and Quarton, 1976).

A summarized description of other potential threats on the validity, such as over- and mis-specification of the regression model, nonlinearity, interactions, maturation processes, and events that coincide with the cut-off, is given by Shadish *et al.* (2002).

The Combination of the RD Design with Randomized Experiments and Quasi-Experimental Designs

It is an advantage, if an RD design can be combined with a randomized experiment. For example, this can be achieved, when two cutoffs are used which define a cutoff interval lying between the two scores. Above the upper score, all participants are assigned to one condition and those below to another one. In between, participants are assigned randomly to both conditions. This results in a randomized experiment that is embedded in an RD design. In **Figure 6** for example, children scoring on the assignment variable below 35 are assigned to the treatment condition (reading training program) and scoring above 65 are assigned to the control condition. Children scoring in between 35 and 65 are assigned randomly to both conditions.

There are many different ways to combine a randomized experiment with the RD (for an overview: see Cappelleri, 1991; Trochim, 1984, 1990). First, all participants below a cutoff that are in need could be assigned to a treatment and participants above a cutoff could be randomly assigned to treatment or control condition. Second, an RD design could be added to an existing randomized experiment. For example, those that usually would not pass a cutoff for entering the randomized experiment could be kept as an RD control group rather than just being discarded. Third, one could use multiple cutoff intervals with randomization in some intervals and RD in others. Fourth, multiple cutoffs with increasing proportions of participants randomly assigned to treatment over intervals could be used. For example, five intervals with probabilities of 0:100, 25:75, 50:50, 75:25, and 100:0 for receiving treatment could be used. This approach is very useful when there are concerns that marginal cases might be inappropriately assigned, because the greater the participant's need for treatment the greater the chance of getting treatment. Fifth, participants within a cutoff interval could receive randomly a treatment, but participants outside the interval could be assigned to just one condition. This design might be used in situations when effects of dangerous drugs are examined to minimize risk for the participants. Participants that do not receive the treatment could receive a placebo.

Figure 6 Extended RD design with a randomized assignment cutoff interval.

The advantage of the combined design is that randomization increases the power of detecting treatment effects (Cappelleri, 1991). In addition to this, the combination of RD and a randomized experiment allows the estimation of the regression lines for both treatment and control participants over the same range of assignment scores within the randomization interval. In a basic RD design, a projection (extension) of the lines is needed to compare the conditions. Another advantage is that the ethical problem of where to set the cutoff can be avoided. By defining an interval in the middle of the assignment variable that assigns randomly to treatment, a justifiable solution could be found.

There are also different ways to combine an RD with a quasi-experimental design. One could use a cutoff interval with RD outside the interval and self-selection of the treatment inside the interval. This design should be most accepted by the participants in medical settings.

If there are enough resources, another way to combine RD with a quasi-experimental design is to use the RD design, but at the end of a study give treatment to all the control participants. In psychotherapy, for example, every participant could get the treatment at the end of a study.

In order to find the correct overall functional form of the relationship between predictors and outcome variables, a control cohort could be added that models the functional form without receiving treatment.

feature. In addition to this, there are several issues that disallow a status equal to the randomized experiment. First, it is a new design and the problems described above are too serious and not yet as clear as with the randomized experiment (Shadish *et al.*, 2002; Stanley and Robinson, 1990). Second, the RD design heavily depends on correctly modeling the functional form of the relationship between the assignment variable and the outcome variable. Therefore, in order to obtain unbiased estimates, more sophisticated statistical analyses are required than is usual in experimental settings. Third, the RD design has less power than the randomized experiment (Cappelleri *et al.*, 1994). This is mainly due to multicollinearity between the assignment and treatment variable. The loss of power is greater the more the cutoff deviates from the mean of the assignment variable. When nonlinear effects (e.g., interaction and quadratic effects) are present, multicollinearity increases as well as reduces the power of the design (Kelava *et al.*, 2008). In order to increase the power to 0.80, the RD design needs up to 3 times as many participants as a randomized experiment (Cappelleri *et al.*, 1994).

As a conclusion, the RD is more than a quasi-experiment. It is somewhere in between a quasi-experiment and a randomized experiment with some pitfalls. However, the RD design yields unbiased treatment effects when its assumptions are met.

Final Considerations

The RD design has to be classified as a quasi-experimental design. Although the RD design has a clear structure of an experimental design, it lacks the random assignment

Sampling

R S Brown, University of Southern California, Los Angeles, CA, USA

Introduction

Throughout the course of our everyday existence, we make judgments, inferences, and decisions based on less than the full collection of potential data. We rate restaurants and hotels based on a few meals or several nights of occupancy. We judge athletes based on samples of athletic performance, appraise students based on relatively few assignments, assessments, or tests, and form impressions of new acquaintances based on limited interactions. Sampling is a pervasive and important part of how we interact with and form judgments about the world in which we live. Sampling occurs both informally – as in the instances stated above – and formally as in virtually all governmental surveys, market research polls, and research studies. This article attempts to provide an overview of sampling for research purposes, including terms and definitions, along with various sampling designs.

The basic premise behind sampling is that we seek to gather information from a subset of a larger group of potential respondents in order to make judgments or inferences back to the larger group. As Pedhazur and Schmelkin (1991) state, “Formal sampling is a process aimed at obtaining a representative portion of some whole, thereby affording valid inferences and generalizations to it” (p. 318). Thus, the goal is to identify a group that can adequately represent the whole – so that inferences and generalizations can be made from their responses to survey items or other measures back to the larger population, with some known, or estimable, amount of imprecision. Sampling theory seeks to develop sample-selection strategies and estimation methods that generate sufficiently precise estimates at minimum cost, thereby making sampling more efficient.

There are a number of advantages to sampling compared to collecting data from an entire population. These include reduced cost, greater speed, enhanced feasibility, and greater accuracy. Clearly, cost can be reduced by limiting the amount of data collected to a sample rather than the full population of potential respondents. Likewise, collecting less data would require less time. This consideration for reducing the amount of time necessary for data collection becomes important in situations in which the outcome measure being collected may be influenced by changing events. In volatile social circumstances, early respondents’ reactions may differ from later respondents’ reactions as influences on the outcomes change over an extended data-collection period. Reducing the timeframe for data collection by employing a sampling

strategy can minimize this impact. It is also possible to enhance the feasibility of a study by sampling. In some cases, a complete census is simply impractical and without sampling the study could not be accomplished. In other cases, a census approach would be infeasible for other reasons – such as lack of knowledge of the consequences of a treatment or intervention. It would not be advisable or appropriate to administer a new drug to the entire population, or to compel all students to undertake a given curriculum without first knowing whether the drug is safe and effective or that the curriculum generates enhanced knowledge acquisition (Pedhazur and Schmelkin, 1991). Sampling can also enhance data accuracy by providing more control over the training and supervision of the collection and recording of data, as well as following up on nonresponses. In addition, sampling frees up valuable resources that can be used in the instrument-development and -refinement stages of an investigation.

Sampling Concepts and Terminology

Population

The population refers to the “aggregate from which the sample is chosen” (Cochran, p. 5). It generally refers to the collection or larger grouping to which one wishes to infer or generalize. In some cases, this can be quite straightforward. In a factory setting, the population may be the total collection of widgets produced in a given month or year. A sample of those widgets may be useful for providing sample statistics that estimate population parameters of interest, such as size, weight, or density. In other cases, the population must be defined explicitly in terms of content, units, extent, and time. An example of a given population could be all children attending preschool in California during the 2009–10 academic years.

Sample Units

The sample units are the elements of the population to be sampled. In aggregate, they define the population to which inferences are to be drawn. The sample units may be individuals, classrooms, schools, or a variety of possible elements, but they are the units from which data are collected and serve as the unit of analysis. Sample units may include single elements from the population or clusters of elements from the population, such as when a dwelling may be the sample unit and individual persons

would be the elements from the population. In the example-population given above, the sample units would be the individual children attending preschool in California during the 2009–10 academic years.

Sampling Frame

The sampling frame is the list of sample units from which the sample is drawn. A perfect frame is one in which each element in the population is separately listed once, only once, and no other population irrelevant or extraneous elements are listed. However, not all sampling frames are perfect, and it takes effort and attention to review potential sampling frames to ensure that they are free from error or that the errors in the frames can be addressed. Kish (1965) identifies four primary problems with sampling frames. The first problem is that some sampling frames are incomplete; thus, they do not include all available elements or sample units from the population. Another problem involves clustering of elements within a single listing, which violates the notion that each element be listed separately. A third problem deals with blanks listing or foreign listings in a sampling frame. This violates the rule that each listing should contain a single element. The fourth primary problem with sampling frames is that occasionally duplicate elements appear in the listing. This violates the edict that each element should be listed only once in a sampling frame.

Selection Process

Following the establishment of an appropriate sampling frame, a selection process must be identified, of which there are numerous considerations depending on the study purpose, resources, timeframe, and sample structure. The process depends upon the list from the sampling frame. As Kish states, “The sampling frame or list is the keystone around which the selection process must be designed” (Kish, p. 53). The selection process may involve probability or nonprobability approaches, which are described in more detail below.

Estimation Process

Samples provide data from which sample statistics can be calculated. These sample statistics are used to estimate population values. A common sample statistic of interest is the mean value for the sample. This mean value is a random variable dependent upon the sample of n units from which it is derived. Another sample of size n from the population may result in a different sample mean. The distribution of sample means (the sampling distribution of the mean) allows for the calculation of the population mean and variance (or standard deviation). In practice, not all samples are drawn, so not all sample means are

available, thus a sample design is used. A sample design is unbiased if the expected value of the sample mean (i.e., the mean value of the sample means) is equal to the population mean. Estimates of the population variance can be obtained from the sample statistics and used to develop standard errors of the mean and confidence intervals around the population mean estimates. The magnitude of the sampling error is reflected in the standard errors of the mean and the confidence intervals provide a range of scores that can be interpreted to provide confidence in the population mean estimate. A much more detailed treatment of estimation formulas and estimates is presented in Cochran (1977).

Probability Sampling

There are a number of probability-sampling approaches. All of these approaches require that each element in the population has a known, nonzero probability of being selected into the sample. Probability-sampling approaches rely heavily on random selection. In fact, Kish states emphatically, “Probability selection demands randomized selection. When randomization is both simple and important, disregarding it amounts to carelessness or ignorance” (Kish, p. 28). Utilization of random-selection procedures such as random-number generators and tables of random numbers is important because human beings have shown they are incapable of identifying a random sample independent of such protocols. As Kish states, “Personal judgment has been shown inadequate for selecting random samples of integers, or stones from a pile, or plants from a field, or people on streets or in homes” (Kish p. 29).

Simple Random Sampling

Simple random sampling is a method of selecting a sample size, n , from the population of N elements such that each of the ${}_NC_n$ distinct samples has an equal probability of being selected. This is usually done by selecting at the unit level, with all units being numbered from 1 to N . A table of random numbers or a computer-generated list of random numbers can then be applied to each unit. A total of

$$N! / [(N - n)!n!]$$

distinct sample of size n can be drawn. For example, with a population of size 10, and sample size of 3, a total of 120 unique, nonoverlapping samples can be drawn. From a practical standpoint, simple random sampling is not frequently utilized in large-scale studies. In addition, many studies are interested in more than just the effects on the general populations, for instance many studies are concerned with the effects on subpopulations. Thus, additional sampling strategies have been developed.

Systematic Sampling

Systematic sampling is similar to simple random sampling in that all N elements of the population are numbered and ordered from 1 to N . However, unlike in simple random sampling in which each of n elements is then randomly chosen, in systematic sampling a element is chosen from the first k elements (k is often defined as N/n), then every k th element is chosen until n elements are selected. For instance, if k is 11 and the first element selected is 7, then elements 18, 29, 40, and 51 would be chosen to complete the sample of $n = 5$. Systematic sampling has the advantage of being easier to execute in some instances than simple random sampling, and may be more precise than both simple random sampling and stratified random sampling.

Stratified Random Sampling

Stratified random sampling utilizes known information about the population elements to separate the sample units into nonoverlapping groups, or strata, from which they are then randomly selected. For example, a population of fourth-grade school children may be stratified into various geographic regions, or types of schools attended. Therefore, the full population, N , is subdivided into k strata, such that

$$N = N_1 + N_2 + N_3 + \dots N_k.$$

Once the strata have been determined, a simple random sample is selected from within each stratum. There are a number of advantages to stratified random sampling. One such advantage is that it provides more precise estimates of the subpopulation parameters than does simple random sampling. Stratified sampling can reduce sampling variability by creating relatively homogeneous subsets of sample units with respect to the outcome variable when the stratifying variable is correlated with the outcome measure, although the gains in precision are often minimal. Another potential advantage to stratified sampling is that sampling frames for naturally occurring strata may be readily available, such as student rosters within schools as opposed to all second-grade students in a given country.

There are disadvantages to stratified sampling procedures as well as potential advantages. Stratified sampling designs are more complex both in the selection process and in the estimation process. In addition, some investigations are concerned with multiple outcomes measures, not all of which will necessarily be well correlated with the stratifying variable. In this case, using a stratified sampling design might be beneficial for one outcome measure, but less beneficial for others. Another consideration is the determination of which variables should be used for establishing the strata, and how many strata are optimal. Kish (1965) suggests that the initial advantage obtained by

stratification diminishes with increasing numbers of strata, and that from three to ten strata should be sufficient for any single outcome variable.

Proportionate Sampling

In proportionate sampling, strata sample sizes are held proportional to their existence in the population. This is often used to show the representativeness of a sample relative to the population's characteristics. The sampling fraction for each stratum is held constant and equivalent to the sampling fraction for the overall population. For example, assume that a study seeks a sample of 200 from a population of 1000 (thus the sampling fraction, f , for the population is $200/1000$ or $1/5$). The population is divided into three strata of differing sizes: $N_1 = 500$, $N_2 = 200$, and $N_3 = 300$. The overall sampling fraction, $f = 0.2$, is applied to each stratum to yield samples of $n_1 = 100$, $n_2 = 40$, and $n_3 = 60$. As a result, the proportions of selected sample units in each stratum match the proportions of the strata units relative to the population (e.g., $N_1 = 500/1000 = 0.5 = n_1/n = 100/200 = 0.5$). The advantage of this approach is that it generates a self-weighting sample and the population mean can be estimated from the simple mean of the sample elements.

Cluster Sampling

Cluster sampling is a probability-sampling design that capitalizes on naturally occurring groups, or clusters, in the population. Examples of such naturally occurring groups are students within a classroom or school, residents of a city block, or patients at a given medical facility. In cluster sampling, the groups or clusters are first randomly selected; then, all members of that group are included in the study. Thus, if the clusters are schools and school A is chosen, all the students (or all sixth-graders, depending upon the sampling frame and study intent) in school A would participate. Cluster sampling has the advantage of reducing cost and time associated with sampling and data collection. However, the selected clusters need to represent the population of clusters. When the clusters are more heterogeneously composed internally, this is less problematic. But when the clusters are more internally homogeneous with respect to the outcome measures, a considerable loss of precision in estimation can occur. This leads Kalton (1983) to conclude that unless the economy of using a cluster-sampling design allows for a sufficient increase in sample size to override the associated loss in estimator precision, cluster-sampling designs should be avoided. In addition to the heterogeneity within a cluster, the variability of the size of clusters makes a difference in estimation using cluster sampling. Since most naturally occurring clusters are of unequal size, this variation in cluster size should be taken

into account. Large variability of cluster sizes leads to less precise estimation, unless adequately accounted for. However, additional sampling designs, such as selection with probabilities proportionate to size provides approximate control over the influence of unequal cluster sizes.

Multistage Sampling

Multistage sampling is an extension of cluster sampling in that, first, clusters are randomly selected and, second, sample units within the selected clusters are randomly selected. In this design, random selection occurs at both the cluster or group level and at the sample unit level. Multistage sampling also may be useful when naturally occurring cluster sizes are rather large, resulting in reduced precision when compared to the stratified random-sampling approach. In this event, smaller clusters can be created and sampled. For example, rather than sampling all sixth graders at a selected school, a secondary cluster, such as classes, could be utilized and sampled. In this case, only students in sampled classes at sampled schools would be included. This has the added advantage of reducing the cluster size, thereby enhancing estimator precision.

Double Sampling

Double sampling refers to the practice of selecting an initial sample in order to obtain information on a potential stratifying variable, then using that information to develop a stratified random sampling plan to obtain information on the outcome measure of interest. This is frequently done when the distributional characteristics of the stratifying variable, x , are unknown in the population. The advantage of this approach is that it provides information that may be used to create strata for the sampling design for the collection of data on the outcome variable, y , of primary interest. The disadvantage is that resources that might otherwise be utilized in data collection and analysis for information on y must be spent to collect information on x . Thus, it is important that the increase in precision of estimation due to stratification offsets the loss of precision due to reduced sample size in the data collection for variable y . This technique is also, sometimes, referred to as two-stage sampling.

Nonprobability Sampling

There are a number of nonprobability sampling techniques that have been identified in the sampling literature. While these approaches may yield subjects from whom data may be collected, these design do not benefit from the main advantage of probability approaches, namely,

that probability designs allow for the development of statistical theory to examine the properties of sample estimators (Kalton, 1983). Nevertheless, these approaches are used widely in social science research and they include convenience sampling, purposive sampling, or quota sampling. In convenience sampling, a sample is selected based on ready availability – such as students in a given classroom, or passers-by on a street corner or in front of a busy market. Other convenience samples may include respondents to an advertisement in a magazine or dial-in number for a reality television program. Purposive sampling differs from convenience sampling in that certain characteristics of the sample are sought out *a priori*; that is, a sample that possesses certain characteristics, often to be seen as representative of some larger population is sought. One example of a purposive sample may involve a researcher selecting communities from across a state to ensure geographic diversity.

Another nonprobability sampling approach is quota sampling. In quota sampling, the researcher attempts to collect data on a specified number of respondents in each of a number of groups of potential respondents. For example, a researcher may seek responses from 20 third-grade teachers, 20 fourth-grade teachers, 20 eighth-grade teachers, and 20 tenth-grade teachers. One advantage of quota sampling is that it can reduce data-collection time and associated costs. It is somewhat similar to stratified sampling in that it seeks to obtain responses from more homogeneous subsets of the total populations. However, the major and pivotal distinction is that with stratified random sampling, the sample units within the strata are randomly selected, whereas in quota sampling, the sample units within the quota groups are not. Further, while some may argue that quota sampling reduces nonresponse, the reality is that quota sampling merely replaces nonrespondents with other respondents in the quota group, thereby underestimating the responses of hard-to-find or unwilling sample units.

The fundamental problem with nonprobability sampling designs is that they are potentially biased in their sample estimators, and the magnitude of this bias is unknown. What is known is that the concern with regard to the bias in sample estimators increases with sample size, since probability-sampling designs become more precise with larger samples. Thus, whereas bias in sample estimators may be of less concern when deploying nonprobability sampling approaches for small-scale studies, more care should be taken to avoid nonprobability designs with larger research efforts. These sampling approaches may be utilized widely, but as Pedhazur and Schmelkin state, “...the incontrovertible fact is that, in nonprobability sampling, it is not possible to estimate sampling errors. Therefore, validity of inferences to a population cannot be ascertained” (p. 321).

Sample Size and Power

One of the most common questions that surfaces when dealing with discussions on sampling deals with how large a sample is required for a given purpose. Samples should be large enough to provide the representativeness desired, but the precision of estimation is also a critical component. Since sample size is a primary component in determining estimation precision, once an acceptable level of precision is identified, the optimum samples for such precision can be readily calculated (see Cochran, 1977, for a more thorough treatment of optimal sample sizes for various sampling designs). The determination of what constitutes an acceptable amount of precision is not easily made, and is determined, in part, by the purpose of the research, practical and economic constraints, and the estimated effect size (ES) for a given treatment or intervention. Sample size also affects the likelihood of identifying statistically significant effects or differences among groups.

Of significant importance is the requisite sample size to provide a research investigation with sufficient power to validly and statistically explore the research questions of interest. Sociobehavioral research is full of analytical overviews of research indicating that, in many disciplines, much of the published research fails to establish high levels of statistical power – primarily due to inadequate sample sizes. The statistical power of an analysis is determined by three components. These include: the ES, the probability of rejecting the null hypothesis when it should not be rejected (α), and sample size (N). The power of a statistical test is defined as $1 - \beta$, or 1 minus the probability of failing to reject the null hypothesis when it should be rejected (β). Thus, for a given or expected ES with an *a priori* determined α -level – given statistical analysis, and desired power level – the appropriate sample size can be calculated. Tables of such values can be found in Cohen (1988). In addition, computer programs are widely available (e.g., G*Power 3, Power and Precision, Power Analysis and Sample Size (PASS) are but a few of the many

programs available) to assist the researcher in estimating necessary sample sizes given a desired power level, expected effect size, and α -level.

Conclusion

Sampling is a necessary and important component of much of the data-collection efforts we undertake both in informal and formal settings. Understanding the importance of sampling, the various approaches to collecting adequate samples, the advantages and disadvantages of different sampling procedures, and the relationship of sample size to statistical power enables researchers to make more valid inferences and generalizations from sample data to the population of interest, and thereby increases our knowledge of the domain in which they operate.

Statistical Conclusion Validity

Glossary

Error rate – The error rate refers to the type I error. When only a single statistical test is performed, then the error rate is that set by the researcher, typically $p = 0.05$. If more than one test is conducted, then the error rate increases with the number of tests performed.

Robustness of a statistical test – Indicates that the results of a statistical test can be interpreted accurately even when the conditions for the test violate certain of its assumptions.

Statistical power – Is the probability of finding an effect or relationship when the effect or relationship actually exists. The power of a statistical test is computed by subtracting the type II error from 1.

Type I error – A type I error is the probability of rejecting the null hypothesis when the null hypothesis is true – that is, rejecting the null hypothesis and concluding that there is an effect when in fact there really is no effect.

Type II error – A type II error is the probability of not rejecting the null hypothesis when it is false or the alternative hypothesis is true – that is, a type II error occurs when the researcher concludes that there is no effect when there really is an effect. (See also the definition for the glossary term ‘Statistical power’.)

Prior to undertaking data analyses, the researcher must determine how assumptions for the statistical test and for the selection of appropriate tests affect the interpretations of results. In other words, the researcher must determine the statistical conclusion validity. The classic definition of this essential was given by Cook and Campbell (1979: 37) as the truthfulness of “conclusions about covariation” between treatment and outcome – that is, the degree of accuracy with which researchers can conclude that two variables are related. Only one of two conclusions apply to the covariation between treatment and outcome: rejecting the null hypothesis or not rejecting the null hypothesis. If the treatment is ineffective, then no evidence exists to reject the null hypothesis (although a type II error could have occurred). If the treatment is effective, then the null hypothesis is rejected (although a type I error could have occurred).

Shadish *et al.* (2002) have listed nine threats to statistical conclusion validity: low statistical power, violated

assumptions of statistical tests, fishing and the error rate problem, unreliability of measures, restriction of range, unreliability of treatment implementation, extraneous variance in the experimental setting, heterogeneity of respondents, and inaccurate effect-size estimation. These threats constitute the reasons why researchers would be incorrect in drawing valid inferences concerning the covariation between treatment and outcome – that is, that two variables are related or correlated.

An Internet search on the phrase “statistical conclusion validity and books” reveals that it is mainly the threats to validity that are mentioned in research methods books. Authors of statistics books, however, would benefit from including details of these validity issues. Although many specifically address certain aspects of statistical validity – statistical power (see, e.g., Cohen, 1988; Lipsey, 1990; Maxwell and Delaney, 2004), violation of assumptions of statistical tests (Wilcox, 1996), and the error-rate problem (Maxwell and Delaney, 2004) – they do not connect these problems to statistical conclusion validity. What is meant by addressing specifically aspects of statistical validity is that there are sections in chapters devoted to these topics. Many of the statistics textbooks will discuss type I and II errors and robustness of the statistical tests, for example, but in general and without separate sections for each statistical procedure presented. The exceptions are rare. Some of the authors have addressed the topic of statistical conclusion validity in detail (see, e.g., De Gruijter and van der Kam, 2007; Kirk, 1995; Saxe and Fine, 1981). Girden (1996) discussed six of the threats in her book on evaluating research articles, and Kirk focused on seven of the threats listed by Shadish *et al.* (2002), although the names for some of the threats do not correspond to those used by Shadish *et al.*

What follows is an explanation of each of the nine threats, as proposed by Shadish *et al.* (2002), to statistical conclusion validity. Included are additional resources and references that will assist the researcher and the statistician in understanding the threats in order to avoid or, at least, to meet them effectively.

Low Statistical Power

Most statistical textbooks focus on the issue of low statistical power, although the articles reporting research results rarely mention power. Low statistical power, often, results in type II errors and is explained by small

sample sizes or by extraneous sources of variation that are not controlled. Analyses of statistical power in published research in the 1970s and 1980s found that the power of statistical tests was 0.50 (see, e.g., Sedlmeier and Gigerenzer, 1989; Lipsey, 1990), and – in a study conducted in the twenty-first century in engineering – low power levels remain weak (Kampenes *et al.*, 2007). Steps can be taken to improve statistical power by performing a priori power analysis to estimate sample-size requirements prior to conducting a research study. Researchers need to specify power size, level of significance, and effect size to find the sample size. Cohen (1988) recommended that one should plan for power of at least 0.80. His book contains power tables that researchers can use to find the sample size required to achieve the desired power with specified level of significance (or type I error) and effect size. Determining the effect size is not straightforward, of course, as it is, generally, unknown and difficult to guess – because basing the effect size estimate on sample data is problematic as the sample estimate is susceptible to influence of the treatment implementation, measures, samples, and research design of a particular study. Lipsey has recommended using results of previous research to create a base for the effect-size estimate. He had provided from research in psychology and in education specifics on 186 meta-analyses that were used to estimate the effect size for other researchers' investigations.

The Internet is a source of websites that provide power-analysis calculators or sample-size calculators. The latter source is especially useful to researchers at the planning stage when they are determining effective sample size.

Extraneous sources of variation that are uncontrolled affect the variance of the sample and hence the standard error or mean square error used to test the hypothesis of interest. Eliminating extraneous variables at the implementation stage reduces the variances, increasing the power. Shadish *et al.* (2002: 46–47) provided additional methods for increasing the power of statistical tests, as well as comments on feasibility, application, exceptions to their use, and the disadvantages. Researchers will also find comprehensive references that are valuable for directing them in designing studies with power to detect the effects that they are investigating.

Violated Assumptions of the Test Statistics

All statistical tests require that certain conditions be met for valid inferences. If these conditions or assumptions are not met, incorrect inferences or conclusions with regard to covariation or treatment effectiveness often result. In-depth presentations on the violations of assumptions can be found in most statistics textbooks (see, e.g., Kirk,

1995; Wilcox, 1996). Research-methods books usually devote only a chapter to inferential statistics – that is, analyzing and interpreting quantitative data – which means that, at most, a few paragraphs or a few pages will be used to address the violation of the assumptions of statistical tests. Often, the authors of research books do not have a background in statistics and may not be aware of the consequences of violating the assumptions. For example, compare Krathwohl's (1998: 486–488) with Shadish *et al.*'s (2002: 48) discussion of violation of assumptions.

As a recommendation to researchers with regard to violations of assumptions, Wampold and Drew (1990) emphasize that “the researcher should never conduct an experiment if he or she is blind to clues about the distributional characteristics of the population under investigation” (p. 152). In order to understand the distributional characteristics of the population under investigation, researchers may derive clues from previous research, from theory, or from the nature of the experiment or the instruments used to obtain the observations. If one is not able to obtain sufficient information from these sources, a pilot study must be conducted.

Fishing and the Error-Rate Problem

When a large number of statistical tests are performed on the same set of data, then – by chance alone – one or more tests may result in a type I error. If a researcher conducts multiple tests but only reports those that are statistically significant, the research conclusions can be misleading. Authors of statistical books (see, e.g., Glass and Hopkins, 1995; Kirk, 1995; Maxwell and Delaney, 2004) have warned against the practice of fishing or multiple comparisons and recommended the Bonferroni correction – which divides the overall error rate by the number of tests conducted, ensuring that the error rate over all tests will not exceed the nominal level of significance. Kirk (1995) and Maxwell and Delaney (2004) have discussed the correct conceptual unit for type I error in light of three different type I error rates – family-wise error rate, per-contrast error rate, and experiment error rate – and the techniques that have been developed to control them. Maxwell and Delaney provided a flowchart for choosing an appropriate procedure. The difficulty arises when researchers only report statistically significant results when they have conducted multiple tests. If results of all statistical tests were reported in published articles, then readers could assess the chances of spurious statistically significant results. Given space limitations in printed journal articles, this recommendation is not likely to occur. With Internet-based publications, however, space is no longer a limitation, and such reporting should occur.

Unreliability of Measures

If the measuring instrument does not obtain consistent results, then the error term for the statistical tests will be inflated – which will result in low power and possibly a type II error. The problem of unreliability will affect the assessment of covariation because bivariate relationships will be attenuated – that is, the correlation coefficient will be systematically biased downward. Attenuation is a topic typically found in many measurement books rather than in research or statistics texts.

Fan (2003) has provided two approaches for correcting attenuation when measurement error is known – that is, when reliability data are available for the measured variables being correlated. Another source of attenuation may result from assessing change in longitudinal studies and in consequences for analysis of covariance (Maxwell and Delaney, 2004: ch. 9). For longitudinal studies, recommendations include assessing and reporting reliability for each measure as well as increasing the number of measurements, improving the quality of measures, and using techniques such as latent variable modeling. For analysis of covariance, Huitema (1980: ch. 14) had proposed a number of corrections for measurement error in the covariate that involve estimating the reliability of the covariate.

Restriction of Range

Restriction of range affects both correlation coefficients and the power of statistical tests. If the sample on which a correlation is based is homogeneous with respect to the variables being measured, then the correlation between the variables will be much less than if the sample were more heterogeneous. This phenomenon of range restriction is problematic for researchers trying to predict performance based on a sample that has a restricted range, for example, predicting performance for the first year in college based on applicants to that college or predicting performance for first year in college based on high-school students who take the Scholastic Aptitude Test (SAT) or American College Testing (ACT). Given that not all high-school students have college aspirations or will be attending a college that requires the SAT or ACT for admission and, further, not all students who take the test are admitted to colleges or universities, the range of scores is restricted for both variables and, hence, the correlation on which the prediction is based is restricted. Glass and Hopkins (1995) provided a formula for correcting the correlation coefficient for restricted variability in one of the samples. This equation should be used only for large samples and only where the conditions of linearity and homoscedasticity are met.

The range restriction on the dependent variable lowers the power of statistical tests. Researchers may be studying restricted samples that will result in floor or ceiling effects for the dependent variable. For example, if severely depressed individuals are studied, their data will result in floor effects as scores will cluster near the highest scores on a measure of depression, and, if highly anxious individuals are studied, their data will result in ceiling effects as their scores will cluster near the highest scores on a measure of anxiety. Researchers conducting studies with homogeneous samples should compensate for low power with larger sample sizes.

Unreliability of Treatment Implementation

When the researcher fails to standardize the administration of treatment levels, unreliability of treatment implementation can occur. Such variability in treatment implementation may result in inflated error variance and in a type II error. Such a threat to statistical conclusion validity is typically addressed in research books. The usual recommendation is that all procedures for the treatment implementation be standardized. Such standardization may be difficult when different instructors are implementing the treatment in their respective classrooms or different observers are collecting data in a research study. Unless trained thoroughly and monitored closely, they may not follow the treatment protocol or may alter the control condition. Such a lack of standard implementation could result in a smaller effect size, which would be more difficult to detect statistically. Again, the researcher could increase the sample size to increase power.

In some situations (e.g., single-case studies), the treatment is tailored to certain participants in order to increase treatment effectiveness. In these cases, the components of the treatment should be measured, and these variations related to changes in outcomes. Shadish *et al.* (2002) have devoted two chapters to methods for improving, measuring, and analyzing treatments that are not implemented reliably. Studies where the treatments are tailored to participants, often, occur in single-case investigations.

Extraneous Variance in the Experimental Setting

Extraneous variance in the experimental setting or random irrelevancies in the experimental setting result when variation in the environment in which the treatment is administered may inflate the error variance and result in a type II error. Variation in environment might be physical or social and could include distracting noises, fluctuations

in temperature or lighting, faulty equipment, or changes requested by site administrators or other nonparticipants in the research – such as parents. Control, usually, can be achieved in a laboratory setting, but, in the field, variances are more likely to occur. The researcher must minimize such distractions. If this is not possible, then the researcher must measure the source of the extraneous variance and factor the variation into the statistical analysis so that the error variance will be reduced and be less likely to result in not rejecting a false null hypothesis.

Heterogeneity of Respondents

Although researchers desire heterogeneity in their samples for detecting correlation among variables, homogeneity of participants on the outcome variable within conditions in experimental or quasi-experimental research will reduce error variance and assist in detecting statistical significance for the treatment – that is, heterogeneity of respondents within conditions on the outcome variable increases the variance and reduces the power of the statistical test. The obvious solution is to obtain a homogeneous sample, but this solution reduces the external validity and may even result in restriction in range. Another solution would be to measure the respondent characteristics that are heterogeneous and use these measurements for blocking or as covariates in the analysis procedures.

Inaccurate Effect-Size Estimation

There are several factors that affect accurate effect-size information. Cohen (1988) defined his effect-size measure as the difference between treatment and control means divided by the pooled standard deviation – which assumes that the two groups have equal or approximately equal sample sizes and standard deviations. If either of these two conditions is not met, then the effect-size estimate is inaccurate. To address this problem, Glass *et al.* (1981) defined the effect-size estimate as the difference between means divided by the control standard deviation, thus eliminating the issue of equal or approximately equal sample sizes and standard deviations. Glass *et al.* made an additional assumption – as did Cohen – that both groups have a normal distribution. In particular, Cohen's nonoverlap is based on a normal distribution as is Glass *et al.*'s graphical illustration of effect-size differences (see p. 29). Problems arise when the distributions are not normal and the means are unequal, because the variances might be unequal as well, which means that the magnitude of the effect size can be misleading and difficult to interpret. Wilcox (1996) proposed alternative approaches for effect-size estimation methods along with a Minitab macro to perform the calculations.

Statistical Conclusion Validity in Meta-Analysis

When conducting a meta-analysis, Cooper (1998) and Wortman (1994) have recommended to judge research quality. Many meta-analysts judge the quality of research articles on whether the designs were randomized, non-randomized, or quasi-experimental. Other design features should be considered in the coding of research studies. Wortman included Cook and Campbell's (1979) statistical conclusion-validity categories in the coding of research qualities. Wortman referenced an early meta-analysis by Devine and Cook (1983) that examined six alternative explanations that could account for the observed effects. In the meta-analysis of effects of psychoeducational interventions on the length of postsurgical hospital stay, Devine and Cook considered six threats to validity including one for statistical conclusion validity: the reliability of treatment implementation. They found that treatments that included content from only one domain had lower effect sizes (0.06) than treatments that included content from more than one domain (0.51 for two domains and 0.32 for three domains). The three domains of psychoeducational care were information, skills training, and social support. This early example is one of the few that include statistical conclusion validity as a moderator variable (note that the second author is Cook of Cook and Campbell 1979; Shadish *et al.*, 2002).

Meta-analysts may find that investigating the threats to statistical conclusion validity will provide relevant moderator variables for investigating differences in effect sizes. Consideration of low statistical power may provide insights valuable both to studies that are published and those that are not. Recommendations for future research would aid researchers in publishing their findings.

Conclusion

Statistical conclusion validity is an integral part of a validity typology proposed by Cook and Campbell (1979) that is composed of four related parts: in addition to statistical conclusion validity, the three other parts are internal validity, construct validity, and external validity. Cook and Campbell (1979) introduced statistical conclusion validity for quasi-experimental research designs, which Shadish *et al.* (2002) broadened to include experimental designs. With this pedigree in research design and methodology, statistical conclusion validity demands a place in the body of statistical literature, rather than a nod in the footnotes – especially given the emphasis in research on interpreting findings. Without the support of statistical conclusion validity and the three other validity components, accurate decisions could be made on the basis of unjustified statistical analysis. Statistical literature

focuses exclusively on procedures for analyzing data; the research design and methodology literature includes statistical analyses, but the focus is not comprehensive. Authors of research-design books, usually, include sections on threats to validity that only include internal, construct, and external validity. It is rare that educational-research books focus on statistical validity threats. One of the few exceptions is nursing-research texts.

Even though studies have been published in the literature, beginning in 1962, with regard to violations of statistical conclusion validity, researchers still have been slow to employ its benefits – despite constant criticism by reviewers of low statistical power in research investigations. These reviews are not restricted to one field, as reports appear in the medical, educational, and psychological disciplines. Reviews of statistical conclusion validity have been conducted in criminal justice and criminology, nursing, business research, and early-interventions research. These evaluations consistently urge researchers in their various disciplines to be aware that the interpretation of the results depends on the assumptions for the statistical test and on the selection of proper tests, as Cook and Campbell (1979) detailed.

As pointed out above, some authors of books have chosen to include a subset of the threats to statistical conclusion validity. This article has detailed the threats which researchers need to address. Although some of the threats are more serious than others, they all affect the validity of the researcher's conclusions. Given the time and energy that a researcher devotes to designing studies and the role these studies have in decision making, researchers should take full account of the, often, readily solvable threats to statistical conclusion validity.

Survey Research Methods

A Fink, University of California, Los Angeles, Los Angeles, CA, USA; The Langley Research Institute, Pacific Palisades, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Categorical or nominal – Categorical or nominal response choices have no numerical or preferential values.

Concurrent validity – Demonstrated when two assessments agree or a new measure is compared favorably with one that is already considered valid.

Construct validity – Established experimentally to demonstrate that a survey distinguishes between people who do and do not have certain characteristics. It is usually established experimentally.

Content validity – Refers to the extent to which a measure thoroughly and appropriately assesses the skills or characteristics it is intended to measure.

Face validity – Refers to how a measure appears on the surface: Does it seem to ask all the needed questions?

Survey's Internal Consistency or homogeneity – A survey's internal consistency or homogeneity. Refers to the extent to which all the items or questions assess the same skill, characteristic, or quality.

Nonprobability or convenience samples – They are chosen based on judgment regarding the characteristics of the target population and the needs of the survey. With nonprobability sampling, some members of the eligible target population have a chance of being chosen and others do not.

Numerical – Response choices call for numbers such as age (e.g., number of years) or height (e.g., number of meters).

Ordinal – Response choices require rate or order choices, say, from very positive to very negative.

Predictive validity – Refers to the extent to which a survey measure forecasts future performance.

Probability sampling – It provides a statistical basis for saying that a sample is representative of the study or target population. In probability sampling, every member of the target population has a known, nonzero probability of being included in the sample.⁷ Probability sampling implies the use of random selection.

Reliable survey instrument – A reliable survey instrument is one that is relatively free from "measurement error." Because of this "error,"

individuals' obtained scores are different from their true scores, which can only be obtained from perfect measures.

Survey – A system for collecting valid information from or about people to describe, compare, or explain their knowledge, attitudes, and behavior (Fink, 2008). The system consists of interrelated activities starting with defining precise survey objectives, choosing respondents, preparing a reliable and valid survey instrument, testing the survey with respondents, and conducting all activities in an ethical manner.

Test-retest reliability or stability – A measure of a survey's stability over time. A survey is stable if the correlation between scores from one time to another is high.

Survey Research: Definitions and Uses

A survey is a system for collecting valid information from or about people to describe, compare, or explain their knowledge, attitudes, and behavior (Fink, 2008a). The system consists of interrelated activities starting with defining precise survey objectives, choosing respondents, preparing a reliable and valid survey instrument, testing the survey with respondents, and conducting all activities in an ethical manner. The survey researcher is responsible for implementing all survey activities and ensuring their quality.

Survey information can be collected directly by asking people to answer questions, or indirectly, by reviewing written, oral, and visual records of people's thoughts and actions. Survey data can also be obtained by observing people in natural or experimental settings.

Surveys are taken of political and consumer choices, use of health services, numbers of people in the labor force, and opinions on just about everything from aardvarks to zyzyvas. Individuals, communities, schools, businesses, and researchers use surveys to find out about people by asking questions about feelings, motivations, plans, beliefs, and personal backgrounds. The questions in survey instruments are typically arranged into mailed or self-administered questionnaires (on paper or online) and in-person (face-to-face) or telephone interviews.

Surveys are a prominent part of life in many major industrialized nations, particularly the United States. US elections are always accompanied by a flood of polls. The US Census, which is administered to the entire nation every 10 years, is a survey. However, most people encounter surveys more frequently in their daily lives in medical, educational, and social settings.

Survey Objectives

A survey's objectives are general statements of the survey's outcomes and provide the direction for selecting questions (**Case study 1**).

When planning a survey, the survey researcher must define all potentially imprecise or ambiguous terms in the objectives (Fink, 2004a). For the objectives above, the imprecise terms are needs; educational services; characteristics; and benefits. No standard definition exists for any of them. What are needs, for example, and of the very long list that the survey researcher can create, which are so important that they should be included on the survey? Definitions can come from the literature and from consultation with knowledgeable individuals.

Survey objectives may be independent of an existing study or related to it. For instance, suppose a school district decides to investigate the causes of a measurable increase in smoking among students between 12 and 16 years of age. The district could then ask the survey research department to design and implement a survey of students who smoke to find out why they do. On the other hand, the school district may be part of a study to prevent

smoking in students, and a component of that study may be a survey of students' smoking habits.

A survey's objectives can be derived from reviews of the literature and other surveys. The literature refers to all published and unpublished public reports on a topic. Systematic reviews of the literature describe current knowledge and reveal gaps. For instance, a review of the literature can provide information on best practices in teaching reading but may not provide sufficient information about the ease of implementing such programs in classrooms. A survey of reading teachers may provide data on implementation.

Survey objectives can also come from experts. Experts are individuals who are knowledgeable about a topic, will be affected by the survey's outcomes, or are influential in implementing its findings. Experts can be asked about objectives by mail or telephone or brought together in meetings. Two types of meetings that are sometimes used to help survey researchers identify objectives, research questions, and research hypotheses are focus groups (Krueger and Casey, 2000) and consensus panels (Jones, 1995).

Straightforward Questions and Responses

Survey questions take two primary forms. When they require respondents to use their own words, they are called open ended. When the answers or responses are preselected for the respondent, the question is termed closed or forced choice. Both types of questions have advantages and limitations.

An open question is useful when the intricacies of an issue are still unknown, for eliciting unanticipated answers, and for describing the world as the respondent sees it – rather than as the questioner does. Some respondents also prefer to state their views in their own words. Sometimes, when left to their own devices, respondents provide quotable material. The disadvantage is that unless you are a trained anthropologist or qualitative researcher, responses to open questions are often difficult to compare and interpret.

Some respondents prefer closed questions because they are either unwilling or unable to express themselves while being surveyed. Closed questions are more difficult to write than open ones, however, because the answers or response choices must be known in advance; however, the results lend themselves more readily to statistical analysis and interpretation, and this is particularly important in large surveys because of the number of responses and respondents. Moreover, as the respondent's expectations are more clearly spelled out in closed questions (or the survey researcher's interpretations of them), the answers have a better chance of being more reliable or consistent over time.

Case study 1

Illustrative objectives for a survey of vocational educational needs

- Objective 1: Identify the most common needs for educational services for three professions: teaching, nursing, and computer programming.
Sample question:
How proficient would you say you are in performing the following job-related activities?
- Objective 2: Compare the educational needs of men and women
Question:
Are you male or female?
- Objective 3: After participation in a vocational education program, identify the characteristics of participants who receive the most benefits.
Questions about the characteristics of survey participants:
What is your occupation? What was your household income last year?
Questions about benefits:
To what extent has this program helped you improve your job skills? How long did you wait to get a job in your preferred profession?

Survey Question Stems

Open-ended survey questions have only a stem: Why were you dissatisfied with the workshop? Close-ended questions have a stem and one or more responses: Which of the following describes the reasons for your dissatisfaction? (The question is followed by a list of potential reasons for dissatisfaction.)

A straightforward survey question asks what it needs in an unambiguous, concrete way and extracts accurate and consistent information (Sudman and Bradburn, 1982; Fink, 2004b). Straightforward questions are purposeful and use correct grammar (**Case study 2**).

Question stems should contain fewer than 20 words and be easy to understand, nonjudgmental, and unbiased. They should be phrased in a socially and culturally sensitive manner and at a reading level that is appropriate for the respondents. The survey researcher should avoid abbreviations and absolute terms (never, always). Question writing is complex, and requires ability to write simply. For many topics (e.g., perceptions, values, feelings, and beliefs) question writing also requires the researcher to understand psychological, social, and health theories and research. The difficulty in question-writing makes survey researchers often adopt or adapt already-existing and commonly used questions and even entire survey instruments to avoid the painstaking and often painful process of writing questions on their own. The Web has numerous sources for questions. For instance, questions on reading and math in schools can be found on the website of the National Assessment of Educational

Case study 2

Survey questions

- Purposeful questions: The relationship between the question and the survey's objective
- Survey objective: To find out about reading habits in the community
- Survey question: In what year were you born?
- Comment: The relationship between the question and the objective is far from clear. An explanation is needed.

Complete sentences:

- Poor: Place of birth?
- Comment: Place of birth means different things to different people. I might give the city in which I was born, but you might tell the name of the hospital.
- Better: Name the city and state in which you were born.

Concrete questions:

- Less concrete: How would you describe your mood?
- More concrete: In the past 3 weeks, would you say you were generally happy or generally unhappy?
- Comment: Adding a time period (3 weeks) and defining mood (generally happy and generally unhappy) adds precision to the question.

Progress. For demographic questions, researchers often search the literature using common article databases of Education Resources Information Center (ERIC), US Census Bureau, or the Web of Science.

Responses

The choices given to respondents for their answers can take three forms. The first is called nominal or categorical. (The two terms are often used interchangeably.) Categorical or nominal choices have no numerical or preferential values. For example, asking respondents if they are male or female asks them to name themselves as belonging to one of two categories: male or female. Any number associated with either category (e.g., 1 = male) has no inherent importance. The second response form is called ordinal. When respondents are asked to rate or order choices, say, from very positive to very negative, they are given ordinal choices. The third response form, numerical, asks for numbers such as age (e.g., number of years) or height (e.g., number of meters). Numerical responses produce data that are continuous (e.g., age) or discrete (e.g., number of books read in the past month). Categorical, ordinal, and numerical response choices are illustrated in **Case study 3**.

Survey Instruments

Self-Administered Questionnaires

A self-administered questionnaire consists of questions that an individual completes by oneself. These questionnaires may be completed on site (in a classroom or clinic) or at a distant location (home). Respondents receive self-administered questionnaires in the mail or are directed (via email) to a website. Many survey software vendors provide easily accessible and relatively inexpensive programs that enable the novice to design easy-to-use surveys that analyze survey responses in real time and provide user-friendly reports.

Interviews

An interview requires at least two people: one to ask the questions (the interviewer) and another to respond (the interviewee). (Group interviews are possible.) Interviews can take place on the telephone, face to face, or via teleconference or web cam. Telephone interviews may be relatively simple, involving just an interviewer and interviewee, or they may be relatively complex, relying on advanced technology to identify and query respondents (Bourque and Fielder, 2004).

Structured Record Reviews

A structured record review is a survey that uses a specially created questionnaire to guide the collection of data from financial, medical, school, and other records including

Case study 3

Categorical, ordinal, and numerical responses

1. Nominal response: Which of these books have you read? Please circle yes or no for each choice.

Book title	1. Yes	2. No
<i>Tom Sawyer</i>	1	2
<i>Tale of Two Cities</i>	1	2
<i>Etc. (six books are listed)</i>		

2. Ordinal: How important has each of the following books been in helping form your image of modern life? Please use the following scale to make your rating:

- 1 = Definitely unimportant
2 = Probably unimportant
3 = Probably important
4 = Definitely important
5 = No opinion/Don't know

Book title	Please circle one for each book				
<i>Tom Sawyer</i>	1	2	3	4	5
<i>Tale of Two Cities</i>	1	2	3	4	5
<i>Etc. (six books are listed)</i>					

3. Numerical: How many books did you read in the past month?

The response choice format dictates the analysis and report of results. For example, a report of the responses to the first question yielding categorical data could take this form:

Nominal or categorical data: More than 75% of the respondents read at least one book on the list, but no one read all six. Of 75 respondents, 46 (61.3%) indicated they had read *Tom Sawyer*, the most frequently read book.

A report for the second question (ordinal data) might look like this:

Ordinal data: Of 75 respondents completing this question, 43 (57.3%) rated each book as definitely or probably important. The average ratings ranged from 3.7 for *Tom Sawyer* to 2.0 for *A Tale of Two Cities*.

Typical survey findings for the third question (numerical) might appear as follows:

On average, respondents read about one book each month.

electronic, written, and filmed documents. An example of a structured record review is the use of a questionnaire to collect information from school attendance records on the number and characteristics (e.g., age, reading level) of students who are absent 4 or more weeks each semester.

Structured Observations

A structured observation is designed to guide the observer in focusing on specific actions or characteristics.

For example, two visitors to school are participants in a structured observation if both are asked to count and record the number of computers they see, look for the presence or absence of air conditioning, and measure the room's area in square feet.

Survey Sampling

A sample is a portion or subset of a larger group called a population. Surveys often use samples rather than populations. A good sample is a miniature version of the population – just like it, only smaller. The best sample is representative, or a model of the population. A sample is representative of the population if important characteristics (e.g., age, gender, and reading level) are distributed similarly in both groups. Suppose the population of interest consists of 1000 people, 50% of whom are male, with 45% over 13 years of age and older. A representative sample will have fewer people, say, 500, but it must also consist of 50% males, with 45% over age 13 years and older.

No sample is perfect. Usually, it has some degree of bias or error. To ensure a sample whose characteristics and degree of representation can be described accurately, the survey researcher must start with very specific and precise survey objectives. The researcher also must have clear and definite eligibility criteria, apply sampling methods rigorously, justify the sample size, and have an adequate response rate.

Eligibility Criteria

The criteria for inclusion in a survey refer to the characteristics of respondents who are eligible for participation in the survey; the exclusion criteria consist of characteristics that rule out certain people. The survey researcher applies the inclusion and exclusion criteria to the target population. Once the researcher removes from the target population all those who fail to meet the inclusion criteria and all those who succeed in meeting the exclusion criteria, the remaining study population, is eligible for participation. A major reason for setting eligibility criteria is that to do otherwise is simply not practical. Setting inclusion and exclusion criteria is an efficient way of focusing the survey on only those people from whom you are equipped to get the most accurate information or about whom you want to learn something.

Sampling Methods

Sampling methods are often divided into two types. The first is called probability sampling. Probability sampling provides a statistical basis for saying that a sample is

representative of the study or target population, and every member of the target population has a known, nonzero probability of being included in the sample. Probability sampling implies the use of random selection. Random sampling eliminates subjectivity in choosing a sample. It is a fair way of getting a sample.

The second type of sampling is nonprobability or convenience sampling. Nonprobability samples are chosen based on judgment regarding the characteristics of the target population and the needs of the survey. With nonprobability sampling, some members of the eligible target population have a chance of being chosen and others do not. By chance, the survey's findings may not be applicable to the target group at all. True probability sampling is extraordinarily complex. Nevertheless, many survey researchers aim to come as close to a probability sample as possible. One approach is simple random sampling.

In simple random sampling, every subject or unit has an equal chance of being selected. Members of the target population are selected one at a time and independently. Once they have been selected, they are not eligible for a second chance and are not returned to the pool. Because of this equality of opportunity, random samples are considered relatively unbiased. Typical ways of selecting a simple random sample are using a table of random numbers or a computer-generated list of random numbers and applying it to lists of prospective participants.

The advantage of simple random sampling is that the survey researcher can get an unbiased sample without much technical difficulty. Unfortunately, random sampling may not pick up all the elements of interest in a population. Suppose a researcher is conducting a survey of teacher satisfaction. Consider also that the researcher has evidence from a previous study that older and younger teachers usually differ substantially in their satisfaction. If the researcher chooses a simple random sample for the new survey, he or she might not pick up a large-enough proportion of younger teachers to detect any differences that matter. In fact, with really bad luck, by chance, the entire sample may consist of older teachers. To be sure that the sample consists of adequate proportions of people with certain characteristics, the researcher can use stratified random sampling.

A stratified random sample is one in which the population is divided into subgroups or strata, and a random sample is then selected from each subgroup. For example, suppose a survey researcher wants to determine the effectiveness of a program to care for the health of homeless families. The researcher plans to survey a sample of 1800 of the 3000 family members who have participated in the program. The researcher also intends to divide the family members into groups according to their general health status (as indicated by scores on a 32-item test) and age. Health status and age are the strata. The strata or subgroups are chosen because evidence is available that they

are related to the outcome – in this case, care for health needs of homeless families. The justification for the selection of the strata can come from the literature and expert opinion.

Stratified random sampling is more complicated than simple random sampling. The strata must be identified and justified, and using many subgroups can lead to large, unwieldy, and expensive surveys.

Systematic sampling is another sampling method used by survey researchers. Suppose a researcher has a list with the names of 3000 students, from which a sample of 500 is to be selected. Dividing 3000 by 500 yields 6, which means that one of every six persons will be in the sample. To systematically sample from the list, a random start is needed. To obtain this, a die can be tossed. Suppose a toss comes up with the number 5. This means the fifth name on the list would be selected first, then the 11th, 17th, 23rd, and so on until 500 names are selected.

To obtain a valid sample, the researcher must obtain a list of all eligible participants or members of the population. This is called the sampling frame. Systematic sampling should not be used if repetition is a natural component of the sampling frame. For example, if the frame is a list of names, systematic sampling can result in the loss of names that appear infrequently (e.g., names beginning with X). If the data are arranged by months and the interval is 12, the same months will be selected for each year. Infrequently appearing names and ordered data (January is always month 1 and December month 12) prevents each sampling unit (names or months) from having an equal chance of selection. If systematic sampling is used without the guarantee that all units have an equal chance of selection, the resultant sample will not be a probability sample. When the sampling frame has no inherently recurring order, or you can reorder the list or adjust the sampling intervals, systematic sampling resembles simple random sampling.

A cluster is a naturally occurring unit (e.g., a school, which has many classrooms, students, and teachers). Other clusters are universities, hospitals, cities, states, and so on. The clusters are randomly selected (called cluster sampling), and all members of the selected cluster are included in the sample. For example, suppose that California's counties are trying out a new program to improve physical education for teens. A researcher who wanted to use cluster sampling can consider each county as a cluster and select and assign counties at random to the new physical education program or to the traditional one. The programs in the selected counties would then be the focus of the survey.

Cluster sampling is used in large surveys. It differs from stratified sampling in that with cluster sampling you start with a naturally occurring constituency. The researcher then selects from among the clusters and either surveys all members of the selection or randomly selects from among them. The resulting sample may not be

representative of areas not covered by the cluster, nor does one cluster necessarily represent another.

Nonprobability samples do not guarantee that all eligible units have an equal chance of being included in a sample. Their main advantage is that they are relatively convenient, economical, and appropriate for many surveys. Their main disadvantage is that they are vulnerable to selection biases. Convenience sampling is a type of nonprobability sampling in which the researcher surveys individuals who are ready and available. For example, a survey that relies on people in a shopping mall is using a convenience sample.

Snowball sampling relies on previously identified members of a group to identify other members of the population. As newly identified members name others, the sample snowballs. This technique is used when a population listing is unavailable and cannot be compiled. For example, surveys of teenage gang members and undocumented workers might be asked to participate in snowball sampling because no membership list is available.

Quota sampling divides the population being studied into subgroups such as male and female and younger and older. Then you estimate the proportion of people in each subgroup (e.g., younger and older males and younger and older females).

Sample Size

The size of the sample refers to the number of units that that will be surveyed to get precise and reliable findings. The units can be people (e.g., boys and girls over and under 16 years of age), places (e.g., counties, hospitals, and schools), and things (e.g., medical or school records). The number of needed units is influenced by a number of factors, including the purpose of the study, population size, the risk of selecting a bad sample, and the allowable sampling error (Kraemer and Thiemann, 1987; Cohen, 1988). When you increase the sample size, you increase the survey's cost. Larger samples mean increased costs to provide participants with financial or other incentives and to follow up with nonresponders.

The most appropriate way to produce the right sample size is to use statistical calculations. These can be relatively complex, depending on the needs of the survey. Some surveys have just one sample, and others have several. Formulas for calculating survey samples can be found on the Internet. Type in the words, "sample size calculator."

Response Rate

All surveys hope for a high response rate. The response rate is the number that responds (numerator) divided by

the number of eligible respondents (denominator). Practically all surveys are accompanied by a loss of information because of nonresponse. These nonresponses may introduce error into the survey's results because of differences between respondents and nonrespondents.

Reliable and Valid Survey Instruments

A reliable survey instrument is consistent; a valid one is correct (Litwin, 2004). For example, an instrument is reliable if each time you use it (and assuming no intervention), you get the same information. But it may not be correct! Reliability or the consistency of information can be seriously imperiled by poorly worded and imprecise questions and directions. If an instrument is unreliable, it is also invalid because inconsistent data are incorrect. Valid survey instruments serve the purpose they were intended to and provide correct information. For example, if a survey's objective is to find out about mental health, the results should be consistent with other measures of mental health and inconsistent with measures of mental instability. Valid instruments are always reliable, too.

Reliability

A reliable survey instrument is one that is relatively free from measurement error. This error, caused individuals to obtain scores that are different from their true scores, which can only be obtained from perfect measures. What causes this error? In some cases, the error results from the measure itself—it may be difficult to understand or poorly administered. For example, a self-administered questionnaire on the value of preventive healthcare might produce unreliable results if its reading level is too high for the teen mothers who are to use it. If the reading level is on target but the directions are unclear, the measure will be unreliable. Of course, the survey researcher can simplify the language and clarify the directions and still find measurement error. This is because measurement error can also come directly from the examinees. For example, if teen mothers are asked to complete a questionnaire and they are especially anxious or fatigued, their obtained scores could differ from their true scores.

Four kinds of reliability are often discussed: stability, internal consistency, and inter- and intrarater reliability.

Test-Retest Reliability or Stability

A measure is stable if the correlation between scores from one time to another is high. Suppose a survey of students' attitudes was administered to the same group of students at School A in April and again in October. If the survey

was reliable and no special program or intervention was introduced, then, on average, we would expect attitudes to remain the same. The major conceptual difficulty in establishing test–retest reliability is in determining how much time is permissible between the first and second administration. If too much time elapses, external events might influence responses for the second administration; if too little time passes, the respondents may remember and simply repeat their answers from the first administration.

When testing alternate-form reliability, the different forms may be administered at separate time points to the same population. Alternatively, if the sample is large enough, it can be divided in half and each alternate form administered to half the group. This technique, called the split-halves method, is generally accepted as being as good as administering the different forms to the same sample at different time points. When using the split-halves method, you must make sure to select the half-samples randomly.

Internal Consistency or Homogeneity

A survey’s internal consistency or homogeneity refers to the extent to which all the items or questions assess the same skill, characteristic, or quality. Cronbach’s coefficient alpha, the average of all the correlations between each item and the total score, is often calculated to determine the extent of homogeneity. For example, suppose a survey researcher created a questionnaire to find out about students’ satisfaction with Textbook A. An analysis of homogeneity will tell the extent to which all items on the questionnaire focus on satisfaction.

Equivalence or alternate-form reliability is a type of internal consistency. If two items measure the same concepts at the same level of difficulty, they are equivalent. Suppose students were asked a question about their views toward technology before participating in a new computer skills class and again 2 months after completing it. Unless the survey researcher was certain that the items on the surveys were equal, more favorable views on technology after the second administration could reflect the survey’s language level, for example, rather than improved views.

Some variables do not have a single dimension. Student satisfaction, for example, may consist of satisfaction with school in general, their school in particular, teachers, classes, extracurricular activities, and so on. If you are unsure of the number of dimensions expressed in an instrument, a factor analysis can be performed. This statistical procedure identifies factors or relationships among the items or questions.

Inter- and Intrarater Reliability

Interrater reliability refers to the extent to which two or more individuals agree. Suppose two individuals were

sent to a clinic to observe waiting times, the appearance of the waiting and examination rooms, and the general atmosphere. If the observers agreed perfectly on all items, then interrater reliability would be perfect. Interrater reliability is enhanced by training data collectors, providing them with a guide for recording their observations, monitoring the quality of the data collection over time to see that people are not burning out, and offering a chance to discuss difficult issues or problems. Intrarater reliability refers to a single individual’s consistency of measurement, and this, too, can be enhanced by training, monitoring, and continuous education.

Validity

Validity refers to the degree to which a survey instrument assesses what it purports to measure. For example, a survey of student attitude toward technological careers would be an invalid measure if the survey only asked about their knowledge of the newest advances in space technology. Similarly, an attitude survey will not be considered valid unless you can demonstrate that people who are identified as having a good attitude on the basis of their responses to the survey are different in some observable way from people who are identified as dissatisfied.

Four types of validity are often discussed: content, face, criterion, and construct.

Content Validity

Content validity refers to the extent to which a measure thoroughly and appropriately assesses the skills or characteristics it is intended to measure. For example, a survey researcher who is interested in developing a measure of mental health has to first define the concept (“What is mental health?” “How is health distinguished from disease?”) and then write items that adequately contain all aspects of the definition. The literature is often consulted either for a model or for a conceptual framework from which a definition can be derived because of the complexity of the task. It is not uncommon in establishing content validity to see a statement like “We used XYZ cognitive theory to select items on mental health, and we adapted the ABC role model paradigm for questions about social relations.”

Face Validity

Face validity refers to how a measure appears on the surface: Does it seem to ask all the needed questions? Does it use the appropriate language and language level to do so? Face validity, unlike content validity, does not rely on established theory for support.

Criterion Validity

Criterion validity compares responses to future performance or to those obtained from other, more well-established surveys. Criterion validity is made up two subcategories: predictive and concurrent. Predictive validity refers to the extent to which a survey measure forecasts future performance. A graduate school entry examination that predicts who will do well in graduate school has predictive validity. Concurrent validity is demonstrated when two assessments agree or a new measure is compared favorably with one that is already considered valid. For example, to establish the concurrent validity of a new survey, the survey researcher can either administer the new and validated measure to the same group of respondents and compare the responses, or administer the new instrument to the respondents and compare the responses to experts' judgment. A high correlation between the new survey and the criterion means concurrent validity. Establishing concurrent validity is useful when a new measure is created that claims to be better (shorter, cheaper, and fairer).

Construct Validity

Construct validity is established experimentally to demonstrate that a survey distinguishes between people who do and do not have certain characteristics. For example, a survey researcher who claims constructive validity for a measure of satisfaction will have to demonstrate in a scientific manner that satisfied respondents behave differently from dissatisfied respondents. Construct validity is commonly established in at least two ways:

1. The survey researcher hypothesizes that the new measure correlates with one or more measures of a similar characteristic (convergent validity) and does not correlate with measures of dissimilar characteristics (discriminant validity). For example, a survey researcher who is validating a new quality-of-life survey might posit that it is highly correlated with another quality-of-life instrument, a measure of functioning, and a measure of health status. At the same time, the survey researcher would hypothesize that the new measure does not correlate with selected measures of social desirability (the tendency to answer questions so as to present yourself in a more positive light) and of hostility.
2. The survey researcher hypothesizes that the measure can distinguish one group from the other on some important variable. For example, a measure of compassion should be able to demonstrate that people who are high scorers are compassionate but that people who are low scorers are unfeeling. This requires translating a theory of compassionate behavior into measurable

terms, identifying people who are compassionate and those who are unfeeling (according to the theory), and proving that the measure consistently and correctly distinguishes between the two groups.

Quality of Survey Data

The quality of survey data depends on how well respondents understand the survey's questions. Their comprehension may be affected by language skills, education, and culture. A pretest of the survey enables the survey researcher to evaluate whether respondents reliably interpret questions and that they do so as they survey researcher intends. Usually small groups (five to ten people) who are similar in demographic and languages skills to prospective respondents evaluate each survey questions individually or in a group. The idea is to decide whether to accept the original question and meaning, to change the question but keep the meaning, or to eliminate the question or write a new one. Pretest participants are also asked to examine the survey with regard to its flow and administrative ease, identifying unusual, redundant, irrelevant, or poorly worded question stems and responses. They are also asked to record the time required to complete the survey.

Pilot testing is a miniature version of an experiment in which a sample of respondents is chosen to complete the survey for the purpose of evaluating its effectiveness in practice. In theory all the technical problems that can be anticipated have already been resolved in the pretest. A pilot test is, however, the reality test. If the respondents in the real setting are not as motivated as those in the pretest environment, differ in their language or other skills, or are unfamiliar with surveys, the researcher may have to go back to the drawing board.

Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality

An Overview of Educational Assessment

M James, University of Cambridge, Cambridge, UK

Introduction

This section on educational assessment is new for this encyclopedia. There is another, on educational measurement, that shares some of its themes but there are important respects in which the two sections differ. Readers who are interested in the general field of assessment and testing are advised to peruse both sections.

As Robert Linn makes clear in his overview of the 'Educational measurement' section, measurement in education is closely associated with formal testing for purposes associated with the placement of students, the award of qualifications, monitoring achievement and progress, and holding teachers, schools, school districts, states, and nations accountable for the quality of the public services they provide. The validity and reliability of such measures is paramount in order to make useful and fair comparisons between individuals, groups, and organizations. The basis for this is provided by the theory and techniques of the well-developed science of psychometrics, which offers criteria for the evaluation of tests, their results, and their uses. These are sophisticated procedures and require considerable expertise, time, and other resources to develop and implement them properly. For this reason, educational measurement is often large scale and carried out, at least in part, by professional agencies external to the schools in which tests are administered. The examples that Linn quotes illustrate this.

Such educational measurement, in the form of tests, is often an element of educational assessment but the latter generally has a wider scope in terms of purpose, form, agency and use. Indeed, the word assessment has its roots in the Latin verb *ad sedere* meaning to sit beside, a notion somewhat remote from familiar images of examination halls with students writing silently at separated desks. In recent years the idea that assessment might have something important to do with the teacher sitting beside

the student (literally or metaphorically), and gaining an understanding of what the student knows and can do in order to help them move on in their learning, has begun to gain new ground. Linn mentioned this formative function of assessment in his overview although it was not dealt with fully because it has more to do with good instructional practices than with technical measurement characteristics. In this section, the relationship between educational assessment, especially formative assessment, and instructional practices in classrooms is a prime concern and a central focus for many of the articles. Some of the subject matter looks similar in both sections, for example, there is an article on 'Achievement testing in mathematics' in the 'Educational measurement' section and one on 'Mathematics assessment in schools' in this 'Educational assessment' section. However, the emphasis shifts from the concerns of test developers to the issues for educators, from the technical to the professional, from tests as the dominant form of assessment to a consideration of alternative activities, and from reliability as perhaps the most powerful criterion of quality to concerns with validity in terms of the consequences of assessments for the experience of students and schools. This is not to imply that the concerns of test developers are unimportant but to offer a somewhat different, and equally important, perspective on these complex phenomena.

There is one more thing that should be said about the meanings of words. English is a rich language with many synonyms for broadly similar ideas although there are subtle variations in meaning and usage in different Anglophone countries. The term assessment is a case in point. In the UK it is used widely for all those activities that involve eliciting evidence of student learning and drawing inferences as the basis for decisions. In the US, these processes are often referred to as student evaluation and we could equally well have used this as the title of this section.

However, in the UK, and elsewhere, the term evaluation is more often used for procedures for collecting evidence and judging the worth of educational programs and institutions. The 'Evaluation' section in this encyclopedia has this particular focus. For all these reasons, we chose 'Educational assessment' for this section.

The articles in this section have been clustered under five loosely defined topic headings but anyone who has the interest and stamina to read them all will note a number of recurring themes and issues. The remainder of this overview article introduces the topics and draws out some of the most prominent cross-cutting themes and issues.

Topics

Key Relationships: Impact of Assessment

Making the impact of assessments a first consideration may seem to be putting the cart before the horse, but the consequences of assessment practices, for learners, for curriculum, for instructional practices and for institutions, are a crucial concern and the source of much debate. Educational practice in classrooms involves interactions among curriculum, assessment, and instruction (key elements), and between teachers and students (key actors). In this complex system of classroom activity, assessment cannot easily be abstracted and examined without reference to the other components because change in assessment practice will almost certainly have knock-on effects – for good or ill. An early illustration of this can be found in the very first annual report, in 1859, of the examiners of the University of Cambridge Local Examinations Syndicate. On the performance of candidates in English history they opined:

...forty-six failed to pass, but this number of failures does not measure the full extent of the general deficiency. The questions were of an elementary character, and the Candidates had received notice of the range of reading within which their knowledge would be tested. But their answers, even when accurate, shewed (sic) a general uniformity of expression which seemed to imply that meager handbooks had been placed before the students to be 'got up', and that little attempt had been made by their instructors to excite the interest of their pupils by questionings or remarks of their own. (reproduced in Watts, 2008)

So history suggests that the consequences of assessment practice, some of them unintended, can be profound and need to be considered in the planning, development, implementation, use, and evaluation of any assessment policy. An examination of current evidence of impact is therefore an important basis for deliberation about future alternatives.

The articles in this cluster focus particularly on impact on classroom practice and on learners. Pollard and Filer

provide an account, drawn mainly from ethnographic research, of the powerful influence of students' experiences of assessment through their school careers on the formation of their identities as learners. Buchwald and Schwarzer focus specifically on the impact of test anxiety. Using conservation of resources (COR) theory, they conceptualize test anxiety as a loss of resources (self-worth, motivation, and productive cognitive processing) that deleteriously affects learning and performance for individuals and groups. Other articles examine the impact on specific learner groups: boys and girls and learners with disabilities. We had wanted to have articles in this collection about the impact of assessment on students from different ethnic groups and on different socioeconomic status groups but lack of sufficient contemporary research with these specific foci, possibly because relevant background data have not been routinely collected, made this unfeasible. Perhaps this gap will be filled in the next edition of this encyclopedia.

Assessment Activities

Teacher-administered tests continue to be a prominent feature of assessment activity in many classrooms. Indeed, so dominant is this experience that the popular press, at least in the UK, tends to substitute the monosyllabic test for assessment even where there is reference to a greater range of activities. In some instances tests are developed by testing agencies or awarding bodies and are mandatory as part of national, state, or school district monitoring or qualifications systems, or they are bought in by schools for their own purposes. Sometimes they are constructed by the teachers themselves but usually without the technical expertise necessary to ensure their quality, which limits the validity of the inferences drawn from their results. For example, Martinez Rizo describes how, in Latin American countries in the mid-twentieth century, teachers were asked to prepare multiple-choice tests and standardize their scores by grading on the (bell) curve without the statistical training that is necessary (see the articles in the section on 'Educational measurement'). This poor practice is not confined to one time or place; the present author confesses to doing it herself as a newly qualified teacher in England in the 1970s, mistakenly believing that she was being scientific.

In character, tests are usually pencil and paper, time-limited, administered to individual students under controlled conditions, and composed of multiple-choice or constructed response items. Multiple-choice tests dominate in the USA but in the UK and elsewhere, constructed response items, essays, and coursework projects are more familiar. Historically, these latter are associated with the different tradition of examinations derived less from the science of psychometrics and more from practices in universities, which, in turn, adapted forms of induction practiced by the ancient guilds. The craft apprentice

traditionally completed his training by producing a masterpiece that is, a piece of work for the master, in which he attempted to demonstrate all that he had learnt in a single project of the highest quality. This resonates with current practice in modern universities where theses or dissertations are submitted by students for examination on completion of masters or doctoral programs.

Within schools, concerns about the value of conventional tests have stimulated debate about alternative forms of assessment. This has arisen especially when there is interest in purposes other than making comparisons between the abilities, aptitudes, or attainments of students in rather narrowly defined domains, some of which are only loosely related to what is actually taught and learned in the classroom. Many of the articles in this cluster focus on these alternative approaches. For interested readers, the article by Stobart and Gipps is a good place to start because it distinguishes alternative forms or formats of assessment from alternative models of assessment and from alternative purposes of assessment. This classification provides a useful framework for locating the discussion in other articles, which have more specific foci. For example, there are articles on computer-based instructional systems that provide feedback, dynamic assessment, diagnostic dialog, peer and self-assessment, portfolio assessment, and records of achievement. On the surface it may appear that these are about alternative forms of assessment but the justification for these alternative approaches is based on arguments about their fitness for different purposes, especially instructional purposes, and their congruence with more powerful models of how assessment practice can contribute to better learning. (This theme is expanded below.)

Assessment in Domains

Large-scale testing for system monitoring at international, national, or state level tends to focus on a limited number of constructs. They typically assess attainments in subdomains of core subjects, notably mathematics and national language and science, or generalized aptitudes for further study (see the section on 'Educational measurement'). There are two main reasons for these domain restrictions.

First, robust and dependable tests are expensive to develop, trial, and administer, especially constructed response tests which demand armies of trained markers. Such testing of all students for all the learning outcomes of potential interest would not be manageable or affordable. Large-scale national testing in even limited subject areas has proved difficult, as the fiasco over national testing in England in 2008 clearly demonstrated. The failure to deliver, mark, and report test results, for around one million 11- and 14-year-olds in English, math, and science, led the Government to cancel the contract with

the testing agency (Educational Testing Service (ETS), Europe), abolish the National Assessment Agency, and suspend the chief executive of the Qualifications and Curriculum Authority.

Second, unless countries have a mandatory national curriculum that applies to all maintained schools, as in England, it is not possible to assume that all students will have the same opportunity to learn and achieve across a whole curriculum, or even that there will be consensus about what curriculum content should be. Therefore what is tested tends to be the basics that most students are expected to encounter. International surveys of achievement are sometimes criticized for focusing on the lowest common denominator, that is, what is covered in most countries, rather than what might best reflect aspirations for future world citizens.

When one moves away from concern with large-scale, whole cohort, or large sample testing, for high stakes accountability purposes, the picture changes. When the focus is on assessment of the achievements of particular groups of students in particular subjects, courses, or phases of their education, for the award of qualifications, for reporting to parents or for diagnostic or formative purposes, then there is more scope for debate and innovation in assessment according to the particular characteristics of the domain. The articles in this cluster therefore focus on these debates and innovations within specific domains.

A large group focuses upon subject domains, especially those of the school curriculum. There are articles on what is widely regarded as the core of reading, writing, oracy, mathematics, and science (for science in elementary schools see the article 'Assessment in schools: primary science' and 'Assessment in schools: secondary science' for science in high schools). There are also contributions on areas of the broader curriculum: creative subjects, history, civics, and social studies, information and communications technology (ICT) and technology. Another small group focuses upon the assessment of what might be called cross-curricular or generic skills and attitudes such as learning to learn, learning dispositions, and the affective domain more broadly. Many countries, for example, Hong Kong and the whole of Europe (stimulated by the Lisbon Strategy 2000), are moving to giving more prominence to such skills and dispositions on the grounds that these are essential preparation for lifelong learning in a rapidly changing world. However, a key issue is the extent to which these can be taught, learned, and assessed in a way that is detached from learning something in a cognate field and whether the expression and application of such skills and dispositions varies with context. The stronger argument is for the importance of context although this creates challenges for curriculum planning, instruction, and assessment. The implication is that skills, dispositions, and knowledge are highly integrated and this needs to be recognized in assessment practice.

Mainstream education in schools is well covered by the aforementioned articles. However, another group of articles within this cluster focuses more particularly on assessment within different phases or sectors of education and training: early years, vocational training, higher education, and the adult workplace. All these articles challenge assumptions about what constitutes good assessment practice, derived as many of these assumptions are from the dominance of experience in schools. They provide thoughtful alternatives to most of the why, what, who, where, and how questions; as such they should cause those who work predominantly in schools to reflect further on the formats, models, and purposes of assessment.

Quality and Use: Classroom Assessment in Policy Contexts

Even in this International Encyclopedia, space does not permit a thorough examination of all the different expressions of assessment policy in all countries of the world. For this reason the articles in this cluster are an indicative selection chosen because they represent interesting and/or important trends in policy and practice, and where evidence is available. Readers should be aware that there is a bias towards accounts of Anglophone countries although some redress is attempted by inclusion of an article on French sources, a comparison between England and France, the article on Latin America mentioned earlier, and others exploring developments in Eastern Europe and Africa. In terms of research, analysis, and commentary, great attention has been paid internationally to the development of assessment systems in Australia, and New Zealand, and articles are included on these. Although a small country, Hong Kong's recent experience also warranted an article because, soon after the former British colony was handed back to China in 1997, this Special Administrative Region embarked on a 10-year program of educational reform that included new senior secondary examinations, basic competency testing, school-based assessment and a commitment to assessment for learning (AfL). Hong Kong has self-consciously struggled to create a system in which assessment of learning for reporting, selection, and accountability is in balance with AfL for educational growth. In this sense it represents, in microcosm, the struggles that are implicit in many other policy contexts although the ways in which the problems are formulated, and tackled, may differ.

In reviewing this cluster of articles, it is worth reflecting on the diverse ways in which assessment systems evolve over time. Where there is little history of assessment policy, the instinct may be to adopt objective, scientific testing as the principal instrument of policy. But as countries become more sophisticated in the use of tests, they also become more aware of limitations in the way they are used and the challenges they present to policy formation, professional

practice, and public understanding. Thus, more mature systems show a shift in focus towards enhancing the quality of everyday classroom assessments, especially for formative purposes, and attempting to find the best balance with summative assessment and testing to meet the legitimate demands for accreditation and accountability. More research would be needed to test this hypothesis but the articles in this group provide some evidence for this proposition.

Concepts and Issues

This final cluster of articles focuses on a number of key ideas and discussions. Many of these ideas have already been mentioned in this overview and some are expanded a little more in the final part of this article.

At the heart of debates surrounding assessment and testing are issues of purpose and use, that is, what assessment practice is intended to do and the functions it actually performs, which may or may not coincide. Newton identifies 22 purposes although he emphasizes that a single assessment can serve a range of purposes, although not all. A number of concepts related to purpose have come to particular prominence in recent years, partly because there are continuing debates about what they mean and how they should be distinguished. Black, who is particularly associated with research in the area, provides an article on formative assessment (or AfL) and Daugherty provides one on summative assessment (or AoL) by teachers. Both were members of the influential UK Assessment Reform Group (1989–2010) who distinguished AfL from AoL (ARG, 1999) and defined AfL in a way that has been widely used and variously reinterpreted (ARG, 2002a, quoted below).

Daugherty makes the point that the quality of teachers' summative assessments and the credibility ascribed to the results are dependent on procedures introduced to increase accuracy, consistency, and fairness in their judgments. Moderation by teachers is one such procedure, discussed by Maxwell. This represents an important and valuable form of assessment training for teachers, which is crucial for effective classroom assessment practice whether targeted at formative or summative purposes. Davies discusses this further. Pedder expands the discussion to focus on the need for teachers to be supported to develop or change their practices, their corresponding beliefs about learning, and their conceptions of classroom roles for teachers and learners. Both he and Sutton, also highlight the implications and challenges for the leadership and management of schools.

At organizational level, in most systems, school managers have to balance the formative and summative uses of assessment data, which sometimes appear in tension. The high stakes attached to school accountability in centralized systems where severe consequences flow from failure to perform well can encourage games-playing and

data manipulation in order to show institutions in the most favorable light. The article by Thomas argues that the publication of raw statistics cannot give an accurate picture of how effective a school and its teachers are at raising and maintaining the achievement of all students, but that value-added methodologies are available for understanding the mechanisms of school improvement.

A final group of articles in this cluster explores the question of what makes assessment educational and some of the deeper issues surrounding assessment practice. In particular, these articles examine the relationship of assessment to progression in learning, instructional planning, the regulation of learning in the activity of the classroom, assessment of group work, and the role of three-way assessment conversations involving students, teachers, and parents. Underpinning all of these concepts and issues are some fundamental debates about the models best able to explain how assessment practice can contribute to better learning.

So far this overview has been very broad brush. The remainder of this article discusses some of the themes, introduced above, in a little more detail because they recur in many of the contributions collected in this section. The aim is to draw out what seem to be the dominant trends in research and scholarship at the current time.

Cross-Cutting Themes and Issues

What Makes Assessment Educational?

Assessment for grading, selection, and certification (summative purposes) has a two thousand year history, stretching back to the Han dynasty in China. In contrast, the stated aspiration that assessments should fulfill formative purposes is more recent. Although the distinction between formative and summative has been used for several decades, a turning point came when Paul Black and Dylan Wiliam, of King's College London, published a pamphlet, *Inside the black box*, derived from an extensive review of research on assessment and classroom learning (Black and Wiliam 1998). (This is referred to in many articles in this section.) The review was commissioned by the UK Assessment Reform Group (ARG), which perceived a need to update an earlier review by Crooks (1988). The central thesis of Black and Wiliam's review was that there is a body of firm evidence that formative assessment is an essential feature of effective pedagogy and its development can raise standards. The authors put a figure on the size of measured gains and pointed to effect sizes in the range of 0.4–0.7, amongst the largest for any educational intervention. It was probably these figures, and extrapolations that indicated what they might mean in terms of scores on national tests, examinations, and international surveys of achievement, which provoked policy makers to take notice. However, some

confusion about what the term formative assessment actually meant encouraged the ARG to adopt a distinction between AfL and assessment of learning as a more accessible version of the formative/summative distinction (ARG, 1999). Both pairs of terms are now widely used, within and beyond the UK, as the articles in this section testify.

All assessments involve certain processes associated with making observations of performance, interpreting the evidence, and making judgments that can inform decisions. For formative purposes these processes have been construed as:

...the process of seeking and interpreting evidence for use by learners and their teachers to decide where the learners are in their learning, where they need to go and how best to get there. (ARG, 2002a)

However, no assessment can properly be described as formative unless assessment information is actually used to bring about improved learning. It is only by so doing that assessment in education becomes educational assessment.

Practices Associated with Formative Assessment

Black and Wiliam's review of research provided important guidance about which particular classroom practices, as part of everyday pedagogy, would help teachers to fulfill the aims of formative assessment (see also the article 'Formative assessment'). These are:

- Sharing learning intentions and success criteria with learners so that they understand criteria of quality (standards). This can be done at any point in a lesson and through various devices, including discussion of exemplars.
- Developing classroom talk and questioning to elicit evidence of knowledge and understanding but also to identify difficulties and opportunities, including those associated with prior learning and experiences.
- Giving appropriate feedback that identifies strengths and weaknesses but, most importantly, helps learners know what to try next in order to improve. Sometimes this is referred to as feed forward.
- Providing opportunities for peer- and self-assessment so that learners can eventually carry out the above practices for themselves and become autonomous learners.

In a follow-up development project, Black *et al.* (2003) also investigated the possibilities of using summative assessments formatively but this tends, because of a time lag, to be formative for teachers' future instructional practices rather than formative for the students who sat the tests. This is a useful reminder that formative for 'what' and 'whom' is a pertinent question to ask.

Relationships between Formative and Summative Assessment

Many of the articles in this section deal with both summative and formative assessment and it is important to emphasize that these labels attach only to the purposes and uses to which assessments are put, and not to their formats. In other words, a pencil-and-paper test, or quiz, can be used formatively in the classroom, provided that the teachers plan time in their lessons for discussions of results that go deeper than scores. Analysis of responses to particular items can lead into productive discussions about what students did well or poorly, what this indicates about their learning, and how they might improve their understanding and performance. Similarly, it is possible that assessments carried out primarily for formative purposes in the classroom, even those of an informal nature such as dialog with a group of students engaged in a learning activity, can be reviewed subsequently for evidence to sum up what individuals or groups have achieved over a period.

What is of concern, certainly in England where AfL has become enshrined in national policy, is that understanding of the formative dimension is unclear and in danger of being lost. For example the Primary and Secondary National Strategies of 2008 made reference to definitions of AfL and research-based accounts of good practice. However, these materials also reveal tensions with researchers' definitions of AfL. For example, they imply that AfL can be formative, or summative, or both. The government in England has invested a great deal in the development of pupil tracking and planning tools, to help teachers and principals use the results of statutory national tests for monitoring, prediction, and target setting. It is politically expedient therefore to promote frequent mini-summative assessment, to secure higher performance on tests to meet prescribed numerical targets, rather than use scarce resources on less-tangible approaches to formative assessment for the purpose of enhancing deep and lasting learning.

The distinction between learning and performance is a subtle one and not well understood. Measured performance should indeed be an indicator of underlying learning (or what Dweck, 2000, calls mastery) but debates about the validity of assessments underscore the difficulties of making such assumptions. It is quite possible to drill pupils to perform well on tests without enhancing learning. Given the high stakes consequences for schools that perform badly, there is increasing evidence that this is happening, at least in England (ARG, 2002b).

Despite a decision, following the debacle in 2008, to abolish national tests for 14-year olds in England, the underlying rationale did not change significantly. The drive was still to raise standards as measured by national curriculum assessment levels and sublevels, and

assessment for learning continued to be seen as an instrument for this purpose. More nuanced ideas, about the role of AfL in pedagogy to enhance the learning of capable, resourceful, and autonomous citizens in a changing world, seemed almost entirely absent. One possible explanation for the mixed messages that appeared in policy documents is that the authors have tried to finesse competing claims between those who are convinced by research that formative assessment is the key to improved learning and achievement, and those who believe that the pressure of regular testing raises standards. Or the mixed messages may simply be indicative of some confused thinking that has elided learning and performance.

Models of Assessment and Models of Learning

If assessment is to become educational, when it is integrated into pedagogy, then there needs to be a considerable degree of alignment or congruence between the learning outcomes sought, learning opportunities and instructional practices, and the assessment processes used to detect outcomes and promote learning. This includes concerns for consistency in the theoretical foundations of practice. A relevant question to ask, as Stobart and Gipps do, is "What models of assessment are consonant with alternative perspectives on learning?" (Alternative models, perspectives or theories of learning are themes in other sections of this encyclopedia; for example, see the article 'Learning, cognition and language: an overview', which provides an overview of learning and cognition.)

Greeno *et al.* (1996) argue that four perspectives on the nature of human mind should be taken into account when constructing assessments: the differential, the behaviorist, the cognitive, and the situative (or what Europeans tend to describe as sociocultural). Pellegrino *et al.* (2001) also note:

Most current tests, and indeed many aspects of the science of educational measurement, have theoretical roots in the differential and behaviorist traditions. The more recent perspectives – the cognitive and situative – are not well reflected in traditional assessments but have influenced several recent innovations in the design and use of educational assessments. (p. 60)

Pellegrino *et al.*'s key text provides many examples from mathematics and science of how the cognitive (sometimes labeled constructivist) perspective has been incorporated into the recent design of assessments. Particular emphasis is given to ways of detecting how people organize information in schema in long-term memory, how they use this knowledge to solve problems, how they develop metacognitive skills, and how they engage in

communicative practices appropriate to subject domains. However, the treatment of situative or sociocultural approaches is slight in that the social dimension is largely interpreted as a context for individual learning, rather than integral and inseparable.

Helpfully, Pellegrino *et al.* advise that assessment methods can be expanded beyond traditional tests by drawing on the ways in which research is conducted to investigate learning according to these different theories in domains. They also suggest ways in which assessment can be integrated with learning. For cognitive approaches, computerized systems are mentioned including intelligent tutoring, time-reaction monitoring, and simulations. For situative approaches they mention possibilities drawing on ethnographic analysis (p. 101) to study social practices *in vivo*. However, this account is given only a single paragraph. There is still work to be done, therefore, to find models of assessment, and develop practice, in ways that are more congruent with the situative or sociocultural theories of learning that are exciting a great deal of interest among educators and researchers in the fields of curriculum and pedagogy across domains, sectors, and continents. Some of the articles in this section record steps taken in this direction.

The roots of most situative or sociocultural approaches to the understanding of learning can be traced to the Soviet psychologist, Lev Vygotsky, although some commentators connect his thinking with earlier transactional psychologists in the US: William James, G.H. Mead, and John Dewey. All of these theorists were interested in the activity of learning and the development of mind but believed that there is dynamic interaction, or transaction, between the individual agent and the structured world, which is mediated by tools and systems of signs and symbols, especially language – the tool of tools. In American sociology this line of enquiry developed into symbolic interactionism; in Russia, Vygotsky initiated activity theory as a psychologically relevant application of dialectical and historical materialism. These theoretical developments blur the boundaries between what have subsequently become separated into distinct disciplines of sociology and psychology. Psychology, cognitive science, and psychometrics have tended to dominate the discourse surrounding learning outcomes and their assessment, although the suggestion by Pellegrino *et al.* that ethnographic methods in research might offer some solutions to assessing learning within a situative or sociocultural perspective encourages a reexamination of these earlier influential approaches and their more recent manifestations.

Vygotsky studied the development of the higher mental faculties of the individual mind, but, in keeping with his identity as a Soviet psychologist, he was also interested in the way that collective consciousness was brought into the individual mind. Central to his theory was the assumption that social interaction is central, that is, much more than a

context for learning. In a much-quoted passage he describes how an interpersonal process is transformed into an intrapersonal process:

Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first *between* people (*interpsychological*), and then *inside* the child (*intrapsychological*). This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relations between human individuals. (author's emphases) (Vygotsky, 1978: 57)

The transfer and translation of cultural knowledge involves both externalization and internalization through shared activity (interaction) and individual learning activity (action). For example, in a life-drawing class the object of an activity (the problem space) may be to make a convincing drawing of a model lying horizontal on a couch with her arms and hands stretched above her head toward the novice artist. Knowing, that the hand is physically about the size of a face, the instinct of the novice is to draw the hand too small: as it would be if the model stands upright. The teacher, or more expert other, can help the novice by introducing a tool, known as the artist's measure. This is simply a pencil that the artist holds at arm's length, with one eye closed, to measure the relationships between, say, the width of the head and the width of the hand. This enables the novice to see what the eye actually sees and not what the mind interprets to be the case based on previously constructed mental models about the proportions of the body. Eventually this technique is internalized and the novice can look more carefully at proportions without using the tool. This achieves the goal, or outcome, of the activity, that is, to understand the concept of foreshortening and apply it to practice. The novice artist therefore learns to look in a different way. In Vygotsky's terms, the object (the learning activity that the subject is engaged with) works back to the subject (the learner) to create new forms of subjectivity.

This theory also predicts creativity or knowledge creation in learning because, once the individual has internalized the use of tools (artifacts, practices, and language), he or she can adapt them or create new ones to tackle new problems with new results. These can be shared with others, thus creating a cycle of externalization, internalization, and externalization. This provides a response to problems with both of Sfard's (1998) two metaphors of learning: the acquisition metaphor (AM) and the participation metaphor (PM). The pervasive acquisition metaphor implies that units of knowledge are possessed, accumulated, refined, combined, and passed on, whilst the linguistic turn of the participation metaphor shifts the emphasis from having to doing. Learning, according to PM, is embedded in the social processes of becoming a member of a community of practice. Apprenticeship is a

familiar analogy. However, these two metaphors provide only partial explanations of innovation and creativity as important learning outcomes. In contrast, Vygotsky's theory of goal-oriented, tool-mediated learning activity can encompass learning outcomes associated with both of these metaphors, but also with outcomes associated with knowledge creation, because it provides a description of how knowledge and practices can be transformed. In other words, it can encompass a very wide range of outcomes: higher and lower mental processes; attitudinal, cognitive, and behavioral outcomes; individual and shared activity; problem-solving processes and products; the acquisition of existing knowledge and the creation of new knowledge. Indeed it accommodates most, if not all, of the learning outcomes discussed in the articles in this section of the encyclopedia.

Vygotsky also has something to offer on the issue of progression. The structures of grades, scales, and attainment levels have accustomed us to regard progression as step by step and linear. According to Vygotsky, the mastery of tools of the mind takes place in the zone of proximal development (ZPD). As Grigorenko (1998) points out:

The word *zone* refers to the nonlinearity of children's development. In this zone, the child might move forward or backward, to the left or to the right. . . . The main characteristic of the ZPD is its sensitivity to the child's individuality – its responsiveness to the unique profile of each child's skills. The ZPD is of tremendous importance educationally. Generally, when educators evaluate a child's skills, they focus on what the child demonstrates in his or her independent performance. . . . Vygotsky stated that the level of independent performance is important, but not the only, index of development. To account for the dynamic process of development, we should consider the level of the child's assisted performance. (pp. 210–211)

There are two points to be made here. First, there is value in plotting a learners' development as a profile within a zone and encouraging them to expand, deepen, and enrich their knowledge, skills, and understanding. Second, there is value in assessing how learners respond to assistance and the introduction of new tools by others. Grigorenko argues that by doing this we are more likely to determine students' true level, than by administering tests of unassisted performance.

Very often, teachers wait for children to demonstrate completely formed functions; teachers think that they can lead a child to the next step only after they have seen evidence that the child has successfully acquired the function taught at the previous step. As a result, children are limited in their learning opportunities to those that correspond to their level of independent performance. In other words, teachers who follow this standard practice

minimize the student's ZPD by almost closing it. On the contrary, ideally, the ZPD should be wide open, so that it can expand developmentally appropriate practices up to the level of assisted performance. (Grigorenko, 1998: 212)

Vygotsky's view that what learners can do at lower levels should not limit opportunities for their development of higher psychological functions was almost certainly influenced by his experience of working at a boarding school for children who were both deaf and blind. He claimed that education targeted on the formation of higher mental processes could help people overcome, or compensate for, deficits because it equipped them with adaptive strategies that might be unique for each person.

All of these ideas have implications for assessment. Practical applications of Vygotsky's theories have been developed in versions of dynamic assessment. Some forms of dynamic assessment have been described as little more than superior intelligence tests, but there are clinical versions (see the article 'Dynamic assessment (two types)') that use hint structures in scaffolded instruction to maximize feelings of competence and efficacy. This affects test reliability, in a psychometric sense, although advocates claim that these concerns are less important than the quality of the insights that result and the likely magnitude of change in a learner's performance (i.e., their validity). Dynamic assessments of this nature are currently used in one-to-one situations, usually with students with learning difficulties; therefore they are often felt to be impractical for wider application. However, the principles could well be adapted for everyday use by teachers if they were to be integrated with instructional strategies. Moreover they could serve both formative and summative assessment purposes although the formative would take priority. In this sense, versions of dynamic assessment could provide tools for formative assessment integrated into pedagogy.

As noted earlier, much current assessment practice derives from behaviorist or differentialist approaches, many of which are now rejected as learning theories except in very limited senses. Pellegrino *et al.*'s (2001) important work provides both the underpinning theory and practical examples of more valuable forms of assessment underpinned by sound cognitive science. James (2008: 31) offers the following pointers to what might constitute 'third generation' (sociocultural) assessment practices:

- If learning cannot be separated from the actions in which it is embodied, then assessment too must be situated.
- Assessment alongside learning implies that it needs to be done by the community rather than by external assessors.
- Assessment of group learning is as important as the learning of the individual.
- *In vivo* studies of complex problem solving may be the most appropriate form for assessments to take. (Some

ethnographic methods could be used, including methods for assuring quality of inferences from evidence.)

- The focus should be on how well people exercise agency in their use of the resources or tools (intellectual, human, material) to formulate problems, work productively, and evaluate their efforts. This would be a proper justification for coursework assignments with students having access to source materials, because it is the way that these are used that is of most significance.
- Learning outcomes can be captured and reported through various forms of recording, including narrative accounts and audio–visual media. The portfolio has an important role here.
- Evaluation needs to be more holistic and qualitative, not atomized and quantified as in measurement approaches.

The main obstacle to implementing this sociocultural approach to assessment is likely to arise from a perceived need to ensure the trustworthiness of such assessments when large numbers of students are involved, and when those who are interested in the outcomes of such learning cannot participate in the activities that generate them. Within vocational education, which often aspires to some aspects of this model, systems of internal and external assessors and verifiers have attempted to assure quality, although such large-scale systems almost inevitably become bureaucratic, unwieldy, and restrictive. Clearly, more work needs to be done to develop approaches to assessment that are more coherent with valued sociocultural perspectives on learning.

Support for the Development of Educational Assessment Practice

Another challenge to the effective implementation of educational assessment relates to the demands it makes on the knowledge and skills of educators. Traditional forms of testing and examinations are usually the product of extensive piloting and trialing of instruments by experts in educational measurement who work in test agencies or awarding bodies. Everyday classroom assessment, however, is the responsibility of teachers and those who manage them. Rarely are educators adequately equipped for this task in their initial training, yet they need to develop sufficient assessment literacy to allow them to examine, and make critical sense of, all forms of evidence of students' learning and performance. Development of an understanding of the use and misuse of statistical data generated by large-scale assessment systems is particularly urgent, but the knowledge and skills of effective classroom assessment practices for formative purposes is equally challenging. This constitutes a specific case of educational transformation to which more generalized insights from research on educational change, professional development, and organizational learning may apply (see the overview in the

section 'Leadership and management'). However, there is also a need to investigate the specific conditions that enable educators to implement effective assessment practice because it is usually a failure of implementation, rather than a failure of knowledge, that stands in the way of success (see the articles '(School) Organizational policies and practices to support effective classroom assessment' and 'Challenges of developing and implementing formative assessment practices in schools').

Although the studies that Black and Wiliam (1998) reviewed provided information about the kinds of interventions that were most likely to be profitable, these were tested in small-scale, intensively supported experiments. If these innovations are to be scaled-up and sustained across a system, they need to be able to grow with much less support. The right conditions for the creation and spread of knowledge and practice are crucial to their successful implementation. These conditions include the professional development of teachers and organizational structures and cultural processes that support and enhance educators' own learning. The development study by Black *et al.* (2003) investigated some of these conditions at individual teacher level. Subsequently, a larger study (James *et al.*, 2007) investigated conditions for the creation and spread of knowledge and practices within and across classrooms, schools, and professional networks. On the basis of their research, the latter identified a number of key conditions for successfully embedding and sustaining effective assessment for learning:

1. The ultimate goal of educational assessment is to promote learning as well as to record achievement. The AfL practices are a useful starting point. However, these practices should serve underlying principles, such as making learning aims, processes, and outcomes explicit to learners and promoting learning autonomy through encouraging mindfulness and strategic approaches.
2. Although teachers appreciate practical advice, AfL practices can become ritualized and mechanistic if teachers are not stimulated to think about the principles of learning that underpin them. The project team made a distinction between those teachers who implemented the letter of AfL by injecting AfL practices into what they usually do without changing anything more fundamentally, and those who captured the spirit of AfL by integrating practices into the flow of lessons to regulate the learning process itself. The latter requires some understanding of underlying principles. Beliefs and practices are interrelated and need to be developed together; it is not sufficient simply to tell teachers what to do.
3. Those teachers (only about 20% of the sample at the beginning of the study) who had most success with implementing AfL in their classrooms were those who demonstrated a capacity for strategic

and reflective thinking and took responsibility for what happened in their classrooms. They were not inclined to blame external circumstances (such as initiative overload) or pupil characteristics (such as innate ability or attitudes) but concentrated on the ways in which they could improve the learning experience for pupils.

4. Although most teachers held clear and positive educational values, the majority of teachers struggled to bring practice in line with their stated values. These values–practice gaps closed somewhat over the course of the project but many teachers felt constrained by a policy context that encouraged rushed curriculum coverage, teaching to the test and a tick-box culture.
5. Values, beliefs, and practices were not uniform over all groups of teachers. In secondary schools, there were differences in the beliefs and practices of teachers with different subject specialisms. The highest percentage of teachers with classroom practices consistent with AfL were teachers of English. In contrast, mathematics teachers seemed to struggle with these ideas. There were also differences between schools. These differences indicate the level of challenge for leadership and support, and particularly for development of differentiated strategies for professional development.
6. Classroom-based collaborative inquiry practices for teacher learning emerged as the key influence on teachers' capacity to promote learning autonomy with their pupils. These include learning from research and also working together to plan, try out, and evaluate new ideas.
7. Such knowledge creation among teachers can extend beyond the classroom through networking across the school and with teachers in other schools. Networking through face-to-face meetings of various kinds builds the social capital (mutual support and trust) that supports the exchange of intellectual capital (ideas and practices).
8. Opportunities for teachers to learn in these ways, through classroom inquiry and networking, depend significantly on organizational structures, cultures, and leadership. Particularly important is a school's knowledge of the expertise in its midst, or available to it, and its capacity to tap into this expertise, grow it, and spread it through professional development activities and networking. The quality of leadership at every level is crucial to making this a reality.
9. The key challenge for leadership is therefore to create the space and climate for school staff to reflect on and share aspects of their practice. This includes encouraging and stimulating dialog and risk taking. In this way, innovations in assessment for learning can be tested, embedded, and sustained. Without it, they remain surface changes that decay and disappear when the next initiative comes along. (adapted from James *et al.*, 2007: 214–217).

Conclusion

This article has traversed a wide territory, starting with reference to testing practice, ending with issues of educational transformation and change, and dealing with assessment in different contexts for different purposes along the way. What it sought to do, in addition to introducing the other articles in this section, was to encourage a thoughtful consideration of the primacy of purpose and to unpack some of the choices that flow from decisions about means and ends. These not only involve choices about techniques but about implementation and use, about relationships between constituent parts of a system, and about the training and support that will enable the goals of educational assessment to be achieved. These are complex, multidimensional issues that require a wide range of skills, knowledge, and understanding: technical, professional, ethical, and political. It may be too much to expect that any one educator will possess all of these but, in that educators work in professional communities, we might hope that collective professional knowledge and expertise will expand in the future in order to promote the educational goals of assessment.

Introduction

In the last two decades, there has been an increasingly worldwide trend to reform national assessment and examination systems with the primary aim of enhancing educational quality. The rationale underlying these reforms is often based on the premise that increasing monitoring, evaluation, and accountability systems will be a positive lever for improvements in student and school performance. For example, Hamilton *et al.* (2002) have reported the development and use of standardized tests for school accountability purposes in USA, particularly in response to the No Child Left Behind (NCLB) legislation. Similarly Kellaghan and Greaney (2004) and Yu and Thomas (2008) in the African context and Peng *et al.* (2006) in the Chinese context have examined developments in assessing student learning and how national examinations are used for institutional accountability. Moreover, the most recent edition of OECD (OECD, Organization for Economic Cooperation and Development) *Education at a Glance* (2007) provides up-to-date evidence of the number of countries that now have national examination systems and which countries provide feedback data to policy-makers, teachers, and parents. In 2005, just over half of the OECD countries (16) had national high-stakes examinations that are completed by lower secondary school students; of these almost all (14) require schools to conduct regular self-evaluation and three-quarters (12) make information on school evaluation available to the local

school community or general public for one or more, sometimes overlapping, purposes including parental school choice, accountability, funding decisions, and school improvement. At the international level, the demand for comparative and monitoring information to inform policy development and evaluation has also led to the increased use of international surveys of educational achievement, such as Programme for International Student Assessment (PISA) introduced for the first time in 2000 (Scheerens, 2004; Goldstein and Thomas, 2008).

Given this apparent global shift toward a stronger emphasis on student testing and assessment, it is more important than ever to highlight and continue to evaluate the impact of these policy developments on educational quality and standards. For example, previous research has explored some of the negative consequences of high-stakes assessment at the level of individual students (Harlen and Deakin Crick, 2002) and similarly at the school level, in relation to accountability, evaluation, and publication of examination results (Volante, 2007; Van Petegem *et al.*, 2005). Further analysis and critique of assessment policy at the student level is vital but nevertheless beyond the scope of this article. However, with regard to either positive or negative consequences for school quality, it is of course particularly crucial to examine in detail how the data are actually used to measure and evaluate institutional effectiveness. Therefore, this article explores the different ways that national assessments are used to measure institutional effectiveness as well as the validity of different methods for different purposes. The article focuses on policy developments and research that has been conducted at the level of statutory schooling and examples will be provided from a large-scale study conducted in England (see Thomas *et al.*, 2007; there has also been equivalent research at other educational phases, for pre-primary see Sammons *et al.*, 2004, and for higher education see MacLeod, 2007.)

The Problem with Raw League Tables

The issue of appropriate and valid ways of reporting institutional performance is of vital importance whatever the purpose, be it public accountability, funding, parental choice, or school improvement. In each case, it is important that the information is fit for purpose, accurate, and the context and limitations of any measures are emphasized, particularly when the data may potentially contribute to

life-changing conclusions or decisions for students or teachers or both. Unfortunately, in terms of both policy and practice, this is not always what happens. For example, in many countries student assessment data are commonly used to evaluate institutional performance through publication of schools' raw examination scores taking no account of the context of the school or the characteristics of the student intake (OECD, 2007). However, schools with high-achieving intakes will tend to do well for that reason alone. Neither the initially high-achieving nor the initially low-achieving school is assisted by accountability in the form of raw league tables. In the former, the need for improvement may not be understood; in the latter, serious demoralization of staff may occur through no fault of their own. It has been strongly argued by many educational practitioners as well as by academic researchers that, taken on its own, information about schools' raw examination results will always be a very inadequate measure of performance and, without any knowledge of the context of that school, can be misleading. For example, Nuttall (1990) argued that "... natural justice demands that schools are held accountable only for those things that they can influence (for good or ill) and not for the pre-existing differences between their intakes" (p. 25).

However, in contrast to raw examination results, what are commonly called value-added measures provide the starting point for a way of evaluating school performance that takes account of intake factors outside the control of the school but which have a considerable impact on pupil attainment.

The Value-Added Approach

The value-added approach stems from the assumption that schools add value to the achievement of their students. It is based on the idea of measuring student progress, usually in cognitive outcomes, such as reading or mathematics attainment, during a given period of time. However, the concept may also be applied to other quantifiable student outcomes, such as measures of vocational competence or citizenship. In order to measure progress baseline and outcome, measures are required at the beginning and end of a particular time period (e.g., covering all or part of the primary or secondary phases of education). Of course, as students grow older, progress or improvement would be expected and average attainment levels to rise. Value-added measures thus seek to establish whether students in some schools make relatively greater or lesser progress than those in other schools over a specified period of time. The most effective schools would be those in which student progress exceeds expectations. For the purpose of internal school self-evaluation, value-added measures provide teachers with more meaningful, valid, and accurate evidence of the relative progress of

their own students, in comparison to raw results, and this information can be used to reflect on their professional practice. Similarly, in the high-stakes context of external school evaluation and accountability, value-added measures provide a more valid source of comparative information about a school's effectiveness, in comparison to raw results. Nevertheless, it is important to remember that the value of schools' educational quality is broader than what can be measured by attainment or progress in a few specific areas of student activity. A comprehensive value-added evaluation framework might also encompass measures related to numerous other aspects of a school's mission, processes, and outcomes.

The Assessment of Institutional Effectiveness

In the last 20 years or so, the significant growth of large national and international educational assessment data sets and associated research findings on school effectiveness as well as significant advances in methodological techniques have stimulated international debate and government thinking on educational policy and practice. As a consequence, national (and regional) policymakers in various European countries and worldwide have focused their attention on the possibilities for improving educational practice and, indirectly, educational standards, competitiveness, and performance, by encouraging more systematic and sophisticated approaches to student assessment and institutional evaluation and self-evaluation (Reynolds, 2007). For example, the UK governments have emphasized the need for schools and teachers to use evidence and data to inform their own internal evaluations of the education they provide. This approach involves an ongoing and systematic self-evaluation of a school's educational practice and improvement processes using information drawn from a variety of sources including, for example, the detailed pupil assessment and tracking information provided confidentially through RAISEonline website by the Department of Children, Schools and Families (DCSF). At the national level in England, the system of external school inspections introduced in 1992 has been developed extensively and the new 2005 framework requires school self-evaluation to be the central element of the inspection process (OFSTED, 2004). Moreover, as noted above in relation to over half of OECD countries, school examination performance tables continue to be published by the DCSF as a mechanism for educational accountability. However, since 2004, the English league tables now also include value-added school performance as well as raw examination performance for schools.

The use of value-added measures provides an important innovation in the assessment of institutional effectiveness – in terms of both external evaluation and

internal self-evaluation. Nevertheless, the methodology of measuring value added is not perfect and of course the typical limitations of measurement still apply and need to be understood by practitioners and policymakers, an issue that will be returned to subsequently.

Data Collection Issues

Calculating the effect a school, or any educational institution, has on student progress is complex. In part, this is because the educational experiences of any individual student and the wide variety of factors influencing her or his progress can be viewed as unique and almost impossible to quantify. However, the more information it is possible to have about all individual students, as well as comparative data across a whole population (or representative sample) of schools, the more valid, reliable, and informative any subsequent analysis is likely to be. The key data required to measure a student's academic progress are baseline and outcome attainment over a specific period of time. Other background and contextual information about individual students and schools is also needed to provide statistical controls for those factors – outside the control of the school – that have a significant impact on a student's attainment, relative progress, or both (Thomas, 2001).

The different types of quantitative data required to create school performance measures are described below.

Student Outcomes

Ideally, student outcomes need to be measured using valid and reliable assessment instruments relevant to the academic curriculum taught in schools or other aspects of the curriculum (such as vocational training and qualifications). This is because it is important to measure only those aspects of a student's education that the school has a clear aim and statutory role to provide and develop. It is also necessary that the assessment methodology employed to measure student outcomes is unbiased and sufficiently reliable to ensure that students at the same level of attainment will be assessed – as far as possible – at the same level irrespective of where the assessment takes place. For example, it may be argued that teacher-assessed outcomes (such as portfolio assessment) are open to unequal standards being applied across schools and are therefore less appropriate for value-added techniques than standardized and externally marked tests such as those from national examination systems and standardized attainment tests.

Student Baselines

In order to measure a student's relative progress overall, or in any particular curriculum area, it is necessary to

obtain information about their previous – or baseline – attainments, either at entry to a phase of education or some alternative and predefined starting point. Ideally, as a minimum, data are required concerning students' baseline attainment in the core curriculum subjects of language or numeracy or both, and if possible other relevant aspects of the curriculum. Again, as noted in relation to outcome assessments, it is necessary that the baseline assessments are valid, reliable, and fit for purpose. Moreover, baseline and outcome measures need to be collected and recorded in such a way that individual student records can be matched accurately over time. The use of unique student, class, and school identification codes are vital in order to facilitate this matching process. Once a longitudinal data set of individual student attainment records has been created, it is then possible to proceed with a statistical analysis to examine both absolute attainment at one point in time and – most importantly – the relative progress of students in a particular school over two or more time points in comparison to students in the wider population (or a representative sample) of schools.

Background and Contextual Information

Information about student baseline and outcome attainment is absolutely essential to provide an accurate and direct measure of students' relative progress in attainment over time and this approach is the only method of calculating valid value-added measures of school effectiveness. However, the collection of other student and school data is also needed in order to examine the impact of various background and contextual factors that are outside the control of the school and also appear to influence the rate of student progress. Previous research has shown that student background characteristics such as socioeconomic status, gender, ethnicity, first language, and mobility are often statistically significantly related to student attainment and progress and therefore are able to provide a means of fine-tuning value-added measures of school effectiveness. Similarly, some previous studies have shown that school context data, such as the percentage of disadvantaged students in a school, have a statistically significant impact on student progress (Thomas, 2001). In reviewing the evidence of institutional effectiveness, it is therefore important to consider whether a straightforward progress measure or, alternatively, a more sensitive value-added measure that also controls for other factors that are outside the control of the school is used (e.g., in England this latter approach is referred to by DCSF as contextualized value-added measures).

Of course, in the absence of progress data, the impact of socioeconomic and other background factors on student attainment is considerable at any one point in time (e.g., at either baseline or outcome or both). This finding is well documented and not surprising given the cumulative

effects of such factors on children's educational experiences since birth. Therefore, student and school background data may also be usefully employed to provide contextualized attainment measures at any one time point as an additional, or an alternative (but conceptually different and arguably less accurate and valid), approach to measuring school performance.

Educational and School Process Information

Educational and school process information is not usually employed in the calculation of value-added measures of school performance. This is because in contrast to the background and contextual data described above, measures of educational and school processes aim to quantify aspects of school life that are defined to be within the control of the school. Measures of this kind include, for example, teacher attitudes, leadership, experience and supply, class size, organization and grouping strategies, school ethos, and organization. However, the rationale of collecting additional information about educational and school processes is to enable school and classroom process variables to be contrasted and evaluated against measures of students' relative progress (see Sammons *et al.*, (1997) for examples and Willms and Raudenbush (1989), for a discussion of this issue). In this case, the aim is to provide evidence to explore and illuminate the reasons underlying any differences in school effectiveness.

Of course, whatever type of quantitative data is collected, it is crucial that quality-assurance procedures and accuracy checks are put in place as an important part of the data-collection exercise. Data errors or missing data, or both, will mean that the results of any analysis will be difficult, if not impossible, to interpret. In order to implement a value-added system of school evaluation and/or self-evaluation, it is important that schools are willing to collaborate with other schools at the local, regional, and national level in order to provide comparative data in an identical format. This approach usually involves the creation of national or regional examination databases and the central organization of collecting, analyzing, and presenting feedback results to schools in a common format for the purpose of supporting and stimulating school evaluation and improvement activities. As an exemplar, at the regional level in England, Lancashire local education authority value-added project illustrates how the ongoing collection of examination and other data from over 130 secondary schools has been organized successfully over a 14-year period (Thomas *et al.*, 2007). Moreover, the English government now provides data to all schools nationally through extensive online access to a wide variety of student and school assessment and evaluation data via the RAISEonline website.

How is Institutional Effectiveness Measured?

Taking into Account of Different Types of Data

Table 1 provides a summary of the data requirements for different value-added and raw school performance measures. The requirements shown relate in each case to a single cohort of students and must include data from a representative sample of schools, if not all schools, in the region or system. Of course, in order to examine trends over time or improvement in value-added performance, it is necessary to collect equivalent outcome and baseline data for at least three consecutive student cohorts (for an example of a value-added analysis across ten cohorts, see Thomas *et al.*, 2007). Similarly, data for consecutive student cohorts would also be necessary to examine trends in contextualized or raw performance measures.

Using Different Methods of Statistical Analysis

A key challenge for researchers has been to develop approaches that allow the statistical analysis to separate out the effect of the school experience on individual student outcomes (what students achieve) and the extent to which student intake characteristics (those things the students arrive at school with) affects student outcomes. A variety of statistical techniques can be employed for this purpose that vary in the sensitivity and sophistication of analysis. There are three main approaches: summary statistics, multiple regression, and multilevel modeling.

The first approach, summary statistics, including measures such as the mean and standard deviation, can be used to calculate aggregate school-level measures from student-level data. These measures provide a crude picture of

Table 1 Data requirements for value added and raw school performance measures

	<i>Variables required/controlled for in analysis</i>
<i>Value-added measures</i>	
Progress only value-added measure	Outcome and baseline assessment measures at two (or more) time points
Contextualized value-added measure	Outcome and baseline assessment measures at two (or more) time points, student and school background and context measures
<i>Raw performance measures</i>	
Contextualized raw attainment measure	Outcome assessment measures at any one time point, student and school background and context measures
Raw attainment measure	Assessment measures at any one time point

school performance through estimates of raw levels of student attainment for each school in a sample (i.e., unadjusted for any other factors) and may be used, for example, to produce simple league tables of average school performance at one point in time. As mentioned previously raw measures are generally considered invalid for the purpose of evaluating institutional effectiveness, given student progress in attainment cannot be estimated. A further disadvantage of this method is that the school is the unit of analysis and therefore detailed information about individual students is lost in the analysis.

The second approach, multiple regression analysis, is the standard statistical technique for calculating the residual difference between a student's observed and expected assessment score. The observed score is a student's actual level of attainment at the end of an educational phase (such as primary or secondary) and the expected score is the level that would be predicted on the basis of his or her previous – baseline – attainment. Consequently, the residual score is interpreted in terms of whether a student is performing above or below expectation on the basis of the overall statistical relationship between baseline and outcome attainment of all students in all schools in the sample. In essence, the residual score – which ranges from a positive to negative value – provides the key statistical measure of student's relative progress, that is, the value added. One advantage of this approach is that several factors, such as baseline attainment and other student characteristics like gender and socioeconomic status, can be employed in the analysis to provide a more sensitive estimate of value added than would result from employing a single baseline predictor. However, the disadvantage of this approach is that the unit of analysis has to be either at the level of the student (i.e., student residual scores are calculated) or the

school (i.e., school residual scores are calculated). In the former case, important information about the clustering of students within a particular school is lost, and in the latter case, detailed information about individual students is lost. **Figure 1** demonstrates this issue using a simple example of aggregated school level data from over 80 English secondary schools to illustrate how value added is estimated. Note that some research has explored alternative regression approaches, such regression-discontinuity analysis that compares the raw outcomes of consecutive school cohorts to estimate institutional effects. However, these methods are limited by a lack of longitudinal data and individual student records matched over time. Each point represents one school and the regression line represents the expected 2001 General Certificate of Secondary Education (GCSE) mean score, on the basis of the mean Cognitive Abilities Test (CAT) score of the same students in 1997. Schools with points above the regression line will have a positive value-added score (i.e., residual), suggesting that performance is above expectation. Schools below the regression line will have a negative value-added score, suggesting performance below expectation. Of course, information is also needed about the level of confidence that is associated with any value-added score (e.g., 95% confidence interval) to indicate whether an individual school's performance is likely to have occurred by chance or, alternatively, is statistically significantly different from what would be expected.

The third approach, multilevel modeling, is a relatively recent generalization of multiple regression that involves the same principle of calculating a residual value-added score. However, this technique takes account of the clustering of students within schools and allows the unit of analysis to include both the student and the school

Figure 1 Estimating value added using aggregated data – schools total GCSE (2001) and mean CAT (1997) performance.

level. Other clustering factors, such as teacher, class, or region, can also be included in the analysis as appropriate. Thus, multilevel modeling is a far more sophisticated approach than both summary statistics and standard multiple regression when the aim is to disentangle the complexity of schools' effectiveness. It is now widely recognized as the most flexible tool for examining the hierarchical nature of student attainment data. This approach can be used to calculate unbiased and accurate estimates of school residuals for all students (or particular groups of students such as boys or girls) as well as, crucially, the statistical significance of an individual school's results. If data are available for consecutive student cohorts, this technique can also be employed to model trends in value-added results over time. New developments in the methodology of calculating value-added measures are ongoing and, for example, have examined the continuity of previous school effects on later attainment and the need explicitly to take into account pupil mobility (Goldstein, 1997).

Validity of Institutional Effectiveness Measures

Previous research has indicated that in order to provide a realistic picture of a school's performance a range of different assessment outcomes and value-added measures is required. This approach is necessary to reveal the internal variations in school effectiveness across one or more dimensions – such as in different aspects of the curriculum, for different student groups, and different time periods or cohorts (Thomas, 2001; Scheerens *et al.*, 2003).

Research has shown that schools doing well with students in one aspect of the curriculum are not necessarily effective in all aspects. This evidence strongly suggests the

need to examine school effectiveness measures across a range of academic outcomes in order to reveal the pattern of departmental or subject-area performance. Clearly, using a single-measure effectiveness may conceal important within-school differences not only across academic aspects of the curriculum but also across other aspects such as vocational or attitudinal outcomes. Researchers have also examined the issue of differential school and departmental effects for different groups of students (such as high and low attainers, boys and girls, or different ethnic groups) and found that not all schools are equally effective for all student groups. Thus, it has been established that using an overall measure of school (or departmental) performance may be misleading or even invalid by masking important differences in the relative progress made by different student groups, particularly those categorized by prior attainment (Thomas, 2001). The issue of teacher, or classroom, effects also impacts on the validity of institutional effectiveness measures. Previous research in UK and USA has identified significant variations in student progress attributable to differences between teachers (e.g., McCaffrey *et al.*, 2004). Therefore again, overall performance measures may conceal important within-school differences in teacher effectiveness that needs to be considered when judging institutional effectiveness.

Recent evidence in England also shows that generally for most schools the linear trend in value-added performance is fairly stable over time, although this conceals both considerable year-to-year variation in performance and an underlying time trend across all schools of increasing raw GCSE performance at KS4 (Thomas *et al.*, 2007). For an example of nonlinear value-added time trends over 14 cohorts from the Lancashire project see **Figure 2**. Moreover, for some schools, results can vary substantially

Figure 2 Schools value-added performance – nonlinear time trends over 14 consecutive student cohorts.

from the average linear trend, indicating either improvement or decline in performance. In this context, it is important to emphasize that real improvement (or decline) in performance, resulting perhaps from a shift in school policy or practice, can only be identified by examining long-term changes in results over time (over three cohorts as a minimum). Therefore, validity of institutional effectiveness measures will be enhanced by examining in detail equivalent outcome measures for consecutive student cohorts, alongside the educational processes associated with different patterns of improvement. The statistical power of the analysis is also improved by the increased sample size when successive student cohorts are modeled simultaneously.

Also relevant to validity of measuring institutional effectiveness is the issue of regional or national differences in the size, extent, and consistency of school effects or the differential impact of pupil and school background characteristics in different regional, socioeconomic, and educational policy contexts – issues that have been addressed by relatively few studies. Although further analysis is required using national databases, Thomas (2001) reports tentative findings which suggest that the difference or similarity in schools' departmental results can and do vary across UK regions, indicating that local context measures and, possibly, region-specific outcomes also need to be considered in order to reflect the possible influence of local area, regional, and national policy and practice on institutional effects.

Thus, the validity of institutional effectiveness measures is dependent on and limited by a number of factors including:

1. Data

- Data employed – are longitudinal data employed including prior attainment data and what statistical adjustments are made for factors outside the control of the school?
- Data accuracy and measurement error – have data and measurement errors been minimized?
- Representative sample – does the sample of schools and students reflect the maximum range and/or variability in performance?

2. Method of analysis

- Statistical method – are descriptive statistics, multiple regression, or more complex data modeling (e.g., multilevel modeling) used?
- Unit of analysis – are the significance of variations in performance at the level of students, classes/teachers, and regions considered, as well as at the institution level?
- Time period – what time period is examined, and are data from multiple/consecutive student cohorts used to examine changes in school effects and improve the power of analysis?

- Statistical uncertainty – are statistical confidence intervals presented alongside all performance measures? Note that this uncertainty prevents any fine distinctions to be made between the performance of most schools.

3. Performance outcomes

- Student groups – are separate measures used for different student groups?
- Subject areas – are separate measures used for different academic areas of curriculum?
- Other outcomes – are separate measures used for other areas of curriculum such as vocational, health, and citizenship education?
- Regional outcomes – are separate measures used for different regions that vary in school policy, practice, or context?

Clearly, the validity of institutional effectiveness measures is influenced to a large extent, by the quality, reliability, and validity of the data analyzed. The methodology is also not perfect in the sense that it is retrospective and, as for any data modeling, today's results cannot necessarily predict future performance. Moreover, it is impossible to measure all relevant factors outside the control of the school. For example, the indicator of student disadvantage eligible for free schools meals (FSM) may be inaccurate because some parents do not apply for an eligibility means test. Furthermore, the system does not completely cover all students likely to suffer from social and economic disadvantage. Other relevant measures of socioeconomic status, such as private tuition and level of parental education, occupation, and income are difficult and costly to collect and, therefore, are often not examined by researchers in sufficient detail. Therefore, it is important to remember that value-added estimates reflect the school effect as well as any other relevant factors not accounted for in the analysis. All the above caveats and limitations point to the critical need to consider the statistical significance of individual school results as well as other relevant data or evidence that may be available in a school in order to avoid making unjustified claims or misinterpreting the results. Value-added approaches can provide a powerful and sophisticated tool for institutional evaluation and self-evaluation; however, crucially, validity issues and limitations need to be well understood by teachers, policymakers, and researchers.

Using Value-Added Measures to Evaluate Institutional Effectiveness

Given the validity issues outlined above, a cautious approach should be employed whereby performance data are seen as a means of raising questions about any particular school results, and a way of identifying where further

evidence is required, rather than a definitive measure of institutional effectiveness. Wherever possible, a broad range of measures are required to reflect more fully the aims of schooling and contrast the results against other types of evaluation data available about schools, such as information about the views of key groups obtained using, for example, student, teacher and parent questionnaires. As a summary, and with these caveats in mind, some of the key uses of value-added measures are listed below:

1. Research

- examine overall trends in pupil and school performance over time;
- examine local, regional, or national differences in value-added results between schools and the implications for local, regional, or national education policy;
- examine case studies of more/less effective schools; and
- examine the school processes and factors related to improvement or decline in school effects.

2. School self-evaluation

- Provide teachers with information that will allow them to reflect on, evaluate and improve their educational practice. For example, examine;
 - (1) departmental, subject, and/or teacher effectiveness versus summary measures of school effectiveness and the implications for whole school policies;
 - (2) differential effectiveness for different groups of students (e.g., boys/girls, high/low attainers, and different ethnic groups) and implications for equal opportunities; and
 - (3) effectiveness for different year groups or age cohorts, such as students at different curriculum stages, and implications for differing rates of progress/curriculum coverage.

3. External evaluation

- Provide school inspectors with information about relative school performance that can be used alongside their own judgments and other evidence of quality and standards.
- Track changes in results over time to examine real improvements, or random fluctuations in performance, or both, in relation to school improvement initiatives.
- Examine the way teachers use data to reflect on past performance and to inform, evaluate, and improve their current policy and practice. Note that this approach is now a key aspect of some national inspection systems, for example, in England.

4. Accountability

- Publication of schools' value-added results. However, note that league tables or ranks will always be problematic due to the need to consider statistical significance of each school's results.
- Inform parental choice of schools.

5. Funding or rewards

- Inform funding review or as one type of evidence in allocating school awards/rewards.

Conclusions

In summary, the general consensus of research evidence from several countries is that raw statistics of student performance alone cannot give an accurate picture of how effective a school is at raising and maintaining the achievement of all its students, or how capable it is of sustaining its standards over time. Moreover, some schools that may appear to be effective overall in terms of value-added performance may not be so effective in terms of individual departments, different groups of students, different year groups, or over different periods of time. Research findings indicate that internal variations in effectiveness need to be monitored at all stages of statutory education. Value-added approaches also provide a powerful methodology for understanding the mechanisms and levers of school improvement – for example, by comparing value-added and school process data at any particular stage or phase of schooling. The analysis and feedback of value-added data are often viewed as an integral part of the development and improvement work carried out with schools by external consultants, school inspectors, and academic researchers. Examining the way teachers and other practitioners use data to reflect on past performance and to inform and evaluate their current policy and practice is a crucial aspect in understanding how schools improve.

The complex issues related to evaluating institutional effectiveness are likely to be particularly relevant in countries that are not currently employing value-added methods, and where the focus is still on raw examination data to judge school performance. In these cases, the availability and analysis of longitudinal individual student-level data are essential to allow schools and teachers to examine different aspects of their school's effectiveness in detail. Research has demonstrated overwhelmingly that value-added approaches provide a powerful innovation to compliment and develop methods of assessing students and schools. As a final point, it is also relevant to note that comparisons of educational quality between countries are often based on international surveys of student attainments that are typically cross-sectional and do not employ value-added approaches (Goldstein and Thomas, 2008). This situation similarly highlights the urgent need for longitudinal data sets to improve the validity of internationally comparative measures of institutional and educational effectiveness.

Assessment in Schools – Dispositions

R D Crick, University of Bristol, Bristol, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Autogenic – Originating in the self.

Disposition – A tendency to behave in a certain way.

Habitus – A system of cognitive and somatic dispositions developed in a sociohistorical context over time.

Hermeneutic – A particular interpretation of phenomena.

Hexis – A habit resulting from behaviour repeated over time.

Telos – An overarching goal, or desired end point.

Virtue – An acquired human quality the possession of which leads to a desired good.

Introduction

The notion of dispositions as educational outcomes has emerged as an important but contested area in educational theory and practice in the last 10 years. In the changing world of the twenty-first century, it is widely recognized that the acquisition of knowledge, skills, and understanding is not enough. On the one hand, proliferation and accessibility of information render simple accumulation impractical, even if there were agreement as to what was important; on the other hand, a sustainable social world requires a range of competences on the part of individuals and communities which enable successful functioning in real situations: such competences include values, attitudes, and dispositions as well as cognitive resources. This article deals first with contemporary psychological definitions of the term dispositions and second with how dispositions are located and operate in social contexts, drawing on the work of Bourdieu in particular. It then identifies two widely accepted candidates for dispositions as educational outcomes and goes on to explore the professional and theoretical issues encountered in their assessment in classrooms. Finally, it summarizes a range of assessment practices drawn from the literature.

Conceptual Issues

Although the term disposition as an educational outcome is imprecise, both theoretically and in practice, it is widely

agreed that it refers to a relatively enduring tendency to behave in a certain way. It is a construct linked to motivation, affect, and valuing as well as to cognitive resources. It is acquired and manifested in a sociohistorical setting. Dispositions may be culture specific as well as a relatively enduring feature of personality. A disposition may be recognizable in the action a person takes in a particular situation – for example, someone who is disposed to be curious will demonstrate it in generating questions and investigating problems. In practice, in education, the term is often used interchangeably with competence, or style, or capability and it is frequently subsumed within the concept of personal development as distinct from academic development or attainment. There are many dispositions relevant to education – ranging from the specific to the very general. In this article, the focus is on two broad types of disposition widely perceived as of educational value: dispositions for learning and for active citizenship.

One of the earliest uses of the term as an educational outcome was Katz who defined dispositions as relatively enduring habits of mind or characteristic ways of responding to experience across types of situations. She went on, in a later review of literature, to define a disposition as a frequently exhibited pattern of behavior which is voluntary, intentional, and related to a particular goal.

A disposition addresses the gap between the ability to do something and actually doing it, between what people can do and what they actually do in real-life contexts. Dewey also recognized this gap and linked it to desire, suggesting that knowledge of methods alone is not sufficient: there must be the desire and the will to use them. This desire, he argued, is an affair of personal disposition.

The concept of motivation, or desire, is importantly related to dispositions, but it is a notoriously complex area in which there is little consensus. There are drive theories – in which motivation arises from basic drives, instincts, or emotions in predictable ways; qualitative conceptions of motivation, such as achievement motivation – attribution theory and motivational style theory. Ames describes motivation as the systematic, qualitative response that people make to the various challenges and threats arising from situations in which either success or failure is possible.

A disposition arises from desire, or motivation, which provides the energy necessary for action. Ritchhart and Perkins proposed a theory of dispositions that incorporates this motivational and agentic role and includes attention

to sensitivity, inclination, and abilities. Sensitivity is an awareness of occasions to engage in certain behavior, inclination is the motivation to do so, and ability is the capacity to do it.

Thus, they argue that in order to nurture a disposition in the classroom, first an opportunity to engage in certain behavior needs to be recognized or noticed (intuitively or consciously), then the person needs to be inclined to engage in that behavior, and then be able to carry it out.

Carr and Claxton describe these elements of dispositions as being ready, willing, and able to engage profitably with a particular goal, whereas Dweck uses the term orientations and Costa uses the term habits of mind. There is merit in understanding disposition as a verb, with qualifying adverbs, instead of a noun, a thing to be acquired; Carr and Claxton argue that a disposition is not acquired, rather one becomes more or less disposed to respond in such-and-such a way.

The Sociohistorical Location of Dispositions

The term disposition has a long heritage in ancient and medieval philosophy. For Aristotle, people had the capacity to act in certain ways by virtue of possessing a disposition to do so. He argued that people become strong or brave by doing strong or brave things and that by consistently choosing such actions, they become better able to act with strength or courage. One who has performed a brave act must have acquired the disposition to act in that way. Aristotle described a disposition as a habit (*hexis*), which is produced by similar acts and inclines to similar acts. He was primarily concerned with the development of character and its relationship to moral behavior, although he applied the same ideas to bodies of knowledge – for example, one who has trained as a scientist is disposed to act in a scientific way.

Building on this tradition, Bourdieu's concept of *habitus* offers a sociological understanding of dispositions. He was concerned with mechanisms of social domination and reproduction and his focus was on bodily know-how and competent practices in the social world. He defined the term *habitus* as a system of cognitive and somatic dispositions internalized through sociohistorical experience. Bourdieu sees dispositions as a form of embodied cultural capital, whereas objective cultural capital may include books, materials, or machines and institutional cultural capital may include certificates and examination results. Accordingly, dispositions and habits are inculcated through childhood experiences and the cultural practices and values of the classroom, which in turn are shaped by the structures and practices of the schooling system. The formation of dispositions is the site for the development of agency in the learner within a limited arena of choice.

Thus, the question of the psychological stability of particular dispositions in an individual over time and in different contexts is debatable since scholars, such as Bourdieu, argue that they are shaped by culture and history. Sociocultural theorists have convincingly argued that human learning and performance are highly situation specific, originating and developing in a context of interaction. Thus, formation of dispositions is influenced by a range of factors: psychological, cultural, historical, and social – and there is an ethical element, since a disposition leads to action in pursuit of a desired goal. In the ecology of the classroom, specifically, there are many factors which are shown to influence students' achievement and hence their dispositions; these include, but are not limited to, quality of relationships and teacher practices; the classroom climate; assessment practices and pedagogic discourse.

Related Concepts

Certain concepts, used as educational outcomes, which are related to dispositions should be discussed and differentiated. In particular, the terms competence and learning styles have been prominent in both policy and practice. A competence is a complex combination of knowledge, skills, understanding, values, attitudes, dispositions, and desire that lead to effective, embodied human action in the world, in a particular domain. Achievement at work, in personal relationships, or in civil society is not simply successful accumulation of received knowledge, but a combination of this knowledge with skills, values, attitudes, desires, and motivation and its application in a particular human setting at a particular point in a trajectory in time. Competence implies a sense of agency, action, and value.

The learning styles field is complex and confusing, with a host of conceptual and empirical problems. A learning style is an individual's preferred way of learning and some scholars have developed a classification of the field based on the degree to which the underlying assumptions about learning styles are fixed. At one end of the spectrum is the assumption that learning styles and preferences are largely fixed and constitutionally based and, at the other, is the assumption that they are changeable and better described as orientations, learning approaches, or learning strategies.

From this discussion, it is possible to develop a limited and an elaborated description of a disposition (**Figure 1**). A limited description focuses on a tendency to behave in a certain way in a particular context. At the other end of the spectrum an elaborated description is of a disposition embedded in sociocultural, historical, and ethical narrative and includes a sense of agency, intention, and capability in real-life contexts of achievement, lifelong learning, and citizenship. The latter locates dispositions

Figure 1 Elaborated description of dispositions. From Dr. Ruth Deakin Crick. Published by Elsevier Limited. All rights reserved.

and their assessment as part of a complex process of sustainable, human learning and change over time. In the elaborated description, the telos of the process is a person competent in a particular domain – for example, a competent citizen, a competent learner, a competent mathematician, designer, or ergonomist.

Potential Candidates for Education

There is no shortage of lists of desirable dispositions for educational outcomes. Carr, for example, derives a set of learning dispositions from the New Zealand national early-childhood curriculum: courage, curiosity, playfulness, perseverance, confidence, and responsibility. Deakin Crick *et al.* identified a set of seven dispositions for learning: changing and learning; critical curiosity; meaning making; creativity; learning relationships; strategic awareness; and resilience. Crick described learning outcomes for citizenship education as a composite including knowledge and understanding, skills and aptitude, and values and dispositions. Among the latter were acting responsibly, caring for others, courage to defend a point of view, and openness to changing one's mind.

One of the challenges for schools is to identify dispositions that are key to successful life in the twenty-first century. Dispositions for learning to learn and citizenship are widely accepted candidates, described as elements of key competencies which are as indispensable for the good life – reminiscent of an Aristotelian notion of virtue.

Issues in the Assessment of Dispositions

The assessment of dispositions raises several important philosophical and methodological challenges. What we assess is, or should be, a function of what we value and there can be little doubt that contemporary educational assessment should take into account the importance of dispositions, particularly learning dispositions. The global accessibility of traditional, factual knowledge means that the question of its value is a local, personal one, concerned with its relevance to a context and purpose brought to it by a learner. What I learn cannot be separated from what matters to me – it is a product of intention and desire. Therefore, knowledge has become no longer simply what I learn, but also how and why I learn. While intentional

learning begins with desire, which is autogenic and personal, the outcomes of formal learning are mostly assessable by publicly agreed criteria set by a particular community of practice and are thus formal, external, and publicly valued.

This integration of the personal with the public opens space for a fresh approach to continuous formative assessment and evaluation. How can what we value, such as learning dispositions, be identified and assessed within each stage of the journey from desire to competence, rather than simply via set pieces of performance at the end? Assessment could then be linked with and derived from the formation of learning dispositions, which begin with desire and move through self awareness, ownership, and responsibility toward the acquisition of formal knowledge, skills, and understanding. Assessing learning dispositions establishes the quality of learning power, recognized, owned, and assessed by the learner in the first instance, along a sequential movement from the autogenic to publicly agreed and formally valued funds of knowledge, skills, and competence.

Desire, as Dewey said, is an affair of personal disposition. To desire to learn, or to be courageous, leads to an inclination to learn or be brave and to make a personal choice rooted in experience, expressing a lived narrative. Narrative is a key concept in relation to the assessment of dispositions: forming dispositions for learning, or citizenship, involves the person who is learning and requires desire, a sense of direction and the hope, agency, and self-regulation to set out in that direction.

An important assessment question in relation to what is personal and intuitive is who has the authority to authenticate and assess this sense of agency and intentionality? How valid can an outsider's judgment of it be? The learner herself must be the arbiter, since desire and dispositions are embodied and unique to the person. Thus, the most valid starting point in assessing dispositions is self-assessment. What can be done from the outside is suggest criteria for it.

The critical questions for the learner at this stage are what really matters to me? Also, what do I really want to know about it? The readiness with which a learner takes up the challenge and identifies the object of a new enquiry, the energy galvanized by his/her perplexity and fascination, and the acuteness of his/her discrimination and selectivity might all ultimately be reflected in the quality and quantity of his/her learning and its outcomes. At the time, however, their power can only be assessed by

the learner himself/herself, perhaps using criteria such as strength of engagement, extent of commitment, degree of critical curiosity, quality of self-awareness, and potentiality of relationship between the self and the object of interest.

Once a desire is stimulated and activated and a learner is engaged and acting on the desire to learn, or doing something about an injustice perhaps, then they are embodying learning or citizenship dispositions – such as, say, curiosity or meaning making – and utilizing them to describe, organize, and sort material and data into their chosen representation of it. Here, the mode of assessment must still therefore be anchored in self-assessment, since only the learner can assess the extent to which his/her representation captures the engagement, strength of purpose, and personal elements that arise from desire and choice. The assessment criteria will move beyond being purely personal at this stage, however, because already the enquiry is beginning to acquire a communicative purpose. A thread between the internal, personal starting point of the learning and the inevitable, ultimate arbiter of an external judgment starts to be visible. Assessment is still grounded in the learner's self-evaluation but with some more objective criteria, such as clarity of observation, accuracy of response, harmony or appropriateness of organization, and breadth and depth of analysis. It is also appropriate, with some sensitivity at this stage, for teacher assessment and peer assessment to be introduced for formative purposes: helping the learner to see how he/she might improve the learning, particularly its capacity to achieve its communicative purpose.

Dispositions, according to Bourdieu, are embodied and historical, linked to individual history and belonging to a genetic mode of thought. They are formed by habit, and reenactment, such that they become durably incorporated into the body. It follows that narrative is an important means of understanding, articulating, and assessing dispositions because narrative enables, captures, and illuminates experiences as human beings live them in time, in space, in person, and in relationship. Narrative attends to a three-dimensional inquiry space – the temporal, the spatial, and the personal-social. Human lives are woven of stories. Individuals construct their identities through their own and others' stories. They experience daily encounters and interactions as stories. Every present moment has a storied past and a storied future possibility.

The use of narrative in the self-assessment of dispositions is therefore important and may provide a key link between the personal and the public, between the autogenic and the formal. Describing, or telling, a learning process as a story enables the construction and expression of a learning identity and the formation of a learning disposition through meaning making and identification. When this story intersects with narratives embedded in the material world, which are the focus of learning, then this is a powerful site for the formation of dispositions for citizenship.

The capacity to tell a story can be assessed and validated against yet-more objective and external criteria, concerned with the achievement of communicative purpose. These may even include technical and esthetic considerations, such as appropriateness of form and language, breadth and depth of view, continuity and consistency of style, range and coherence of narrative or plot between arousal or surprise at the new and resolution, or satisfaction in its relationship with the known. In formulating, recounting, and evaluating the story of the learning itself, the learner is enacting and embodying the disposition of reflectiveness in the context of an even stronger emphasis on learning relationships or reciprocity and, thus, engaging in self-evaluation.

In tracking the formation of dispositions, as the learner moves toward the public end of the journey, the issues in the assessment of dispositions come closer to what has been traditional in the assessment of knowledge, skills, and understanding: recognition and interpretation of public or imposed problems, questions, and issues; selection and use of information/evidence to address them; relevance and breadth of reference; and reasoning/logic to justify opinions/solutions. The knowledge, skills, and understanding outcomes of the learning process can be assessed summatively against externally validated criteria and assessments can be demonstrated to be more or less reliable in the traditional sense.

However, since dispositions are enacted in the process of learning – whether that is learning to become an active citizen or learning how to become a better mathematician – any summative assessment of dispositions at the end of the process can only engage with what the learner asserts or the teacher observes to have been achieved, either directly or deductively on the basis of the evidence presented in the product of learning. Such evidence may be identified in learners' narrative accounts of the real-life issues they have explored in the formulation of their learning outcome, or in metacognitive reflection on the process of learning. Polanyi argued that criteria for validating knowledge can be subjective while offering a valid basis for objective judgment – suggesting criteria such as beauty, simplicity, and coherence. The point is that assessment criteria for summative purposes, at the end of a process, need not only be technical and subject specific, but also be ethical and esthetic, taking account of ephemeral evidence of the process as well as of tangible evidence in its more durable products.

Validity and Reliability – or Authenticity and Trustworthiness?

At the heart of the debate about the assessment of dispositions is the question of reliability. Traditionally, reliability is operationalized by examining consistency, defined

quantitatively, across independent observations, which are intended as interchangeable. Thus, measurements can be standardized and generalized across populations. Reliability is a necessary condition for validity.

However, while we should not abandon reliability in assessment, we should consider it as just one means of serving important epistemological and ethical purposes. The purpose of assessment should be to improve learning and teaching and, in addition to the post-positivist notion of reliability, there is a need for a more hermeneutic, or interpretive approach which honors the purposes and lived experiences of students and the collaborative judgments and discernment of teachers.

Since dispositions are embodied in people, and people are idiosyncratic, the choice of the traditional reliability criterion, couched within a psychometric, post-positivist paradigm, is inappropriate for their assessment. Even if it were possible to achieve a consistent, quantitative measure across observations of students' dispositions for, say truth seeking, or reflectiveness, what educative purpose would that serve? People are not the same, nor should they be. The purpose of the assessment of dispositions is to enable and strengthen the individual learner – as a learner, or an active citizen, mathematician, or an artisan, and to provide teachers and mentors with diagnostic information so that they can target their pedagogical practices more precisely.

In the assessment of dispositions, authenticity and trustworthiness, rather than reliability, are the necessary conditions for validity. Does this particular assessment represent an authentic picture of the individual at a particular point in time and in a particular domain? Is it true to the experience of formation, as well as to the enactment or product, of his/her disposition? While there may be public agreement that curiosity or courage is manifest in certain behaviors, such as asking questions or standing up for one's beliefs, their manifestation *in situ* cannot be generalized, nor can they be quantitatively compared between individuals or across cultures, because of the presence of so many confounding variables, both internal and external to the learners. At most, a range of possible criteria for curiosity might be drawn upon in making judgments in relation to an individual and a context. Then, ultimately, the face validity of the assessment, for the individual and the authoritative community around him/her, must be the final arbiter.

One exception to generalization of assessment data in relation to dispositions is in self-report questionnaires such as the Effective Lifelong Learning Inventory, in which students respond to questions designed to elicit information about their levels of strategic awareness, or creativity. Here, the assessment data are fed back to individuals in graphic form, but the raw data can be captured across whole populations and can be subject to statistical analysis. The European Union (EU) Commission is currently exploring

the possibility of assessing learning to learn dispositions through self-report as a means of evaluating the development of learning-to-learn competencies across the EU. Here, however, what is being measured, and thus possibly generalized across a population, is what individuals say about themselves in relation to the characteristics of a disposition, rather than an objective measure of the actual performance of a particular disposition. The former is what matters, and the latter is not possible or desirable.

Dispositions as Learning Outcomes

So far the discussion has been about the formation of dispositions in the process of learning how to learn or how to be an active citizen, rather than as an outcome. There is a growing body of evidence that attending to the process of learning to learn, particularly through the development of metacognitive strategies and habits, self-regulation, self-efficacy, and motivation, has a positive impact on learning outcomes and overall achievement.

However, the accumulation and practice of dispositions over time, such that they become relatively permanent features of a person's character or identity, may be an educational goal or outcome as much as the accumulation of standards of excellence in a particular discipline or skill. As an outcome this is akin to MacIntyre's notion of a virtue defined as an acquired human quality, which enables the individual to achieve those goods which are internal to particular practices. Learning to learn and active citizenship are types of human social practice that have their own internal goods, standards of excellence, and, in themselves, lead to a certain kind of good life – that of the lifelong learner or active citizen.

Modes of Assessment of Dispositions

The mode of assessment for dispositions can be divided into three types:

- self-assessment by the learner;
- analysis of self-report questionnaires or interviews; and
- observation of behavior and outcomes by teachers, mentors, or peers.

The information derived from these assessments can be used formatively – in order to stimulate awareness, ownership, and responsibility in becoming a better learner or active citizen, or summatively – in order to summarize learners' achievements at a particular point in time. Classroom assessments for dispositions need to be valid and authentic: Do they measure what they claim to measure and include the learner as well as the teacher in their validation? They need to be flexible and pedagogically

useful: Can learners and their teachers adapt them to particular contexts, domains, and individuals? They also need to be relational – since there is an implicit movement within the assessment of dispositions between the self of the learner and the formal text of what is being learned, requiring trust in pedagogical relationship(s), which affirm and challenge the learner to take responsibility for his/her own journey.

A holistic approach to reflecting learners' achievements, which recognizes the complexity of development of skills and competencies, might use criteria of depth and quality of contribution in an identified context and range of application in a diversity of contexts. Similar criteria include robustness and sophistication in the use of dispositions.

Assessment Practices for the Formation of Dispositions

Figure 2 builds on an elaborated description of dispositions to locate their assessment in the formation of competence(s) over time. It shows how assessment practices and relationships are complex and dynamic and it is impossible to separate questions of assessment of personal capabilities from curriculum, pedagogy, and culture. Assessment should be integrated into the process of learning; it should be sensitive to context, and promote self-worth; be meaningful and owned by learners; act as a bridge between learners and the community; and be flexible, evolutionary, and responsive to diversity. Their proposal for assessment in this domain is a relational one: that

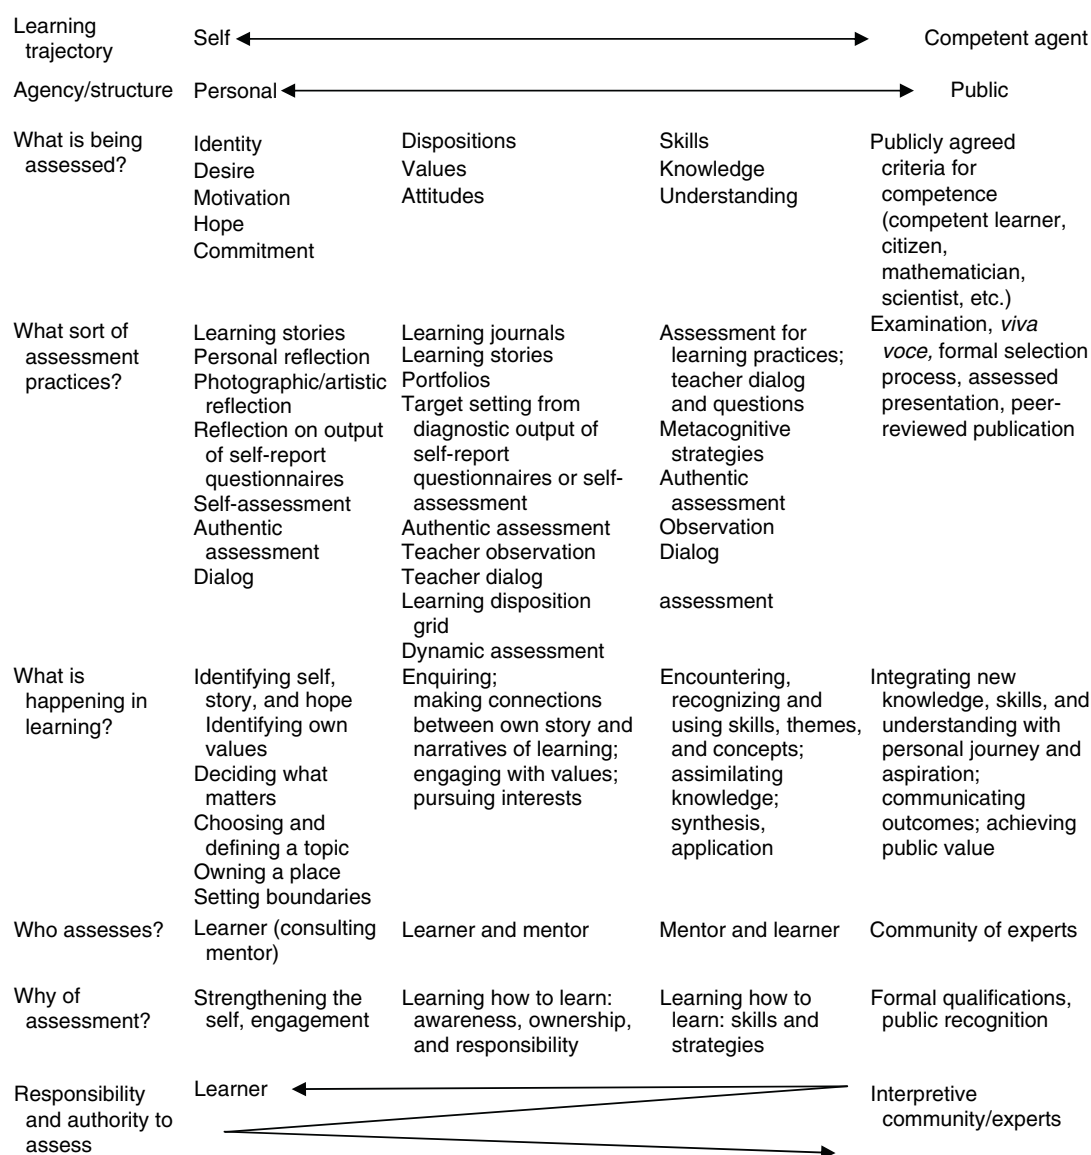

Figure 2 Assessment practices and purposes for dispositions in the trajectory from self to competent agent. From Dr. Ruth Deakin Crick. Published by Elsevier Limited. All rights reserved.

is, it is based on key questions to be explored through dialog between learners and their teachers, together with forms of modeling through examples of work and role models. The dialog and modeling is based on agreed characteristics of the dispositions, values, and attitudes and skills deemed to be necessary for becoming competent and capable as learners. **Figure 2** illustrates the idea of assessment as dynamic and relational, between learner and mentor and between the personal and public domains. The assessment of dispositions can be described as the mentored movement of selective attention between the self and the formal texts of the expert community.

Thus, there are several genres of assessment practice which are relevant to dispositions. The models of dynamic assessment developed by Feuerstein, which draw explicitly on the Vygotskian notion of the zone of proximal development and identify a person's learning power through the way they negotiate scaffolded interaction with the assessor, are relevant. Although perhaps not easily manageable in regular classrooms, they can have a place in the assessment of dispositions. Assessment for learning practices is centrally important and well discussed as a vehicle for developing learning strategies, skills, and dispositions. The use of stories in early childhood assessment has been developed substantially by Carr, while Mahn and John Steiner have shown how the use of interactive journals facilitates the development of second-language learning. Carr and Claxton suggest that portfolios are a powerful tool in tracking dispositions because they can potentially include data from the full range of assessment methods, and demonstrate both progress and achievement over time. They also recommend a learning disposition grid as a vehicle for capturing samples of evidence of a learner's dispositions over time and *in situ*. In terms of self-report questionnaires, there is a plethora of learning styles questionnaires and, more recently, the concept of learning power and its assessment has emerged as a means of reflecting back to learners what they say about themselves in relation to learning-to-learn dispositions and using that information formatively to strengthen learning power.

Conclusions

The concept of dispositions is a contested, but important area in education, particularly at a time when there is increasing international concern for social sustainability, through the development of a range of competences on the part of individuals and communities which enables successful functioning in real-world situations: such competences include values, attitudes, and dispositions, as well as cognitive resources. A limited description of a disposition focuses on an individual's tendency to behave in particular ways over time, but a more complex, elaborated

understanding locates dispositions as part of an embedded and embodied journey over time, from personal desire and motivation to the achievement of competence in a particular public domain. Competence in this sense incorporates dispositions, knowledge, and know-how as well as a contemporary reading of virtue. The focus of this article has necessarily been restricted to dispositions as part of competence for learning and for citizenship, since these are widely accepted educational outcomes. The challenge of assessing dispositions, in this more complex reading, is rooted in their relationship both to the deeply personal and to learning-to-learn skills, strategies, and achievement. Thus, assessing dispositions can be described as the mentored movement of selective attention between both self and text and between the self and the expert, competent community. Dispositions both scaffold the process of the journey toward competence and form part of the outcome of the journey. Validity of assessment is demonstrated through interpretation – primarily by the learner himself/herself, using the criteria of authenticity and trustworthiness. The purpose of assessment of dispositions is to enable learning and growth. Aggregated data from student self-report questionnaires can also be used for organizational learning. Finally, a range of types of assessment practices can be identified, providing an indication of the sorts of resources which could be drawn upon in developing local and situated assessment practices.

Assessment in Schools Related To Literacy: Reading

K J Topping, University of Dundee, Dundee, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Adaptive – A computer test which responds to student performance to shorten test.

Auditory discrimination – The ability to tell the difference between similar sounds.

Auditory sequential memory – The ability to remember sounds in sequences of increasing length.

Authentic assessment – An assessment in the context of real reading.

Informal Reading Inventory – Graded reading paragraphs at independent, instructional, and frustration levels.

Item-banked – A computer test with many items, of which a few are presented at each testing.

Phonic/phonetic/phonological – The sign–sound correspondence in reading.

Prosodic demands – The requirements for expression and audience communication when reading.

Reading Miscue Inventory – The analysis of nature of reading errors.

Reliability – The extent to which the same thing is measured on repeated occasions.

Validity – The extent to which measure focuses on what is intended to be measured and only that.

Visual discrimination – An ability to tell the difference among similar visual stimuli.

Visual sequential memory – An ability to remember visual stimuli in sequences of increasing length.

The purpose of this article is to explore those reading assessments which take place in the classroom under the complete control of the class teacher. Other kinds of reading assessments are high-stakes or psychometric tests, both dealt with in another section of this book. High-stakes tests are, typically, scored and interpreted by stakeholders at the school, district, state, or national/federal level. Psychometric tests are typically carried out by professionals other than the class teacher, who may or may not obtain some insight into their results. However, this article focuses on class-teacher assessment.

Teacher Use of Tests

Teachers may, of course, use different types of tests to help them understand student reading progress – or lack

of it. However, these tests represent only one aspect of a total reading assessment, and excessive credence should not be given to an individual test score in isolation. A key issue is whether the test or tests are being used for screening (to indicate which students might be in need of help with reading or at least more intensive assessment) or progression (cumulating year-on-year scores to indicate how a student is developing as a reader). Screening tests are, usually, shorter than progression tests.

Group norm-referenced tests are given to a group of students at a time, and compare each student's performance to a much larger group of students whose overall scores indicate what is normal for all students and how far from normal each newly tested student is. They may be quite brief (and, therefore, of less reliability) or they may be longer and involve weaker students struggling with many items that are too hard for them. They may be embedded in a suite of tests of other areas or be free-standing. Examples in the US include the Iowa Test of Basic Skills and the Metropolitan Achievement Test (including other areas) and Gates-MacGinitie Reading Tests and Woodcock Reading Mastery Tests (free-standing), and – in the UK – the Bristol Achievement Test (including other areas) and the Primary Reading Test and the Group Reading Test (free-standing). Countries with a less widely used language than English as the mother tongue, may have fewer tests, and countries which are also relatively economically underdeveloped, may have very few or none at all.

Computer tests of reading may be merely a computer version of a hard-copy test (replicating all the problems of the hard copy) or may have been specifically designed to be item-banked and adaptive. In this latter case, the student can take the test frequently (because different items from the bank will be presented each time), and because the test adapts to each student (considering at each question whether the answer was right or wrong and choosing to offer an easier or harder question), the testing time is much shorter and students are not stressed by being presented with too many questions they cannot answer. However, all group norm-referenced tests will indicate the quality of student performance by a number (or maybe three similar numbers) – this only suggests the level of the reading, it does not give any deep insight into the nature of the student's reading. The latter is necessary if any kind of relevant intervention program is to be considered.

Some schools subscribe to a testing service. The service provides tests (often, short and in a number of different areas) which are administered by class teachers. The papers

then go off to the service to be scored and the teacher receives a detailed report by way of feedback – which indicates the strengths and weaknesses of each child, often in relation to local as well as national norms (e.g., nearby schools with similar socioeconomically disadvantaged catchment areas). While this is more complex, it still indicates only levels, so the teacher is still left not knowing how to intervene to accelerate learning.

Beyond group tests, there are also individual tests of reading – so called because they are given individually to students, although still norm-referenced. Obviously, this requires much more time per student, so only a few students in the class are likely to receive such assessment. Individual tests are likely to be much more complex – perhaps, involving not only the assessment of accuracy of reading (ability to decode and correctly say a word) but also the comprehension of reading (the ability to understand the meaning implied) and, indeed, also the rate of reading (the speed at which words are correctly decoded). Such tests are also more likely to look more like real reading – they might include passages of some length to read (with an accompanying picture), rather than a list of separate sentences to be completed such as one might find in a group test.

The rate of reading is, however, tricky to interpret – Is a slower but more accurate reader better than a faster but less accurate one? Individual tests might also have a miscue- or error-analysis protocol, encouraging the tester to note down the nature of all individual errors while the student is completing the test, with a view to subsequently allocating to the categories of errors of a more diagnostic nature (see below). These diagnostic indications are much more closely linked with implications for intervention. Computerized diagnostic tests are also available – which require no immediate interaction between the teacher and the student – and these may be useful with somewhat larger numbers of students.

Authentic Assessment

While group-reading tests usually have information with regard to their reliability and validity published in their user manuals, this information is, of course, aggregated – often, reflecting very large numbers. However, the teacher is often most interested in the scores of those students who are not doing well at reading, and these scores are often of atypically low reliability and validity. Thus, there is also a need (and, maybe, primarily a need) for an authentic assessment – which is rooted in the actual processes of real reading in the classroom and beyond. Such an assessment may have a higher reliability and validity for the individual student, especially the one with difficulties. Teachers may be used to making comments concerning their students at the end of the year, and these comments are passed to the next class (or school). However, the length of these comments will not be great, and they are subject to

interpretation by the next teacher, who might – in some cases – decline to read them.

Of course, the teacher will frequently – during the course of teaching – observe students reading, and may, indeed, have sessions where students read aloud to her or him. Observations made during these sessions might be very useful diagnostically – but will the teacher have ways to formalize these observations? They include the cognitive, affective, social, and cultural contexts in which children read. Unfortunately, they all involve time – and the time spent on assessing, is the time not spent on teaching. On the other hand, teaching without assessment is unlikely to be effective, so a balance needs to be struck between teaching and assessment. Teachers need to make strategic choices with regard to the kind of authentic assessments they employ and with how many students each might be employed.

Group Discussions

An excellent way of enhancing class interactivity is to engage students in discussions relating to reading. If working with the whole class seems unlikely to be productive, start with a brief teacher-led session, then break the class into cooperative small groups, and then have the groups report back to a plenary. The focus can be simple to start with – what books have you read in the last 3 months which you really like? This can lead to many ancillary activities – displays of favorite books, charts of most liked books, deeper discussions of the most read books, suggestions for related reading, and so on and so forth. Once the class is somewhat practiced in the skills of working in this way, more contentious topics can be introduced. What things would really improve our reading enjoyment? Or ability? Helping students to realize that there are nearly as many different views as there are students – and that the teacher's job is not an easy one – are some of the side benefits.

Affective and Motivational Aspects

The emotional aspects of reading are enormously important if students are to become readers in adult life. Students may have preferences for nonfiction (information) books rather than fiction (story) books which are usually more common in classrooms (and more often used by elementary school class teachers). They may have idiosyncratic interests in particular areas, where they prove able to read and comprehend to a far higher level than in other books. They may prefer easy books which make no demands on their reading capability, or they may choose some books that are far too hard because they can get some sense from the pictures and it looks good to have them. Of course, they may be much more interested in newspapers, magazines, and the Internet than in books. Various interest and attitude surveys attempt to explore students'

feelings with regard to reading and books. These can be of written questions soliciting written answers, but there are also versions for emergent readers which require them to indicate on smiley and grumpy faces where their feelings lie. Of course, the extent to which students complete the survey honestly all the way through, might be questionable, and again teachers need to correlate the responses with observations of the students' demeanor when actually reading different kinds of texts.

Pre-Reading Sub-Skills

With emergent readers, teachers, sometimes, try to assess the component sub-skills which are assumed to underlie and contribute towards the development of reading skills. The most common of these are visual discrimination (the ability to discriminate between similar visual stimuli), visual sequential memory (the ability to remember visual stimuli in sequences of increasing length), and similarly, auditory discrimination and auditory sequential memory. The stimuli can be pictures, letter-like symbols or sounds, letter symbols or sounds, or written or spoken words (according to the abilities of the student). These assessments might indicate if a student is weak auditorily while strong visually, or vice versa – with implications for intervention. Or that discrimination is strong while memory is weak, likewise. However, a difficulty is that correspondence between the ability to complete the subtest and actually use these sub-skills in the much more complex act of reading is, often, quite weak. Consequently, teachers should also be preoccupied with the examination of the early reading attempts of these students, to see whether these sub-skills actually appear (or not) in real life.

Phonic Skills

Nearly half of the words in the English language are phonically regular, so phonic (or phonetic or phonological) skills are important. These are skills in sign-sound correspondence – the signs representing the elementary sounds of speech or expressing the pronunciation of words. Checking the phonic skills of readers may be important long after they are assumed to be independently capable. Student knowledge of lower-case letter-sound correspondences comes first, but the upper case (capital) letters must also be learned. Of course, student knowledge of the individual letter sounds needs to be checked, but also their awareness of phonic digraphs (two or more letters and sounds put together with effects different from what might be expected). These will include ee and oo; the long a, i and o with a final e; ar, er, or and all; sh, st, th, ss and ch; wh, bl, tr, fr, gr, fl, cl, gh, final y, ea; ck, ai, ay, oi, oy, ou, ow, oa, au, aw; igh, er, ur, ir, ew, ge, dge, air, are, ie, nk, ng, mb, ll, ff, tion, ation, ection, sion, ph, qu, kn, gn, wr, zz, and hard and soft c. As with other sub-skills (above), the extent

to which students can actually use phonic skills in the context of reading is potentially rather different from their ability to chant to a checklist; so teachers need to be aware when searching for examples of student use of phonic skills while reading.

Systematic Observation

It is difficult to capture observations that are made informally. Some teachers always have a clipboard or self-stick labels to hand out for this purpose. However, recording can easily get in the way of actively exploring the literacy incident further. Checklists of relevant reading skills might be helpful, but the long ones are very long (and thus, not very usable), while the short ones probably do not mention all the skills one is observing. It is, perhaps, better to look at checklists before observing – in order to refresh concepts of the wide range of reading skills – rather than actually use them while observing. Then, maybe, one can tick off skills following the event or simply record observations continuously and less formally. Remember that the teacher is only one person – others may have valid (and different) observations to make – classroom assistants, parents, and so on and so forth. Training classroom assistants to complete systematic reading observations may be a good use of their time.

Informal Reading Inventories

Informal reading inventories (IRIs) have been used for many decades. Teachers can devise their own or use commercially available IRIs. They have three graded reading paragraphs of different levels of difficulty: one at the level at which the student can read independently, one at the instructional level at which a few mistakes are made, and one at the frustration level – where many mistakes are made and the student cannot extract meaning from the text. The paragraphs for reading aloud are accompanied by comprehension questions. The independent level features 99% accurate word recognition and 90% correct comprehension, the instructional level 95–98% recognition and 75–89% comprehension, and the frustration level 90% and below recognition and 50% and below comprehension. On each passage, the student's performance is expressed in percentages and compared to these benchmarks. The grade level at which the student should be reading individually and with instruction becomes evident, together with any discrepancies between accuracy and comprehension.

Reading Miscue Inventories

Reading miscue inventories (RMIs) have less emphasis on determining the appropriate level for student reading and have a more elaborated analysis of miscues (as errors are now more kindly known, as something which is informative).

When teachers learn to do miscue analysis, it is, often, helpful if they audiotape or videotape an assessment session, and then compare their written analysis to the tape to make sure that they observed everything correctly.

Teachers make a copy of the passage chosen and write above each miscued word the nature of the miscue. Correct words should not be ticked as the child may see this and become preoccupied with teacher behavior. **Table 1**

Student performance can be coded thus: E = uses in a consistently Effective way, S = strategy used Sometimes effectively and sometimes ineffectively, I = uses strategy in an Ineffective way, N = Not observed to use the strategy. For more precision, the actual numbers of times students do each can be recorded.

shows a running record and **Table 2** shows a sample analysis. Teachers can write A if the child asked for the word, and T if they were told about it. A dot above a word indicates the child pointed. Interpretations from running records are, of course, subjective – the teacher constructs reasons for student error which may or may not be the actual ones. However, the running record can prove highly revelatory of the precise nature of each student's pattern of error – and every student's pattern will be different and have different implications for intervention.

Retellings

Retelling of a text is a powerful diagnostic tool for students whose abilities of comprehension are not good. The retelling can be audio-recorded for a more detailed analysis, including the ability to summarize, the level of retention of detail (main and supporting), the order of events, coherence, completeness, generalization beyond the text, and so on and so forth. Some students may be preoccupied with reporting facts – they should be encouraged to consider the wider message of the text. Other students may not be confident in their language abilities, and this can, erroneously, suggest poor comprehension. It is unwise to have the retelling in written form, since the act of writing interposes another variable to be considered.

Fluency

It has been said earlier (under Teacher Use of Tests) that the rate of reading is a somewhat doubtful indicator of competence in reading. So, how can we assess fluency, which is closely connected with the rate of reading? Fluency is an adaptive, context-dependent process that can

operate at a number of layers or levels. Even expert readers will show dysfluency when confronted with a text on an unfamiliar topic that provides a challenge which is beyond their independent reading level – however high that level might be. For silent reading, fluency can be defined as the extraction of maximum meaning at maximum speed in a relatively continuous flow, leaving spare simultaneous processing capacity for other higher-order processes. This assumes that the text is at an appropriate level of difficulty for the reader. For reading out loud, the task – and, therefore, the definition – is more demanding because, among the higher-order processes, the reader must have an awareness of audience needs and the capability to manage the prosodic demands for expressiveness (varying phrasing, stress, intonation, pitch, rhythm, loudness, pauses, etc.). Fluency can be considered as: (1) surface fluency (speed of accurate and automatic word recognition), (2) strategic fluency (control of speed of reading to yield comprehension and expression at the optimal level required for a specific purpose), and (3) deep fluency (control of speed of reading to maximize comprehension, expression, and deep reflection for specific purposes, enhancing explicit awareness and self-regulation of these processes). Deep fluency is tricky to assess. It can only be done in the context of systematic observation, RMIs, and self-assessment (above and below).

Portfolios

Portfolios give a longitudinal perspective on student performance and show a broader range of literacy achievements than other methods. Portfolios can also give greater depth on a particular piece of work or project. They, certainly, enable students to explore their reflections and feelings about what they are doing. They may include recordings of oral reading, student voluntary-reading logs, drawings pertaining to reading, book reports, journals, discourse during reading interviews, videotaping of book dramatizations, research projects, oral histories, parent questionnaires, and other material. Much of this can be stored electronically rather than in hard copy. Toward the end of a year, students can select and promote what they see their best work from their portfolio – this eases the assessment burden, since, otherwise, there is too much for a teacher to assess. Portfolios, often, have a section for out-of-school reading – otherwise easily overlooked. Portfolios can, of course, be taken home for parents to see and comment on longitudinal progress.

Computer-Aided Assessment of Real Books

At present, a number of software programs enable students to self-assess in relation to their comprehension of real books (e.g., Accelerated Reader, Reading Counts, and

Book Adventure). These require the student to read a real book of their choice independently, then – at the end – take a quiz on a computer to see if they understood the book. The basic quizzes are of literal comprehension in the interests of psychometric stability, but there are also quizzes requiring more inference which are less stable. The software gives feedback to the individual student (hopefully enhancing their motivation to read more and more carefully) and also to the teacher (who can see who is reading what, at what level and how effectively). Feedback is also available for parents. Students need to read a sufficient quantity of books at the right level and with the right degree of comprehension in order to make progress. Older students have been particularly found to read books at levels below their ability, resulting in a lack of challenge.

Self-Assessment

If assessment is to be formative as well as summative, the student's role in it must not be merely as a passive recipient. Students must be encouraged to actively engage in learning how to evaluate their own progress and do this better over time, since this reflects what will happen when they are adults. Self-assessment enables students to reflect and give feedback on whether teacher diagnosis is correct, as well as enhancing their ability to self-diagnose and become less dependent on teacher input. Increased student control of assessment is likely to enhance student self-confidence and self-regulation of their own learning processes – and these are important for reading beyond school – at present and in the future. Thus, self-assessment is actually a powerful intervention. Self-assessment should occur frequently, not be scheduled for occasional sessions. Students should choose what they want to evaluate (assuming they are not avoiding their problem areas). Teachers can help by giving information about what they think students are doing well. If students struggle, they should be provided with a short checklist of reading activities – as a basis for reflection. Which do they do better, which worse? **Table 3** gives a list of suggestions.

Peer Assessment

Of course, self-assessments may be highly subjective – more able students might overestimate their capabilities, while weaker students might underestimate theirs. Practice with teacher feedback is likely to improve accuracy. However, teachers have too much to do. Peer assessment has the advantage of offering some degree of external objectivity, albeit not nearly as competent as that of the teacher, but much more readily available. For peer assessment, pairs should be matched which are not too disparate

Table 3 What would help me read better?

Name _____

Date _____

Think about these items. Think about yourself as a reader.

Number the items in order from 1 to 10 to show which might be most helpful for you.

_____ Having someone listen to me reading and give me suggestions

_____ Working one to one with the teacher

_____ Having more time to practice reading in class

_____ Learning more strategies to help me understand what I read

_____ Helping tutor someone else become a better reader

_____ If I could get rewards for improvement

_____ Being able to work at my own speed

_____ Work should be more challenging (or less)

_____ More group work rather than doing everything individually

_____ Assignments should be more interesting

_____ I need to read more non-fiction (or fiction)

_____ I need to read more out of school

Please add anything you can think of that would help you become a better reader – do not worry if it is actually available just now.

in reading ability. Activities should be suggested, and simple checklists provided for students to assess the performance of other students. The pair might begin by discussing each other's self-assessment, to become familiar with the other's perceptions, and give them some sort of reality check. Beyond this, peers can discuss the selection of best work for portfolios, give feedback on retellings, render evaluative comments in group discussions, and discuss the motivational and affective aspects of their book readings. Maybe, they could even do more complex things.

Conclusion

Thus, a range of different measures, which teachers can use in the classroom, have been considered in this article. These are of various utilities and are also various in terms of the teacher time they consume. Consequently, teachers need to consider, very carefully, which measures they will use for which students. However, teachers also need to consider to what extent computers can be used to lighten their assessment load, or at least to place them as interpreters of richer information. Even more important is consideration of the extent to which students can be involved in their own self-assessment and peer assessment, since through these means, students can become more engaged in self-regulating their own performance and less dependent on teacher intervention. Certainly, these means for formative assessment of reading in the classroom lead more directly to intervention and are, thus, more important than external high-stakes or psychometric testing.

Glossary

Authenticity – This criterion is meant to convey that assessment assignments need to include all relevant knowledge, skills and attitudes that are also needed to operate in realistic contexts.

Consequential validity – Refers to the effect of assessment on learning and instruction.

Fairness – This implies the absence of bias towards certain groups and the exclusion of irrelevant variance in the assessment process.

Generalizability – This describes the extent to which tasks and performances cover a broader 'universe' of similar tasks that measure the same content or task performance.

Post-assessment effect – Assessment influences student learning by looking back at the learning process and the learning product after the completion of the assessment task. It refers to the backwash effect of assessment on learning.

Pre-assessment effect – The influence of assessment on student learning *before* a student has taken the assessment. It refers to the pro-active behaviour of students, based on their expectations of what the assessment will look like and what will be required from them.

Pure assessment effect – Assessment itself becomes a rich learning experience for students. By working on assessment assignments, students develop their thinking and understanding of the subject, supported by the continuous loop of feedback and feed-forward of teacher and/or peers.

Systematic validity – 'Evolutions in the form and content of instruction and students' learning engendered by use of the test' (Frederiksen and Collins, 1989, p. 28).

Transparency – This criterion indicates that the assessment process itself needs to be clear and comprehensible to all participants.

Introduction

As far back as the early 1970s, researchers were engaged in studies of student learning at prestigious universities (e.g., Snyder, 1971). They found, unexpectedly, that what influenced students most was not the method of teaching, but the method of assessment. Students described all aspects of their studies – what classes they attended, how much work they did, and how they went about studying – as being completely dominated by the way in which they perceived the demands of the assessment. Snyder's work particularly gave birth to the notion of the hidden curriculum – the different and unwritten curriculum that students had to discover and pay attention to if they wanted to succeed.

During the past 20 years, the issue of the positive or negative impact of testing and assessment on learning, teaching, and achievement has come very much to the fore. Findings of a number of studies (e.g., Ramsden, 1992) have demonstrated that assessment that is perceived as threatening and that provokes anxiety may push students to employ surface learning approaches. This problem is not new. Already, in 1984, Frederiksen was claiming that educators have to concentrate on developing assessment instruments that improve the educational process instead of damaging it (Frederiksen, 1984). In this regard, Frederiksen and Collins (1989) introduced the term systematic validity, referring to "evolutions in the form and content of instruction and students' learning engendered by use of the test" (p.28). Since the 1990s, the concept of consequential validity has been commonly used to refer to the effect of assessment on learning and instruction.

Over the past decade, many classroom teachers have experimented with the implementation of so-called new modes of assessment, such as peer assessment, portfolio assessment, and case-based assessment. Educators expected that – compared to conventional testing – the effects on student learning would be more positive. More precisely, it was theorized that using modes of assessment that required students to use higher-order thinking skills – such as problem-solving and reflection – would stimulate students to approach their learning in a deep, instead of a surface, way. This would, in turn, lead to significant learning gains.

The studies of Scouller (1995, 1998), Scouller and Prosser (1994), and Tang (1994) were the first to compare traditional multiple-choice (MC) tests – asking students to reproduce learned information – with an essay test and portfolio assessment. The authors concluded that the essay test and portfolio assessment were perceived by the students as assessing on a deep level and were related to deep learning approaches; the reproduction-oriented MC tests were perceived as measuring on a surface level and were related to surface learning approaches. Since then, the effects of assessment – and, more specifically, of new modes of assessment – have been a subject of discussion. Although the discussion on the existence and proof of effects is interesting for educators, far more interesting is the question of what conditions are necessary for assessment to support student learning. To date, the evidence for any conclusive answer to this question is still very scarce. This article summarizes a few recent studies addressing this issue.

A distinction is made among three kinds of effects: pre-, post-, and pure assessment effects. Pre-assessment effects refer to the influence of assessment on student learning before a student has taken the assessment. It refers to the proactive behavior of students – based on their expectations of what the assessment will look like and what will be required from them. The post-assessment effect refers to the backwash effect of assessment on learning. How does having undergone the experience of assessment practices influence student learning behavior and products? Post-assessment effects can be formulated in terms of motivation (e.g., the influence of assessment on student self-efficacy), in terms of learning approach (e.g., how does having long-term experience with knowledge-reproduction tests influence student learning approaches?), as well as in terms of cognitive gains (e.g., to what extent does the feedback received following the assessment support or deepen understanding of the learning content?). Finally, it might be expected that, by working on assessment assignments, students develop their thinking and understanding of the subject – supported by the continuous loop of feedback and feedforward of teacher and/or peers. This is called the pure assessment effect. Project-based assessment is an example where students have ample opportunity to learn from working on the assessment assignment itself (the project).

Evidencing Pre-Assessment Effects

It has been argued that assessment can have an effect on different levels which depends on the function of the assessment (summative vs. formative) (Gielen *et al.*, 2003). The influence of summative assessment on learning behavior is

mainly proactive. The question “do we have to know this for the examination?” will be recognizable for nearly every teacher and illustrates that students tend to adjust their learning behavior to what they expect to be assessed. These effects can be described as pre-assessment effects, since the effects occur prior to the assessment. An example of an empirical study on the pre-assessment effect of new modes of assessment is the study by Segers *et al.* (2006). These researchers explored the conditions for assessment to steer learning – by investigating the impact of the implementation of a new assessment instrument (the OverAll Test) on students' learning strategies. The OverAll Test is a case-based assessment instrument which measures the extent to which students are able to use knowledge (models, theories, etc.) to define, analyze, and solve authentic problems. The OverAll Test is implemented as part of a course redesign and in alignment with the features of the redesigned learning environment. The main differences between the original and the redesigned learning environment are the format of learning tasks (study tasks in the original course and problem tasks in the redesigned course) and the mode of assessment (a knowledge-reproduction test in the original course and the OverAll Test in the redesigned course). When redesigning the course, it was expected that, by implementing the OverAll Test, the students would change their learning strategies. More specifically – given the features of the OverAll Test – it was expected they would adopt more deep learning strategies in the OverAll Test condition than in the original condition. In order to unravel the mechanism through which the OverAll Test influences students' learning, students' intended learning strategies as an indicator of their habitual learning strategies were addressed, as well as their perceptions of the assessment's demands. In addition, students' learning strategies were measured. The results indicated that – in contradiction with expectations – the students in the original course adopted more deep learning strategies and fewer surface learning strategies than the students in the redesigned course. Although the students were informed concerning the differences between both courses in the various course information resources, there were no significant differences between both groups of students in the learning strategies they intended to employ as well as in their perceptions of the assessment's demands.

In both conditions, the students – who intended to employ surface learning strategies – perceived the assessment's demands as surface and actually used surface approaches to learning. The results showed, clearly, that those students who expressed their intentions to employ a certain learning strategy perceived the assessment demands as such and actually employed a related learning strategy. In short, the change in assessment practice did

result in a change in learning strategy; however, this was toward more surface learning. Lack of familiarity with this mode of assessment might have stimulated them to go back to old habits, using the learning strategies they had experienced as being successful in the past. Students seem to be more stable than expected in the learning strategy they employ and perceived the assessment's demands accordingly.

Evidencing Post-Assessment Effects

Assessment influences student learning by looking back at the learning process and the learning product following the completion of the assessment task. This is referred to as post-assessment effects. When teachers give students information with regard to the quality of their performance and support students in reflecting on the learning outcomes and the learning processes they are based on, gains in terms of achievement and learning approaches can be expected. When students dispose the necessary metacognitive knowledge and skills, teacher feedback can be reduced. Students may become capable enough to draw conclusions themselves with regard to the quality of their learning behavior (self-generating feedback or internal feedback), following the completion of the assessment task. It is clear that, especially when assessment tasks are used for formative purposes, the feedback supports students in diagnosing their own learning and in taking the next steps in their development. However – in comparison with formative assessment – post-assessment effects of summative assessment on student learning are small. Moreover, it is evidenced that the effects of testing on the long term are negative for student motivation (Harlen and Crick, 2003). Regular exposure to conventional testing leads to significant motivational problems.

A recent study by Segers *et al.* (2008) illustrates the post-assessment effect of portfolio assessment, or more precisely how portfolio assessment influences student learning.

This study was conducted within a competency-based program on applied sciences, with portfolio assessment as its core mode of assessment. Based on an intake assessment, students developed a personal development plan (PDP) and a personal activity plan (PAP). Within the PDP, the student reflected on his/her personal competence development in relation to the levels and behavioral indicators described in the student-competencies guide. It formed the basis for coaching interviews with the study coach. The PAP consisted of the student's concrete working plan; the activities he/she would undertake to develop the competencies at the required level. The digital portfolio consisted of the PDP and PAP of the student, his/her study dossier (the work – such as project reports, project products, and performance assessments – that he/she was actually doing and had finished), and a private

dossier with documents the students wanted to keep for personal purposes. The development of the digital portfolio was supported by a study coach who had regular meetings with students (individually and in small groups). There was feedback on the work done and the progression shown, discussions were held about which competencies, at what level, and which specific behavioral indicators that a student will work on in the next step. It was expected that reflection and feedback – as part of the portfolio process – would result in students adopting a deep approach to learning. More specifically, the researchers were interested in unraveling the elements of the portfolio-assessment practice that were related to how students approached their learning. Therefore – at the end of the academic year – students' perceptions of these assessment practices (after experiencing the portfolio assessment) and how they approached their learning (deep and surface approaches to learning) were measured. The results indicated that students who adopted a deep approach to learning read the feedback carefully and used it to look critically at their portfolio, then tried to improve it based on the suggestions made. Additionally, it was found that students who adopted a deep learning approach perceived the portfolio assessment as stimulating their learning, being motivational, and requiring a deep understanding of the learning materials; they perceived the criteria for the portfolio to be clear and perceived the portfolio assessment as challenging.

In short, these findings suggest that how the students went about their learning was influenced by how they had experienced different features of the portfolio-assessment practice.

Evidencing Pure Assessment Effects

Nevo (1995) and Struyf *et al.* (2001) point to a third kind of learning effect from assessment. The main idea is that – when assessment is part of daily classroom pedagogy – there is an ongoing feedback and feedforward loop informing students concerning their growth and the next steps to take. This means that assessment itself becomes a rich learning experience for students. This means that – contrary to the old American saying “weighing the pig doesn't fatten it” – in some cases, high-quality learning is fostered by simply assessing the learning outcomes, or “weighing can fatten the pigs.” This can be called the pure assessment effect. Illustrative is the study of Gijbels *et al.* (2005). This study investigated the effect of integrating written assessment tasks into the learning environment on students' performance in final exams. The study can be seen as a small, but progressive, step toward the integration of assessment, learning, and instruction. In order to gain more insight into the effects, the researchers formulated two research questions. First, did students

who did the assessment tasks perform better in their final exams compared to students who did not? Secondly, what were the most important concerns in students' and teachers' perceptions of the assessment tasks? Students' final exam results were used to find out whether students who did the assessment tasks performed better than students who did not. Answers from questionnaires and semi-structured interviews were used to discover the most important concerns in students' and teachers' perceptions of the assessment tasks.

The research was carried out within the context of a compulsory second-year law course. A total of six assessment tasks were distributed over different topics and weeks in the course. Assessment on the course was two-fold. The final exam consisted of 40 MC questions and took place at the end of the course. During the course, students had the opportunity to complete the six assessment tasks on a voluntary basis, which could result in an extra bonus point – added to the score of the final exam. Both the assessment tasks and the MC questions set several cognitive problems to the students in line with the instructional goals of problem-based learning.

Students were stimulated to produce high-quality learning activities by giving the one extra bonus-point only if all six assessment tasks showed sufficient quality and effort. The feedback students got from their tutor and from the plenary discussion in the tutorial group could help them to do their next assessment task better and to get a better understanding of the learning materials to be studied in order to pass the final exam at the end of the course.

The results of the study indicated that working with assessment tasks had a significant positive influence on the students' performance – not only on assessment task-related topics, but also on nonrelated topics. These results indicated that the introduction of the assessment task helped students to address more appropriate student learning activities – going beyond the six assessment tasks and their content. This was confirmed by the results of the survey, indicating that students who took on the integrated assessment tasks worked in a different way – in terms of learning approach as well as time management. A crucial condition for the integrated assessment tasks to affect learning seemed to be the feedback students received – the clarity of goals, the criteria of the assessment tasks, and the implementation of the tasks.

Quality Indicators of Assessment

The aforementioned studies illustrate how classroom assessment practices influence how students go about learning. However, various quality aspects of the assessment practice might hinder or enhance the consequential validity of the assessment. For example, portfolio assessment might not lead to the expected reflection and

growth in competence development when the procedures are not transparent. Moreover, when portfolio assessment is mainly based on written artifacts and written reflections, English as a Second Language (ESL) learners might be disadvantaged. In the case of project-based assessment, the learning effects might be jeopardized by using unrealistic projects or projects that require students to only perform routine procedures and tasks to reach the project goals.

These examples illustrate the importance of reflecting on quality indicators for current classroom assessment practices. There has been an ongoing debate on the relevance of psychometric quality indicators. During the past decade, our thinking about assessment as well as classroom assessment practices has been changing. In general, these changes are:

- There is a stronger emphasis on the integration of assessment and instruction. Many assessment specialists take the position that appropriately used educational assessments can be seen as tools that enhance the instructional process as well as the student learning process.
- The position of the student is increasingly that of an active participant who shares responsibility for the process, practices self-assessment, reflection, and collaboration, and conducts a continuous dialog with the teacher. Students participate in the development of the criteria and the standards for evaluating their performance.
- Both the product and process are being assessed.
- The assessment takes many forms, all of which could generally be referred to as unstandardized assessments embedded in instruction. There is, often, no time pressure, and a variety of tools that are used in real life for performing similar tasks are permitted.
- The assessment tasks are more often interesting, meaningful, authentic, challenging, and engaging, involving investigations of various kinds.

The question is whether the traditional psychometric quality indicators align with the aforementioned features of assessment. Various authors have proposed replacing or extending the traditional quality criteria of reliability and validity. To illustrate the quality criteria that are argued to align with current assessment practices, the quality criteria as expressed in the literature on peer assessment are described as follows:

- *Authenticity*. This criterion is meant to convey that assessment assignments need to include all relevant knowledge, skills, and attitudes that are also needed to operate in realistic contexts. It refers to the requirement that assignments must measure how students learn actively in settings that resemble reality itself. In the literature referring to authenticity, four alternatives – or

for that matter underlying or subsumed criteria – are to be found. First, representativeness refers to the criterion or requirement that assessment tasks must do the reality domain at stake. Second, the criterion meaningfulness stresses the importance of assessing relevant and worthwhile contributions of the learner. Third, the criterion cognitive complexity involves inclusion of higher-order skills. A fourth criterion – content coverage – is meant to highlight the breadth of inclusion of the assessment domain.

- *Transparency*. This criterion indicates that the assessment process, itself, needs to be clear and comprehensible to all participants. Only then can it be expected that assessment has the potential to support student learning.
- *Fairness*. This implies the absence of bias toward certain groups and the exclusion of irrelevant variance in the assessment process. In essence, this criterion indicates that each student must receive the same chance to demonstrate their knowledge, skills, abilities, and competencies.
- *Generalizability*. This describes the extent to which tasks and performances cover a broader universe of similar tasks that measure the same content or task performance. Under generalizability, three more specified criteria are to be found: Comparability is defined as measurement under same conditions and criteria for everyone. Reproducibility is defined as the accuracy and consistency of decisions over time and assessors. Transferability refers to the extrapolation of measured performance to other situations and tasks.

Conclusions

During the past decade, the world of assessment in education has been dominated by a plea for the implementation of an assessment culture where learning in its various aspects, as well as the learner, should be central in the process. As part of this assessment culture, so-called ‘new modes of assessment’ have been widely implemented, in general, being characterized by measuring higher-order thinking skills and competencies. Examples of this are peer assessment, performance assessment, and portfolio assessment. Studies have been conducted to better understand the hypothesized positive effects of new modes of assessment on student learning: pre-assessment effects, post-assessment effects, and pure assessment effects.

Moreover, organizing assessment to positively influence student learning demands critical monitoring of the quality of our assessment practices. Several authors have argued that new forms of assessment require new quality criteria. When we want to make assessment practices supportive for learning, attention should be paid to quality

criteria, such as authenticity, transparency, fairness, and generalizability. The research agenda of the coming decade will be dominated by the search for empirical evidence, not only for the right conditions of assessment to support learning, but also for valid quality criteria to enhance the quality of these modes of assessment.

Glossary

Dynamic assessment – A form of diagnostic assessment which looks at what progress a learner can make when offered adult support in a one-to-one situation.

Educational assessment – An approach which focuses on an individual achievement relative to him or herself rather than to others, places little emphasis on standardization and seeks to help the individual progress. It is contrasted with psychometric testing.

Formative assessment – Assessment used to inform teaching and learning so that further learning takes place.

International Baccalaureate (IB) – A high status international diploma offered in three languages around the world.

Performance assessment – Judging what students can do in terms of the actual tasks and end performances that are the goals of instruction. (Used interchangeably with 'authentic assessments' and 'direct assessments'.)

Psychometric testing – Assessment which focuses on standardization of tasks and scoring, on norms and distributions.

Realistic simulation – Seeking to represent the intended real-world performance, for example, a flight simulator for trainee pilots.

Social constructivist – Cognitive and sociocultural theories of learning which emphasize the

importance of students actively making meaning in their learning.

Summative assessment – Assessment which 'sums up' where learners have got to in their learning.

Systemically valid testing – Assessment which leads to curriculum and instructional changes that foster the cognitive skills that the test measures.

Definitions

Alternative assessment is an elastic term which stretches from doing the same thing in a different format to describing radically different ways of approaching assessment. These include performance, authentic, formative, and diagnostic assessments which reflect alternative approaches to learning. A function of this contribution is to clarify, and question, the way the term is used.

As part of clarifying usage, we classify alternative assessments into three levels: alternative forms of assessment, which we will call alternative formats; alternative models of assessment; and alternative purposes of assessment, where purpose can drive form. While there are considerable overlaps among these, we believe that the distinctions are useful in discussing the claims that are made. Examples are considered from each of these levels.

Level 1: Alternative Formats

The alternative label is usually applied at this level to new or different delivery of an assessment – for example, transferring a pencil-and-paper test to a computer screen. The test content and demands remain much the same while the means of delivery changes. It may be the case that as the computer testing becomes more sophisticated, it begins to make new demands and might move to the next level – for example, using multimodal stimulus materials or forms of computer-adaptive testing.

Where a particular form of assessment is dominant – for example, multiple-choice testing in the USA – then, more open-ended tests requiring constructed answers have also been claimed to be alternative, in the sense that they are different. It may be that, once again, little else changes in the test demands and accompanying pedagogy. We would challenge whether this kind of claim should automatically be called alternative, since it is essentially business-as-usual with varied assessment formats. Little changes in what is assessed and in classroom teaching and learning.

Level 2: Alternative Models of Assessment

At this level, changes in assessment are underpinned by the intention to provide a different approach to assessment to reflect a different approach to learning and pedagogy. We illustrate this through developments in performance assessment and through approaches resulting from social constructivist views of learning. Performance assessment emphasizes direct, or as direct as possible, demonstration of the skill being assessed and minimizes the use of tests as a proxy for actual performance. This is a long-standing tradition in many occupational areas, and we consider moves to apply this within more general education. We use the term social constructivist loosely, to cover those cognitive and sociocultural theories of learning which emphasize the importance of students actively making meaning in their learning. These approaches have encouraged a more holistic approach to assessment than the knowledge-in-bits of most multiple-choice tests – underpinned for many years by more behaviorist views of learning.

Along with new conceptions of learning, the drive to develop alternative models of assessment received support from the fact that traditional types of test (multiple-choice standardized tests in the US and formal written examinations in the UK) have had unintended and negative effects on teaching and on the curriculum. “Under intense political pressure, test scores are likely to go up without a corresponding improvement in student

learning. In fact, distortions in what and how students are taught may actually decrease students’ conceptual understanding” (Shepard, 2000: 13).

Performance Assessment

Shepard and Bleim (1995) have argued for the equivalence of some of the key terms: “We use the terms performance assessments, authentic assessments and direct assessments interchangeably, the idea being to judge what students can do in terms of the actual tasks and end performances that are the goals of instruction” (p. 25). While this equivalence may not satisfy all, it provides us with a broad base from which to work. The spirit of this approach is to offer assessments which relate as closely as possible to the real-life knowledge and skills required. How close this match is may depend on the context. The philosophy behind this approach is straightforward: to be assessed as having a skill or competency we need to demonstrate it. This seeks to counter what Hanson has called “fabricating quality of tests” in which “the likelihood that someone will be able to do something, as determined by the tests, becomes more important than one’s actually doing it” (1994: 288).

We begin by briefly considering two well-established forms of performance assessment. Both have their roots in occupational and vocational training – where the emphasis is on practical demonstrations of competence. With pencil-and-paper testing so dominant in the education sector, these serve as a reminder of models of assessment which predate standardized testing.

Competency assessment in the workplace

The most direct correspondence would be competency assessments in the workplace; we would expect our trainee doctors, plumbers, and pilots to have demonstrated competency in real-life situations. We would require something similar of musicians and drama students; they will be assessed on the basis of actual performances. A key feature of these assessments is that they rely essentially on expert human judgment. This is a distinct difference from psychometric approaches which seek to minimize judgment and in which competency is often reduced to achieving the cut-score on multiple-choice tests. Work-based assessment has a distinguished history and predates our use of written assessments. It was embodied in the medieval guild system, in which persons would be apprenticed and would then – after learning their trade for a number of years – demonstrate the skills in their craft through their products. It was the quality of these products that determined their admittance to the guild.

Realistic simulation

This approach also seeks to align the assessment closely with the intended real-world performance, but may take

place in a context which relies on simulation – for example in a college. So medical training may involve direct simulation – for example, working with actors who mimic patients’ symptoms. Similarly, trainee pilots will use flight simulators and trainee mechanics work on workshop engines. Another form of realistic simulation may be working under highly controlled and supervised conditions – for example, special catering events for trainee chefs, or conducting scientific experiments in school science laboratories. We consider these alternative assessments because they represent a model of learning-by-doing which differs from the dominant educational model in which tests become a proxy for the required skills and practical knowledge.

While we categorized early computer-based testing as little more than changing the format of the tests (paper to screen), many of the more sophisticated applications are able to offer realistic simulations through multimedia stimulus materials. We also recognize that adaptive testing – which responds to the student’s choices and decisions – offers an alternative when, for example, it works to capture the student’s own understanding of a problem.

Alternative Educational Assessment

Here, we consider examples of school-based assessment which are based on models of learning and assessment which challenge some of the assumptions on which conventional standardized assessments are based. Some of these may be loosely described as performance assessments since they focus on what learners can demonstrate in less constrained settings than conventional standardized tests. These are often summative in purpose, though they contain many opportunities for formative assessment (see below).

The philosophy behind these alternative approaches distinguishes educational assessment from psychometric assessment. For present purposes, the key issues are that – in the psychometric model – the focus on reliability requires the standardization of administration and tasks as well as of scoring. The preoccupation of psychometrics with norms and norm-referenced testing stemmed from tests focused on aptitude, selection, and prediction. An individual’s performance was reported in relation to that of his/her peers, so that performance was seen in relative, rather than in absolute, terms.

In contrast, Wood (1986) has argued that educational assessment deals with the individual’s achievement relative to him or herself rather than to others; takes place in relatively uncontrolled conditions and so does not produce well-behaved data; looks for best – rather than typical – performances; is most effective when rules and regulations characteristic of standardized testing are relaxed; and embodies a constructive outlook on assessment, where the aim is to help rather than sentence the individual.

Shepard (2000) has developed a conceptual framework for this understanding of assessment based on social constructivist theories of learning. She summarizes this view of learning in the following principles: (1) intellectual abilities are socially and culturally developed; (2) learners construct knowledge and understandings within a social context; (3) new learning is shaped by prior knowledge and cultural perspectives; (4) intelligent thought involves metacognition or self-monitoring of learning and thinking; (5) deep understanding is principled and supports transfer; and (6) cognitive performance depends on dispositions and personal identity.

Educational assessment seeks to realize these principles through the kind of assessment tasks presented to students. These require a greater emphasis on broader-based performance tasks which encourage a deeper understanding. Frederiksen and Collins’ (1989) have approached this through their principles of systemically valid testing. At the heart of this approach is the principle that:

A systemically valid test is one that induces in the education system curricular and instructional changes that foster the development of the cognitive skills that the test is designed to measure. Evidence for systemic validity would be an improvement in those skills after the test has been in place within the education system for a period of time. (p. 27)

They proposed standards for assessment which included:

Directness. This involves assessing the cognitive skill of interest – the emphasis being on the authenticity of the extended tasks. They call for sets of tasks which are ecologically valid, which are representative of the way knowledge and skills are used in real-world contexts, and for which the primary traits have been identified.

Scope. This considers the range of skills needed to do well in the tasks.

Reliability. This seeks effective ways of assessing which, at the same time, fosters learning.

Transparency. This is the concern that those being assessed are clear about how they are being judged. This should enable learners to “assess themselves and others with almost the same reliability as the actual test evaluators achieve” (p.30).

In practice, this approach has been expressed through approaches such as portfolio-based assessment, extended assignments, and assessment by teachers which contribute to credentials. We briefly describe examples of each of these.

Portfolio assessment

At one level, portfolios may be regarded simply as collections of pieces of student work which are kept as a record. However, these collections can also be used as a basis for

assessment, and so portfolios are often described as a method of assessment.

A portfolio used for assessment and learning purposes involves documentation of achievements, self-evaluation, process artifacts, and analyses of learning experiences. It is, therefore, significantly more than a collection of assignments (Klenowski, 2000: 219).

Using collections of student work for assessment allows a wide range of approaches to marking – from traditional marks and grades assigned by teachers, through detailed written comments by teachers (with no grades), teacher–student discussion, and negotiation of the assessment, to student self-evaluation. As with other forms of alternative assessment, the proponents of portfolio assessment present a rationale based on the enhancement of learning. First, assessment that celebrates achievement on a self-referenced or criterion-referenced basis builds students' confidence and ultimately enhances their performance. These can be contrasted with the situation in which assessment draws attention to failure through the use of grades and marks, particularly when norm-referenced. Second, learning is enhanced if students understand clearly what they are trying to achieve, and are provided with personal and substantive feedback in trying to reach their target. Third, collecting, sorting, and annotating evidence to demonstrate achievement in the form of a portfolio of work is a valuable aid in developing the skills of self-evaluation, as well as for communicating standards in a relatively unambiguous and accessible way.

Advocates see portfolio assessment as the embodiment of good social constructivist principles. While the validity of using these for summative purposes at a local level is strong, there have been far more challenges when portfolios have been used in relation to wide-scale accountability testing. Portfolio experiments in the USA, in the states of Vermont and Kentucky, led them to be incorporated into accountability measures, which then raised questions of reliability. For high-stakes purposes, portfolio assessments remain vulnerable to reliability problems relating to sampling, standardization, and scoring. In high-stakes assessment contexts, this will often leave them exposed to criticisms of bias and unreliability, particularly where it is the student's own teacher who is making the assessment.

Extended assignments/projects

In standardized tests, even the inclusion of constructed (open-ended) answers offer the candidates little room to express their own understandings since they generally require convergent answers which are anticipated by the mark scheme. An alternative approach, which sits well with constructivist principles, is to provide the learner with opportunities to create a substantial piece of work in which they have choice over what they do. At classroom level, this may be projects which explore local issues – for

example, history projects, or which feature the students' own designs in technology. This may also incorporate group activities which would encourage the collaborative aspects of learning.

As with portfolios, it is possible to construct a strong case for the validity of such approaches when the summative purposes are restricted to local use. Their use in high-stakes assessments will again raise issues of consistency in their assessment and the problems of equating performance on very different tasks. In England, the use of such projects – assessed by teachers – has been a part of external qualifications such as the national examinations at ages 16 and 18. However, reliability concerns have led to the progressive erosion of the individual's choice of projects; so in subjects such as mathematics and science, the tasks were externally defined. This, in turn, led to such predictability about what was needed for a good grade that model solutions were easily available on the Internet. This in turn caused a further tightening of the specifications in the form of controlled assessments. These have to be done largely in the classroom under teacher supervision – giving students very little choice or autonomy in their work.

A more constructive example of how individual projects can be managed is provided by the extended essay in the International Baccalaureate (IB) – a high-status international diploma for 16–18-year-olds offered in three languages around the world. The extended essay is an independent, self-directed piece of research, culminating in a 4000-word paper which contributes to the diploma. It involves an in-depth study of a topic of interest within a chosen subject, with the emphasis placed on the research process: formulating an appropriate research question; engaging in a personal exploration of the topic; communicating ideas; and developing an argument. The assessment of this process is by the students' own teachers, who have received professional development in marking the essays. There is considerable external confidence in the dependability of IB assessments, especially among universities for whom the extended essay is a good preparation for similar work at degree level.

Assessment by teachers for external purposes

Teachers regularly assess their students' classroom learning for both formative and summative purposes. Our interest here is in those assessments which are used as part of external certification or for high-stakes selection purposes. Such assessments can be considered as alternative assessments when they both replace conventional standardized testing and involve the principles of educational assessment we have previously outlined. Thus, we would look for different approaches to teaching and learning that educational assessment encourages – Frederiksen and Collins' systemic validity.

Much classroom assessment may not meet these requirements since it mimics standardized tests and is little more than frequent summative testing which is used for reporting or management purposes rather than as formatively contributing to students' further learning. Continuous assessments such as the grade point average (GPA) in US classrooms can be seen as a means of keeping learning and effort on track – a form of classroom control, rather than encouraging the principles of educational assessment.

A more positive example of assessment by teachers is that found in Queensland, Australia, which abolished examinations over 30 years ago and replaced them with criteria-based subject-achievement assessments by teachers. The system involves extensive moderation by over 400 district review panels, composed mainly of teachers. These panels review samples of work across subjects and schools and provide advice to schools. The process is seen as an effective form of professional development in assessment. The only external assessment is the Queensland Core Skills Test (cognitive skills based on the common curriculum elements) which is taken by 17-year-olds. This – together with teacher assessment – provides the basis for entry to tertiary education. We believe this qualifies as alternative assessment by providing an alternative to selection examinations and encouraging a richer curriculum in which teachers and students are actively involved in the assessments.

Summary

This section has reviewed examples of alternative assessments which seek to directly measure the desired skills and competencies rather than through the proxy of written tests. This is an approach historically grounded in occupational and vocational approaches to learning represented by the guild system. In educational settings, we have considered alternative approaches to assessment based on different models of learning. Social constructivist approaches encourage students to make meaning and to understand the principles behind what they are doing. This leads to forms of assessment such as portfolios and extended project work. Classroom assessment by teachers will need to be interrogated to see if it is offering such opportunities. One way of ensuring this is through more effective formative assessment, which we now consider.

Level 3: Alternative Purposes of Assessment

The assessments we have considered so far have been primarily used for summative purposes, summing up where students have got in their learning. This section considers an alternative uses of assessment: the formative and the diagnostic. Formative assessment serves different

purposes since its main intention is to assist the learning process rather than to measure what has been learned. Diagnostic assessment can be seen as a subset of this in seeking to find out what is known in order to help with further learning. There are some considerable overlaps with the previous level: summative assessments can be used formatively if the results are used to guide further learning; performance and educational assessments will often involve the kind of self-regulation and feedback which characterize formative assessment.

What is the Purpose of Formative Assessment?

The purpose of formative assessment is to inform learning and teaching processes so that further learning takes place. This can be contrasted with summative assessment, in which the intention is to provide a summing up of where learners have got to in their learning. At the heart of formative assessment is the assumption that assessment, broadly understood as information gathering, can help identify what learners know – so that further teaching can build on this. It also assumes that learners will play an active part in the process and will increasingly be able to monitor and regulate their own learning. A key mechanism in this process is feedback, since this can help the learner bridge the gap between current and desired performance. We prefer to call this approach assessment for learning as this makes the purpose clear. A useful definition is:

The process of seeking and interpreting evidence for use by learners and their teachers, to identify where the learners are in their learning, where they need to go to and how best to get there. (Assessment Reform Group, 2002: 2–3)

This is essentially about day-to-day classroom assessment and depends on the quality of classroom interactions. It supports a pedagogy in which teachers seek to negotiate, and make explicit, learning intentions and success criteria ('where they need to go to'). It also involves finding out where learners are in their learning. This may be by diagnostic assessment – for example, miscue analysis in reading or investigating errors on tests. On a day-to-day basis, it occurs through classroom interaction – for example, questioning and dialog.

One small example of the way in assessment for learning can modify approaches to teaching and learning is the practice of wait-time. It is known that when teachers ask questions they expect an almost immediate reply. If effective learning is about the student-constructing meaning, what chance is there for this when an immediate answer is expected? Also, what kind of question only takes a second to process before answering? Wait-time, therefore, encourages the teacher to ask richer questions and allow students more time to process the answers (and there

maybe more than one correct answer). This approach also encourages students to discuss briefly the answer with each other before the teacher asks for responses. This may also lead to following up on unexpected or incorrect answers since these misconceptions may help in understanding where learners are in their learning.

Wait-time is just one small example of how formative assessment may change the quality of classroom interaction. This is no longer the teacher using surface-level questions to check quickly whether students know the correct answers, it involves a more deliberate attempt to gauge their understanding.

Feedback

One of the key components of assessment for learning is feedback. Its role is to help move learners from where they are toward the desired standard – the ‘and how to get there’ of our definition. What we know about feedback is that it does not always work as intended. In their meta-analysis of research on feedback, the psychologists Kluger and DeNisi (1996: 275, 277) concluded that:

In over one third of cases Feedback Interventions reduced performance . . . we believe that researchers and practitioners alike confuse their feelings that feedback is desirable with the question of whether Feedback Intervention benefits performance.

Whether feedback has positive learning effects depends on many interacting factors: motivation, the complexity of the task, the expertise of the learner, and the level and quality of the feedback. This makes it highly situational: the same feedback given to two learners could have opposite effects. Simply telling novice learners that they are wrong may set back learning, telling engaged experts the same may be enough to get them to increase their efforts and change their strategy.

Assessment for learning encourages feedback which focuses on the task rather than on the learner, and which has the goal of learners who become increasingly self-regulating. This involves being sufficiently aware of the desired standard that they can begin to give themselves, and their peers, feedback. This leads to alternative thinking about classroom practices, for example, questioning whether praise is an effective form of feedback (how does praise provide information to close the gap in learning?). It may also question routine marking and grading practices. For example, if the feedback to a piece of work is a mark (7/10) how does that provide information to move learning forward? Most teachers may put a comment alongside this – but research suggests that this is largely ignored, it is the mark that counts.

Where this leads is to classroom practice with an emphasis on developing self-regulated learners who receive informative feedback. This involves more focus

on the task, with feedback information intended to inform future performance. It will also lead to less emphasis on marks and grades, and more encouragement for comment-only marking.

Our claim is that formative assessment represents an alternative purpose for assessment: to contribute directly to the learning process. In terms of the approach to learning, it overlaps with the social constructivist views that we considered in the previous section and aligns well with approaches such as performance assessment and portfolios.

Diagnostic assessment

A further example of different purposes of assessment is its use for diagnostic purposes. Genuine diagnostic testing can be seen as a subset of formative assessment (where the learners are in their learning). We distinguish this from diagnostic testing which is used for managerial purposes – for example, to allocate students to groups. Diagnostic testing can involve informal analysis – for example, of a pupil’s reading skills and limitations – or the use of test results to identify what has not been understood. This test-and-remediate approach would often be called formative assessment in the US. In this, the formative element is in the remediation work following a test, occupying, for example, 1 week in a 6-week module. This approach to formative assessment differs from assessment for learning, which treats it as a continuous everyday classroom practice.

Dynamic assessment

An alternative approach to diagnostic assessment is provided by dynamic assessment. This has drawn on the sociocultural theories of Vygotsky (1978), who pointed to the importance of tools and aids in learning. What this diagnostic approach seeks to find out is what progress a learner can make when offered adult support in a one-to-one situation. So it is not so much what learners know, but how effectively they learn when assisted. In the traditional examination and test, the student is denied the use of external tools. As Lunt (1994) explains:

Dynamic assessment procedures . . . involve a dynamic interactional exploration of a learner’s learning and thinking process and aim to investigate a learner’s strategies for learning and ways in which these may be extended or enhanced. Since it offers individuals an opportunity to learn, dynamic assessment has the potential to show important information about individual strategies and processes of learning and, therefore, to offer potentially useful suggestions about teaching. (p. 152)

This approach – like formative assessment and educational assessment – represents a challenge to approaches to assessment found in the psychometric tradition. They

are alternative not because they do the same thing differently but because they attempt to achieve something different. This difference is rooted in current understandings of how we learn and in a search for ways of aligning assessment with approaches to teaching and learning which emphasize the importance of using assessment to support good-quality learning. As such, it requires a different relationship between assessor and learner, just as learning theory tells us the learner should be an active participant in his/her learning.

Glossary

Classroom assessment – The process of observing, collecting, analyzing, and interpreting evidence that can be used to draw inferences and inform decision making.

Formative assessment – The assessments used by teachers to guide them in adjusting instruction so as to improve learning (also called assessment for learning).

Performance assessment – The assessments designed for students to create an original response that showcases their competencies, which are then judged on predetermined criteria and observation.

Portfolio assessment – A systematically selected sample of student work intended to demonstrate growth and progression toward a specified learning goal.

Scoring rubric – A set of criteria against which student work is scored.

Summative assessment – The assessments used to evaluate how well a student has attained a certain learning goal or level of competency (also called assessment of learning).

Validity – Refers to how well what is being assessed actually corresponds to what was intended to be assessed and is intrinsically linked to the inferences one makes from an assessment.

Classrooms are filled with situations requiring teachers to make difficult decisions with important consequences: Should Sam and Jack be sitting next to each other? Is Charlie still struggling with his reading? Has the class mastered the content needed to pass the next benchmark assessment? What topics should be covered in math class tomorrow?

Some of the decisions that teachers have to make are about individual students, while others pertain to the class as a whole. Some decisions are related to what content to teach and how to teach it, some concern the classroom environment, and others involve evaluating how well students are learning the material and responding to the curricula. Many of these decisions must be made on a daily basis, while others may only happen once or twice a year. The common thread tying all of these decisions together, however, is that they should all be based on evidence gathered in the classroom, through the process

of classroom assessment. In this article, we describe some of the tasks, tests, and other routine classroom activities – or assessments – that provide a basis for observing, analyzing, interpreting, and judging students' learning and achievement in order to make these decisions.

What Is Assessment?

How are my students doing? Classroom assessment is the process of observing, collecting, analyzing, and interpreting evidence that can be used to draw inferences and inform decision making, helping you to answer this fundamental question. Moreover, careful consideration of the question helps to reveal that it is a question that can (and must) be answered in many different ways; classroom assessment is not a one-size-fits-all activity.

There is no single way to collect assessment evidence. Paper-and-pencil tests come to mind as the stereotypical classroom assessment, but many other options are available. These include the more traditional classroom assessments including quizzes, homework, written tests, final examinations, and so on, as well as many newer assessment methods such as portfolios, performance assessments, open-ended questions, online assessment, and computer simulations – sometimes considered alternative assessments. We should note that assessments delivered online or in an electronic format tend to be very similar to other assessments – however, with a different delivery and scoring method. Simulations are often outgrowths of more traditional-type assessments – designed to create a more realistic context in which learning and assessment can take place. For more on simulations and assessment, see the article by O'Neil elsewhere in this encyclopedia. Just as there are multiple types of classroom assessment, so too are there multiple reasons for teachers to use classroom assessment. These include: assigning a grade, quantifying the effectiveness of a new teaching method, gauging improvement toward a learning goal, and evaluating mastery of state standards.

Purposes of Assessment

Educational assessments are used for many purposes. On the one hand, teachers may use results of an assessment to form different reading groups, or assess the impact of various teaching strategies on the understanding of a

mathematical algorithm. On the other hand, assessment results may be used by organizations outside of the school walls to evaluate the effectiveness of a new district-wide reading program, or to evaluate the school as a whole. Thus, assessments can perform evaluative functions just as they can be used in a summative way to measure student achievement or in a more formative way to help refine student learning. Here we focus on the latter two, using assessment as a tool for measuring student achievement and for refining student learning within the classroom context.

Some assessments provide very detailed information about a particular student while others provide broader snapshots of achievement at the school or classroom level. The information useful to a teacher in figuring out how well a group of students understand chemical bonding differs from the large-scale assessment information designed to test mastery of the state chemistry standards. The specific purpose of an assessment, of course, plays a central role in how the assessment is designed. In the next section, we review the chief principles of assessment design. We also discuss examples of each, highlighting their particular value to teachers.

Assessment Design

Effective classroom assessment requires that teachers have a clear and complete understanding of the learning goals, have tasks that will allow them to see if these goals are being met, and finally, have the ability to interpret the evidence collected from these observations. Here, we discuss some of the important issues in satisfying each of these requirements.

Learning Goals

When designing an assessment, you must define clearly the learning goals. These learning goals encompass the knowledge or skills you wish to assess in your students. They must be articulated in such a way that students have a clear picture as to what the goals are and what they can do to achieve them. In many areas, models of cognition and learning have been developed and these can be used to guide design of both curricula and assessments. For example, in a middle-school math assessment project underway at the Center for Research on Evaluation, Standards and Student Testing (CRESST), development of formative assessments was preceded by a detailed analysis of the domains to be assessed and the creation of an algebra ontology. Experts were asked to consider which ideas were most important in their own thinking and problem solving. The expert panel first identified the big ideas that organized their thinking and work in the domain, then the subordinate or supporting ideas that elaborated and gave meaning to the organizing concepts.

An ontology showing the big ideas and relationships between them is shown in **Figure 1**. The ontology was then used to guide assessment-development efforts.

Learning goals also may be closely tied to standards set by the state, or may include the performance of a skill such as ballroom dancing, or painting. A model of knowledge to be learned (such as the one outlined above) can be used to make sure that what is being taught in the classroom is the important content. In any case, it is critical to identify the set of skills and body of knowledge that is important to know and measure. First and foremost, learning objectives must cover the most important concepts in a subject area, and assessments in turn should be closely aligned with those objectives. Assessment design must also focus on the cognitive demands of an assessment task – and not the superficial features.

Interpreting Evidence

Once the model of learning is in place, the types of inferences to be drawn from the assessments must be considered. What are the educational goals: memorization of multiplication tables or the application of acquired knowledge to a novel situation? If the former, then a complex performance task will be a poor choice, but if the latter, such an assessment would be valuable. The interpretation of evidence determines how information will be taken from the assessment task and used to produce results, ultimately allowing instructors to make inferences about whether or not their students have mastered a particular concept or acquired a particular skill.

Assessment Tasks

Assessment design – as well as the procedures for evaluating performance – should take into consideration both the learning goals and the way that evidence from the assessment will be interpreted. Of chief importance to designing a useful assessment is that it will provide you with information you can use to draw inferences. Assessments must be intrinsically connected to both the curriculum and classroom instruction and provide students the opportunity to show that they have attained a learning goal. Another key feature is construct validity – does the assessment task actually tap into the skills and content you intend it to? In other words, are you measuring what you want to be measuring? For a biology course with a learning objective focused on understanding Charles Darwin's theory of evolution by natural selection, an assessment task asking the name of the ship he sailed on around the world is poorly aligned with the objective. A task requiring students to describe the three conditions that must be present for natural selection to occur, on the other hand, will allow a useful measurement of what students know. Knowing whether a student responded

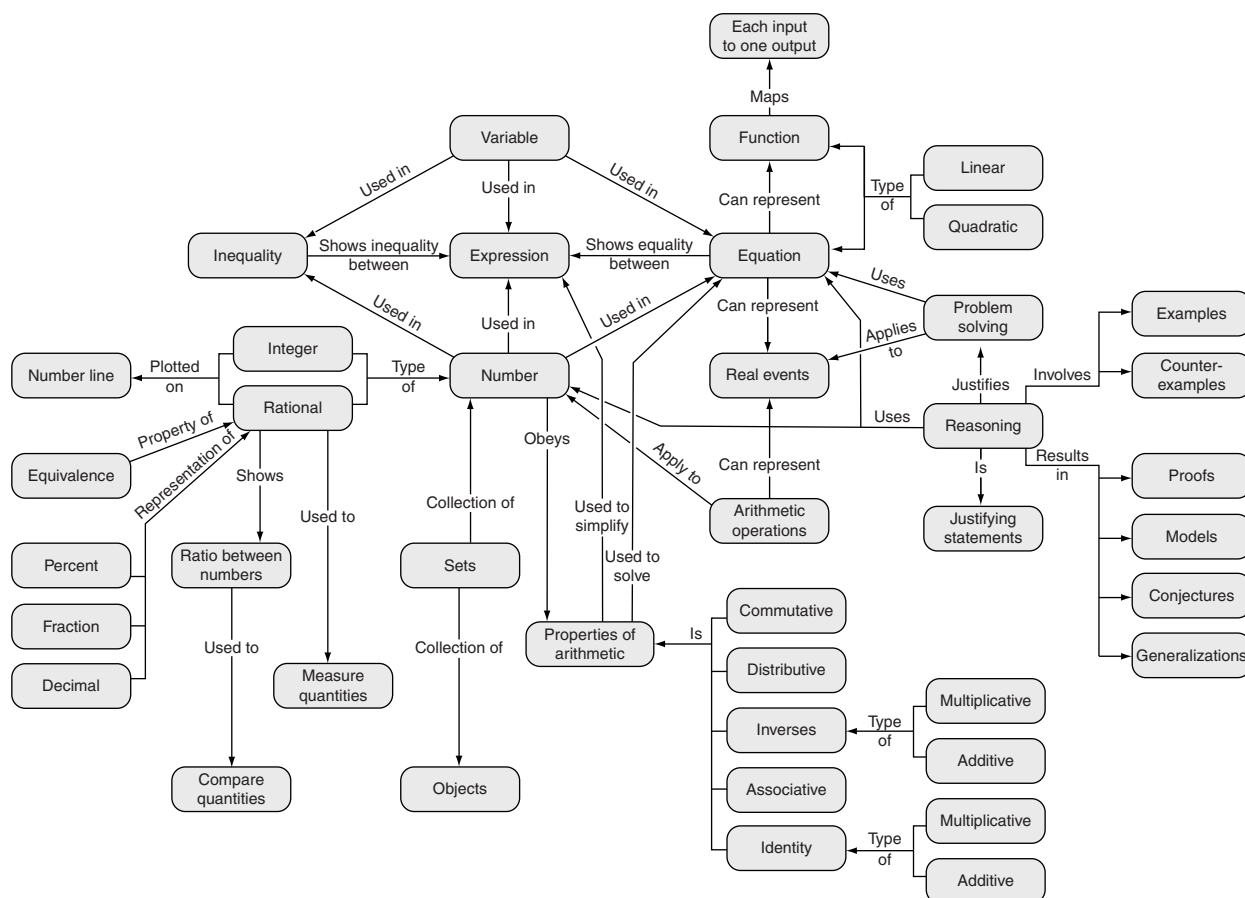

Figure 1 Map showing relationship of key big ideas.

correctly or incorrectly to the question about Darwin's ship, does not give you any information about whether they understand the concept of evolution by natural selection.

The method of generating assessment evidence – whatever it may be – varies. The common thread, however, is that an assessment should provide enough of the right information for teachers to be able to make appropriate decisions based on the results. There are many examples of classroom assessments, more than we have room to discuss here. We briefly describe the two most broad categories of assessment and then discuss some different types of classroom assessment, how they are designed, and the types of evidence and inferences we can expect to get from them.

Types of Assessment

Classroom assessments can be grouped into two main categories: summative assessments and formative assessments. This distinction rests primarily on how the information from these assessments is used. We will not focus too much here on the distinctions between the broad types of assessment used within the classroom. There is

more information on formative assessment and summative assessment elsewhere in this encyclopedia. It is, however, critical to understand that the two types of assessment described here do not necessarily align with different forms of assessment. What defines the assessment categories is how the results of the assessments are used – and not how they were collected. The key here is that formative assessment is used to make decisions that impact teaching and learning and summative assessments are used to evaluate how well a student has attained a certain learning goal or level of competency.

In the following sections, we describe some of the assessment types and techniques used within the classroom. Some of these assessment types are considered formative while some are more summative in nature and all with varying degrees of formality. What becomes clear as we survey the different assessment types is that formative and summative assessments are not necessarily mutually exclusive. An end-of-term test may be used to provide a grade for a course, but may also be used to gather information to be used in the next grade level. Teachers may not have the opportunity to use information from assessments to change their instruction mid-stream. They may, however, file the information away

until the next year when they revisit a topic with a new set of students. So we see that some assessments can be summative in the short term, but formative in a long-term way.

Among the many types of classroom assessments that we discuss below, some are more traditional and some fall into the category often called alternative assessments. For each of the assessment types discussed, we describe the features of the assessment and illustrate the potential benefits and possible pitfalls surrounding their use in the classroom.

Classroom Assessment Methods

Paper-and-Pencil Tests

For most grades, formal paper-and-pencil tests are the most commonly used form of gathering evidence about student learning. Tests can come from myriad sources, including textbooks, teacher created, online, or standardized tests designed by school districts. The selection of assessment items on such tests is critical. If students have gained a rich understanding of a particular historical period, for example, but are presented with confusing test questions, they may not be able to demonstrate their knowledge of the material. If students are not able to accurately demonstrate what they know, the opportunity for teachers to make effective instructional decisions based on the results is greatly diminished. Indeed, the use of a poor-quality assessment measure can cause teachers to make inappropriate decisions, perhaps concluding that a class has mastered a topic when that is not the case.

Paper-and-pencil tests comprise a set of questions or items. Typically, the questions on a test are independent of each other (although they may be on similar topics). Here we present some general principles to keep in mind when creating paper-and-pencil tests for use in the classroom. The overarching goal is to maximize the opportunities for students to demonstrate what they have learned, while minimizing confusion and ambiguity. There are two basic types of items: selected-response items and items where students construct their own responses. First, we consider selected-response items.

Selected response items

There are several different types of selected response items commonly used on classroom assessments, including multiple choice, true/false, and matching tasks. While there are some specific guidelines appropriate to the specific types, in general, items should focus on the learning goals previously determined, provide as much information as to how well students have mastered these goals, and be constructed in a valid way so that we know we are assessing what we want to be assessed.

Multiple-choice items

Multiple-choice items – including a question stem and a set of answer choices from which the student must pick the best one – are appropriate both for measuring factual information and for evaluating mastery of tasks with higher-level cognitive demands. Some of the limitations of multiple-choice items are that students can guess the answer, they only need to recognize the correct response (rather than generating it), and students do not have the opportunity to construct their own responses. Properly designed multiple-choice questions can, however, be a useful classroom-assessment tool and can measure a rich variety of student knowledge and skills.

Students may either choose an answer if they know it is correct. Five of the most frequently cited item-writing guidelines for multiple-choice items are:

1. The question stem should present a self-contained question or problem, for example, “How many chromosomes are there in a human gamete cell?”
2. Negatively stated stems should be used sparingly, for example, “Which of the following cities is NOT in Europe?”
3. The correct response should not consistently be markedly different than all the incorrect responses (e.g., much longer or shorter). This may give unintended clues to the students.
4. The correct answer’s position among the possible responses should be randomly assigned.
5. “All of the above” should be used sparingly as an answer choice. Students may either choose A (e.g.,) if they know it is correct and not read the rest of the answer choices, or they may only select “all of the above” if they know at least two of the answer choices are correct. “None of the above” can be used if it aligns with the goals of your assessment. Some have argued that it will cause students to be more careful about guessing one of the first four answer choices, without carefully considering each option. If students are not certain that the correct response is there, they will be less likely to pick an answer which is a close approximation to the correct one.

Contrary to common belief, a multiple-choice test is not limited to factual recall tasks. Multiple-choice items can also be used to assess complex skills, such as interpreting a graph or piece of data, or identifying a relationship between two phenomena, and so on. For example, **Figure 2** shows a multiple-choice item that requires students to analyze an experimental situation and determine how to manipulate the experimental setup in order to get a particular outcome.

Matching items

These items consist of two columns, or lists of words or phrases. The list for which students are looking for a match

Problem: In the following situation, two identical steel marbles M1 and M2 are to be launched horizontally off their respective tracks. They each leave the ends of their respective tracks at the same time, but M2 will leave its track traveling twice as fast as M1. The track for M1 can be set at any height in relation to M2.

(a) If we want the two marbles to collide, how will we need to arrange the horizontal launch tracks?

- A. The track for M1 should be much higher than the track for M2.
- B. The tracks for M1 and M2 should be at the same elevation.
- C. The track for M1 should be much lower than the track for M2.

Figure 2 A multiple-choice item constructed to tap complex cognitive processes. Adapted from Minstrell (1992).

is called the premises, and the list from which they will find the match is called the responses. The task for students is to match an entry on one list with an appropriate entry on the other list, see **Figure 3**. A matching item is a relatively easy way to assess factual material and one that takes up a small amount of space and can be easily scored.

When creating matching items, the lists should be homogenous, relatively short, have logically ordered responses, have more responses than there are premises, be all placed on the same page, and be preceded by a concise description of the match to be made. Instructions should also be clear on how many times a response can be used. It is important to have more responses than premises to reduce the likelihood that students can guess the correct answer once they have eliminated a few choices. A limitation of this type of item is that it can encourage memorization rather than deeper comprehension of concepts.

True-false items

The true-false format consists of a statement which the student must determine is correct or incorrect. There are two response categories, for example: yes/no, correct/incorrect, or true/false. The main feature is that there are two choices. A strength of this type of classroom assessment is that students can typically respond to many of these items in a short period of time and so a large amount of content can be covered in a relatively short assessment session. Limitations of these questions are that students have a 50% chance of guessing the correct answer, and in some cases, it may be hard to find statements that are unequivocally true or false. Typically, true-false items are quite short, but this should not necessarily lead to them being easy questions. Guidelines for creating true-false items include:

1. Care should be taken to not construct items that are very obviously true or false.
2. Avoid using negatives in true-false items; this may cause difficulties for students. For example, London is not the capital city of France. Students may know that London is not the capital of France but may not know if they should say true it is not, or that the statement is false.

On the line to the left of column A, write the letter of the person, from column B, with whom Tom Cruise co-starred in that movie.

Column A	Column B
___ <i>Top Gun</i>	A Dustin Hoffman
___ <i>The Color of Money</i>	B Nicole Kidman
___ <i>Far and Away</i>	C Thandie Newton
___ <i>The Firm</i>	D Paul Newman
___ <i>Rainman</i>	E Richard Gere
	F Gene Hackman
	G Val Kilmer

Figure 3 Example of a matching item.

3. The number of true responses should be approximately equal to the number of false responses.
4. The length of the statements should be similar for both the true and the false question stems. The correct statements should not necessarily be longer than the incorrect statements.

Constructed-response items

Constructed-response items require students to generate their own answer, rather than choosing a correct answer or simply indicating whether a statement is true or false. Here, we discuss two types of constructed response – the short-answer question and the essay. Although portfolio and performance assessments can be classified as constructed-response items, we discuss them separately in the next section. The major value for constructed-response tests is the ability to gain insight into what students are thinking and the depth of their knowledge.

Short answer

Short-answer items require students to answer a direct question such as, “Who is the Prime Minister of England?” Some may also write completion items which require students to complete a sentence such as, “The Prime Minister of England is _____”. Most guidelines for writing short-answer questions suggest using direct questions rather than the fill-in-the-blank option. The direct question is a more familiar format and leads to less confusion than the alternative. Typically, the answer required is very short – either one word, or a short phrase.

The strength of using a question like this is you decrease the likelihood that students will simply recognize the correct answer as they have to generate it themselves, rather than choosing it from a list of options. As with all constructed-response items, the main limitation of this type of question is that it is more difficult to score than a selected-response item. The longer the response, the more difficult it is to accurately score. The trade-off between getting richer information and reduced accuracy in scoring must be weighed.

Essay or extended response

Essay questions provide opportunities for students to create longer, more detailed responses, and to draw their own conclusions. Students have latitude in determining how they organize their response and what they include. Essay questions have the potential to provide teachers with a more detailed, richer response and can be especially useful in allowing teachers to evaluate students writing and composition skills. An example essay question is shown below:

What does scientific testing reveal about the accuracy of eyewitness testimony in courtrooms?

This question would allow you to see if students understood the limitations of eye-witness testimony and if they could adequately explain them using logical arguments.

Limitations of essay questions include that they are harder to score, rely heavily on students' writing ability, which can cause the score to reflect something other than what you are trying to measure, are time-consuming to answer, and allow for less breadth of coverage of the content taught. Guidelines for creating essay items include:

1. be clear as to how extensive the response to a question should be;
2. explicitly describe the task;
3. provide students with the point value for the question; and
4. create an example of a possible response prior to administering the assessment.

Scoring essay-assessment items is more time intensive than scoring other assessments. There may also be a greater degree of subjectivity than in multiple-choice or selected-response tests. One of the most important issues when scoring an essay is to decide if it will be scored analytically – with a more finely grained, point-by-point approach, or as a whole. When scoring an essay as a whole, teachers can use their general impression of the work, or have some criteria against which they will judge the student's response. If scoring a written composition, these criteria might include organization, clarity, word choice, spelling, consideration of the audience, and so on. If scoring an essay in a more analytic fashion, teachers

may create a scoring guide in which they allocate a specified number of points depending on the satisfaction of a particular criteria. For example, there may be between 0–3 points available for organization of the essay. An advantage of scoring an essay in a more analytic way is you can better identify areas where students need help. It may also be the case, however, that by combing through an essay looking to see if a student has satisfied particular specific criteria, a grader misses the overall feel of the essay as a whole. Both subgroups of question types – selected and constructed response – can allow teachers greater insight into higher-order thinking skills (e.g., analyzing, explaining, evaluating, and creating).

Performance Assessment

All assessments require some element of student performance – be it checking a box, selecting a response or writing an answer. Performance assessment, however, specifically refers to an assessment designed for students to create an original response that showcases their competencies that is then judged on predetermined criteria and observation. Performance assessment is an assessment approach designed to investigate how a student completes a particular task and demonstrates what he/she has learned. The components of a performance assessment are such that they build directly on learning and measure students' ability to apply their knowledge in new situations. Performance assessments have three basic features:

1. allow students to apply the skills and knowledge they have learned;
2. students complete tasks in the context of a real or simulated assessment; and
3. the assessment response or product is observed and rated according to specific predetermined criteria.

The latter point is crucial to the success of both instruction toward a goal and the performance assessment to see if students have achieved that goal. Just as you would not assign an essay without knowing what a good response would entail, so also a performance assessment must have clearly defined performance criteria against which students are compared. These criteria define the key aspects of the task and provide a guide as to how students should be both taught and assessed.

With performance assessments, it is possible to evaluate a student's ability to translate what they have learned into an action of some sort – be it a speech, speaking a foreign language, a response to art, or the art itself. These assessments may be in response to a written prompt or to directions given by an examiner. Consider students learning to speak French. After several months of study, they are called into a room and are asked to engage in conversation in French with the examiner. They have no idea ahead of time what the topic of conversation will be

and so they must draw on what they have learned and attempt to generalize it to the topic at hand. The examiner makes notes on the student's performance during the conversation based on predetermined criteria (which might include their accent, number of incorrect words, use of the incorrect tense, and so on). Following the conversation, a score is given to each of the students indicating how well each of them satisfied the various criteria.

Another example of a performance assessment might be dissection of an animal in biology class, an identification of an unknown chemical substance, or an evaluation of a historical document (see **Figure 4** for an example of a writing performance assessment).

Performance assessments can, alternatively, be more informal – perhaps based on observations made by a teacher as to how well a student can read aloud or even shoot a free throw in gym class. Performance assessments are particularly valuable when evaluating how well students can translate or transfer their mastery of a topic or task to solve a problem they have previously not had experience or practice with. Performance assessment is supposed to focus on tasks calling for complex thinking, deep understanding of subject matter, and open-ended responses. As school districts place more emphasis on higher-level thinking and problem solving, they increasingly turn to performance assessments to evaluate student learning.

Some issues associated with performance assessments, as compared with other types of assessment, are: (1) they take a long time to evaluate and require skilled judges and detailed rubrics; (2) some curricula and even teachers may not teach in a way that lends itself to performance assessment; (3) they can be difficult and expensive to develop; and (4) the amount of information gleaned from a 30 minute performance assessment may not measure up to that learned from a 30 minute multiple-choice test. The stakes become somewhat higher for students,

given the reduced breadth of material covered in a performance assessment. The student who succeeds at the task may have been lucky and the topic assessed could be the only thing about which he/she has any mastery. Given that most teachers will only have time for a small number of performance assessments, it is crucial that they are used to assess important content and content that will allow teachers to accurately generalize about their students' capabilities.

Performance assessments can be scored using rubrics, or checklists (as described for essay questions). Scoring may focus on specific skills (an analytical approach), or be very general (a holistic approach). Regardless of the approach, there must be specific criteria identified to judge the student responses against and there must be clear descriptions of the differences between score points. But if the assessment is to serve the purpose of highlighting specific areas of weakness in a student's performance, a rating scale, rubric, or separate score for a set of performance criterion may be more appropriate. Some rubrics may be a combination of a holistic score for overall quality or level of understanding followed by more specific criteria (see **Figure 5**).

Rubrics such as the above depend heavily on strong teacher knowledge. Teachers must be able to readily identify any misconceptions revealed by a student's performance and determine the degree of importance. Specific examples can be added to rubrics to help provide more structure, although doing so increases the risk of having teachers look for exact phrases or sentences, and also the idea that there is only one correct performance.

Portfolio Assessments

Portfolio assessments are a form of performance assessment created in part as a response to the need for greater authenticity of assessment tasks. In educational settings, a portfolio is a systematically selected sample of student

Writing assignment

Imagine you are taking a chemistry class with a teacher who has just given the demonstration of chemical analysis you read about earlier.

Since the start of the year, your class has been studying the principles and procedures used in chemical analysis. One of your friends has missed several weeks of class because of illness and is worried about a major exam in chemistry that will be given in two weeks. This friend asks you to explain everything that she will need to know for the exam.

Write an essay in which you explain the most important ideas and principles that your friend should understand. In your essay you should include general concepts and specific facts you know about chemistry, and especially what you know about chemical analysis or identifying unknown substances. You should also explain how the teacher's demonstration illustrates important principles of chemistry.

Be sure to show the relationships among the ideas, facts, and procedures you know.

Figure 4 Sample prompt for a writing-performance assessment in chemistry. Adapted from Baker, Aschbacher, Niemi, and Sato (1992).

Essay scoring guidelines

1. General impression of content quality (GICQ)

How well does the student know and understand this historical content?
(0–5 point global rating; 0 = no response, 5 = highest level of understanding)

2. Misconceptions (MIS)

This is measure of the amount of incorrect information, or the number of misconceptions or misinterpretations, in the essay.

Score point guidelines:

- 0 no response
- 1 one or more serious misconceptions central to the essay
- 2 at least one serious misconception
- 3 several minor errors and/or a moderate misconception
- 4 very minor misconception
- 5 no misconceptions.

Figure 5 Example of two essay scoring guidelines used in a historical-writing performance assessment. Adapted from Baker, Aschbacher, Niemi, and Sato (1992).

work intended to demonstrate growth and progression toward a specified learning goal. One of the most commonly used applications of educational portfolios are writing portfolios. These consist of collections of students writing – including outlines, rough drafts, finished essays, and various different forms of writing. These writing portfolios can be used by pupils, parents, and teachers to get a sense of development and improvement over time.

Effective portfolio assessment requires more than just the evaluation of a nonstructured collection of a student's work. As in performance and other assessments, there must be clear purposes for the work included, performance criteria on which students can be evaluated, and also rating or scoring criteria. Thus, the collection of the student work must be guided by a particular educational purpose – for example, to demonstrate improvement in writing persuasive essays. In terms of the writing portfolios, students may be working toward a particular learning goal and the portfolios can be a way of measuring whether they are adequately doing so. If the learning goal is to be able to identify conflict in a narrative passage and create one's own conflict in a written piece, the portfolio may showcase samples of student work along the road to this goal – a piece of criticism, drafts of works in progress, a response to literature, or an essay. Then when the portfolio is examined as a whole, it is possible to evaluate where the student began in terms of a particular goal and how he/she improved over a period of time.

Methods for scoring portfolio assessments depend on the purposes for the assessments. Like all of the assessments we have discussed, portfolios may serve summative or formative purposes. The particular function of the assessment should inform how it is evaluated. If the portfolios are meant to serve as a collection of student work to provide descriptive information to parents, or other teachers, the contents may not need to be scored at all. If the

purpose of the portfolio is to document growth or provide a grade for a student, some form of scoring is necessary. Most use checklists, rating scales, or rubrics to score portfolios as the amount of work contained within is typically large and scoring can be quite a cumbersome and time-consuming task.

Rating scales for portfolio assessments may include criteria such as level of understanding, quality of reasoning skills used, and use of voice or tone. When scoring a portfolio, the scoring must reflect a larger body of work than just one assignment, so different scoring criteria must be used than those used for scoring individual assignments. If the purpose of a portfolio is to determine how much a student has improved in literary-analysis skills, for example, attention must be paid to the change over time, from the early assignments to the later ones.

While portfolios can provide a unique insight into the development of skills and provide a view of a large body of work, there are challenges associated with their use. One challenge is that portfolios should be looked at as a form of performance assessment and the same steps taken in creating them. Without doing so, the portfolios will simply consist of a collection of student work with no clear way to get useful information or evidence. Therefore, there must be a clearly stated purpose of the portfolio, which will influence the type of work collected. If the purpose of a portfolio is to demonstrate improvement in writing, samples must be collected across the whole period being assessed. If only final drafts are included, there will be no way to determine if the students have improved. It must be clear from the start. Another potential pitfall of portfolios is that the support provided to students may be varied and the work in the portfolios may not reflect just the student's own work, but be a combination of student work with outside help.

Informal Classroom Observations

The classroom environment is filled with opportunities for teachers to gather valuable, but less-tangible information about students and their behavior. However, these characteristics of students (such as motivation, interest in school, or level of attention to a class discussion) are difficult to assess using formal, structured classroom assessments. Teachers frequently use informal observations to collect information about students that they are unable to collect in a more traditional way. They may want to gather information to make instructional decisions (should I speed up, or slow down this lesson?), in which case, the focus is more on the class as a whole. Or they may make an observation about an individual student, for example, “Andy does not talk much to the other students,” or “Elisabeth always puts her hand up first when a question is asked.” Unlike formal assessment, where there is an *a priori* decision made to collect information, with informal assessment, the information gathering has a spontaneous nature. Like formal assessment, however, informal assessment also requires interpreting and synthesizing information, determining what characteristic the information gathered is describing, and taking action based on evidence.

A teacher might ask – why does Andy not talk much to the other students? Then form a tentative explanation of why this might be. Next, a teacher might determine whether the current observation fits with previous observations of the student. If Andy was previously extroverted, the sudden shyness may be indicative of a change in another area. This is something the teacher must decide. There are many opportunities to gather this sort of information about a student – and this information may or may not fit with the teacher’s prior conception of that student. It is then up to the teacher to interpret the information and add it to that already collected. In this cyclical process, new information is constantly coming in and a teacher must be able to reassess a student if subsequent information contradicts the prior information. The cyclical nature of informal assessment is crucial.

Classroom observations have the benefit of providing more realistic information about student behavior than traditional formal assessments, but some limitations also exist:

1. Behavior must occur for it to be observed. So you can only measure behaviors that occur spontaneously.
2. Different characteristics for different students are also observed. So, one may get a more complete picture of one student than another.
3. The observations have a great degree of subjectivity. If a student is not paying attention and looks bored, they may not be understanding the material, they may be tired, or they may have already mastered the material and are wishing they could move on to something else.

There are many possible explanations for an observed behavior and the way the teacher responds to it relies heavily on their interpretation of the behavior.

4. Informal classroom observations are descriptive in nature. A student may be categorized as confident, lazy, motivated, bored, etc. Thus, students may be given descriptive labels that can be difficult to change even if future behavior is incongruous with the behavior that shaped the original impression.
5. Informal observations are rarely recorded. So the perceptions formed from the observations exist in memory only.

More systematic observations can improve the value of classroom observations. Simply recording observations, for example, can increase the value of such observations for helping to make educational decisions. This can be done in several ways:

1. Narrative, for example, audio/videotapes that can be coded or rated;
2. Checklist – set of predefined categories for tallying and classifying observed behavior of narrative data. These checklists can be used to gather information about how much a student understood in a lesson, or how much effort they put forth and so on; and
3. Rating scales – either graphic, numerical, or descriptive.

Validity

Teachers have at their disposal a great deal of assessment information from the many sources discussed above – some very formal, and some more informal. They use this assessment information to help make myriad decisions – about student understanding of a learning objective, about their own teaching, about the way their classroom is organized, and so on. Whether or not the assessment information available to teachers will help them make good decisions depends on the quality of that information. Classroom assessments must, therefore, allow teachers to arrive at valid inferences about their students. The accuracy of the decisions they make depends on the accuracy of the assessment.

Assessment validity is concerned with the accuracy of the inferences that teachers make about their students and may be the most fundamental consideration when developing assessments. Validity measures how well an assessment actually corresponds to what was intended to be assessed and is intrinsically linked to the inferences one makes from an assessment.

Teachers need to know how well students have mastered a particular learning goal – for example, determining equivalent rational numbers – in order for them to make effective decisions – such as how to proceed with instruction, or how well their students have mastered a concept. As it is difficult to create an assessment covering

everything that was taught in an instructional unit (or lesson, or part of a lesson), however, teachers must select a representative sample of content to be assessed.

Validation begins with the explicit statement of both the interpretations you would like to make (all students understand rational number equivalence, in the example above) and a good rationale for the relevance and importance of the material being tested (your original model of cognition). If a good model exists, choosing the appropriate content to assess becomes easier for the teacher. Not only must the content be clearly defined, but the assessment must also closely match that content. Including something extra may be just as problematic to validity evidence as leaving something out.

Consider a 12-item math test on rational number equivalence given to a group of students. The test is given after a course of study on rational number equivalence and the items are similar to those used during instruction. Validity is an overall evaluation of the degree to which we can conclude that a student scoring 100% on the 12-item test has actually achieved a full mastery of the rational-number-equivalence concepts. In other words, if the test was constructed well, and the domain or construct to be assessed was defined well, then the decision made based on the results is said to be valid. It is not the test that is valid, but the inferences made about the results of the test that are valid. If a test has a high degree of validity, one can be confident about the inferences made from a particular assessment.

In formative assessment, evidence that students have achieved particular learning goals is used by the teacher to determine the next instructional steps. Feedback is considered by the teacher and helps determine both the pace and content of subsequent instruction. So, when considering the validity of formative assessments, again there must be strong alignment between the specified learning goals and the criteria by which the evidence of achieving those goals are judged or compared. In the earlier example, we discussed a test focused on rational number equivalence. If we were to create a formative assessment in this domain, the lesson goal might be that students had to understand and be able to explain why any number multiplied by 1 is equal to that same number. So, when looking at the results of the formative assessment, the teacher would be looking to see if students understood this specific concept. If they did not, then additional instruction would be required. This assessment would be said to have a high level of validity if the intention of the lesson is well captured by the collected evidence.

Another consideration to be taken into account when designing assessments is reliability. The reliability of an assessment refers to the consistency with which the test measures what it is supposed to be measuring when repeatedly given to groups of students. An assessment is

not reliable if it yields significantly different results when administered by different individuals, or in different environments, or at different times.

In the context of classroom assessments, reliability is less of a concern than validity. Unlike in situations such as large-scale testing, teachers interact with the same students over an extended period and so there are multiple opportunities to compare assessments over time and adjust judgment accordingly. Particularly in the case of formative assessment, when there are no grades being assigned, assessment involves only the teachers and the student – no outside observers or other students to whom scores will be compared. In these cases, judgments based on the assessment are used in determining how best to proceed with instruction, and information is primarily used by the teacher to provide feedback to the student. Thus, reliability is not a strong concern. If however, test results were to be used by other people in order to compare students, reliability becomes more important. An example of this arises when applying to a new school, for example, middle school. The new schools require applicants to take a standardized test (one with consistent test materials, and administration and scoring procedures), results of which can be used to make comparisons across the whole applicant pool. This type of assessment has high reliability and is of great value relative to a comparison of students' classroom grades, which are likely to have been obtained in less-consistent ways (different schools, different teachers, different curricula, and so on). The consideration of the standardized tests scores allows students to be compared on a common measure with a higher degree of reliability.

Conclusion

There are a variety of diverse methods for assessing student learning. Some are summative, used to evaluate how well a student has attained a certain learning goal or level of competency, and others are formative, used by teachers to guide them in adjusting instruction so as to improve learning. In all types of assessment, however, it is essential that teachers have a clear and complete understanding of the learning goals, have tasks with high validity that allow them to see if these goals are being met, and have the ability to interpret the evidence collected from these observations.

We have presented here a description of some of the most useful types of classroom assessment, ranging from the more traditional paper-and-pencil tests to some alternative assessments including portfolios, performance assessments, and informal classroom observations. Each type of assessment has particular strengths and weaknesses, which we describe, that should be considered when formulating a comprehensive assessment strategy.

With proper design and implementation of classroom assessment, significant and valuable educational gains are possible.

Glossary

Clinical DA – An approach to dynamic assessment in which the tester is free to determine the nature and form of feedback that should be provided to the testee.

Dynamic testing – An approach whereby contingent feedback is provided during the test session so that learning can take place and the testee's capacity for improvement can be gauged.

Learning potential/potential for learning – One's capacity to learn when optimal conditions are provided.

Standardized DA – A dynamic approach in which the nature of contingent feedback is not determined by the clinician but follows a prespecified path.

Static testing – The traditional approach to testing whereby the tester assumes a neutral stance and any feedback on performance during the testing session is proscribed.

Zone of proximal development – A term introduced by the Russian psychologist Lev Vygotsky to describe, "... the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers."

The Need for a Dynamic Approach

When standardized intelligence tests are employed in educational settings, their primary purposes are usually for clinicians to be able to predict and describe the likely academic progress of the child, offer a diagnosis, and explain reasons for failure. Most tests used in schools have a static nature, even though, at the very beginning of the twentieth century, Binet the father of intelligence testing, defined intelligence in terms of the ability to learn. A static test, usually employing a set of standardized instructions at the outset, is characterized by its absence of contingent feedback to the child. Test scores are aggregated and global test or factor scores are interpreted in terms of the (cognitive)

abilities of the child. Scores on static instruments are indicative of the child's actual level of performance(s) reflecting learning that has taken place in the past.

Despite their continuing popularity, the weaknesses of traditional intelligence tests are widely recognized. It is often argued that such measures can underestimate the abilities and potential of children, in particular, those from minority groupings, disadvantaged socioeconomic contexts, or those with linguistic difficulties. Conventional intelligence tests are typically measures of achievement involving skills and knowledge that are generally acquired at home or in school. Children from economically disadvantaged contexts, or from non-Western cultures, are more likely to struggle with tasks and test procedures that are unfamiliar and unpractised and may become disconcerted by a formal testing situation. As a result, their performance in such contexts may be far from optimal.

A second criticism of such tests is that they typically have little utility for guiding classroom-based educational interventions. Static-intelligence test scores emphasize an end product (i.e., a set of scores of some kind) rather than an ongoing process (e.g., a description of problem-solving processes). Thus, test performance on these measures sheds little light upon how an individual learns, or fails to learn. For this reason, it is argued that rather than focusing exclusively on the end result of previous learning, cognitive testing should be concerned with underlying latent abilities, the child's potential. Testing while learning (Sternberg and Grigorenko, 2002) or learning while testing, usually called dynamic testing or dynamic assessment (DA), is hypothesized as yielding more predictive and diagnostic information about the level of the individual's intellectual functioning and the cognitive processes and strategies they employ. While dynamic approaches are employed with adults in a wide range of diagnostic activities, even for broader clinical purposes, the focus in the present article is upon the use of this approach with respect to children's learning.

A dynamic test procedure is primarily aimed at examining how training or individualized instruction during the test session(s) can lead to an improvement in a person's performance. While differing in structure, content, and degree of standardization, all such tests have one element in common; children are given hints or training to enable them to show individual differences in progress made during the process of solving a variety of cognitive tasks.

Drawing upon the Vygotskian concept of the zone of proximal development, the approach seeks to go beyond the assessment of existing capacities to examine the individual's learning potential. Rather than focusing upon where the child is now, given her previous educational experience, educationalists and psychologists should be concerned with where they can be tomorrow, given appropriate forms of education. It is considered that such potential is more likely to be revealed within a reciprocal testing situation in which assistance is offered as necessary and close examination is made of the individual's response to this (i.e., his/her modifiability) and, subsequently, his/her ability to transfer new learning to other items and problems. The aim is not to achieve permanent progression but, rather, to detect individual differences in progression during the test sessions. Clinicians typically seek to gain insights into the way in which these differences emerge, the variability or constancy in children's use of cognitive and metacognitive strategies, differences in the ways they verbalize their solving processes, their reactions to failure and success, and how they react to the provision of assistance.

Forms of Assistance

Dynamic testing or assessment can be seen as an umbrella term describing a heterogeneous group of approaches all linked by one essential element: instruction and feedback are provided as part of the assessment process (for an outline summary of major approaches, see Elliott, 2003: 29–32). Depending on the theory behind the specific model of dynamic testing or assessment, the form of feedback is either fixed, that is, it is the same for all children tested, or individualized, that is, it is applied in a tailored fashion contingent upon the child's ongoing performance in the test situation. In this latter situation, the nature and amount of assistance provided depend upon individual differences manifested within the assessment context. This instructional component within the testing situation represents a significant departure from most conventional testing procedures which usually prohibit any forms of assistance other than strictly delineated inputs geared to assist administration and maintain rapport.

Dynamic approaches can be differentiated on the basis of the timing of the provision of assistance during assessment. Sternberg and Grigorenko (2002) differentiate between the two most common forms of intervening – the sandwich and the cake formats. In the former, a pretest is administered without any assistance. After this, instruction is provided geared to helping the child maximize his or her performance. This intervention can be given in group or individual testing settings and may be standardized and scripted or left to the clinician's own judgment. Subsequently, a posttest is provided. While some testers seek to measure the differences between pre- and posttests as a measure of

learning potential, it has been noted that these gain scores pose a number of significant measurement difficulties (e.g., Sternberg and Grigorenko, 2002). For this reason, it is generally accepted that it is wiser to use posttest scores in isolation. The alternative approach – the cake format – dispenses with the pretest/posttest format altogether. Here, the testee receives assistance as soon as a significant difficulty is encountered, item by item during a single testing period. Again, intervention can be based upon a structured approach with a predetermined hierarchy of hints or individualized according to the particular understandings and perceptions of the tester. However, since there is no baseline measurement, it is impossible to predict the level of performance the child would have attained without such assistance.

Dynamic tests also differ in their content. While some have drawn upon academic areas such as mathematics, reading, and spelling, and others upon speech and language, including second-language learning, the majority of researchers in DA utilize items very similar to those used in intelligence tests. These are typically abstract in nature and are considered to tap cognitive processes deemed to underpin learning and problem solving. Many of these involve inductive reasoning tasks that require the generation of an underlying rule based upon systematic observation and comparison, in particular the examination of communalities and differences. This rule can then be used to solve future problems. Typical tasks often involve classification, series completion, or analogical reasoning using either verbal or spatial–figural modalities.

DA: Standardized or Clinical?

Yet another way to categorize dynamic approaches is to divide them into those which are predominantly clinical in their operation and others which seek to conform to rigors comparable to those of the traditional psychometric approach. To a significant extent, tester preferences reflect different agendas, purposes, and roles. Those who adhere to a traditional scientific approach tend to emphasize the importance of a strictly standardized approach in order to ensure test reliability and validity. Here, when errors are made, assistance typically takes the form of a series of scripted hints or prompts that offer progressively more guidance.

Those who emphasize a more clinical approach, usually adopting the cake format (e.g., Feuerstein *et al.*, 1979) contend that a heavily standardized procedure reduces the unique diagnostic contribution that dynamic approaches can offer. They argue that in order to maximize the power of the assistance offered, it is necessary to provide finely grained scaffolded or mediated instruction, aiming to maximize feelings of competence and efficacy

that cannot be detailed in advance as a set of preordained procedures. For this reason, the nature and extent of the assistance provided to the child is individually determined by the tester and is likely to vary from one clinician to another, and perhaps, from day to day with the same child and clinician. While this necessarily impacts upon test reliability (an element that is a *sine qua non* for most psychologists), advocates of Feuerstein's approach argue that psychometric concerns are less important than the quality of clinical insights or the magnitude of change in the child's performance.

Believing that the performance of many students on intelligence quotient (IQ) tests belied their true potential, particularly when they were from disadvantaged backgrounds, Feuerstein and his colleagues set out to devise measures that could assess the individual's modifiability. To aid in this process, a detailed list of cognitive functions (e.g., lack of, or deficient need for precision and accuracy in data gathering) were identified which were assessed by a suite of specially designed subtests that constituted the learning potential assessment device' (Feuerstein *et al.*, 1979). Although the procedure is very different, the content of many of these subtests is similar to that found in traditional IQ tests.

While the work of Feuerstein and his colleagues has had a seminal influence upon many psychologists and educationalists, his approach has failed to gain widespread acceptance by researchers or clinicians. Criticisms include the suggestion that his theory and techniques have changed little over time and thus fail to reflect more recent thinking and theorizing. Others, for example, Büchel and Scharnhorst (1993) and Sternberg and Grigorenko (2002) contend that a lack of conceptual clarity renders operationalization difficult and validation of the theory problematic. They point to the lack of a standardized approach (in test administration, analysis, and interpretation of results), weak test-retest reliability, and the poor quality of empirical studies examining the approach. Others have queried low rates of interrater reliability, which, perhaps, might be anticipated given this approach. In order to address these criticisms, some have tried to modify Feuerstein's approach by employing rather more standardized forms of assistance (e.g., Tzuriel, 2001; Lidz, 2000) although it should be noted that their use of these measures is primarily to inform intervention.

At the other, fully standardized end of the dynamic testing and assessment continuum are approaches that seek to assess learning potential that is defined in terms of the maximal degree of improvement in performance that can be achieved by training. Irrespective of whether these learning potential tests have a sandwich (pretest – training – posttest) or a cake (training-within-test) format, children are provided with the same kind and amount of instruction. This form of help appears to offer heightened predictive validity but the use of such high levels

of structured response limits its value for educational intervention.

In other tests, the nature and amount of standardized hints are more varied. Here, short-term dynamic tests employ only one test session comprising all stages – pretest, training, and posttest. Training consists of structured feedback indicating whether the response is correct or not, and, in some cases, is supplemented by very short explanations. This approach can be found in recent dynamic tests such as the Leipzig Learning Test (LLT), the *Evaluación del potencial de Aprendizaje*, and the Analogical Reasoning Learning Test (ARLT). A further measure, the Learning Potential Test for Ethnic Minorities (LEM), is a Dutch test (more recently extended to Switzerland) that is designed to assess the general cognitive abilities of young children, from ethnic minorities, who have limited knowledge of their host country's language. It provides standardized feedback that consists of repetition of items, and nonverbal feedback or demonstration appropriate to the task.

Other structured approaches provide a series of prompts or hints in response to errors or omissions. An early example of this is the graduated-prompts approach developed by Campione and Brown (1987). This approach involves the ongoing provision of assistance to the child until she is able to solve the test item concerned. Of particular interest, is the child's ability to transfer newly acquired learning to other items. The approach differs in emphasis from that typically used by other dynamic assessors in that, rather than focusing upon the ultimate level of performance that can be achieved with help, it is principally concerned with the amount of assistance that is necessary to achieve prespecified outcomes, and then transfer the learned rules and principles to novel situations. Thus the child's learning potential is not defined in terms of maximizing task performance but rather, is represented by the inverse of the minimal number of hints necessary to reach a specified amount of learning.

Resing's (1993, 2000) approach, using inductive reasoning tasks, similarly seeks to measure the minimum amount of help necessary for the child to succeed in independent problem solving. In order to draw inferences about the child's capacity for improvement (i.e., their zone of proximal development), hints are ordered hierarchically: from general, metacognitive prompts to concrete, cognitive, task-specific ones. After providing the correct answer, the child is asked to verbalize the reasons for her selection. The time taken, the number and type of hints necessary to reach a learning criterion, and posttest scores, are all seen as indicators of learning potential.

The shift toward more adaptive models of testing, in which test items presented to the child vary in difficulty according to their performance, adds to the complexity of the DA process. Computerized approaches such as the adaptive computerized intelligence learning test battery, are

one way of managing this. After correctly solving a number of target items, all operating at a similar level of complexity, the program moves to a higher level. If the child fails on the subsequent item, suggesting that the jump in complexity was too great, the next item presented is reduced in difficulty. After each response, the child receives feedback (correct/wrong), and where an error has been made, a series of prompts is provided until the right solution is found. The program can provide a detailed printout of the child's performance with information on the number of tasks completed, the number of prompts required to solve the questions, the latency times for each item (from presentation of the item until the child enters a response), and the total time taken to complete the test.

While most studies in DA have taken place in the Western world, it is possible that these approaches may have particular value in countries where children have very limited experience of traditional intelligence test measures. In a series of research studies in Africa, Sternberg, Grigorenko, and colleagues have shown how using various tests, normally employed in static mode, in a dynamic fashion can yield more meaningful information about children's intellectual potential.

What Are Dynamic Approaches Seeking to Achieve?

Despite the theoretical appeal of dynamic testing and assessment, its relatively long history – it is only slightly younger than the notion of intelligence testing itself – and growing interest in the topic, it is notable that the approach occupies relatively little space in the assessment literature and is rarely practised by clinicians. It is this relatively low profile that sees it erroneously as a novel assessment paradigm.

Elliott (2003) argues that the lack of recognition and impact of DA is, in large part, a consequence of the professional psychologist's long-standing emphasis upon classification. Some researchers and clinicians continue to see the approach as primarily representing a more sophisticated means of answering the questions for which IQ tests were originally designed. One of the key roles of the educational (school) psychologist has long been to obtain a measure of the child's intellectual ability in relation to others. Those scoring significantly below average (traditionally two standard deviations or more) were typically deemed to require some form of special education. While a seductively simple process, it is essential that data obtained from such measures do not misrepresent the individual's true capacities, especially where these are used to guide decision making about the child's educational future.

The early designers of DA (e.g., Feuerstein, Budoff) were driven by a desire to ensure that children's true potential was not underestimated because of his/her unfamiliarity

with the artificial test situation or the test content. Thus, their primary concern was to improve upon the level of prediction afforded by traditional IQ tests. Nevertheless, this is a contested area with some (e.g., Sternberg and Grigorenko, 2002) remaining unpersuaded, despite the claims of leading researchers in this field (Beckmann, 2006). To some extent, the debate is muddled by the use of differing external criteria: teacher grades, test scores, and problem-solving tasks. It is also likely that prediction will vary according to the groups that are under consideration. Beckmann (2006), for example, argues that traditional IQ test scores are likely to provide as sound an indicator of intellectual ability as dynamic measures in the case of those who have grown up under optimal conditions and who have had every opportunity to achieve a level of performance that reflects their true level of ability. In contrast, the greater predictive potential of DA is more likely to be evidenced when employed with minority or disadvantaged children.

A particular difficulty with respect to prediction concerns the role of the environment in maximizing the child's potential. Consider, for example, an underperforming child whose true potential is revealed by a dynamic measure. Should the child's environment not be subsequently modified or enriched, it is very likely that underperformance will continue and the child's potential will remain unrealized. Thus the predictive power of the measure is inherently intertwined with practitioner action.

The suggestion that notions of potential should be used to make decisions about special education (and, in a few cases, eligibility for gifted programs) has been shown to be oversimplistic as it makes sweeping and sometimes inappropriate assumptions about the nature of provision and resource levels in different types of classrooms, for example, that special-education settings will typically have lowered expectations of the children in their care (Elliott, 2003). However, given the widespread shift toward more inclusive approaches to education, particularly for those with learning difficulties, this debate is now less relevant.

In an inclusive education system, the classification function of the psychologist is less important and the value of psychological assessment would appear to lie increasingly in its capacity to optimize educational intervention, a task for which IQ tests are largely unhelpful. Thus, English educational psychologists' reports have been criticized (e.g., Wood, 1998) for being of little use to practitioners on the grounds that they tended merely to repeat what had been reported by others, and typically offered little insight or understanding about specific difficulties or guidance as to how to overcome these. As another commentator stated, education services appear to need more psychology, not necessarily more psychologists. Dynamic measures, with their emphasis upon children's response to intervention

appear to offer powerful ways by which the psychologist may address such criticisms.

Rendering observations from DAs in clinical settings into meaningful prescriptions for practice in busy classrooms is, however, rather more difficult than has often been acknowledged. While many leading proponents of DA continue to be heavily dependent upon Feuerstein's work, his theory and concepts are complex, and classroom implications are not always easy to provide or make accessible to teachers. Other clinicians appear to be drawing upon a broader and more eclectic theoretical base. Elliott (2000), for example, argues that psychologists can draw upon dynamic approaches to provide helpful accounts about the children's cognitive functioning, their dispositions, motivations and effect, and their various responses to differing forms of adult support and guidance. Such information can complement that which focuses upon academic mastery such as curriculum-based assessment (Jeltova *et al.*, 2007). In fact, the concept of response to instruction, currently being featured in the USA's system of eligibility for special education, is closely related to that of DA (Grigorenko, 2009).

However, the requirement that psychologists should be classroom-based problem solvers is tempered by their continuing role as gatekeepers to resources. Decision making based upon short and standardized procedures is seemingly more easily addressed by traditional psychometrics. The more complex, qualitative accounts that emerge from DAs may not be considered helpful by administrators whose primary concern involves resource allocation based upon clear and reliable diagnostic criteria. Furthermore, it should be recognized that the power and influence of educational (school) psychologists has long been rooted in their classificatory and diagnostic functions. Thus, greater challenge to the professional autonomy of psychologists, together with an increasingly litigious culture, may render conservative and defensive practices that draw upon longstanding approaches to assessment, more attractive.

Although it is widely accepted that dynamic measures should complement rather than replace conventional tests, it remains the view of most researchers and clinicians that this approach requires a strong psychometric foundation involving the use of standardized forms of assistance. While some accept Feuerstein's (1979) argument that the key issue for the purposes of validation is whether student functioning, informed by DA, can be shown to have improved after intervention, it is unlikely that anecdotal evidence will result in widespread acceptance. To date, we continue to have little strong supportive evidence beyond case-study exemplars, and calls for controlled studies that can provide strong support for the incremental benefit of interventions based upon dynamic, as opposed to static, assessments (Elliott, 2003) continue to go unheeded.

Future Possibilities?

Where does the future lie for DA? The development of reciprocal scaffolding techniques (Granott, 2005) and graduated-hint structures (Resing *et al.*, in press), in combination with advances in computerized testing (e.g., Beckmann, 2006), may provide new test instruments that can offer both adaptive and standardized means of investigating (variations in) item-solving processes and learning (Sternberg and Grigorenko, 2002; Resing, 2006). The difficult task ahead is to attune the hint structures of dynamic tests to classroom instructional processes and strategies. Reciprocally, teaching strategies may also be moderated in the light of the results of the dynamic test. As a result, teachers and other classroom-based practitioners would be offered a renewed view of how best to elicit optimal change in the child's learning. Such an eventuality would signal a successful paradigm shift for DA from its former (aspired) position as a superior intelligence test, to becoming a tool by which psychology, and psychologists, can offer teachers more meaningful insights for educational practice.

Instructional System Provided Feedback

H F O'Neil, University of Southern California, Los Angeles, CA, USA

S Chuang, National Taiwan Normal University, Taiwan, Republic of China

T Huang, Wenzao Ursuline College of Languages, Taiwan, Republic of China

The use of feedback to inform learners of their state and progress in learning is an essential condition of learning. Feedback is an important element for learning, motivation, and self-regulation. With feedback, learners can restructure their knowledge, correct what they do wrong, and further support their metacognitive processes. Extensive research has been done in the area of feedback in the 1960s and 1970s, mostly in the behavioristic tradition. More recently, feedback research has declined and what is published reflects either a cognitive or situated learning focus.

The purpose of this article is to review the literature on feedback provided by an instructional system. Instructional systems, defined broadly, would include teacher-led classroom environments. However, our use of the term implies some technological aspect. The article is organized into several parts. First, the authors address the definition, different types of feedback in learning situations to include both system-assigned versus learner-controlled feedback, and timing of feedback. Subsequently, representation of feedback, feedback provided by technology-based system, and dynamic testing are discussed. Finally, the authors describe a current implementation of an instructional system that provides formative assessment feedback. The authors' intent is to describe the big ideas in instructional system feedback and provide a representative research study. Only seminal or recent critical references are provided.

Definition and Feedback Type and Timing

Historically, research on feedback started with feedback provided by teachers. Pintrich and Schunk (1996) summarized and distinguished four types of teacher feedback. Their distinction was made based on the type of information included in the feedback. The types were performance feedback, motivational feedback, attributional feedback, and strategy feedback. **Table 1** gives a definition and examples for each type of teacher feedback. The table has been adapted from Pintrich and Schunk (1996: 336).

Even though there were four types of teacher feedback identified by the researchers (Pintrich and Schunk, 1996), their overall implementation in the classroom is not equal. Research found that among teachers who were observed over a 10-week period, there was a significantly high use

of performance feedback, whereas significantly lower use of attributional feedback. The situations in the classroom and in the instructional system situation were the same. Most feedback in technology-based systems is performance or motivation oriented.

According to the amount of information included in the performance feedback, feedback can be categorized into verification, elaboration, and adaptation. Verification feedback includes knowledge of response feedback, knowledge of correct-response feedback, and answer-until-correct feedback.

Knowledge of response only informs the learner whether the answer is correct or incorrect. Knowledge of correct response not only points out whether the answer is correct or incorrect, but it also goes on to inform the learner of the correct answer. Answer-until-correct feedback only informs the learners when they come up with a correct answer. Elaboration feedback provides an explanation for why the answer is correct or incorrect, in addition to knowledge of correctness of the response. Adapted feedback was designed in computer-based instruction with attention to customizing feedback for the users' needs rather than just one fixed form of feedback. Task-specific adapted feedback, which provides more information to students, has the most effective influence on students' performance. In general, elaboration feedback is better than verification feedback. Adapted feedback is also more effective than elaboration feedback. Task-specific adapted feedback works the best (Chuang and O'Neil, 2006).

Feedback timing can be immediate or delayed. Kulik and Kulik (1988) defined immediate feedback as performance feedback provided to a learner or examinee as quickly as the computer's hardware and software allow after a test item or after a whole test. Delayed feedback was defined by them as performance feedback provided to a learner or examinee after a specified delay interval following a test. Furthermore, the idea of immediate feedback and delayed feedback is relative rather than absolute. Immediacy and delay only have meaning when they are in contrast with each other. Immediate feedback can result in a faster rate of task acquisition. Delayed feedback is more effective when used with feedback focusing on task processing (Hattie and Timperley, 2007). Immediate feedback produces a better result for automatic processing, while delayed feedback is favored in deliberative and effortful processing. When students

Table 1 Teacher feedback type

Type	Description	Examples
Performance	Performance feedback provides students with information on accuracy of work; it may include corrective information	"That's right." "That's correct. Do not forget to deduct the number."
Motivational	Provides information on progress and competence; may include social comparison and persuasion	"You are getting better." "Great job."
Attributional	Links student performance with one or more attributions	"You've been working hard and you are doing well."
Strategy	Links student performance with one or more strategies used	"The tutoring after school works, you are now very good at this."

have a low mastery level of the material or acquire the material in the beginning, giving them immediate feedback may be more appropriate. Providing delayed feedback results in a better outcome for long-term retention and students who have prior knowledge or a high mastery level.

Several interpretations were proposed to explain why delayed feedback was more helpful in test-acquisition conditions. A theoretical possibility is that delayed feedback in the task serves as a repetition that reinforces the item again for the learners. Therefore, when compared to immediate feedback, the delayed feedback group was provided two chances for processing and therefore had better performance. There is some empirical support for this theory provided by Clariana *et al.* (2000). Among items with differential difficulty, they found retention of initial learning responses was greater for delayed feedback compared to immediate feedback across all items; however, the result was more pronounced with difficult items.

King *et al.* (2000) found similar evidence for an interaction of feedback type (immediate or delayed) with the nature of the learning task (rote or requiring effortful processing), immediate feedback being more effective with verbal learning tasks and delayed feedback more effective with concept learning or problem-solving tasks. The presumed mechanism for the effect is that a delay allows more time for metacognitive activities, identifying and filling knowledge gaps, and restructuring knowledge, activities that make the delayed feedback more effective.

Representation of Feedback

Representation is an important aspect in feedback research as well. Basically, two categories of feedback representation were frequently compared. They were visual and verbal representations. A visual form of feedback may include feedback in a graphic format, while the verbal form usually contains linguistic information coded in texts or words. Before discussing the visual and verbal feedback effects, an introduction of cognitive load theory and dual-coding theory is indispensable.

Cognitive load theory has two assumptions (Sweller, 2006). The first is that the human cognition process has two parts: working memory and long-term memory. The working memory is limited in terms of its capacity and duration, while the long-term memory is unlimited. The second assumption is that schemata are cognitive structures that allow information temporarily stored in working memory to be transferred into long-term memory and thus reduce working memory load. Thus, it would be expected that when presenting more information in the feedback than the cognitive load can handle, the information is lost rather than being used by the learners. This situation is called cognitive overload. Cognitive load theory offers many helpful solutions to overcome this problem. For example, two kinds of feedback representations are compared and discussed: verbal mode and visual mode. In substance, visual-audio presentation or auditory presentation of text is superior to text-only visual form. When instructors use a text-auditory presentation of the to-be-learned text, text feedback should not appear on a computer screen but audio should be used (Mayer, 2006).

As another example, research in Sweller's lab and University of New South Wales, Australia, demonstrated that by appropriately mixing auditory and visual representation modes, cognitive load was reduced for mathematics learning. Their research also revealed that a visual-audio presentation mode promotes a deeper understanding of materials than a visual-visual presentation mode. They experimented with the effects of animated graphical feedback and textual feedback on undergraduates in a computer-based simulation program concerned with the laws of motion. They found that when given animated graphical feedback, subjects performed better, completed the game task in less time, and were less frustrated.

Likewise, O'Neil *et al.* (2000) examined training applications of a virtual environment simulation. They chose understanding an F-16 aircraft's fuel system as the learning task. They fixed most basic instructional design variables and only allowed the feedback representation to vary (e.g., audio and text feedback). They have shown, consistently with other Mayer research, that the audio group did better than the on-screen pop-up text group on three measures: the transfer test, the matching test, and the knowledge mapping test.

Another theoretical framework is the dual-coding theory proposed by Paivio (1991). Dual coding suggests that human cognition is divided into two processing systems: visual and verbal. The visual system deals with graphical information processing and the verbal system deals with linguistic processing. These two systems are separate and are activated by different information. Paivio also suggested that words and pictures are coded and decoded mentally in different ways. For example, pictures are most likely to be coded both visually and verbally, whereas words are usually coded verbally rather than visually. Following these assumptions, Paivio went on to propose that if the information to be processed is coded both visually and verbally, the acquisition chances for learners would be doubled because the information is presented physically as a whole. Cognitive load theory and dual-coding theory, together, have been widely used to explain feedback presentation research. In general, these theories have much empirical support.

Feedback Provided by Technology-Based System

Computerized instructional systems with interactive multimedia features are potentially optimal for feedback delivery as all types, delays, and representations are available. A critical issue is whether feedback is assigned by the system, or system control, or the learner chooses the type and characteristics of the feedback, or learner control. The research evidence (Clark, 2005; Niemiec *et al.*, 1996) is clear, system control works better than learner control in general. The exception is that for students of high aptitude, high prior knowledge, and high motivation, learner control is appropriate.

Traditionally, the majority of computer-based instruction programs that include feedback mostly utilize performance feedback. However, a new trend in educational research is to include strategy feedback into the instructional system. Strategy feedback has been used in several studies and was effective in helping students learn (Chuang and O'Neil, 2006). In these studies, strategy feedback in a collaborative computer-based instruction task was provided to students to help them complete a science concept mapping task on a computer networked system. The adapted feedback group did better on the concept mapping than the knowledge of response feedback group. When search information was added as task-specific feedback while keeping the adapted feedback, Chuang and O'Neil found that task-specific feedback was better than adapted feedback when it comes down to content understanding and problem-solving skills, such as general searching and Boolean search.

Based on these studies, the National Center for Research on Evaluation, Standards, and Student Testing

(CRESST) researchers sought to investigate the effect of after-action review feedback on team performance in the same collaborative problem-solving tasks, that is, a computer-based searching and knowledge-mapping task. The after-action review (AAR) is a method for providing feedback to learners commonly used in military team training, for example, following a simulated tactical exercise, the action. As it is not possible to interrupt the training exercise to provide feedback on specific responses, the AAR is necessarily delayed. The AAR reviews what was supposed to happen, identifies what actually happened during the execution, and stimulates team discussion on why it happened. During the discussion, team members learn from their mistakes and benefit from the lessons learned by other team members. The AAR becomes the bridge between the completed training event and the next training event, providing learning on how to improve that enables leaders to fix training weaknesses (Meliza and Goldberg, 2008).

The military considers AAR an effective form of feedback. The literature on delay of feedback would indicate that delay strengthens the effect of feedback when the learning task requires effortful cognitive processing, for example, problem solving.

Given the United States military's success with AAR in team training, and the suggestion that delayed feedback may be more effective with learning tasks requiring effortful problem solving, AAR feedback may be effective in distance learning for the training of teams on a collaborative task with high germane cognitive load. CRESST research indicated that after receiving the AAR feedback, the AAR group, compared to a control group, indicated significantly more content understanding, problem-solving strategies (e.g., searching), and an increase in team communication. CRESST researchers also manipulated the delivery mode of the AAR feedback. The feedback was presented to one group in traditional text format and to another with partial text plus partial audio. Their study indicated that the text-plus-audio feedback had significant effect on the content understanding as measured by their map scores compared to the text-only group. Moreover, compared to the control group the text-plus-audio-feedback group performed significantly better on all measures. These results are similar to those reported by Mayer (2006).

As Mayer (2006) pointed out, the cognitive processing differs for processing spoken words versus printed words. For the text-only condition, the feedback information often exceeded the capacity of the visual working memory. In contrast, for spoken words, a person hears it through his/her ears. There is a hypothesized aural working memory. For printed words, a person first sees it through his/her eyes. There is a hypothesized visual working memory. Thus, this textual spoken condition lessens the impact on working memory and improves performance.

Effects of Feedback in Dynamic Testing

Another type of feedback in assessment that has been investigated is dynamic testing. According to Grigorenko and Sternberg (1998), "Dynamic testing is a collection of testing designed to quantify not only the products or even the processes of learning but also the potential to learn" (p. 75). In order to fulfill the claims made for it, dynamic testing involves testing not only end products but also learning processes at the same time. This type of testing is quite different from traditional, static testing which only assesses the learned end products. Another difference between dynamic testing and static testing is the role of feedback. In traditional static testing, feedback about the performance is usually not given during the test. In dynamic testing, feedback is given during the test to help assess learning. In dynamic testing, an examiner presents a sequence of gradually more difficult tasks. After each performance from the student, the examiner gives the test-taker feedback and continues until the examinee either solves the problem or chooses to give up. The basic goal of dynamic testing is to see when feedback is given whether test-takers change and how they change. This is done through provision of feedback. However, there are no agreed-upon ideas about how much information should be included in the feedback. Currently, different approaches of dynamic testing vary in the amount of information contained in the feedback (Grigorenko and Sternberg, 1998). In general, dynamic testing increases learning.

Future Trends: The Formative Assessment Challenge

Formative assessment has been a characteristic of technology-based systems from their initial implementation in the 1950s. More recently, there has been renewed interest in formative assessment in teacher-led classroom environments. For example, the POWERSOURCE intervention (Baker, 2007) is a formative assessment classroom strategy that can be integrated with an ongoing mathematics curriculum to improve teachers' knowledge and practice and, in turn, student learning. In other words, POWERSOURCE includes both a system of learning-based assessments and an infrastructure to support teachers' use of those assessments to improve student learning. Its initial testing focuses on middle school mathematics, starting in grade 6, and on helping to ensure that students possess the required key understandings for success in algebra. This focus comes from most research findings showing the relationship between unsuccessful command of algebra and subsequent academic performance, including high school graduation and college entry.

Formative assessment with feedback information is extremely influential on learning (Black and Wiliam,

1998). For example, in Black and Wiliam's (1998) meta-analysis of 250 studies, effect sizes averaged between 0.4 and 0.7. In addition, the effect sizes are even more pronounced for low-achieving students, including students with learning disabilities.

Yet, the use in classrooms of formative assessment is not so encouraging. Assessments used in districts and schools are mostly summative rather than formative. The assessment is still considered by most, if not all, as the peripheral step in the curriculum rather than a core, essential element in teaching and learning. Moreover, teachers who should be using formative assessment often lack the ability and time to develop adequate assessment practices. Further, teachers' professional training on the subject matter brings another challenge. According to research, many US teachers have insufficient mathematics knowledge to teach and to assess effectively.

The result of implementing POWERSOURCE indicated an effect size of 0.83. This effect size is large for classroom interventions. Teachers become more proficient in their subject-matter knowledge and more skilled in their use of formative assessment. They also focus their instruction better on key ideas, and, as a result, are more effective in helping students to improve their understanding, as shown by measures of student learning. Ultimately, we expect the improvements in student understanding to drive better performance on No Child Left Behind (NCLB)-mandated state tests, transfer measures, and future coursework.

Therefore, in order for formative assessment to be used efficiently on a large scale in districts and schools, it requires significant changes at the district level, and more importantly, at the teacher and student level. The districts need to make sure that teachers have enough time and resources to support their assessment-related activities. Teachers need to deepen their level of mathematical concept understanding, familiarize themselves with key ideas and skills, and use their knowledge to plan strategically for increasing students' learning. For students, change will involve understanding the feedback information provided by the teachers from the assessment.

Although feedback in general has been demonstrated to have positive effects on learning in many studies, the specific influence of feedback on cognitive processes and achievement is involved with characteristics of students and tasks. Feedback needs to be properly designed to meet the needs of students. Inappropriate use of feedback can inhibit learning (Clark, 2005).

Peer and Self-assessment

C Harrison, King's College, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This type of assessment involves students in the assessment process where they can learn to make judgments concerning their own work (self-assessment) and that of their fellow students (peer-assessment). Through self- and peer-assessment, students can become involved in an analysis and constructive criticism of their work. Taking part in peer- and self-assessment practices may also form a learning opportunity for students. This helps students develop a sense of what standards of work is expected of them by their teachers and can begin to acculturate them in the assessment process.

Classroom assessment plays a major role in how students learn and the way teachers teach. Peer- and self-assessment is not evident in all classrooms and, where it does occur, teachers have generally made pedagogic decisions with regard to its importance in learning because it requires time, preparation, and skill to implement successfully. This article attempts to pull together the research on peer- and self-assessment and is organized into three sections titled 'Peer and self-assessment in practice', 'Self-assessment is intrinsic to learning', and 'Self-assessment is part of lifelong learning'.

Peer and Self-Assessment in Practice

Moving to peer- or self-assessment is not a simple process as it requires training and experience before it can be successfully employed. A peer-evaluation experiment in a United Kingdom (UK) higher education institute found peer grading correlated positively with teacher grading. A survey of participants ($n = 70$) found that students believed their work had been marked fairly and the marks should count toward final grades (Conway *et al.*, 1993). The majority of studies compares the reliability of peer and teacher rating and indicates that peer-assessment is generally a useful, valid, and reliable method of assessment. An experiment in self-assessed learning – in which college students set their own goals weekly and prepare a self-assessment open to discussion by peers – encountered some problems in the implementation phase but was found to be the only method of achieving deep, as contrasted with surface, learning (Boyd and Cowan, 1985). This suggests that peer- and self-assessment are not simply replacements for teacher assessment but have merit in themselves.

Peer- and self-assessment can take many forms. There is a substantial amount of literature referring to peer-assessment of performance both in work settings such as hospitals and in theatrical and dance productions. Peer- and self-assessment may or may not involve discussions of quality before an assessment is undertaken. It may simply involve the use of rating instruments or checklists or mark schemes, which may have been designed – by others – before the peer-assessment exercise, and which peers simply apply to the work of their fellow students. Sometimes, self- and peer-assessments in classrooms are carried out on products or completed pieces of work, and here the purpose of making the assessment may be summative or formative, or applied during the process of learning when the main function is to utilize its formative function.

Peer-assessment is an organized event where learners of similar status consider and come to recognize the quality of work of one or more fellow peers. Sometimes, peers are asked to allocate marks or grades to a peer's work and, possibly, to provide some feedback on the judgment that they have reached. Peer-assessment can be formative or summative. Such feedback can be corrective, suggestive of alternatives, or simply confirmative. Peer-assessment is available in high volume, as there are generally more students than teachers in any class, and is generally more immediate than teacher-assessment (Topping, 2009). Peer-assessment is also perceived differently, by the learner, to feedback from their teacher. It is less authoritative and, thus, the student receiving feedback is less likely to simply accept the judgment – preferring to weigh up the options suggested by their peer and make decisions about improvements suggested. In this way, it can be an effective feedback mechanism for students as it can provide scaffolding for improvement by allowing the learner to review and renegotiate the quality of their work.

In many educational institutions, peer-assessment is introduced alongside, or as a precursor to, self-assessment. This is because teachers find it easier to model self-assessment practices through the vehicle of peer-assessment. Often, teachers begin training students in assessment by helping them peer-assess anonymous work so that they start to develop the ways and means of making judgments and of expressing these in an appropriate manner. Developing sufficient assessment-skill and literacy, to convey to others what our judgments are, takes time and experience to develop. By evolving these practices on anonymous work, supported by peers, students' self-esteem and motivation

is not affected. It is also easier for students to peer-assess rather than self-assess as they find it easier to stand back from the work and judge it for its strengths and weaknesses, rather than confounding such judgments with concern about the efforts they have put into the work or how they appear compared to their peers.

Most of the research studies that have focused on reliability of peer-assessment are set in higher education settings, with over 70% evaluated as adequate in assessment quality. Social processes that are indicative of any group of learners can mitigate against the reliability of peer-assessment, with friendship bonds, anxiety about sharing work with fellow students, or commenting on the work of others being likely inhibitors to full engagement with the process. Indeed, some studies noted a tendency for peer marks to bunch around the median. These studies also indicated that reliability was increased when supported by training and accompanied by checklists or exemplified and involved teachers in assisting or monitoring the process (Topping, 2009). While on the one hand, peer-assessment might save the teacher time in that she is not required to mark as much work, time and effort, on the other hand, are required to coach the students in peer-assessment practices.

Over the last decade, there has been a growing and sustained interest in formative assessment following the publication *Inside the Black Box*, by Black and Wiliam (1998b). Self-assessment has a key role to play in formative assessment. Black and Wiliam's (1998a) review of research on assessment and classroom learning showed a strong body of evidence that formative assessment practices raise standards in student learning. The review also indicated that such practices were only weakly developed in most classrooms. Since then, attempts to strengthen and develop formative assessment in classrooms in several countries have been underway.

The term assessment for learning was suggested by the Assessment Reform Group (1999) to try to help teachers differentiate the formative practices in classrooms from the summative ones, which tend to dominate in many classrooms. The Group stated that the research indicates that improving learning through assessment depends on five, deceptively simple, key factors:

- the provision of effective feedback to students;
- the active involvement of students in their own learning;
- adjusting teaching to take account of the results of assessment;
- a recognition of the profound influence assessment has on the motivation and self-esteem of students – both of which are crucial influences on learning; and
- the need for students to be able to assess themselves and understand how to improve.

Self-Assessment Is Intrinsic to Learning

Self-assessment is an essential component in the learning process because it helps students gauge suitable targets for their learning. This is because learning has to be done by learners, it cannot be done for them (Black *et al.*, 2003) and so helping them evolve a means of setting self-targets that fosters this process is useful. The assessment activity could be a test but, more often, it takes the form of a searching question or challenging activity, which encourages the learner to show what they know, what they partly know, and what they do not know (Black and Harrison, 2004). The assessment activity will, therefore, take place alongside or as part of the learning and is used as a tool to diagnose current understanding. Using self-assessment information requires control over one's cognitive activities or metacognition: understanding what strategies and skills are needed for a task and knowing how and when to use them (Brookhart, 2004).

This process helps them form frameworks for assessing their own work and also when applying assessment criteria to new pieces of work. When they can do this, learners are able to steer their own learning toward the learning goal because they have developed self-assessment techniques that help them in learning the ideas and developing the skills for that piece of work at the same time. By doing this, it can help students regulate their future learning and to keep on track and ensure that they are progressing. Through this ipsative process, learners realize what they have learnt and become more aware of what they need to do to improve, and – as a consequence – are often more motivated to learn. However, many studies of self-assessment do not involve students in the selection of criteria and simply ask them to rate themselves according to some preestablished scale. This inhibits students in acquiring a sense of quality that they can use to look at their own work – and that of others – in a variety of contexts. In other words, it prevents students developing self-regulatory skills.

For self-assessment to work, learners need to be able to gauge how much their current ways of working fit with expected practice. Teachers often model their expectations of students by referring to the work of previous students or by producing work themselves that would be typical of student work. This degree of anonymity allows students to engage with the work without conflicting concerns for their own or fellow students' self-esteem and, thus, discussions about work quality are entered into freely. In the UK, this approach has been popular over recent years and has been encouraged through professional development for teachers on strengthening questioning skills and collaborative group-work so that the teachers have the skills to support their students in these discussions (Black *et al.*, 2003).

When students are faced with new experiences, they need to make sense of them, and they do this by linking new ideas with old ones and then self-monitoring and generating new ways of thinking. Language is at the heart of this process. The learner uses talk to engage with the new knowledge and to try to understand it within their own personal frameworks through interactions with other learners and their teacher. They achieve a part of this through comparison with their previous thinking in that area, but the major part of this learning is in negotiating common meaning with others who are also engaged in the learning experience. Learners know when they do not understand the ideas arising within a learning situation. It is only through entering the dialog about shared ideas that the learner can begin to see other aspects of the ideas and so make judgments about where they are in their own sense-making. Nonengagement not only deprives the group of the learner's position but also prevents the learner from revealing their own sense-making to themselves. When the learner offers their emergent understanding, then they can both assess and modify their learning since movement forward – in terms of improvement or progress – rests on the reaction from others in the group. In this way, new knowledge is socially constructed (Vygotsky, 1978) and the immediacy of communication through dialog is essential in achieving this.

It is not simply that the learner hears several voices through dialog but that the ideas from individuals get challenged, molded, and reexamined through the collective voice of the group. Each individual student is able to check their own understanding against that emerging from the group dialog and, thus, self-assessment is at the centre of this process. Isaacs (1999) argues that this is not simply shared knowledge that arises from dialog but a sense of meaning that he terms “collective sensibility” that has evolved from the interactions and from which learners can capture their own sense of understanding. Because each learner brings their own knowledge, aspirations, and limitations to the interactive process, they will have a particular lens on the shared knowledge that arises through the dialog. Therefore, what they focus on, capture, and retrieve from the shared knowledge will depend on the lens they select as well as their capacity to engage with the shared knowledge as it arises. This process helps students regulate their learning. They can consider what they understand and misunderstand against the backdrop of what the group understands. This helps them locate where they are in their learning and where they need to focus to improve. So, for assessment for learning, classroom talk is an exploratory process that enables learners to match their current understanding against that of the groups and through which they might gain better understanding, since the cumulative knowledge of the group is likely to be more than that of any one individual within

the group. In engaging in the classroom talk, the learner is not only revealing to themselves their current understanding but is also providing their teacher with the evidence with regard to this and thus is also setting into action teacher planning for the next steps.

Deakin-Crick *et al.* (2007) review of the impact on students of self- and peer-assessment highlighted the need to include learners in decisions concerning how and what is being studied and insights into how the work is being assessed. In this way, learners become more informed regarding the learning process and play a more equal role with the teacher in making learning decisions. This has important messages for pedagogy since it is the ecology of learning that is called into question here and many teachers will need to change their classroom environments significantly to treat learners as co-constructors of the learning process.

A further factor to consider is self-efficacy, which involves the learner's estimate of their capabilities and their likely success in a particular task. Students with high expectations of their capability will tend to persist with tasks and put in greater effort than those with low self-perceptions. The former are, therefore, likely to be more successful and this feeds into a cycle of success for these learners (Schunk, 1995). The concern is that students with low self-efficacy believe that they cannot achieve and avoid tasks where they cannot quickly gain success, and so their self-assessment skills do not get a chance to develop very much.

Self-Assessment Is Part of Lifelong Learning

The fundamental role of school is to foster lifelong learning and to support children in learning how to learn. The dilemma for teachers is how to provide learning experiences that help children develop the skills they will need in their adulthood for a world that is in the future. Most university prospectuses, at present, include some statements relating to lifelong learning. In general, these focus on two aspects – active learning approaches and reflection. Universities increasingly expect their students to utilize active learning approaches where the student is encouraged to engage, research, and analyze ideas and to develop these collaboratively with others. Second, many courses encourage students to be more reflective by revisiting learning experiences, by making explicit how they approached the learning, and evaluating what they learnt about the task itself and their response to the task. In most institutions, this approach tends to emphasize:

- Learning-how-to-learn skills
- Disposition to learn and take learning opportunities
- Problem-formulation and problem-solving

- Ability to learn with and from others, teamwork
- Ability to identify and access appropriate resources for learning and assessment. (Boud and Falchikov, 2004)

Carr and Claxton (2002) suggest the way forward is to focus on developing learning power, which – they argue – consists of two related facets: skills for learning – which they call capabilities – and willingness and readiness to learn – which they term dispositions. The researchers believe that disposition requires high degrees of resourcefulness and reflectiveness and that these dispositions are inherent and evolvable in all children. Their approach to lifelong learning suggests that these dispositions can be trained and nurtured.

Developing these skills of self-regulation is not simple. Boud and Falchikov (2004) highlights that it is not simply a matter of adding self-assessment to the learning and assessment experiences, but of rethinking learning and assessment from a new point of view and examining the consequences for practice. The problem that arises is that, in learning-how-to-learn and becoming a lifelong learner, the capacity to become an assessor of learning is sometimes omitted, retained by the teacher, or not given sufficient focus. While self-assessment is implicit in learning how to learn, many approaches to develop lifelong learning skills fail to recognize and develop this aspect sufficiently to allow the learner to develop these skills and become more independent in their learning.

Sadler (1989) in his seminal paper on formative assessment highlights the importance of developing assessment skills in learners:

... providing guided but direct and authentic evaluative experience for students enables them to develop their evaluative knowledge, thereby bringing them within the guild of people who are able to determine quality using multiple criteria. It also enables transfer of some of the responsibility for making evaluative decisions from teacher to learner. (p. 119)

To implement this in the classroom, requires skill and time. Rolheiser (1996) suggests a four-stage plan for introducing self-assessment into the classroom that gradually skills the students in assessment practices, while gradually increasing their involvement in the assessment process.

Stage 1 – involve students in defining the criteria.

Stage 2 – explore with students how to apply the criteria to their own work.

Stage 3 – give students feedback on their self-evaluations.

Stage 4 – assist students in developing productive goals and action plans.

Rolheiser found that such approaches helped both teachers and students engage with self-assessment in the classroom and that these processes had a marked effect on intrinsic motivation.

Assessment practices can undermine students' capacity to judge their own work and this can work to constrain the lifelong learning agenda. It encourages students to look to their teachers to make judgments and inhibits them from developing their ability to assess their own learning outcomes. In other words, if students are always passing the responsibility for assessment to others, they may not acquire self-assessment skills.

... if students are to be encouraged to be lifelong learners, they must be weaned away from any tendency towards over-reliance on the opinions of others. Ultimately, in real world contexts, they must be able to judge or evaluate the adequacy, completeness or appropriateness of their own learning, so whatever assessment practices are used must be comprehensible to the learners so that they can be internalised as criteria for critical self-evaluation. (Candy *et al.*, 1994: 150)

Marshall and Wiliam (2006) introduce the notion of apprenticing pupils into the guild knowledge as the chief lever of progression and formative practice. Before learning can even commence, there is a need for learners to identify for themselves what they need to learn – taking into account a range of contextual factors – and to judge for themselves what counts as good work. The work by Orsmond and colleagues suggests that teachers need to carefully scaffold developing assessment ideas to enable students to begin to understand and utilize the criteria for quality (Orsmond *et al.*, 2002). Nevertheless, the goal must always be that students themselves can learn to judge for themselves what constitutes quality work. Students will not develop this if they do not have practice in determining appropriate standards for themselves.

There are substantial barriers to having students accept assessment as a key element of their continuing learning. The greatest of these are their prior experiences of being assessed and the ways in which these experiences influence their expectations and behavior in the present. While this has been little discussed in the literature, it appears to us to be an issue of such importance that it must be considered high on the agenda. Indeed, James (2000) suggests that grades and inadequate feedback to students on specific work can negatively impact on students' overall self-perception and confidence. If peer- and self-assessment is handled in such a way that it negatively affects student self-esteem, then this can demotivate learners and may lead to situations where students refuse to take part in future learning.

Summary

Peer- and self-assessment involve learners in the assessment process and this provides these individuals with an insight into how successful they have been in their performance

or with their product. This way of working can also have a formative function in that it can be utilized by the student formatively so that they become aware of their next steps for improvement. Teachers need to be aware that students require support and training if they are to acquire the necessary skills to assess themselves and others effectively. Involving students in peer- and self-assessment can lead to an understanding of the quality that teachers expect in pieces of work and this can lead to self-regulation of learning, which is the ultimate goal of lifelong learning.

Portfolio Assessment

V Klenowski, Queensland University of Technology, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

E-portfolios – A digital collection of diverse evidence of an individual's achievements over time involving selection, design, and reflection for a particular purpose and presentation to one or more audiences.

Portfolio – A purposeful collection of process artefacts and products that involves selection of evidence to demonstrate achievement over time and reflection on the process and value of the learning itself.

Introduction

At a time when global uncertainty is paramount and when a new form or re-form of curriculum is emerging – with content displaced by skills and knowledge acquisition by learning – assessment, too, begins to take on a new form or re-form. The focus for assessment has shifted to that which engages and promotes learning as a process rather than an assessment that focuses solely on measuring and reporting learning as product or score. The use of the portfolio for assessment offers the potential for the process and progress – integral to learning – to be included.

Portfolio use for assessment purposes – at the individual or systems level – to support different kinds of decision, process, or action “for which assessment results are used,” has expanded over recent years to include digital media. At present, portfolios are used in all phases of education from early childhood through to higher education and in diverse fields of study such as the arts, engineering, medicine, sport, and recreation. Both students and teachers make use of the portfolio for purposes ranging from improving learning, acquiring and demonstrating new knowledge and skills, to preparing professionally for employment.

This article commences with an analysis of the numerous definitions of the portfolio. An overview of the historical and contextual use of portfolios and the utility of emergent classificatory systems is offered. There has been limited conceptualization and theorizing with regard to the development and the assessment processes of the portfolio and these issues are examined. The article concludes with an examination of digital portfolios and implications for future use.

Definitions

By the early 1990s, the term portfolio had become a popular buzz word in educational contexts. It was first defined as a systematic collection of learned material (McLean, 1990). More comprehensive definitions followed (Paulson *et al.*, 1991; Linn and Baker, 1992; Herman *et al.*, 1992; Forster and Masters, 1996) with the essential features that remain constant in these definitions, including the notion of the portfolio as:

- a collection of student work;
- an opportunity for student selection of items for inclusion in the portfolio;
- active student engagement in the assessment process by demonstrating through evidence what he or she knows and can do;
- student self-assessment on progress and accomplishments; and
- reflection on the process and the value of the learning itself.

The portfolio has also been described as “expansionist” (Mabry, 1999) because of the possibility of submitting a large amount of information and a variety of modes and types of evidence for the assessment of student achievement of knowledge, skills, attributes, or competencies. In this way, the portfolio offers an alternative to more reductionist strategies such as multiple-choice-type testing where achievement is reduced to a score.

Overview

Adult Learning

In an adult learning context, portfolios have been used since the mid-1980s. In England, for example, the field of medical education recognized the value of portfolio-based learning in the professional development of general practitioners, in particular, and for the medical profession, in general. The English National Board for Nursing, Midwifery and Health Visiting developed a framework for post-registration, education, and practice which is used by members of the nursing profession to plan and implement continuing professional education. The portfolio requires record keeping and critical reflective practice and is used as a method of accreditation. The important shift in this context is toward self-directed learning as the

learner assumes responsibility for planning, managing, and evaluating the learning.

Serving teachers too have made use of portfolio assessment since the late 1980s. Teachers' competences – defined as their knowledge, skills, and attributes – are performance assessed using the assessment tool of the portfolio. It is possible to assess the level of attainment, the range of skills, and/or the progression achieved. The complexity of teaching, its multifaceted nature, and the qualities of effective teaching can be captured in the portfolio (Shulman, 1998), if the selection framework offers appropriate guidance for implementation of the portfolio and for judging the evidence included.

In the context of teacher education, the use of the portfolio for the assessment of achievements of pre-service teachers has thrived (Lyons, 1998; Chetcuti, 2007). Pre-service teachers use portfolios to develop their personal philosophy of teaching, to record their learning with regard to teaching, to engage in reflection (Zeichner and Wray, 2001, Reis and Villaume, 2002, Groom and Maunonen-Eskelinen, 2006), and to self-assess (Klenowski, 2002).

Primary and Secondary Education

Records of Achievement (RoA) – implemented in England – were an alternative to traditional forms of assessment in that profiles were used to engage students in dialog about their achievements and to record these in the form of a collection of certificates and/or work samples (Broadfoot, 1988). Arter and Spandel (1992) were the first to provide guidelines to assist in the development of portfolios for teaching and assessment purposes. These included:

- identifying the purpose of the portfolio;
- directions for selecting work samples;
- student participation;
- self-reflection in the purposeful selection of evidence;
- criteria to judge performance; and
- portfolio use to improve and to assess learning.

More specific guidelines for assessing the portfolio developed, in that, the number and nature of the selections of evidence to be included began to be specified to illustrate how the acquisition of certain abilities, understandings, and attitudes related to particular learning experiences could be demonstrated in the collection of evidence.

By the late 1990s, portfolios were beginning to be used for large-scale summative assessment purposes in Vermont (Koretz, 1998), Kentucky (Callahan, 1997), and England, Wales, and Northern Ireland in vocational qualifications programs (Wolf, 1998). Problems emerged from the lack of alignment of curriculum and pedagogy with the purposes and paradigms of educational assessment which included portfolio use. Teachers in their classroom assessment practice need to be aware of the

interrelationships of the structure of the body of knowledge, the curriculum design, and key concepts being taught to make effective use of assessment evidence to understand and promote learning.

Developments in the use of portfolios for large-scale purposes revealed a mismatch of policy contexts and assessment and learning paradigms. The tensions arising from conflicting paradigms meant that the impact of portfolio use for large-scale assessment purposes was limited. Teachers found the workload associated with classroom assessment demanding, particularly while simultaneously trying to meet the competing demands of accountability pressures of summative assessment at a systems level.

Purposes

As is evident from the range of contexts in which portfolios have been used, there is not one portfolio – there are many. They have been used for: learning, teaching, assessing, appraising, promotion, and professional development. These portfolio purposes have been described in summative terms of accountability, certification, selection, promotion, appraisal, and, formatively, to support teaching and learning (Klenowski, 2002). However, as Newton has expressed, attempts to classify and simplify can confuse rather than clarify because such classifications can suggest a level of similarity in the forms and function of the assessment used. It may be more useful to consider each purpose and context for which the portfolio is used as a category in, and of, itself.

Numerous classification systems of portfolio use have emerged in the context of teacher education (Hauge, 2006). One such classification includes: a “learning portfolio” that engages pre-service teachers in “authentic enquiry” (Harland, 2005) with regard to their teaching and records progress; a “credential portfolio” for standards-based assessment of pre-service teachers' readiness for certification and a “professional portfolio” of best work samples for interview and employment (Zeichner and Wray, 2001).

In the context of professional education programs, portfolios have been classified into four types: “a dossier portfolio” of stipulated work samples for selection or promotion to a profession or program; “a training portfolio” of collected evidence – reflective of achievements gained in the program; “a reflective portfolio” of best work to showcase the extent of achievements for promotion or further study; and a “personal development portfolio” a record of personal growth and personal evaluation (Smith and Tillema, 2003).

In higher education, four modes of portfolio implementation have been classified: upon admission, during the course, on entry to the profession, and for ongoing professional development (Meeus *et al.*, 2006). The portfolio types are categorized according to the profession-specific or

learning competencies they aim to develop. It is the learning competencies of: working independently, planning, reflecting, and modifying behavior that are claimed to add value for continuing learning. The purpose of the learning-competencies portfolio is to foster a self-directed learning process. However, these authors claim that if the learning processes involved in attaining the learning competencies are assessed and the same assessor assesses both the profession-specific competencies and the learning competencies, then tensions emerge. The implications are that, in high-stakes assessment, the purpose of the portfolio must be made clear and if, indeed, progress is to be illustrated and assessed then the assessment criteria must be inclusive of this quality. The ethics of allowing the demonstration of progress in a safe and secure manner needs to be respected.

These classifications strengthen Newton's argument that such schemes need to highlight the differences between and within purposes and supports the need to tailor assessment design to assessment purpose.

Portfolio-Development Processes

Most models of portfolio development include processes such as selection, collection, reflection, and connection. The development of the portfolio involves documenting achievements, judging work samples or artifacts for inclusion, self-evaluation of achievements, analyses of learning, experiences, learning strategies, and dispositions. The portfolio is, therefore, significantly more than just a collection of artifacts or assignments. The portfolio-development processes involved are equally important and need to be recognized. They include: critical self-evaluation, interactive learning conversations, reflection on practice and/or learning, and connection to learning experience, theory, and/or practice. These processes are integral to the development of a portfolio and are common for all purposes and audiences for which the particular portfolio can be constructed.

Selection and Collection

All portfolios include a collection of selected work samples or evidence in support of claims with regard to learning and achievements. The varying portfolio purposes of learning, assessment, or employment require different evidence to be collected and selected. A key property in selecting evidence is the relevance – the more relevant it is, the more useful it is for the assessment purpose (Forster and Masters, 1996).

In designing any assessment task, “fitness for purpose” and the positive impact of assessment on teaching and learning need to be considered (Gipps, 1994). These principles apply equally to the design of the selection framework for the development and collection of evidence for

the portfolio itself. Research into the design of a content-selection framework (Simon and Forgette-Giroux, 2000) for the use of the portfolio as an assessment instrument indicates that showcasing or selecting evidence of one's best work is inadequate. For example, in the holistic assessment of a particular competency, cognitive, affective, behavioral, metacognitive, and developmental dimensions need to be identified in the selection framework with explicit examples of entries suggested. This approach maximizes the potential for the assessment of progress and the processes of learning, yet, students require directions with regard to how to use the standards-referenced and selection frameworks when making judgments concerning their own work and selecting evidence for inclusion.

Reflection and Connection

Portfolio-based learning and assessment is characterized by valuing: one's past experience and learning; autonomy; reflection in the learning process; and the connectivity among experiences, learning opportunities, and role requirements. The importance of reflection in learning is well documented in directed and self-directed contexts (Boud *et al.*, 1985; Moon, 1999). The reflective statements or commentaries included in the portfolio are intended to illustrate how students connect their learning and/or their professional experience with the theoretical understanding gained from course work, assessment tasks, critical readings, writings, and/or research. However, such reflection has proven to be a problematic process. Students need guidelines – which specify the nature, scope, purpose, and audience when writing self-reflective statements.

Clarification is also needed regarding the value of this process in its intended positive contribution to learners in supporting them to develop confidence and competence, in the tensions created between academic and professional knowledge, and between learning and understanding of the process of becoming a professional. Reflecting on that process is to be valued and supported in the pursuit of critical, learner agency and metacognitive development. However, achieving the full value of portfolio-based learning and assessment requires teachers or mentors who have particular skills (Pietroni and Millard, 1997). They work with students or colleagues in portfolio development to facilitate the important intellectual work of moving beyond description – of what has been learnt and achieved – to analysis of what further learning and education needs to occur. The importance of critical reflection in the learning process and its role in new learning is realized through portfolio use.

Assessment and Teacher Judgment

Summative assessment of the portfolio is designed to provide quality information with regard to student learning in

a timely, manageable, and inexpensive manner without impacting negatively on teaching and learning. It is high stakes and occurs for certification and selection in a range of contexts. The selection or certification process can provide the individual with a statement of achievement for entry into a profession, to further education, or it can even lead to promotion. An adequate level of reliability is, therefore, required for comparability purposes. Consistency of standards, and consistent grading, must be implemented to ensure equity and fairness and to ensure quality in the overall assessment process and outcomes. Specified standards and contents frameworks aim to achieve a reasonable degree of reliability and to ensure a level of confidence in the results and comparability across institutions. The standards framework and attributes to be assessed are generally specified by awarding or professional bodies such as: teacher education (Lyons, 1998), higher education (Fry *et al.*, 1999), and doctoral studies (Shulman *et al.*, 2006). Professional development for continuing learning and development is also assessed using portfolios (Baume and Yorke, 2002; Orland-Barak, 2005; Jackson and Ward, 2004; Hay and Moss, 2005).

When assessing the portfolio summatively, the consistency of approach to the assessment tasks and consistency of teacher judgment in assessing the portfolio of work, using the standards framework, need to be monitored. Replicability and comparability are the key qualities (Gipps, 1994). Professional judgment in the use of criteria and standards for assessment is developed through moderation practice. Such professional collaboration helps to maintain consistent application of standards.

Holistic or analytic approaches can be adopted to assess the portfolio of work. In the latter approach, different aspects of the portfolio are assessed independently and judgments with regard to the quality of the parts are aggregated to obtain a total grade. Holistic approaches require a judgment with regard to the overall quality with attention to how the individual tasks or samples of work contribute to the whole. The multiple entries of the portfolio require the assessor to engage in iterative and cyclical processing sequences which differ to the assessment of a single work. Major threats to validity and reliability can occur when assessors omit the use of important criteria provided, “construct underrepresentation” or give particular weighting to criteria while not attending to the given criteria with equal evaluative attention, “construct-irrelevant variance” (Messick, 1995).

The use of portfolios for formative purposes to enhance learning and for professional development is well established. One of the major advantages of the portfolio for learning purposes is the opportunity it provides to monitor development and for teachers and instructors to provide feedback to the learner to fulfill a transformative function in the learning. To achieve this, there is a need for substantive conversation concerning

the qualities of the learning. This implies a facilitator role for mentor or teacher. Student self-reflection – promoted through conversation – requires interactive dialog that facilitates student recognition of strengths or weaknesses in their learning. Insights regarding how to improve are an intended consequence of this process. Thus, the portfolio provides the structure and process to facilitate understanding of one’s own learning or professional practice (Klenowski *et al.*, 2006) and for increasing one’s self-regulating capacity.

Research on how best to support learning in professional contexts and how to assess the rich, qualitative materials in portfolios concludes that a hermeneutic, interpretative approach is appropriate (Tigelaar *et al.*, 2005).

The resource implications of this approach are acknowledged any method for interpreting portfolio evidence in an equitable and responsible manner will require time and substantive conversation. Professional dialog in the context of teacher education, for instance, is fundamental for realizing the potential of this form of assessment and for engaging pre-service teachers in understanding deeply the meaning of effective teaching.

The problematic nature of the use of reflective statements in portfolios for learning and professional development has been researched and is more apparent when portfolios are assessed summatively (Chetcuti *et al.*, 2006; Orland-Barak, 2005). Students are reluctant to include authentic reflections that illustrate their areas of weakness or gaps in learning and can revert to “tactical writing” to convince the assessor of their achievements (Meeus, *et al.*, 2006). Students will not be inclined to reveal their failures (Smith and Tillema, 2003). Such reflections incorporated in the portfolio will not be reliable or genuine.

E-Portfolios

Electronic portfolios – also referred to as e-portfolios, digital portfolios, or webfolios – were developed in the early 1990s (Barrett and Wilkerson, 2004). The term e-portfolio has been adopted as an umbrella concept (Siemens, 2004) to include webfolios as in the concept of e-learning which includes web-based training. The characteristics that distinguish the e-portfolio from the paper-based portfolio are electronic access and digitization. Webfolios are static websites that make use of links to HTML-driven sites; however, e-portfolios are dynamic. They have been defined by the EDUCAUSE National Learning Infrastructure Initiative (NLII, 2003) as:

a digital collection of authentic and diverse evidence, drawn from a larger archive representing what a person or organisation has learned over time on which the person or organisation has reflected, and designed for presentation to one or more audiences for a particular rhetorical purpose.

This larger archive can also be considered an e-portfolio that contains multiple views of the contents constructed for a range of audiences. The multiple views relate to the purpose and the reader of the e-portfolio. For instance, the e-portfolio can be developed to demonstrate achievement, to meet formative or summative assessment requirements, or be used in searching for a job. The collection includes evidence of learning and performance, reflections or interpretations on the evidence, and representations of relationships between and among evidence, interpretations and evaluation criteria (NLII, 2003). An e-portfolio-management platform supports the learner in organizing the archive and enables connection to services that facilitate transactions and processes such as getting feedback from peers or cross-referencing of evidence with competency or professional standards.

Given the context of the knowledge society, the changing nature of the curriculum and of learning the e-portfolio offers features that address the changing needs of learners themselves (Siemens, 2004). E-portfolios are multipurpose, adaptable, interactive, transportable, and searchable (Cotterill *et al.*, 2004). The digital nature enables the adoption of a range of structures, facilitates cross-referencing, reduces administration, and allows secure access from a range of locations. Such features provide a rich learning tool for the learner to demonstrate their knowledge and understanding through evidence that can take the form of work samples, artifacts, or illustrations of development and learning including feedback from teachers, self-, and peer-assessments. The use of multiple media to facilitate, enhance, and demonstrate learning is epitomized in the e-portfolio.

At present, learning takes place in contexts that are no longer confined to the traditional, formal education settings. Learning on the job – in communities and through networks (Siemens, 2004) – is common and it is technology that has aided learning at a distance and in remote locations. With online teaching and learning becoming increasingly popular (Russell and Finger, 2005), there are important implications for teacher education and development. Teacher educators must teach pre-service teachers to be competent in the use of information and communication technologies (ICTs). It is, therefore, not surprising that the growth in the use of e-portfolios has occurred first in the contexts of teacher and higher education (Lane, 2007; Lind, 2007; Mason *et al.*, 2004).

Research has indicated that e-portfolios offer certain benefits to learners in that they provide valuable opportunities for reflective learning (Zubizarreta, 2004) and encourage students' active engagement with learning. The interactive nature of the e-portfolio assists learners to make connections between formal and informal learning experiences and among components within a subject, across subjects within a program, between field experiences, and components of programs. Young

learners, at present, who have a confidence with the use of multimedia are multi-processors and are more comfortable with a hyperlinked approach to thinking, as opposed to one that is linear (Brown, 2002). For such a learner, the advantages are many as they manage personal knowledge, the growth of their learning, planning, and goal setting, and take control over their learning history (Siemens, 2004). Meta-learning (Klenowski *et al.*, 2006) is facilitated when, in this context, the learner has the opportunity to review the learning in the e-portfolio and learns about their own learning – which can then be applied to future learning. It is the identification of new insights and understandings that brings about the changes.

The Web enables the user to be both receiver and sender of broadcast, which has been described as both push *and* pull (Brown, 2002). In this new learning context, it is possible for young people to engage in their preferred way of learning because multiple intelligences are honored in this medium. Students acquire skills in multiple literacies (text, screen, and image) and learn how to navigate through multiple-media genres and complex information spaces. Unlike the formal learning environments of the previous generation, young people today are engaging in discovery learning when browsing the digital “libraries” and the information available on the Web (Brown, 2002). The skills of judgment, discernment, and synthesis become crucial.

Research – in the context of teacher education – suggests that e-portfolios can help enhance pre-service teachers' meta-abilities. These include: higher-order cognitive skills, self-knowledge, personal resilience, and management of knowledge and time. Another finding suggests that a greater sense of interconnection seems to be fostered for pre-service teachers across and between disciplines and between theory and practice. There appears to be a greater acceptance for responsibility to plan, develop, and evaluate one's own learning outcomes and achievements (Broadbent, 2005).

Some of the principles of electronic portfolios as identified by (Cotterill, 2004) are as follows. E-portfolios have significant advantages over those that are paper based, they need to be considered in a social context of human processes, they must have clarity of purpose, they should be learner-focused, integral to the learning process, support lifelong learning, continued research and evaluation is essential, and one particular view will not suit all purposes.

Some of the limitations of the e-portfolio are that they preclude the inclusion of physical objects that may have been constructed by the student and, in terms of equity, students will have different levels of information technology (IT) experience and varied access to computers and Internet while the reliability of some IT systems could present another weakness.

Conclusion

While the potential value of portfolios remains significant in addressing the varied learning needs of students and professionals a number of uncertainties still remain. Further research to guide the use of portfolios for assessment needs to be conducted. There is also a need for further development of conceptual frameworks to guide the pedagogy and assessment of the portfolio that engage students in the negotiation of these. The emergence of the e-portfolio offers exciting opportunities for promoting learning through assessment that values reflection, participation, and narrative; however, research and development will remain a priority in this creative, digital, context.

Glossary

Formative assessment – An assessment that is designed to support the learning process.

National record of achievement – The government-sponsored records for English school students.

One of the central purposes of educational assessment is the reporting of learners' achievements. Although educational assessment has a key role to play in providing feedback to learners that can guide, inform and motivate the learning process, it is the role of educational assessment in communicating the results of learning – in recording achievement – that is arguably its most visible manifestation. It is certainly the most powerful in determining the priorities of students and teachers. As records of achievement, in one form or another, are the basis for certification and selection, they act as a powerful gatekeeper to opportunities for further study and for prestigious jobs.

As is now widely accepted, over the last 150 years, educational assessment has gradually become the major means by which society selects and allocates individuals, first to different schools, colleges, and universities and afterwards, to employment. Given the widespread belief in the appropriateness of such procedures to provide for the necessary social processes of educational and occupational selection, we have come to recognize and accept the consequence that what is assessed, when, and how, exerts a major influence on curriculum priorities and on the way in which learners approach the task of learning. Teachers train students to hone the skills that will be required to obtain a good result in the assessment and students focus their study on what will be tested.

Traditionally, such assessments, in the context of formal education at least, have typically taken the form of paper-and-pencil tests which are easy to administer and police as well as relatively easy to mark. Whether in the form of multiple choice, the so-called objective tests, or in the extended essay type, such written tests and examinations have necessarily emphasized those achievements that can most readily be tested in a written form – the recall of knowledge and the demonstration of understanding. We accept that it is very difficult to design tests and examinations that go beyond such intellectual operations in their

scope, if the results are to be sufficiently comparable for the outcomes to be an acceptable basis for certification and selection. The concept of the reliability of assessment, that is, broadly speaking, the degree to which a given test or assessment is likely to produce a similar result on a different occasion or with a different test, has long been deemed a top priority for any assessment with so-called high-stakes consequences. Implicitly and explicitly, the principle that assessment results must be trustworthy and defensible to key stakeholders has long been regarded as of the utmost importance, because without such trust, the legitimacy of assessment as the central gatekeeper for life-chances is likely to crumble.

It is now increasingly widely recognized, however, that the prioritization of reliability in assessment design, has tended to squeeze out the equally important issue of validity – broadly, whether the assessment addresses the full range of learning goals in a given course of study. Messick's seminal work, exploring the different aspects of validity and the consequences of the tension between validity and reliability for the educational process, has powerfully demonstrated the high price currently paid within formal education systems as a result of the prioritization of reliability over validity (Messick, 1995). If, as suggested above, what is tested is what is taught, the emphasis on narrowly framed forms of assessment and testing must necessarily constrain curriculum priorities such that some of the most sought-after learning outcomes are ignored. In short, as is often said, there is a tendency to value what is measured rather than measuring what is valued.

This is the issue, and the dilemma, that lies at the heart of the recent trend toward the development of portfolio and records of achievement schemes. Such developments are a direct challenge to the history of educational assessment over the last 100 years and more, in which by far the greatest proportion of summative assessment at least, has focused on a very narrow range of skills and achievements. The development of portfolio and records of achievement schemes reflects a recognition that many of the other achievements and skills that students have are neither assessed nor recorded, despite being in many cases, both centrally important curriculum goals and also of great potential interest to selectors and recruiters. Qualities such as the ability to work in a team, or to solve problems, and dispositions such as creativity and resilience, are typical of the aspects of individual achievement that are of increasing interest to employers in particular but

which traditional forms of assessment cannot readily address. In short, the significant mismatch between many curriculum priorities and many of the skills needed for successful employment in today's world is now fueling the search for novel ways of promoting and recording learning and achievement through innovative forms of assessment.

Reasons for Change

In their 1998 international review of developments in the use of portfolios and records of achievement, Koretz and co-workers include examples of initiatives from Canada, the United States, and South Africa, as well as from the UK. They could have easily taken similar examples from Australia and New Zealand, Hong Kong, and many other countries since such initiatives have become so widespread in the search for forms of assessment and certification that are more appropriate to today's educational goals and student's needs.

At the heart of this search, as suggested above, are the following concerns:

- the need for a better match between the content and mode of assessment and curriculum goals;
- a recognition that examination and testing systems conceived when a minority of students were able to participate in senior secondary school and higher education are inappropriate for an era when the vast majority of the age cohort aspires to high school and college; and
- a recognition that if the new curriculum goals associated with preparation for work are to become central to the curriculum, they must be recognized in assessment procedures.

As Koretz and co-workers point out, such recognition can be expressed in terms of three key themes that are broadly characteristic of the contemporary portfolios and records of achievement movement. These are:

- An increased emphasis on validity in ensuring that the full range of learning goals is represented in the assessment;
- An increased emphasis on the authenticity of the task so that the predictive validity of the assessment is maximised; and
- The encouragement of skills related to '*action planning*' including the ability to identify one's own learning needs, to set an appropriate course through the diverse range of materials and provision and to evaluate one's own achievements and recognise where one has gone wrong. (Koretz *et al.*, 1998: 303).

The last of the three themes characterizing the recent development of records of achievement identified by

Koretz and co-workers – action planning – is perhaps the most novel highlighting as it does, an increasingly important formative dimension to such new developments. What was initially very largely an initiative focusing on summative assessment issues, has now become a substantially more generic concern for greater integration of learning and assessment goals throughout the educational process.

Thus, recent decades have seen a sustained international attempt to create not only new, more comprehensive, approaches to recognizing students' attainments in the form of summative records of achievement. They have also seen a growing concern to develop new formative assessment procedures that support the development of the capacity to learn itself, procedures that help students develop the skills they will need to be autonomous and independent, equipped to manage themselves as learners throughout life.

Not surprisingly, as Klenowski describes, the representations of these aspirations in practice are hugely varied depending on the age and stage of the students concerned, the principal purpose of the assessment and often, specific national assessment traditions and institutions. One of the countries in which records of achievement and portfolio assessment have arguably been most comprehensively developed is the United Kingdom. A brief review of developments in this national context can thus offer a useful case study of the impact of the international trends currently underpinning the evolution and use of new approaches to assessment and reporting.

The Evolution of Records of Achievement in England

The first stage of this development took place in the late 1970s and took the form of an attempt to offer the otherwise unqualified school leavers who lacked any external examination credentials, a broad-based profile in the form of a documentary record of their other achievements and experiences while at school drawn both from within the curriculum and from their life more generally. It was felt that many young people could provide evidence of significant achievements and personal qualities demonstrated in activities such as social service, sport, work experience, and family and community life. Moreover, it was argued, that many of the achievements and skills so demonstrated were more relevant to future working life and citizenship than conventional examination and test success.

The idea of recording and celebrating a much wider range of student achievement rapidly developed into a major educational movement that captured the enthusiasm of teachers across the country and convinced the government to adopt a policy of offering all students an accredited record of achievement. Thus, in 1990, the

government instituted the requirement that all school leavers in England should be issued with a National Record of Achievement (NRA).

The National Record of Achievement

The NRA could be produced in both hard copy and electronic forms. Compiled by each student individually, with support from teachers, the NRA was usually given more status as a credential by the involvement of an external accrediting body. The substantial portfolio provided a detailed account of a student's academic attainments, supplemented by information about other kinds of achievement such as sporting and artistic successes, social, cultural, and service activities. Where appropriate, evidence of these achievements, such as certificates, was also included. The NRA also included a personal statement written by the student which was intended to highlight their key achievements and experiences. Given its emphasis on positive achievements and inclusivity, the NRA was intended to give all students a sense of achievement and self-esteem. Many schools organized presentation ceremonies at which students would receive their NRA and so have their achievements publicly celebrated by friends and family.

The NRA was also intended to provide useful information about the individual for recruiters. It was felt that this kind of more comprehensive documentation of a student's achievements, experiences, and skills would provide potential employers with much more useful evidence about a student's suitability for the post in question. It was also anticipated that the possession of such documentary evidence of their achievements would make it easier for students to sell themselves at interview (Broadfoot, 1998).

In practice, the outcomes of the initiative were very mixed. Many students found the process of organizing and recording the evidence to go into their NRA, tiresome and tedious. They did not believe that employers and other recruiters would take such a record seriously even when, as in many cases, the NRA bore the stamp of an external validating body to testify to the authenticity of its evidence base. In the face of continuing and often increasingly intense pressures for more high-status traditional examinations, students and teachers were prone to seeing the whole exercise as an irrelevant chore.

Records of Achievement as a Formative Assessment Tool

In one of the many ironies of educational development, however, while the introduction of summative records of achievement in England largely failed to achieve its explicit intentions, it nevertheless resulted in some significant new insights concerning the potential use of such records for formative purposes. During the 1980s and 1990s, there was a growing recognition that young people

were growing up in a world where lifelong learning would be necessary if they, and the economies in which they worked, were to prosper. This underpinned a developing interest on the part of policymakers in how such dispositions could be developed and supported. Increasingly, both those involved in education and policymakers formed the view that young people were growing up in a society in which technological change would make multiple careers and hence, regular retraining, a necessary norm. In such a portfolio society, individuals would thus need to be equipped with the skills to manage their own learning; to recognize for themselves their own strengths and weaknesses and hence, the new knowledge and skills they would need to acquire in order to fulfill their personal life and career goals.

Personal Development Planning and Progress File

Thus, the concept of a record of achievement as a one-off, summative record, which was issued to the student on leaving school, gradually became transformed into the much more generic concept of a student's ongoing portfolio of recorded evidence and aspirations. Officially, the NRA was renamed Progress File, the new name reflecting the ambition of the new scheme to train and support individuals potentially throughout their whole life and certainly throughout formal education, in the skills needed to monitor their own learning, communicate achievements to others, and to plan next steps. Thus, at the present time, throughout their time in school, college, or university, students are to be helped to engage in personal development planning (PDP). Progress file will provide them with tools which they can use to record particular achievements both within and outside the institution; record examination and test results, reflect on their achievements, and to engage in curriculum and career planning. Increasingly available as an online set of tools, progress file is intended to be a dynamic system which institutions can adapt to suit their own learning priorities and concerns.

Thus, what started out in England, at least as simply an initiative to provide a more comprehensive form of school-leaving certificate, has become transformed into the concept of PDP. This transformation has heralded a much more profound educational change than simply a change of emphasis in the recording of achievement. It has been the engine for, and the visible manifestation of, a growing recognition that the curriculum must contain more than just predefined packages of knowledge and skill. Rather, changes in society and the world of work are fueling the recognition that individual learners must also have opportunities to articulate and navigate their personal learning journeys as part of their curriculum experience.

Clearly, this evolving emphasis on recognizing and equipping the individual as the driver of their own learning, represents a fundamental challenge to traditional models of formal education. Typically, these have been based on a designated curriculum which is to be taught to students in order that they may acquire the knowledge and skills deemed to be needed for adult life. Assessment then determines whether that process of inculcation has been successful. PDP, by contrast, requires provision within the timetable for students to engage in the necessary reflection and recording – a not insignificant challenge for the instructional and administrative systems of most educational institutions. It also requires teachers to engage with students in different ways. In the development of the NRA in England, for example, it was found that real educational benefit was demonstrated where teachers were able to engage with students individually to discuss their achievements, progress, and future objectives on a one-to-one basis. This finding was particularly significant given that few students reported that they had ever had the opportunity for such a planned, one-to-one conversation with a teacher before.

More General Lessons

The development of records of achievement in England, their subsequent translation into the progress file initiative, and, more recently, into more generic approaches to PDP, highlights an increasingly widespread recognition that students' learning is likely to be facilitated by a more personalized approach to curriculum and pedagogy, as well as to assessment. As such, this represents a significant broadening of understanding concerning the range of potential purposes for educational assessment. Alongside the undiminished international importance of summative educational assessment for certification and selection, there is now widespread international recognition of the potential role of assessment as a tool to support learning. In particular, it is increasingly being recognized that the processes that support the preparation of student portfolios are likely to play a central part in supporting and equipping learners to cope with a world of rapid change.

Thus, around the world, a host of contemporary assessment initiatives reflect this growing awareness and hence, share a similar focus on PDP. Their rationale typically includes:

- an increased use of evidence in the form of portfolios for formative purposes, to stimulate student reflection, to enhance summative communication and as a base for setting standards.
- An increased emphasis on comprehensive descriptive recording rather than the use of grades and marks;
- An increased emphasis on teacher assessment in recognition that only the teacher can access students'

performance on some of the most significant competencies and

- A growing involvement of students themselves in the preparation of portfolios in recognition of the power of assessment to inhibit or enhance student motivation. (Koretz *et al.*, 1998: 303)

One of the most powerful and generic manifestations of this new approach to assessment concerns its incorporation as part of many professional training programs. As such, it provides a second case-study illustration of the more general characteristics of records of achievements and the educational trends they reflect.

A Success Story: Professional Portfolios

The training associated with preparing for a professional role typically has several dimensions. In addition to the need to inculcate the would-be practitioner with the relevant specialist knowledge for their chosen profession, there is a need to engender a particular value system and a commitment to continuing professional development. Indeed, within programs of professional training such as those for doctors and accountants, lawyers, and teachers, it has long been recognized that such professionals need to be equipped with the capacity to reflect critically on their own work so that they can be self-managing and self-motivating, for such attributes lie at the heart of what it is to be a professional. It follows that, while traditional forms of summative assessment in the form of tests and examinations can provide for the attestation of achievement in relation to professional knowledge, the associated emphasis on personal development and the creation of a professional identity requires a rather different set of assessment tools.

Thus, in recent years, many such training programs have involved the preparation of a reflective portfolio of evidence in which the trainee professional regularly engages in critical reflection on their performance. The resultant dossier often forms part of the final summative assessment for the program as the basis for judging not only whether the student has demonstrated sufficient understanding of key professional issues and skills in their reflective diary, but also whether they have sufficiently developed the skill of reflection itself. (Klenowski, 2002).

Electronic Portfolios

The ready access to e-learning platforms in recent years has added a new dimension to such developments with the increasing use of electronic (e)-portfolios. The ability to incorporate within e-portfolios a much wider range of types of evidence, such as sound recordings and video

clips, has served to extend still further the potential authenticity of such portfolios as records of both achievement and the student's critical reflection. As such, these developments represent the latest stage in the search for the best possible match between espoused learning goals and assessment procedures. Moreover, it is not hard to see how the skills developed for such program-specific portfolio preparation may in due course complement the more generic skills that an individual will need to manage the kind of overarching progress-file type of portfolio related to their learning career as a whole.

Transcripts and Transferability

The developments referred to above hardly merit the term assessment in its traditional sense. In place of the familiar emphasis on the standardization of tasks and the comparability of outcomes in the form of grades and marks, is a highly individualistic, often narrative-based record that does not readily lend itself to either of the traditional approaches of norm or criterion referenced assessment. It is rather an ipsative assessment – a term that echoes the emphasis on a more personalized curriculum approach referred to above. The familiar distinction between formative and summative assessment also begins to break down in relation to portfolios since the latter is likely to be explicitly formative while in preparation, yet are also often used for summative accreditation purposes as well. The result is the relatively frequent juxtaposition of two different types of evidence in one overall record.

A similarly hybrid approach is developing within the European Union where the use of a transcript that documents a student's achievements while at university is now a requirement. The Diploma Supplement, as it is called, is intended to provide a common currency of assessment information in all the countries of the Union. Typically, these transcripts contain the conventional mixture of coursework and examination results. Increasingly, however, students are also incorporating a more broad-based portfolio of other accredited achievements and evidence of relevant experience. Currently the Higher Education Achievement Record (HEAR), being piloted in a number of English Universities, presents a good example in this respect.

The Future for Records of Achievement?

The coexistence of different kinds of assessment data in one record of achievement highlights the central issue that will define the subsequent evolution of such initiatives. On the one hand, there is now a substantial body of research evidence that documents the educational benefits of portfolio assessment as described elsewhere in the

encyclopedia. The use of portfolios, when students are appropriately supported and trained, appears to provide both a positive motivational effect and the capacity to enhance students' learning. This evidence is arguably in turn further reinforced by the much larger body of research evidence testifying to the role that formative assessment more generally can play in supporting learning and learners. (James *et al.*, 2007; Black and Wiliam, 1998; Crooks, 1988) There is now compelling evidence to suggest that the use of assessment to support learning is potentially just as significant as its role in measuring learning outcomes, and that new assessment tools, such as portfolios and records of achievement, have a significant part to play in such developments.

However, to the extent that the role of assessment is defined as one of supporting learning, rather than simply measuring it, there are significant implications for prevailing modes of educational organization and system delivery. These focus on problems of implementation and practical constraints on the one hand, and the continuing hegemony of apparently less-resource-hungry and well-understood existing mechanisms for selection, allocation, and accountability, on the other.

Practical Issues

It is implicit in the above account of the development of records of achievement in England, that one of the biggest hurdles to be overcome has been that of finding time in an already-crammed curriculum for students to engage in reflection and recording and even more difficult for time to be found for teachers to talk to students individually. Over and above these practical problems, the need for significant training for both teachers and students if they are to engage positively with these new approaches, and the scale of change management required, is readily evident. Portfolios and record of achievement schemes of all kinds are almost always resource hungry in terms of both time and skill. Thus, to be successful, they require the whole-hearted commitment not only of the students and teachers involved, but also of the institution as a whole and indeed, in the end, of the educational system itself.

These findings are reinforced by the findings of Anderson and Bachor (1998) reviewing the use of portfolios in Canada and by Stecher in reviewing developments in the United States. In both cases, the authors also highlight the fact that the impetus for portfolio use is their perceived instructional benefits in encouraging students to take responsibility for their own learning; that the use of portfolios is being driven by their perceived educational benefits for students rather than by external assessment agencies. Stecher (1998) provides further validation of the difficulty of using portfolio assessment in high-stakes accountability contexts. Moreover, Koretz *et al.* (1998) identifies a tension between the role of portfolios in

encouraging improved instruction and the difficulty of using portfolio assessment for large-scale external assessments.

Tensions and Contradictions

It is perhaps ironic that the development of the new approaches to assessment and recording described here has been paralleled in many countries by a significantly increased emphasis on the accountability of educational institutions. Such accountability arrangements typically involve some form of national testing and the use of the results of such testing to judge the quality of individual institutions and teachers, as well as the system as a whole. There is now compelling evidence that such testing negatively impacts the way in which individual students engage with the learning process and further compounds the washback effect of focusing energy on teaching the test. As Mabry and Stake point out: “in the past several years, the few have become the many, decrying and documenting the disastrous effects of large-scale, high-stakes standardised and criterion-referenced testing,” their “invalidity and negative educational effects,” and their “obvious failure . . . to improve education” (Mabry and Stake, 1994: 33). However, despite such criticisms, there is little indication that the more traditional roles of assessment associated with accountability and selection are reducing in significance.

Thus, in educational systems around the world, there is currently an increasing tension between the continued dominance of a testing discourse on the one hand, with its characteristic emphasis on reliability and comparability and, on the other, the emerging and powerful evidence in support of more personally empowering forms of assessment as the key to motivating and preparing learners to acquire the skills, attitudes, and dispositions they and their societies will need if they are to be successful in the twenty-first-century world.

This tension is likely to exert a strong influence on the future development of portfolios and record of achievement initiatives. High-stakes, summative tests exert an overwhelmingly powerful influence on students’ priorities. In this context, records of achievement and other more descriptive, personalized forms of assessment are likely to continue to suffer from not being valued by students posing

the question whether there is any real future for such developments in the mainstream of formal education.

Introduction

Assessment principles and practices across all sectors of education have many characteristics in common. This article is mainly about those aspects that are distinctively related to higher education.

Internationally, interpretations of the scope of assessment in higher education differ widely. The broadest use is probably that in the USA. As an unadorned term, assessment includes the evaluation of all aspects of an institution, including teaching and course quality, research output, health services, academic support, physical facilities, public relations, and financial performance. The student side includes admissions, retention, credit transfer, and student learning. The narrow interpretation focuses specifically on the appraisal of student learning in courses that lead to academic degrees. The other matters listed above are then referred to as institutional research. The narrow interpretation is in widespread use outside the USA, and is the one adopted for this article.

Assessment inevitably shapes how students approach learning, including what they focus on and how they go about learning it. Information arising from an assessment event may be used for a variety of purposes, including:

- formal certification of achievements as grades which are recorded on student transcripts for future reference

or decision making in employment, professional licensing, or admission to advanced studies;

- provision of diagnostics and advice to students on how they could improve their work or performance, this feedback ideally being clear, informative, timely, and relevant;
- evaluation of the quality of teaching, the curriculum, and course structure, with a view to facilitating their improvement; and
- accountability to the institution, accrediting bodies, employers, and the wider community.

Of the various purposes for assessment, the first two are primary and have their own descriptors. The summary record of attainment is said to be summative, whereas assessment geared specifically toward improving student performance is formative.

The Assessment Process

The typical pattern runs as follows: faculty design (or adapt from elsewhere) specific tasks relevant to a course of study; students respond to those tasks; the teacher or a competent marker appraises the quality of the student responses; and the appraisal is coded in compact numerical or verbal form.

(For objective tests, scoring may be simplified by using a template or high-speed scanner.) The assessment process produces primary data from which an inference is made about the learning that has taken place by the end of the course. Assessment tasks may take a wide variety of forms, and responses may take a variety of formats. These include class quizzes, multiple-choice or other objective tests, field or project reports, take-home essays (term papers, assignments, etc.), seminar presentations, studio works, creative designs, specialized artifacts, clinical consultations, client interviews, professional performances or procedures, and traditional time-restricted examinations.

Summative performance in a course is usually reported as a grade on a fairly coarse scale. The anchor points on the scale may be denoted by words (distinction, merit, credit, etc.), numerals (7, 6, 5, etc.), or letters (A, B, C, etc.). Pass/fail grading has only two steps on the scale; expanded scales can have ten or more. The scales may be fixed by the higher education institution, or be required to comply with provincial or national policies. Where grade scales or systems differ across higher education institutions, equivalence tables allow conversion to facilitate student transfers with academic credit. For example, the European Credit Transfer System, by adopting a uniform scale across all signature countries as part of the pan-European Bologna Process, has student mobility across Europe as one of its major aims.

Grades may also be used for reporting appraisals of individual student responses to assessment tasks. For this purpose, the scale may be elaborated by the use of \pm symbols. Alternatively, numerical marks or scores on an arbitrary fine-grained scale such as 0–30, or 0–100 may be used for individual responses to assessment tasks. A course grade is then calculated by adding marks sourced from different assessment tasks. Nonoverlapping ranges of aggregate values correspond to the various grades. Because the same grade is assigned to all total scores within a given range, a course grade represents an achievement band, not an exact position.

A grade point average (GPA) is calculated as a weighted average of all the course grades a student receives over a specific period of time (such as one semester) or over a number of completed courses (such as an entire degree program). The weightings reflect the relative magnitudes of the contributing courses. Literal and verbal grades are given numerical equivalents for purposes of calculating GPAs. Institutional rules based on grades typically govern the conditions under which students may or may not progress to more advanced studies. Too low a GPA, or too many marginal or failing grades, may preclude a student from enrolling. Consistently poor performance may lead to a period of exclusion from the degree program or the institution.

The second primary purpose of assessment is formative. In ordinary discourse, formative activity is associated

with forming or shaping something during developmental stages in order to bring it closer to a desired end. Formative assessment is concerned with how the outcome of a competent appraisal of a student work can improve the quality of the learner's future performance. Feedback is the main formative tool, and consists of information about how successfully something has been done, with advice as to how it could be improved. The primary distinction between formative and summative relates to purpose and effect, not to timing. In a purely technical sense, any feedback that makes no contribution to the improvement of future performance is not formative, by definition. However, information arising from an appraisal may serve other (nonimprovement) purposes, such as explaining the grounds for a particular mark or grade that has been awarded. A frustrating aspect about feedback is that, despite the effort that generally goes into providing comprehensive guidance to students, little improvement often occurs. Turning this state of affairs around is an enduring challenge. The design of course assessment programs (including timing) is crucial if the likelihood of improvement through assessment is to be increased.

Although assessment tasks should closely reflect the purposes and aims of each course, the actual tasks specified form only a sample of all possible tasks that could be devised. Furthermore, students make real-time choices as to how they will respond on a particular occasion, and markers typically differ somewhat in their judgments about quality. The combined effect of these and other factors is to introduce a level of fuzziness into allocated marks and grades, and consequently into inferences about learning. Quite apart from the coarseness of typical grading scales, small differences in marks between students do not necessarily reflect differences in underlying achievement.

Because a mark or grade can tap into learning only indirectly through inference, it is different in nature from a physical measurement, such as the length of a table. The assessment procedures in all disciplines employ blunt instruments that invariably rely on subjective judgments at various stages in the process. As a consequence, marks can never be made exact, or equivalent to one another. Further discussion of this topic quickly leads into consideration of the basic measurement concepts of reliability and validity, and is not pursued here.

If different assessment programs were developed and implemented for the same students in the same course, and if it were assumed that students could respond to them as independent events, scores for individual students would rarely be identical. There is always some margin of error. Despite this, marks are typically regarded as strictly accurate measurements once they are allocated. Marks are also treated as if they were units of currency, with those from different sources being given equivalent worth. Numbers, in particular, have the appearance of objectifying judgments. Measurement error can be reduced (but

not eliminated) by paying strict attention to the design of assessment programs, quality control on the assessment task specifications, and the proper calibration of markers. However, these three aspects do not account for all potential sources of error.

Reference Frameworks

Universal scales with standardized units for measuring academic achievement do not exist in higher education. Assessing and grading student work always take place within a frame of reference which confers meaning on the marks or grades. Each reference framework consists of a set of conventions, rules, and procedures for deriving, interpreting, and using the grades. The most commonly employed are the norm-referenced and the criteria-based (criterion-referenced) frameworks. The norm-referencing framework has a long history. It is so deeply embedded in higher education practice that, for many teachers, at least elements of it seem to come naturally.

In principle, norm referencing uses the performance of a group of students as the comparative background for grading decisions, the group usually being defined as all of the students enrolled in a course at one time. Technically, it is the group performance that constitutes the norm. Marks or grades reflect not only how student performances are ranked but also their relative separation. If all course groups could be assumed to perform at roughly equivalent levels on the whole, a reasonable corollary would be that the top performers in each group deserve the same grade. The same would hold true for middling performers and for poor performers. Despite differences in course content, structures, and outcomes, and although the top performers in one course are not necessarily the same students as the top performers in another course, this presumption prevails. Norm referencing is simple to conceptualize as a principle and to operationalize.

Institutions that embrace norm referencing have procedures in place to ensure that the grades in different courses are apportioned according to the same basic rules (grading on the curve). For example, only the top 10% of students (within some acceptable tolerance) might be awarded the highest grade, the next 15% the second-highest grade, and so on. In this way, the proportions of the different grades awarded are subject to fairly strict control. The proportions are determined essentially arbitrarily but, once fixed, apply to all courses. The aim is to ensure that the relative worth of grades is comparable across the institution. This principle depends only on the apportionment of the various grades, so the shape of the frequency distribution of the underlying marks is irrelevant. It could be symmetrical and bell shaped; it could be skewed, or even rectangular. There is no intrinsic connection between norm referencing and the normal probability distribution in

statistics, although it often happens that the distributions of aggregate scores for large classes turn out to be roughly bell shaped.

Norm referencing provides perhaps the simplest type of brake on grade inflation, the latter referring to the award of undeservedly high grades. The basic principle is that limiting the supply of a desirable commodity (high grades) is a way of maintaining its relative value. This is the classic market approach to determining worth or value in contexts where there are no absolute reference points or independent standards. Regardless of how well students perform individually, or the caliber of the performance of the cohort as a whole, the apportionment of grades is always about the same.

Not surprisingly, this grading framework is the subject of concern for several reasons, some of which have ethical substance. Among them is that it is unfair to compare a particular student's performance with the performances of others in a group over whose membership neither the student nor the teacher has any control. Strict norm referencing avoids considerations of academic standards in any absolute sense. It is also structurally self-adjusting in that it is automatically blind to such factors as the quality of teaching and the design of the assessment program. This could be seen as either a liability (because it masks poor teaching and assessment) or a strength (because it compensates for them), depending on the observer's vantage point. Even where norm referencing is not embraced explicitly as the grading framework, norm-based practices are still common. Two examples are: reading through a set of essays to set a baseline of expectations before beginning to assign marks, and scaling marks (using the mean or standard deviation) before or after combining them.

Criteria-based assessment has a shorter history than does norm referencing. The theoretical basis is less familiar and not as well developed. The basic idea is to award marks and grades according to absolute levels of academic achievement. In this context, absolute means that the quality of work submitted is compared with fixed reference points that, once set, function independently of other students' performances and remain stable over successive offerings of the same course. Hypothetically at least, all students in a defined group could be awarded the highest grade if their work were of sufficient quality to meet or exceed the required threshold level. In practice, of course, this is unlikely to occur, although probability theory suggests that, other things being equal, it is more likely for very small groups. The criteria (and associated standards, if applicable) are communicated to students at the time the task is set. Students can then attend to them while shaping their work before submitting it. Apart from this proactive role, the stated or implied aims of using explicit criteria include: increasing the transparency of the assessment process by enabling students to understand the

grounds on which grades are determined; making more efficient and timely provision of specific formative feedback; and minimizing grade inflation by ensuring that grades directly reflect the quality of student work. The latter can be achieved only when appropriate standards are set for the various grade levels, which is a challenging task in its own right.

In practice, criteria-based grading has been open to a wider variety of interpretations than has norm referencing. Interpretations differ fundamentally on their definitions of what constitute the criteria. The first of three examples given here is the criterion as a threshold aggregate score. For example, on a 0–100 scale, an aggregate score in the range 90–100 might correspond to high distinction, 80–89 to distinction, and so on. With this interpretation, a score of 90 forms the (minimum) criterion for the highest grade. This approach to grading has long been common practice in higher education, predating the criterion-referencing label by decades. As it fails to address the issue of actual achievement standards and makes few, if any, assumptions about the basis on which the underlying marks are derived, it is not intrinsically criteria based.

The second interpretation of criteria is as specified qualities of performance set out as verbal descriptions. For example, the highest grade in a course may correspond to the following description: clear attainment of all course objectives, with complete and comprehensive understanding of course content; development of relevant skills, and intellectual initiative to an extremely high level. Although these provide some guidance, key terms such as clear, complete, and comprehensive are open to interpretation. In the third interpretation, the criteria are the characteristics or properties of responses to assessment tasks. For written works, relevant criteria could include: support for assertions, validity of arguments, logical organization, and quality of presentation. To date, the lack of a common understanding of what criteria based means and implies for practice has inhibited high-quality discourse, research and development among scholars and practitioners.

In recent decades, approaches to higher education teaching and learning have shifted away from being teacher centered (a retrospectively applied label) and toward being student centered. Assessment that is student centered not only incorporates a wider range of assessment techniques but also reflects a resolve to bring students into an appreciation of how extended or complex responses are graded. Criterion referencing forms part of this international movement. Particular tools used to facilitate these approaches include the use of rubrics, grading schemes, and scoring guides that typically set out the criteria which the markers will use in appraisal, along with other information such as standards on the criteria, the weightings of the criteria, and how levels on the individual criteria are combined into aggregate scores.

Besides the norm-referenced and criteria-based grading frameworks, other informal bases of reference can affect the actual assignment of marks for individual students at the point of appraisal. These tend to operate implicitly rather than as formal frameworks. They include awarding bonus marks to reward risk taking, dogged persistence, significant effort, or substantial improvement. (The last of these is a simple form of self-referencing.)

Approaches to determining academic achievement standards vary widely. Among the subissues is the authority of individual academics to determine standards. Internationally, perspectives on this extend right across the spectrum, the positions at both ends being strongly advocated and defended by their respective constituencies. At one end is the view that academics, departments, and institutions are accountable to students and society for the standards they employ, and that broad consistency across courses is both desirable and achievable. It is therefore entirely appropriate for institutions to formulate and implement policies and procedures aimed at establishing and maintaining the meaning and worth of grades. Although academics often retain substantial degrees of autonomy in the design of assessment programs and the award of grades, many universities insist on collaborative review procedures intended to assure the integrity of grades. These procedures include having all assessment task specifications reviewed by peers; requiring cross-marking (moderation) of completed student work in all courses; reviewing all distributions of grades to protect against grade inflation; and using networks of external examiners to scrutinize the structure and content of assessment tasks along with samples of actual student works (with the grades assigned). This list reflects aspects of both norm-referencing and criterion-referencing frameworks. Regardless of the grading framework adopted, they have in common an underlying concern with the maintenance of academic achievement standards. Ultimately at stake, of course, are institutional reputations.

At the other end of the spectrum is the view that, because academics are highly qualified professionals and presumed leaders in their respective disciplines and fields, they are in an authoritative position to judge the quality of students' work in the courses they teach, without interference. This position may be reinforced by contextual conditions. In particular, the sovereignty of academics to decide grades can be viewed as a fundamental aspect of academic freedom (essentially a professional norm), or the right to free speech (a national constitutional right), or both.

Quality of Assessment Programs

Attention to the design of all elements of the assessment program for a course is critical in obtaining high-quality data, regardless of the assessment approach used. All

assessment designs involve sampling from the possibilities. The initial step is to tap into course outlines, objectives, and desired outcomes to identify those aspects of the curriculum to be assessed. Especially important are the relative emphases on lower order outcomes (memorized knowledge, understanding, and application) versus higher order outcomes (analysis, critique, design, and synthesis). Certain assessment task types lend themselves more to particular classes of outcomes than to others, so getting a good match is crucial. However, the lines are not entirely fixed, so generalizations about the appropriateness of various types of response formats are inevitably broad brush. Multiple-choice items often default to testing factual knowledge. However, with time and expertise they can be constructed to test higher order intellectual outcomes. Similarly, essays are often suited to assessing complex cognitive outcomes. However, the literal interpretation of many essay task descriptions allows them to be fulfilled by regurgitating memorized knowledge. Ultimately, it comes down to two factors: how precisely the task specifications are formulated and, for nonobjective items, how strictly the marker holds student responses to the task specifications.

Administration of the assessment process also offers choices, especially among modes of communication between student and teacher. These involve the format and medium for task specifications and student responses. Although the award of formal grades takes place within the applicable institutional framework, prior decisions often depend on the standards that individual markers employ. The nature and extent of feedback and other information supplied depend on later steps in the learning path. Effectiveness and efficiency are key factors, because of the prevalence of semester-length courses, intensives, and online course design. The key to effectiveness is to ensure that important learning outcomes take precedence over lesser outcomes in assessment. The key to efficiency is designing assessment events that maximize information yield within the resource constraints, including time available for marking. Extensive guidelines are readily available on all of these aspects. They are listed here to emphasize that although innovations and advances in teaching and technology properly reflect the changing character of higher education, certain fundamental principles of good assessment practice are not negotiable.

Group Assessment

Group assessment in higher education is a troublesome area on which experience and opinion are mixed, and on which the literature is large and growing. Often associated with group work and peer assessment, a common form of implementation involves dividing the students into teams, each team working on a complex group project.

The single major piece of work produced is assessed by the teacher, or by members of other groups as peers, or by all involved. Various schemes have been proposed for awarding individual student marks that eventually contribute to course grades. Options include awarding the same mark to each group member, and creating a notional mark pool which is apportioned according to each individual's contribution to the finished work. If handled properly, quality, productivity, and student satisfaction with group assessment can be high. Poorly handled, group assessment gives rise to disputes about the influence of team composition and group dynamics on individual marks, and consequent fairness to individuals in marking and grading. However, group work that is directed toward creating highly productive collaborative sites for learning does not necessarily entail using group-assessment tasks as well. Individual assessments are often appropriate.

Technology and Assessment

Information and communication technologies are revolutionizing teaching and learning in higher education, including assessment. The rate of development and shifts in terminology are rapid; however, the following is indicative of directions to date and possibilities opening up. In general terms, online technologies provide access to, and high speeds of, synchronous, asynchronous, and isosynchronous communications. These enable interactions among students, teachers, course materials, and learning processes in radically new ways. Equally, they facilitate certain types of assessment, including testing modes for which the marking and the return of results are virtually instantaneous.

Commercial and open-source course and learning management systems generally include modules that facilitate record keeping of student results as these accumulate from periodic assessments. Scores are entered, weighted appropriately, and aggregated in a standardized grade book. Students may arrange to take tests at times and places that suit them, and may opt to take practice tests. The tests themselves may be adaptive in the sense that software selects graded items from an item bank, allowing acceleration through simpler items which students find easy. The testing density increases as the limit of the student's existing knowledge and understanding is approached. This minimizes the time and number of test items needed for a sound determination of proficiency yet still provides relevant feedback to students. The structure of items can also be dynamic, and schematically show the development of some phenomenon, in color and complete with labels. Sophisticated technological problems can be posed as simulations with which students engage interactively, and the path or solution strategy tracked automatically. In such cases, the strategy used may be as important as

the actual solution arrived at. Complex task structures, such as these, are time consuming and expensive to develop.

Another form of testing, labeled as certainty based or confidence based, requires students to respond to objective items not only with their primary responses, but also, by indications on a simple scale, their degree of confidence in the answers selected. The aggregation algorithm takes confidence into account, giving most weight to correct answers about which the students are confident.

Significant developments are also occurring for non-objective assessment. For assessment tasks that require extended written responses, model responses or student's actual responses may be shared quickly and securely within a cohort, subject to appropriate ethical clearances. This can provide students with authentic evaluative experience, which is necessary if students are to develop the ability to self-monitor the quality of their own works during construction. A group of students can also peer-share their work online in order to provide mutual feedback, including tentative grades, and can participate in processes that calibrate them as appraisers.

Technology can facilitate diagnostic quizzes during face-to-face classes to enable faculty to gauge how well students are grasping particular concepts on which the next segment of material builds. All students have access to a small keypad, which is either permanently wired into the teaching space or is wireless and hand held. The teacher poses questions about the material covered, students respond individually, and the class distribution of results is projected on a screen and discussed.

The requirement for students to use word processors when producing text-based assessment responses is standard in most developed countries. When coupled with widespread Internet access, word processing both simplifies and complicates production, handling, appraisal, and the provision of feedback. Electronic submission is common. Many markers read student text directly on the screen, annotating it as necessary. Software packages allow markers to tap into banks of stored, previously composed comments, which are then incorporated into the feedback using one or two keystrokes. The same capability is available through creating macros within regular word-processing applications.

On the negative side, digital communications in general, and Internet technology in particular, have facilitated student plagiarism. The dominant issue in discussions on academic integrity tends to be about plagiarism and its control. Issues, such as cheating and data fabrication, generally take second place, unless an institution already has sound measures to make plagiarism unattractive. One key way of dealing with it routinely is to screen all electronically submitted student works using plagiarism detection software. These applications compare a student's work with all works in an enormous database (which may include Internet sources, and term papers

available from commercial distributors or class peers) to identify overlap. A different approach is to make plagiarism-detection software available to students, who are then responsible for running their own works through before submission. This transfers the onus to the student, and can play a significant role in shifting the teaching and learning culture away from policing by the institution and toward acceptance by students of responsibility for the academic integrity of their submissions.

Automated essay grading is being promoted as a cost-effective way to mark essays, provide feedback, and improve student learning. Algorithms are generally based on research in artificial intelligence, natural language processing, text structures, and concept maps. Claims for these packages indicate that they may be best suited to assessing students' substantive knowledge about a topic, their ability to reason about the subject matter in specified ways, and their ability to comprehend specific written works and express it in their own words. In some systems, the software developer compiles a bank of assignment items from which the teacher chooses. In others, the teacher submits an essay topic together with a batch of pregraded student responses. This allows calibration for the purpose of grading future responses to the same assessment item.

Conclusion

Assessment is a high-stakes activity for students, and has a major impact on how they approach learning. Regardless of innovations in assessment techniques, developments in interpretive frameworks and increased adaptability made possible by new and forthcoming technologies, the core activities that cover the design and production of appropriate assessment tasks, the emphasis on higher order cognitive outcomes, the criteria for appraisal, the assignment and interpretation of marks and grades, and the overall maintenance of academic standards clearly remain ongoing responsibilities for the higher education enterprise as a whole.

Glossary

Five-factor model (FFM) – A leading personality model that proposes there are five major universal personality dimensions: extraversion, neuroticism, agreeableness, conscientiousness, and openness.

Meta-analysis – A data analytic technique that uses study sample means and correlations to derive summative evaluations to a research question.

Situational-judgment test – A test that presents complex work or social situations in a written or video format, and requires the respondents to assess the desirability of various action alternatives.

Understanding human emotion has been one of the most enduring topics in philosophy and a principal driver in the development of the modern science of psychology. For example, both in the Rhetoric and Nichomachean Ethics, Aristotle provides one of the earliest known systematic accounts of what the Greeks called *pathe* (emotions), with much of these treatises focusing on the varieties of human emotion and speculation as to how they might ultimately influence human judgment and lead to a virtuous life. In modern psychology, one of the most important and influential classifications of human behavior involves the tripartite division of cognition, conation (motivation), and affect (emotion), originally suggested by the Platonic school. Not surprisingly then, the relationship between affect and academic outcomes has been an important topic within both education and psychology. Regrettably, the role of emotion in education has often been overlooked by researchers. Furthermore, despite over a century of research, the empirical relationships between affective factors and school outcomes remain relatively poorly understood, largely because the methods for measuring affect are often less precise than those assessing cognitive factors, in particular.

This article presents an overview of several affective factors deemed to have some importance in the school context. In any discussion of affective factors, it is essential to distinguish broad, relatively stable personality traits or dispositions to behave in predictable ways (e.g., trait anger) from relatively fluctuating and ephemeral emotional states (e.g., state anger), which change as a function of the individual's personality traits and parameters of the

social situation. Thus, the degree of anger a student will manifest in a classroom altercation will be a function of her personality trait and the degree to which she feels slighted or frustrated by her classmates. First, we describe constructs that might be labeled as affective traits and supporting literature for the impact of these traits in influencing valued educational outcomes. Next, we introduce various methods that have been used to create assessments of affect, including some that are newly emerging such as the situational-judgment test. Finally, we review assessments of affect and their exemplary application in specific school contexts.

Affective Traits

Although there is little consensus among scholars with respect to the term affect, it is often used to refer to the experience of feeling or emotion. Whereas a person may either be conscious or unconscious of the specific emotion being experienced, feeling refers to the person's conscious awareness of an emotion. There are two fundamental dimensions of affect, positive affect, referring to pleasant, excited emotion, and negative affect, bringing together anxiety, sadness, and anger. The role of personality in emotional responses assumes particular importance in the educational context. Personality traits, as we will show, are linked to negative and positive affect, and so may influence the educational experience. Personality factors also influence vulnerability to emotional disorders including anxiety, depression, and cognate personality dysfunctions. Increasingly, psychological research involving traits is structured around the five-factor model (FFM) of personality. Below we discuss several traits that are fundamentally affective constructs. These include neuroticism and extraversion from the FFM, and subconstructs that may be subsumed under these super-factors, as well as measures assessing the state–trait continuum of mood and emotional intelligence (EI).

Neuroticism

Neuroticism is characterized as displaying persistence states of fear, anxiety, anger, guilt, and depression. Meta-analyses have suggested modest negative relationships between neuroticism, assessed via trait-anxiety, as proxy

measure, and academic achievement measures (e.g., Seipp, 1991), plausibly mediated through cognitive interference or reduction in working-memory capacity. In general, high levels of neuroticism predict poorer academic performance among school-aged children. Many cross-sectional studies show that facets of neuroticism, aside from anxiety, such as hostility, impulsivity, and low self-esteem, are associated with various indices of aggression, delinquency, and illegal acts, in both children and adults. A meta-analysis has shown that the traits associated with antisocial behavior typically relate to dimensions of the FFM including neuroticism (Furnham and Heaven, 1999). Comparable findings are obtained in school settings, using criteria such as violence, vandalism, and theft. Others have found that angry hostility and impulsiveness, measured as facets of neuroticism, correlated with antisocial behavior, but other facets, such as anxiety and stress vulnerability, did not (for a review, see Matthews *et al.*, 2006).

Various longitudinal studies in the USA and Europe have also confirmed that childhood temperament measures related to neuroticism are predictive of misconduct later in school life. Studies have shown that children classified as being high on neuroticism and aggression are more likely to report antisocial behaviors, to have a criminal conviction, and to be diagnosed with antisocial personality disorder. Situational factors such as parenting style and deprivation also influence antisocial behavior; these factors may moderate the impact of temperamental factors (Matthews *et al.*, 2006). Bullying children also tend to be high on aspects of aggression, but their victims are marked by reactive aggression only. Studies have shown that while envy and resentment may be motives for bullying, there is little evidence to suggest that bullies suffer from any deficit in self-esteem. However, bullying can also be used as a tool to conceal shame or anxiety or to boost a person's self-esteem – by demeaning others, the abuser him/herself feels empowered.

Coping with Stress

Coping is another key factor in understanding the role of affect. Stress researchers have differentiated several strategies of coping, with most results converging around three dimensions (Folkman and Lazarus, 1988). Problem-focused coping involves determining effective strategies for reducing strain levels, establishing specific behavioral targets, and engaging in the behavior that will help solve problems. Researchers in the stress literature usually describe problem-focused coping in positive terms, with evidence that frequent use of this coping style reduces long-term strain levels. Emotion-focused coping involves direct efforts to reduce one's strain level without affecting the actual presence of stressors and includes activities like reappraising the situation, receiving reassurance from

friends, and focusing on one's strengths. Avoidance coping consists of not thinking about the problem, distracting oneself, drinking or using drugs, or removing oneself from situations that instigate the stress process. For chronic school-setting stressors, avoidance coping is considered maladaptive and may lead to considerably higher levels of strain in the long term. Research has shown that students with higher levels of neuroticism choose more maladaptive coping strategies. Other researchers note that individuals who are prone to negative emotions have less hope that they can solve problems effectively, and this lack of hope may reduce efforts to combat stressors. In addition, recent research has underscored the pivotal role of positive emotions in moderating the negative effects of stressful emotions on adaptive outcomes.

A widely used measure related to stress and coping in high school students is the ways-of-coping questionnaire (WCQ) (Folkman, and Lazarus, 1988). The WCQ considers coping as a process that is determined by the person–situation–transaction and, therefore, can only be adequately represented by the combined analysis of both the person and the stressor. In the WCQ, students report stressful events that have occurred in the last 2 months, then describe how well they coped with the stressful event. Coping strategies can be classified broadly along the three main coping strategies mentioned (problem, emotion, and avoidance coping) and more specifically under dimensions such as aggression, denial of guilt, avoidance, and relaxation.

Test Anxiety

The term test anxiety refers to the negative affect, worry, physiological arousal, and behavioral responses that accompany concern about failure or lack of competence on an exam or similar evaluative situation. Hundreds of studies have investigated the complex pattern of relations between anxiety and a wide array of conventional measures of school performance at elementary, high school, and college levels (Zeidner, 1998). Meta-analysis of available data reveals the moderate mean correlations between anxiety and achievement, somewhere around -0.20 , with academic deficits somewhat more strongly related to the worry component of test anxiety (e.g., Seipp, 1991). It is also acknowledged that effect sizes are larger for low-ability versus for high-ability students and for difficult tasks relative to those perceived as easy. Hence, detrimental effects of anxiety in the real world may represent more than just distraction from performance by the person's immediate worries about the test situation.

Behavioral avoidance also plays a key role in maintenance of evaluative anxiety and concomitant skill degradation. Procrastination, including failure to study or to complete homework, leads to failure acquiring requisite

knowledge. In turn, this lack of preparation leads to poor performance and anxiety under test conditions, increasing subsequent anxiety, and avoidance of study. However, the nature of the task plays an important moderating role. Generally, test anxiety is more detrimental to demanding tasks, and may even facilitate performance on easy tasks. In any case, it is important to diagnose and attempt to assess the specific etiological factors underlying a specific student's test anxiety (anxiety blockage, deficient study skills, self-handicapping, procrastination, and low ability) before attempting to intervene to alleviate the student's test anxiety (Zeidner, 1998).

Extraversion

A second affective trait under the FFM is extraversion. Extraversion is characterized as being social, outgoing, and assertive. Studies suggest that positive affect is a main component of extraversion and that the effect of extraversion on academic success appears age dependent. Whereas before the age of 11–12 years, extraverted children seem superior to introverted children, among adolescents and adults, introverts show higher achievement than extraverts. This change in the direction of the relationship has been attributed to the move from the sociable, less competitive atmosphere of primary school to the rather formal atmospheres of secondary school and higher education, in which introverted behaviors such as avoidance of intensive socializing become advantageous. Extraverts and introverts also differ in parameters of information processing such as speech production, attention, and reflective problem solving, with performance varying along meaningful dimensions. For example, extraverts have been shown to be better at oral contributions to seminars but poorer at essay writing than introverts (see Matthews *et al.*, 2006).

Traits of extraversion promote interaction with the environment, leading to greater opportunities to engage in social interactions in the classroom and elsewhere due to the positive affective states that are generated from such interaction. Thus, extraversion may influence emotional development both directly through rewarding affective states and indirectly through exposure to situations for practicing and learning skills for specific emotional challenges. By contrast, the qualities of the distress-prone child, such as hyper-awareness of threat and personal deficiencies, may lead to avoidance of feared social situations. This behavior pattern in turn affords fewer opportunities to develop emotion-recognition skills, leading to poorer understanding of what happens in emotional situations and hence poorer management of such situations. The resultant skills deficits lead to further avoidance and maladaptive self-beliefs that typically lead to further withdrawal.

State-Trait Measures of Mood (Positive and Negative Affect)

Both neuroticism and extraversion are traits that empower positive and negative emotions. An assessment for measuring affective states is the positive affect negative affect scale (PANAS; Watson *et al.*, 1988). There are ten descriptors for the positive affect (PA) scale (attentive, interested, alert, excited, enthusiastic, inspired, proud, determined, strong, and active), and ten descriptors for the negative affect (NA) scale (distressed, upset-distressed; hostile, irritable-angry; scared, afraid-fearful; ashamed, guilty; and nervous, and jittery). Participants are asked to rate how they felt for each of the emotions at various time periods (e.g., present moment, past few days, or past few months). High-NA is epitomized by subjective distress and unpleasurable engagement, and low NA by the absence of these feelings. By contrast, PA represents the extent to which an individual experiences pleasurable engagement with the environment. Thus, emotions such as enthusiasm and alertness are indicative of high PA, while lethargy and sadness characterize low PA. The PANAS has been useful in predicting important outcomes in school and at home. NA has been shown to be associated with more stress and coping problems, whereas PA is associated with increased engagement in school and healthy social relationships.

Emotional Intelligence

Recently, the construct of EI has emerged as an important affective component in school. Broadly defined, EI represents a set of core competencies for identifying, processing, and managing emotions (Mayer *et al.*, 2008). There are four branches to the model: (1) perception – perceiving and expressing emotions; (2) facilitation – integrating emotions into thought processes; (3) understanding – knowing the relations between emotions, between emotions and circumstances, and transitions among emotions; and (4) management – managing emotions to moderate negative emotions and enhance positive emotions. Studies have shown that even after correcting for statistical artifacts, there is a modest relationship between EI and school achievement (Mayer *et al.*, 2008).

Research has shown that EI predicts academic and social outcomes in youth. For example, a recent meta-analysis showed that emotional understanding is related to performance on cognitive tests, and particularly tests of the acculturated or learned knowledge that is valued in school curricula (Roberts *et al.*, 2008). In this analysis, emotion management is shown to be linked with pro-social behaviors, including the behavioral tendencies to be kind and trusting. In another study, Rivers *et al.* (2008) found that higher levels of emotional skills were related

to higher grade-point average and greater social outcomes (both positive and negative). Specifically, the following significant relationships were revealed for negatively valenced social outcomes: less emotionally skilled students displayed more negative attitudes toward school and teachers, higher self-reported clinical maladjustment, a higher amount of negative emotional symptoms, higher externalization and internalization of problems, more school problems, more behavioral symptoms, and more positive attitudes toward fighting, drinking alcohol, and smoking cigarettes. Significant relationships were also found for more positively valenced outcomes: that is, more emotionally skilled students had better interpersonal relations, greater self-reliance, more positive relationships with their parents, and better social, leadership, and study skills. At present, however, the intervening causal mechanisms through which EI impacts on academic outcomes is still unsettled.

Given the links between EI and both academic achievement and student well-being, one obvious question is how EI can be improved. Equally important is whether such improvement will result in concomitant gains in achievement and well-being. This is an emerging field of lively research where clearly affective assessment might play a vital role in evaluation.

Assessment Methods

Affective characteristics can be assessed in many different ways. In this section, we briefly describe both well-established and recently developed assessment tools, namely self-report, other-report, and situational-judgment tests. Some consideration is also given to more objective techniques that are also used in this domain.

Self-Report Assessments

Self-report assessments are the most widely used approaches to capturing traits such as neuroticism and extraversion. Most insights concerning the relationship between affect and educational outcomes stem from research conducted with questionnaires. Self-assessments usually ask individuals to describe themselves by answering a series of standardized questions. The answer format is often a Likert-type rating scale, but other methods may be used (such as Yes–No questions or constructed response). Typically, questions assessing the same construct are aggregated; this aggregated score serves as an indicator of the relevant affective domain.

At first glance, assessing affective qualities with self-assessments seems to be an easy, fairly cost effective, and efficient way of gathering information about the individual. However, many issues need to be taken into account

when developing a psychometrically sound questionnaire. For instance, the response-scale format has been proven to influence individual's responses. Whether one should use positively and negatively keyed questions (to avoid acquiescence) is still a controversial issue. Research has also shown that especially young male respondents are likely to use extreme answer categories and that individuals attribute different meanings to scale points along the response continuum (e.g., frequent vs. very frequent, or to some extent vs. to moderate extent).

Another problem with self-assessments is that respondents can fairly easily fake their responses to appear more attractive to a prospective institution. When self-assessments are faked, the validity of the assessment score can be compromised. Faking is a major obstacle in using self-assessments (say, of test anxiety) in high-stakes-testing situations such as taking the ACT or SAT. However, recent research on the issue of faking suggests that this confounding factor may not be as serious a threat to self-assessments as previously thought. Nevertheless, more work is needed to address how faking can be reduced in assessing affective components. The next section introduces one such methodology that addresses this issue.

Other-Report Assessments

Others' ratings are assessments in which raters (e.g., teachers, parents, or friends) judge applicants on various qualities. There is a long history of using other's ratings in schools to address the problem of faking and because it can be used at virtually any age level. The child behavior check list (CBCL; Achenbach, 1991) is one such instrument, and it involves parent- and teacher-ratings of behavioral and emotional problems and competencies for children aged 6–18 years. Constructs assessed by the CBCL include anxious/depressed, withdrawn/depressed, somatic complaints, rule-breaking behavior, and aggressive behavior. In addition, the 2001 revision to the CBCL features six new scales to be consistent with diagnostic categories of the American Psychiatric Association's fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM–IV). The DSM–IV-oriented scales are designated as affective problems, anxiety problems, somatic problems, attention-deficit/hyperactivity problems, oppositional defiant problems, and conduct problems.

CBCL items span diverse behavioral and emotional problems but are not assumed to include every possible problem that might be reported for every child in every society. CBCL findings for general population samples have been published from more than 25 societies. Across societies, girls scored significantly higher than boys on somatic complaints, anxious/depressed, and internalizing, whereas boys scored higher than girls on attention problems and delinquent behavior. At the time of writing, the test had been re-normed to include both classroom and

recess observations on a large sample of ethnically diverse 6–11-year-olds. Inter-rater reliability for the revised form across the scales was reported to range from 0.71 to 0.97.

Situational-Judgment Tests

Situational-judgment tests (SJTs) represent an assessment methodology that can be applied to measure many different constructs. Generally, SJTs present scenarios that describe incidents critical to effective behavior. A typical scenario could show several students involved in an activity that requires teamwork. One of the students might admit that he or she did not prepare for the task. After the description or display of scenarios, respondents are prompted to either specify the most appropriate behavior in such incidents or indicate their level of agreement with a given behavior. In short, SJTs can be regarded as fairly simple, economical simulations of understanding affect in social situations. For this reason, SJTs are commonly used in assessing EI, although in principle the technique could be used to construct tests of each of the affective constructs covered previously.

Virtually any critical incident given by a respondent can be used to create a scenario in a SJT, with the technique lending itself quite well to subtle manipulation (and hence assessment) of affective components. Numerous SJTs, ranging from print-based measures of emotional management to video-based measures of communication skills and social competence have been developed by industry. For the most part, however, SJTs remain mostly research devices in education. As this research shows that SJTs predict more nuanced and often neglected outcomes of the educational experience, such as retention, and appear less prone to adverse impact, the educational community is beginning to take the approach seriously. It is certainly a methodology that we suspect will grow in relevance in school settings, more especially given educational imperatives by influential groups such as the Conference Board to assess twenty-first-century skills, including affect-laden components such as teamwork, leadership, and communication skills. Of note, SJTs may also be repurposed as training tools.

Other Measures

Isard has pioneered the use of objective tests of emotion knowledge in children (see Mayer *et al.*, 2008). He has employed tasks such as identifying facial emotion from photographs, and asking children to say how characters in vignettes would feel. These emotional-knowledge tests have been shown to be useful predictors of social maladjustment and emotional pathology. Additional measures may include psychophysiological indicators (e.g., salivary cortisol to assess exam-related stress), unobtrusive indices

(e.g., assessing test anxiety through pressure students exert on pen or pencil, amount of nail biting), or unobtrusive observations, such as fidgeting.

Affective Assessments in School Settings

Many individuals have argued for a need for early identification of and intervention for children who are at risk for emotional and behavioral disorders (EBD). In this context, EBD could be defined as low levels of EI and above normal levels of neuroticism, for example. Current legislation has required school personnel to become proactive in their identification of children who display problem behavior. Specifically, the Individuals with Disabilities Education Act has mandated that children in the United States who are in need of specific early intervention or special-education services be identified through the statewide, comprehensive Child Find System. The increased emphasis on early identification and prevention encourages professionals to intervene with children before problem behaviors develop into EBD. As a result, many preschool and school personnel have incorporated the use of positive behavioral-support programs to address children's behavioral difficulties.

Behavior-checklist measures from parents or teachers are helpful in identifying children who might be at risk for EBD and in need of systematic intervention. The use of measures such as the CBCL has appeared to be a proactive step to identify children and to provide them with early intervention. A behavioral measure for use at a universal level is dependent on several features. The measure must be reliable, developmentally appropriate for preschool and kindergarten-age children, economical in terms of time and resources, and relatively easy to administer with large numbers of children.

The collaborative for academic, social, and emotional learning (see e.g., Zins and Elias, 2007) aims to reduce EBD through after-school program interventions. Such ideas and their practical implementation are collectively referred to as social and emotional learning (SEL), a broadly defined term encompassing understanding affect in school and social settings. Zins and Elias (2007) categorize SEL competencies as “the capacity to recognize and manage emotions, solve problems effectively, and establish positive relationships with others” (p. 2). SEL programs tend to be heterogeneous, broad ranging, and diffuse in their approaches to learning and to the goals of the learning itself. However, the goals of an SEL program are generally to increase children's self-awareness, social and emotional knowledge, ability to make responsible decisions, and level of competency in self- and relationship-management. Over the past decade, numerous published studies have demonstrated that SEL is a crucial factor to academic success as well as life outside of the school

environment. SEL plays an important role both in learning and in understanding issues related to school retention–attrition. For example, the National Center for Education Statistics (2002) reports that students cite social and emotional factors as the main reason for dropping out of school (e.g., 35% of students report that they dropped out of school because they do not get along with teachers or peers, and 23% of students said they dropped out because of feeling left out).

With the increasing awareness of SEL influence in school, the need for more affective-based assessments are needed to evaluate how these interventions impact students. Measures such as EI, mood, and stress and coping are key affective traits that should be affected by SEL interventions. With the growth in using affective-based assessments, counselors and school administrators can more easily understand how to diagnose and ameliorate social and emotional problems in school.

Beyond use as diagnostic and evaluation tools, affective assessments also play a role in educational policy both at the micro- and macro-level. Various accreditation agencies demand, for example, levels of accountability concerning student's level of stress and coping, and there is a move to replace anecdotal evidence with firmer metrics such as might be possible with some of the assessments currently reviewed. In addition, various large-scale assessments such as the National Assessment of Educational Progress (NAEP) and the Programme of International Student Assessment (PISA) have included assessments of affect such as anxiety and self-efficacy along with cognitive measures in every test cycle, with these ultimately influencing economic and political decisions at the local, state, national, and international levels.

Concluding Comments

In this article, we have surveyed the pervasive influence of affective traits on academic outcomes. Next, we reviewed a number of different assessment techniques that may be used to develop affective assessments. Finally, we showed how these affective assessments can be used helping policymakers, administrators, and teachers understand how to reduce many social and emotional problems in schools. The range and variety of educational issues raised by studies of affect in schools is vast, and we emphasize that our coverage here has been somewhat selective.

Glossary

Authentic assessment – Evaluative tools that reflect the nature of the learning activity that is being assessed.

Formative assessment – An evaluation of student learning in process.

Performance assessment – An evaluative method in which the learner demonstrates his or her knowledge and understanding of concepts, and skills and technical abilities by producing something.

Summative assessment – Final evaluation of student learning that comes at the end of a project, assignment, or course.

Introduction

Challenges and Common Practices

Assessment in fine arts education has been a challenging topic for educators, whether they are early childhood, elementary, or secondary school arts teachers, artists in residence or teaching artists, or educators in higher education studying arts education or preparing arts teachers. Traditionally arts educators have been uncomfortable with making an evaluative judgment by assigning a grade in subjects that are characterized by inherently creative processes and products. This attitude is changing, as arts educators understand that assessment is not necessarily focused on the outcome but can be used as a tool for helping teachers and students reflect on the learning process. Elliot Eisner makes the point that “without some form of assessment and evaluation, the teacher cannot know what the consequences of teaching have been. Not to know, or at least not to try to know, is professionally irresponsible” (2002: 179).

A complementary way of framing the importance of assessment is in terms of how cultural and societal values influence what are perceived as the most important kinds of knowledge. The famous question asked by Herbert Spencer, “what knowledge is of most worth?” reflects the role of values in education. The kinds of knowledge a society values will directly influence which content and skills are assessed. This is applicable in both the microcontext of a teacher’s perspective in the classroom

(as Elliot Eisner refers to above), and the macrocontext from a disciplinary and institutional perspective.

An oft-cited challenge by arts educators has been how to assess learning in a discipline whose processes and products are essentially nonverbal – in the case of visual art, music, and dance (drama is more verbal, whether oral or written, with the exception of pantomime) – and personal creative expressions of meaning and understanding – in the case of all the fine arts. Essentially, the arts go beyond the verbal and the numerical and what can be predicted *a priori*. Esthetic philosopher Morris Weitz has noted that the nature of art is to go beyond those *a priori* expectations. For this reason, the arts do not lend themselves to the prespecified measures that most other academic subjects accommodate. As Eisner (2002) has insightfully explained, the diversity of forms of representation in the arts implies that there is no easy translation between the modes of the discipline and the evaluation tool. Assessing the arts is further complicated by the unpredictable nature of the processes and products to be evaluated. In other words, traditional modes of assessing learning through objective, often quantifiable criteria applied to observable outcomes are typically not effective in assessing learning and development in the arts disciplines where ways of knowing and representation are inherently interpretive, metaphoric, and symbolic. The power of the arts is in their expressive and interpretive qualities, but expression and interpretations are harder to evaluate than the lower levels of Bloom’s taxonomy, such as knowledge and comprehension, which are more easily assessed through objective measures. In arts assessment, therefore, there is an important need for both analytic and holistic measures.

Considering this legitimate challenge, arts educators at all levels emphasize performance and authentic assessment strategies utilized frequently for formative as well as summative purposes. Performance and authentic assessment strategies reflect the process of revision that is inherent to arts practice as artists from all arts disciplines create, reflect, revise, and create again in an ongoing cyclical process. The critique, practice, rehearsal, and presentation components of the visual and performing arts are natural examples of authentic assessment. Authentic assessments refer to evaluative tools that reflect the nature of the learning activity that is being assessed; indeed, authentic assessments are often the actual learning activity. Dorn, Madeja, and Sabol provide this definition “Authentic

assessment does not focus on factual knowledge as an end in itself. Rather, it focuses on the ability to use relevant knowledge, skills, and processes for solving open-ended problems during meaningful tasks” (2004: 15). Performance assessment is an evaluative method in which the learner demonstrates his or her knowledge and understanding of concepts, and skills and technical abilities by producing something, whether it is, for example, a written essay (an example of performance assessment commonly used in nonarts disciplines), an abstract painting, an improvised eight-part dance, and so on. Often, a student’s performance assessments will be collected in a portfolio that demonstrates growth in the student’s learning over time. This portfolio will include authentic assessments. For example, in the visual arts, a portfolio might contain gesture drawings, compositional studies, a figural painting, and written statement from the artist. Examples of formative performance assessments include the in-process critique in a painting class or the dress rehearsal in a drama, dance, or music performance. Summative uses of performance assessments might be an exhibition of student artwork or a recital. The emphasis on formative performance assessments by arts educators reflects the nature of art practice, which is an ongoing iterative process of creation, reflection, and revision according to the perceived effectiveness of expressive products.

A third significant challenge in arts-education assessment, in addition to arts teachers’ traditional reluctance to formally assess, and the difficulty of assessing primarily nonverbal creative processes and products, occurs in a broader context in the form of standardized assessments at the national and state or regional levels. The current political context of high accountability and standardized curriculum, especially in the United States and the United Kingdom, puts pressure on the fine arts disciplines to consider standardized assessment in order to secure a place in the curriculum, heeding the warning that what gets tested gets taught. A recent example of research from the Center on Education Policy (McMurrer, 2008) regarding the influence of the No Child Left Behind Act on narrowing of the curriculum in the United States shows that subjects that are not currently tested through standardized assessment instruments receive reduced instructional time in elementary schools, including 36% of reporting school districts reducing instructional time on social studies by 76 min each week, 28% of reporting school districts indicating 75 min less per week in science, and 16% of reporting school districts reducing instructional time in art and music by 57 min per week. This reflects a decades-long pattern in the United States going back to the Sputnik-generated curriculum reform of the early 1960s prioritizing standardized curriculum and objective assessment.

There are actually two challenges within standardized assessment of fine arts learning: the first is how to assess arts knowledge and ability in a standardized way that

reflects the central bodies of knowledge characteristic of each arts discipline, rather than test what is easier to test and hence make what is assessed a central, highly valued body of knowledge. The second challenge is how standardized arts assessment might affect arts-education policy. In other words, there are benefits and disadvantages to national or regional standardized assessments of fine arts learning which are discussed briefly below.

Related to this, an additional challenge is how to assess the long-term impact of arts learning. Arts educators often emphasize the significance of arts instruction for developing habits of mind that support creative and critical thinking, such as persistence, comfort with ambiguity, and divergent thinking (e.g., Eisner, 2002; Hetland *et al.*, 2007). Standardized assessments consisting of multiple choice questions will not capture this kind of arts learning. A performance-based longitudinal standardized assessment is more appropriate for providing one perspective on this kind of learning to inform policy decisions, such as the 1997 and the 2008 fine arts national assessment of educational progress (NAEP) in the United States.

With the challenges and common practices of arts assessment outlined, the remainder of the article briefly discusses standardized testing of fine arts learning in order to acknowledge this context, but then focuses on classroom/individual student assessments in each fine arts discipline, as the most significant activity in arts assessment occurs at the classroom level.

Standardized Assessments in the Fine Arts

The Standards Movement

While the United Kingdom has had a national standardized curriculum including the arts since the Education Reform Act of 1988, standardized assessments in the fine arts became prominent in the United States in the late 1990s within the context of standardized curriculum brought on by the national reform movements resulting in Goals 2000 and the No Child Left Behind Act. Eager to be included in the national effort, the fine arts disciplines created national standards for visual art, music, dance, and drama, published in 1994. Individual states followed suit, developing their own state content standards in fine arts, in the mid- and late 1990s. As of 2006, according to the Arts-Education Partnership’s state arts-education-policy database, 49 states have developed state content standards for the fine arts, with most of these standards mandated as part of the curriculum (Nebraska has developed fine arts curricular guides for districts to use to develop local fine arts standards), while a few states have voluntary adoption by districts (e.g., North Dakota, South Carolina, and Wisconsin).

Along with the development of state fine arts standards in the late 1990s came the development of state

standardized assessments of fine arts learning. In some cases (e.g., Illinois), student achievement on the state fine arts standards was assessed in the social studies section of the annual state assessment, administered to specific grades. As of 2006, only Kentucky administered a statewide fine arts assessment (in grades 5, 8, and 11). Several states require fine arts assessment at the local school district level, and many states provide assessment resources for local districts that voluntarily assess their students' achievement on the fine arts standards.

The lack of statewide assessments for mandatory fine arts content standards reflects several realities about large-scale assessments. Importantly, standardized assessments are costly to develop and administer. A large-scale fine arts assessment would have to include performance-based test items to meaningfully assess student knowledge of and aptitude in the fine arts that reflect the content standards' emphases on creating and responding to works of art in all disciplines. Performance-based national assessments have been used successfully internationally, specifically the use of portfolios in the visual arts in the International Baccalaureate Program, the Dutch National Assessment System, the British GCSE art assessment, and in the twelfth-year state and national assessments in Australia and New Zealand (Boughton, 2004).

Considering the increase in standardized assessment in language arts and math under the No Child Left Behind Act in the United States, there are little to no funds available to states and local districts to develop fine arts standardized assessments. Performance-based assessments are also complicated and costly to score. The schedule for implementation of standardized assessments in the No Child Left Behind Act reflects societal priorities – language arts and math first (basic literacies), then science, and then social studies. With statewide-standardized arts assessments discontinued for the foreseeable future, the only other primary means for assessing students' knowledge of and ability in the arts disciplines on a large scale is the NAEP. There is a benefit in trying to assess arts knowledge and abilities on a large scale (as with the NAEP), as poor performance could galvanize support for increased instructional time in the arts and acceptable performance could safeguard the current level of instructional time.

National Assessment of Educational Progress

The US Congress mandated the NAEP in 1969. Called the nation's report card, the program's objective is to track US students' knowledge of and ability in academic disciplines over time (mathematics, reading, science, writing, the arts, civics, economics, geography, and US history). NAEP first evaluated visual arts achievements in 1974 and visual arts and music in 1978. The next NAEP arts assessment in 1997 included visual arts, music, and theater, and

consisted of items designed to measure eighth-graders' knowledge and skills in creating, performing, and responding to works of music, art, and theater (items compatible with the national arts standards and with current classroom practices). The 1997 arts assessment did not include dance because there was not a nationally representative sample of dance-education students. In other words, too few schools offered dance instruction at the eighth grade.

The 1997 NAEP assessment had a significant influence on how large-scale arts assessment is conceptualized. In addition to the expected multiple-choice and written-response items, it also included performance-based items. For example, music students were asked to create and perform a rock-and-roll improvisation on an MIDI keyboard. Theater students worked in groups to develop an improvisation about a camping trip. After analyzing a collage by Romare Bearden, visual arts students were asked to create a collage based on a memory of a childhood place.

Students' arts achievement on the 1997 assessment was not encouraging. On a 100% scale for creating and performing, the national average for music was at 34%, for theater 49%, and for visual arts 43%. On a 300-point scale for responding to works of art, the national average was 150 points in each discipline (music, theater, and visual arts) (Persky *et al.*, 1998). The NAEP arts assessment in music and visual arts was administered most recently from January to March of 2008 to eighth-grade students across the US. The results were comparable to the 1997 assessment.

Classroom-Based Assessment

On standards, Eisner (1995) writes that "In assessing works of art, standards are inappropriate; criteria are needed. Standards fix expectations; criteria are guidelines that enable one to search more efficiently for qualities that might matter in any individual work" (p. 763). Definitions of art in contemporary postmodern societies are open and contested. While this relativity can be applied to art made by children and youth (Bresler, 2002), there are criteria that can be assessed, such as specific parameters outlined in an assignment. Moreover, each arts discipline emphasizes different criteria for different genres within each discipline. For example, in classical music, accuracy and obedience to the score is all important as well as playing in the performing practice of the period. In contrast, jazz requires the ability to improvise. The ways in which artistic achievement is assessed also reflects philosophical (and often times political) assumptions regarding the goals and nature of teaching, learning, and the subject matter (arts discipline). This is elaborated upon within the discussions of each arts discipline below.

Assessing understanding about the arts (i.e., content knowledge) requires fundamentally different types of assessment from creating/performing in the arts. For example,

in discipline-based approaches to arts education, which incorporate history, criticism, and esthetics as content areas in addition to creating/performance, the first three fall more easily into the categories of other disciplines and can be assessed through objective measures, such as multiple-choice and written-response items. This is a particular issue in Continental Europe, where the understanding of the art of music is emphasized more than the making of music. In the US, there is more emphasis on music performance whereas in the United Kingdom and Australia music composition is integral to the curriculum. The visual arts in both the US and the UK emphasize creating. The emphasis on creation and performance requires more performance-based and authentic forms of assessment.

Visual Arts

With the prevailing approach to art education being creative self-expression in the first half of the twentieth century, assessment of students' artwork was considered detrimental to their learning and creative development. This is reflected in the prominent textbooks prior to the 1970s, including several editions of Lowenfeld & Brittain's *Creative & Mental Growth* and Wachowiak's *Emphasis Art*. Art-education curriculum began to change significantly at mid-century with the Russian launch of Sputnik, the cognitive revolution and the resulting emphasis on disciplinary knowledge in curriculum reform (under the leadership of Jerome Bruner). In the 1960s, influenced by Bruner's writings on the structure of knowledge in the disciplines, educators in higher education, most notably Manuel Barkan, Elliot Eisner, Harry Broudy, Ralph Smith, and Edmund Feldman began to apply these ideas to art-education curriculum. These concerns for art-education-curriculum reform were articulated at the Penn State Seminar in 1965 and subsequent book publications by Eisner & Ecker (*Readings in Art Education*) and Smith (*Aesthetics and Criticism in Art Education*) in 1966 and Broudy in 1972 (*Enlightened Cherishing*) emphasizing the disciplinary structure of art and the role of evaluation. This work was the precedent for the development of discipline-based art education (DBAE) in the 1980s, which emphasized a written sequential curriculum balanced with content from the four art disciplines of art production, esthetics, art criticism, and art history, and structured assessment of student learning. With the support of the Getty Center for Education, DBAE had a significant influence on art-education curriculum and the development of systematic assessment of student knowledge of and ability in art. The development of DBAE in the 1980s and 1990s closely follows the standards movement at the national level in the US. The national visual arts content standards and most states' visual arts standards reflect a DBAE approach to curriculum by

addressing art production and art history and responding to works of art (aesthetics and art criticism).

With a DBAE approach reflected in the standards, assessment of visual arts knowledge and ability could potentially be more concrete. A recent in-depth study of K-12 visual arts assessment in the US documents teachers' common practices (Dorn *et al.*, 2004). The most common tools, listed in order of priority, include: "work samples, professional judgment, teacher-developed tests, portfolios, discussions, critiques, sketchbooks, checklists, exhibits, reports, and research papers" (p. 16). The majority of these tools are performance-based, reflecting the emphasis on art making in US schools. This study also found that elementary-level art teachers use the fewest types of measures and secondary level, the most. Secondary-level teachers also use written assessments more often (reports, journals, research papers). With the emphasis on art production in US schools, the researchers in this study asked art teachers at all levels how they determined their evaluative criteria for art work. There was wide agreement on five criteria out of a participant-generated list of 23; these five included elements of art, the principles of design, composition (use of space), and creativity (p. 25).

Contemporary, twenty-first-century arts-education curriculum is becoming significantly influenced by social reconstructionist aims, embodied especially in the visual-culture approach to art education (VCAE) (Chalmers, 2005; Duncum, 2002). VCAE emphasizes developing students' visual literacy skills and abilities to critique visual culture represented especially in the popular media, with art production serving as a means of reflection and representation, often, of this critique. With this new curricular emphasis on critique in greater proportion to art making for creative self-expression, it remains to be seen to what extent and in what ways this might influence teachers' assessment practices.

Music

Assessment and evaluation have been a continued focus in the field of music. Historically, these centered on aptitude tests, used for nearly a century, reflecting the belief that when resources are limited, they should be expended on students who will benefit the most, in other words, the talented. Early pioneers are Carl Seashore's work on evaluating music talents, and later on, Ed Gordon's theory of development of musical aptitude, focusing on rhythmic and tonal pattern tasks. These assessment tools focus on reproduction rather than on the creative aspects of music.

The prevalence of these tests reflects the focus of school and out-of-school music on reproduction (as compared to the visual arts, dance, and creative drama focus on composition). A focus on listening is manifested in the other important measurements – the assessment of attitudes and preferences, for example, attitudes to music

classes, toward performing music, and toward listening to particular musical styles, among others (Cutietta, 1992).

The systematic study of creative thinking in music and its meaningful evaluation are relatively new, starting in the 1970s and 1980s. The work of Howard Gardner, and following him, Bennett Reimer on specific musical intelligences has been influential in expanding the scope of evaluation. Assessment of creativity in music has been shaped by psychometric research, cognition research, and environment research (Webster, 1992).

Dance

Unlike visual arts and music, which, for the most part, are part of the school curriculum, most dance education happens in magnet schools for the arts, private schools, and dance studios. Assessment tends to center on students' performances in dance class, based on criteria set by the instructors or the institutions. Where students take dance regularly over a period of years, the criteria for evaluating success and quality are usually specific, ongoing, and formative, primarily directed toward helping students and teachers monitor progress and improve learning (Oreck, 2007). In a globalized, technological world, many effective tools for assessing dance are accessible from Internet sites developed in England, Canada, New Zealand, and Australia. Video and computer technology can be powerful learning and evaluation tools. Students collect and analyze movement, add personal commentary, and examine and reflect on stages in the dance-making process (Parish, 2007).

Often, dance programs articulate broad educational and personal outcomes as primary goals of dance education, for example, in England's national dance curriculum, where evaluators are asked to consider how dance contributes to students' spiritual, moral, social, and cultural development (see the Office for Standards in Education website (Ofsted)). Other aspects of affective development are creativity, attitudes toward life, behavior toward others, self-management and self-esteem, and identity, which require long-term data collection.

Drama

School drama, when it is practiced, is often incorporated into other curricular disciplines (e.g., English/language arts). In general, it includes two distinct subdisciplines: creative drama, mostly for early childhood and elementary level, and drama as theater, typically in middle and high schools. These two are characterized by fundamentally different contents, forms of representation, and criteria (see Bolton, 2007; O'Toole and O'Mara, 2007). As in all the arts, the issue of assessing a product versus assessing a process is a key issue, but is manifested differently in these two subdisciplines.

Addressing the difficulties of assessment of process, Schonmann (2007) suggests drawing on a set of dialectical questions that create a profile of the student's achievement, including the student's journey to become an artist in the making and reflective understanding of drama. The issues of how we know whether students have undergone a change and what constitutes enough change are perennial questions. The deliberation process through a series of dialectic questions is formative, a motivational way of assessing students' achievements. It examines process versus goal orientation; discovery versus didacticism; rational versus intuitive methods; collaborative and cooperative versus solitary and competitive; breadth, versus specialized; and personal versus impersonal (the relationships between self and the content of drama that the student is learning).

Conclusion

The above discussion details the emphasis on formative performance assessments in classroom assessments of the fine arts within historical and contemporary contexts of both a push toward standardization and, most recently, a concern for students' social and emotional learning and development of habits of mind conducive to creative and critical thinking. As governments are concerned about remaining economically competitive, there is heightened discussion about the need to develop creative and innovative thinkers (e.g., the UK national curriculum emphasizes creativity), thereby providing an economic justification for increased arts education. It remains to be seen how the increasing globalization of curriculum and the influence of shifting economic powers and competition will influence assessment of the fine arts at local and national levels internationally.

Assessment in Schools – Learning to Learn

A Hautamäki, J Hautamäki and S Kupiainen, University of Helsinki, Helsinki, Finland

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Globalization and the development of information technology (IT) have set new challenges and options for education. Factors pertaining to lifelong learning are gaining momentum in educational discourses. The concept of learning to learn (L2), that has a central position amid the cross-curricular competences, has been adopted in response to these demands. Especially within the European Union, L2 has a place among the key competencies intended to be catered by educational policy considerations (Centre for Research on Education and Lifelong Learning (CRELL); Fredriksson and Hoskins, 2007).

L2 is used to refer to two diverse domains of discourses. On the one hand, L2 refers to the cognitive and affective-dispositional factors central to the application of existing skills and schemata to novel tasks and to new learning (commitments) in adult life and in the constitution of knowledge at work. On the other hand, L2 refers to potential new educational practices in basic or adult education – which would increase the appeal of education and learning to all pupils in order to enhance the acquisition of skills, abilities, and dispositions necessary in future society. Depending on the approach, there are also differing answers to the question of the criteria of L2 (Klauer, 1988). Different answers lead to different choices in assessments.

L2 is to be seen to comprise and adhere to several theoretical traditions within educational sciences. Even if, in psychology, L2 refers to repeated practice with tasks in which material varies, which enhances learning of new material, there is no general agreement in the educational literature on the definition of L2. On a general level, the search for an understanding of L2 can be seen to fall under Hirsch's (1996) Tool Conception of Education. Hirsch's idea comprises notions such as accessing skills, critical-thinking skills, higher-order skills, lifelong learning, metacognitive skills, and problem-solving skills. The L2 notion embraces this idea of general tools formed through good teaching, but acknowledges many structural constraints embedded in learning and development. Yet, L2 should be more than a set of study or survival skills (Smith, 1990). Study skills, strategies, and techniques with the related dispositions and beliefs may be the narrow(est) area of L2, but there are also attempts to broad(er) interpretations (Claxton, 2007; Hautamäki *et al.*, 2002).

L2, as an assessment issue, can be approached applying Snow's 1990-model for educational assessment. When L2 assessment is based on learning tasks that require

reflection and adaptation by the student, the tasks of the assessment exercise can be seen as both aptitude (input) and achievement (output) assessment and also to tap students' attitudes or beliefs. Snow (1994) shows – in his extended model – that, before being accepted as a task, an assignment or an exercise activates the orientation to task type, subject-matter characteristics (relevance to learner, novelty to learner, dominant symbol system, etc.), treatment dimensions (ambiguity, risk and evaluation, stress and importance of outcome, novelty, meaningfulness, complexity of information processing required, structuredness and completeness, adaptiveness to learner, etc.), and the instructional-social context. Sometimes, these orientative actions are considered to be the core of L2, together with components or elements which have been referred to as metacognition (after Flavell).

L2 leads to a state of mind which could be named: the prepared mind of Shayer and Adey, the epistemic mentality and resilience of Claxton, or the autodidactic learner of Klauer.

History of L2

Early History

Cronbach and Snow, in their treatise on aptitudes and instructional methods (ATI; 1977), point out that any study of aptitude–outcome relations ought to take learning-to-learn (Cronbach and Snow use the acronym LTL) into account: “A learner does considerably better after he has experience with many tasks of the same kind. The learning ability he displayed on the first few tasks of that series may not be the most significant indication of his ability to perform in an instructional situation or in any long-continued learning. This understanding leads to a definition where LTL is defined as a repeated practice with one kind of tasks but learning different material each time, which facilitates the ability to learn new material.”

The early start for this definition is in Harlow's (1949) studies on monkeys' learning. He demonstrated L2 – or learning set – by teaching monkeys discriminations between pairs of objects. Harlow used two experimental conditions: (1) the oddity problem, where the correct answer is determined not by the choice of one stimulus as correct but by the application of a concept: “3 stimuli, two alike, choice of the odd object is rewarded.” A subject who discovers operating rule is able to solve a new problem on the first trial. (2) The learning-set problem, where one of two objects is arbitrarily chosen as correct. Subject cannot

choose correctly on the first trial save by chance, but he can achieve perfect success on the second trial. The second type of study gives evidence of L2.

Later History

Later cognitive and developmental psychological traditions have provided the understanding of thinking and higher cognitive functions as malleable (theoretical ideas by Adey, Bruner, Flavell, Demetriou, Gardner, Klauer, Kuhn, Markman and Gentner, Nuthall, Piaget, Resnick, Shayer, and Sternberg). In this tradition, one can emphasize – when constructing a framework for assessments – the different modes of the tasks, automated skills in new contexts, identifying and using propositions, or mental tools. In the cognitive domain, critical thinking, problem solving, use of resources and rules, and formal operational reasoning are core skills. By combining differential-experimental and developmental traditions, Resnick (1987) showed the importance and possibility of thinking about thinking as something to be learned and accordingly teachable.

Flavell introduced metacognition, which has, since, made a major impact on learning studies. Sometimes, the term is used to refer assessments where the learning activity itself and acts of learning have vanished and metacognition is disembodied from cognition and reasoning as something independent. However, to plan, to monitor, and to evaluate learning activity is paramount in regulating learning. It is possible to test pupils for their knowledge of them (Meijer, 2007).

The sociocultural tradition (theoretical ideas by Bruner, Claxton, Cole, Galperin, Leontjev, Lompscher, and Vygotsky) can provide ideas relating to learning activity, to relations among motives, goals, and actions, to the roles of context factors and significant others, and to the general idea of an epistemic mentality. The contextual variables, which should be taken into account in analyzing the conditions and implications of L2 assessment, include not only the school, class, and teachers but also students' interpretation of the attitudes of their parents and peers toward school. These relate to students' self-efficacy and not only to students', but also to teachers', understanding of L2 as well.

The motivational and volitional tradition (theoretical ideas by Atkinson, Covington, Harter, Little, Niemivirta, Pintrich, Shavelson, and Skinner) attests to both positive and negative effects of beliefs in goal-oriented action. Even if the motivational, volitional, and dispositional factors can also be analyzed independently, it is important to remember that dispositions do not replace mental activity or the use of mental powers to solve tasks and to learn. All mental acts – based on comparing ideal goals and representations of the actual situations – produce emotions (happy when a goal is achieved, sad when there is a discrepancy). Therefore, cognitive development is tied to

the development of also mastering emotions. Emotions, interests, and other dispositional factors assist reasoning, and as teaching or an intervention increases children's abilities, their belief in those abilities also changes, slowly leading to a process of growth of self-concepts and self-awareness. Accordingly, only studying and assessing generalized emotions as beliefs, orientations, and motivations will not provide a complete description of the status of L2 in some school class or in school.

Current Trends in Assessment

Theoretically, the link between L2 competence as a cognitive process, and the will or attitudes and beliefs that steer its use, can be built through the construct of the autonomous personal control in the upkeep of reflective thinking and the self, learning, and personal development. Seen from this perspective, the concept of L2 is closely attached to those of voluntary learning (Vygotsky and Lompscher) and goal-directed action (Leontjev, Nuttin, and several other modern writers).

Students' goals at school are seen to be linked to learning tasks that the teacher gives and students are expected to accept them as their own. In this process, the outer social context is to be replaced – for a moment – by the inner context of the self. Then, the solution – be it positive or negative – will be evaluated by the student on two fields. Social comparison and achievement assessment tie it to the social system – to teachers, classmates, and parents – whereas inner evaluation ties it back to the goals set by the student, and the inner norm either gets reinforced or gets an incentive for change.

In the assessment of L2, students are given tasks that they are invited to accept as their own with all the motivational, goal related, and ability conditions (or beliefs thereof) attached, and the processes of L2 are set in motion in this acceptance. Irrespective of the knowledge or skill level of the student, the acceptance of the task (or the refusing of it) activates processes that either enhance or hinder flexible intellectual work necessary for learning a new thing. However, with the noncurricular nature of the L2 tasks as compared to regular curricular assessment, it is easier to see the task itself as instigating and summoning up the appropriate skills and abilities in the student, anticipating his/her willingness for lifelong learning.

As a summary, L2 could be defined as the learning set of the prepared mind to adapt to novel tasks in new and surprising circumstances and, often, within constraints which mean a high mental load.

Variation and Individual Differences

Cronbach and Snow (1977) address the issue of individual differences. They point out that the L2 generalization is

practically significant only if individual differences in learning are fairly consistent. If individual differences prove to be stable and predictable, one can capitalize on findings from the assessment in which learning is observed only for a short time, perhaps on just one task or topic. If individual differences are radically altered during learning-set formation, the short-term experiments on ATI will not give practically useful conclusion. That also implies that L2 studies would not give added value to other types of studies in learning and teaching.

Between-student differences in any cognitive and educational measure are large and significant for teaching. This is also true for L2 measures, both in cognitive and in belief factors. This outcome arouses some ideological discussions, even to the extent of creating debate of the validity of a measure which shows the L2-scores correlating with school achievement. Some of L2-discussants would like to have a measure that would show a compensatory outcome saving those pupils who do not do so well in formal education. The hoped-for L2 measures as saving virtues should show both zero or even negative correlations with school achievement and positive correlations with some later criterion measure, which also correlates positively with school marks, and, say, Organization of Economic Cooperation and Development (OECD)'s Programme for International Student Assessment (PISA) measures. However, without variations in scores, one cannot do meaningful empirical studies and describe education, and, without a good description, no modeling (theory formation) is possible when planning for a new school for all – where everybody would be better able to learn the modern contents.

When the L2 is understood from the psychological point-of-view – that is, to include studies and theories of learning – then it is useful to analyze the relation of L2 to learning ability, and, accordingly to general cognitive ability. This generalized L2 expresses itself, for example, in the developmentally most important change, when a child who has been learning-to-read moves into the mode of reading-to-learn.

Collectively Weaved Definition: Social Practice Creating Meaning

There is a relatively new phenomenon where international political institutions (United Nations (UN), United Nations Educational, Scientific, and Cultural Organization (UNESCO), OECD, and European Union (EU)) define educational terms. This process is an example of measures and activities, which create new social practices. These definitions are constructed as a response to attempts to try to achieve compromises, using methods such as the EU's open method of coordination. This process can be described as collective and institutional weaving – where participating countries try to defend their options for a leading position and, possibly, money and various experts

defend their academic fields. An example is the frameworks of OECD's PISA program. Similarly, the EU has worked on a framework for key or basic competencies, of which L2 is one. The following political or working definition is given in the EU documents.

'Learning to learn' is the ability to pursue and persist in learning, to organise one's own learning, including through effective management of time and information, both individually and in groups. This competence includes awareness of one's learning process and needs, identifying available opportunities, and the ability to overcome obstacles in order to learn successfully. This competence means gaining, processing and assimilating new knowledge and skill as well as seeking and making use of guidance. Learning to learn engages learners to build on prior learning and life experiences in order to use and apply knowledge and skills in a variety of contexts: at home, at work, in education and training. Motivation and confidence are crucial to an individual's competence. (paragraph 5, annex, Education Council, 2006)

This definition is a compromise of educational experts and policy advisors from EU countries, and is, therefore, creating new social practices when countries and schools are looking for resources and sources of innovation. In this sense, the EU definition is weaved collectively to provide a politically convenient definition upon which to also base decisions concerning money and joint actions.

Examples of L2 projects

L2 assessments in educational settings seem to be targeted to studies on how to learn in educational settings, learning how to learn, or to studies on the outcomes of processes intended to form L2 competencies, learning to learn or learned to learn. *The Curriculum Journal* has devoted a special issue for L2 (2007, volume 18, number 2).

Studies of Learning Low to Learn

Learning How to Learn – in classrooms, schools and networks is a part of Teaching and Learning Research Programme in UK (Black *et al.*, 2006; James *et al.*, 2006). The project worked with teachers, schools, and networks of teachers and schools in order to learn the actual practices of promoting how to learn. One of the frameworks has been Assessment for Learning (AfL). Studies were also conducted to understand conditions for school improvement and innovation. There are, in the literature, other good examples of careful studies of life in classrooms, and of practices expected to support the making of prepared minds.

In these studies, the researchers are taking part in life in classrooms observing, video recording, and interviewing teachers and students. In addition, questionnaires are used. Often, the programs produce www-newsletters and other support for discussion, debate, and innovations. The

approach could be called collaborative research and development. This kind of research can be placed also under the tradition of social and educational practices. There are also other L2 projects under the name learning to learn in schools in the United Kingdom (University of Durham, Steven Higgins), as well as in Italy (Christina Stringher) and in adult education in several European countries.

The Already Achieved Level of L2: EU L2-Pilot

An attempt to combine the cognitive and the affective approach to L2 is the EU prepilot (Frefriksson and Hoskins, 2007), where a combination of the Finnish definition of L2 as the commitment (ability and willingness) to adapt to novel tasks, activating one's mastery of thinking and the perspective of hope by means of maintaining one's cognitive and affective self-regulation in-and-of learning action, and British scales, Dutch scales, and Spanish metacognition scales has been prepared and tested in seven countries (Kupiainen *et al.*, 2008). It is expected that this attempt will lead to further studies and empirical reports.

Instruments are paper-and-pencil tests and questionnaires, which comprise three dimensions – the cognitive, the affective, and the metacognitive. The cognitive is divided into identifying a proposition, using rules, testing rules and propositions, and using mental tools. The affective dimension is divided into learning motivation, learning strategies and orientation toward change, academic self-concept and self-esteem, and learning environment. The metacognitive is divided into metacognitive monitoring, accuracy, and confidence. The test is given in two booklets and the testing time has been two lessons (45 min).

Transfer as an evidence for L2

Transfer is one kind of evidence for good learning – and is very relevant for L2 studies. Transfer refers to those processes which should be improved if one has learned to learn. A person is showing his/her L2 competencies when he/she faces unexpected chance encounters, can reflect upon his/her own situation, and can adapt him/herself to possibilities and options in the task situation in order to start to learn new requirements.

Speelman and Kirsner (2005) aim to generalize transfer and learning studies into a coherent framework. According to them, transfer reflects the way in which a person adapts to a task situation. In an efficient adaptation to a task environment, people will learn to cope with a task or lesson variation, and to do so efficiently they, say, will rely on the abstraction of features that are common to many items – that is, people will acquire skills that represent their adaptation to the environment in which they are performing at present.

Schooling can be conceptualized in many ways but, in connection to L2, it is possible to say that one of the major

objective tasks of schooling is to arrange teaching and training to adapt to student variation by organizing education in schools and, within schools, in classes. The curricula determine – in their nationally specific ways – the lessons, tasks, and textbooks to provide suitable variation of instructional tasks for ensuring as general a transfer as possible. However, in this process, schooling is determined and limited to take into account student variation. These variations can be analyzed in terms of plastic general abilities or in terms of mastery of L2 cognitive competencies. It is not a question of given, unchangeable, or nonmalleable intelligence, but more of the ways through which pupils adapt themselves in the learning–development transitions at school, and of how former pupils as adult persons have learnt to cope with unanticipated task and environment variation. This learning is also a process of the growth of self-awareness in the pedagogical and intentional relation between teachers and pupils.

So What?

L2 assessment attempts to measure nonspecific outcomes of learning using tasks which are both taught in principle (as required by the curricula) and new in some (surprising) sense. Irrespective of the practical assessment solution, the whole assessment is for learning (Black *et al.*, 2006), and should guide innovation of schooling.

L2 assessments in their two major forms – learning how to learn and learned to learn – are both needed in a comprehensive system for assessment for learning. The observations and real-time interviews provide information of the ongoing processes of the lessons in a school, and the measurement and description of variations and their different contextual factors provide information about the school as an institution; both of these require communication. It appears that this communicative act can take place in three instances. L2 assessment outcomes inform (1) teachers about their success in communicating during and through lessons how failures and errors are treated post-failure, reflectively – that is, it is how pupils learn that errors and failures can be of use in the process of learning; (2) how teachers have succeeded in telling the criteria of records and markings which are delivered to pupils at the ends of terminus – that is, how well the seriousness of schooling has been understood; and (3) how accurately the school as a whole has understood tasks and goals of education, as a mediator of precious knowledge of past generations to the next new generation.

Assessment in Schools – Literacy Writing (Extended)

J M Parr, University of Auckland, Auckland, New Zealand

L Earl, Aporia Consulting, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Writing research is a potentially dynamic field as the practices, uses, and modes of writing are constantly changing, particularly with the rapid growth of new technologies. Research in the field is eclectic, drawing on varied traditions, notably those of rhetoric, cognitive psychology, and linguistics. As a theoretical construct, writing is complex. Writing is a social and cultural act; it is problematic to specify what develops or progresses in writing and what it develops toward. Evaluation of writing is an area under-researched and under-theorized. (The term evaluation is used to refer to the process of making a judgment. If the use of the information is for an end-point type decision, a summative purpose, the word testing is employed. If the purpose is to inform the teaching and learning of writing, then the term assessment or formative assessment is used.) Links between theory in writing and evaluation of writing are not well articulated; equally, the links between evaluation and the teaching of writing are underdeveloped.

This article examines the current status of evaluating writing, particularly in relation to classrooms and teaching. This is particularly apt, given that key ideas and principles from cognitive, constructivist, and sociocultural theories have reconceptualized assessment and its role in teaching and learning. While the written form has long been used to examine knowledge, it is only relatively recently that evaluation of writing has been seen as something that is an integral part of informing teaching and learning. This article commences by briefly considering the substantial body of work on writing tests designed to make a specific judgment – to select, place, and grade – then moves to portfolios as a means of gathering data to evaluate writing. Finally, the relatively limited research related to assessing student writing in ways that potentially inform teaching and learning is examined. There is brief reference to response to writing in the form of conferences which have the potential as a site for formative assessment, and written response which is, sometimes, employed formatively on draft work although, more commonly, it accompanies a grade to justify it and/or provide feedback designed to improve subsequent performance. The use of assessment tools in writing designed to provide information for formative purposes concludes the discussion on assessment of writing.

Evaluating Performance: Tests of Writing

Writing is the means by which students in educational settings present and display what they know. As students move through the schooling system, their competence in using writing for this purpose assumes greater importance. Some tests may examine the ability to write directly or the ability to write may impact indirectly by content being tested in essay form. The widespread use of written tests to select, place, certify, or hold to account has been a shaping influence on writing scholarship. Writing as a means of testing literacy skills and intellectual abilities was seen in the Han dynasty (206 BC to AD 220) with its formalized system of written examinations for selection for imperial, governmental, or feudal service; in Britain, written tests became an efficient way to select candidates for the civil service. Universities employ written tests to select and place although, more commonly now, student writing performance is tested to determine the need for support to increase chances of success in tertiary study.

The resulting emphasis in writing evaluation research has been on judgments whose purpose (and timing) suggests they are of a summative nature. A measurement emphasis has led to issues in the evaluation of writing being framed technically. In fact, scholars have often characterized the history of testing of writing as one of balancing the requirements of reliability and validity with a large body of literature discussing how to obtain, maintain, and enhance agreement among markers and other literature dealing with the effects of testing variables such as prompts or time limits.

Criticism has centered around two major issues. The first concerns the fact that scholarship around testing of writing was based on outmoded notions of validity and seldom considered the implications of decisions – including how testing might connect to, and improve, learning. Teachers of writing tended to shun writing tests as something that either seemed unrelated to teaching or had a negative effect in that administering and scoring placement tests, for example, took time and energy away from teaching. There was little questioning of why some methods of evaluating writing are privileged and what the outcome of use of writing-test scores is both in terms of making the best educational decisions and in terms of unintended consequences.

There has been relatively limited attention to the consequences of testing writing, although unintended consequences have been a focus of some recent research. Tests impact on curricula and instruction – a complex phenomenon referred to as washback. At present, widespread accountability testing has highlighted views with regard to the negative effects of assessment on teaching. Hillocks – in *The Testing Trap: How State Writing Assessments Control Learning* – points out that assessments, not standards, have an influence on what happens in classrooms in terms of rhetorical stance, instructional mode, and writing process; they privilege curricula content that appears related to the assessment, such as particular forms of writing. They downplay the communicative interaction between writer and readers, turning writing into an act of formal display. Scoring rubrics can indicate what is perceived as important in writing and promote a narrow definition of writing by students.

The second focus of criticism centered around the idea that writing testing – unsupported by resources commonly used by writers and involving a single, often timed, response to a prompt – was out of step with current views of literacy and how it is acquired. As writing theory changed, its conceptions no longer matched the construct implied in – and the information provided by – traditional formats for evaluating writing.

Moving Beyond Traditional Test Formats: Writing Portfolios

The introduction of portfolios as a means of gathering writing for evaluation came at a time when composition studies moved from a focus on form and products to the processes involved in writing. The portfolio concept as it applied to writing has been discussed in a number of collections that incorporate diverse perspectives. Similar to the craft origin of the concept, portfolios are, essentially, multiple examples of writing which could be gathered over time to present richer, more complex information concerning a writer's efforts, processes, progress, or performance. Portfolios allow writers to demonstrate writing for a range of purposes, for different audiences, and in different contexts, thus seeming to encompass a view of writing more aligned with theories of writing as social practice to accomplish communicative goals (although social motives and functions of communication were not necessarily captured in the writing represented). They were also thought to be a way of collecting information to evaluate writing performance that might impact positively on instruction and student outcomes.

Although they originated in the classroom as part of a move to connect assessment to the process of learning, portfolios have morphed and the initial uses

for which they were designed have been extended and adapted. They have been widely employed for large-scale assessment – for comparisons across classrooms at different levels from school to state. These attempts to link classroom portfolio assessment to large-scale testing are seen as problematic. The limitations of portfolios – from pragmatic, resourcing issues to questions of scoring and standardization to notions of empirical validation – were widely addressed in scholarship of the 1990s.

Portfolios have the potential to be used for different purposes – to illustrate development or patterns in writing behavior over time or differential expertise across genres, purposes, or social contexts; to allow teachers insight into a writer's strengths and weaknesses and to help teachers to hone teaching to meet student needs. They provide a potential site for collaborative inquiry of student and teacher into student writing and an opportunity for students to learn to exercise judgment with regard to their own work to reflect and to self-assess. Ideally, portfolios would not be used to summarize performance but to serve a formative function linking instruction, performance, and ongoing assessment to guide the learning process.

Assessment of Writing for Teaching and Learning

While a major issue in testing writing has been aligning evaluation to theories of writing, a major concern in formative assessment is working out how to move toward the desired outcome whatever that may be. Whether – in writing – this outcome is a defined goal or a broad horizon is a dilemma discussed in the literature. The goal model of progression is like a skills or knowledge model which assumes that what is necessary to be good at writing is not only known but can be measured and then turned into some form of teaching program. The horizon model suggests less specified outcomes but also multiple pathways.

In order to understand progression in writing, it appears that teachers may rely less on a knowledge model than on value judgments that are formed through the extensive process of making those judgments. Teachers are thought to develop understandings of progression and make reliable judgments of written work through the process of construct referencing. Understanding of a construct is refined through experience and processes, such as moderation where collegial discussion is involved. The shared meaning that develops among those interpreting the evidence in the form of the writing has been referred to as guild knowledge.

Underpinning formative assessment is the promotion of student autonomy and self-regulation. To promote these, students are initiated into the guild knowledge that guides teachers' judgments with regard to student

writing. Knowledge is built for students through classroom practices closely associated with formative assessment such as sharing goals and what counts as success with the learner – through feedback, peer reviews, self-assessment, and the use of exemplars.

The research community has barely begun to consider formative assessment in writing. Formative assessment can be seen to be of two kinds: planned and interactive. The purpose for planned formative assessment is to obtain information from the whole class with regard to progress in learning through undertaking a specific activity. Interactive formative assessment, on the other hand, is that which takes place during student–teacher interactions arising out of a learning activity. In writing, the research literature is framed around the traditional, major ways in which teachers of writing would consider they gain information in order to use it to give feedback to writers, namely, by responding to the writer through conferencing and by providing written feedback. As potential sources of information to be used formatively, peer- and self-assessment have received some research attention with respect to writing.

Potential for Formative Assessment: Responding to Developing Writers

Teachers need to make an assessment of student writing in order to respond. Researchers have struggled to delineate the conditions for constructive response in writing. Writers need such response to be in a form that allows them to monitor their own progress toward a desired outcome and to help decide how to move forward; but they also need the response to be such that they discover their readers' needs. Teacher response is given in the context of an unequal power relationship; they have an ambiguous, often conflicting, role as facilitator, evaluator, and audience and the issues of text appropriation and ownership surface. Various vehicles for feedback on writing are possible, including conferencing, teacher-written feedback, and peer feedback. There is also feedback from self-assessment. While conferencing is more a feature of elementary writing classrooms, written feedback characterizes classrooms beyond this level. The sites for response only provide the opportunity for obtaining and using information for formative purposes.

Conferencing as a Site for Responding to Writing

Conferencing is viewed as fundamental to teaching and learning in process-oriented writing classrooms. In conferences, teachers learn about writers and developing writers learn to interact with – and craft meaning for – a reader.

Effective conferences provide writers with opportunities to develop the meta-cognitive awareness related to the writing process and the self-regulatory strategies required for reflecting on their texts, together with the personal responsibility necessary to becoming a writer.

Literature on conferencing is grounded in practice. Practice-oriented, classroom-based writers clearly locate the role of the teacher as a follower of a developing writer's lead, rather than that of an instructor. Young writers are to take responsibility for managing and reflecting on their own learning. The role of the teacher is couched in terms of listening for clues with regard to the kind of support writers need and providing that support at the appropriate moment. For teachers, even the most skilled conferencing is complex and challenging. The research illustrates numerous problematic issues surrounding conferencing, such as teacher control and a predominance of a narrow, low-level focus. There is little research that illustrates how the properties of the interactions are used to achieve targeted instructional purposes in a particular context. Conferences contain opportunities for evidence-informed, moment-by-moment decision making by teachers assessing where the writer currently is and the best way to move them forward. Effective writing conferences – where teachers understand and respond appropriately to student need – move learners' development forward in meaningful ways.

Written Comments as Response to Writing

Although feedback on writing products has been considered a common form of writing instruction at secondary and tertiary levels, scholarship on response to student writing has not been theoretically grounded and linked to assessment and improvement. Written feedback is intended to improve student learning in writing; however, most of the studies have been conducted outside of any context – pedagogical, theoretical, or communicative. Research has treated the texts that teacher-responders create as if they stand alone, ignoring the perspective that the meaning of text will be constructed differently depending on the discourses brought to bear on the text by the reader.

In general, students do not find written feedback on their writing either helpful in itself or as a catalyst for discussion; the traditional ways in which teachers make comments on students' drafts are seen as not effective in improving students' writing; perhaps, because the work is not often viewed as one in progress and feedback is corrective rather than designed to foster development.

A major stumbling block to instructive feedback is the nondialogic nature of much of the reported practice. In commenting on drafts, teachers – in their role as expert and ultimate evaluator – impact on what decisions students make with respect to revision. Student writers,

arguably, have a constrained level of choice with regard to whether or not to use the feedback. Students are seldom co-negotiators, co-evaluators. The lack of critical involvement by the student lessens the likelihood of the feedback becoming internalized and having effect beyond the current piece. Huot argues that comments should be transformative; they should be open-ended and force students back into their text.

Reflective and interactive logs are one way to do this. Dialoging is a means by which teachers help students to think about their writing and writing processes and to develop agency and control. Logs have taken the form of a learning journal where the teacher may write feedback and the student records thoughts and goals and examines and explores these to better understand their writing. Through the log, the student interacts with the teacher (or others) in an ongoing, formative, and dialogic fashion to enhance writing performance.

Self and Peer-Assessment

Teachers of writing describe methods by which they incorporate student self-assessment into their classroom through reflective writing including through contracting criteria that describe the work required to reach a particular level or grade, and through written or oral dialogs in which student and teacher evaluate writing together. The benefits of reflection and self-assessment are readily claimed and there is a developed rationale for linking self-assessment to achievement, but there is limited empirical support in terms of research into the forms and consequences of this, particularly in writing.

The dominant form of self-assessment in writing discussed in the literature involves the selection of work for portfolios or reflection on the completed portfolio and the recording of the evaluation often through a memo or covering letter. These acts are, generally, not for a formative purpose and are, arguably, too late to impact student learning. Inviting student input in an attempt to change the teacher–student dynamic of grading does not necessarily change the consequences or outcomes of the activity. The argument is made that the very nature of teaching makes it reasonable that, in self-assessing, students may simply reflect back teacher language and judgments; it is also noted that both selection and reflection are frequently teacher guided.

In the broader self-assessment literature, there has been an emphasis on explicit articulation of assessment criteria in order to promote understanding of what is needed. Describing standards in relation to writing is acknowledged as difficult and such is best transferred in joint evaluative activity through using annotated exemplars, together with the verbal descriptors. In writing, approaches to understanding assessment have utilized the principle of annotated samples which help students

gain a sense of perspective with regard to the quality of their written work and to both self- and peer-assess appropriately.

Peer response has been primarily utilized as a means to enable writers to receive feedback from an audience rather than as an explicit form of peer assessment. It has been instantiated in practices in elementary school, such as the author's chair. It is regarded as easier to evaluate and give feedback on a peer's work than on one's own. However, research suggests that peer-evaluation and assessment tasks that cede control to students are not a common occurrence in writing classrooms.

Supporting Formative Assessment Practices in the Classroom: Planned Assessment of Writing

The message in many writing-resource books for teachers presents a traditional view of classroom assessment as almost an afterthought phase in the planning cycle where what is taught is determined by curriculum objectives and writing-process specifications. A focus on instructional goals, however, does not help in decision making concerning student learning needs. Planned formative assessment can provide the teacher with insight into the particular learning needs of individual students and groups of students and form the basis for differentiated teaching of writing.

A major issue with respect to enabling formative assessment in writing relates to the notion of guild knowledge – the teacher's professional and content knowledge in the area of writing. Teachers have been shown to lack knowledge of how language works. This knowledge is needed in order to notice and recognize what is significant in terms of written language and then to respond. Arguably, teachers need considerable support in working out how to diagnose and teach to the needs of their developing writers. How to provide this support without an entirely prescriptive lock-step progression to a closely defined horizon is a problem that was addressed in the design of a planned formative assessment tool to assist teachers to gain information from student writing in their classrooms. (The tool is part of project as TTle (Assessment Tools for Teaching and Learning) which provides detailed assessment against curriculum objectives in reading, writing and mathematics for years 4 to 12. It is a CD Rom-based/web-based assessment suite which gives teachers choice in the design and timing of assessments and access to a range of reporting formats, including comparisons to norms.)

This tool is an example of a diagnostic assessment that aligns with current theory of writing as a social and cultural practice where the term genre refers to the processes involved in getting things done through language.

The theoretical framing views writing broadly as serving social purposes: writing was conceptualized as serving six major purposes – a core set of generic processes that encapsulate what the text is doing. For each of the major purposes that inform – or processes that form – texts, an analytic rubric was developed. The content of these rubrics drew on research which considers that a text can be seen from two perspectives, namely, as something that can be recorded, analyzed, and discussed, but also as a process that is the outcome of a socially produced occasion. Forms of text (i.e., genres) produced in and by specific social institutions (such as within schooling) will have some stability. Therefore, descriptions of features and text structures commonly associated with a generic social purpose were provided in the scoring rubrics.

The rubrics assess student performance using criterion statements relating to seven dimensions of writing. While, all dimensions of analysis of the text are seen as interdependent in terms of judging the effectiveness of the piece of writing, for purposes of assessment, the dimensions are considered and scored separately. Within the same framework and dimensions, the criteria at each of the levels articulate a developmental progression. This helps teachers to work out what the next level of development – the way forward – might look like for any given writer. They map a writer's development, allowing diagnosis of areas of difficulty and those of strength to be situated within the context of the communicative purpose of the task.

The diagnostic assessment tool is intended to be just one of those in the writing-teacher's armory, albeit a fairly powerful one. The classroom teacher who knows the students in a variety of contexts is able to view the results of a single assessment piece of writing in the light of other sources of information and make informed decisions concerning, likely, the most efficacious instruction. Further, the discussion surrounding moderating writing samples builds teachers' knowledge.

Conclusion

A consideration of the scope of the literature related to evaluation of writing suggests that scholarship has spent considerable time and effort focusing on performance testing for summative purposes. Technical concerns are an instance of a research literature which reveals a surprising disconnection to practice. Even in an area as fundamental to teacher practice in writing as response – while principles of sound written feedback or conferencing have been advocated – research has not established links between these and efficacious outcomes for developing writers. The field has been tardy in taking on board notions of validity that foreground the use and consequences of evaluation. There is a significant gap in the literature in terms

of research that considers the assessment of writing for formative, diagnostic purposes, to inform teaching, and to support learning in a forward-looking manner.

Assessment in Schools – Mathematics

M Brown and J Hodgen, King's College London, London, UK

Trends in Assessment in Mathematics: 1970–90

In the 1970s and 1980s, the main developments in assessment in mathematics were new and wider forms of assessment than the traditional written tests and examinations of technical performance, which had previously predominated in many countries. Whereas the earlier models had been mainly for purposes of teachers' and schools' monitoring of learning, end-of-course certification, or academic/vocational selection, the new forms of assessment were intended to improve the validity of the assessment of individual students against wider curricular objectives.

This broadening of the objectives of learning mathematics mainly reflected socioeconomic changes resulting from greater automation of employment and growing social equality. Previously, for the majority, it was thought that some basic calculation and measuring skills would suffice in everyday life and in jobs requiring manual and/or office-clerking skills. An elite minority were inducted into traditional mathematical knowledge in order to pass examinations allowing entry to careers, predominantly in mathematics teaching, engineering, and accountancy. A few of these would be needed to be original thinkers, but this was a talent perceived to arise rarely and naturally. Thus, assessment was mainly of proficiency in calculating or more technical procedures, and of knowledge of mathematical results.

With the advent of computers, calculators, and automation in the workplace, it was clear that numbers in purely manual jobs would decline and many more people would need to be able to interpret and make decisions based on the output of computers, calculators, and other machines, and to employ this technology to solve problems in both work and life. The pace of change and the degree of complexity of life were accelerating, alongside a greater respect for the rights of, and thus increasing autonomy for, all classes and races, and both genders.

Mathematics education adapted to become more utilitarian and less elitist, and more oriented to interpretation, reasoning, problem solving, and communication skills (e.g., National Council of Teachers of Mathematics, 1989). Tests of knowledge and procedures alone, whether set in abstract contexts or in artificial real-world contexts where there was just the right amount of information in easily manipulable form, were no longer perceived to provide valid ways to assess the wider set of skills and processes which formed the

new curriculum. Further, traditional tests were perceived as not allowing students who could, given time, use mathematics effectively to solve practical problems, to demonstrate their competencies; some such students had frequently scored few marks in abstract written tests.

Thus, mathematical assessment had developed in the 1970s and 1980s to incorporate more authentic assessment based in classrooms and allowing students to demonstrate their wide range of skills over longer time spans than traditional examinations. Evidence might be presented in the form of student portfolios, which allowed external validation of grades. Some countries introduced assessment of mathematics through practical tasks, using everyday equipment. Others used extended practical problems and/or mathematical investigations, either in the classroom or in controlled conditions. Some of these more open tasks allowed students to tackle the problem using whatever level of mathematics they knew, demonstrating assessment by outcome rather than assessment by task.

These assessments were designed not only to be more valid using the traditional sense of validity, but also in relation to the more contested notion of consequential validity (Messick, 1994). Thus, widening the assessment was designed to encourage broader forms of classroom teaching, demonstrating the power of assessment as a lever for curriculum change.

The purposes of assessment were no longer limited to monitoring of achievement, certification, and selection, but reflected both the greater technical background to assessment and the human rights developments in wanting to provide a broad description of the developing mathematical competencies and skills of individual students across the full attainment range, using the notions of criterion-referenced assessment which took into account the broad categorization of assessment objectives first outlined by Bloom *et al.* (1971). Rather than tests taken at particular times of year, ages, or grade levels, assessment could document progression in individual mathematical attainment – in England, this linked with the graded assessment movement.

With the increasing use of information and communication technology (ICT) in assessment, in the US criterion-referenced testing developed into adaptive testing, where the computer could adapt the later questions asked to the knowledge demonstrated in answers to earlier questions, thus providing a more efficient use of testing time and a more comprehensive description of individual attainment. However, the items used were restricted to multiple-choice

computer-marked format, which were better suited to knowledge, procedures, and understanding rather than analysis and synthesis. Adaptive tests required the design and use of an item bank related to specific objectives in the assessment domain. Item banks were also introduced during this period and used in the 1980s for a number of purposes, including (e.g., in Scotland) teacher-based national assessment.

Trends in Assessment in Mathematics: 1990–2008

What has changed in mathematical assessment since about 1990 has been less the modes and techniques of assessment and more the purposes. These include a desire for greater accountability for student progress not only at national or state level but also at school and teacher level. This requires more standardization, a process to which increasing deployment of ICT can contribute. However, the consequences of such assessments in terms of narrowing the mathematics curriculum require continuing searches for practical ways to broaden summative assessment in schools.

Finally, in opposition to these influences on summative assessment, there has been a growing emphasis on formative assessment in mathematics as a means to improve both teaching and student attainment.

These trends are described in more detail in the sections which follow.

Assessment of Mathematics as Part of School Accountability

Alongside mathematical assessment for national accountability, using the now well-known international Trends in International Mathematics and Science Study (TIMSS) and the Programme for International Student Assessment (PISA) surveys which provide league tables of countries, in some countries, there has been a significant growth in assessment for school accountability, holding schools accountable for their students' results and progress. Test results are also being used to evaluate and manage the performance of individual teachers.

The growth in accountability testing may also reflect a change in perceptions of the nature and distribution of mathematical ability. While external assessment of mathematics was once regarded as appropriate only for the minority endowed with mathematical talent, it later became a democratic necessity to recognize and improve all students' mathematical attainments, and now all students are regarded as capable of and entitled to attain a specified national standard, or at least a minimum degree of progress, with schools held responsible if they fail.

Such systemic use of assessment for evaluation and accountability has spread with the increased use of large

and complex databases, some at national level, which allow monitoring of the progress of individual children at intervals through their whole period of schooling. In England, the government has announced new plans for parents to be able to check using the Internet, at any time they wish, their child's detailed progress up the levels of the national curriculum. Partly because of its perceived hierarchical structure, mathematics has been a key subject in these developments, often alongside national languages.

Initially, school performance may be judged on the proportions of students who reach one or more specified attainment standards. This requires either strict moderation of teachers' assessment within and between schools, or national- or state-designed tests to guarantee comparability. Where teacher performance is also being measured, there is likely to be a call for external forms of assessment.

The more sophisticated databases, which include results of successive test administrations, such as those used in England and in separate states in the USA, allow schools to be judged not only on absolute standards but also, more equitably, on the progress their students make from their previous test results. They also allow school data to be reported in terms of ethnic, gender, and socio-economic groups. This systematic testing and data collection forms the basis of the No Child Left Behind Act introduced by the Bush administration in the USA and the national testing in England. One result of the detailed reporting of results for different groups and the raised expectations for all students is that the gender gap in mathematical achievement has been almost eliminated in most countries and differences between ethnic groups are at last gradually closing. However, differences in mathematics attainment between different socioeconomic groups, although generally less than those in languages, seem more intractable.

External testing provides a measure of school success that is open and apparently objective, enabling identification and remedial action for schools where mathematics teaching is poor. However, the downsides are now being discovered in England and in the USA, where the testing systems have been running for the longest.

In relation to mathematics, externally designed tests tend to not only lead to excessive time being spent on test practice but also to narrow the curriculum to include only those topics, and those types of artificial single-step question, which are included in the tests. There is little incentive for teachers to include in the curriculum work on longer and more realistic problems, for them to organize students to work in groups, or to spend time using calculators or computers, if this is not included in the external assessment. Teachers, who are under pressure to achieve high test results, have limited opportunities to concern themselves with wider aims of education, such as independent thought, creativity, positive attitudes to learning,

application to novel situations, depth of understanding, or ability to retain ideas and skills over long periods.

Children may become anxious about the assessments and those who know as the result of repeated practice that they are likely to do badly in mathematics may well develop negative attitudes. Data from TIMSS (Mullis *et al.*, 2008), for example, show that between 1995 and 2007, during the period when there has been increased emphasis in England on schools meeting test targets, student attitudes to mathematics have dropped significantly although their test results have risen.

Some administrations have sought to reduce these ill-effects by not publishing the results (e.g., Scandinavian countries), or by testing at the start rather than at the end of the academic year (e.g., France). In such countries, the results are less to evaluate school performance and more to provide teachers with comparative information about their students' performances on which they are expected to act.

Finally, the more complex the testing system the more likely it is to become logistically difficult to administer it. Such problems are one reason, but not the only reason, to lay more emphasis on ICT-based assessment which avoids the need to employ and train large numbers of markers.

The Use of ICT in Mathematics Assessment

As elsewhere in education, the use of ICT in the assessment of mathematics has increased, particularly in marking and administration. In mathematics, this use of technology in assessment lags behind its use in teaching and learning. This lag, in turn, has a limiting effect on technology use in classrooms as teachers prioritize preparation for high-stakes assessments, which remain predominantly pencil and paper based.

Calculators of all types remain distrusted by many. Hence, although students are commonly allowed to use them within high-stakes assessments, this use is still sometimes restricted.

It is likely that pressures to increase efficiency and to reduce costs will result in greater use of computer-based testing, including adaptive testing as already noted, although there remain significant difficulties that are yet to be overcome. Increasingly, in the developed world, students have ready access to computers in and out of schools and access is no longer as significant a problem as it once was. However, students taught in a pencil-and-paper mode may find it difficult to fluently handle mathematical symbolism on a computer in an assessment.

Computer-based tests are dominated by the multiple-choice format. However, there have been various innovations that allow students to use computers to do mathematics using constructed-response items. Some innovations have explored the potential for the use of more realistic contexts in school mathematics (Richardson *et al.*, 2002). There is some evidence that dynamic and colorful

on-screen presentation leads to greater student motivation, although this may be a novelty effect.

Computer-based assessment does have several potential advantages over pencil and paper, such as single-screen item presentation and interactivity. Interactivity can lead to less emphasis on visualization strategies. Candidates tend to use guess-and-check strategies more often and appear less willing to use pencil-and-paper jottings. Whether these different affordances lead to increased validity may depend on the interpretation of the concepts being assessed. Comparison of equivalent items presented in both formats reveals that for some items on-screen presentation increases validity, whereas for others validity is reduced (Threlfall *et al.*, 2007).

There has also been increasing use of technology for formative assessment purposes, for example, technologies that allow students to vote in real time thus providing immediate feedback to the teacher. There is little evidence as to whether such technologies are effective. Some research points to the efficacy of integrated learning packages in which computers provide feedback on learning, although such studies are generally small scale and related to specific interventions. There is increasing use of the Internet, particularly for students' individual use in preparing for high-stakes examinations, although again research in this area is limited.

Practical Ways of Broadening Summative Forms of Assessment

In the section titled 'Trends in assessment in mathematics: 1970–90' of this article, it was noted that by the 1980s experimental forms of assessment found richer and more practical tasks were being pioneered by a number of agencies in different countries, for example, the Freudenthal Institute in the Netherlands, the Shell Centre, the National Foundation for Educational Research, and King's College London in England, and the University of California at Berkeley in the United States.

To some extent, this was incorporated into international, national, or state-organized assessments, mostly using centrally designed tasks which were either centrally marked or assessed by trained teachers or local markers. For example, the TIMSS survey of 1995 included voluntary participation in the assessment of practical mathematics using problem-solving items administered and assessed by trained visiting staff. Mathematics examinations at age 16 in England included alongside external tests an element of rich activities set in the classroom and for homework over several weeks and marked by teachers according to clear instructions. These activities were voluntary from the late 1980s, but compulsory by the late 1990s. In other countries, teachers included students' performances in this type of activity into school-designed and/or portfolio-based summative assessment.

There is a major problem with the inclusion of these longer tasks in high-stakes summative assessments. Accountability measures have encouraged teachers to provide more guidance than was intended to increase the standards achieved by the teacher and the school, and have encouraged students to demand assistance from teachers, parents, and peers to enable them to submit perfect pieces of work. The availability of the Internet has also made it difficult to stop students accessing solutions posted by others inside or outside the school. Furthermore, if the problems are complex then marking equally becomes complex and it will be difficult to ensure reliable marking across students, teachers, and schools.

Although there is pressure in high-stakes assessment to avoid or remove rich, extended, problem-solving items (both pure and applied), investigation, discussion, and use of computers wherever appropriate, to encourage teachers not to narrow the curriculum it would seem to be necessary to incorporate some form of this activity as part of the summative assessment. There are several possible solutions to this problem.

One of the solutions is that adopted by the PISA surveys. PISA is administered for the Organisation for Economic Co-operation and Development (OECD) by the Australian Council for Educational Research, and in mathematics the aim (in contrast to those of TIMSS) is to assess the attainment only of mathematical literacy (the ability to apply mathematics to model and solve realistic problems). The assessment framework was developed internationally but the initial mathematics items were mainly developed by the Freudenthal Institute, reflecting a tradition of realistic mathematics education (Van Den Heuvel-Panhuizen and Becker, 2003).

Although some PISA items are short and can be computer marked, others are designed to be more complex, to require application of more than one idea or process and some degree of strategy/creativity/reasoning/communication skills. However, these still have to be restricted in scope to fit within a short timed test and, hence, none can take longer than about 20 min. They are externally marked by trained markers. Such short items are not ideal as an assessment of extended problem solving. Furthermore, in the absence of an explicit curriculum focus on the application of mathematics, the greater linguistic complexity and cultural assumptions associated with such items may bias the assessment against students from lower socioeconomic groups. Nevertheless, such items at least incorporate some of the features of extended problem solving while allowing assessment under controlled conditions.

An interesting consequence of the introduction of PISA is that countries as diverse as South Africa and Israel have adapted the PISA framework as a model for their own mathematics curriculum and assessment for students who are not planning to specialize in mathematics.

Of course, where assessment is less high stakes, more autonomy can more easily be given to teachers to assess students' abilities to solve holistic problems, including working in groups and using computers and the Internet. Such assessment increases validity but at the cost of reducing comparability between students, teachers, and schools.

Formative Assessment

While some countries have relied on national summative assessment to raise mathematical standards, others have attempted to reach the same ends by introducing more formative assessment, sometimes known as assessment for learning. Here, assessment is not being used so much a measure of attainment but to provide feedback to improve the quality of curriculum provision and teaching.

Although the recent interest in formative assessment can be linked to the influential review by Black and Wiliam (1998), the term itself has a long history in education. Building on advances in diagnostic assessment in the 1980s and early 1990s, formative assessment focuses on how assessment can be used by teachers to inform and adapt the teaching of mathematics to suit the learning needs of students. While formative assessment, in general, has been shown to be a particularly effective pedagogic strategy, it is poorly described in ways that can be implemented in practice. Hence, recent research addresses how to use assessment to inform learning in typical classrooms where the time a teacher has to spend with individuals is extremely limited.

Somewhat paradoxically, given that much of the evidence relating to the efficacy of formative assessment has been collected in the context of mathematics, the descriptions of formative assessment in practice are largely generic. Here, we discuss the specific mathematical issues relating to the key generic aspects of formative assessment:

- sharing learning intentions;
- eliciting students' ideas and understandings; and
- regulating learning through feedback.

Sharing learning intentions is remarkably difficult in mathematics. Recent policy initiatives in mathematics education in the UK, for example, have emphasized the importance of sharing lesson objectives with students. However, while the aims behind this are laudable, the tendency is to focus on short-term lesson objectives, whereas the majority of learning objectives in mathematics is medium or long term. Hence, lesson objectives are likely to be either trivial or meaningless to students. An alternative approach is to encourage students to engage in more discussion, yet this implies a considerably more dialogic approach to teaching than is currently the case in most mathematics classrooms.

Teachers have traditionally used classroom tests to elicit students' understandings and one formative approach is to develop better classroom tests. For example, the didactical assessment approach developed at the Freudenthal Institute in the Netherlands has shown how open-ended pencil-and-paper questions can elicit a variety of student thinking. Of course, for such assessment to be formative, it needs to be carried out before the relevant teaching. Another approach has been to examine ways in which teachers can use rich tasks and questioning to find out what students know in the course of normal classroom activity. Asking richer and more challenging questions is not in itself sufficient; responding appropriately to students' answers requires teachers to listen more interpretively in order to work out why students respond in particular ways rather than the more common evaluative practice of listening for correct answers (Davis, 1997).

Feedback can enable the teacher to adapt, or regulate, teaching to the learning needs of students. It can also inform students about their next steps in learning, thus enabling students to self-regulate their learning. A great deal of feedback to students in mathematics is in the form of marking. Typically, this marking identifies correct and incorrect answers and the number of correct answers is given as an overall mark. This is of limited use formatively, because it gives no advice to students on what to do to improve their mathematical understandings. In addition, such marking tends to de-motivate low attainers. Rich comments providing specific feedback to the student can be very effective. Yet, providing comments together with marks is just as ineffective because students focus on the marks not the comments (Butler, 1988). An effective alternative is providing comments without marks.

An important factor in the success of formative assessment has been the communication of this powerful pedagogic idea in simple terms. This has enabled a widespread take-up of the ideas, for example in Australia, New Zealand, Scotland, and England. Much of this take-up has involved a loose, weak, and, at times, procedural implementation of the core ideas. Inevitably, this has attracted a great deal of criticism. While much of this criticism is misplaced, formative assessment does nevertheless place considerable demands on teachers' pedagogic skills and their knowledge of school mathematics and mathematics learning. However, evidence suggests that engaging in professional development relating to formative assessment can improve teachers' pedagogic practice. It is not yet clear the extent to which improvements in knowledge can be achieved in the same manner. Further, the predominance of generic descriptions of formative assessment can lead to an emphasis on generic process skills, over and above mathematical processes and content (Watson, 2006). Another issue relates to misinterpretations by policymakers of formative assessment as

either continual or more personalized assessment and, hence, as simply a justification for increased summative assessment.

Looking Forward

The development of assessment in mathematics, as in other subject disciplines, has been shown to follow an ever-widening spread of purposes for assessment as well as reflecting a broader set of aims for learning mathematics and incorporating an expanding set of assessment techniques in response. In assessment, there is always a tension between validity and reliability/comparability. Consequential validity, in the form of washback on curriculum and pedagogy, is a very significant issue as it potentially affects the whole of a student's learning experiences.

We can expect greater computer power to deliver closer and more continuous monitoring of student progress, greater accountability of all partners in education, increased emphasis on formative assessment, and a closer connection between formative and summative assessment, where summative assessment is mainly to verify the ongoing record of student progress. All these depend on the existence of a sound and proven framework for mathematical progress with a bank of matching assessment tasks generated within and outside the school, and with a knowledgeable and well-trained teaching workforce – these are exacting requirements. However, the risks associated with high-stakes summative assessment, which is simplistic in form and purpose and narrow in scope, are likely to remain a constant political threat to a broad and effective mathematical education, internationally, nationally, and locally.

Assessment in Schools – Oracy

A L Bailey, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Discourse – The organization of language beyond the sentence/utterance level (e.g., conversation, narration, exposition).

Grammar – The rules/conventions governing word order and inflections.

Lexicon/Vocabulary – Receptive and expressive world knowledge.

Oracy – Oral language skills (i.e., listening and speaking) and proficiency.

Phonology – The sound system of a language.

Pragmatics – The socially appropriate uses of language.

Oral language, or oracy, and its assessment for educational purposes have often been overlooked by individual educators and school systems. The teaching and testing of student knowledge of print-based language skills are tantamount to much, if not all, the focus of language-arts skills that native-speaking students experience during their formal education. For example, review of publicly available documents published by the 50 US states and the District of Columbia, reveals that 41 of their education agencies do not include an oral-language component in their state-wide tests of English language arts (ELA), despite the fact that 48 of the agencies include oral-language skills in their mandated language-arts-content standards. (At the time of writing, six US state education agencies have an oral-language component to their annual assessment of students; one state only assesses children at the kindergarten through second grades; and documentation for three states is not clear on their practices. One state has standards for oral-language skills during the early grades only; one state has standards for oral-language skills from ninth grade and above only; and one state has no reported standards for oral language.) Assessment of ELA for accountability purposes is required under federal law (No Child Left Behind Act, 2001) in order to annually evaluate all students in second through eighth grades (7–14-year-olds).

The first section of this article provides the rationale for assessment of oracy in school. Next, construct definitions of oral language that are commonly given in the literature are discussed and major skill areas are described. The article then continues with key aspects of oral-language assessment, including testing for different

purposes, test development, and administration considerations, and the assessment needs of students who have language-learning difficulties or are second-language learners. It concludes by identifying several areas for future research and development.

Motivating the Need for Oral-Language Assessment in School

The demands placed on students by advancements in media technology as they become young adults in our society have increasingly called for a level of spoken language abilities that puts oracy sophistication on par with advanced literacy skills. True, the invention of text messaging, e-mail, online communities, and the use of blogging for personal and business purposes have all led to a heightened need for reading and writing abilities. However, also witness the use of digital video and audio for sharing ideas orally via personal blogs, e-journals, and YouTube, and even via more formal conduits such as business-related podcasts and academic webinars. Moreover, as information technology increasingly makes modern societies dependent on the service industries that require face-to-face or telephonic interactions rather than on the nonverbal skills often used in manufacturing, oral language emerges as critical for a competitive edge in the labor force of the twenty-first century.

Beyond these and other functional aspects of oral-language proficiency related to student needs once they have completed formal education, there are other important reasons for monitoring the progress of children's oral-language abilities in school. Assessment of oral language is critical for knowing how much of instruction across the entire academic curriculum a student is able to comprehend and make use of. Listening comprehension is a prerequisite for any learning that takes place through classroom interaction – from discussions with peers to listening to explanations and directions from the teacher. Subsequent display of this knowledge through students' own verbal responses and contributions to classroom discourse can alert a teacher to the level of learning, be that in mathematics, science, social studies, or the language arts themselves (Cazden, 2001; McKay, 2006).

Knowing how well a child is acquiring oral-language skills is important information for teachers as children learn to read and write. Oral-language skills are closely tied to children's development of literacy skills in terms of

the rate and ease by which they acquire reading and writing abilities, as well as their ultimate attainment in these domains. Certain forms of oral language, for example, narrative discourse which requires the child to decontextualize information for the listener, may even serve as early rehearsal for print-based skills encountered later on. Thus, the information yielded by assessment of these earlier acquired oral-language skills can be useful to educators even before students have documented signs of reading difficulties.

Knowing how well children are able to listen and speak the language that is spoken around them is particularly important with diverse populations of school children; specifically, those who speak a nonstandard variety of the language, those who have a history of language delay or impairment, and those who are acquiring the language of school as a second or additional language alongside their first language. When the language spoken at school is still being acquired or is a source of difficulty for a student, the student's opportunity to learn from instruction and, consequently, the validity of all content-area assessments, are called into question (e.g., Kopriva, 2000).

So why is there neglect of oral language in schools, especially for native speakers of a language and, most pertinently for this article, its assessment? Perhaps the most salient reason is that the assessment of oral-language skills is made challenging by both the amount of time and specialized arrangements it often necessitates. Unlike the assessment of literacy skills, oral-language assessment largely requires one-on-one administration. For administration of standardized assessments, individually testing students in a suitable quiet place takes time. Often administration of this kind requires test administrators to have training in order to obtain the required homogeneity in testing conditions (e.g., uniformity in prompts, types of allowable feedback or responses by the tester, etc., so that the test remains fair and its interpretation valid for a student). Understandably, administration of this type is costly. Nor is spoken language readily measured if scored in real time without audio recording for later verification. Oral language is transitory and must be processed immediately by the test-taker, unlike printed language that students can read and write and possibly reread and rewrite at their own pace. Moreover, oral-language assessment of both listening and speaking skills has to contend with performance characteristics (e.g., anxiety of responding aloud) not just the test-taker's accuracy on the language skill(s) being measured. As a result of these restrictions placed on traditional assessment formats, by its very nature oral language may have been ignored in large-scale, standardized testing.

Classroom-based assessments (both commercial and teacher created) offer more flexibility than large-scale assessments. For example, with small-group administration of speaking and listening assessments, a teacher can

take note of each student's ability to comprehend or respond. However, even these assessments may miss the communicative abilities of students interacting in authentic ways in the classroom rather than interacting in a testing context. Alternatively, formative assessment can allow a teacher to gauge and monitor each student's oral-language abilities within the classroom context, for example, through observation of spontaneously occurring student dialog. This type of classroom-based assessment is only just becoming part of most teachers' assessment repertoires in the US (Bailey and Heritage, 2008; Butler and Stevens, 1997; Wiliam and Thompson, 2007), but has already become a major focus in the UK. England, for instance, has adopted Assessment for Learning, an initiative that has recognized the importance of assessing speaking and listening skills and is replacing the national curriculum tests at the secondary level with a focus on individualized evidence of pupil progress through teacher observations of group work, class discussion, informal conversation, and role play. The Department for Children, Schools, and Families (DCSF, 2009) has developed standards and descriptors of oral-language progression, using exemplars in an attempt to establish a degree of consistency in Assessment for Learning.

Separate from the challenges of administering oral-language assessments in schools, a second reason oral language has likely suffered neglect in both instruction and assessment is because oral-language development among native speakers is traditionally thought to be complete by the time students arrive for formal schooling at about age 5. Yet, there are many important aspects of oral language that are only acquired once children start school. For example, the specialized knowledge of how to use language (pragmatics) for different academic tasks, and the ability to reflect on language as a object of study (metalinguistic awareness) are just two aspects of oral language that are expected to develop throughout the school years and consequently require monitoring and evaluation.

Defining the Oral-Language Construct for Assessment Purposes

There are many facets of language that can make up the oral-language construct that is purported to be measured by an assessment. **Table 1** catalogs the different characteristics that can be identified as making up a definition of oral language, including oral-language registers, oral-language domains, and oral-language skills. (The domains of language include listening, speaking, reading, and writing and are more commonly referred to as modalities by applied linguists.) **Table 1** also lists the major purposes of oral-language assessment, and provides examples of different types of assessment.

Table 1 Key characteristics of oral-language assessments in schools.

Contexts of language use	Oral-language domains	Oral-language skills	Assessment purposes	Assessment examples
Social	Listening (receptive)	Phonological	Instruction: a. Screening b. Formative c. Portfolio d. Benchmark	Language sampling a. Story (re)telling b. Personal narrative c. Picture description d. Dialogue
Academic: a. General b. Specialized (technical)	Speaking (expressive)	Lexical		
	Listening and speaking combined	Grammatical Discourse/pragmatics	Diagnosis Accountability: a. Summative b. Benchmark	Scoring Rubrics: SOLOM (observation) Rating scales Large-scale: a. Norm-referenced b. Criterion-referenced (standards-based)

Oral-Language Registers

There are many registers of oral language, such as casual speech to friends, technical language used by scientists to colleagues, and mothers' simplification of language as they talk to their young children. The types of language most pertinent for the school context are social language used in school and academic language. The social language that students encounter in school can be considered the everyday language of casual conversation between school friends during break time, lunch, or in the home-room, and between teachers and students when they are not engaged in formal instruction. For some students, this register can be predominant in their oral-language use and exposure even during formal instruction; not all teachers teach using a formal academic register all the time, nor might they always hold students accountable for academic language use.

Academic language itself has been characterized in different ways, with some questions of whether academic language is necessary for learning in school, whether it is limited to literate uses of language only, and even if it is meaningful to postulate such an overarching construct for the language of school given that different content areas may have very different linguistic characteristics. Bailey and Heritage (2008) further divide academic language into two subtypes: the language used for navigating a school environment that may still be more formal than social language (e.g., requesting and understanding teacher directions), and the language needed for teaching and learning the content of curricula. Within the latter, researchers have identified aspects of language that may make it challenging, for example, complex grammatical structures such as nominalizations and passive voice, language specialized to specific content areas, such as the technical vocabulary used in subfields of science, as well as the language that cuts across many different disciplines

that can be thought of as general academic language (e.g., Bailey and Butler, 2007). Specialized vocabulary can include words and phrases such as *circumference*, *base*, and *absolute deviation* used during algebra, for example, and general academic vocabulary can include words and phrases such as *evaluate*, *refer*, and *explanation* that tend to have the same meanings across content areas.

Domains of Oral Language

Oracy encompasses two language domains – listening and speaking. Listening is the receptive domain, while speaking is the expressive domain. Together they are needed to carry out human interaction in the here and now. Listening requires the comprehension of spoken language, whereas speaking requires the production of spoken language. In terms of assessment, educators need to test listening and speaking skills in isolation or they may fail to distinguish between abilities in the two domains. However, sometimes educators will want to test combined listening and speaking abilities because it is often at the intersection of the two that instruction occurs (McKay, 2006). For example, students first listen to a textbook passage read aloud by their teacher then answer questions orally to communicate their comprehension.

Oral-Language Skills

Regardless of which register and domain of language is being assessed, it is important to be clear what skill or skills of language are the target so that the assessment can be an effective measure of the skill(s). The following are brief descriptions of the different oral language-skill areas. While all skills are necessary for oral-language development, not all are readily tested (e.g., authentic conversation skills).

Phonological skills

Knowledge and facility with the sound system of a language are fundamental to oral-language development and proficiency. For younger students in school, this means the ability to distinguish units of sound at different levels of organization (e.g., phonemes at the single-sound level, syllables combining vowels and consonants). Later, students will need to use prosodic features (e.g., word stress, sentence intonation) to speak fluently and comprehend accurately (e.g., stress distinguishing nouns from verbs sharing the same form, such as ‘pro’duce (noun) and pro’duce’ (verb)).

Lexical skills

Word recognition, a receptive skill, and word use, an expressive skill, are key components of oral-language development and proficiency. A student’s lexicon, or store of known words can be measured in terms of its breadth and depth. Breadth of word knowledge is the number of different words known, whereas depth includes semantic connections between words. Lexical skills also include student knowledge of derivational morphology (e.g., the variety of affixes that can be added to known words to create additional words with different parts of speech, such as chemic’al’ (adjective) and chemist’ry’ (noun)).

Grammatical skills

Oral abilities include knowing the rules that govern the order of words in a sentence. In English, this syntactic knowledge includes the abilities to comprehend and use: (1) simple sentences (e.g., simple declaratives and imperatives), (2) complex utterances that contain embedded clauses (e.g., relative clauses), (3) compound sentences, and (4) certain phrase structures, such as nominalizations, long noun phrases, and long or multiple prepositional phrases.

Discourse and pragmatic skills

The skills necessary for the organization of language beyond the level of the single sentence include the knowledge of different genres of discourse, namely conversational, expository, and narrative. Each is characterized by its own set of rules for effective communication, with conversation requiring abilities in face-to-face interaction (e.g., taking account of audience knowledge of a topic), expository used for conveying factual information about people, objects, and processes, and narrative used for relaying sequenced past events, both personal and fictional. Discourse-level skills also include the repertoire of language functions or the communicative purposes for which we use language. These include a large range of functions but in the school setting will most likely require students to comprehend and produce explanations, descriptions, and comparisons, for example, and be able to integrate the vocabulary and syntactic features that predictably

attend these functions (e.g., comparative adjectives such as bigg’er’ and great’er’ in service of producing comparisons). Pragmatic rules, the rules that govern how we use language, must also be acquired; knowledge in this area is critical for knowing when it is culturally appropriate to use a particular register. These rules dictate use of vocabulary such as *locate* and *indicate* during geography instruction, whereas their everyday equivalents *find* and *show* are expected in noninstructional conversation with peers and teachers.

Oral-Language Assessment: Development and Use**Operationalization of Oral-Language Constructs**

All assessment users – not just those assessing oral-language abilities – face the issue of interpreting the meaning of test scores. In the case of oral-language assessment, test developers need to make a convincing argument that they are testing listening skills, for example, and not a student’s ability to write a response if a written-response format is being used for a comprehension test. To guard against such eventualities, a well-articulated construct definition at the beginning of all test specifications (i.e., the guiding document for ensuing test item-writing and construction of a finalized test) is critical in order to make the argument that a test is a valid test of oral language. This holds whether creating a large-scale commercial assessment of oral language or a teacher record of student vocabulary use during math problem solving.

Purposes and Uses of Oral-Language Assessment

Oral language is difficult to assess but oral language is at the core of early curriculum (McKay, 2006). Data generated by interpreting the scores obtained on oral-language assessments can be used in many different ways, but the three main purposes of oral-language assessment are to inform instruction, diagnosis, and accountability.

Instruction

Oral-language assessments used for instructional purposes are all designed to provide feedback for the teacher and in many cases for students as well. These can include screening tests, formative assessment, portfolio assessment, and benchmark assessment. Results from these assessments are meant to inform classroom-level decisions and are commonly referred to as classroom assessments of oral language. A screening test may be teacher created or a commercial test that provides sufficient information about a student’s potential oral-language abilities to decide whether certain kinds of instructional experiences will be suitable for a student or if further testing is needed.

Formative assessment is not one specific assessment but rather an approach to the continual monitoring of student progress so next-steps instructional decisions can be made. Formative assessment tools are commercially available, but formative assessment, as already mentioned, can be the observation of student oral interactions during class time with a teacher noticing which students will need further help with question formation or conditional tenses, for example. Providing students with information on desired learning goals and feedback about what they have observed are key components of teachers assessing formatively. Learning goals can be systematically reflected in a learning progression to which a teacher can target instructional activities and articulate success criteria for students meeting the goals (see, e.g., the Speaking and Listening Progression Chart for English 11–16, of the Secondary National Strategy, DCSF, 2009). Formative assessment can also focus on student self-assessment with students taught how to monitor their own learning, for instance, asking themselves key questions about the sequence of events in a story to be sure of comprehending the main idea.

Portfolio assessment is an accumulation of evidence of student learning taken from a variety of student work produced in different contexts. This evidence could take the form of oral reports from different content areas, such as a science report, a review of a novel, or a history-project presentation. Finally, benchmark assessments are typically created by external test developers and may be tied to a specific curriculum. They provide teachers with periodic information about how well a student is acquiring key content of a curriculum.

Diagnosis

The primary purpose of a diagnostic assessment of oral language is to provide teachers and education specialists with very specific information about a student's language abilities. Diagnostic assessments include sufficient items of a given skill area to provide detailed information about the skill so that a teacher or specialist can intervene as necessary. For example, assessments of language production in the areas of vocabulary and pragmatics are used to help determine an expressive language delay. In addition, diagnostic assessments often provide norming information usually by age and grade so that an individual student's performance can be compared with and understood in relation to the performance of typically developing students in a norming sample.

Accountability

Assessment can be used to hold educators accountable for student achievement. Often, summative assessments that come at the end of a school year or course of study (as well as benchmark assessments that come after a unit or a period

of study) are used to monitor student progress for the purposes of evaluating student performance and evaluating program efficacy (and implicitly, teacher and school performances). These assessments tend to be norm referenced or standards based (i.e., a form of criterion-based assessment discussed further below). The information these assessments yield can be used for reporting to governing or funding bodies (e.g., local and state education agencies, or central governments) to fulfill obligations or learning targets such as raised test scores or increased numbers of students reaching certain standards for oral language.

Approaches to Oral-Language Test Development and Administration

In terms of the content of an oral-language assessment, the test items should match the content of a curriculum, or match a set of standards for skills previously identified and valued by a set of stakeholders (e.g., national teacher organizations or state education agencies). The array of test items should ideally be tied to a theory of language use or development. For example, if a communicative theory of language is adopted, then tasks should capture the authentic language demands of classroom interactions between teachers and students and between students. Assessments that will be used to measure growth or annual gains in language development must take account of theories of acquisition (e.g., attention to the order and weight given to knowledge of complex/late-acquired grammatical structures).

Establishing test validity with oral-language assessments

Establishing the validity of an oral-language assessment involves constructing an argument that the test measures the language constructs it claims to measure. While this involves the explicit articulation of the construct and the content of the test in the test specifications, there are also qualitative and quantitative analyses that play a role. For example, small-scale pilot testing of item types and administration procedures using think-aloud protocols allows the test developer to examine how students respond to item difficulty, formatting, and administration at the very moment test-takers are answering test questions. Field testing with larger numbers of students allows the test-developer to use psychometric techniques to supplement the validity argument with statistical analyses of item difficulty, item discrimination (e.g., between known groups of low- and high-performing speakers), reliability, and differential item functioning for different groups of test-takers to investigate, for instance, potential gender or cultural biases. However, in building a convincing validity argument, these analyses cannot substitute for test specifications that clearly articulate the construct to be measured and the process of item content selection.

Threats to test validity

Perhaps in no other scholastic testing environment does face-to-face interaction play so critical a role than in the assessment of oral-language skills. The assessment of oral-language skills requires the student to interact with the tester, and different testers will have different styles of interaction and degrees of support to elicit responses from students. The heterogeneity in interaction between testers and test-takers during administration is a threat to the validity of oral-language assessments because it violates the assumption that each test administration is essentially carried out in the same manner. There are also age-related considerations that must be taken into account when developing, administering, and interpreting oral-language assessments. Performance can be impacted by the cognitive and social developments in young students that are construct-irrelevant for language skills. It is also important to keep demands on the memory of young children to a minimum, else memory load also inadvertently becomes part of what is measured by an oral-language assessment.

Standards setting for oral language

As mentioned, large-scale summative assessments are often used for accountability purposes and can provide a scale score and a percentile ranking of students if norm referenced (i.e., evaluation of a student's performance relative to other students taking the assessment). However, to be most useful to educators, assessments should also provide levels or bands that are accompanied by descriptors of what skills students at a particular level can be expected to perform. Thus large-scale assessments can be both norm referenced and criterion based. These assessments undergo standards setting in order to determine what levels or cut scores on the test are considered good, fair, or poor performances. Standards setting is typically conducted by a panel of educators familiar with the language expectations of the different grade levels and the skills associated with different levels of oral-language proficiency. The issue of which standard or standards should be used to gauge a student's fluency is a continuing challenge and must be established anew for each testing situation and student population. In recent years, there has been a shift to standards-based assessment in schools worldwide. However, while these tests attempt to be overtly aligned to a set of desired standards, often the standards themselves have not been validated (e.g., shown empirically to be skills necessary for functioning as a proficient speaker). Even the most proficient speakers are known to make dysfluencies and errors at times (Davidson, 1994). Moreover, there are few norms for the oral-language development of monolingual school-age children (Nippold, 1995) that test developers can turn to for guidance.

From a sociocultural perspective, the standards-setting procedure faces the issue of privileging certain oral-language characteristics over others. For example, correct pronunciation is a cultural artifact. Setting the target

pronunciation consistent with a particular regional or even national variety of a language is primarily a function of sociolinguistic preferences and even prejudices and not any inherent correctness of spoken English. (For example, Received Pronunciation in the UK and the Midwestern dialect in the US are used as the standard variety of the language in native speaker and English as a second language (ESL) contexts, and American-accented English may be chosen instead of British-accented English in the English as a foreign language (EFL) context.) Standards setting should at the very least be guided by which forms of the language will make the language learner intelligible to most speakers of the language, as well as take account of what level(s) of functioning society desires of the language learner.

Box 1 provides examples of classroom-based assessments by language domain that reflect points made in the prior discussion. Note that depending on the purpose of use, with little modification, these assessments can be

Box 1 Examples of classroom-based assessments by domain of oral language

Listening-only assessments

Novel natural speech input

Tying the topic of the stimuli to other content areas can maximize information gained by the teacher (both language and concept knowledge).

Responses can be nonverbal: drawing, picture matching, diagramming, model building, total physical response (head nod/shake; or pointing to objects) to show comprehension.

Grammaticality judgment task

Response can be simple check marks or true/false circling to indicate whether a spoken utterance is a legal sentence in the language.

Speaking-only assessments

Production of oral reports, story retelling, personal narratives, or picture descriptions

Again, the stimuli can be made maximally useful by choosing topics from other content areas.

Production will overtly require discourse skills (e.g., genre knowledge, organization of language); however, other language skills will be revealed (e.g., pronunciation, lexical knowledge and diversity, and grammatical accuracy).

SOLOM (student oral-language observation matrix)

Production is spontaneous speech during classroom activities scored using a multilevel rubric for a variety of oral-language skills.

Listening and speaking assessments combined

Grammatical imitation task

Response is the direct imitation of the stimulus utterances. Students typically cannot accurately imitate what they do not already have command over.

Authentic interaction

These include question-and-answer sessions with the teacher, interviewing peers, participating in plays, and partner/group discussions and debates.

Referential communication tasks

These can take the form of a barrier task, for example, describing a route or an object separated from a naive partner by a screen.

used formatively for guiding ongoing instruction, diagnostically to drill down to a specific oral-language challenge for a student, or summatively to judge student attainment after a period of instruction.

The Oral-Language Assessment of Diverse Learners

Special education and the education of linguistic-minority students are two areas that have tended to be exceptions to the neglect of oral-language assessment. Many oral-language assessments administered with monolingual students in school are used for diagnosing language delay or impairment. Speech-language pathologists working in schools have at their disposal norm-referenced assessments that can help diagnose whether a student has an issue with speech production or comprehension, including pronunciation difficulties, expressive language delays, specific language impairment that often affects grammatical abilities, and receptive language difficulties that suggest a language-comprehension disorder.

Due to the No Child Left Behind Act (2001), the US has seen much activity in language test development in the last decade. This activity is directed at new large-scale language assessments that capture the language demands that English-language learners encounter in school and will need in order to succeed academically. Performance on previously available assessments did not reflect whether a student was ready to perform in an academic setting because they tended to primarily measure everyday or social language. Educators now recognize the importance of academic language to academic-concept knowledge and the need to track its development in second-language learners (Bailey and Butler, 2007; Gottlieb, 2006).

Assessment of the language skills of second-language learners is recognized as highly complex and prone to biases that result from a lack of awareness about cultural practices for language usage. For example, students may have been exposed to a tradition of learning rich descriptors for objects, people, and concepts rather than the names of objects that are the typical content of vocabulary assessments used with school-age children (Peña *et al.*, 2001). Assessing second-language learners in culturally sensitive ways is critical for determining whether a language impairment or developmental disorder (e.g., autism) is at issue or whether a student is still in the process of learning his or her second language (Rollins *et al.*, 2000). The same holds for students who speak a nonstandard variety of the language such as African-American English (Craig and Washington, 2002).

The Future of Oral-Language Assessment

Technology initiatives and research of the oral-language construct are among the necessary future developments

in this area. Two areas in which technology can assist are (1) enabling test developers to overcome the challenges of individually administered assessment. For example, automated speech recognition (ASR) technology can record and process student responses so that they can be assessed by computer reducing the administration burden on teachers and standardizing procedures (e.g., Alwan *et al.*, 2007). This and other technology initiatives (e.g., telephonically administered assessment) will need further study to determine whether these approaches yield the same results and interpretations as traditional face-to-face assessments, and (2) innovations such as web-delivered videoed lessons, that can be used in teacher professional development for formative assessment; an area with acknowledged need for greater teacher learning and system-wide initiatives to increase the consistency with which formative-assessment strategies are applied (e.g., DCSF, 2009). (The Center for Applied Linguistics is also active in this area.)

Neglect of oral assessment in schools is mirrored by a lack of research of what language demands all students need to master in order to succeed academically. Future research can redress this dearth of information by focusing on at least three identifiable areas of research and development: (1) expanded study of first and second languages as they are acquired by school-age children, (2) creation and study of professional-development strategies that enable teachers to recognize discipline-specific oral language that is prerequisite for successful academic performance in mathematics, science, etc., and to integrate the evaluation of these language demands with their assessment of content-area knowledge, and (3) creation and validation of new standards and learning progressions for oral-language development to which new assessments (both formative and summative) can be aligned. Research of the oral-language construct in the different ways suggested will not only further our ability to develop fair, valid, and useful assessments but will also expand our fundamental understanding of how oral language is acquired and operates in school, thus fulfilling both the applied and the basic purposes of the research endeavor (e.g., Stokes, 1997).

Assessment in Schools – Primary Science

W Harlen, University of Bristol, Bristol, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Assessment in primary science, as in other subjects, can serve a number of purposes:

- a formative purpose – when assessment is part of, and supports, teaching and learning;
- a summative purpose in relation to individual students – to record and report on progress to parents, other teachers, and the students themselves; and
- a summative purpose in relation to the achievement of groups of students – giving information that can be used in the context of evaluating school effectiveness.

(Primary here refers to students from the age of 5 to 12 or 13. In some countries schools for students of this age are described as elementary and at the upper end of the range students may be in middle or junior high schools.)

The great majority of primary science programs includes some guidance for teachers for summative assessment; very few directly support the formative use of assessment. The summative assessment material may take the form of tests taken prior to and following a module or unit of work and, sometimes, teachers are helped to assess students' written work within the unit. When a program is newly being introduced, this information is used to evaluate its impact as well as to report progress of individual students. However, deeper understanding of the goals of primary science – as now identified – brings with it the realization that to assess the understanding, inquiry skills, and attitudes involved requires a range of information beyond that provided by conventional tests.

This discussion of assessment, therefore, begins with a brief overview of the nature and goals of learning in science at the primary school level. Proceeding further, it considers how the challenges that these present for assessment can be met in relation to the three purposes above.

Learning in Science at the Primary School Level

Primary science programs that reflect modern views of learning share several key features:

- building on the ideas that students bring to the classroom at each stage;

- setting out a progression in small ideas toward a relatively small number of big ideas which students gradually grasp;
- providing activities in which students collect evidence from firsthand investigation of materials and phenomena around them and from other sources; and
- promoting collaborative learning through dialog, discussion, and argumentation among students and between students and the teacher.

These features are summed up in the concept of learning through inquiry – the active participation in the construction and reconstruction of their ideas by the students themselves. The concept of inquiry is not new, being implicit in Dewey's ideas with regard to active learning. Nor is it confined to science education, although it is often defined in that context, for example, by the National Research Council (NRC, 1996: 23). Inquiry is now a widely adopted approach for science education and there are over 30 developed and developing countries where it is in operation in at least some primary schools (Harlen and Allende, 2006). Its focus is both on the processes involved in inquiry and on the understanding of scientific ideas developed through the use of these processes (National Science Foundation (NSF), 1997: 7). Indeed the rationale for inquiry – and the reason for inquiry-based science programs being so strongly supported by scientists as well as by science educators throughout the world – is that it aims to promote scientific literacy.

Through engaging in scientific inquiry, students acquire a general understanding of the important ideas of science, of the nature of scientific investigation, and of how to evaluate and interpret evidence. The development of this scientific literacy has to start in the primary school grades – for the ideas and frameworks that students need to know are big ones that cannot be taught directly. They need to be built from the small ideas relevant to the objects and events familiar to the students. The role of primary school science is to help in building understanding by ensuring that the small ideas are consistent with evidence and are not just the students' preconceived ideas.

Active participation in learning is no longer taken to mean only hands on experiences – as it once was in the days of the first wave of primary science programs in the 1960s and 1970s. The importance of social interaction is seen as having a central role in the development of understanding.

Teachers are urged to encourage students to express their ideas, however unformed, to speculate about the meaning of evidence, to challenge each other's interpretation, and engage in what is described as exploratory talk (Barnes, 1978; Asoko and Scott, 2006; Mercer *et al.*, 2004).

Teaching for understanding, in this way, necessarily takes more time than the transmission of facts that has been the traditional way of teaching science in some countries. It requires a curriculum that is based on a few broad concepts rather than on a large number of narrower ones presented in what is often a fragmented way. Such a curriculum is described by Duschl *et al.* (2006) as being based on "learning progressions." A learning progression is a sequence of understandings about a topic that build on each other as students move from starting to completing their primary education – a span of 6–8 years.

It follows that the learning outcomes of primary science will include cognitive skills relating to obtaining and using evidence, conceptual understanding of science and how it works, and attitudes or dispositions.

Assessment to Help Learning in Primary Science

There is much in common between the activities of teachers and learners when engaged in inquiry and when assessment is being used to help learning (formative assessment). Inquiry-based science education requires teachers – in addition to providing opportunity for students to encounter materials and phenomena to explore and investigate – to do the following:

- Ask open, rich, questions to elicit present understandings and how students are explaining what they find.
- Listen to students' ideas and take them seriously.
- Engage students in suggesting how to test their ideas or answer their questions through investigation or in finding evidence from secondary sources.
- Set up opportunities for collaborative learning and dialogic talk.
- Scaffold alternative ideas that may explain the evidence from their investigation.
- Gather information – through observation, questioning, and interaction – with regard to students' developing skills and ideas.

The practice of formative assessment requires very similar conditions to these. This is not surprising since formative assessment aims to develop learning with understanding and to enable students to take responsibility for identifying what they need to do to achieve the goals of their activities. In science, assessment for learning is closely associated with inquiry (Black *et al.*, 2003). It could almost be said that inquiry requires formative assessment. The additional features of formative assessment – the provision of formative

feedback and the involvement of students in self- and peer-assessment – all support active engagement in learning and encourage students to take ownership of their learning and progress. However, as already noted, few current primary science programs include all the features that would support formative assessment.

Formative assessment is a continuing cyclic process which informs ongoing teaching and helps learners' active engagement in learning. The cycle involves the collection of evidence concerning learning, the interpretation of that evidence in terms of progress toward the goals of the work, the identification of appropriate next steps and decisions with regard to how to take them, so as to close the gap (Sadler, 1989) between what has been achieved and what is aimed for, or to move on. The cycle is repeated and the effects of decisions at one time are assessed at a later time as part of the ongoing process. The value of students' participation at all stages in this cycle is widely recognized (Hein and Price, 1994; Stiggins, 2001; Black *et al.*, 2002). It requires that the students as well as the teachers have a clear idea of the goals of the work. We now consider how the main elements of the formative assessment cycle are practiced in primary science, beginning with the clarification of goals.

Specific and General Goals

Clarity of goals is a pivotal requirement for all assessment; the difficulty that this often presents to primary teachers, in science, accounts for a good deal of poor practice in assessment in this area. Goals in science learning can be expressed with different degrees of specificity. The identification of standards, attainment targets, or other ways of specifying intended learning in national curricula has helped to communicate overall goals. However, these are in very general terms, such as ability to plan and conduct a scientific investigation or understanding the diversity and adaptation of organisms. Such statements are too general to be achieved in a single lesson or even a set of lessons on a particular topic. The goals of a specific lesson might include the understanding of how the structure of particular plants or animals is suited to the places where they are found. This will contribute to a broader goal of understanding how living organisms, in general, are suited to their habitats, but achieving this understanding will depend on looking at a variety of organisms, which will be the subject of other lessons with their own specific goals. Similarly, skills such as planning a scientific investigation are developed not in one lesson, but in different contexts in different lessons and topics.

Gathering Evidence

The specific goals indicate the evidence to be gathered to help learning. Without goals, there can be no way of

deciding what to pay attention to. This is particularly important in primary science because what students do and produce in their regular work is the main sources of evidence for formative assessment and while almost everything a student does can give useful evidence, not knowing what to look for will mean that relevant signs will be missed.

Observation of actions and review of written work may not be sufficient to indicate students' thinking and need to be supplemented by questioning and discussion. Not all questions are helpful in this context. The useful one are expressed as open and person-centered, for example, 'what do you think will happen if ...?' or 'what do you think could be the reasons for ...?' Stiggins *et al.* (1989) found that few teachers ask questions of this kind, focusing instead on asking for recall. Black *et al.* (2002) listed questioning as a particular feature of talk between teacher and students that requires change if formative assessment is to be implemented in classrooms. Further, questions that are carefully worded to provoke thought should be followed by time for thought. Row (1974) found that increasing wait time from the average of less than one second to eight or more seconds was found to increase the quality of the students' responses.

Interpreting Evidence

The evidence collected in these various ways as part of teaching is used in formative assessment to decide where students are in the progression toward achieving the goals and so to identify the next steps to take. This is based on a view of learning as producing a qualitative change both in development of processing skills and conceptual understanding. Skills become more elaborate, more consciously and widely used; small ideas – relating to particular phenomena – are linked together to form big ideas that are widely applicable. Although not enough is known to map out the course of development of some learning outcomes, research findings (SPACE research reports, 1990–1992; Black and Lucas, 1993; Harnqvist and Burgen, 1997) have been used to provide frameworks for describing progression. For instance, Masters and Forster (1996) have produced progress maps in several subjects and Wilson and Sloane (2000) describe progress variables as a key principle of the BEAR assessment system. **Table 1** displays suggested indicators of progression in development of ability to plan and conduct investigations:

For conceptual development, the statements in **Table 2** bring together common threads of development from small to big ideas in generic statements which can be translated into the context of particular activities.

Although the statements in **Tables 2** and **3** are numbered, this is for ease of reference only. There is no claim that there is an equal scale of progression, merely an ordinal sequence. The statements can be related to stages

Table 1 Indicators of progression in planning and conducting investigations

Students:

1. Suggest a useful approach to answering a question or testing a prediction by investigation, even if details are lacking or need further thought
2. Make suggestions about what might happen when certain changes are made
3. Identify the variable that has to be changed and the things which should be kept the same for a fair test
4. Identify what to look for or measure to obtain a result in an investigation
5. Select and use equipment and measuring devices suited to the task in hand
6. Succeed in planning a fair test using the support of a framework of questions or planning board
7. Spontaneously structure a plan so that variables are identified and steps taken to make results as accurate as possible.

Based on Harlen, W. (2006). *Teaching, Learning and Assessing Science 5–12*, 4th edn., p 107. London: Sage.

Table 2 Indicators of progression in ideas

Students:

1. Offer a description only with no attempt to explain a situation.
2. Use a preconceived nonscientific idea to explain a situation or make a prediction.
3. Name a relevant idea (e.g., friction, gravity) without explaining its relationship to the situation.
4. Use a relevant idea to explain a specific situation but not other situations where it also applies.
5. Use a relevant idea to explain several related experiences or situations.
6. Refer to a bigger idea that explains a number of linked phenomena.
7. Use a bigger idea to predict events not yet encountered.

Based on Harlen, W. (2006). *Teaching, Learning and Assessing Science 5–12*, 4th edn., p 148. London: Sage.

Table 3 The walled-garden task: An example of an embedded task

These materials take the form of a small class project about an imaginary walled garden. The students are introduced to various features of the walled garden – water (in a pond with a fountain), walls, wood, mini-beasts (i.e., small creatures), leaves, bark, and a sundial. For each of these seven features a poster is displayed in the classroom, giving suggestions for activities and posing some questions. Students work on one poster at a time, answering the questions in the answer booklet linked to the activities for that feature. They carry out the activities in any sequence and so a whole class can be working at the same time. The questions are designed for written answers, but the element of active exploration in arriving at the answers extends the range of skills tested. The questions focus on inquiry processes, the different content provided by the seven features creating opportunities for the skills to be used in different contexts and so reducing some of the task-sampling variation. Since the activities are well designed, attractively presented, and intriguing, students readily engage with them as if they were normal work.

or levels but, for the purpose of formative assessment, this is not necessary. What matters is to see what progress has been made and to identify what needs attention.

Feedback to Students

The decision with regard to next steps and how to take them is ideally shared by the teacher and students but there are also many occasions when the teacher provides feedback either through marking written work or spoken comment. The manner in which this feedback is given has a critical impact on motivation. The seminal research of Butler (1988) indicated that giving feedback in terms of comments had a positive effect on students' achievements and interest in undertaking further work compared with feedback in the form of grades, or grades plus comments. These results suggest that giving grades or marks diverts attention from any comments, however useful these may be. Good practice in feedback is identified as having a focus on the work, saying what is good about it, as well as how it can be improved, avoiding superficial comments (such as a good try), and reflecting the goals rather than other qualities such as tidiness or spelling, unless these were part of the task.

The Students' Role

Involving students in their own assessment means that they themselves gather the information that they need to make progress. It gives them direct feedback, without waiting to receive it from the teacher. Taking part in assessment of their own and their peer's work also means that students perceive assessment as something in which they have an active part rather than being the object of others' assessment. It helps them to be responsible for taking action and to be committed to the goals that they have participated in deciding. Developing these skills in students is not a simple matter and indicates that teachers have to take action to ensure that students understand the standards of quality that they should apply to it. While directly stating these criteria of quality is advocated sometimes (e.g., Clarke, 2001), it is more effective to involve students in thinking about what makes good work in a particular case. This can be done, for instance, by brainstorming on what makes a good investigation, or a good report, or discussing examples of satisfactory and unsatisfactory reports (Hein and Price, 1994). Students can then be encouraged to refer to the agreed criteria when they are working and particularly when reporting to each other and reflecting on their work.

Peer-assessment is a particularly useful form of interaction among students. As Sadler (1998) points out, students may accept and take criticism more seriously from their peers than from their teacher. They express it in language they would naturally use and so avoid misunderstanding. Arranging for students to talk to each other about their

work encourages them to review and explain it without the pressure that comes from the unequal relationship between learner (novice) and teacher (expert). It helps the development of a learning environment where learners recognize each others' strengths and are prepared to help each other. It also requires such an environment – where there is an ethos of cooperation rather than competition – which is a prerequisite for the practice of several features of formative assessment.

Reporting Individual Student Performance

Summative assessment provides information with regard to what students have achieved at certain times. As in the case of formative assessment, the assessment process involves gathering evidence, interpreting it, and reporting it. In some circumstances, the information is fed back into teaching, but this is not the primary purpose.

Evidence for summative assessment can be gathered in various ways:

- by special tests or tasks designed for students to show what they can do at a particular time;
- by summarizing evidence from regular workup to the time of reporting; and
- by combining evidence from ongoing work and special tasks of tests.

Special Tasks or Tests

Assessment for summative purposes needs to be highly reliable as it may be used for grouping or selection that can affect the future learning opportunities; for that reason, there is an attraction in using special tasks or tests. The items or tasks can be specified and controlled and presented in the same way to all students, and marked using the same rubrics or criteria. Thus, they appear to give students the same opportunities to show what they can do at a particular time and, therefore, are fair. However, giving the same tasks is not the same as giving the same opportunities; students vary in their reaction to – and, therefore, in their performance in – different tasks which appear to make the same demands. The reliability of a test is limited by the facts that only a small number of tests items or tasks can be included and a different selection from all possible ones could lead to a different result. Calculations based on the national tests taken by students in England at the end of the primary school indicate that this effect could result in at least a third of pupils being given the wrong level (William, 2001).

The effect of the selection of items or tasks is particularly serious in science since tasks that attempt to assess inquiry skills, problem solving, and the application of

concepts in real situations are necessarily time consuming and only a small number can be included in a test. Students' response to them is highly dependent on the choice of content. In a study, in the United States, by Pine *et al.* (2006), fifth grade students were assessed using several hands-on performance tasks, including one based on Paper Towels (in which they had to test which of three different kinds of paper towels would hold most water) and one called Spring (about the length of a spring when different weights were hung on it). The researchers found "essentially no correlation for an individual student's scores. Students with either a 9 or a 1 Spring score had Paper Towels scores ranging from 1 to 9" (Pine *et al.*, 2006: 480). Because this is a large task-sampling variation, obtaining a reliable score for an individual student would require the individual to tackle a totally unacceptable number of tasks.

This is an example of the interdependence of validity and reliability – where greater validity tends to mean lower reliability. The corollary is also true. Where greater reliability is paramount, the selection of items for a test gives preferences to those that can be marked unambiguously as correct or incorrect. These are usually ones requiring factual knowledge rather than the application of skills – lowering the overall validity of the test. Low validity is a serious defect of tests since what is tested is inevitably taken as an indication of what is important to teach. The effect is exacerbated by high-stakes use of test results, which not only demand high reliability in the items but put pressure on teachers to use methods that seem to be necessary for passing the tests (Harlen and Deakin Crick, 2003). This was shown clearly by Johnston and McClune (2000) in their work on the effect of the high-stakes tests taken by students at the end of primary school to decide the type secondary school to which they transfer. They found a high proportion of teaching through transmission of information and highly structured activities, with little time for direct investigation by students. When interviewed, the teachers indicated that they felt constrained to teach in this way on account of the nature of the tests.

Summarizing Evidence from Regular Activities

The problems of test validity are avoided by using the evidence that teachers collect during teaching. In theory, this will cover all goals of learning and will mean that evidence can be used both for formative assessment and for summative assessment. However, the important difference between these purposes has to be borne in mind – that, for summative assessment, the evidence has to be interpreted in terms of levels or grades, whereas, in formative assessment, interest is only in identifying next steps and how to take them. The indicators of development in **Tables 2** and **3** are at too detailed a level for summary reports. What is needed for reporting to parents or to other teachers is, at most, an

overall judgment concerning what has been achieved in terms of, for instance, knowledge and understanding of life processes and living things or scientific inquiry skills.

The process of making a judgment involves comparing the best evidence from the work during the time over which performance is being reported with the criteria defining grades or levels. This does not require the retention of vast amounts of work since the aim is not to arrive at an average level of performance, but one based on the most recent and best performance. In the case of written work, this can be accumulated in a folder in which earlier pieces of work are replaced by later ones that better reflect students' developing abilities. Students can also help in this selection and, in the process, acquire some understanding of the broader goals of their work and of the criteria by which its quality is judged.

While teachers' observations and the collection of students work can provide highly valid information, its reliability may well be low – unless appropriate action is taken to ensure consistency in using criteria. There are various ways in which teachers' judgments can be aligned, or moderated. These include teachers meeting to discuss specific examples of work and comparing their judgments, using exemplars of assessed work – either those published or created within a school, or using a brief test or set of tasks designed to indicate work at a certain level.

A Combination of Ongoing Work and Special Tasks

In some systems, both teachers' judgments and test scores are required in summative assessment – in recognition that tests cannot cover the full range of goals. However, difficulties arise when attempts are made to combine or compare these measures. For reasons mentioned earlier, greater weight is generally given to tests, and it is often forgotten that since tests and teachers' judgments assess different aspects, it is to be expected that their results differ. Thus, using tests to moderate teachers' judgments is a dubious practice. It is preferable for tests and special tests to be used to supplement the evidence teachers have in coming to their judgments. Used in this way, tests and tasks can fill the gaps where regular activities have, for one reason or another, not provided evidence of certain kinds. They are also particularly useful, as good examples, for new and inexperienced teachers. In order to avoid some of the disadvantages of tests, these tasks can be embedded in normal work. The Walled Garden tasks described by Schilling *et al.* (1990) provide an example of embedded tasks (see **Table 3**).

Reporting the Performance of Groups

It is the practice in several jurisdictions – including England, some states of the United States, and several

countries of Southeast Asia – to publish student performance results for schools and to use them as measures of the effectiveness of teachers, schools, and district administrations. When sanctions or rewards are attached to the results, attention is inevitably focused on maximizing the outcomes that are assessed, which then acquire high stakes. The consequence is to focus teaching and the curriculum on what is assessed. As noted earlier, test results are preferred for this purpose – whether or not this can be justified – and the importance of high reliability has the effect of restricting what is tested largely to factual knowledge and consequently narrowing students' learning opportunities. Teachers become concerned that to spend time on inquiry-based work would endanger coverage of the required subject matter. Although this by no means follows, since students develop knowledge and understanding while engaged in inquiry, the perception is a strong one and is reinforced by parents' views of science education.

For a more positive impact, accountability is best based on information about a range of student achievements and learning activities – judged by reference to the context and circumstances of the school and used positively to improve students' opportunities for learning. If the aim is to improve school effectiveness, then – as in the formative assessment of students – self-evaluation at the school level ought to have a role in systems of accountability.

Conclusion

Current views of the goals of primary science emphasize the use of inquiry skills by the students to develop their understanding of key broad ideas in science and of the nature of scientific activity. The assessment of these goals presents a considerable challenge, which conventional tests are far from being adequate to meet. Fortunately, there is an alternative since primary teachers – being generalists in contact with the same pupils for most of each day – are in a good position to gather the rich variety of evidence about their students that can be used both formatively and to summarize learning. Evidence collected by teachers – covering the full range of goals – can be used in the short term to adjust teaching and provide feedback to students to help them identify and take their next steps. The same evidence can be used to identify where students have reached at times when performance is to be reported, by judging the latest and best evidence against the criteria for grades or levels of achievement. Moderation of these judgments through discussion among teachers benefits understanding of goals and how to achieve them as well as the reliability of the assessment results.

Further changes in current practice are desirable to reduce, to the extent possible, the emotional impact which is associated with assessment (Assessment Reform Group

(ARG), 2002). A good deal of this impact derives from fear and anxiety of the unknown. This can be avoided by greater openness about the need for and purposes of assessment. Those more closely involved – parents and students as well as teachers – ought to be fully aware of how evidence is gathered and how judgments are made. Even the youngest students can be given some understanding of what evidence they and their teachers can use to judge whether they are making progress. The involvement of students is particularly important in using assessment to help learning but equally important for summative assessment so that there are no surprises (for students or parents) in the reports of the level reached at a particular time.

The practice of using the results of assessment to set targets for schools and teachers is adding to the stakes of assessment and creating obstacles to achieving the goals of inquiry teaching. The effectiveness of schools and teachers ought to be based on a range of indicators which can also support self-evaluation. Experience in a range of countries (see Harlen, 2007) indicates that disconnecting school accountability from assessment of individual students enables the latter to be used most effectively to improve learning.

Assessment in Schools – Secondary Science

J Shemwell, A Fu, M Figueroa, R Davis and R Shavelson, Stanford University, Stanford, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Computer-adaptive testing – A method for administering tests that successively selects questions so as to maximize the precision of the test based on what is known about the examinee from previous questions.

Concept map – A network showing the relationships among named ideas (concepts); concepts are connected with labeled arrows that describe the nature and direction of the connection.

Conceptual inventory – A test of student conceptions about the natural world which has been developed from research on student difficulties with particular topics and has been refined, tested, and validated by detailed observations with a robust sample of students.

Conceptual item cluster – A focused set of conceptual questions embedded in a larger assessment. Item clusters are designed to probe student conceptions in detail; they are developed and validated in the same manner as questions for conceptual inventories.

Diagnostic testing – A form of formative assessment usually administered before a sequence of instruction that informs the subsequent planning process.

Formative assessment – An assessment that takes place in the midst of the learning process and is used to guide further instruction and student learning.

Performance assessment – An assessment that involves concrete, goal-oriented tasks in which students manipulate physical objects to try to solve a scientific problem or address a scientific question.

Psychometrics – The field of study concerned with the theory and technique of educational and psychological measurement, including measurement of knowledge, abilities, attitudes, and personality traits.

Question–demonstration assessment – A question and discussion assessment activity involving prediction followed by explanation of a demonstrated science phenomenon.

Reliability – The extent to which an assessment consistently obtains the same scores with the same group of students while they are in a steady state.

Science notebook – An ongoing written account of what students do and learn in their science class.

Scoring rubric – A set of criteria and standards linked to learning objectives that is used to score student performance on a variety of tasks.

Summative assessment – An assessment of learning after it has occurred that is primarily used for reporting the results of instruction to stakeholders in the educational process.

Validity – The extent to which an assessment measures what it is intended to measure.

Introduction

Science assessment in secondary schools ranges considerably in purpose and use, from formative assessment that is indistinguishable from instruction to strictly summative assessment such as standardized testing for accountability. Some assessment tasks lend themselves to both uses, but the differing goals and requirements of formative versus summative assessment result in different design logics and implementation strategies. When formative assessment is melded with instruction, to change assessment is to change teaching directly and vice versa. Yet, both kinds of assessment are inextricably linked to classroom practice. If the school environment, particularly its economy of scale, necessarily shapes science assessment, then assessment – either directly or indirectly – shapes the school environment. Whether formative or summative, the process of assessment – especially the form and content of assessment tasks – signals to students, teachers, and other stakeholders what science in school is supposed to be about.

To assess science learning is to find out what reasoning and actions a student will perform across a range of scientific knowledge domains and situations. In secondary schools, the enduring challenge is for one teacher or proctor to efficiently assess the learning of many students while doing justice to what it means to know and do science. Doing justice to science – the validity of assessment – necessarily involves value judgments and interpretations of what knowing and doing should look like in different situations and across disciplines. While particular content standards vary, most acknowledge that assessed performance depends upon students' knowledge (of theories, facts, concepts, procedures, and strategies), on the one hand, and their acts of reasoning, on the other.

Reasoning and knowledge are inseparable. For example, students who can reason effectively to control experimental variables in one science domain may perform differently in another. Knowledge and reasoning also differ with the social, cultural, historical, and environmental contexts that are reflected or embodied in assessment activities. For example, students' explanations relating force and motion for realistic situations can stand in direct opposition to those they provide when answering textbook questions. For these reasons, valid assessment of science learning requires a wide array of contexts and tasks, a diversity that mirrors the manifold and interconnected ways of knowing and doing that characterize science itself.

In what follows, we briefly describe six categories of science assessment, sampling widely from extant and developing formats and techniques. This sample, while by no means comprehensive, is nevertheless intended to convey some idea of the breadth of available assessment practices in secondary science. In the interest of brevity, we place less emphasis on some time-honored, yet effective, formats such as multiple-choice items and classroom questioning. Instead, we focus on certain advances in assessment that have helped science educators meet the challenge of achieving ever-better validity (doing justice to science) while working within the demands of the secondary school setting.

Question–Demonstration Assessments

Demonstrations of science phenomena, when structured as interactive, question-driven activities, can be powerful tools for probing students' developing knowledge and reasoning. While question–demonstration formats vary, the predict–observe–explain (POE) sequence popularized by Richard White and Richard Gunstone is typical and depicted in **Figure 1**. In this version, students are presented with the initial conditions of a situation with an uncertain outcome and asked to: (1) predict the outcome; (2) observe what happens; and (3) interpret and explain their observations, reconciling them with their initial predictions.

Question–demonstration sequences are especially useful for formative assessment, and when amplified and extended with discussion and group problem solving, they can form the core of the classroom learning process. They also lend themselves well to larger group settings in which an expert moderator or teacher can intensify engagement, dynamically assess student thinking, and promote and guide the productive exchange of emerging ideas.

Some form of prediction is the signature element of a question–demonstration assessment. While a demonstration's initial conditions will be designed to focus students' attention on specific facts, features, and relationships, the

act of making a prediction brings these ideas into heightened awareness. An important feature of prediction, in contrast to more general forms of questioning, is that students must decide what knowledge applies to the situation at hand. As a result, the act of predicting often elicits students' initial, naive conceptions, making them visible as part of the assessment process.

Observation of the phenomenon provides students with feedback on their predictions. Typically, a teacher or facilitator will perform a single demonstration for the group to observe. Students often observe different things, so teacher and peer mediation are involved in interpreting what happened. With careful moderation, the observation process can stimulate not only productive thinking about science principles but also awareness of the foundations of science in the sense that observed facts are fundamentally interpretations, not mere recordings, of physical reality.

The process by which students explain what they have observed, reconciling these explanations with predictions, is a knowledge building process. When used as formative assessment, a question–demonstration sequence will involve bringing explanations to light while simultaneously assisting students to advance them further. Typical procedures involve short writing prompts extended by discussion and lecture. Responding effectively to students' initial attempts at explanation can demand considerable skill and experience on the part of the teacher, a requirement that stands as a significant challenge to widespread use of this kind of formative assessment. Another limitation is the restricted role allocated to students in the highly scripted question–demonstration process. Although this process may provide for intense engagement and prompt deep reflection, it nevertheless denies students the chance to pose questions and manipulate materials for themselves.

Question–demonstration assessments can be cast in summative form. In one version, students are presented with an initial demonstration setup and asked simply to predict an outcome and justify their prediction; in another, they observe a phenomenon and explain it in terms of science principles and causal mechanisms. These kinds of items are sometimes incorporated into large-scale assessments to signal what is valued in science learning – not only answering questions but also reasoning about and making sense of the physical world.

Performance Assessments

Implementing hands-on tasks in the classroom and in large-scale assessments reflects the importance of doing science. This involves reasoning not just with knowledge in memory but also with an external environment that simulates the conditions and resources with which science is done. Thus, hands-on performance assessment involves concrete, goal-oriented tasks in which students manipulate physical

	
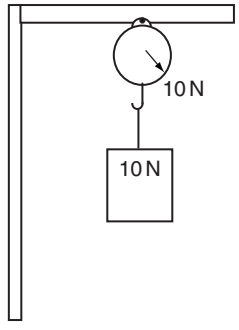

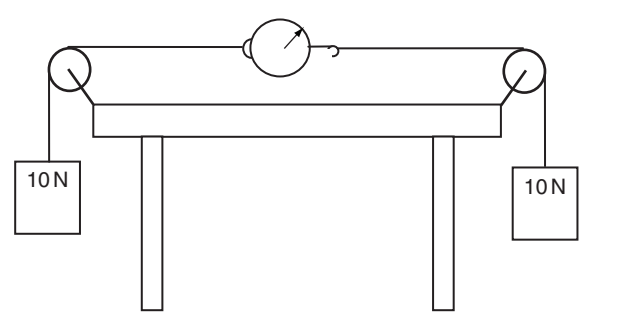

<p>Situation I: In this case, the spring balance reads 10 N</p>	<p>Situation II: What will the spring balance read in this case? (ignore the mass of the balance itself)</p>
<p>Part 1: Prediction</p> <p>Which of the choices below best predicts the reading on the balance in situation B?</p> <p>A. 20 N B. 10 N C. 5 N D. 0 N E. 15 N</p> <p>In the space provided, fully explain your reasoning.</p> <p>{A student might predict that the answer is choice A, 20 N, because in the second situation there are two forces, not just one, acting on the balance, providing twice as much force overall.}</p> <p>Part 2: Observation</p> <p>What do you observe? That is, what is the reading on the spring balance in situation II?</p> <p>{The balance in situation II reads 10 N as a result of two opposite 10 N forces. Does the balance in situation I also have 2 opposite 10 N forces? Yes it does!}</p> <p>Part 3: Explanation</p> <p>Why did that happen? Explain the physical principles involved that provide for the reading you observed.</p> <p>{In order for a spring balance to register a force of 10 N and remain at rest, two equal but opposite forces, each of 10 N, must be exerted. Any time there is a tensile force on a static object, an equal and opposite force must also be present.}</p>	

Figure 1 Question–demonstration item in predict–observe–explain format.

objects to try to solve a scientific problem or address a scientific question. The solution or answer is evaluated by a rater or teacher who takes into account not only the student's final result but also the method by which the result was achieved.

Technically, a performance assessment includes a challenge, a response, and a scoring system. The challenge requires students to work with concrete materials to solve a problem and does not specify the steps to be taken. For instance, a student could be given a wire, a bulb, and a battery and asked to light the bulb. The student's response includes his or her actions as well as artifacts produced in the process of tackling the challenge. Responses can be

registered in different formats extending from multiple-choice questions to science-notebook entries. The scoring system delineates the critical knowledge and reasoning expected of students and captures the full range of performance demanded by the task. This could include identification of the right answers, justifiability of procedures, appropriate use of evidence, and effectiveness of problem-solving approaches. **Figure 2** shows a physics performance assessment; and **Figure 3** shows its task instructions and scoring rubric.

Task demands for performance assessment may be thought of as ranging from knowledge-rich to knowledge-lean and process-open to process-constrained. Some tasks,

Students are asked to identify the contents of each of the six boxes (A–F) by using the batteries, bulbs, and wires they are given to complete a circuit. This task requires knowledge of series circuits but leaves problem-solving procedures up to the student.

Figure 2 Electric mystery boxes performance assessment. From National Assessment Governing Board. (2006). *Science assessment and item specifications for the 2009 National Assessment of Educational Progress* (pre-publication edition).

The following is a brief description of two warm-up tasks:

1. Students are asked to connect one battery, one bulb, and wires so the bulb lights. They are then asked to draw a picture of this simple circuit.
2. Given mystery box '?,' students are asked to identify whether it contains a battery or a wire. They are told that they can determine the contents of the mystery box by connecting it in a circuit with a bulb.

The following is an excerpt from the main task instructions given to students:

Find out what is in the six mystery boxes A, B, C, D, E, and F. They have five different things inside, shown below. Two of the boxes will have the same thing. All of the others will have something different inside.

[The five options – two batteries, a wire, a bulb, a battery, and a bulb, nothing at all – are presented in words and drawings. Drawings are not provided here.]

For each box, connect it in a circuit to help you figure out what is inside. You can use your bulbs, batteries, and wires in any way you like.

When you find out what is in a box, fill in the spaces on the following pages.

The following is an example of the student response format:

Box A: Has _____ inside.

Draw a picture of the circuit that told you what was inside **Box A**:

The following is a brief description of the scoring system:

For each of the six boxes (A–F), students' responses are scored on two components: (1) identification of the contents of the box and (2) the circuit used to make the conclusion. For each box, if both components are correct, the student receives 1 point; if one or both components are incorrect, the student receives 0 points. Total maximum score is 6 points.

Figure 3 Instructions and scoring guide for electric mysteries task. From Shavelson, R.J., Baxter, G.P. and Pine, J. (1991). Performance assessment in science. R. Stiggins and B. Plake (Guest Eds.), *Applied Measurement in Education* [Special issue] 4(4), 347–362.

like the electric mysteries assessment shown in **Figure 2**, focus on domain-specific knowledge. Other tasks may focus on more general scientific skills. An assessment of this latter type might ask students to determine which of three paper towels soaks up more water and allow them to design an experiment to answer this question.

Hands-on performance assessments have a wide range of applications from small-scale formative assessment in classrooms to large-scale summative assessment such as the US National Assessment of Educational Progress (NAEP) and the Trends in International Mathematics and Science Study (TIMSS). Whether in the classroom or on large-scale assessments, the use of hands-on tasks signals the importance of doing science.

Performance assessment in science is challenging. Tasks are difficult to design and costly in terms of materials as well as the time and effort required for administration and scoring. In particular, large-scale assessments require meeting exacting standards for materials and scoring systems. Yet, these challenges are not insurmountable. For instance, the electric mysteries assessment can be used in ordinary classrooms at reasonable cost and with reasonable effort. The use of information technologies to simulate performance tasks can also reduce many of these difficulties.

Information Technologies and Assessment

By transforming the medium in which students carry out science-related tasks, information technologies have the potential to extend the reach of assessment to probe unique aspects of what students know and can do. For example, computers can support interactive models of hard-to-replicate phenomena such as predator–prey interactions. However, information technologies cannot replace other modes of assessment, such as hands-on performance assessment.

As one example of how information technologies can yield rich assessments, the Science Framework for the 2009 NAEP described several types of interactive computer tasks (ICTs), including information search and analysis, empirical investigations, and simulations. While these types are specified in the framework for summative assessment, they illustrate the techniques that potentially apply to both summative and formative purposes.

Information search and analysis tasks echo how scientists and science learners progress by working with the accumulated knowledge of a domain. These tasks provide students with an information database, pose questions, and ask students to find answers by querying the database. Students are assessed on their abilities to select, evaluate, and synthesize information.

Empirical investigation tasks move performance assessments to the computer platform. Doing so can bypass

certain challenges of the hands-on format. For example, computer simulations of experiments can eliminate the hazards of working with certain materials; facilitate manipulation of variables; collect data automatically; and alleviate the costs and logistical complexities associated with procuring, distributing, and storing the physical materials required for hands-on investigations.

Simulation tasks allow students to model, manipulate, and observe scientific phenomena in ways that are difficult with other formats. Some things are not easily seen in real time (e.g., erosion, planetary motion, and chemical reactions) or by the naked eye (e.g., atoms and bacteria), but they can be sped up, slowed down, or magnified in simulations. For example, students could use a simulation of erosion to analyze the effects of various farming practices on erosion rates. **Figure 4** shows a computer screenshot from an assessment that asks students to use a model to conduct experiments about population dynamics in a mountain lake ecosystem.

Information technologies can capture a range of student responses. Evidence of students' knowledge, reasoning, and skills can be gathered not only from their final answers but also from the actions that they take while working through an assessment task. On a computer-based task, certain keystrokes and actions can be automatically identified and recorded. Examples of relevant actions include the proportion of time spent on various websites in an information search and analysis, the number of trials performed in an empirical investigation, and the manipulation of parameters for a simulation. Scoring these captured sequences of actions yields an unusually direct assessment of students' strategies for approaching scientific tasks, an important but often elusive aspect of science learning.

Information technologies can also improve the efficiency of assessment. Computer-adaptive testing selects items from an item bank based on a student's responses to prior items. By choosing items that are targeted to a particular student, this technology provides an accurate estimate of individual capability with fewer items. Information technologies can scaffold the administration of complex tasks such as concept maps. Software can machine score students' constructed responses (e.g., essays and concept maps), which is faster and less expensive than human scorers while achieving roughly the same accuracy.

Improved efficiencies can support formative uses of assessment. Information technologies are able to efficiently analyze and summarize the vast amounts of performance data that may easily confound teachers' efforts to understand the state of students' learning. With more information on student performances gathered and summarized more quickly, teachers and students can receive feedback and change courses of action on shorter and potentially more effective timescales. Immediate feedback and interactivity built into information technologies can also directly guide student learning. For example, a

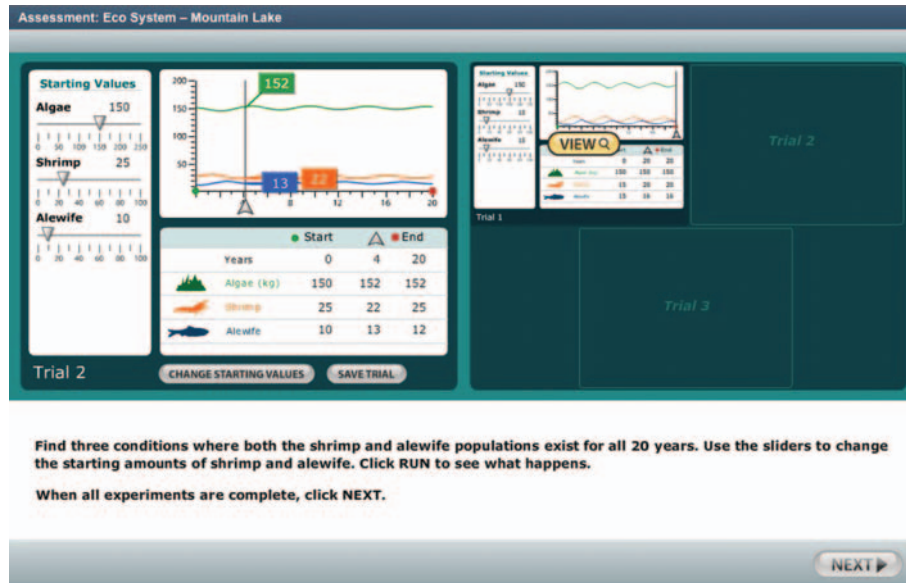

Figure 4 Screenshot from Calipers II predator-prey populations modeling tool. From Quellmalz, E. S., Timms, M. J., and Buckley, B. C. (2009). Using science simulations to support powerful formative assessments of complex science learning. Presented at the annual meeting of the American Educational Research Association, San Diego, CA.

computer-based assessment may immediately alert students if they answer or do something incorrectly, permitting an opportunity to reflect on their understandings and resubmit their answers.

The above examples highlight the promise of information technologies, but significant challenges remain. Unresolved issues include those concerning equity, privacy, and financial and other practical constraints. Further, the use of information technologies in assessment largely represents new psychometric territory. For example, it has not been firmly established whether computer tasks measure the same competencies as hands-on tasks and whether they measure these competencies with comparable reliability and validity. As the use of information technologies in science assessment progresses and expands, these and other challenges will require considerable attention and research.

Conceptual Inventories and Item Clusters

Conceptual inventories and item clusters are developed and used to probe students' knowledge and reasoning about specific science topics in depth. Unlike traditional tests with stand-alone items, these instruments use sets of conceptually related items that allow for deep and explicit investigations of students' particular explanations or mental models of the natural world. The degree of item relatedness ranges in scope from instruments covering broad topic areas to those targeting a single idea or conception. Conceptual inventories and item clusters may be used as tools for diagnostic testing that in turn inform

instructional planning, or researchers and curriculum developers may use them to evaluate students' performances in a randomized trial before and after an experimental intervention. Item clusters probing particular conceptions in depth can be used in large-scale standardized testing. Such clusters provide samples of more detailed information about student learning than typical science achievement items.

Conceptual inventories and item clusters are developed in conjunction with rigorous research into typical naive science conceptions. These instruments generally take the form of relatively short multiple-choice tests, but open-ended questions with detailed scoring systems may also be used. Multiple-choice items such as the one shown in **Figure 5** are carefully constructed and validated such that each distractor corresponds to a prevalent conception identified from the research literature. Thus, incorrect responses can reveal as much about students' knowledge and reasoning as correct responses.

Responses to questions such as the one in **Figure 5** may seem to suggest that students hold relatively stable and coherent conceptions of the natural world. However, such interpretations should be made with caution, as students' science conceptions are influenced by a range of contextual factors, including the unique sociocultural and affective features of a given situation. The confidence with which an individual's response to an item might be interpreted as reflecting stable knowledge and beliefs therefore depends upon the conditions under which the item was developed and tested.

The Force Concept Inventory is one of the best-known and most widely used conceptual inventories (see **Figure 6**).

This 30-item multiple-choice test probes conceptions of force and motion using everyday language and semi-realistic situations. Physics students taking this test can often exhibit profoundly nonscientific conceptions despite having mastered more traditional, problem-based assessments. Results like these demonstrate that being able to solve problems does not necessarily entail well-grounded conceptual understanding. This fact, together with continuing research on students' conceptions, has led to a proliferation of conceptual inventories in other science topics. **Figures 7 and 8** show sample items from two of these.

Many conceptual inventories and item clusters are not intended for formative assessment. An exception is a web-based instrument called Diagnoser (see **Figure 9**). This instrument provides students with immediate feedback on their responses to dynamically ordered multiple-choice and short-answer questions. Diagnoser takes more time and asks more questions than most conceptual inventories

with items tightly clustered around specific science ideas (e.g., the effect of pushes and pulls, explaining constant speed). The result is an intensive assessment of student conceptions that can guide both teachers and students in their choices regarding further instruction and study.

Conceptual inventories and item clusters define, through the questions they ask, what it means to have a strong grasp of fundamental principles in a domain. These instruments can impact science teachers' views about what should be learned in science and how this should be achieved. Generally, teachers voluntarily select and employ conceptual inventories and item clusters. Students' performances on these instruments confront teachers with the prevalence and sturdiness of students' naive conceptions. By exemplifying essential knowledge and reasoning, conceptual inventories and item clusters illustrate an important way in which science assessment can guide and contribute to teaching practice.

Concept Maps

Concepts maps are important tools for measuring the structure of students' conceptual knowledge in a science domain. The integration of ideas, including connections between key concepts, is an important aspect of expert knowledge and a key feature of scientific literacy. As students acquire expertise in a domain through learning, training, and experience, their representations of knowledge begin to more closely resemble the highly integrated knowledge structures that are characteristic of experts.

A concept map consists of nodes and labeled directed lines (see **Figure 10**). The nodes correspond to key terms representing concepts; the lines symbolize a relationship between a pair of concepts (nodes); and the label on the directed line indicates how the concepts are related. Two nodes and a labeled directed line combine to form a proposition, the essential unit of meaning in a concept

What causes day and night?

A. The earth spins on its axis. (0.66)

B. The earth moves around the sun. (0.26)

C. Clouds block out the sun's light. (0.00)

D. The earth moves into and out of the sun's shadow. (0.03)

E. The sun goes around the earth. (0.04)

Figure 5 Example item from the 47-item Project STAR Astronomy Concept Inventory. Some conceptual inventories include proportions of students typically selecting each response option. Here, 26% of students in the research sample responded that day and night are caused by the earth's movement around the sun. From Sadler, P. M. (1998). Psychometric models of student conceptions in science: Reconciling qualitative studies and distractor-driven assessment instruments. *Journal of Research in Science Teaching* 35(3), 265–296.

Imagine a head-on collision between a large truck and a small compact car. During the collision:

A. The truck exerts a greater amount of force on the car than the car exerts on the truck.

B. The car exerts a greater amount of force on the truck than the truck exerts on the car.

C. Neither exerts a force on the other; the car gets smashed simply because it gets in the way of the truck.

D. The truck exerts a force on the car but the car does not exert a force on the truck.

E. The truck exerts the same amount of force on the car as the car exerts on the truck.

An elevator moves from the basement to the tenth floor of a building. The mass of the elevator is 1000 kg and it moves as shown in the velocity-time graph below. How far does it move during the first three seconds of motion?

- (A) 0.75 m
- (B) 1.33 m
- (C) 4.0 m
- (D) 6.0 m**
- (E) 12.0 m

Figure 8 Example item from the Test of Understanding Graphs – Kinematics (TUG-K). The pie chart on the right shows the proportion of students choosing each response option. From Beichner, R. J. (1994). Testing student interpretation of kinematics graphs. *American Journal of Physics* **62**(8), 750.

John and his friends watch their radio-controlled car move along a straight path at their school track. John’s friends mark the position of the car as it travels down the track. Some of the data are shown in the table below. Determine the car’s average speed for the time interval shown in the table.

Position (m)	Time (s)
10	2
15	3
18	4
21	5
23	6
24	7
25	8

Type your answer in the box below.
Your answer must be a number.

m s^{-1}

Feedback to response of 3 m s^{-1} :

While the method you used might work in some situations, it will not give you the average speed for the motion unless the object is changing speed uniformly (at the same rate) throughout the motion.

Figure 9 Example item and feedback from Diagnoser. Diagnoser, unlike most conceptual inventories, provides immediate feedback. The correct answer is 2.5 m s^{-1} . From Minstrell, J. (2008). *Diagnoser project: Instructional tools for science and math*. Retrieved February 27, 2008, from <http://www.diagnoser.com>

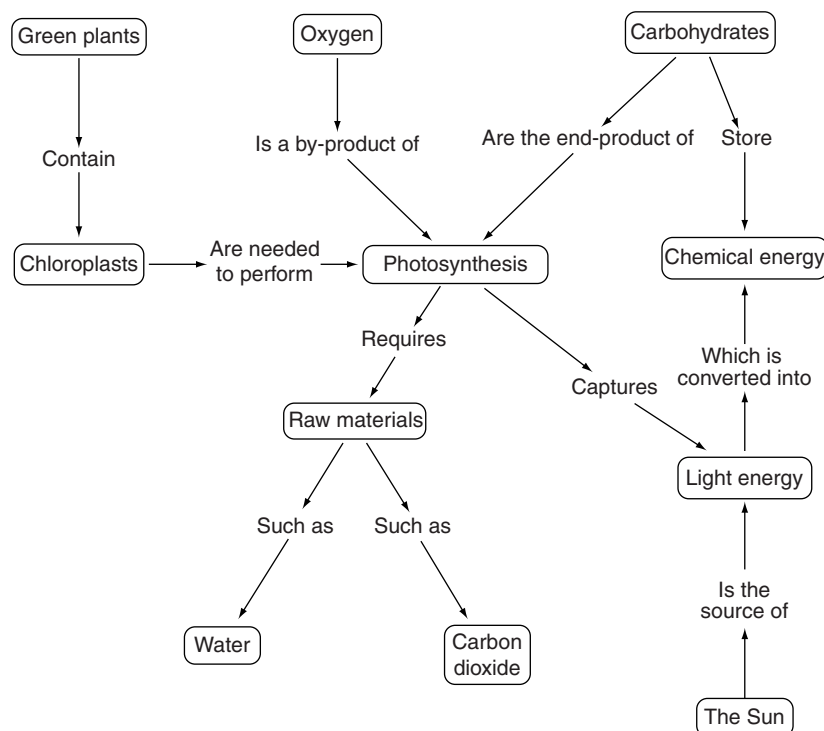

Figure 10 Photosynthesis concept map.

map and the smallest unit that can be used to evaluate the validity of the proposed relationship between two concepts. Concept-mapping tasks encompass a wide variety of techniques that can generally be grouped into two main categories: construct-a-map tasks and fill-in-map tasks. Construct-a-map tasks provide a set of concepts and require students to create all of the nodes and labeled lines in their maps, whereas fill-in-map tasks provide students some or all of the nodes or lines.

In a strict sense, a concept map used as an assessment tool should include a task that draws upon a student's knowledge structure in a domain, a format for the student's response, and a rubric for scoring maps accurately and consistently. Such structured concept-mapping assessments require advanced planning and provide unique challenges in scoring. Scoring concept maps involves evaluating each proposition on the map or comparing students' propositions (two nodes and a labeled directed line) to those on an expert or criterion concept map.

Scoring construct-a-map assessments is generally more challenging than scoring fill-in-map assessments. When students construct their own maps, choices about how to score missing propositions, incorrect propositions, partially correct propositions, and superfluous propositions must all be considered in defining the scoring system. However, while fill-in-map tasks are easier to score than construct-a-map tasks, research suggests that the two techniques do not tap identical aspects of students' understanding:

- Concept terms appear only once on the map
- The map can be organized any way you want
- Use only the concept terms that are provided
- Use only one labeled arrow between two concepts
- You can link a concept to more than one other concept, but you must use separate labeled arrows
- You can only draw arrows between concepts, not to another arrow

Figure 11 Rules for constructing a simple concept map (made available by the Stanford Education Assessment Laboratory); <http://www.stanford.edu/dept/SUSE/SEAL/>

construct-a-map tasks more accurately measure differences in students' knowledge structures.

Training students in the construction of concept maps is an additional challenge of concept map assessments. Concept maps also require students to follow a strict set of instructions (see **Figure 11**). Yet, once the process is understood, concept-map assessments can be easily administered to large numbers of students with minimal direction. Many computer programs are now available to assist students in constructing concept maps, and these programs help to minimize the learning curve.

Concept maps can be used effectively as both summative and formative assessments. They appear in science classrooms as homework assignments, small group work activities, full class collaborations, and individual formal and informal assessments. In formative use, teachers sorting through a set of maps can quickly develop an

understanding of prevalent student conceptions. Spontaneous construct-a-map assessments can be assigned in the middle of a lesson, and more structured fill-in-map assessments are often included on major summative assessments in the classroom as well as on large-scale standardized tests. The Science Framework for the 2009 NAEP specified construct-a-map items. It remains to be seen whether this becomes a standard for such items on other large-scale science assessments.

Science Notebooks

Science notebooks are a compilation of entries that provide a partial and time-bounded record of students' classroom experiences. As instructional artifacts generated alongside student activities, notebook entries are tightly linked to everyday classroom learning.

The characteristics of notebooks vary as a reflection of diverse classroom activities and routines. Entries may include defining concepts, identifying relationships, describing experimental procedures, recording observations, and discussing theoretical models. However, science notebooks go beyond writing; they incorporate drawings, data sets, diagrams, graphs, and tables (see **Figure 12**). These varied forms of representation are essential aspects of scientific inquiry and communication for both students and scientists. Indeed, an important reason for treating notebooks as assessments is to survey students' learning as they engage in a practice that is prevalent among professional scientists.

Scoring criteria for notebooks vary with type of entry. The scoring of an entry on experimental procedures may focus on replicability, while the scoring of recorded observations may focus on level of descriptive detail. When scoring a student's explanation, assessors may focus on the quality of the claim, the type of evidence provided, and the reasoning that links claim and evidence.

Scoring must be carefully aligned to the overall purpose of an assessment. For example, scoring for formative purposes may require looking for particular conceptual difficulties and learning needs. When teachers provide feedback and guidance as written comments, notebooks serve as a valuable record of the ongoing dialog between teacher and student. Teachers and external stakeholders can also score notebooks at the end of an instructional unit for summative purposes.

One challenge of assessing science notebooks is the considerable time and effort required to read and comment on them. This may be ameliorated to some degree by sampling among entries and using tightly focused scoring rubrics. Another difficulty is the requirement to carefully establish procedures and expectations for using notebooks as authentic scientific tools. Failing to do so can result in entries that misrepresent students' true processes of learning or underrepresent their knowledge and skills. These challenges notwithstanding, notebooks provide a unique source of insight into students' knowledge and reasoning in the context of day-to-day classroom activity.

Conclusion

Assessment of science learning in secondary schools is a challenging endeavor. It must encompass a large sphere of activities, many of which can be difficult to render faithfully in a testing environment. It must address complex ways of knowing that are distributed across individuals and specialized tools, and which can shift with changes in context. It must deliver useful information quickly, so that teachers, students, and other stakeholders can readily decide where they stand and what adjustments to make. It must do all of these things at limited cost and with reasonable effort on the part of teachers and proctors.

We have presented here a sample of methods and resources that can begin to address these challenges. In doing so, we have not tried to circumscribe the field but to

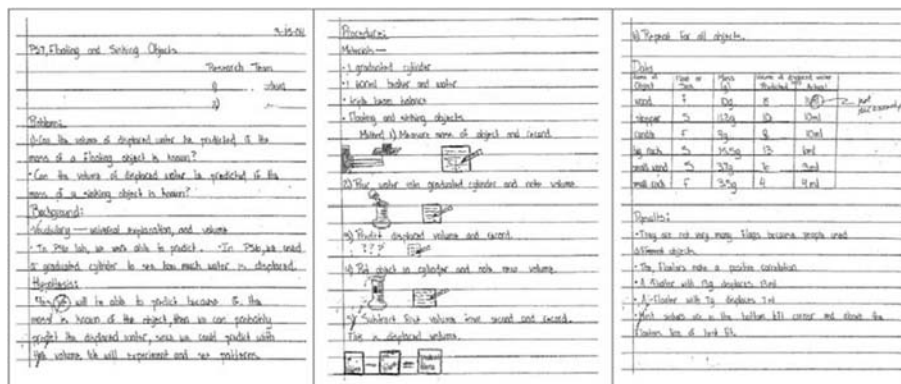

Figure 12 Example of a student's science notebook From Ruiz-Primo, M. A., Li, M., Tsai, S., and Schneider, J. (2007). illuminate certain points of progress within it. Such progress is critical if science educators are to close the gap between what is truly valued in school science learning and what comes to be valued because it can be readily assessed.

Assessment in Schools – Technology Education and ICT

A Jones, B Cowie and J Moreland, University of Waikato, Hamilton, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In this article we address the issues related to school-based assessment of student learning in technology, including information and communication technology (ICT). We begin by explicating the nature of technology and the characteristics of technology education and then explore the relationship between curriculum, assessment and pedagogy. A sociocultural perspective on the nature of the discipline, curriculum, learning and assessment, and their associated interrelationships underpins our analysis.

Nature of Technology and Technology Education

People use technology to intervene in the world to expand their possibilities, applying both intellectual and practical resources. Technology encompasses a broad range of activities, including the transformation of energy, materials, and information. Technology is not only about artifacts, but also how and why those artifacts are developed and the impact they might have on people and our world. It encompasses more than ICTs, such as computers, the web, and e-mail; it is about products, systems, and environments. It can include electronics and control technology, materials technology, food technology, structures and mechanisms technology, and production and process technology.

Technology is included as a curriculum area in many countries in all continents and regions, including Europe, Asia, Pacific, Africa, and the Americas, where increasing the levels of technological literacy is seen as of intrinsic value for individual development, as a particular insight into culture and for the betterment of society. The most compelling personal reason for studying technology is that it is a major and, some would argue, a determining feature of the world we inhabit. As part of culture, young people need to be introduced to technological practice so that they can understand its nature and be able to participate in it at some level. If technology is indeed a determining feature of the world we inhabit, it follows that young people, as future citizens, need to understand how it shapes the world.

Technology Education and Assessment

Assessment models must accommodate the specific features of the subject and the characteristics of teaching and

learning in that subject. In the case of technology, there is a need to accommodate its complex multidimensional nature. When we look at the development of technology education many of its roots can be traced to traditional technical subjects that emphasized only skills teaching. More recently, it has been linked with and subsumed by science and also conflated with ICT. Consequently, technology education has struggled to establish itself as a school subject with its own identity. The primary focus of technology is to intervene in the made world to extend human capabilities as opposed to understanding the world. Technology encompasses both technological knowledge and technological practice and their interrelationships. Technological knowledge and practices are context dependent. They are associated with and structured by objects, artifacts, and tools in action embedded in social and cultural practices. It's characteristics as practices, as well as a body of knowledge that are crucial to technology education. The uniqueness of technological knowledge, processes, and skills has not always been recognized in general education. Technology education needs to be concerned with involving students with the identification, exploration, and solving of technological problems. Technological problems encompass multiple and interrelated conceptual, procedural, societal, and technical aspects. A comprehensive technology curriculum includes an understanding of the nature of technology, technological knowledge and understanding, technological practices, and the relationship between technology and society. This complexity poses a number of challenges to traditional approaches to assessment.

Assessment and Views of Learning in Technology and ICT

This article offers an analysis of assessment in technology and ICT that is grounded in a sociocultural view of learning. Individual and cognitive notions of learning and achievement have dominated the thinking about assessment. This has contributed to the predominance of individual testing as well as to a focus on written assessment tools in tightly controlled environments. Such approaches are inappropriate for technology and technology education. Social views of learning endorse the view that knowledge is socially constructed and context dependent. Human actions are situated within a historical, cultural, and institutional setting. Sociocultural theory proposes that knowledge emerges through social and cultural activity where tools,

artifacts, and systems mediate thinking, action, and interaction. From this viewpoint, technology assessment is a situated social and cultural activity that cannot be separated completely from the classroom or from ongoing student–teacher interaction.

Assessment of Technology Including ICT

Assessment brings with it connotations of testing but international research suggests that formative assessment, now often referred to as assessment for learning, is one of the keys to enhancing student learning and engagement. In formative assessment, teachers and students use assessment information to enhance student learning within the classroom and on a daily basis. In summative assessment, teachers and students use assessment information to sum up what has been learned. Traditionally, distinct summative assessment tasks have been used to generate data for this purpose. Formative assessment and summative assessment do not need to be seen as independent practices. Effective formative assessment practices can contribute to summative assessment. When formative and summative assessment practices mutually inform each other, teacher assessment practice can become seamless and optimally productive. Effective summative practice reviews learning and can contribute to decisions about further teaching and learning and thus can have a formative function for both teachers and students.

Role of the Teacher in Classroom Assessment

Teachers cannot design and evaluate valid assessment tasks or interact formatively unless they have a clear sense of the ideas of the subject. Teachers need to have an appreciation of the nature of the discipline, its organizing concepts, mediational tools, cultural values, and symbolic and language systems. For teachers to be effective technology assessors, they require clear understandings of the complex multifaceted nature of technology. Valid teacher assessment in technology needs to encompass:

1. conceptual (knowledge and understanding of relevant concepts and procedures);
2. procedural (knowing how to do something, what to do, and when to do it);
3. societal (aspects related to the interrelationship between technology and groups of people); and
4. technical (skills related to manual/practical techniques) aspects.

Teachers need a clear sense of the conceptual terrain and a pedagogical sense of the understandings the students will bring. Teachers cannot provide experiences and activities that guide and monitor student progress toward the understanding of ideas if they themselves do not know

what the ideas are. Successful facilitation of student–teacher formative interaction requires a flexible grasp of the subject matter being explored. With sound content and pedagogical knowledge, teachers can respond to student ideas both formatively and summatively.

Often in technology lessons, students design and create an artifact or a virtual solution in response to a scenario undertaken over several days. The long-term nature of such technology tasks poses particular issues for assessment. One way to help with building connections, continuity, and coherency is to think about these aspects when planning. Teachers can first define the macro-task, that is, the overall task. This macro-task needs to encompass the technological conceptual, procedural, societal, and technical learning outcomes. Then teachers can arrange a series of interrelated subtasks, meso-tasks, which are mutually important for achieving a solution to the macro-task. Micro-tasks may also be planned by teachers and are more localized tasks, embedded within meso-tasks. The macro-, meso-, and micro-tasks form a connected network that provides structure, support, and direction for students. In technology, it is essential that students work iteratively when designing, making, and testing. Often in technology classes, the design process is treated as a series of steps. These steps can become ritualized with lessons structured around each step so that students undertake the process in a stepwise fashion, giving rise to a veneer of accomplishment. When teachers include opportunities for students to distil out the essential criteria for the creation of a technological artifact, and these criteria are used as the foci, students are able to work iteratively across designing, making, and testing process.

Research indicates that when teachers plan for technological, conceptual, and procedural goals, they pay less attention to social and managerial aspects in the classroom, such as the need to take turns, work in groups, work independently, and finish on time. Technology goals can be expressed in terms of the knowledge, design processes, and technical skills. After planning appropriate technology goals, teachers are able to identify appropriate tasks that afford opportunities for students to accomplish the goals. Consideration of the demands and affordances of tasks is essential for planning for the incorporation of assessment for learning strategies, including the provision of feedback. By knowing the ideas and skills inherent in the tasks, teachers can be more clear about their focus for assessment. Teachers may anticipate students' possible actions and ideas and they may rehearse how they might respond. Rehearsal enables teachers to ascertain the technology knowledge and skills required, the suitability of the activities for their students, and to foreshadow potential problems. By prior testing the teachers are more aware of the demands, both conceptually and technically of the tasks, and can interact more confidently and effectively with students.

Effective assessment in technology, both formative and summative, focuses on the multifaceted and multimodal nature of technology. Effective assessment accommodates multiple modes such as drawing and modeling, not just talk, but to communicate and develop ideas. Technologists draw, make models and prototypes to develop and test ideas. In technology, teachers typically engage students in tasks that have a practical aspect. This provides students with access to multiple modes for developing, representing, and communicating their technological ideas. Drawing, modeling, and manipulating materials can contribute to, and are integral to, teachers and students exploring tasks and negotiating ideas together. ICTs provide a tool in technology for representing ideas. They can also engage learners in building understanding through the collaborative construction of an artifact or a shareable product in a virtual environment. They can construct a virtual reality, play with animated puppets, or build a three-dimensional (3D) model of solar system. It is important that students are allowed to use these multiple modes to represent their ideas in assessment settings.

Classroom Interactions and Assessment for Learning

Classroom interactions and feedback are central to teaching technology formatively. One of the strengths of technology lies in the way that ideas and concepts can be expressed in concrete, practical ways. Through exploration of technological ideas through talking and designing, students can begin to see for themselves what they know and can do, and how well they know and can do it. By listening to and interacting with students, a teacher can provide feedback that suggests ways in which students can improve their learning. Feedback, whether from teacher or students, is useful to both teachers and students in providing information that enables both teachers and students to modify the teaching and learning activities in which they are engaged. There are a variety of design and technology pedagogical approaches that can contribute to students learning through formative interactions and assessment for learning practices. These include: comparing and contrasting technologies, categorizing and grouping examples of technology and recognizing exceptions, and making predictions about technology activities. Examining existing technologies helps students distil the features of the technology. What is essential in these activities is that the teacher makes it clear to the learners that the activity is to explore what they think rather than for them to guess the answer the teacher has in their head. This process helps the teacher and the students to identify their current understandings and what they might need to know more about and where they might go next.

Categorizing and grouping examples of technology and recognizing exceptions and talking about them are

activities that challenge students to justify their classifications in terms of technological ideas. These types of activities enable learners to test their understandings about the nature of technology and about particular technologies. Incorporating prediction activities encourages students to apply their knowledge and understanding to future situations, through which they can then either test or realize their ideas. Problems may not be foreseen by the students, and therefore need to be dealt with on the spot by themselves, their peers, and/or the teacher. How teachers deal with the emerging problems students face as they engage with the task at hand, impacts on students' learning. Hence, how teachers' engage with students formatively strongly affects how students undertake technological processes and their learning in technology. One strategy that teachers have used successfully is to keep the key goals (learning intentions) upfront so that students can identify and clarify their own problems within the bounds of the learning goals. When students are engaged with drawing, designing, and making activities, it is important for the teacher to work alongside them so that they can interact with the students' emerging ideas. Leaving the students to work unassisted conveys the message that design and technology is a self-help activity. Teachers need to model techniques, processes, and procedures in front of students.

The process of formative assessment includes students finding out about their learning, recognizing, reacting, and evaluating their learning from their own viewpoint or others. When students monitor their own progress, evaluate their strengths and weaknesses, and devise strategies for improving their learning, their commitment to learning is strengthened. Technological specifications, intended learning, and success criteria align strongly with the technological process and self-assessment process. Key to the success of both peer- and self-assessment in technology is teachers and students discussing about technology together, as this provides students with the language to discuss technological concepts and processes. When teachers target conceptual and procedural aspects and talk about them with their students, more opportunities are afforded for students to learn about these technological aspects and include them in their work. When teachers concentrate on technological learning outcomes and make these clear to the students as outcomes for them to achieve, students are able to review their work and undertake self-assessment focused on these aspects. Technological concepts and procedures require embedding in learning activities through constant articulation and exploration, so that students begin to understand their strengths and weaknesses and how to deal with them. Engaging students in conferring, consultative conversations related to technological aspects, along with the provision of continual support, reinforcement, and overt cueing by teachers, leads to effective student understandings. In technology, teachers need to help

students focus on the conceptual aspects inherent in the processes and procedures involved in reaching solutions. Often a practical focus can overshadow conceptual aspects. When students are encouraged to review their accomplishments in technology in an ongoing manner they are able to do this throughout the technological process, rather than undertaking self-review only as an endpoint summative process. Discussion plays an important part in the classroom assessment. Through discussion students are able to help each other, clarify and develop ideas, communicate ideas and solutions, critique, and seek help. Class and peer discussion provides the teacher with opportunities to notice, recognize, and respond to students' ideas as they are brought to light. ICTs can allow for group collaboration over time and space.

Classroom Summative Assessment

Teachers are responsible for summing up and reporting on student learning. Teachers can summarize formative assessment information during and at the end of a teaching sequence. This information can be used to improve teaching and inform students on where to go next. Accumulated formative assessment information can assist in developing a richer picture of the sum of student learning and achievement, one that includes both the process and product of their learning. Summative assessment as a summing up of learning across time, across individuals, and across classes can support a formative function. Effective formative assessment practices can also contribute to summative assessment, and vice versa. This can be of benefit to teacher, students, and their parents.

Student performance in technology is often assessed by an evaluation of the end product. When this is the case, the product should first be assessed holistically against criteria pertaining to its form, function, and quality. This judgment needs to be followed by identifying strengths and weaknesses. This way the whole can be evaluated and also how the individual elements work together. Judgments need to be a balanced reflection of the whole of student learning, which are then backed with detail. Such summative assessment includes information that can be used to set the next direction for learning. At the same time as looking back at what students have accomplished, teachers also look forward to what they might accomplish next. This fits with a sociocultural perspective that is concerned with learning and achievement over time.

Assessment and ICT

There are three broad overlapping views of the role of ICT in schools, namely, ICT as:

1. a set of skills or competencies to be mastered in an information-rich society;
2. a vehicle for supporting and enhancing the teaching, learning, and assessment of other curriculum subjects; and
3. a subject in its own right as part of technology education.

The first focus is associated with current concerns that students leave school with the knowledge and skills to take an active part in society, that is, with a focus on information and ICT literacy. The second focus is associated with research and development that seeks to utilize the affordances of ICT to enhance student motivation, make teaching more relevant, incorporate multimodal items in lesson materials, represent and communicate ideas, and to generate, store, and analyze student assessment data for formative and summative purposes. The latter role is currently related to ICT as an area of study computing, software design, gaming, and development of ICT-based systems. ICT now lies at the heart of most activities that constitute social inclusion. ICT use is ubiquitous in what it means to be socially, economically, culturally, and politically involved in current society. In this section, we elaborate on the second view of ICT as the first is beyond the scope of this article and the third has been covered in the previous section on technology and technology education generally.

ICTs can enhance teaching and learning through a contribution to formative and summative assessment. They can be used for assessment purposes at the national, school, class, and individual level. National electronic (e)-assessment banks provide access to well-designed assessment items that allow teachers to make comparative judgments in real time to provide evidence of learning which can be used both formatively and summatively. Not only are assessment banks online but ICTs also are useful for developing electronic (e)-portfolios to document learning and achievement in a multimodal way. E-portfolios can contain written work, photographs, video, audio, and other digital media. These allow both teachers and students to document the process and products of learning as well as the teacher feedback and the student response to this. This type of e-portfolio can be used in national assessment and moderation processes.

Digital evidence is easy to share, easy to search, and easy to ask analytical questions of. This means that teachers and schools are able to ask probing questions about the nature of the learning of their students and to think about the implications of this for their teaching and learning programs. School and class e-portfolios allow for ease of sharing between teachers and provide a productive forum for discussion between teachers to compare and contrast student work to explore possibilities and potential for learning through questioning each other on how students have been supported to achieve to a high standard. Teachers are able to expand their teaching repertoire to enhance student learning. Students are also

able to see the potential in the learning tasks and what might be possible for them. For example, the use of photographs as a story line of images adds to student confidence and the sense that they are making progress. Social technologies are on the rise for classroom use. Students can immerse themselves in contexts that challenge and extend their understanding and use these social networkings as part of peer-assessment processes. These social networking ICT environments allow for multiple perspectives in assessment for learning and assessment of learning, including peers, teachers, students, and their families. As ICTs become more integrated into classrooms the process of assessment has the potential to become more dynamic, multimodal, and interactive.

Conclusion

Technology encompasses a very broad range of activities, including the transformation of energy, materials, and information. It encompasses products, systems, and environments. Technology is a multifaceted discipline with a strong multimodal aspect. Technology education requires students to develop and use knowledge, procedures, skills, and ethical/value/societal sensibilities to create technological solutions. A sociocultural view of learning accommodates the social, cultural, and historical dimensions of technology. Assessment models need to reflect this complexity. Too often assessment models do not reflect the characteristics of the subject under consideration. Classroom assessment for technology can have two main purposes: formative and summative. For teachers to assess in both a valid and reliable way, they need to have an understanding of the nature of technology as well as insights into its knowledge and practice. Technology is often taught and learned in long-term tasks requiring that teaching and assessment establish a sense of continuity and coherence. Effective planning not only addresses the multifaceted long-term nature of technology tasks but also accounts for how students and teachers might be actively involved in the assessment process. Clear learning goals and a shared understanding of the specifications of the technology solution enable teacher, student, and peer formative assessment. When teachers systematically collect formative evidence, this can serve a summative function and valid summative

assessment can be used formatively. ICTs have the potential to enhance classroom assessment practices through the provision of additional modes of representing, recording, and reviewing information on student learning process and products.

Assessment is often constructed as an external evaluation of learning. However, school-based classroom assessment has a greater influence on student learning and perceptions of a subject. Valid and reliable classroom assessments in technology need to represent and reflect the multidimensional and multimodal nature of technology. When this occurs the student's experience of teaching, learning, and assessment is enriched.

Assessment in the Early Years

Introduction

There are at least three reasons why assessment in the early years merits an entry of its own: first, because of the age of the learners, the youngest children in society, who have not yet learned to be pupils. More important for the discussion of assessment is the fact that these young children are not inexperienced learners: indeed, they have been learning from the day of their birth, if not before. As they enter our preschools and kindergartens, they bring a wealth of learning to the new experiences on offer. However, what they bring is not school learning, the result of the sticks or carrots of the education system; it is the spontaneous learning of children who are, in Wells' (1987: 120) words, "innately predisposed to make sense of their experience." Their learning is not confined by curriculum boundaries or specific subject areas; it is a robust foundation for learning throughout life. One of the challenges for early years educators is to respond to the undisclosed riches and appetite for learning that children bring with them into preschool.

Second, the settings that receive children of 3, 4, and 5 years of age are almost entirely nonstatutory, and, thus, likely to be free from imposed curriculum structures, policies affecting pedagogy, or prescribed assessment practices. There are, inevitably, some pressures and constraints on early years educators, but, on the whole, the early childhood sector is relatively unaffected by the pervasive discourse of levels, standards, and outcomes that characterizes primary/elementary education. Therefore, in looking at assessment in the early years, we may be able to see how learning might be fostered, indeed improved, through practices that are uncoupled from the very different project of documenting individual test scores, or compiling test scores into sets of results for classroom, school, and local systems. This is the central theme explored by Fleer (2002) in a paper speculating on the current Australian context, and the possibility of devising assessment practices in harmony with a sociocultural perspective on early learning.

We may note, in passing, that the alternative that Fleer is advocating, an education for early childhood that eschews levels and standards, is by no means a new invention. In England and Wales, for example, the 1933 Hadow Report on Infant and Nursery Schools took a very firm line on the undesirability of applying standards to the learning of young children:

In none of this should a uniform standard to be reached by all children be expected. The infant school [for children aged five to seven] has no business with uniform standards of attainment. (Board of Education 1933: para. 105)

Third, as a result of these first two factors, there are far more choices for early years educators to make in their assessment practices than for educators in other phases of education: choices about children, about learning, about the purposes of early education, and about the methods, purposes, and outcomes of assessment. These choices are examined in the remainder of this article, which takes as its starting point a definition of assessment as the process by which, in their daily practice, educators observe children's learning, try to understand it, and then put their understanding to good use (a definition used by Carr, 2001).

Choices About Children

A fascinating anthropological study, *Preschool in Three Cultures* (Tobin *et al.*, 1989), explores the very different beliefs about children held by educators in Japan, China, and the USA. The Japanese have found an elegant solution to the problem of defining their shared understanding of early childhood. When asked what sort of child they are trying to educate in their preschools, the Japanese educators reply *kodomorashii kodomo* – a child-like child. A fast and furious debate ensues among the educators from all three countries, revealing strongly contrasting versions of the salient qualities of a child-like child.

Turning to history, rather than geography, Dahlberg *et al.* (1999) offer an analysis of conflicting constructions of children and childhood, starting with the empirical philosopher John Locke (1632–1704), who conceptualized the child as an empty vessel or *tabula rasa*. In this model of childhood, the early years are spent in being prepared for school, being made ready to learn (a view that is by no means extinct, as we shall see). In contrast to Locke's child, Dahlberg *et al.* place "Rousseau's child . . . an innocent in the golden age of life" (p. 45) and "Piaget's child . . . the scientific child of biological stages" (p. 46). Dahlberg *et al.* argue cogently for their own preferred construction, "the child as co-constructor of knowledge, identity and culture," but their strongest argument is about the significance of the choices that have been made in the past and continue to be made today:

We have choices to make about who we think the child is and these choices have enormous significance since . . . they determine the institutions we provide for children and the pedagogical work that adults and children undertake in these institutions. (Dahlberg *et al.*: 43)

Moss and Petrie (2002) take up the theme of alternative categorizations and their determining effect upon provision, arguing that, in the UK, children's services are based on a construction of children as "poor, weak, and needy"; as a result, these services "are not provided as places for children to live their childhoods" (p. 63). The settings where poor, weak, and needy children spend their childhoods are places of rescue, where children can be protected, normalized, shaped, and developed. Moss and Petrie advocate a different way of thinking about children and public provision for them, a way that "addresses questions about the good life, including a good childhood, and starts with ethics and politics" (p. 79).

Moss and Petrie are not alone in seeing other possibilities: in recent years, the thinking of preschool educators in Reggio Emilia, Italy, has become increasingly well known, though it is not always sufficiently recognized that their construction of childhood has its roots in many earlier theorists, from Dewey to Piaget, and, significantly for English educators, the great Susan Isaacs (1885–1948), whose proud claim was to study children as they really are, not as we would like them to be. Her chief contribution to our understanding was to document, richly and analytically, the intense intellectual and social activity with which children spontaneously fill their days. Only in early childhood, she insisted, "before children have been taught to separate learning from playing, and knowledge from life, will you see the strength and spontaneity of the wish to know and understand" (Isaacs 1932: 113).

Malaguzzi, one of the founding fathers of the Reggio system of infant/toddler centers (for children from birth to 3) and preschools (for children from 3 to 6), takes a similar position on the intellectual lives of young children: "Children show us they know how to walk along the path to understanding . . . always and everywhere children take an active role in the construction and acquisition of learning" (Edwards *et al.*, 1998: 67). Rinaldi, who succeeded Malaguzzi as Director of Services to Young Children in Reggio insists, in words that have almost become a slogan for the Reggio approach, that

the cornerstone of our experience is the image of children as rich, strong and powerful . . . They have the desire to grow, curiosity, the ability to be amazed and the desire to relate to other people. (quoted in Edwards *et al.*, 1998: 114)

In a more recent text on the Reggio approach, Rinaldi (2006) elaborates on the same theme, claiming that "the image of the child" is "a cultural and therefore social

and political convention," which allows educators to give children the experiences and opportunities ("the space of childhood" and "a space of life") that value their qualities and their potential, rather than negating or constraining them: "What we believe about children thus becomes a determining factor in defining the education contexts available to them" (p. 83). In addition, of course, part of those contexts, in every early years setting, is the practice of assessment. Our constructions of children shape, for good or ill, the ways in which we assess their learning.

Brooker (2002) gives a telling example, in a disturbing study of 4-year-olds starting school in a single class in a run-down, inner urban neighborhood in England. She shows how assessment practices in that classroom create a "powerful hierarchy of achievement." Brooker describes one apparently child-friendly task, designed for assessing early mathematical learning, in which individual children are invited to sort miniature farm animals into fields; she points out that this task is, in fact, "unfriendly to those children who have never visited an English farm, played with farm animals or encountered small-world toys of any description" (p. 103). She observes one child, Jemma, who assembles in a single field a cat, a farmer, a chicken, and some sheep; when asked why she has placed them together, she replies "Because they friends." Brooker herself takes a credit, not a deficit, view of children, and so her response to Jemma's reasoning is to record her thinking as matching the descriptor "sorts objects using one criterion." However, the official math record card describes her as "unable to sort." Here a construction of children has prevailed in which their divergent, unpredictable responses have no value. Jemma is thus seen as a weak, incompetent child, rather than as "rich, strong and powerful," making the best of a pointless, dead-end task in a way that makes human sense to her.

Choices About Learning

In thinking about learning, there is an abundance of models and metaphors to choose from, some of which will serve children's interests better than others. In recent years, English educators of children under 5 have been offered the construct of "Early Learning Goals", now embedded in the statutory requirements for the Early Years Foundation Stage (for children from birth to 5). These numerous goals, organized into 13 scales, are specified in such bland terms that they are unlikely to do justice to what experienced educators see as the most significant qualities of young children's learning: its unpredictability, its inventiveness and creativity, and its purposefulness and emotional engagement. The metaphor of goals suggests a much more convergent, normative process, in which children proceed, in an orderly manner, from one observable

achievement to another: one by one, the goals are ticked off, and one of the nine levels for each scale is recorded. This process culminates in the completion of the Early Years Foundation Stage Profile, a statutory requirement, for every child, including those in independent, private, and voluntary preschools. The individual profiles, with spaces for 117 ticks, are to be put on record, and submitted, school by school, to the local authority, at the end of the year in which the children turn 5. It is as if learning were a ladder, up which, rung by rung, every child must go.

A different perspective on learning comes from Fromm (1976), psychologist and social theorist, whose books offer a series of critical perspectives on the ills of society. In *To Have or To Be*, he describes what he sees as a confusion between the two alternatives of his title, arguing that we have come to think of certain key concepts – such as love, happiness, and knowledge – as things to have, rather than as ways of being. He suggests that the Western obsession with material goods has spilled over into other categories of experience, so that we have come to treat happiness and love as if they were thing-like, as if we could accumulate them, and lay up ever-increasing stores of them.

We may apply these alternatives to early learning: is it a thing that young children have? Will some children have more and others less? Or is it more important for young children to be learners, fully engaged in being the rich, strong, and powerful learners that the Reggio educators describe?

If we choose to think of learning as a way of being, we will want to know more about the characteristic features of the beings who are immersed in their learning: we can do no better here than turn to the work of Carr and her colleagues in New Zealand. Rejecting levels, goals, targets, and other manifestations of the ladder model, Carr and her colleagues have chosen a narrative metaphor: they see each child's learning as a story. In early childhood settings in New Zealand, each child's learning is recorded, day by day, in individual books, with entries made spontaneously by the observant educators, by parents, and extended family members, and often by the children themselves.

The Learning Stories approach is holistic, not divided into areas of knowledge or specific skills. The stories recognize the unique developing individuality of every learner; they draw families in – parents find their children's stories irresistible. What is more, they document progression: over time, the stories get longer, broader, and deeper. The educators attentively observe the dispositions of the learners, the characteristics that dispose them to be ready, willing, and able to learn. They are especially interested in the five dispositions that reflect the five broad strands of their national early childhood curriculum:

Five broad strands

- belonging
- well-being
- exploration
- communication
- contribution

Five important dispositions

- taking an interest
- being involved
- persisting with difficulty
- communicating with others
- taking responsibility. (Carr, 2001)

In a more recent publication, Carr (2008) claims that resourcefulness and agency are the two most significant dispositional outcomes for early education. Linking her work to the Assessment for Learning projects in the UK, Carr argues that when assessment focuses on learning dispositions, then those dispositions are promoted; indeed, she suggests that when educators focus on resourcefulness and agency, children too begin to recognize and respond to opportunities for expressing just those qualities.

Learning dispositions are also central to the work of Laevers and his colleagues at the University of Leuven, in particular the learner's well-being and involvement, which are seen as essential factors in successful early learning. Laevers (2000) characterizes this as "deep level learning," opposing it to superficial learning, which does not affect the basic competences of the child, and does not transfer to real-life situations. Without high levels of well-being and involvement, only superficial learning is possible: when well-being and involvement are maximized, children function at the height of their capacities, with intense energy and concentration, experiencing the deep satisfaction of purposeful exploration. Laevers and his team have developed observation schedules for identifying levels of well-being and involvement, which are widely used by early years educators, in England as well as in the Netherlands.

Fleer's (2002) critique of current Australian practices in assessment, mentioned briefly above, concludes with an exposition of her preferred approach to learning, which is based on a sociocultural perspective. She echoes a number of themes that have already appeared in this discussion, especially the principle that learning is a process, not a test score, and should be seen as "the transformation of understanding and not some end-point" (p. 112). Here Fleer espouses a view of early learning that is practically synonymous with living. Carr describes an educator who has taken this view one step further, into her own professional life:

When I asked one early childhood staff team whether they had made any changes to the Learning Story process, one of them replied: "Well, we live a Learning Story here." (Carr, 2001: 187)

The choices educators make about learning, Carr reveals, affect their own lives, as well as those of the learners in whose interests they act.

Choices About the Purposes of Early Education

For Rinaldi (2006), the choices are already made: “the entire education system today . . . is involved in the process of evolution from a school of teaching to a school of learning.” She amplifies this position in terms of values, those that “inspire and orient daily life in the schools in Reggio.” One of these core values, she explains, is democracy; she describes how, in Reggio, the schools do more than merely transmit culture, they aspire to be places where

culture is constructed and democracy is lived. School and democracy, a theme that was dear to Dewey, is an important commitment for all of us: school as a place of democracy, where we can all live democracy. (pp. 141–142)

Dewey’s work is, indeed, threaded through with the grand theme of democracy, and equally with the metaphors of direction and growth – powerful alternatives to the ladder model. Indeed, his pithiest of summaries of the overall purpose of the entire educational enterprise centers on the notion of learning as growth: in a late work, *Democracy and Education*, he claims “Education has as its aim at every stage an added capacity for growth” (Dewey, 1916: 54).

However, there are other constructions of the purposes of early education. A striking example appears in an unexpected place: Zigler *et al.* (2006) describe *A Vision for Universal Preschool Education* (in the US, the term universal applies to programs open to all children, rather than programs that target children at risk or in poverty). Their vision is based on a highly successful school-based program known as the School of the 21st Century, a comprehensive program of family and child-care services, based in public (i.e., state-funded) schools, offering all-day, all-year provision for all 3- and 4-year olds. There is a very great deal to admire in this program, and, for English early years professionals, much to envy. However, there is a fatal flaw in the vision, announced in the introductory pages:

We all agree that the primary goal of pre-school education is school readiness. (p.xviii)

This “agreement” is reiterated throughout the book and appears one last time in the closing pages:

The purpose of pre-school, after all, is school readiness. (p. 245)

Malaguzzi is not the only one who would violently dissent from this view, but he speaks for many. He declares roundly:

If the school for young children has to be preparatory and provide continuity with the elementary school, then we as educators are already prisoners of a model that ends up as

a funnel. I think, moreover, that the funnel is a detestable object . . . Its purpose is to narrow down what is big into what is small. This choking device is against nature. (Edwards *et al.*, 1998: 88)

Malaguzzi chooses to see the purpose of early years education very differently: as a sequence of rich and provocative opportunities for children to become 2-, 3-, 4-, and 5-year-olds, on their own terms, in their own ways, nourished by a healthy curriculum diet of big ideas, supplemented with experiences and activities that matter to them. Far from it being the Reggio educators’ first concern to get children ready for school, the overriding priority is to ensure that when rich, strong, and powerful learners enter the statutory system (the elementary school in Italy, the primary school in England, or the K-12 system in the US) the schools are ready for them.

Zigler’s interpretation of the purpose of preschool has serious implications for assessment in the early years, its practices, and its purposes. In the chapter ‘Defining school readiness’, the persistent theme is that when children fail to succeed, or even to thrive, in school or kindergarten, the fault lies in themselves. Two examples will illustrate this position:

Citing results from a survey of more than 7000 kindergartens across the nation, Boyer (1991) reported that 35 per cent of all kindergarteners start school without the skills they need to succeed, and 42 per cent of teachers feel the problem is getting worse. (p. 22)

In a sample of childcare programs in Massachusetts, nearly 3 per cent of the preschoolers exhibited behavioural difficulties so great that they were permanently excluded from their program . . . their inability to negotiate the social and behavioural demands of their early care and education setting meant they could not take full advantage of the learning opportunities open to them . . . the best curriculum and literacy training in the world offer nothing to the child who is . . . disengaged from the lesson. (pp. 27–28)

Who is to blame for this shocking state of affairs? Why, the children! Who have not learned, the authors explain, the necessary school or kindergarten skills of self-control, paying attention to the teacher, following directions, working independently, managing the anxiety of parting from their parents, and ignoring noise and distractions: children, in short, who are simply “poorly prepared” (p. 99).

These are examples of a very strange form of assessment: a form that, as a default position, locates learning problems in the learners, a classic expression of the deficit approach. However, there are still choices to be made: there is another way of seeing. If schooling results in widespread failure for children, might there not be something wrong with the school, its curriculum, and pedagogy? Or with the

preschools and kindergartens that failed to prepare children properly? How good is the best curriculum and literacy training if it does not engage children? If kindergarten teachers can only educate properly prepared children, what sort of education are they offering?

The message from the choices that Zigler and his colleagues seem to have made is plain: if we are to do our best by young children, we need to rethink our attributions of blame, transferring them from the 3-, 4-, and 5-year-old learners to the settings that are failing them.

Choices About Assessment: Methods, Purposes, and Outcomes

This section turns to more practical issues, to consider how assessment is done in the early years, what it is for, and what it does for children. Everything that follows from this final set of choices is rooted in those outlined above, choices about children, about learning, and about early education as a whole.

In New Zealand, as we have seen, the use of Learning Stories as an assessment tool is based on a particular view of learning and learning dispositions. However, it has still deeper roots, in the four principles on which the national early childhood curriculum is founded, which are integral to their assessment practice. The principles are:

- empowerment – the early childhood curriculum empowers the child to learn and grow;
- holistic development – the early childhood curriculum reflects the holistic way children learn and grow;
- relationships – children learn through responsive and reciprocal relationships with people, places, and things;
- family and community – the wider world of family and community is an integral part of the early childhood curriculum.

These principles are enshrined in legislation: they have statutory force. The Learning Stories approach has been designed to realize the principles in practice; the approach is indeed empowering, it enhances children's sense of themselves as competent learners. It reflects the holistic way that children learn, and the reciprocal relationships between children, people, and the learning environment; parents, guardians, and the extended family are seriously involved.

For all these fine-sounding claims, the approach is also entirely practical and down to earth; in a series of booklets to be used as an early childhood assessment resource, educators are encouraged to tackle assessment as a sequence of five active verbs: noticing, recognizing, responding, recording, and revisiting. Carr (2008) reports that "Professional development with this resource indicates that as teachers record and revisit the learning, they notice, recognise and respond to children's activities with

more understanding" (p. 44). Such is the power of a simple, practical resource, rooted in both values and principles.

Where the New Zealand educators turn to narrative and story, the Reggio educators use the concept of pedagogical documentation. This term refers to a whole family of practices (video and audio recording, photographs, transcripts, observations, and notes of discussion and debate) through which they make learning visible. Rinaldi (2006) explains the consequences of using this process as the basis for assessment: "[it] gives us an extremely strong 'antibody' to a proliferation of assessment tools which are more and more anonymous, decontextualised and only apparently objective and democratic" (p. 62). Her definition of the process of assessment is breathtakingly simple "deciding what to give value to." The next step is plain; since assessment is, essentially, "a perspective that gives value," it is a perspective that allows educators "to make explicit, visible and shareable the elements of value" as they work together in the process of documentation (p. 70). It is striking how, in this approach, the responsibility of ascribing value to particular acts of learning is located firmly in the hands of the educators, who are face to face, in relationship, with the children. It is not the task of those constructing "anonymous and decontextualised" assessment tools.

However, not all early years educators are lucky enough to work in Reggio Emilia, or New Zealand, where, over the years, through collaborative enquiry and extremely well-supported continuing professional development for educators, these innovative forms of assessment have gradually taken shape. Fortunately, there are still choices to be made, in every early years setting, whatever the local or national frameworks within which educators work. There are still choices to be made about the curriculum, about pedagogy, about the educators' every interaction with their children, and so on – too many to discuss here. We will just note, in passing, how the provision of a "generous environment," to use an evocative phrase from Susan Isaacs, can have an enormous impact on the quality, depth, and intensity of children's learning.

For example, Worthington and Carruthers (2003) describe how young children's spontaneous mathematical explorations, discoveries, and acts of mark-making are significantly fostered by the availability of materials from the real world, rich in mathematical meaning (such as telephone directories, books of raffle tickets, clocks, diaries, real stamps, real money, and so on). In such a generous environment, Worthington and Carruthers demonstrate that there is more, richer, deeper mathematical learning for educators to assess.

In terms of the pedagogical relations established through talk between adults and children, educators can always choose between, on the one hand, traditional, empty, question-and-answer routines, and, on the other,

what the important Effective Provision of Preschool Education (EPPE) and Researching Effective Pedagogy in the Early Years (REPEY) studies have called “sustained shared thinking,” passages of meaningful, purposeful talk, in which both adults and children contribute ideas worth listening to and thinking about. The REPEY project has identified this style of interaction as a significant factor in settings of the highest quality; what is more, in the settings where this kind of talk is a frequent element of the children’s experience, educators have many more opportunities of seeing children’s minds actively at work, making meaning for themselves. They will be able to recognize the validity of the Reggio concept of “rich, strong and powerful children,” and act on their responsibilities to them.

Conclusion

This exploration of educators’ choices in assessment has shown that their practices can sometimes act against children’s best interests. However, there are always positive alternatives. In defining these, it is necessary, first, to distinguish between the purposes and outcomes of any set of early childhood assessment practices: purposes are nearly always benevolent and can certainly be made to sound benevolent, while the consequences of assessment, what it actually does to or for children, for parents, for educators, may be far from benevolent. The damage done by “ability labeling,” for example, and by “ability-focussed” practices, such as setting and streaming, has been fully documented by Hart *et al.* (2004), who also propose an alternative “anti-determinist” pedagogy. A detailed paper by Rogers (1989) reviews a number of studies on the effects of early labeling, showing how educators’ expectations of individuals, for good or bad, have long-lasting outcomes for young children, especially in the formation of their attitudes to themselves as learners. Carol Dweck and her colleagues, in a long series of ingenious problem-solving experiments, have identified two distinct patterns of learned behavior, which they term “mastery” and “helplessness,” and which have a significant effect on later learning (Dweck, 1999).

Assessment practices in early childhood are most likely to have benevolent outcomes when values (what we value in young children, in learning, in early education) and principles (the carefully considered ways in which we enact our values) are tightly aligned in the pursuit of a shared vision for children, a shared understanding of their powers (not least their spontaneous search for meaning and understanding), and a shared view of the kinds of learning that matter most.

When all these considerations are in place, when wise choices have been made at every level, early years educators are well placed to practice assessment in ways that

work for children. In effective assessment, the educators’ tasks of observing children’s learning, trying to understand it, and their responsibility to put their understanding to good use, are all at the service of young children.

Assessment in the History, Civics and Social Studies Domains

P G Avery, University of Minnesota, Minneapolis, MN, USA

Assessment in the domains of history, civics, and social studies is associated with a myriad of complex issues. Similar to other content area domains, the content, format, and purposes of assessment are the subject of intense debate, as is the impact of assessment on teaching and learning. However, there are also challenges and issues associated with the assessment of history, civics, and social studies that are unique. This article describes large-scale assessments in the domains, classroom-level assessments, and the issues that make assessment in these domains particularly problematic.

Large-Scale Assessments

Large-scale assessments such as the National Assessment for Educational Progress (NAEP) in civics and US history, the National Assessment Program (NAP) in civics and citizenship in Australia (MCEETYA, 2006), and the International Association for the Evaluation of Educational Achievement (IEA) CivEd study (Torney-Purta *et al.*, 2001) are not intended to provide information about an individual student's achievement, but rather to give a profile of student achievement at a particular point in time. Using complex sampling procedures, the results often serve as a baseline for trend studies; the NAEP assessments in civics and US history are conducted in grades 4, 8, and 12 in the United States approximately every 5–10 years; the NAP in Australia is scheduled to be conducted every 3 years in grades 6 and 10; and the IEA, which has conducted two international studies of adolescents' civic knowledge and understanding, is scheduled to conduct another study of civic and citizenship education in 2008–2009.

National and international frameworks provide insight into how the domains are conceptualized for the purpose of assessment. In the area of civics and citizenship, the frameworks for the 2006 NAEP in the United States, the 2004 NAP in Australia, and the 1999 (IEA) CivEd Study conducted in 28 countries, provide interesting comparisons. The NAEP framework includes civic knowledge, skills, and dispositions; the NAP divides the domain into two components: civics knowledge and understandings, and citizenship skills and dispositions. The CivEd study assessed students' knowledge, skills, understanding of concepts, attitudes, and actions. It is significant that even in large-scale assessments the subject is recognized as more than knowledge and skills. This broad conceptualization of civics and citizenship, which includes dispositions and

behaviors, is supported by civic leaders, professional organizations, and educational mission statements across many countries.

The NAEP and NAP items assessed students' dispositions; however, items were worded such that they assessed whether students could identify and describe the significance of particular civic dispositions in a democracy; importantly, an individual student's civic dispositions were not assessed. For example, students were asked to identify the significance of a sense of civic duty in a democracy as opposed to reporting their own sense of civic duty.

The IEA CivEd study included a test of knowledge and skills with right or wrong answers, and a survey of students' conceptions of democracy, citizenship attitudes, and their current and expected political behaviors, with no right or wrong answers. Whereas national assessments often focus on the structures, functions, and characteristics of government of a given country, the IEA CivEd assessment was framed around broad democratic concepts and principles not specific to a particular nation-state. The primary concepts underlying items in the CivEd study were democracy, citizenship, national identity, international relations, social cohesion, and diversity. The NAEP and NAP assessments included multiple choice and constructed response items; the CivEd Study did not include constructed response items (presumably because of the many languages of the students), but did include Likert-type response items in assessing student attitudes as well as current and expected citizenship participation.

The framework developed for the 2006 NAEP US history is organized around four major themes (e.g., change and continuity in American democracy), eight chronological periods in American history, and two cognitive domains. The two domains are described as "ways of knowing and thinking about U.S. history," and are (1) historical knowledge and perspective, and (2) historical analysis and interpretation. Approximately two-thirds of the items are focused on what the test developers identify as historical analysis and interpretation.

Although multiple choice items still dominate large-scale assessments, constructed response items now often comprise a significant portion. On the 2006 US Civics NAEP, for example, 20% of the items for grade 12 were constructed response. One item asked students to "explain three ways in which the power of the president can be checked by the legislative or the judicial branch." Responses were scored as 'Complete', 'Acceptable', 'Partial', or 'Unacceptable'. Note, however, that constructed

response items do not necessarily require higher order thinking skills. Although there are a range of possible correct responses to this item, it is still knowledge that is being assessed.

In the United States, the No Child Left Behind Act (NCLB) has led to an increased use of statewide tests. Grant and Salinas (2008), who have conducted the most comprehensive review of state assessments in the social studies to date, report that approximately half of the 50 states administer tests in social studies subjects, and about 10 states attach high-stakes consequences to them. They note that the exact number of states engaged in testing is a moving target, with two to three states opting into testing the same year that two to three states opt out.

There is wide variation in what is tested, how it is tested, the consequences attached to the results, and for whom the consequences apply (student, teacher, school, and/or school district). Even the name of the test is not necessarily an indicator of the content of the test. Social studies tests can be predominately tests of history knowledge, while history tests can include items that could easily be interpreted to be within the broader field of social studies. Passing scores are determined by the states, and vary widely. A student who passes a social studies test in one state could quite conceivably move to a neighboring state and be rendered a failure in social studies. The results are not comparable across states because of wide variation in content and the determination of proficiency levels.

As with national assessments, multiple-choice items dominate the state-level assessments because of the ease and efficiency with which they can be scored. Further, when high stakes are attached to the results, such as student retention or failure to graduate, the scoring of multiple-choice items with clear right or wrong answers is more defensible from the standpoint of the test administrators than is the scoring of open-ended, constructed response items.

The document-based question (DBQ), however, has been used in the New York Regents History exam since 2000. The format is to present students with parts of 5–8 historical documents, such as newspaper articles, political cartoons, letters, speeches, advertisements, and posters, each followed by short-answer questions, culminating with an essay question. In the 2008 New York Social Studies Regents Examination for US History and Government, for example, students were given eight documents related to reform movements in the 1800s and early 1900s (e.g., an anti-child labor poster). The directions for the essay were: “Discuss the social, political, *and/or* economic problems addressed by reformers in the 1800s and early 1900s. In your discussion, include the methods used by reformers to expose these problems.” Students were further instructed to:

- develop all aspects of the task;
- incorporate information from at least five documents;

- incorporate relevant outside information;
- support the theme with relevant facts, examples, and details; and
- use a logical and clear plan of organization, including an introduction and a conclusion that are beyond a restatement of the theme.

The task clearly requires more high-level thinking than the typical multiple-choice or short-answer question. However, is it more authentic with respect to the type of work historians do?

Grant *et al.* (2004) analyzed another DBQ from the New York State Regents Examination in Global History and Geography, and concluded that the task fell far short in terms of representing or reflecting the type of work historians do. They noted that historians always examine an entire document (the New York exam often edits primary source documents), engage in sourcing (evaluating the source of documents) and corroborating (comparing the facts presented in different documents), and present historical arguments based on their analyses. The researchers concluded that “if statewide tests claim to assess accurately students’ historical understanding, then those tests should resemble more closely the work that historians do” (p. 337).

The results and secondary analyses of large-scale assessments provide some insights into student achievement in subject areas. Some of the conclusions are predictable; for example, all studies show students of parents with higher incomes, education, and resources outperform their counterparts. Achievement gaps exist between dominant and nondominant groups, and between native-born students and immigrants. However, other findings are somewhat less expected, and potentially more valuable. For example, frequent (weekly) tests in social studies classrooms are associated with lower achievement levels on the US History NAEP. Minority and lower income students often receive less of the high-quality, active instruction that is associated with higher achievement scores (Smith and Niemi, 2001). Students who report participating in frequent, substantive discussions in their social studies classrooms tend to demonstrate higher achievement scores in history and civics, and are more likely to state that they expect to vote as adults (Torney-Purta *et al.*, 2001). But it is unclear if and how results such as these impact policymakers and classroom teachers.

The national climate of accountability and testing in the United States appears to affect most social studies teachers, regardless of whether their state mandates social studies tests or uses the tests to determine student promotion or graduation; however, the degree to which it changes individual teacher’s classroom practices varies widely. Grant (2006) surmised that teachers are most likely to change their selection of social studies content as a result of testing, less likely to change their assessment

procedures, and least likely to change their instruction. The next section describes what we know (and do not know) about classroom-level assessments.

Classroom-Level Assessments

The content of classroom assessments is presumably shaped by state/national standards, textbooks, and local curriculum guidelines. However, there has been very little research on the content, format, or impact of classroom assessments. On the IEA CivEd survey, teachers of civics-related subjects in 26 countries reported that written essays and oral participation were the most common type of assessments used in classrooms. Teachers from Eastern European countries were more likely to report the use of multiple-choice tests than were those from Western European countries.

In the United States (not included in the IEA teacher reports), the NAEP studies provide an indication of the types of assessments used most frequently in social studies classrooms. On the 2006 US History NAEP, teachers were asked to report how often they used five different types of assessments (see **Table 1**). Fill-in-the-blank assessments were used most often in grade 4, while written paragraphs were the most frequently reported type of assessment in grade 8. It is difficult to draw any conclusions about the use of projects without knowing the type and quality of projects, but unlike the other four assessments, projects are more likely to involve peers. The other four types of assessments are almost always conducted at the individual level. Not surprisingly, the emphasis on writing increases from grade 4 to grade 8; however, the preponderance of fill-in-the-blank assessments, which almost always require lower level recall, at both grade levels is striking.

As reported by the students responding to the 2006 US History NAEP, the emphasis on writing decreases at grade 12, perhaps because teachers at this level often have a much higher number of students than do teachers at grade 4 or 8 (see **Table 2**). One of the more interesting (or alarming) findings is that 66% of the grade 12 students report taking a test or quiz at least once a week. Students

who take a test or quiz 1–2 times a month, however, score significantly higher on the US History NAEP than do students who are tested more frequently.

There are no systematic studies that examine the use of more nontraditional assessments in the classroom. Similar to educators in other subject areas, however, social studies teachers' repertoire of assessment types was enhanced when notions of alternative assessments and authentic assessments received greater attention in the 1990s. Portfolios, performances, exhibitions, debates, etc. – all modes of assessment teachers had used previously – became more legitimized as valued means of assessing students' understandings. Rubrics, appropriately developed, prompt teachers to be more explicit about their goals, and the criteria associated with those goals. For students, well-designed rubrics can clarify tasks and grading criteria.

Fred Newmann's work on authentic assessment has had a special impact on social studies education, in part because his original work was with the social studies. He conceptualized assessment as integrally connected to instruction and student performance. In the early 1990s, Newmann and his colleagues at the University of Wisconsin's Center on Organization and Restructuring Schools (CORS) initiated a major research program focused on students' authentic intellectual achievement. They reasoned that meaningful teaching and learning should focus on the quality of work that students produce. The CORS group suggested that authentic intellectual achievement should involve: (1) students constructing knowledge through (2) disciplined inquiry that has (3) value beyond the classroom (Newmann *et al.*, 1995). Their conceptualization of authentic intellectual achievement reflects much of what we know about good teaching and learning: students are actively involved in producing and developing understandings, rather than reproducing isolated bits of information; they are using disciplinary methods, concepts, and generalizations; and they are recognizing a strong connection between the form and substance of the work they are doing in school and the intellectual work that takes place outside of school.

Newmann and coworkers suggest that authenticity may be reflected in three areas: assessment tasks, instruction, and student performance. They developed parallel,

Table 1 US social studies teachers' report of assessments used one or more times per week^a

Type of assessment	Grade 4 teachers	Grade 8 teachers
Extended essays	20%	36%
Fill in the blank	72%	74%
Projects	53%	62%
Written paragraphs	62%	81%
Multiple choice	13%	22%

^aData from the 2006 US History NAEP, public schools.

Table 2 US grade 12 students' report of assessments used one or more times per week^a

Type of Assessment	
Take a test or quiz	66%
Write short answers to history/social studies questions	59%
Write long answers to history/social studies questions	18%
Group project	18%
Give a report	11%
Write a report	11%

^aData from the 2006 US History NAEP, public schools.

Table 3 CORS standards for authentic assessment tasks^a*Construction of knowledge:**Standard 1. Organization of information*

The task asks students to organize, synthesize, interpret, explain, or evaluate complex information in addressing a concept, problem, or issue.

Standard 2. Consideration of alternatives

The task asks students to consider alternative solutions, strategies, perspectives, or points of view as they address a concept, problem, or issue.

*Disciplined inquiry:**Standard 3. Disciplinary content*

The task asks students to show understanding and/or use of ideas, theories, or perspectives considered central to an academic or professional discipline (e.g., democracy, social class, market economy, and theories of revolution).

Standard 4. Disciplinary process

The task asks students to use methods of inquiry, research, or communication characteristic of an academic or professional discipline.

Standard 5. Elaborated written communication

The task asks students to elaborate on their understanding, explanations, or conclusions through extended writing.

*Value beyond the classroom:**Standard 6. Problem connected to the world beyond the classroom*

The task asks students to address a concept, problem, or issue that is similar to the one that they have encountered, or are likely to encounter, in life beyond the classroom.

Standard 7. Audience beyond the school

The task asks students to communicate their knowledge, present a product or performance, or take some action for an audience beyond the teacher, classroom, and school building.

^aFrom Newmann, F. M., Secada, W. G., and Wehlage, G. G. (1995). *A Guide to Authentic Instruction and Assessment: Vision, Standards, and Scoring*, pp 81–85. Madison, WI: Wisconsin Center for Education Research.

though different, standards and scoring criteria for each area. The authenticity of assessment tasks was evaluated according to seven standards (Table 3).

The CORS researchers conducted an extensive study of authentic intellectual achievement in math and social studies classes in 24 restructured elementary, middle, and high schools. They found a high correlation between level of authentic pedagogy and student performance, that is, the higher the quality of instruction and assessment, the higher the quality of student performance. Their observations of classrooms and review of student tasks, however, suggested that in most classrooms, the authenticity of pedagogy (i.e., instruction and assessment) was fairly low. When teachers did implement more authentic pedagogy, all students benefited, regardless of ethnicity, socioeconomic status, gender, or achievement level. The study is one of the few that has looked systematically at the quality of classroom assessments used by social studies teachers.

Although the criteria for authentic intellectual achievement can be applied across subject areas, social studies educators have been particularly receptive to the framework.

The National Council for the Social Studies (NCSS) published sets of professional development materials at the elementary, middle, and high-school levels based on the CORS work. Social studies curriculum materials have been developed around the framework for authentic assessment. At least two states, Wisconsin and Michigan, have embedded parts of the framework into their state standards and assessments.

Frameworks or rubrics have been developed for assessing many of the rich experiences that take place in engaging social studies classrooms, such as mock trials, role plays, historical debates, and simulated legislative hearings. Discussions about controversial contemporary or historical issues in open and supportive classroom environments are considered by many social studies educators and researchers to be critical experiences for young people in preparing them for adult citizenship. Discussion formats that have received the most attention in social studies include Socratic seminars, structured academic controversies, or public issues discussions. An assessment for an issues discussion, such as the one developed by Harris (2002), includes substantive and procedural criteria. For example, students receive credit for stating and identifying issues, using disciplinary knowledge, and elaborating with reasons or evidence (substantive), or for inviting other students to contribute, recognizing another student's contribution, and providing summarizing statements (procedural). Credit is deducted for negative behaviors such as monopolizing the discussion.

Although professional organizations are very supportive of more authentic assessments, little research has been conducted to indicate how widely such assessments are used in social studies classrooms or how they impact student learning.

Issues and Challenges

There are at least five significant challenges and issues that are particularly salient to assessment in the domains of history, civics, and social studies. First, and perhaps most important, the purpose of each of these subjects in the schools is integrally tied to citizenship education. The social studies is defined by NCSS as "the integrated study of the social sciences and humanities to promote civic competence." The study of a nation's history is undertaken in part to give students a sense of their heritage, and a historical perspective that will enable them to make more informed decisions as citizens. Civics as a subject of study, of course, has as its focus the knowledge, skills, and values that enable participation in a democratic society. The citizenship purpose associated with these domains can be problematic in terms of assessment. Engaged and enlightened citizenship, the goal of most democratic societies, entails much more than knowledge

of the structures and functions of government or even an understanding of the principles of democracy. It also involves values and behaviors that are not only difficult to agree upon, but are also very difficult to assess. Many argue, for example, that service learning provides students with experiences that are likely to promote more concerned, community-oriented citizens. However, the understandings of people and communities that often develop through service learning do not lend themselves well to traditional assessments.

Although it is possible to assess citizenship attitudes and behaviors (as the CivEd study did), if the results are linked to individual students, how should the results be used? Also, at what point does the assessment of an individual student's citizenship values and behaviors become undemocratic? This is particularly troublesome in countries that are home to peoples with different ethnic, religious, and cultural backgrounds. However, if assessment is limited to knowledge and skills, it becomes what most social studies educators would consider a very shallow and minimalist vision of citizenship.

Second, the domains of history, civics, and social studies are more likely to provoke public debate than many of the other subject areas in schools. The controversial nature of these domains has implications for assessment. The question "Whose history should we teach?" is intertwined with "Whose history should we assess?" Do we assess students on their knowledge and understanding of the dark side of our countries' histories? Do we teach and assess conceptions of citizenship that are critical, participatory, community oriented, and/or law-abiding? Assessments often reflect the knowledge and skills about which there is the most agreement in a society and those that are least likely to provoke controversy; unfortunately, this sometimes reduces history to trivial pursuits and civics to a dull study of the structures and functions of government, all of which are unlikely to engage many students.

Third, there is less agreement within the profession as to the nature of history, civics, and social studies, particularly in comparison to disciplines such as math and science. In a study of five subject-area departments at 16 high schools, Grossman and Stodolsky (1995) found that English and social studies teachers viewed their subject areas as less defined than faculty in science, math, and foreign languages, and were less likely to develop common exams with their colleagues. The Ministerial Council in Australia reported that "the definitions associated with certain key [citizenship and civics] concepts were not generally agreed across jurisdictions, nor was their appearance in formal curriculum documents universal" (MCEETYA, 2006: 3). Similarly, in the IEA CivEd study, teachers from across 26 countries reported a lack of consensus as to what constitutes civic education. Moreover, the study conducted by the European Commission (2005) on citizenship education in Europe found different

conceptualizations of citizenship and citizenship education across the 30 countries surveyed. The ambiguity associated with the social studies field, and citizenship education in particular, suggests greater variation in the content of classroom-based assessments, and a difficulty achieving consensus among social studies educators about the content and nature of assessments.

Fourth, increased calls for accountability, combined with the lower status of civics and social studies in schools, present difficult dilemmas for social studies educators. The NCLB, passed in 2001 in the United States, identifies civics, government, history, economics, and geography as core subjects. However, unlike reading and math, states are not required to administer tests in these areas. When social studies tests are mandated at the state level, social studies tends to enjoy increased status and resources. The negative consequences of mandated state-level tests often include the narrowing of the curriculum, teaching to the test, and a focus on the recall of information. However, when social studies is not among the state-level mandated tests, it becomes marginalized. The intensive focus on reading and math has led to a decrease in social studies instruction, particularly at the elementary level in high-minority, low-income schools (Jennings and Rentner, 2006; von Zastrow and Janc, 2004). It may take 5–10 years before we can assess the effect of less social studies instruction on young people's social studies knowledge and understandings.

Concerns about the marginalization of social studies led the NCSS, in collaboration with national history, economics, geography, and civics education organizations, to issue a joint statement on NCLB in 2007 calling for the US government to include the social studies disciplines among those for which state-level assessments are mandated. At the same time, the NCSS (1994) supports the development of comprehensive assessment plans that:

1. are designed to inform pedagogical practices;
2. are aligned with local standards and curriculum;
3. include multiple types of assessments, such as portfolios, teacher observation, essays, student performance, and multiple-choice responses;
4. directly connect to the goals of citizenship education; and
5. assess students' knowledge, thinking skills, values, and social participation.

Most social studies educators are supportive of comprehensive assessment plans, and are concerned about the use of single, high-stakes tests that determine whether a student is promoted to the next grade level or graduates from school. They tend to view assessment more as a classroom-based tool integrated into curriculum and instruction for the purpose of providing ongoing support and feedback to teachers and students. They also express concern about the validity and reliability of all assessments, but particularly those with high stakes attached. Yet, the intense pressure for accountability, and concerns

about the marginalization social studies when it is not tested, suggest that state-level testing will continue and possibly increase.

Fifth, history education, in particular, is often ill-served by the way in which assessments have been conceptualized and implemented. That which can be readily tested in civics and history is often that which is least significant and meaningful. The broad survey nature of courses makes it difficult to assess students' in-depth knowledge and understandings. The type of historical skills that are most meaningful, that help students to understand historical significance, take historical perspectives, and develop and analyze historical interpretations, for example, are not those that can be assessed well in one setting at one time with one test or assessment task. Levstik and Barton (2005) noted that perspective recognition, an aspect of historical interpretation, "cannot be taught, practiced, and mastered during the course of a single, seven-step lesson; it requires sustained attention in a variety of contexts over the course of many lessons, many units, and many years" (p. 160). They advocate the type of comprehensive assessment plan that integrates curriculum, instruction, and assessment; is an ongoing part of the students' educational experiences; and involves students in reflecting on their own development. This vision stands in contrast with, say, the high percentage of students who report completing fill-in-the-blank exercises on a weekly basis in their US history classes.

In summary, the knowledge and skills that can be easily assessed in the history, civics, and social studies domains are often those which are least significant to academicians, and least meaningful to students. The movement toward more authentic assessments holds promise, but is frequently at odds with a culture of testing and accountability. Most striking, however, is the lack of systematic research on the ways in which assessments are implemented in history, civics, and social studies classrooms, and their impact on teaching and student learning.

Assessment in the Workplace of Performance, Developing Expertise and Competence

A J Brown, University of Warwick, Coventry, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Competence-based assessment – An assessment process involving the collection of evidence about the ability of a person to perform a particular activity to the required standard.

Workplace-based assessment (WPBA) – The assessment of performance based on what a person (often a trainee) actually does in the workplace when engaged in work tasks.

Introduction

Assessment in the workplace has historically performed a number of functions that have included use in job allocation, appraisal, pay or promotion procedures; recognition of achievement; accreditation of competence; facilitating access to further education and training; and encouraging further personal learning and skill development. Assessment in the workplace in this article is considered in three contexts: assessment of performance linked to initial education and training (as in medical education); assessment of the development of expertise in knowledge-intensive work (as in aerospace companies); and the accreditation of competence, as represented in national systems of competence-based assessment. Assessment in the first two contexts is strongly situated and generally works well, whereas the success of national competence-based systems is much more mixed. There has been some success where the primary concern has been on supporting individuals getting their skills, knowledge, and understanding related to current work roles assessed and accredited. However, recent trends have seen growing interest in how more-formative workplace assessment can align individual development with organizational development. This interest has included an examination of the extent to which processes of formative assessment and critical reflection in the workplace can support employees' commitment to lifelong learning and knowledge-transformation processes at work. This article examines the success of situated approaches to performance assessment and expertise development in the workplace, some of the shortcomings of national competence-based systems, and the characteristics

of an approach to the assessment of workplace learning that is oriented toward the future, focusing upon how best to support employees' commitments to lifelong learning and active knowledge transformation.

Workplace-Based Assessment of Performance in the Workplace

Thomas Huxley famously argued in 1876 that something should be done to aid the medical student toward the acquirement of real knowledge by modifying the system of examination so as to have a greater focus upon practice and performance. Finally, in clinical education in most countries, there are now moves toward systems of which Huxley would have approved, where examinations of knowledge and clinical skills are retained but now they are part of an overarching assessment framework that has extensive workplace-based assessment (WPBA) of performance. The WPBA involves an evaluation of a doctor's progress in his/her performance over time, in hospitals or other clinical settings, in those areas of professional practice best tested in the workplace. WPBA in this context works well because it offers the opportunity to reconnect teaching, learning, and assessment and is authentic. It provides an opportunity for the assessment to get as close as possible to the real situations in which doctors work. WPBA has also led to a softening of the distinction between formative and summative assessment, with trainee doctors being provided with continuing feedback on their performance. WPBA therefore provides feedback to individuals on areas of strength and development needs; identifies trainees who require additional support; drives learning in important areas of developing expertise; and determines fitness of individuals to progress to the next stage of their careers. The UK Postgraduate Medical Education and Training Board (PMETB, 2004) has published the principles underpinning the approach and Schuwirth and van der Vleuten (2006) have highlighted the challenges that this provides for educationalists to increase the effectiveness of clinical education. In order to assemble evidence of performance, increasing use is made of portfolios, mini-clinical evaluation exercises, and 360° feedback. In a mini-clinical evaluation exercise, a consultation is observed and scored on a generic rating scale including items such as problem analysis, history

taking, and organization and efficiency. In 360° feedback, the candidate asks colleagues to complete a questionnaire on his or her performance that rates technical skills, interpersonal skills, team skills, education and research skills, etc. These instruments focus on observable behavior and can be used to provide feedback to trainees, but it is also clear that rather than using a single instrument to provide an assessment of a particular competence, it is better if the whole picture of someone's medical competence is portrayed using a variety of assessment instruments (Schuwirth and van der Vleuten, 2006>). Clinical education and training therefore provides a powerful example of the value of WPBA in the assessment and development of performance in initial education and training.

Assessment of the Development of Expertise in Knowledge-Intensive Workplaces

Another area where WPBA has become increasingly important is in the assessment of the development of expertise in knowledge-intensive workplace such as aerospace companies. In such contexts, WPBA faces two particular challenges. First, a focus on competence in the workplace in the sense of outlining what workers did in the recent past will be an insufficient basis for preparation for future performance. Second, much learning takes place while working, rather than in recognizable education or training settings. In knowledge-intensive work settings, such as aerospace, it is important to look beyond current competences as a basis for development, and instead take a developmental view of expertise. Such an approach requires that the development of expertise should itself be viewed as a continuing process. Thus, even if employees are able to produce competent performance in a range of more-or-less challenging work settings, there has to be a facility within teams or the workforce as a whole to go beyond this. From this perspective, it is interesting that some companies are explicitly using a developmental view of expertise that goes well beyond expecting technical proficiency and a commitment to continuing improvement. Thus, some companies, working in technologically advanced sectors, build up competence inventories of their staff in order to differentiate between:

- those who are technically able to perform a task but have very limited practical experience of actually doing so (e.g., the company could use them in an emergency or, if necessary, for a one-off activity);
- those who have successfully performed the task on a small number of occasions (e.g., the company could use them if the intention was to develop their expertise further; in a support role or if time is not necessarily a key criterion);

- those who have performed the task many times and under a variety of conditions (i.e., experienced worker standard – they are completely reliable);
- those who have substantial experience but are also able to support the learning of others (i.e., they can perform a coaching or mentoring role); and
- those who are world class, that is they are able to think through and, if necessary, bring about changes in the ways that tasks are tackled (e.g., could be chosen as a team leader for performance-improvement activities).

The interesting thing here is that this approach to professional development recognizes the importance of having a capacity to support the learning of others as well a capacity to change the way things are done. Now, WPBA has traditionally focused on the first three levels with a clear focus upon how workers perform the tasks being assessed. If the assessment is broadened to cover aspects of interaction with others, both on task and at other times, it might also be possible to pick up those who are able to support the learning of others, although in Germany such assessments have long been part of the *Meister* examinations for skilled workers seeking development and the attainment of higher-level qualifications. The highest level of performance can be recognized retrospectively (and the examples documented), but it is very difficult to predict through other forms of assessment. This difficulty is because this type of expertise is often partly built around recognition of the importance of the integration of different kinds of knowledge. Professionals and other highly skilled workers often find that the most important workplace tasks and problems require the integrated use of several different kinds of knowledge. Eraut (2004)> argues that this process typically involves five interrelated stages:

- the extraction of potentially relevant knowledge from the context(s) of its acquisition and previous use;
- understanding the new situation, a process that often depends on informal social learning;
- recognizing what knowledge and skills are relevant;
- transforming them to fit the new situation; and
- integrating them with other knowledge and skills in order to think/act/communicate in the new situation.

The whole process is much more complicated than just de-situating and re-situating particular pieces of knowledge. However, trying to predict in advance whether someone will be able to combine knowledge from education, training, work, and possibly other settings is very challenging, but WPBA in the form of recording of instances of such performances is authentic, fit for purpose, and signals that the overriding concern is with the holistic nature of performance in the workplace, if organizational performance is to be improved.

Competence-Based Assessment in the Workplace

Assessment in the workplace in the two contexts illustrated above is strongly situated and generally works well, but can these lessons be applied to the development of national competence-based systems where the picture is much more mixed. Assessment and learning in the workplace are not only related to each other, they are also linked to qualifications. Indeed national competence-based assessment regimes explicitly seek to link workplace assessments more toward qualifications than learning, in that they are expressly concerned with outcomes and downplay the significance of how things are learned. Such qualifications are assessment driven and the link to individual development is through achievement of qualifications, including progression to the next level in the qualification framework. These systems are by definition, national in outlook and do not necessarily engage with individual development in the workplace or improved organizational performance; nor do they necessarily encourage individuals to continue learning in the workplace. Indeed, Grugulis (2000) shows how compiling evidence of achievements at work against detailed performance criteria for competence-based qualifications, such as national vocational qualifications in England, can actually be antithetical to learning and development, because so much time was spent on the bureaucratic requirements of assembling evidence of existing competences.

Furthermore, competence-based work-related qualifications sometimes portray learning progression as an individual going through a single hierarchy of levels, whereas, in practice, an individual's learning requirements are likely to vary between domains and contexts and an expert in one area may be a novice in another, even if the fields are closely related. Moreover, individuals have to learn to make judgments in different spheres (e.g., in academic, cognitive, managerial, interpersonal, and experiential contexts) and again an individual may be at very different levels in the different spheres. Grugulis *et al.* (2004)> pointed out that the major failing of narrow views of competence was that they had an almost exclusive concern with measurable outcomes. Through qualifications, competences were seen as a proxy to measure the increase in skills of a population.

National competence-based work-related qualifications typically are drawn up according to similar templates that focus upon immediate achievements and measurable outcomes in the workplace. The qualifications supply information primarily about a person's skills and the knowledge necessary for carrying out the tasks and functions associated with particular jobs: that is, the assessment is concerned with the skills and knowledge necessary to underpin current performance. Such an approach says nothing at all about a person's potential or

his/her broader skills, knowledge, and understanding that may not be needed in his/her current work but that could be utilized in future. Assessment in the workplace, however, does not have to focus narrowly upon immediate achievements and outcomes, as it is possible for even competence-based assessment to reflect a developmental view of performance in the workplace that acknowledges the value of promoting continuing learning. For example, more sophisticated notions of competence have been developed that acknowledge that competence can be viewed as being held collectively by, for example, a workgroup and that there can be considerable value in competence development being contextualized for particular work environments (Mills *et al.*, 2000; Sandberg, 2001>).

The narrow approach to competence-based assessment has a focus upon measurable outcomes and an essentially binary conception of competence: you have either reached the appropriate standard (typically defined as experienced worker standard) or not. However, it is far more beneficial in inducing a more expansive frame of mind toward learning among employees to have a developmental view of competence as demonstrated by the example quoted earlier of companies working in knowledge-intensive industries. A developmental view of competence reflects attitudes toward learning and development that go well beyond achievement of simple technical or behavioral competence. That such orientations are not amenable to reductionist, analytical approaches to competence development is clear from the work of Sandberg (2001)> who shows that there are very different ways in which highly skilled professionals can approach their work: competence needs to focus upon higher levels of aggregation than just effective task completion. The increasing need for employees with proactive approaches to learning and knowledge transformation makes this requirement ever more pressing.

Formative Assessment and Critical Reflection in the Workplace Supporting Employees' Commitment to Lifelong Learning

One common method of professional development, used in a wide variety of occupational and organizational contexts such as healthcare, is to get employees to make an assessment or critical reflection on their own learning and development through, for example, the use of personal development portfolios or discussions with peers. The use of reflection upon learning at work can be a powerful formative assessment process, especially if it has a strong dialogical component, and can highlight not only what was learned but also the nature of the learning process. One outcome of a reflective formative assessment process might be the production of a portfolio that couples

hard achievements with development of soft processes that provide examples of experience and achievement. This reflective process can provide a spur to lifelong learning because it recognizes the emotional component to learning; it aligns with the idea of continuing personal development (as the examples can be updated); and it acknowledges the interrelatedness of changes in work practice and organization, personal development, and organizational performance. Williams (2001)> highlights how when learning is mainly coming through working rather than formal education and training, then the development of self-consciousness (reflection) and continual self-critique (critical reflection) are crucial to continued competence. Such workplace-based self-assessment, in this case in nursing, could be facilitated either through active repeated guided practice or could be an outcome of earlier education and training that was focused on problem-based learning.

This type of assessment does not have to remain formative. At any stage of the process, it should be possible to authenticate any particularly striking examples of experience and achievement through formalizing the process, such that it could form the basis of a later claim for credit against vocational or academic qualifications at a future date. This type of approach to assessment is primarily, rather than exclusively, formative, with the goal being encouraging learners to engage in further learning and skill development, and the use of mediating artifacts (portfolios, diaries, records, photographs, etc.) can encourage active reflection and review. The assessment process thereby adds value to the learning process in recognizing the achievements of the learner and the context in which the learning took place. One key aspect of this approach to assessment is that it increases the likelihood that learners would value the process and outcomes of assessment as supportive of their learning and further development.

Workplace-Based Assessment Supporting Processes of Knowledge Transformation

One of the key characteristics of a move toward a more knowledge-based society is that processes of knowledge development and transformation of different forms of knowledge become much more ubiquitous in where they are situated. In particular, organizations and workplaces are becoming important sites of knowledge generation and transformation, and some forms of WPBA have been designed to support such processes. The underlying idea is that there is considerable value in attempting to link processes of knowledge creation with approaches to tackling the core problems of manufacturing practice or service delivery as a means of engaging employees as

learners, including those employees in contexts such as small companies that have traditionally been difficult for formal education and training institutions to reach (Brown, 2005>). These ideas link to processes of continuing improvement in that attention is given to problems and dilemmas that are central to manufacturing practice or service delivery and performance improvement, although there is also express concern for work-related learning, development, and assessment. These problems and dilemmas have significance both for individual and organizational performance. The problems are likely to contain combinations of practical concerns, organizational issues, and sociocultural problems.

Processes of continuing development and process improvement require not only individuals to be reflective about their own learning but also for the networks involved in these development processes to be able to move knowledge and understanding between the individual and collective, the tacit and the explicit, and assessment in the workplace can play a role in these transformations. While a focus on the core problems of practice (and projected performance improvements in quality, cost and delivery) can act as a strong catalyst to galvanize the interest of companies and individuals, a vehicle is also needed to broaden the interest of companies and participants in both learning and organizational effectiveness (Brown *et al.*, 2004>). The approach to learning through networking could be seen as an example of an active model of learning whereby learners are engaged in processes of self and peer assessment and reflection leading to the creation of new contextualized knowledge, not recipients of a largely passive process of knowledge transmission (compare the processes of organizational knowledge creation outlined by Nonaka and Takeuchi, 1995>). This approach makes use of a social model of knowledge creation and transformation, where for genuine knowledge transformation to occur, knowledge has to move from the individual level into wider communities of interaction that cross organizational boundaries. This approach involves the spiraling of knowledge creation and transformation through continuing cycles of socialization, externalization, combination, and internalization. Processes of formative assessment are critical in order to allow ideas to be fed into the immediate change processes and to form the basis of continuing reflection on learning in the workplace over time that can form the basis of a step change in how organizations think about and support processes of learning, development, and knowledge transformation as a foundation for both individual learning and organizational development. This approach, when it works well, possesses the dynamism continually to create new knowledge, fueled by processes of assessment, reflection, and development.

The assessment processes used to power the knowledge development cycle include critical reflection, with

a focus on adaptability and forward thinking, and learning portfolios allowing individual and collaborative reflection on learning and knowledge-transformation processes. The portfolios could help employees pull their learning together; provide supporting evidence for use in company appraisal processes; help learning become more shareable, portable, and transferable; and act as a stimulus to innovation and the development of adaptability of the team as a whole, evidenced by the ability to perform effectively in a range of contexts (Brown *et al.*, 2004>).

Assessment of Workplace Learning Supporting Lifelong Learning and Active Knowledge Transformation

Exemplary forms of WPBA as outlined here are already supporting processes of lifelong learning and active knowledge transformation at an organizational level. At the national level, however, such approaches will need to be underpinned by a developmental view of competence. This change would imply that rather than the focus being on individuals being viewed as competent to perform current tasks at a particular level, it would recognize that people could still develop in a number of ways (at a range of levels) in order to improve their own performance, that of a team, or enhance the effectiveness of the organization. The forms of WPBA of engaging in peer assessment and self-reflection in order continue to develop a range of skills and to have a broad conception of expertise would also seem to offer, at a societal level, some possibility of moving toward a knowledge-based society. In such a society, there would be a need to focus more upon supporting the processes of formative assessment, learning and development, and to adopt a more expansive view of the nature of skills, knowledge, and competence development. This more expansive view could pay particular attention to the need to address issues of transfer of skills, knowledge, and experience between different settings; how to support individuals in developing a frame of mind whereby they continually look to improve their own performance through learning and development and to support the learning and development of others; and to recognize that in any organization a commitment to continuing growth and development of its members is strategically important.

The narrow view of competence-based assessment, by contrast, could be seen as the societal equivalent of what, at an organizational level, Argyris (2004)> called skilled incompetence, where the focus on doing current activities well can result in neglect of professional growth and longer-term development. A drift toward skilled incompetence could be challenged, however, by the use of processes of formative assessment and critical reflection within a more developmental view of how competence

and expertise can be fostered. This broader view could also help deal with a second problem: in many occupations, the types of knowledge developed through education and work differ, and either is often insufficient as it is the combination and integration of different types of knowledge that is often the major challenge. From this perspective, processes of formative assessment and critical reflection in the workplace could play a key role in the immediate post-qualifying period by recognizing that this is a time in which a great deal of learning takes place and support offered to individuals for their learning and development could have significance for establishing themselves in their career. People early in their careers learn a great deal from challenges at work, and provided that they receive support as required to facilitate processes of formative assessment and critical reflection, a virtuous circle of confidence, support, and challenge can be created (Eraut *et al.*, 2004>).

There is also value in building a stronger dialogical element into the assessment of work-related competences, especially where there is a focus of work-related learning upon the core problems of practice (Onstenk and Brown, 2002>). Learning from their own experience is important for the newly qualified, but so is learning from the experience of others. Newly qualified staff need opportunities to discuss and practice thinking about complex cases handled by their more experienced colleagues. The approach seeking to tackle complexity through processes of formative assessment and critical reflection puts interpretation and a shared search for understanding at the heart of “the discursive nature of professional practice” (Webb, 1996>: 111).

Assessment of workplace learning also needs to help meet the challenge of coping with the demands for flexibility, adaptability, and the ability to transfer skills, knowledge, and understanding between contexts in the workplace, particularly for those operating in highly skilled or professional contexts. The hallmark of successful occupational practice is the ability to draw on knowledge, abilities, skills, and attitudes used in an integrated, holistic way (Gonczi, 1994>). This approach to the performance of professional practice draws attention to three important features. First, complex professional duties can be performed in a variety of ways. Second, these duties can draw on different combinations of knowledge, skills, abilities, and attitudes in effective performance. Third, this approach implies that there is scope for professional judgment, not least in the ability to balance competing demands and the pressures of time. This means that individuals may come up with very different ways of responding to the demands for flexibility and transferability in the workplace. Indeed, one way forward for the newly qualified and experienced practitioners alike may be to use processes of formative assessment and critical reflection to review the different ways individual

practitioners seek to tackle their workload as a whole. By this means, it should be possible to discuss and share ideas about the most effective ways to tackle a range of problems in practice.

Summary

There is increasing evidence drawn from practice in a number of settings of how workplace assessment has affected employees' willingness to engage in lifelong learning and/or has supported processes of knowledge transformation in the workplace. From these particular examples, it is possible to put forward the design characteristics of an approach to the assessment of workplace learning that is oriented toward the future in that it focuses upon how best to support employees' commitments to lifelong learning and active knowledge transformation. It is possible to devise pedagogically driven assessment regimes that support employee development and improvements in organizational performance in ways that are meaningful to the learner and encourage further learning, thereby facilitating commitments to both lifelong learning and active knowledge transformation. The cornerstones of such an approach would acknowledge:

- the importance of formative assessment;
- focus upon individual performance in the enterprise or wider labor market rather than being almost exclusively concerned with seeking alignment with formal education and training programs and qualifications;
- build a stronger dialogical element into the assessment of work-related competences with the focus of work-related learning and assessment being upon the core problems of occupational practice;
- value in acknowledging the importance of soft qualifications in strengthening individual commitments to undertake continuing vocational training; and
- draw on the experience of organized programs of learning and development for organizational change agents that focus both upon organizational development and the value of continuing learning and development.

Assessment in Vocational Education

K Ecclestone, Oxford Brookes University, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The ways in which definitions of outcomes, standards, and curriculum content for vocational education relate to the content and criteria of assessment are affected by competing purposes for vocational education in relation to academic or general education. Some countries have particular difficulty in creating parity of esteem or status between vocational and academic education. Although the status of vocational education in relation to academic education varies between countries, questions about what differentiates general and vocational education, and which young people are suitable for both or either options affect all systems to a greater or lesser extent.

These underlying problems affect assessment approaches and methods used for summative purposes in vocational education which has to show credible standards of achievement in comparison to academic standards, while also opening up and widening opportunities for young people to participate in meaningful education and to progress either to workplace learning or further and higher education. Assessment in vocational education is therefore more complex than in workplace training or general education. This section cannot do justice to the complex theoretical and political debates about what standards of assessment are in academic and vocational education but simply note at this point that such debates affect assessment systems in different ways (see Goldstein and Heath, 2000).

While the particular problems of repeated reform and confusion about the relationship between academic and vocational education are more starkly evident in the UK than in other countries, many of its characteristics apply to assessment systems in other countries, particularly Australia and parts of Europe. This article draws on the features of vocational education in the British education system to summarize the main purposes for a general vocational education pathway, to describe typical assessment methods for formative and summative purposes, and to evaluate some of the links between goals for assessment, learning identities, and uncertainty about what vocational education comprises.

Although this section draws mainly on the UK's vocational education system, many of the features it describes and the questions it raises about goals, identity, and status of vocational education are pertinent to other countries too, albeit in different ways.

General Vocational Education

In the UK, general vocational education has evolved after 30 years of repeated attempts to create a coherent alternative to general academic education into a clear pathway. This runs alongside general academic education, workplace training, and vocational education and training courses that prepare people for different roles within a broad occupational area. General vocational education is now (since 2008) an option for young people at age 14 years before leaving compulsory education, an option after compulsory schooling at age 16 years as an alternative to general academic education or a work-based apprenticeship.

The roots of the general vocational education pathway are in earlier programs for prevocational education that enabled young people deemed to be unsuitable or unwilling to do general education to explore very broadly defined areas such as leisure and tourism, health and social care, or business studies, and to do practical assignments and projects rather than examinations as an alternative to general education.

At the ages of 16 and 18 years, a general vocational education qualification enables young people to progress to more focused vocational education and training courses in postcompulsory education (in Britain, further education colleges and universities, in Finland vocational colleges and polytechnics) that prepare them for occupational roles in a clearly defined area, such as media and performing arts, catering, nursery nursing, and engineering (among others).

One problem in creating stable assessment systems for vocational education that is well-understood by teachers, admission tutors in universities, and employers is confusion created by 30 years of reform and changes to the vocational routes available, and to their assessment systems and methods. In contrast, most Western European countries have managed to create a coherent, long-standing vocational education and training pathway that prepares young people for occupational roles at different levels, from leaving compulsory schooling at 16 years, to workplace apprenticeships and/or to higher level qualifications in polytechnics.

While parity of esteem between vocational and academic qualifications is often an underlying question in many countries, good levels of resourcing, including

highly qualified teachers, and continuity in policy have enabled countries like Finland to have clearly differentiated, well-respected pathways for vocational education and training courses that take place in a college and a local workplace, work, or general academic education.

Purposes

In a context of changing employment patterns, the decline of unskilled jobs (or home populations unwilling to do them), and social change in many countries which sees growing numbers of young people disaffected from compulsory schooling, vocational education and its assessment methods have to meet a growing number of sometimes competing aims:

- motivating learners who would otherwise not stay on in postcompulsory education or who are disaffected at school, by responding to, and rewarding, learners' expressed interests and notions of relevance;
- expanding routes into higher education while also making sure that expansion does not lead to oversubscription for limited places;
- preparing students for progression into work- and job-related training and assessment;
- encouraging young people to carry on gaining qualifications;
- convincing young people, teachers, admissions tutors, and employers that vocational education has parity of esteem with academic qualifications;
- ameliorating poor levels of achievement in numeracy and literacy through key/basic/functional skills;
- satisfying demands from different constituencies, such as employers, subject, and professional associations, etc., to include essential content and skills; and
- having credibility in compulsory schooling where there is less vocational expertise among teachers than there is in vocational/technical colleges in postcompulsory sectors.

Assessment Methods

Shifts from Norm-Referenced to Criterion-Referenced Assessment

The current system of assessment for vocational education in the UK has evolved over the past 50 years to offer diverse forms of certification and these derive from strong norm-referenced, graded systems, strong criterion-referenced systems, open-ended records of achievement, and non-graded competence-based assessment.

Since the late 1970s, the educational and social purposes of assessment have been to encourage wider access and participation and to motivate and engage those disaffected

from schooling and traditional academic assessment methods. A corresponding impetus is for assessment systems to recognize and certificate a much broader range of life and personal skills than in the past and to engage people with their learning in deep rather than instrumental ways.

Such goals have shifted strong norm-referenced systems developed in the 1950s to strong and weak forms of criterion referencing (see Baird *et al.* 2000). In theory, criterion-referenced systems can measure a wider range of real-life skills and attributes while enabling people to get the grade they deserve, providing they meet the publicly defined criteria. Such aims have dominated the strong criterion-referenced system of competence-based workplace qualifications. In criterion-referenced systems, standards come from raising levels of competence and performance in relation to well-defined specifications, thereby providing more valid, authentic measures of performance and coverage or mastery of performance that can be specified in the criteria. Formative assessment, feedback, setting, and reviewing targets not only enable more students to reach the required standard but are seen to be inherently democratic and motivating (see Jessup, 1991).

A Hybrid Assessment Model

Increased participation in both general academic and vocational pathways has eroded old beliefs that any cohort contains a limited pool of innate ability that can be measured reliably as the basis for selection through competitive examinations and norm-referenced grading. In this approach, failure is an inevitable adjunct to success. Although norm-referencing still operates in contexts where summative assessments must select people for licenses to practice or limited jobs and places for higher education, the expansion of work-based assessment and general vocational education has moved all the UK's assessment systems toward a hybrid model, with varying degrees of strong or weak criterion referencing. A powerful influence is the rise and dominance of competence-based assessment (see Jessup, 1991).

Assessment in general vocational education reflects the shift in many countries towards weak criterion-referencing, with the following features:

- the idea that specifications and criteria can be defined in more detail as an impetus for higher achievement because it enables better formative assessment, transparency of assessment demands for students, shared understanding of the criteria, and standardization of assessment decisions;
- strong emphasis on teacher assessment and locally designed assessments against predefined outcomes, with a focus on initial diagnostic assessment, individual target setting based on the criteria, recording achievement, and portfolio building;

- external assessment and moderation by an external authority such as an awarding body, or other national/state agency, and standardization of grading which combines criterion referencing and loose notions of rank-ordering; and
- a contrast to demotivating images of assessment that compare students with each other in general academic education through an upbeat focus on achievement and opportunities to succeed.

Methods of assessment in vocational education combine approaches used in academic education, practical subjects, and workplace training. There are broadly three types of assessment tasks in a vocational education course:

- summative tests such as an end of unit/module multiple-choice test on underpinning theory or knowledge or a written examination paper requiring short answers;
- compilation of a portfolio of evidence that enables students to accumulate different pieces of work (these might include testimonials from work experience, evidence of tasks carried out during work experience, photographs, audio and film recordings, and written work) to show competence or achievement against a set of predefined outcomes; and
- coursework summative assessment based on discrete modules or units, where students complete group and/or individual projects or assignments that have practical and written elements and come in a variety of sizes in terms of credit value. For example, students on a health and social care course might plan and run a health-awareness day for fellow students or for a school that involves research into different topics, presentations through posters, talks and written work, interviews with local health practitioners, and a written evaluation of how well they did in the project.

Many assignments can be locally devised and teacher assessed, provided they address the specifications of outcomes and criteria. There may also be nationally set assignments by the awarding or accrediting body, marked by teachers locally and standardized or moderated regionally or nationally.

Grading criteria and detailed descriptors are based on skills in learning to learn, teamwork, self-assessment, and communication as well as on evidence of subject understanding. A final summative qualification mark is usually derived from a grade-point average from the modules completed during the course, with some weighting given to a final project.

Formative and Summative Activities and Processes

In the UK's vocational education system, many tutors regard their main assessment role as a translator of official criteria and specifications which are usually detailed and

prescriptive. It is commonplace for tutors to break up strongly framed assignment briefs into sequential tasks to meet each criterion. However, at higher levels of the vocational pathway, this becomes less prescriptive and more open ended. Students prepare their assignments by working to the official criteria specified for grades in each unit. In many courses, students can submit a completed draft for feedback which tells them how they can improve their responses to different criteria. However, there is wide variation in formal arrangements for this: in some courses, drafting is done numerous times while in others, only one opportunity is offered. A large amount of lesson or contact time is used to introduce students to each assignment and also to talk through the outcomes of draft assignments, and to allow students to work on assignments.

Formative feedback often takes the form of written advice to plug and cover gaps in the criteria, cross-referenced to the assessment specifications. Vocational students have strong expectations that teachers would offer advice and guidance to improve their work.

Portfolios and assignments or projects provide opportunities for both formative and summative assessment. Reviews of progress and formative feedback can be based on a discussion of the portfolio of achievement, while unit/module-based assignments can be improved through feedback on a draft, or a number of drafts in order to pass or gain better summative marks.

Different countries place different emphases on formative or summative purposes. For example, the two purposes are blurred in the UK, with a strong emphasis from awarding bodies (regulatory examination bodies) on standardization of summative judgments between different centers. In Finland, vocational teachers working with workplace assessors are accustomed to using skills tests and other projects for formative purposes and less accustomed to national regulation or standardization. However, a project by the National Board of Education in Finland aims to use the outcomes of summative tests for national evaluation purposes (see Rakkolainen and Ecclestone, 2005).

In the UK's system, summative assessment, achievement and learning have become to a large extent synonymous, where assessment is not merely for learning or of learning: instead, it is learning:

The clearer the task of how to achieve a grade or award becomes, and the more detailed the assistance given by tutors, supervisors and assessors, the more likely the candidates are to succeed; but succeed at what? Transparency of objectives, coupled with extensive use of coaching and practice to help learners meet them, is in danger of removing the challenge of learning and reducing the quality and validity of outcomes achieved. . . . assessment procedures and practices come completely to dominate the learning experience, and 'criteria compliance' comes to replace 'learning' (Torrance *et al.* 2005: 46).

The Effects of Assessment on Attitudes to Learning in General Vocational Education

Discussion in this section draws on research studies on students' and teachers' attitudes and practices in relation to formative and summative assessment in the UK's system (see Ecclestone, 2002; Torrance *et al.* 2005; Ecclestone and Pryor, 2003; Ecclestone, 2004; Ecclestone, 2008). It summarizes some key features of the ways in which assessment affects students' and teachers' educational goals, attitudes to learning, and choices of pathway.

First, vocational teachers and students emphasize the importance of ipsative (self-referenced) achievement based on students' growing confidence and their ability to overcome previous fears and failures. They regard personal development as more important than the acquisition of skills or subject knowledge. In contrast, staff and students in general academic courses see achievement as predominantly about progression in subject-related knowledge and understanding and gaining suitable grades for progression to higher education.

Second, vocational students often have a strong sense of identity as second-chance learners, an image that their tutors empathize with from their own educational experience. Teachers' and students' attitudes to achievement and failure and their beliefs about students' preferences, capabilities, and attitudes both reflect and reinforce the ethos and culture of different qualification tracks. Attitudes about the purpose and ethos of a qualification and its assessment methods are reinforced by teachers' images of what students liked and wanted. Vocational tutors regard good assessment as practical, authentic, and relevant activities, work-experience, and field trips: there is often a strong view that these students do not want or like written assessment, that they are less secure, need more group affinity and be in a more protected, safe environment. In their beliefs about comfort zones and protecting students, vocational teachers see assessment as integral to a strong ethos of personal development that minimizes stress or pressure.

Third, assessment methods have had a strong impact on expectations for particular types of teaching and assessment activity, and for particular relationships between teachers and students. Many vocational education courses offer students a lively and relaxed atmosphere that enables group work, teacher input, and time to work on assignments individually or in small friendship-based groups. Vocational students also like the familiarity of continuing with teaching and assessment methods they had experienced in an intermediate vocational qualification in the final year of school.

Fourth, students have strong expectations of appropriate feedback, help, and support to enable them to get a good grade. A cultural understanding of assessment, used in the studies cited in this section, illuminates the ways in

which techniques such as feedback, explaining the criteria, encouraging student self-assessment, and using detailed grade descriptors are seen widely as good practice. Yet, in some assessment cultures they can encourage superficial compliance with tasks derived from the assessment criteria, bureaucratic forms of self-assessment against the criteria, and high expectations of coaching and support.

Finally, despite have a strong identity as vocational students, and despite a progression route from vocational courses to university, many young people following vocational courses, particularly at age 14 have erratic, uncertain, and vague aspirations and understanding of what this might mean for progression (see Davies and Biesta, 2006).

Uncertainty about Vocational Education

Thirty years of initiatives in the general vocational curriculum in the UK system have not clarified what vocational knowledge and skills really are. An emphasis on creating assessment methods to foster motivation, confidence, and personal development has led to growing uncertainty about what vocational means in the vocational education pathway. There is a strong view that assessment in vocational education should encompass relevant life skills and attributes associated with lifelong learning, personal development, basic and generic interpersonal and communication skills, and dispositions and attitudes for employability. Themes of relevance and real-life application are reinforced by concerns that assessment methods should engage and retain young people in formal education who are deemed to be demotivated and disengaged.

One effect of uncertainty about vocational knowledge and skills as opposed to generic ones, and particular images of types of young people and their attitudes to education and learning is a growing tendency to avoid burdening vocational students with too much written work or with methods that alienate them from formal education. A more recent phenomenon is to associate ideas that young people are disaffected or disengaged with images that they have fragile learning identities and low self-esteem (see Ecclestone and Hayes, 2008).

These images reflect and reinforce an enduring problem in the UK's education system, that vocational education and its assessment continue to be associated with practical activities and the need to motivate, rather than being a coherent curriculum in its own right. Assessment initiatives over the past 30 years have been a central factor in creating and maintaining these images (see also Hayward *et al.* 2005).

Finally, confusion is exacerbated by different constituencies and bodies being involved in deciding a vocational curriculum and assessment methods. In the UK, this is extraordinarily complicated with occupational

sector councils, employers' representatives, awarding bodies, the government's regulation agency, and educational providers all involved in processes to design vocational education qualifications. In contrast, countries such as Finland involve the key social democratic partners of unions, employers, and educationalists in a more stable and simple system.

Conclusions

General vocational education has become a crucial option for young people deemed to be unable or unwilling to undertake general academic education or who are not ready for workplace training. Assessment methods that are seen to motivate and engage young people, while also providing a credible basis for summative assessment that enables them to progress to further and higher education and to work, have evolved into a distinctive system. This system is criterion referenced and adapts methods from competence-based approaches developed for the workplace and approaches used in academic courses.

However, questions remain about the purposes of assessment in vocational education and the subject base and skills that are seen to comprise vocational'as opposed to practical or'relevant-to-life education. There are also questions about the status and identity of young people opting to follow a vocational education pathway and whether these reinforce particular attitudes to assessment and learning. Although these questions are particularly pertinent in the UK's system, readers need to relate them to the particular features of vocational education in other countries.

Assessing Group Work

M Galton, University of Cambridge, Cambridge, UK

The need to have pupils working in groups has become a universal panacea among policymakers for the problems of globalization in the workplace. In Singapore, despite its favorable positioning at the top of the league table of international studies, the Prime Minister's 2007 National Day speech urged schools to teach less so that children could learn more. In Hong Kong, since the millennium, the revised curriculum, learning to learn, has also stressed the need to move away from teacher-directed approaches toward greater pupil participation through the use of group work. The social constructivist viewpoint that talk drives learning has become an accepted part of current educational wisdom worldwide.

Yet, although studies in the West, where working in groups has a longer history, attest to the value of group working as an effective pedagogy, both in terms of improving pupil attainment and also attitudes, particularly racial ones, the fact remains that in many classrooms, group work is still a neglected art. While pupils often sit in groups, presumably for social reasons, they rarely work as a group. In the UK, research by Kutnick *et al.* (2007) has confirmed that teachers use groups relatively infrequently in subjects such as English, mathematics, and science. When group work was undertaken, it was often for practical reasons, as in the science laboratory where the determining factor was the availability of equipment. In other cases, the decision to move to group work was often arbitrary. For example, in one instance reported in Kutnick

et al. (2007) the rationale for changing from class to groups was "because children were becoming bored with the classwork and I thought they needed a change."

Assessment: One Possible Impediment to the Use of Group Work

When teachers were asked why they did not use group work more often, they presented a number of arguments. Pupils who were asked to work in groups usually wished to choose the composition. Since these choices tended to be based on friendship, groups were often unbalanced because their composition was strongly associated with the attainment level, gender, and ethnicity of the pupils. Teachers claimed that they were under too much pressure, because of the demands of the curriculum, to find the necessary time for setting up and carrying out group tasks (Kutnick *et al.*, 2007). Other practitioners had concerns about loss of control over the learning environment since it was difficult to be certain that the talk among pupils was productive, or even on-task. This contrasts sharply with the situation during whole-class discussion where pupils generally only speak when requested to do so by the teacher. Teachers also saw the use of mixed-ability groups as an additional source of difficulty, since it often meant placing a disruptive pupil among others who normally worked well together with likely consequences

of aggression or withdrawal. Many teachers said that they did not know what to do with the loners who withdrew from group activity completely (Kutnick *et al.*, 2007).

Another key reason for teachers' reluctance to use grouping to enhance academic performance concerns the requirement that to work effectively, pupils needed to be trained in communication skills (Mercer, 2000) and this took valuable time. A recent study of teachers' work-life balance in several countries has shown that workloads have increased, mainly because of the extra administrative burdens connected with the target-driven curriculum which requires that increased time be spent on assessment and therefore in marking (Galton and MacBeath, 2008). Many teachers thought that assessing the individual contributions to a group task was likely to be both problematic and time consuming (Kutnick *et al.*, 2007). For this reason alone, teachers were reluctant to promote group activity in their classrooms.

Johnson and Johnson (2004) argue that if teachers are to be persuaded to use group work more often for academic purposes, they need to be disabused of a number of misconceptions about the assessment process in general and its use for groups in particular. The first of these misconceptions, and perhaps the most powerful, is that an individual assessment always requires an individual performance since an assessment to be valid needs to measure unassisted learning. Hence, it follows that assessment data can only be collected once the pupil has completed the piece of work on which the marks are to be awarded. A further misconception is that it is only possible to have unbiased assessments if they are carried out by the teacher. From this viewpoint, therefore, asking pupils to assess each other, or assessing the contribution of individual pupils to a group product provides unreliable and invalid data. For teachers to accept that it is possible and feasible to assess group work, they need to be convinced that groups can have a powerful effect on the individual performance of its members. Thus group work can offer insights into the potential of some pupils that might not emerge when more conventional forms of testing are used.

What Aspects of Group Work Should Be Assessed?

There tends to be a division of opinion as to what aspects of group work should and should not be assessed. Most proponents of group work agree that it is important to distinguish between the assessment of group working skills and the assessment of what is learned during group work but not all agree with Dunne and Bennett (1994) that the pupils' cognitive achievements, both individual and joint constructions, should be included in any assessment. In designating what constitutes essential group work skills, Webb (1995)

puts the emphasis on interpersonal skills including the nature of the interactions with other group members (active listening, raising questions, making useful suggestions, explaining, etc.) and an individual's role in bringing about successful collaboration (acting as gatekeeper, as an organizer, as negotiator in attempts to arrive at a consensus view, etc.). Others emphasize various social processes such as degree of participation, the degree of empathy with other points of view, and sensitivity to the needs of others. Some writers argue that individual contributions should not be assessed as this weakens the extent to which certain pupils, particularly the more able ones, are willing to share their ideas, while others argue that if only the group's contribution as a whole is assessed, then social loafing will occur whereby some pupils will stand aside and let other group members do most of the work. For these reasons, a compromise position has been adopted by most advocates of group work whereby both the individual and the group contributions are assessed. Slavin (1995) reports that when both contributions are assessed, the improvement in pupils' performance produces medium-effect sizes of the order of 0.40 whereas when only one of the contributions is used, the effect sizes tend to be much smaller (typically 0.17).

Assessing Individual Contributions to Group Work

Perhaps the most straightforward method of assessing individual contributions to a group task involves various forms of team games tournament approaches as designed and used by Slavin (1995). The gist of the assessment procedure is that each individual takes a test before and after the group activity. The raw-score gains of each individual in the group are then added together to give a group score. Only by working together with the more-able pupil helping the slower learning ones can a group achieve a winning total. At the same time, the teacher can assess the improvements of individual team members by examining differences between pre- and posttest scores. Slavin argues that this method deals with the criticism that individual assessments tend to make more-able pupils less willing to share their knowledge with others. Slavin's approach has been modified by Race (2000) who suggests that the individual pupil's score should be weighted in some way by the group's score.

Race's recommendation is similar to that suggested by Johnson and Johnson (2004) who argue that an individual's grade should also reflect how well the group worked together. Johnson and Johnson suggest combining the individual score with the average group score or providing bonus points based on either the lowest individual score or the average improvement score. However, critics of the original Slavin approach, such as Jacobs *et al.*

2002 point to the fact that there is a need to distinguish between the products resulting from working in a group and the effectiveness of the group working skills which bring about these as a satisfactory joint outcome. These latter skills include understanding and implementing the task, making best use of available resources and the degree of appropriate help offered to others.

As a solution to this problem, Johnson and Johnson (2004) suggest the use of peer assessment whereby each group member rates the others on various group working skills such as listening carefully to other points of view, taking one's turn, offering reasons when making suggestions, and so forth. It is argued that this not only avoids potential teacher bias when basing their judgments on informal observations, but it can also be a learning process for the pupils since as the list of skills are added to over time, to include, for example, maintenance strategies, pupils gradually gain metacognitive understanding of what it is to be a good group member. A variation of this approach involves self-assessment with the pupil's own evaluation being compared with those of his or her peers. Other methods involve choosing a pupil to carry out assessments on the rest of the group using a simple category-observation system (Dunne and Bennett, 1994). These authors also offer a variety of alternative methods including post-task interviews, whole class debriefings, and video or audio recordings. Although the work involved can be considerable for teachers, Dunne and Bennett argue that it can provide them with important insights into pupil behavior. This, in turn, can have positive effects on their teaching and their expectations, since teachers may be surprised at the amount of work that some pupils can do unaided and the extent to which others turn out to be effective collaborators.

Assessing the Group's Contribution

When the group's contribution is to be assessed, a number of additional considerations need to be taken into account. In this connection, Webb (1995) points out that it is sometimes the case that the most often-cited reasons for using group work in the classroom do not match the choice of assessment method. This situation generally arises because only certain methods constitute a valid measure of a particular purpose of assessment, particularly when these purposes represent competing goals of learning from group work versus group productivity (Webb, 1995). It is therefore important in designing group assessments to appreciate that the manner in which groups are required to function will influence the outcomes of the assessment and these group processes need to be taken into consideration in the design of the assessment procedure.

Where the purpose of the assessment is to establish how much learning over and above the pupil's individual

competence has been constructed in collaboration with others, it is necessary to employ some pretest measure prior to the group activity. Webb (1995) cites an example in science, where pupils first had to list the various factors that influence yeast's activity in food. They then carried out an activity in groups which required them to design, carry out, interpret, and summarize the results of an experiment which investigated what happened when yeast was mixed with food. The summary was constructed by the group written up and then presented orally to the rest of the class. Then, in the third part of the exercise, pupils again worked individually to analyze and critique a summary written by another group. The difference in scores on the first task and the third task was then taken to represent the extent to which each pupil's learning was enhanced as the result of the group's collaborative activities. A group assessment can then be arrived at by adding the scores of individual members.

When, however, the purpose of the assessment is group productivity, then the effect on individual members is ignored and only the group outcome is considered. In this case, either the quantity or the quality of the product or a combination of both measures can be used in the assessment. However, it is important from the start that pupils understand the criteria that are being employed since an assessment based on the amount of the product (the number of ideas generated by the group) may result in different kinds of collaborative behavior than when the quality of these ideas is the main criterion. In the former case, where the quantity of the ideas matter, success does not depend on every group member understanding what is being proposed. Thus there may be fewer attempts by group members to justify their ideas or to give and receive elaborated explanation as an aid to understanding, whereas when quality is the criterion, then these kinds of interactions are an important part of the group process when attempting to arrive at a consensus about the most appropriate idea or the best solution to a problem.

A different kind of purpose of assessment concerns itself with the functioning of the group itself. Here social constructivist theories allied to that of Piaget's emphasis on promoting cognitive dissonance, as a way of enabling individuals to construct new schema and to reconstruct existing ones, provide a theoretical framework for the kinds of interactions that need to take place within the group if learning is to take place. These include higher-level cognitive behaviors such as making alternative suggestions, raising questions, offering explanations, and the social skills of being able to participate in the cut and thrust of debate by agreeing and disagreeing without provoking animosity on the part of other group members.

In all these different interpretations of what it means to undertake a group assessment, there is a need to ensure that the composition of the groups is such that, as far as it is feasible, no one group enjoys an advantage over another.

Johnson and Johnson (2004) summarize the research which shows that the ability, gender, ethnicity, and status of individual members influences the way in which the group performs. Lower-achieving pupils have been found to make greater progress when in heterogeneous groups, provided the more-able pupils have been trained to offer appropriate help, particularly in the matter of offering relevant explanations. The evidence concerning high achievers is less clear. Some studies show that it matters little whether the groups are homogeneous or heterogeneous, while others show that in the latter type of group, the more-able pupils tended to assume the role of the teacher and clarify their own ideas by having to explain them to others.

There is considerable evidence that boys tend to dominate the group conversations whether in a majority or a minority, although in the United States, this phenomenon is not so prevalent among African-American pupils. Social status is often associated with ethnicity in Western societies, where most of the research has been undertaken. Status can also be relative (Cohen, 1994) so that a pupil might participate actively in one group but not in another. It is generally recommended that teachers try to ensure, as far as possible, that the membership of the group is representative of the individual social and personal characteristics which define status in that particular classroom. In particular, there is a need to avoid placing single individuals of a particular status within a group such as a white male among a group of Afro-Caribbean pupils or of varying more than one status characteristic such as having a mix of ethnicity and gender. Thus, it is preferable to have two white males and two Afro-American females or vice versa rather than have one white and one Afro-American male (Miller and Harrington, 1993).

Procedures for Assessing Group Productivity

Race (2000) argues that assessing group tasks is one of the most difficult things to do well. He suggests that there is no ideal way to carry out this process. The main problem is that allocating a single group score can be perceived as unfair by those who do most of the work. For this reason, he suggests that all assessments should carry with it some form of additional differential. If, for example, a teacher gives a group of four pupils, a mark of 60%, then the group can be asked to partition this mark according to their estimate of individual contributions. These contributions can stand and be recorded separately or carry an added mark for particular contributions. While this approach may be perceived to be fairer, it requires a certain maturity on the part of the participants to obtain a consensus about who should get most marks. If there is some borderline level, such as an award of a credit for a mark above a specific score, then groups may distribute

the marks accordingly to gain the maximum advantage for its members. To avoid this possibility, Race (2000) recommends that the individual contributions should also be assessed by means of a short oral viva. Even here, there are problems since some pupils do not perform well under this form of assessment, either due to shyness or modesty, and there may be some advantage from being interviewed last since the questions asked become common knowledge and allow later participants to prepare for the interview. Moreover, in a class of 30 pupils, conducting the assessment adds enormously to the teacher's workload.

All commentators agreed, however, that pupils need to be informed, prior to the assessment, not only about what is to be assessed, but also the means by which the assessment is to be carried out. Where group processes are to be included, then the choice usually lies between the use of some simple observation checklist where the teacher follows different pupils from each group in a predetermined order or a self-evaluation sheet which pupils complete at the conclusion of the group activity. A refinement of this approach is to ask pupils to complete some form of learning diary or narrative log of group work which charts progress over time or to fill in trigger sheets at selected time intervals during the group activity. Most of the suggested observation schedules are watered-down versions of research instruments. They include categories such as whether the pupil was on task, whether he or she initiated or responded in a conversation with other group members, and whether the conversation was sustained. More detailed systems will also attempt to record the nature of the conversation; whether it involved making a suggestion, raising a question, offering an explanation, or expressing disagreement, etc. Other versions of this approach use videotape or audiotape to capture these pupil-pupil exchanges and then award a summative rating for each group on the various categories. As this form of assessment can be time consuming, it has been suggested that it is carried out by means of a one-off specially chosen assignment and that as far as possible, the task chosen as part of the group activity should be an authentic one which is designed to measure pupils' performance in real-life contexts (Crotty, 1994).

In creating criteria which allow pupils to evaluate their group's performance, it is necessary to cater for different levels of complexity which match the expected capabilities of the group. At elementary level, pupils might be required to report on whether members of the group took turns in talking and listening, helped other members to express their ideas, stayed on task, and so forth. In the middle and high school, the questions would more likely also to concern the planning process (whether deadlines were met), execution (the division of labor), degree of cooperation (all members contributed to decision making), participation (all took an equal part), and how the group responded to feedback from other groups and the teacher. Whatever the sophistication of the evaluation sheets,

however, it is essential that training in carrying out these assessments is provided in the provision of guidelines and exemplars. Not only does this ensure improved reliability, but it also conveys to the pupils what is required of them when working in groups. Through this self-evaluation process, pupils therefore gradually also gain a metacognitive understanding of what it is to be a good group person and this is likely to enhance future performance. Johnson and Johnson (2004) suggest that the assessment procedures work best when it includes both group products and processes. Furthermore, they report that when teacher and pupils share responsibility for the assessment, the improvement in performance was greater than when the processing was the sole responsibility of either the teacher or the pupils.

The growth in the use of information and communication technology in most schools has led to increased interest in the use of portfolio assessment described by Johnson and Johnson (2004) as an organized collection of group work samples accumulated over time, including individual work samples from each member, together with accounts of presentations and the subsequent critiques of teachers and peers. Electronic portfolios allow pupils to display evidence of both academic and social growth over time and when these are made publicly available, they can become a powerful tool for sharing learning with teachers and peers. To be effective, however, teachers need to instruct pupils in the best ways of planning and implementing their portfolios so that the criteria for good work are recognized and examples which articulate these qualities are selected. Johnson and Johnson (2004) also suggest that group assessment can be carried out through a series of conferences. At the first of these, the goal-setting conference, groups or the whole class set targets. At the second progress-assessment conference, groups assess the extent to which these targets are being met while at the final postevaluation conference, the groups discuss and decide their level of achievement. This, in turn, leads to the next goal-setting conference.

A Final Comment

The above review suggests that there are a number of principles which should guide the teacher or researcher when seeking to assess group work. First, a fair system should be used that rewards both individual effort and group collaboration. Second, the assessment of group productivity should involve both teachers and pupils in the undertaking. Third, in designing an assessment of group productivity, a distinction should be made between quantity and quality because this may well change the way in which group members approach the task. Fourth, a judgment also needs to be made between the purposes of the group work, whether the emphasis is to be on learning outcomes or on the group processes such as the kind's interactions that

theories and empirical evidence suggests enhance learning through cooperation. Fifth, the criteria to be used in the assessment must be made explicit to pupils beforehand, and training opportunities for practice and for review should be provided. Sixth, if the assessment is to be a one-off measure, akin to a summative test, it is better to design an activity which is as authentic as possible.

This is a formidable list of requirements so it is not surprising that much of the evidence which underpins these principles has been collected through compact, carefully designed research studies, including some that took place in the laboratory rather than in a classroom. So far, there are few attempts to collect evidence of the consequences of putting these principles into practice in naturalistic classroom settings, where teachers and pupils go about their business within the usual constraints which govern teaching and learning in a typical school.

It is partly because the task of assessing group work appears so complicated that teachers have, in the past, fought shy of using this teaching strategy, particularly in an era of targets and high-stakes testing where numbers are everything. It is for this reason that teachers who do favor the use of groups tend either to assess individual performance by written tests, or base their judgments on informal observations using a simple form of checklist, supplemented by a PowerPoint display to provide a summative evaluation of the group's productivity (Gillies, 2007). If the measures used to assess group work in naturalistic classroom situations are to become more reliable and result in increased validity, two things need to happen. First, teachers need to gain a better understanding of the impact of certain types of assessment on the kinds of behavior which pupils will exhibit when placed in groups. Second, researchers need to spend more time in classrooms working alongside teachers to make use of these various assessment procedures more suited to the ups and downs of a typical school day.

Assessment and the Regulation of Learning

L Allal, University of Geneva, Geneva, Switzerland

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Affordances – Resources and constraints that are provided by the design of an instructional setting and can be incorporated into the learner's activities.

Formative assessment – Assessment that allows adaptation of teaching and learning activities in order to take into account students' knowledge, strategies, goals, needs, and interests.

Summative assessment – Assessment that sums up information in order to certify students' attainments at the end of a segment of an educational program.

Predictive assessment – Assessment that provides information for decisions about admission to an educational program or about placement in one of the sectors or tracks of a program.

Regulation of learning – Entails the processes of goal setting, monitoring progress towards the goal, interpretation of feedback from monitoring, adjustment of goal-directed actions and/or of the definition of the goal.

- Self-regulation: The processes of regulation are carried out by the learner
- Other-regulation: Another person (teacher, mentor, peer) intervenes in the processes of regulation

The assessment of student learning provides information that is analyzed, interpreted, and used for the regulation of educational activities. Two directions of regulation can be distinguished in association with the functions of student assessment defined in the well-known handbook edited by Bloom *et al.* (1971). The first direction concerns regulation of students' progression through the entrance, transition, and exit points of the educational system. It includes predictive or diagnostic assessments used for decisions about admission to an educational program or about placement in one of the sectors or tracks of a program. It also includes summative assessments that certify the quality of student achievement at the end of the segments of a program. These assessments, which determine students' access to educational resources and assure public recognition of their accomplishments, are based on the degree to which students' knowledge, competencies, or other attainments meet the standards fixed by the educational system. The second direction of regulation concerns the

adaptation of teaching and learning activities in order to take into account students' knowledge, strategies, goals, needs, and interests. This direction of regulation is closely linked to the formative function of assessment. In the initial conception of Bloom and co-workers, formative assessment intervenes in each unit of instruction and provides feedback that guides the choice of corrective measures aimed at the remediation of learning difficulties.

The concept of regulation has introduced, particularly in the French-language literature, a broader approach to formative assessment (Allal and Mottier Lopez, 2005). It includes remediation, which is a form of retroactive regulation that intervenes when students return to a task they have failed to master and, through the use of corrective materials or other forms of assistance, devote additional time and effort to attain the instructional objectives. Regulation of learning can, however, take on two other forms. Interactive regulation occurs when formative assessment is integrated into ongoing instructional activity; it results from the student's interaction with the components of the activity – that is, with the teacher, other students, and/or with material designed to encourage active reflection and self-assessment. Proactive regulation occurs when several sources of assessment information allow the preparation of new educational activities designed to take into account differences among students. It entails differentiation of instruction to ensure enrichment and consolidation of learning, according to the needs and interests of all students, rather than focusing on remediation of learning difficulties.

The remainder of this article examines two topics: first, the models of regulation that have been developed in research on learning and their implications for the design of assessment and, second, the contributions from research on assessment aimed at promoting student learning. The conclusion looks at how the continuity between formative and summative assessment can support the regulation of learning.

Models of Regulation of Learning

All theories of learning propose a mechanism of regulation that ensures adaptation of the learner's behavior and thought processes. Well-known mechanisms include reinforcement in behaviorist theory, equilibration in Piaget's constructivism, feedback devices in cognitive models, and social mediation in sociocultural and social constructivist approaches. Although there are important differences

among these theories, they all consider the processes of regulation to be a central feature of learning.

Regulation involves four main processes: goal setting, monitoring progress toward the goal, interpretation of feedback derived from monitoring, and adjustment of goal-directed actions and/or of the definition of the goal itself. A large number of empirical studies of these processes have been carried out in research on self-regulated learning, often abbreviated as SRL (Zimmerman and Schunk, 2001). This research aims at determining the ways students regulate their learning activity, the instructional, social, and contextual factors that influence self-regulation, and the effects on student achievement and well-being. Several models have been developed to describe self-regulation as an individual psychological process. One of the most comprehensive models is the three-layer model proposed by Boekaerts (1999). The inner core of the model consists in the regulation of cognitive processing, and particularly the choice of cognitive strategies. The next layer entails the regulation of learning and the use of metacognitive knowledge and skills to direct one's learning. The outermost layer corresponds to the regulation of the self and is linked to the formulation of goals and the allocation of resources (time, effort, etc.) to their attainment. Complex linkages among the layers allow self-regulated guidance of the individual's activities.

Self-regulation is often contrasted with external regulation or other-regulation. External regulation is associated with the structural features of the learning environment that stimulate and support learning, such as the types of tasks proposed and the sequencing of tasks, the tools and other available resources, the organization of time and space in the instructional setting, and the mechanisms of feedback and reinforcement that are present. Other-regulation refers to the interventions of other persons (e.g., teachers, mentors, and peers) who provide scaffolding and interactive guidance for learning. It has been observed that, in the classroom context, there is often a complex interplay between student regulation and teacher regulation of learning (Vermunt and Verloop, 1999). Perspectives derived from social constructivism, from sociocultural theory and from work on situated cognition treat learning and teaching as interdependent dimensions of educational activity. This has led to recognition of the reciprocal, or even dialectical, relations between student self-regulation and the sources of regulation situated in the learning environment (structure of the tasks, teacher interventions, peer interactions, and assessment tools). The regulation of learning in educational settings can thus be considered fundamentally as a process of co-regulation or of shared regulation (Hadwin and Oshige, 2007). This means that student self-regulation develops in interaction with multiple sources of regulation in the learning environment and, at the same time, contributes to the deployment and exploitation of these sources in the learning activities undertaken in class.

To take an example from ordinary classroom practice: the teacher's way of formulating questions provides a framework for students to learn to ask themselves questions; the questions they ask themselves frame, in turn, how they respond to the teacher and, more importantly, how they contribute to the evolving dialog.

The transition from models of individual self-regulation to models emphasizing the interplay between individual and social or contextual aspects of regulation has several implications for the design of assessment. First, it means that assessment is embodied as much in the social interactions taking place in the classroom as in the formal assessment tools and procedures that are used. Ways of structuring these interactions are therefore part of the design of assessment. A second implication is that the effects of assessment tools on learning can be amplified by their integration in social interactions. In order for an assessment tool, proposed in curriculum material or devised by the teacher, to have positive effects on student learning, it needs to become an object that students are able to appropriate. This means designing activities that allow students to discover the aims and properties of assessment tools and that encourage them to enter into discussions about the uses of assessment.

Contributions of Assessment to the Regulation of Learning

A review of the research by Black and Wiliam (1998) showing how assessment affects student learning, both positively and negatively, was the starting point for the development of the concept of assessment for learning, formulated by the Assessment Reform Group (1999). This concept includes several guiding principles for the conceptualization of assessment designed to promote learning. Assessment for learning is primarily concerned with the formative function of assessment, with how assessment is embedded in teaching and learning activities, with the quality of feedback provided by assessment, and with student involvement in assessment. Assessment for learning can, however, encompass forms of summative assessments that are devised to exert a positive influence on the way students approach learning. Shepard (2000) has described the transformations of the curriculum and the movement toward social constructivist learning theories that provide the foundations for a new vision of classroom assessment.

Integrating Assessment in Teaching and Learning

The initial conception of formative assessment, as described by Bloom and co-workers, divided instruction

into successive phases: teaching (or another form of delivery of instruction), formative testing, and remediation based on corrective material. Formative assessment can play a more pervasive role in the regulation of learning when it is integrated from the beginning in each teaching and learning activity. This implies looking for ways of embedding formative assessment in curricular materials, in teachers' ways of interacting with their classes, in the collaborative activities that students undertake in small groups, and in the individual tasks that students perform inside and outside of the classroom. Learning environments need to be designed so that they include resources and constraints (referred to as affordances in the literature on instructional design) that enhance the regulation of learning. This means the introduction of feedback at each stage of a learning activity, the use of questioning techniques that stimulate student reflection about alternative ways of carrying out a task, and the provisions of some degree of task differentiation to take into account learner interests and choices. The interactions that take place in class, between teacher and students, and among students, are the principal occasions for ongoing formative assessment.

The in-depth study carried out by Torrance and Pryor (1998) in English primary schools is an outstanding example of research on the formative assessment components present in teacher–student interactions. This study combines a social constructivist perspective on learning with an interest in the micro-sociology of classroom interaction. Although it does not frame its analyses and interpretations in terms of the concept of regulation, it provides a multitude of insights into the processes of regulation identified in the first section of this article. Torrance and Pryor's research is based on extensive audio and video recordings as well as on interviews with teachers and students. Through the presentation and interpretation of a large number of transcripts of assessment incidents, the authors reveal the patterns of interaction that embody formative assessment. They also describe the ways in which the meaning of assessment is negotiated in teacher–student dialogs and the influence exerted both on students' learning and on teachers' conception of their role. Their research is particularly important because it shows that teacher interventions in group settings can make a positive contribution to the regulation of learning for some children but not for others. It raises, in this respect, questions about the equity of interactive formative assessment. Several transcripts demonstrate, nevertheless, the power of this form of assessment when the teacher is able to appropriate individual children's words and actions and integrate them into a collective strategy for scaffolding and regulating learning. In a social constructivist interpretation, teacher–student interactions, and the processes of co-regulation they assure, are the contexts in which students construct and consolidate their individual strategies of self-regulation.

Providing Effective Feedback

In the literature on regulation of learning, feedback is information derived from monitoring the learner's progression toward a goal. It indicates how close the learner is to reaching the goal and may also provide indications on the types of obstacles to be overcome. It is the learner's or the teacher's interpretation of feedback that allows it to be used for the adjustment of goal-directed actions and/or of goal definitions. In this perspective, feedback is merely one aspect of regulation, albeit an essential one. In much of the literature on assessment, however, feedback is considered to be a system that includes several components: information about the student's present level of learning, a mechanism for comparing this level to a reference level (goal, objective, and standard to be attained), and a means for closing the gap between the two levels (Black and Wiliam, 1998). This broad conception of feedback encompasses the mechanisms of regulation that allow the student to progress.

In discussions of feedback, closing the gap generally means enabling students to adjust their behavior and understanding so as to reach the reference level of attainment defined by the educational system. There are circumstances, however, in which differentiation of the reference level may be needed in order to better take into account differences in students' needs and interests. A partial differentiation of goals, and not only of means for attaining them, does not mean a reduction of educational expectations for some categories of students but rather a more fine-tuned adaptation of goals so as to allow all children to acquire essential competencies while being able to express their individuality and cultural heritage. When feedback is integrated within a larger framework of co-regulation of learning, teachers and students discuss the goals to be attained, the criteria and standards of reference, and look for ways of personalizing goals, of making them meaningful in the learning trajectory of each individual.

A synthesis of meta-analyses on the effects of feedback has shown that it is one of the most powerful mediators available for fostering student learning (Hattie and Temperley, 2007). The average effect size of feedback is nearly 0.80, which is considerably higher than the effects of most other instructional factors. This synthesis also reveals that feedback can have powerful negative as well as positive effects on the regulation of learning. Learned helplessness and the fear of failure are as much the result of feedback as improved cognitive processing and feelings of self-efficacy. For a better understanding of the effects of feedback, Hattie and Temperley propose a model that distinguishes four types of feedback:

1. feedback about the student's level of performance or degree of understanding of a task,
2. feedback about processes (procedures, strategies, etc.) needed to understand and perform the task,

3. feedback that concerns the student's self-regulation (goal-setting, monitoring, and adaptation) with respect to the task, and
4. feedback about the self concerning the student's qualities as a learner.

Their review of the research evidence indicates that feedback about the processes involved in the task and about the student's self-regulation are more effective in promoting learning than feedback focused on task performance or on the learner as a person.

Since feedback about the learner as a person can have negative consequences, precautions need to be taken in the way information from assessment is communicated to students. Feedback that is useful for self-regulation of learning cannot, however, be entirely disconnected from feedback about the self. Learning involves the construction of one's identity, in addition to the acquisition of knowledge and skills. Moreover, all students, whatever their strengths and weaknesses, need to have the conviction that they are valued members of a learning community. This means that assessment procedures need to engage students in active reflection about what it means to be a learner and in participation with others in the construction of shared knowledge.

Involving Students in Assessment

Even in standard assessment situations based on teacher-made tests or external examinations, students not only demonstrate what they have learned but also learn new things about themselves. In this sense, self-assessment is ubiquitous; it intervenes implicitly in all assessments and continually affects students' learning and identity formation. It is possible, however, to introduce ways of conducting assessments that encourage active student involvement as well as a certain degree of student empowerment. Self-assessment tools can be embedded in curriculum materials or devised by the teacher. The impact of these tools on student self-regulation is likely to be enhanced when teachers conduct discussions that allow students to analyze the tools (their aims, their uses, and their possible misuses) and to confront the results of their ways of using them. Teachers can also go a step further and assist students in the construction of self-assessment instruments, such as a personal checklist of problems to look out for when writing texts, or a list of three questions to ask one's self when solving word problems.

Student involvement in assessment also includes various forms of peer assessment or of peer participation in the formative assessments conducted by teachers. Reciprocal peer assessment occurs when students assess the work produced by other students and then communicate their observations and suggestions for improvement. Joint peer assessment occurs when students examine a piece of

work together and share their ideas on how to improve it. Peer assessment can also be integrated in whole-class discussions orchestrated by the teacher in which criteria for an activity are constructed collectively and applied to various student productions.

In addition to the use of self-assessment and peer assessment tools, student involvement can go further in regulating learning when students actively participate in reflection about learning goals and about the meaning of different learning activities. This implies looking for ways in which at least some of the standard goals of education can be adapted or personalized so as to foster their appropriation by all students, given their learning histories and cultural backgrounds.

Research, demonstrating the effects of self-assessment and peer assessment on achievement, has been conducted primarily in the context of higher education (Boud, 1995). There are, however, research findings that offer support for the implementation of student-involved assessment during the entire course of schooling, and a wide variety of procedures, practices, and tools have been developed in this direction (see Stiggins *et al.*, 2004).

Continuity between Formative and Summative Assessment

Although formative and summative assessments have clearly different goals, the question can be raised as to their possible synergy in promoting learning (Harlen, 2005). The pressure of summative assessment, particularly when it is linked to frequent standardized testing, often leaves little space for the practice of formative assessment to develop. The consequences for the regulation of learning can be highly detrimental, especially for students who encounter failure repeatedly and cease trying to exert any control over their own learning. At the same time, summative assessment is necessary as a means of assuring social recognition of students' accomplishments both in school and outside. Students themselves inevitably ask: What knowledge and skills have I in fact acquired? Also, how do they measure up to expectations in society at large?

Continuity between formative and summative assessment can be developed in several ways. The first is through the alignment of both types of assessment with the curriculum goals underlying teaching and learning in the classroom. If this alignment is clearly perceived by students, the impact on their own goal setting can be very strong. A second point of continuity concerns the development of means of reporting the results of summative assessment so as to provide students with high-quality feedback about learning outcomes. When students receive a profile of test results, a graph comparing outcomes on different parts of a test, a set of rubrics describing the

qualities of a text, or teacher comments that accompany a grade, they can use this information to regulate their subsequent investment in learning. A third point of continuity has to do with student involvement in summative assessment. This form of assessment inevitably entails a judgment formulated by a professional (teacher, examiner, or other expert) about the quality of student learning. It is possible, nevertheless, to develop some degree of active student engagement in the way summative assessment is conducted. For example, in portfolio assessment used for summative purposes (grading and certification), students can participate in the selection of the work samples to include in the portfolio and be asked to write self-reflective commentaries that accompany and put into perspective their work. In professional education, summative assessment often takes place in conferences where the self-assessment expressed by the student is confronted with the assessment formulated by the teacher or supervisor. Students' knowledge of the conditions in which summative assessment will take place can have an important influence on the regulation of their investment in learning prior to being assessed. Teachers' knowledge of these conditions can have an equally important influence on how they organize learning activities and interact with students. To conclude: both formative and summative assessments provide explicit frames of references that guide the processes of co-regulation of student learning.

Challenges of Developing and Implementing Formative Assessment Practices in Schools

R Sutton, Education Consultant, Cumbria, UK

Case-Study Approach

Elsewhere in this encyclopedia, various authors have drawn our attention to the principles and purposes of assessment. The key purpose of this contribution is to explain and illustrate some of the practical implications and outcomes of implementing current assessment ideas in real schools and classrooms. For this purpose, two case studies are presented here. Ourtown Elementary School and Neartown High School do not exist: they represent a wide range of the issues surrounding the development and implementation of formative assessment in two stages of schooling. The content of these two case studies is supported by research but not entirely drawn from others' work. The author's own work over the past 20 years has been with schools and teachers, mainly in the UK, New Zealand, and Canada, supporting the introduction of assessment strategies that support learners and learning. Some, but not all, of this work has been published elsewhere.

The choice of a case-study approach is deliberate, to highlight the complex reality of every school, riddled with contextual variables that crucially influence the change process. Technical understanding of formative assessment is of little use without respect for the historical, logistical, and emotional context of the institution.

From Principles to Practice

In their synthesis of the international research on classroom and school-based assessment in 1998, Paul Black and Dylan William reported that researchers are often puzzled by the gap that repeatedly emerges between teachers' apparent understanding of the principle of assessment and their classroom practice. What follows is an attempt to focus on what schools do, not what they know, and to explain why this gap may exist and what could be done to close it. There is much to gain: formative assessment can have a marked positive impact on both the short-term achievement of students and their longer term success as learners. It can also affect positively the motivation and engagement of students, which will make the teacher's day easier.

Case Study 1: Ourtown Elementary School

Ourtown Elementary School could be anywhere. Typically, it would have one or two classes for each year or

grade level. The teachers will have been well-trained, but – at least until quite recently – many of them will not have been made deeply aware of the principles of formative assessment and how to apply them in their teaching. Over the past decade or so, the teachers and the school's leadership will have been challenged by the introduction of new, comprehensive, and specific curricula emanating from outside – the state, or the province. These new requirements come with a strong sense of accountability and pervasive systems of monitoring.

Summative assessments are undertaken to ascertain the measured success of learners relative to these mandated expectations. The results of these assessments will be reported to the parents. At Ourtown Elementary external tests are required, which have had the effect of making teachers anxious and prone to overprepare their pupils. Some of the teachers believe that external tests make the results more reliable, but others insist that there would be a more positive impact on teachers' professional practice if moderated teachers' judgments were used instead of a test result. In any case, they have no choice, and the school principal has had to steer a delicate path between discussion about the purpose and impact of the tests and the recognition that they are mandatory. Damage limitation has been her private motto since the testing regime started several years before, and in public she speaks regularly about the school's overriding interest in learning, motivation, and meta-cognition, all of which will deliver better test results and, more importantly, make children better prepared for their learning lives. The principal and the teachers have also found useful ways of using the school's test results formatively.

Making Formative Use of Summative Results

The tests used at Ourtown Elementary are developed externally and sent away to be marked. The results are sent back to the school several weeks later, too late to be useful for that group of children, but useful as a means of raising questions about the teachers' future practice. Encouraged by the leadership team, when the test results arrive, the teachers and the leadership take a really detailed look at them. The overall average is of no formative interest to them: they want to know which aspects of the tests children did well on, and which not. They need to analyze which groups of children did well, and less well.

They look for patterns and trends that indicate where possible improvements in teaching and learning can be made. These next steps are then built into the teachers' plans and classroom practice, and into the overall improvement plan for the school.

In the first year or two of these test results being available, the school was not sure how best to respond. Some teachers were inclined to be defensive, wanting to blame the circumstances of the school, and even the children or their parents, if the results were not as good as they had hoped for. Gradually, however, they have become less defensive, more curious and more willing to examine the evidence, looking for questions rather than answers.

Assessment Data and School Self-Review

Last year, it was clear that the pattern of boys achieving less well in writing in the later years of the school (ages 8–11) was more than a temporary blip and was becoming a worrying trend, worsening over time. The teachers needed to find out more about what was really going on, and how they might tackle it. Accordingly, they re-examined how they were teaching writing, spoke to a sample of boys about their approach and their response to writing, and what the school might do to make it better. Individual teachers were dispatched to other schools, and to various courses, to bring back ideas for improvement. They shared what they had learned and incorporated the most promising strategies into their future programs. The improvement in boys' writing began to show almost immediately: now the teachers will look forward to the test results as part of the evidence and they will investigate to check for the desired improvement. They will also look for evidence in the children's classroom work, and their responses to more interview questions. The school also decided to canvass parents on the issue, to discover the types of support available at home, and to find ideas to share about parents' contributions to their children's progress in writing.

Using Triangulated Evidence

Triangulating the evidence in this way, looking at three sources rather than just one, provides the school with a far richer picture of the issue and its remediation than they could have gleaned from the test results alone. The test results piqued their professional curiosity: the rest of the improvement strategy was led and fostered by the school's leadership team through building a climate of enquiry, distributing the responsibility for research, and involving all the people whose efforts could lead to improvement – the teachers, the children, and their parents. Summative assessment at Ourtown Elementary is used for evaluative purposes, intelligently, professionally, and effectively.

Developing Formative Assessment

The province and the school district have both been influenced by the wealth and depth of research evidence about the potential of assessment for learning to enhance children's learning. The teachers attended the training provided, but some felt that they were just being asked to do things they already did. "We know all this," some of them said, "So what are we expected now to do differently?" Other teachers understood and accepted the strategies being presented to them but felt that they simply would not have the time to make them work, or that their classes were too large. One or two argued that children in their early years of schooling are not yet ready to manage any responsibility for self-critique and self-correction.

Gradually, again with patient and continual encouragement from the school leaders, the teachers reflected more deeply about the implications of the principles of assessment for learning (as formative assessment was now relabeled) and their implications for the fundamentals of teaching. Here are some the insights they gained, through their reading and discussion, and – just as importantly – through experimentation in their classrooms:

- Children can successfully critique and correct their own and each others' work if they are clear about the criteria to be applied.
- This understanding of criteria can be found in very young children: in the nursery, for example, the teacher talked to her children about lining up. She and her children discussed this basic classroom routine, its purpose, and the criteria for success. Then through questions and specific feedback the teacher routinely involved the children in self and peer critique and correction. As the children absorbed responsibility for their actions, their lining up improved, and the teacher needed to remind them less frequently. Investing in self and peer critique saved the teacher both time and patience.
- Clear criteria will help, but the children still need to feel safe and able to examine their work critically, recognizing the difference between feedback and friendship.
- Teachers will need to understand the criteria for quality themselves, and to find ways of sharing these with the children.
- In order to achieve this, teachers will first need to be clear about what the children are going to learn, not just what they are going to do.
- Once the criteria are clear and shared, and the children have a safe climate to examine their work and provide effective feedback for each other, the teachers need to plan opportunities for the children's assessment skills to be developed and practiced, so that they can receive high-quality feedback – so necessary for improved learning – from each other as well as from the teacher.

- Parents will need to understand that involving the children in the assessment process is not an abdication of the teachers' responsibility but an intentional step toward both improved learning and also meta-cognitive development.

In response to these insights, the school took the following action:

1. *Planning.* They reiterated that the purpose of teachers' planning was learning, not coverage.
 - They looked at the level and type of involvement of children that they would expect to see year/grade level by level, so that everyone would be clear about this vertical articulation and the contribution being made by each year/grade level toward the overall meta-cognitive development of the children.
 - Each teacher plans time to involve children in the coconstruction of success criteria. This will focus on the learning to be achieved, not just the activities to be completed. Time is also included in their plans for regular brief reviews of progress relative to these criteria, as a whole class, a small group, a pair, or by individual children. These reflections are planned into the work as it progresses, so that children are encouraged to improve their work, rather than wait until it is done, when they might be less inclined to go back and fix it.
2. *Questioning.* Realizing that one of the purposes of assessment for learning is to encourage children to think, the teachers at Ourtown Elementary next looked at the way they pose questions to children. They realized the importance of the wording of questions, shared those that seemed to generate the most thoughtful responses, and wrote them into their plans. They practiced waiting longer in class to allow children time to think and possibly discuss their responses. They changed the hands-up rule in class so that children no longer raised their hands to answer a question and the teacher was then able to include more children in building effective answers, rather than looking for the right answer straight away and picking different children until she found it.
3. *Marking and feedback.*
 - The teachers agreed that feedback makes most sense if it connects with clear criteria understood by the learner. They investigated ways of co-constructing criteria with rather than for their students, tried out various methods and invited other teachers into their rooms to see how they did it. The principal helped by providing class cover for these short visits to take place, or by taking the opportunity to spend time in the classroom herself while the teacher was visiting another room.
 - They realized that parents expected some marks on the reports, especially in the later years of schooling,

and that they should look again at their reports to see how they could manage this need for marks without adversely affecting the self-efficacy of the children. The principal took responsibility for sharing with parents, in writing and through a meeting, the reasons why the school is interested in formative assessment and what changes parents might expect to see.

- It was not difficult for teachers to agree on what constituted effective feedback. One of the teachers shared what she had learned from her assigned task of checking the research in greater detail on this point. She convinced her colleagues that their praise must focus not on who the child is ("You are so smart"), but rather on what the child has done, "I really like the way you used colourful adjectives/describing words here." The feedback also needs to be descriptive rather than evaluative, and to help the child to understand the process by which they he/she achieved success, rather than just the outcomes he/she have achieved. Sharing these ideas, and ways in which they translated into daily teacher practice, helped to improve the overall quality of feedback right across the school.

Changing Teachers' Habits

Changing these basic classroom routines was much harder than the teachers had expected. For a while, they wondered if they could ever make it work. From their own previous experience of change, and from the experiences of other schools, the school's leadership understood that this is a long game, requiring clear goals, small steps, continuing feedback, practice, and perseverance. The principal herself undertook to articulate the principles that they were striving for, and to keep these regularly at the front of people's minds. She and her colleagues were determined to model these principles in action, both in their own teaching, and in their approach to the teachers as adult learners, providing for them the clear purpose, expectations, criteria, feedback, and opportunities for improvement that they wanted to see teachers offering to their pupils. Gradually, through teachers' trying out and sharing their formative-assessment strategies, the norms of teaching changed and formative assessment became embedded in the classrooms of Ourtown Elementary.

Case Study Two: Managing Assessment at Neartown High School

In the high school, summative assessment has been part of schooling for many generations. Teachers are so accustomed to the requirement to cover the given program and prepare students for regular testing that some of them find

it difficult to consider assessment in any other way. Marks, scores, and grades are what they, their students and their parents take for granted as the way the classroom does business. Some subjects were less likely to organize assessment in this way: the physical education (PE) department, for example, had always used feedback in terms of specific words and advice – as good coaching always does – and did not mark students' work in the same way as others. The art teachers too used group critique as a routine part of assessment for improvement in their rooms. The more academic subject teams might not know what happened in subject areas other than their own, and in any case would not regard these practices as necessarily relevant to them. Different subject areas have often been organized in quite different ways within the same school. In this environment, the challenge was to find some degree of consistency across the school, while still respecting the rich variety of experiences, ideas, and skills that form the beauty of secondary education.

There were technical questions also about the school's assessment habits. Prompted by presentations at conferences, and by their own reading, some teachers began to question how they handled late assignments, for example, or gave students zero under some circumstances. The calculation of final grades and the allocation of merit awards were critically examined for the first time in quite a while, and some existing practices were hard to explain or defend. The school began to divide on these issues, and the leadership worried about allowing this fragmentation to continue. The assessment habits of this school, like many others, were very hard-wired indeed: questioning them caused many teachers disquiet, and this rethinking had to be led rather than merely managed. As in the elementary school, teachers looked to the school's leaders rather than to outside experts for a clear sense of purpose and direction. The first essential, therefore, was for the leadership team to do their homework, find out what the technical issues were, and then decide how best to motivate the diverse range of adult learners among the teaching staff. They could, and were prepared to, impose a certain amount of change from the top, but they knew that real change in classroom practice and attitudes toward assessment practice would only truly happen by encouraging a gradual change in teachers' daily practice. Appealing to teachers' enlightened self-interest would also be an important part of the change strategy at the high school.

Introduction to the Principles of Assessment for Learning

Like their colleagues at the local elementary school, the secondary teachers were first introduced to the ideas of assessment for learning through a professional development event offered by the school district. It was clear that these ideas had been developed from extensive research,

but this was not sufficient for the teachers to truly grasp their implications. As the implications of these principles gradually became clearer, how did the high-school teachers react? These are some of the reactions:

- Some teachers were simply daunted by the workload implications of providing high-quality feedback for all the students they teach. They could not see how they would have the time to provide such detail for all the work the students did. They had to find a pragmatic way through this discomfort: the easiest choice for this group was to reject the ideas altogether and continue with what they had always done and knew to be achievable.
 - Other teachers felt that they were unavoidably constrained by the demands of others: parents demand marks and teachers must therefore supply them; entry to college makes students compete for grades, and competitive grading will therefore backwash through the whole school. "Our hands are tied," they said: adoption of formative assessment practice, however desirable, was pragmatically impossible. The principal acknowledged these constraints, but still argued that the learning needs of the students were the school's first priority: formative assessment was not a distraction from the focus on achievement but rather a vital step toward it.
 - Given a clear message from the school leadership team that no change was not an option, teachers then looked at ways of providing effective feedback through formative-assessment strategies, using the students themselves as one source of feedback rather than all of it coming from the teacher. They looked again at the learning activities they were planning and considered the appropriate type and source of feedback to be provided.
1. *Teacher feedback to individual students.* They agreed that work that was new to the students, and important as the basis for further learning, would need and deserve the best-possible feedback from the teacher herself. This would entail clarifying criteria with the students beforehand, providing students as soon as possible with as much specific feedback as they could absorb, and giving them the chance in class to focus on this feedback and correct their work before moving on.
 2. *Teacher feedback to whole group.* Some of the work set for the students did not need detailed individual feedback, but it did need to be looked at by the teacher. In this case, the teacher took a quick look at all the students' work, used what she learned from it to share with the group, and adjusted her plans to accommodate any necessary consolidation or remediation. She did not provide individual feedback for each student.
 3. *Peer and self-assessment.* Another type of work done by the students could be assessed by the students themselves, given the necessary training and practice. They would

learn how to apply criteria to a given piece of work, and then practice doing so and provide useful feedback to each other. As the teachers discussed how best to make this work, a couple of examples of existing practice emerged, that helped others to see what they might do.

This pragmatic approach to formative assessment was achieved by lowering the temperature of the debate, to release the practical creativity and ingenuity of the teachers involved. It was helpful for the principal to accept and state that he did not expect a complete change in all teachers' assessment practice immediately. He suggested that each teacher choose one teaching group with which to try new strategies. Teachers would then be given time first in their subject teams and then in cross-curricular groups to share and discuss what they did and what happened. They were not expected to get it all right first time, and were forewarned that both they and the students might find the unfamiliar practices more difficult to start with, as is the case whenever we change our habits. The schedule and purpose of subject-team meetings was changed slightly to accommodate the necessary sharing. The vice principal talked to all the subject-team leaders about the particular circumstances and approach to change in team, and how to support the team leader in effecting change.

Two months later, when subject teams had been trying out formative assessment strategies in their classes for a while, subject leaders came together, led by the same vice principal, to share their experience with other colleagues, to look for common themes, and identify the road blocks. At this meeting, a number of issues were raised:

1. Some teachers were concerned that the students could not separate feedback from friendship, and this affected the accuracy of feedback in peer assessment. They agreed that students would be given plenty of training with applying criteria to neutral examples of work before graduating to peer assessment when the teachers felt that they were skilled enough not to be deflected by their relationship with the person they were working with.
2. The teachers' experience bore out the research finding that students are distracted by marks, scores, and grades on their work, and it was agreed that they would try keeping marks separate from feedback, where possible, to encourage students to focus on improvement. This raised the whole question of the frequency of marks, which led in turn to further discussion about how students' final grades are determined. As this issue affected every subject team, a special task group was created to investigate the issue in greater depth and report back with a number of ways forward for the whole school to decide on.
3. The group discovered that when formative-assessment strategies had been running for a while the students themselves began to see the positive impact on their work and performance. It was decided that the school's planned explanations to parents should include input from the students themselves, with concrete examples of improved achievement.
4. With more time to focus on classroom strategies, the teachers reporting back to the vice principal began to highlight examples of the effect on students' motivation and levels of independence. It was decided that another meeting for parents and senior students should be addressed by a representative from the local college, talking about the students' need in postsecondary to be less dependent on their teachers and more able to accept responsibility for their own learning, both of which were goals of the school's changing assessment practice.

Roadblocks

During the school's implementation of their intentional and consistent approach, they ran into several roadblocks that needed to be handled carefully:

- Some subject areas appeared to lend themselves to these ideas more easily than others. In English, the teachers' normal way of working was through feedback and revision, as the students practiced a sets of skills repeatedly in different contexts and at growing levels of complexity. In math and science, on the other hand, the teachers felt they needed to be constantly moving on to different aspects of the subject that were not clearly related to what had gone before. They struggled to help students see the links, and the relative fragmentation of the subject, in view of some of the teachers, meant that they could not afford the time to correct skills that would not necessarily be used again. Other math and science teachers argued to the contrary, using problem solving, investigations, or lab-work as the continuing skills to be improved through clear criteria, feedback, and improvement. The best help for the math team came from detailed work with the math team from another school, where their special context allowed them to get down to more detailed and useful discussion, next steps, practice, and sharing their successes.
- A further roadblock arose from the high-stakes nature of the summative assessments undertaken at various stages in the high school. Teachers, students, and parents all took these results very seriously, and teachers were unwilling to experiment with new teaching strategies if they felt any uncertainty about the outcome. The principal's pragmatic suggestion in this case was to start changing the approach to criteria, marking, and feedback and the involvement of the students in lower stake years – not grade 12 in the first instance – so they could practice the skills involved and gather the evidence they needed of the positive impact on student performance.

- A further roadblock, encountered when this apparently new initiative was introduced, was that many Neartown teachers believed that this was separate from other requirements and initiatives that confronted them. Lacking the means to find connections with their daily work, and already annoyed by the increase in external interference and accountability, some of the teachers kept their heads down and hoped it would go away, while the skepticism of others affected their motivation to try the strategies with any real conviction. In this case, the excellent leadership of Neartown High School clarified and communicated the connection between assessment for learning and other initiatives. Instead of merely reacting to these external mandates, and treating them all separately, the leadership team developed its own vision of the school's goals for excellent learning and teaching, to which the external imperatives were then connected. Various initiatives were woven together, and the big picture was presented as clearly as possible, including in visual form. The daily behaviors of all the school's leaders were then influenced by their collective interest in formative-assessment strategies. As they observed teachers and teaching for the purpose of teacher evaluation, they would be applying agreed criteria for high-quality teaching that included formative-assessment strategies. As they walked through teaching areas they would pick up and comment on evidence of students' involvement in both learning and assessment. They would use open-ended questioning in their conversations with teachers to encourage reflection on their classroom practice.

School Change Is Influenced by System Change

All publicly funded schools will be influenced by the political and educational imperatives that accompany their funding. Our two case-study schools, which could be anywhere, will be affected by both these external factors and also, crucially, by the reactions of the school-based leadership. The monitoring of schools – by the state as in the UK and New Zealand, or by the school district – for example, can be handled by schools as either a curse or a blessing: the intelligent leadership team will use the event as a welcome opportunity to benchmark their pursuit of quality against external benchmarks, and not further undermine the motivation of their colleagues by raising anxiety about something beyond the school's control. In other forums, of

course, school leaders will try to use their collective influence to improve the inspection process, but in school they maintain a cheerful and encouraging stance.

Conclusion

The key question in assessment is about its purpose. Schools are expected to both help children learn and to check and report their achievement. Both formative and summative assessment practices are needed to achieve this, and schools have to manage them side by side, despite the continuing tension between the two, competing for space and attention in a space already crowded with expectations to cover fixed curricula and programs. Gradually, assessment for learning is affecting teachers' and schools' practice, but the progress is slow.

Formative Assessment

P Black, King's College London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

The Early Development

The use of the term formative in education was introduced in the context of curriculum evaluation by Scriven and extended 2 years later to the improvement of teaching by Bloom (1969):

By formative evaluation we mean evaluation by brief tests used by teachers and students as aids in the learning process (p. 48).

However, as Black (1986) pointed out, the use of feedback from assessments to guide learning has always been a feature of education. His development of diagnostic assessment in Scotland was however exceptional in that the growth of standardized testing overshadowed formative developments for many years. Crooks (1988), in his survey of the literature on the impact of classroom evaluation practices on students, contrasted the many positive effects of good assessment with the evidence that classroom assessment often encouraged rote and superficial learning, with the grading function overemphasized; several authors described the difficulty of preventing the summative process from swamping formative work (Black, 1993).

This article presents a brief account of developments in formative assessment in the last 30 years, and goes on to discuss the principles and practices as they have emerged to date. A closing section reviews some of the obstacles to further development.

Policy Impact in the UK: The Task Group on Assessment and Testing Report

Fresh emphasis on formative assessment was developed in the UK with the report of a government-appointed Task Group on Assessment and Testing (TGAT), which recommended that a new national assessment system should:

- be criterion referenced,
- be formative,
- use moderated teachers' assessments, and
- be based on a framework of progression in learning.

In its closing summary, the groups' report emphasised that:

Our terms of reference stress that the assessment to be proposed must be "supportive of learning in schools". We reiterate that the four criteria set out in Section 1 are

essential if this support is to be secured. . . The **formative** aspect follows almost by definition. For the system to be formative it must produce a full and well-articulated picture of the individual child's current strengths and future needs. (DES, 1988 paragraph 221)

While the report's recommendations were accepted in principle, important reservations were expressed by the government. For the national tests taken by all at ages 7, 11, and 14, they rejected the TGAT proposal that these be based on moderated teacher assessment combined with scores from external tests, ruling instead that the test results and teachers' assessment results should be published separately. The predictable, and no doubt intended, result was that the test results became dominant (Black, 1997).

In and from these events, three of the problems that obstruct the implementation of formative assessment were emerging. These were:

- the lack of clear definition of formative assessment, which was seen only as the formative use of testing;
- the conflict between formative assessment and the accountability pressures of summative testing; and
- the failure to accept that formative assessment was not merely current good teaching, but rather a practice which would require from teachers a radical and difficult change in their role.

These three problems continue to inhibit formative work to the present day.

The New Perspective – 1990–2000

While several individuals made further study of formative assessment (e.g., Black, 1993), the main source for new thinking was the activity of the Assessment Policy Task Group of the British Educational Research Association (BERA), subsequently renamed as the Assessment Reform Group (ARG), which developed a critique of the development of national assessment policy in the UK, and were led to obtain funding for a comprehensive review of the literature on formative assessment. For this task, they commissioned the author and Dylan Wiliam, who produced a 55-page review (Black and Wiliam, 1998a) titled 'Assessment and classroom learning'. The first of its six main sections gave summary accounts of eight selected studies, the subjects of which ranged from 5-year-olds to university students, which described a variety of formative assessment practices, and all of which showed firm evidence

that these practices produced significant learning gains. There followed five sections which surveyed studies of:

- students and formative assessment – including discussions of goal orientation, self-perception, self- and peer assessment, and links to theories of learning;
- strategies and tactics for teachers – including choice of task, discourse, questions, the use of tests, and quality of feedback; and
- systems – including mastery learning, assessment-driven models of instruction, portfolios, and summative examination models.

These were followed by two more reflective and theoretical sections on:

- feedback – including discussions of the nature of feedback, meta-task processes, and motivation and learning processes;
- the prospects for theory and practice of formative assessment – commenting on the current theoretical basis, expectations and the social setting, further research, and potential implications for policy.

This review has been very widely cited – it was indeed long overdue. One reason for its influence was that it set out a broad agenda for further work on formative assessment. It gave particular impetus to such work by publicizing evidence, from many rigorous experimental studies, that formative assessment did indeed raise standards of performance in learning. These findings have been confirmed by re-analyses of the same and later evidence by other authors.

Widespread impact among teachers followed through a short booklet for teachers titled *Inside the Black Box* (Black and Wiliam, 1998b) in which the main conclusions, and their implications for both policy and practice, were summarized. This attracted wide publicity and to date over 50 000 copies have been sold, mainly in the UK.

Developing Practice

While the ARG followed the Black and Wiliam review in 1999 with a booklet developing its implications, what was lacking was evidence about how teachers might apply the many potential lessons from the review in their everyday practice. This challenge was taken up by a group at King's College London in a collaborative project with two local school district authorities (LAs) entitled the King's Medway Oxford Formative Assessment Project (KMOFAP).

The KMOFAP Project: Practices

Between 1999 and 2002 this project involved 48 teachers of mathematics, science, and English in six secondary

comprehensive schools. It was collaborative in that the King's group and the LAs emphasized that the lessons from research did not provide recipes for success, but were a source of suggestions which teachers might use as starting points to develop new practical knowledge about formative assessment. This strategy (described in Black and Wiliam, 2003) helped to encourage both the full engagement of, and practical innovations from, the teachers. Evidence collected from schools' test results confirmed that significant learning gains could be achieved within the normal working conditions of secondary schools, while the teachers involved also felt that the work had enhanced their own commitments to, and realization of, their professional values (Wiliam *et al.*, 2004).

The findings of the project led to the production of materials to guide schools and teachers in their own development of formative assessment methods. A short booklet, *Working inside the Black Box* (Black *et al.*, 2002), and a book (Black *et al.*, 2003), have both proved very popular. They set out the two main outcomes, which were to specify the principles on which formative assessment should be based, and to map out the main areas of formative practice. These two are discussed in the following two sections.

Basic Principles

A test as such may be either formative or summative or both – the distinction lies in the purpose for which information is interpreted and used, not in the means used to elicit that information (Wiliam and Black, 1996). The distinction is emphasized in the following definition:

Assessment for learning is any assessment for which the first priority in its design and practice is to serve the purpose of promoting pupils' learning. It thus differs from assessment designed primarily to serve the purposes of accountability, or of ranking, or of certifying competence.

An assessment activity can help learning if it provides information to be used as feedback, by teachers, and by their pupils, in assessing themselves and each other, to modify the teaching and learning activities in which they are engaged. Such assessment becomes 'formative assessment' when the evidence is actually used to adapt the teaching to meet learning needs (Black *et al.*, 2002 – inside front cover).

Others have produced essentially similar statements (ARG, 2002a).

Given that evidence is collected to promote learning, its use must be consistent with established principles for effective learning, which may be summarized as:

- Start from a learner's existing understanding.
- Involve the learner actively in the learning process.

Develop the learner's understanding of the aims and criteria for effective learning.

Promote social learning, i.e. learning through discussion.

These are concerned with the cognitive dimension of learning. The affective and motivational dimensions are also important. The work of Butler (1988) showed that feedback given as rewards or grades enhances ego rather than task involvement and that task-involved students did better than the ego-involved. The more extensive work of Dweck (2000) likewise showed that for ego-involvement, with a mind-set focused on competitive performance, both high and low attainers are reluctant to take risks and react badly to new challenges, while failures simply damage self-esteem (see also ARG, 2002b), whereas with task-involvement, learners believe that they can improve by their own effort, are willing to take on new challenges and to learn from failure.

Areas of Practice

Oral and Written Feedback

One of the KMOFAP teachers summarized very effectively the changes she made in her use of questions in class:

Questioning

- My whole teaching style has become more interactive. Instead of showing how to find solutions, a question is asked and students given time to explore answers together. My Year 8 target class is now well-used to this way of working. I find myself using this method more and more with other groups.

No hands

- Unless specifically asked students know not to put their hands up if they know the answer to a question. All students are expected to be able to answer at any time even if it is an 'I don't know'.

Supportive climate

- Students are comfortable with giving a wrong answer. They know that these can be as useful as correct ones. They are happy for other students to help explore their wrong answers further (Black *et al.*, 2003: 40).

Research results on wait time impressed teachers with the need to give pupils time to think; many encouraged students to talk with one another before answers were called for, so that as many as possible would feel confident about expressing their ideas. The corollary of this approach was that each question had to be sufficiently open, from the learners' perspective, that it called for thought, and had to be sufficiently central to the learning aims that it justified the time spent on discussing the ideas that ensued. It followed that closed questions, checking only on knowledge, would be seen to make little contribution to students' learning. If students had to think, their

wrong or partly right answers would give teachers the information about the students' understanding, which would help them choose the optimum way for the work to proceed.

The key issue was that the formative purpose of a question is achieved only if it elicits from students some significant indicator of their understanding and then enables the teacher or other students to respond by trying to correct or develop that understanding, and perhaps through several responses lead the whole class to share a discussion of the issue. Thus, what is required is very different from the all-to-frequent, and still dominant, pattern in which the teacher may dominate by a sequence of triads of initiation, response, and judgment/correction. What is needed, if the classroom is to engage all students in thinking, is a radical shift toward dialog (Alexander, 2006) or, in Van Lier's (1996) terms, toward conversation. This latter view highlights the delicate task of teachers, for on the one hand tight control over the discussion can inhibit involvement of the learners, but on the other hand loose control can lead to digression so that the purpose of the learning is lost. Given that student participation is often unpredictable, the task of steering such dialog is a delicate one: this is an issue that requires further study.

Just as in questioning, in written work the purpose has to be to provide feedback that helps learning. The difficult change here was for teachers to stop giving marks or grades on written work. They were encouraged by research findings that comment-only marking led to improved learning (Butler, 1988), and came to justify the new practice as follows:

- students rarely read comments preferring to compare marks with peers as their first reaction on getting work back;
- teachers rarely give students time in class to read comments that are written on work and probably few, if any students, return to consider these at home;
- often the comments are brief and/or not specific, for example "Details?";
- the same written comments frequently recur in a student's book, implying that students do not take note of or act on the comments (Black *et al.*, 2003: 43).

In consequence, teachers' realized the need to spend more time on careful formulation of comments that would help students to understand their faults and to improve their work. Such comments as "Be more sensitive" and "You are mixing up the words 'solution' and 'mixture'" give the learner no useful guidance, but if the latter were expanded to read "Allan, this is generally fine but you are mixing up the words 'solution' and 'mixture'. Look up what we all wrote down about the difference and then check through this piece again." should help Allan to improve his understanding. The key point is that the written work is not

to be treated as a terminal test, for which the marks produced are the end of the matter, but as an opportunity, through formative feedback, for improving learning.

One feature that distinguishes written from oral feedback is that there is time to frame comments that encourage further learning, with more opportunity for differentiation through separate interaction with individuals. The effects on motivation of the type of feedback are also important: as one teacher expressed it:

The results were especially noticeable in lower attainers since grades can often have a de-motivating effect with such students which can be extremely destructive to their self-esteem (KMOFAP project, unpublished transcript).

For all feedback, any intervention by the teacher must be based on some assumptions about the nature of the thinking that produced that response. In the absence of any effective model of that thinking:

...part of the feedback given to pupils in a class is like so many bottles thrown out to sea. No one can be sure that the message they contain will one day find a receiver. (Perrenoud, 1998: 87).

This judgment highlights the difficulty of the problem. Authors concerned with the self-regulation involved in learning have explored relevant models (Greene and Azvedo, 2007), but whether, and how, such models might guide the day-to-day formative interventions by teachers has yet to be explored. Comparisons with dynamic assessment, which is centered on formative interpretation of feedback using a specific theory of cognitive development, might also be helpful (Leung, 2007).

Peer- and Self-Assessment

Self-assessment by students is essential for their development as independent and responsible learners. To meet this need, practice must involve them in assessing one another's work so that they might thereby develop the skills both of peer assessment and, by seeing their work through the eyes of their peers, of self-assessment. To do this, students have to understand the aims of the work involved, and the criteria by which this work should be assessed. In certain topics in some subjects, the criteria might be well defined (e.g., calculating the value of a force in a physics problem), in others there might be many different ways in which work could achieve excellence (e.g., writing a critical appreciation of a poem). Overall, the aim was to move students away from dependence on the teacher toward independence in the power to guide their own learning. As one teacher expressed it:

The kids are not skilled in what I am trying to get them to do. I think the process is more effective long term. If you invest time in it, it will pay off big dividends, this process

of getting the students to be more independent in the way that they learn and taking the responsibility themselves (Black *et al.*, 2003: 52).

In helping students to develop their self-assessment, teachers must clearly specify aims so that students can both steer their work toward attaining them and understand the criteria by which that work can be judged.

Peer assessment is another powerful tool: helping pupils collaborate effectively in groups is essential to such work. However, while there is strong evidence that collaborative groups can improve attainment, a survey of group work in a large sample of UK classrooms (Blatchford *et al.*, 2006) shows that the type of collaboration that can engage pupils in reasoned arguments about their own and one another's contributions is not often found. Intervention programs by Blatchford and colleagues and by Mercer *et al.* (2004) have demonstrated that students trained in such collaboration produce improved attainments, both in the quality of their arguments and in subsequent tests. The work of Dawes *et al.* (2004) is a good example of dissemination of the lessons learned about effective group work.

The formative use of summative tests extends this area of practice. Students learn by marking one another's test responses, particularly if they have to develop the marking schemes in the light of their understanding of the criteria. As for the new way of looking at written work generally, the point is that a test, while serving the summative function, might also be used, through formative feedback, as an opportunity for improving learning. One addition in this area was that teachers would strengthen preparation by asking students to compose questions which might well be suitable for the coming tests, for in so doing they would have to identify for themselves the main aims of the work. They would also learn about the need to frame the text of a question with care, and to exercise similar care in responding to questions framed by others.

Growing Points

The above accounts indicate areas where further work is needed to deepen understanding and improve the practical implementations of formative assessment. There is also a need to explore the differences in formative practice between different school subjects (Hodgen and Marshall, 2005). Insofar as formative interaction is at the heart of teaching and learning, it may seem inevitable that ideas about it may expand into a complete theory of pedagogy. It is necessary here to be more specific: the heart of the formative interaction is the active involvement of the learner who produces evidence that is used to guide further learning. The means to produce such evidence, and the aims to which the guidance is directed, are also essential aspects of pedagogy, but the specific

formative element is the contingent and unpredictable interactions which advance the learning by challenging and extending the learners' thinking.

Why Is It Difficult?

Attempts to implement formative assessment have been hindered by superficial interpretations. For example, teachers may ask open questions, but then correct the answers rather than use them to redirect their work, or they may ask pupils to self-assess their work but then fail to use this information to formulate formative feedback. Many have interpreted the related terms assessment for learning as incorporating all uses of assessment, and in this perspective focused on frequent summative testing, while Bloom's (1969) account in terms of brief tests showed a limited perspective on the practice. Such particular misinterpretations have been prevalent in the USA where, with a few notable exceptions, discussions often present the topic under the heading 'Classroom assessment' in terms which leave unclear whether it is the summative of the formative functions which are being considered. A recent text titled *Learner-Centred Classroom Practices and Assessments* does not even mention, let alone discuss, formative assessment (McCombs and Miller, 2007).

There are outstanding obstacles to further improvement of formative practices. The first is that implementing new formative practices is a very demanding task for any teacher. For many, a deep change in their beliefs about their role in the classroom is required, with practical implications which many find pretty scary. As one teacher put it:

It was clear that new ways of working together with new boundaries had to be established and to do this successfully took all my skills as a teacher. . . (Black *et al.*, 2003: 90).

Such difficulties pointed out in much earlier literature:

To incorporate formative assessment into their teaching would involve teachers in far more than acquisition of the necessary skills. . . The changes in their classroom practice might also involve profound changes of role, even for teachers regarded by themselves and others as already successful . . . devotion to formative assessment is risky, taking a great deal of time and energy. In particular, since many pupils may have acquired habits of doing just enough to get by, or have ceased to believe that they can be competent at the subject, the contract between teacher and pupil has to be reformulated. (Black, 1993: 79)

The initial disorientation was felt not only by teachers but also by students:

The first time I asked a Year 10 top set to work in groups to examine the errors they had made in a test and to help

each other to understand fully what was being asked of them, it was unsuccessful . . . That lesson I heard several times 'Why don't you just tell us?' . . . they have realised that they have more to do in my classroom than absorb the syllabus – they have to take responsibility for their learning (Black *et al.*, 2003: 87).

The changes needed cannot be produced by a short training session – they need the sustained support of collegial collaboration. Studies of individual teachers show that each changes in a different way and with different personal perceptions of the task (Black *et al.*, 2003: chapter 6; Lee and Wiliam, 2005).

A second obstacle is the dominance, in many national systems, of external summative testing with attendant high-stakes consequences. The perceived need to teach the superficial tactics which improve performance on superficial tests, limits teachers' freedom of maneuver in classroom work. The resolution of this problem will depend on trusting teachers to play a more responsible part in the summative assessment of their pupils (ARG, 2006). Then the problems of establishing synergy over the formative summative interface might be tackled.

A third obstacle is that to achieve such synergy, teachers need to have a basic expertise in such assessment issues, based on a broad understanding of the main principles and practices of assessment, including a thorough understanding of the criteria of validity and reliability. The lack of such expertise is a notable weakness because it means that the profession cannot take control of an essential component of its work, it is a partial profession. This view is borne out in work that has sought to develop teachers' summative assessment practices (Black *et al.*, 2007). Thus, developing understanding and skills in formative practices is only one component in building the assessment strengths of the profession – one that can only achieve limited success on its own.

Formative Assessment and Instructional Planning

B Marshall, Kings College London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The term assessment for learning (AfL), or formative assessment as it is sometimes referred to, has recently gained great currency in education, particularly in the UK. It has become a coverall term for improving learning of pupils and has been adopted into various frameworks including the inspection of schools. One aspect school inspectors consider is whether AfL is in evidence in lessons. In other words, they consider whether or not the teacher has used instructional planning to further the learning of the children in that class. In this way AfL and instructional planning are intimately entwined. AfL cannot take place unless it has been planned for. In this article, assessment and instructional planning are referred to almost, but not completely, synonymously because there are differences.

Two things are important in assessment and instructional planning – what the teacher thinks about what he/she is teaching and what he/she subsequently does in the lesson. What the teacher thinks is crucial for two reasons. The first is that AfL has at its heart, the desire to create an independent learner (James and Pedder, 2006). As part of a major research project, Learning How to Learn, it was found that unless teachers believed it was important that their lessons created autonomous learners, the spirit, as opposed to the letter, of formative assessment did not prevail (Marshall and Drummond, 2006). Black and others, have called it the Trojan horse of AfL (Black *et al.*, 2006).

The second is slightly tangential but nevertheless important. Dweck (2003) observed that there were two contrasting and complementary views of learning – task versus ego involvement and incremental versus entity theories of learning. Those who hold task and incremental views of learning tend to believe that learning makes them smarter, than what they learn from experience; whereas, ego and entity learners concentrate on their ability, which they think of as fixed, or the circumstances in which the task is undertaken. Those who believe in the importance of autonomous learning tend to share Dweck's profile of task/incremental views of learning (Marshall and Drummond, 2006).

High Organization Based on Ideas

However, what teachers actually do in lessons is also important. John Dewey, the originator of progressive education, claimed that lessons and so learning ought to be high organization based upon ideas (Dewey, 1966). In other

words, they should not be just a piecemeal series of activities, however entertaining, but should have some overall rationale or logic behind them. It is this principle that underpins the planning of formative-assessment lessons. John Dewey, in his defense of progressive teaching, wrote that it was a difficult task to work out the kinds of materials, of methods, and of social relationships that are appropriate when trying to discover and put into operation a principle of order and operation which follows from understanding what the educative experience signifies. He was debating the kind of teaching and planning that needs to be in place if one is to put into practice a high organization based upon ideas. In other words, Dewey, the originator of progressive teaching, was saying it is not easy to plan a lesson.

For Dewey, education was about the promotion of independent learners but crucially it was to come about in a social situated setting. The teacher's role was to construct learning in such a manner, through the activities that he/she organized, that pupil autonomy was fostered and so gained. Independent learning, therefore, came about through high organization based upon ideas practically worked out in the lesson. It was less about questioning, feedback, sharing the criteria with learners, and peer- and self-assessment and more about the realization of certain principles of teaching and learning.

Assessment and Instructional Planning in Practice

So what does it mean to plan for assessment to take place in a lesson? If we look at an English lesson, which is based on peer assessment, we can begin to see what Dewey meant when he said that the lesson must have high organization based upon ideas. Each of the activities builds on the one preceding it so that as the pupils come to each new activity, they can use what they have already learned through earlier tasks. There is a rationale to the lesson.

Year-8 lesson (12- and 13-year-olds) pre-twentieth century poem

- Class draw up list of criteria guided by teacher
 - Teacher and learning-support assistant perform poem
 - Pupils asked to critique performance
 - Pupils rehearse performance
 - Pupils peer assess poems based on criteria
 - Pupils perform poems based on criteria
-

Above is an outline of the main events of the lessons.

In the lesson the teacher, Angela, asked the pupils to consider a dramatic rendition of a nineteenth-century poem that they had begun looking at on the previous occasion. The lesson has the potential for pupils to engage with the question of what makes for quality in a piece of work – an issue which is difficult in English and hard for pupils to grasp. Significantly, Angela adopts the procedures of formative assessment identified – sharing the criteria with the learner, and using peer and self-assessment as a means to this end. For this, two activities – modeling and peer assessment – are linked. The modeling activity at the start of the lesson appears to be designed to help pupils know what to do when they peer assess.

Angela began the lesson by asking the pupils to draw up a list of criteria for performing a poem. All suggestions came from the pupils while she probed, challenged, and polished their contributions. For example:

Pupil: You could speed it up and slow it down

Angela: Yes – pace, that's very important in reading
[teacher then writes the word 'pace' on the board].

Interestingly, the Japanese have a useful term for describing such a process – *neriage*, which literally means polishing. In Japan, recapitulating the contributions made by pupils is an important part of teachers' classroom practice. It provides an opportunity for teachers to synthesize the contributions made by different pupils, to interject specific vocabulary, and also to refine or re-contextualize ideas.

The next activity built well on the previous task when Angela and the classroom assistant then performed the poem to the class and then invited pupils to critique their performance based on the criteria. A similar form of probing took place in these exchanges too:

Pupil: It [the performance] was boring.

Angela: What do you mean boring?

Pupil: There wasn't enough expression in your face when the poem was being read or in the reading.

Angela: So what could I have done to make it better?

Pupil: You could have looked and sounded more alarmed

Angela: Like this? [strikes a pose]

Pupil: Not quite

Angela: More like this? [strikes another pose]

Pupil: Yeah.

These three tasks in Angela's lesson the creation of the criteria, the performance of the poem, and the application of the criteria to Angela's and the learning-support assistant's performance all governed the pupils' thinking about what was needed when they acted out the poem themselves and the peer assessment of those performances. So we see again that each stage of the lesson built on the one that had preceded it. There is a logic to

it. Angela's questioning of the pupils provided further opportunity for both her assessment of their performance and the pupils ability to improve on it, as Dweck suggests. Angela takes a more task/incremental view of learning believing that something can always be done or changed to make the pupils in her class understand better what they can do to improve.

Two crucial but subtle elements emerge – the potential scope of the tasks, the way they interlock, and the opportunities these afforded for current and future pupil independence. Although it is hard to separate out the various aspects of the lessons, as they overlap, it is possible to use James and Pedder's (2006) analysis, which has certain headings, as a way of organizing the analysis – making learning explicit, promoting learner autonomy, and performance orientation.

If we start with making learning explicit we find that pupils in Angela's lesson engaged both in technical considerations, such as clarity and accuracy, as well as the higher-order, interpretive concepts of meaning and effect. In addition, the modeling of what was required in Angela's lesson ensured that pupils went beyond an imitation of that model because it challenged them to think about the variety of ways they might enact their interpretation of the poem.

The sequence of activities, each building on the other, guided the pupils in Angela's lesson toward being independent or autonomous learners (the second of our factor headings) because the tasks, including encouraging the pupils to create their own criteria, helped them to think for themselves about what might be needed to capture the meaning of the poem in performance.

Pupils in Angela's lesson, therefore, also began to engage in the more complex issues of any performance be it verbal or written. That is the pupils were asked to explore the relationship between the meaning of a product and the way in which that meaning is expressed – between form and content. This leads us to the final element of performance orientation. Crucially, Angela always described the tasks as opportunities for the pupils to improve their performance. In this way, the activities had an open, fluid feel which corresponded with the notion of promoting pupil autonomy; it reinforced a sense of limitless progress whereby assessment is always seen as a tool for future rather than past performance. This was mainly done by creating tasks, all of which worked effectively together, designed to enable children to enter the subject community or guild (Sadler, 1989). More importantly, Angela has prepared a lesson which is high organization built upon ideas.

The Regulation of Learning and Dialog

Another way of understanding Angela's lessons is to examine the way they were regulated both in the way

they were planned and carried out. Perrenoud (1998) describes the regulation of learning, as the key concept on which AfL is based. To illustrate this, he describes different types of classrooms. In some, those he calls traditional, learning is highly prescribed, the scope of the activities tightly defined. The outcomes of the learning are largely content driven and predetermined and pupils complete a series of narrow activities, which are designed to cover the prescribed learning objectives. There is little opportunity for the pupils to own their own learning and the only information it gives the teacher is a deficit model of what they cannot do according to the narrowly defined terms of reference.

The other type of lesson is much more like Angela's. Here, the tasks are more open ended, thus, the scope for pupils to govern their own thinking is greater, and the possibility for the teachers to provide feedback meaningfully enhanced. For in this type of classroom, "regulation does not include setting up activities suggested to, or imposed on, the pupils but their adjustment once they have been initiated" (Perrenoud, 1998: 88). If we consider Angela's classroom we can see, to an extent, what that means. In her dialog with the pupils, she adjusts the pattern of her teaching once they have been initiated.

And dialog is the final consideration we must take into account. Without effective dialog between pupils and between the teacher and pupil, little AfL can take place. Black and Wiliam observed that "the quality of the interaction [between pupil and teacher] ... is at the heart of pedagogy" (Black and Wiliam, 1998: 16). What counts is the relationship and the aspirations teachers have of their class – the very language of learning.

Vygotsky, the Russian psychologist's view of learning, like Dewey's, was socially constructed and his notion of the zone of proximal development (ZPD) was crucial in understanding the way in which he believed pupils progressed toward autonomy. In particular, Vygotsky saw the teacher's role in facilitating activities to encourage pupils to engage with the lesson as part of this process. This is redolent of Bruner's concept of scaffolding learning within Vygotsky's ZPD. Within the ZPD, Bruner suggested, pupils need to interact with those who are more capable. This interaction with peers and teachers provides a scaffolding for the learner, through which the learner develops the capabilities herself.

If we look at a history lesson, we can begin to see what this might look like. This lesson examined the slave-trade triangle between England, Africa, and the Caribbean. In it, the pupils were being asked to consider what type of evidence certain sources might proffer, how to use such sources, and also about the role of chronology. Toward the end of the lesson, they also began to consider the type of language and register necessary for writing about historical sources. What is significant again is how one activity naturally gives rise to the next – as with Dewey, all

activities are connected, and each relies on dialog either among the pupils themselves or between the pupil and teacher, very much like Vygotsky's ZPD.

The lesson was divided into three main activities – a recap on the previous lesson; in the second and main activity of the lesson, the pupils were given first five, and later four more, contemporaneous pictures that illustrated aspects of the slave trade and finally they were asked to write captions underneath the pictures. Each section had significant discussion but if we consider the dialog in the last of these sections, we see how important both types of conversation are in AfL. As with the English lessons, the teacher, David, modeled the type of writing required before they embarked on the task. Taking what was arguably the first picture of the sequence he asked for contributions. Again, like Angela's lesson, he developed and refined these. He began with:

T Why would you not write 'Slaves walking across a field'?

P Because they could be anywhere.

T So?

P Captured Africans taken to a ship.

T Can we see a ship? How else could we add to it?

P Captured Africans being marched to a ship on the West African coast.

T Have we left anything else out?

P Fellow African tribes capturing and taking their own people to captivity.

What is interesting about this exchange was the way that through questioning, the teacher pushed the pupil to develop the density and precision of the caption. As with Angela and the classroom assistant's performance, David set up an initial response, such as a pupil might make, to be critiqued and developed. Again, through the model he makes the criteria for a good caption clear. But this was done less in terms of what was right and wrong but by what would make for quality in a caption – in this case evidential and inferential density about the slave trade from a visual source. In this way, subject content and processes were blended in the articulation of a caption. Moreover, the use of a caption is, in itself, a stepping stone to enable pupils to use this type of language or discourse within an essay.

David then developed their language or discourse capacity as he went around the class listening to and reading their attempts, again selecting one caption and exchange, as a result of his sampling of pupil engagement, and getting the whole-class feedback to reinforce it. Moreover in doing so, he added another, what might be called moral, dimension to the exercise. As he went around, he had found two girls who had written of a picture, "slaves being sold at auction."

T How can you tell they are being auctioned?

P Because there's a sign that says 'Horses, negroes, cattle.

T What's so bizarre and shocking about how that's set up?

P They're being sold as if they are cattle.

In the whole-class feedback, using the same two girls, he rehearsed this exchange for the rest of the pupils, having focused their attention on the relevant picture.

T What does that sign tell you?

P That they think of people in the same way as they do cows and horses.

T What else might you add to the caption, 'slaves sold at auction'?

P Slaves who are sold at auction are treated like items not people.

The teacher used the girls as experts to enable the rest of the class to develop their own understanding. In this way, although he was orchestrating the commentary, by focusing attention on the girls' observations, he reinforced the sense of the classroom as a community where all learned from one another. At each stage, the teacher uses dialog to develop the pupils.

Conclusion

This article focused on two lessons to identify what assessment and instructional planning can mean. It has considered the overall plan that a teacher must have before embarking on a lesson, but it has also shown that impromptu dialog or conversations within a lesson, once it has started are also vital. Good AfL and the instructional planning that has to go with it depends on the teacher. As Angela commented, "If I've taught a lesson, then I'll go over it, reflect, think, what could I do better next time?" And again, "So I do a lesson with one and then I think, okay, how could I improve that for the next time?" That is the key. For Angela, nothing is fixed or beyond her control, everything is left to play for. If the children she has taught have not learned what she intended, she sees it as her job to revise what she has done and try again,

differently. The classroom is the place where she learns and in learning she considers the way she can improve her performance. It should always be so.

Progression and Assessment: Developmental Assessment

M Forster and G Masters, Australian Council for Educational Research, Melbourne, VIC, Australia

Glossary

Developmental assessment – The process of monitoring students' progress through an area of learning so that decisions can be made about the best ways to facilitate further learning. The unique feature of developmental assessment is the use of a progress map.

Progress map – A map (also sometimes referred to as a learning continuum, learning progression, developmental continuum, or progress variable) that describes the nature of development in an area of learning: the knowledge, skills, and understandings of a learning area in the order in which they typically develop.

Introduction

There is no concept more fundamental to teaching and learning than that of progress. This concept is invoked whenever teachers describe, for example, students becoming better readers, using more sophisticated language, becoming more tolerant of others, developing deeper understandings, acquiring higher order skills, solving more difficult problems, or mastering more advanced knowledge. Teachers talk about students developing and improving and they use such words such as better, deeper, and higher to describe the direction of student progress.

This article explores the conceptual and empirical underpinnings, and practice of developmental assessment – an approach to the assessment, reporting, and monitoring of learning that directly addresses the concept of progress through the construction and use of progress maps.

Progress maps describe typical progress in an area of learning: the developing knowledge, skills, and understandings against which students' learning can be assessed and monitored over time. They provide a framework that bridges the apparent conceptual gap between teachers' classroom assessments and the assessments undertaken for system accountability. They provide teachers with a shared understanding of the nature of development across the years of school, and a language for talking about growth with each other, with parents, and with students. They provide education systems with a coherent frame of reference for monitoring learning, for comparing the

achievements of subgroups of the student population, and for setting expectations of performance.

The construction and use of these explicit frameworks of progress can be understood in part in terms of advances in two fields: measurement theory and learning research. Advances in these two fields have converged around a few key ideas:

- learning is an ongoing, continuous process;
- at any given time, in any given domain of learning, every learner is at some point in their learning or development;
- while learners are at different stages and are progressing at different rates, every learner is capable of progressing beyond his or her current level of attainment;
- assessment is fundamentally about establishing where individuals are in their learning/development; and
- progress in most areas of school learning involves the development of deeper understandings resulting in increased abilities to organize, generalize, transfer, apply, and use knowledge.

Definitions and Conceptual Underpinnings

Developmental assessment is the process of monitoring students' progress through an area of learning so that decisions can be made about the best ways to facilitate further learning.

The unique feature of developmental assessment is the use of a progress map. A progress map is the backbone of developmental assessment – the framework against which evidence of student learning is collected, assessed, recorded, reported, interpreted, and monitored.

A progress map (also sometimes referred to as a learning continuum, learning progression, developmental continuum, or progress variable) describes the nature of development in an area of learning: the knowledge, skills, and understandings of a learning area in the order in which they typically develop; the things that teachers can watch for and collect evidence about. The terms developmental assessment and progress maps first appeared in the 1990s in materials published by the Australian Council for Educational Research.

A progress map is a construction that begins in the imagination as an attempt to deal with the complexity and multidimensionality of student development. A progress

map focuses attention on a particular area of learning and proposes that, within that area, individuals have levels of achievement which can never be known exactly, but can be estimated. These levels of achievement can be described and illustrated with the kinds of performances

and student work typically observed at particular levels of attainment from the lower more elementary levels of knowledge, skills, and understandings to more advanced levels. An example of a speaking progress map is provided in **Figure 1**.

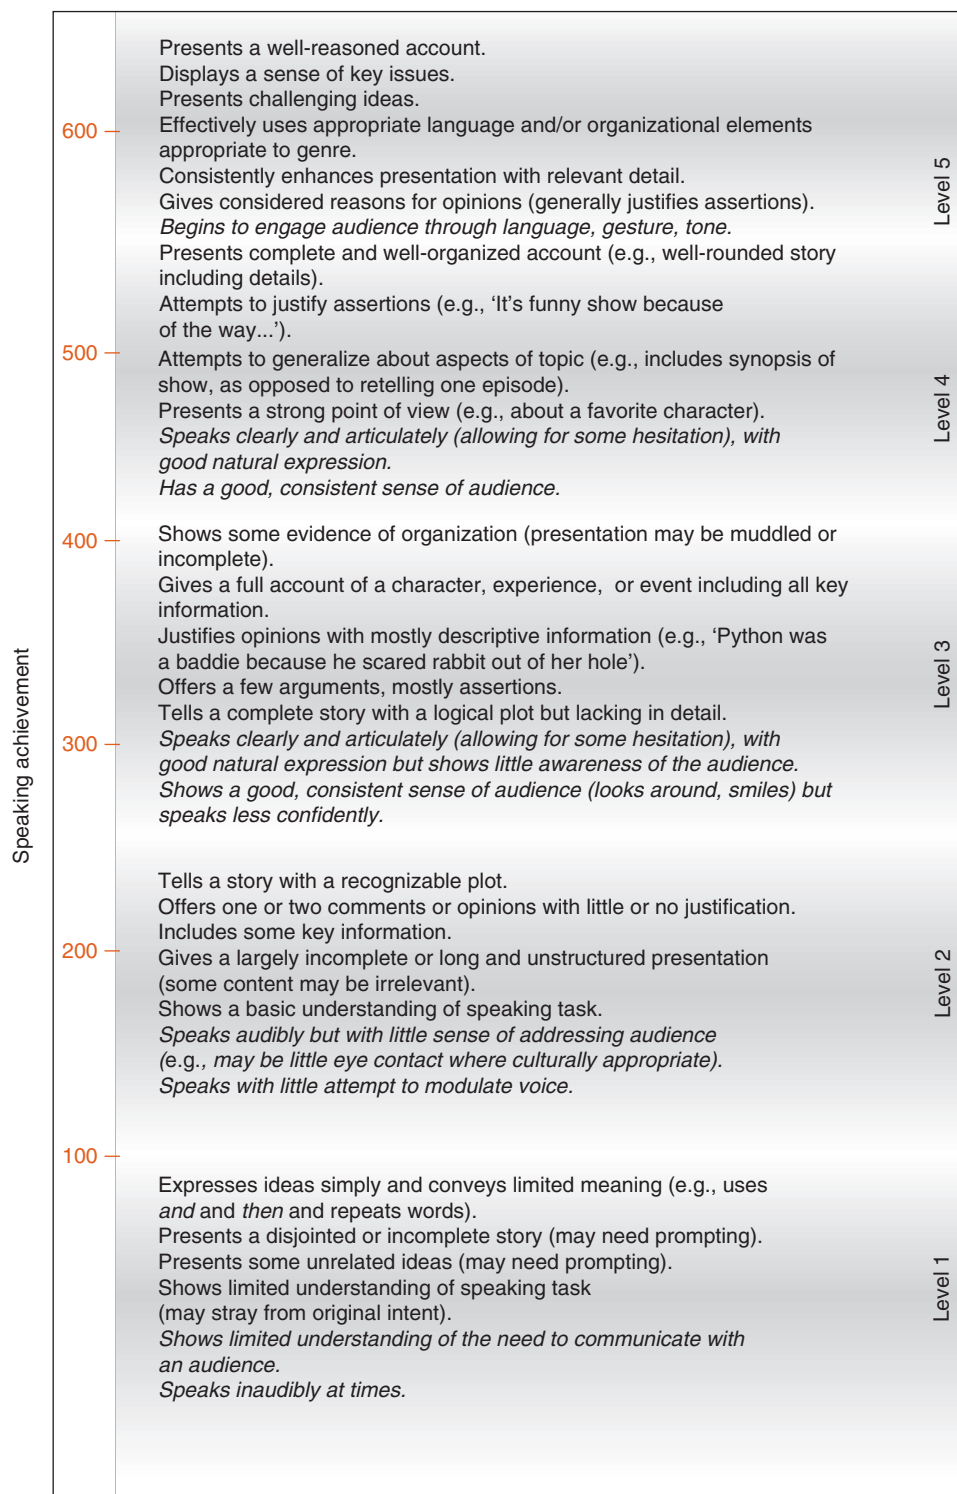

Figure 1 Speaking progress map. Adapted from Masters, G. and Forster, M. (1997). *ARK Progress Maps*. Camberwell: Australian Council for Educational Research.

The structure of many curriculum documents attempts to deal with the complexity and multidimensionality of student development in a similar way, focusing attention on a particular area of learning and describing achievement in that area. Examples include the Hong Kong Curriculum, the United Kingdom Attainment Levels, and the Australian State curriculum documents (e.g., the Victorian Curriculum and Standards Framework).

A progress map is built on the pragmatic observation that it is possible to identify and describe a path of typical progress through an area of learning. That is, although every learner has his/her own idiosyncratic path of development, it is still possible to see a common pathway (the wood as well as the trees). This path of typical progress is not based on a single theory of learning (e.g., Piagetian, constructivist, socioculturalist) or a natural sequence of development. Rather, it is the result of both natural sequences of student development and common conventions for the content and delivery of curricula.

In developmental assessment, progress is monitored against a progress map in much the same way as a child's physical growth is monitored against a framework. From time to time an estimate is made of a student's or a group's location on a progress map and changes in location provide measures of growth over time. The map provides a frame of reference for teachers (and education systems) to monitor an individual's or a group's development and for studying the idiosyncratic development patterns of individuals. It does not provide a prescription for a learning sequence or specify a sequence of learning activities.

If expectations of achievement are set along the progress map (e.g., the level of achievement expected of students by the end of the third grade), then development can be monitored against these expectations also.

Perspectives on School Learning

Developmental assessment represents a paradigm shift in the assessment, monitoring, and interpretation of student learning. Traditionally, assessment and monitoring focus on whether a student has learned what has been taught at grade level – at the end of a lesson, the semester or term, or the school year. For example, the end-of-year report marks the end of the school-year cycle for teachers, for students, and for parents who receive information about their child's achievement before the child moves on and up to the next year level. What have they learned during the year? Have they learned enough to pass? How are they doing relative to others in the class? How well will they cope next year? Do they need to try harder? The child then moves on . . . to the new grade, to the new yearly cycle, to the new teacher.

Developmental assessment takes a rather different perspective on the assessment, monitoring, and interpretation

of student learning. It begins with the understanding that learning is an ongoing process that transcends particular lessons, teachers, classrooms, grades, and even schools and jurisdictions. From this perspective, the main purpose of assessment and monitoring becomes one of tracking a student's development in an area of learning over time. In this context, the interpretations drawn about a student's achievements are drawn primarily in relation to their individual trajectory in an area of learning rather than age/grade expectations or the achievements of others. Where are the students in their learning now, compared with where they were before? What knowledge, skills, and understandings do they demonstrate now in relation to where we want them to travel next in their learning? What misconceptions that might block further learning do they still hold? What do they still need to know and what might be done to support their further development? The progress map provides the framework for teachers, parents, and students themselves to monitor and interpret learning across the years of schooling.

Advances in Modern Measurement

The use of a progress maps as the reference against which student learning is assessed and monitored also represents a paradigm shift of a different kind – an outcome in part of advances in measurement. Perhaps the single most important development in educational measurement in the twentieth century was the shift in focus from stand-alone instruments to underlying reporting frameworks. For much of the twentieth century, educational and psychological measurement was based on the construction of individual instruments (tests, questionnaires, examinations) and the development of norms for each instrument. Each instrument and its accompanying norm tables allowed students to be compared with each other.

The second-half of the twentieth century saw the development of methods for constructing and using reporting frameworks that are not tied to any particular instrument (in much the same way that measures of temperature or length have meanings that transcend the particulars of the instruments used to obtain them). One consequence of this development is that assessment instruments have moved from the foreground to the background: they have become mere vehicles for collecting evidence about students' levels of attainment within a domain of learning.

Advances in measurement theory have also made many of the old dichotomies less relevant. Modern educational assessment is fundamentally about inferring where individuals are in their learning. Students' performances on particular tasks are of interest only to the extent that they can be used to infer levels on attainment on the relevant underlying reporting framework. Inference is thus central to modern assessment, to developmental assessment, and to the use of progress maps.

An individual's level of attainment can be interpreted by reference to the underlying reporting framework (i.e., criterion or standards referencing) or by reference to the achievements of other students (i.e., norm referencing); but with the use of progress maps these different interpretations do not require different approaches to assessment. Similarly, an understanding of the stage a student has reached in his or her learning – including an identification of his or her knowledge gaps and misunderstandings – can be used either formatively to inform further learning or summatively to report that student's current level of attainment or to report progress since some earlier occasion.

In developmental assessment, the progress map provides the structure for this new way of assessing and monitoring learning. Regardless of the instrument used to collect evidence of learning, a student's level of achievement can be estimated (inferred) as a location along the map and can be reported in relation to the domain itself. That is, descriptively in terms of the attainments (knowledge, skills, understandings, attitudes, or values) typically demonstrated by students at that location or level of achievement in the particular domain. When the locations of a number of students are plotted on the same map, an individual's level of achievement also can be interpreted in relation to the achievements of others.

Progression

A progress map describes the knowledge, skills, and understandings of a learning area in the order in which they typically develop. These descriptions, sometimes called learning outcomes (descriptors, or indicators), are broadly described student behaviors, or sets of behaviors. For example, an outcome in physics might be “defines common forces using mathematical expressions and diagrams.” An outcome in writing might be “writes for a range of audiences and purposes.” Outcomes are accompanied by specific examples, sometimes called indicators or pointers, which illustrate and clarify the scope of each outcome. Locations along a progress map can be further illustrated with samples of student work: exemplars or work samples.

To facilitate the reporting and monitoring of student learning, a progress map is usually divided into stages, phases, or levels. The levels are sometimes numbered or given verbal labels that attempt to summarize in one or two words the kinds of observations typically made in each phase. For example, the levels of a reading progress map might be emergent, beginning, bridging, and expanding. The number of levels is always somewhat arbitrary.

Map Construction

The construction process begins with a decision about the number of maps to be defined within a domain.

For example, will a single progress map be developed for science, or will separate maps be developed for different aspects of science such as biological concepts and principles, and physics concepts and principles? The development of progress maps in some domains is more difficult than in others. For example, it is relatively straightforward to describe growth in factual and procedural knowledge when there are existing, well-defined grade expectations on which to draw. But for domains made up of key discipline concepts and principles, or for cross-curricular competencies, there may be less available knowledge about how learning progresses.

The next step is to develop a first draft of the progress map following one of two general approaches. Using the first approach, a top-down approach, teachers and subject-matter specialists draw on their professional knowledge together with relevant research findings about student learning to develop a picture of the sequence in which the knowledge, skills, and understandings of a learning area are typically developed. The draft that results from this approach is based on expert knowledge and opinion. Maps developed in this way need to be tested, refined, and enriched using actual student performances.

The second, bottom-up approach, uses only observations of student responses to develop a picture of progress. The draft that results from this approach is constructed from an analysis of recorded observations and judgments of actual student work. Because draft maps developed in this way are usually based on a small set of assigned tasks, they also need to be refined, enriched, and generalized by reference to a much larger bank of tasks and student work samples.

The step of constructing a first draft is followed by a refinement and enrichment stage. At this stage, two issues in particular are considered: the degree to which the described learning outcomes work together in practice to define a single learning domain against which students' levels of attainment can be estimated and monitored; and the degree to which the sequence of the described learning outcomes is supported by observations of student performance. The usefulness of the map as an assessment framework will depend on clarity about the nature of progression within each domain. If the learning outcomes do not work together to define a single learning domain, or if the map does not reflect progression of learning as observed in classrooms, then it will be difficult for teachers to use the framework to make decisions about attainment. If there is a very poor match – for example, if students typically demonstrate the knowledge, skills, and understandings described at level 4 on a map before they demonstrate those appearing at level 3, the draft map may be of little use as a frame of reference for monitoring learning.

Both issues are addressed through the collection and analysis of information about actual students' achievements. Common refinements include the reordering of misplaced

outcomes, the rewording of ambiguous or unclear statements, and the removal of outcomes that are not helpful in estimating a student's level of attainment (e.g., if the statement is true of all levels of attainment).

A further and ongoing task is to enrich the progress map. Each new assessment task, and its associated student work samples, has the potential to further elucidate the nature of development in an area of learning.

Progress maps developed from empirical evidence (bottom-up frameworks) are now used in international achievement surveys including the Programme for International Student Assessment (PISA), the Trends in International Mathematics and Science Study (TIMSS), and the Progress in International Reading Literacy Study (PIRLS); in national surveys such as the US National Assessment of Educational Progress (NAEP) and, in Australia, in the national literacy and numeracy tests (NAPLAN) and in resources for classroom use. **Figure 2** provides an example from PISA. In this figure, six levels of overall scientific literacy are described. These levels are constructed from an analysis of recorded observations and judgments of actual students' responses to multiple choice questions and constructed response tasks.

Assessment

The progress map provides the framework against which evidence of student learning is collected and assessed. In developmental assessment, records of observations of student achievement provide the evidence needed to estimate or infer a student's level of achievement on a progress map. Developmental assessment recognizes that different assessment methods provide relevant information about different kinds of learning. For this reason, a range of assessment methods will be needed to ensure that observations are relevant. For example, if the learning outcomes require evidence of students' abilities to write for a range of purposes and audiences, then a portfolio will be the most appropriate assessment method. One piece of writing will not provide the specified range of evidence. If the outcomes require evidence of students' abilities to collect, analyze, and report information, then a project may be the most appropriate assessment method.

Developmental assessment also recognizes that a wide variety of methods will be used to judge and record students' work. Some records will indicate whether tasks have been completed correctly; others will record partial

At level 6, students can consistently identify, explain, and apply scientific knowledge and knowledge about science in a variety of complex life situations. They can link different information sources and explanations and use evidence from those sources to justify decisions. They clearly and consistently demonstrate advanced scientific thinking and reasoning, and they are willing to use their scientific understanding in support of solutions to unfamiliar scientific and technological situations. Students at this level can use scientific knowledge and develop arguments in support of recommendations and decisions that center on personal, social, or global situations.

At level 5, students can identify the scientific components of many complex life situations, apply both scientific concepts and knowledge about science to these situations, and can compare, select, and evaluate appropriate scientific evidence for responding to life situations. Students at this level can use well-developed inquiry abilities, link knowledge appropriately, and bring critical insights to situations. They can construct explanations based on evidence and arguments based on their critical analysis.

At level 4, students can work effectively with situations and issues that may involve explicit phenomena requiring them to make inferences about the role of science or technology. They can select and integrate explanations from different disciplines of science or technology and link those explanations directly to aspects of life situations. Students at this level can reflect on their actions and they can communicate decisions using scientific knowledge and evidence.

At level 3, students can identify clearly described scientific issues in a range of contexts. They can select facts and knowledge to explain phenomena and apply simple models or inquiry strategies. Students at this level can interpret and use scientific concepts from different disciplines and can apply them directly. They can develop short statements using facts and make decisions based on scientific knowledge.

At level 2, students have adequate scientific knowledge to provide possible explanations in familiar contexts or draw conclusions based on simple investigations. They are capable of direct reasoning and making literal interpretations of the results of scientific inquiry or technological problem solving.

At level 1, students have such a limited scientific knowledge that it can only be applied to a few, familiar situations. They can present scientific explanations that are obvious and follow explicitly from given evidence.

Figure 2 Summary descriptions for six levels of overall scientific literacy in PISA. Adapted from Organization for Economic Co-operation and Development (OECD). (2006). *PISA 2006 Science Competencies for Tomorrow's World. Volume 1: Analysis*. Paris: Author.

understandings. Sometimes ratings of student work may be recorded either based on separate judgments of aspects of a piece of work (analytic ratings) or based on single overall (holistic) ratings.

As a progress map is a description of the path students typically follow as they progress through an area of learning, the records made for any particular student will only more or less resemble this path and an on-balance (or best-fit) assessment of the student's level of achievement will need to be made. For example, the levels of a progress map for the domain of writing may include descriptions of attainment that relate to the quality of ideas expressed in an extended piece of writing, the organization of those ideas, and the evidence of control over the conventions of punctuation, spelling, and grammar. The writing of an individual student may demonstrate strengths in all areas except spelling and punctuation, requiring an on-balance judgment of the student's level of achievement. In developmental assessment, there is no assumption that students will demonstrate all the skills, knowledge, and understandings below their estimated level of achievement.

Reporting, Interpreting, and Monitoring Learning

The progress map provides the structure against which the point-in-time achievements of an individual, a cohort, or subgroups are reported, and against which progress over time can be monitored. Where both individual and group information is reported concurrently, it is possible to compare the achievements of an individual with the achievement of others (norm referencing).

Figure 3 shows the point-in-time reading achievement of an individual in relation to the achievements of a cohort of students who were assessed at the same time. To the left of the figure is the scale against which achievement is reported; to the right is the alignment of the scale with the levels of the reading progress map. In the center of the figure is the distribution of the cohort of students' achievements. Students with the lowest levels of reading achievement are at the bottom of the picture; students with the highest levels are at the top. The level of an individual's achievement (student #201) is marked with an arrow.

Figure 4 shows the distribution of reading measures at years 3 and 5 for a subgroup of the population: low, medium, and high socioeconomic background.

Figure 5 shows the distribution of reading measures of the same cohort of students at year 3 and then at year 5.

While the progress map, by itself, does not answer questions about the adequacy of students' achievements in relation to expected achievement (absolute benchmarks) age/grade expectations are sometimes overlaid.

Figure 3 Individual student and cohort achievement in reading.

Figure 6 provides an example. Here, the level of expectation for year 3 students in reading is set at upper level 2 on the progress map (or 250 on the reading scale).

Whether the reported achievements relate to an individual or group, they are interpreted in relation to the map level descriptions – the kinds of knowledge, skills, and understandings typically demonstrated at each level of attainment. The level descriptions provide signposts – where a student has come from and where he/she is yet to advance in learning. What is the nature of the work that a student produces? What is the evidence of his/her learning? What does this evidence tell us about his/her ongoing learning? How much progress has he/she made over time, and what does further improvement look like?

The level descriptions send the message that all learners are on a path of development across the years of school and all learners are capable of making progress. They encourage teachers and parents to focus on the central issue of teaching and learning: what it means to get better (to grow, improve, or progress) in an area of learning. In addition, they provide a framework for students to monitor and reflect on their own progress and to develop metacognitive skills important in taking control of their learning.

Advances in Learning Research

The use of progress maps as a central support for teachers and students is consistent with advances in learning research. Research shows that learning is enhanced when teachers:

- see learning as a continuous, lifelong process;
- adopt a learner-centered approach focused on understanding the learning progress of individuals;
- draw out and work with individuals' current knowledge and beliefs;
- use this knowledge as a starting point for instruction and further learning; and
- carefully monitor individuals' developing understandings.

To do these things effectively, teachers require a deep understanding of learning and how it typically occurs within particular domains: the typical paths students traverse in achieving understanding, the difficulties they commonly encounter, the misconceptions they commonly develop, and effective strategies for promoting further learning. These understandings are an important part of a teacher's pedagogical content knowledge.

Research into the nature of learning in a range of domains is also drawing attention to the kinds of learning that result in deeper understandings of concepts and their application. The development of conceptual understanding allows knowledge to be organized and relationships to be understood. Deep understandings of concepts make it easier for learners to retrieve knowledge, interpret new information, and transfer learning to new situations.

Finally, learning research is identifying the importance of supporting learners to monitor and take control of their own learning. Learning is enhanced when students are supported in identifying where they are in their own learning, in identifying gaps and failures to comprehend, and in monitoring their progress over time. These meta-cognitive skills are important in students' development as lifelong learners.

The implications of these research findings are that assessments must be based not on the testing of disconnected facts (which may actually undermine learning with understanding), but on the depth of students' understandings. New technologies are needed for assessing learning in ways that track the growth of understanding, not just the accumulation of facts. A well-constructed progress map organizes knowledge in a way that brings conceptual

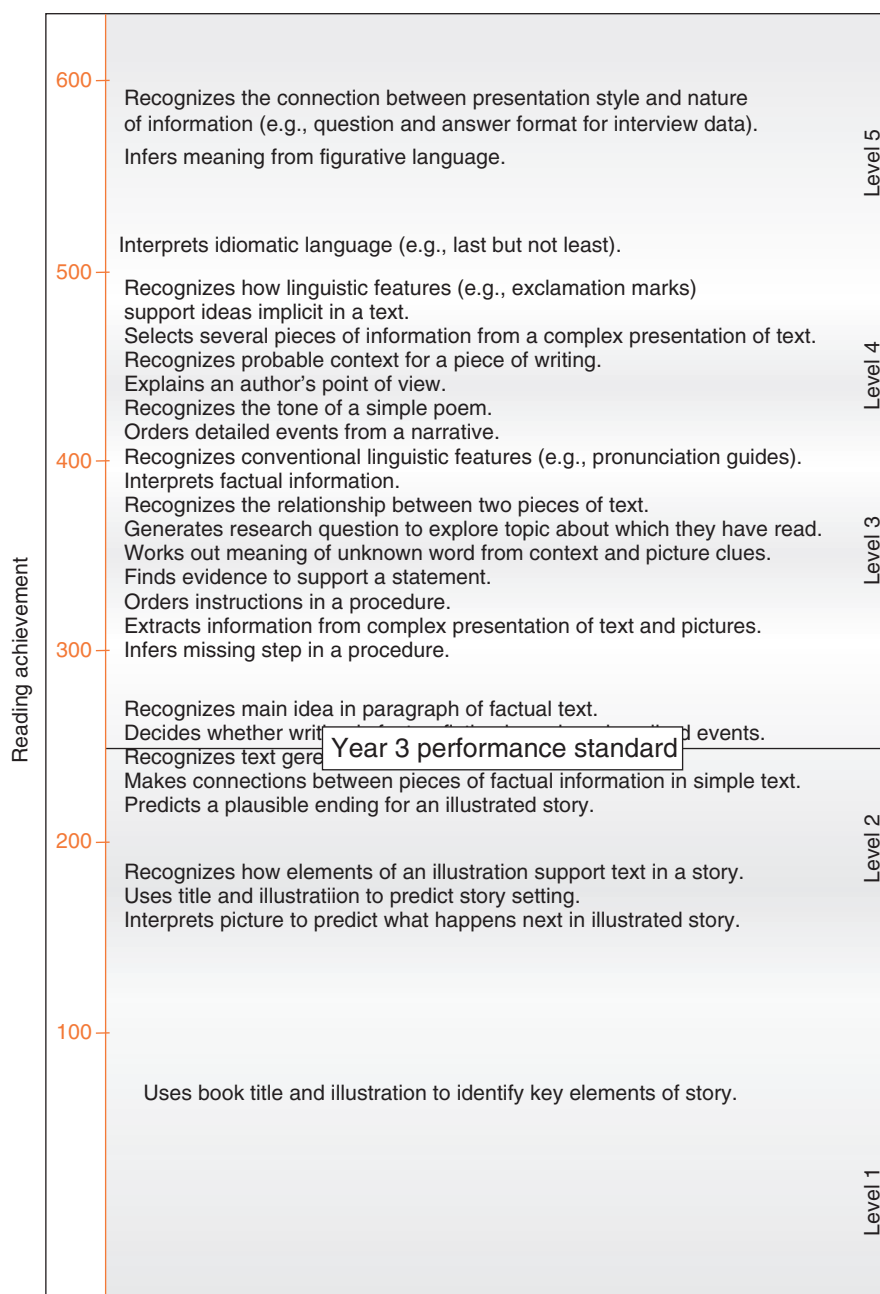

Figure 6 Reading-performance standard.

ideas to the fore, assists teachers to identify students' current beliefs, and provides a map of where students have come from and are going in their learning.

The use of progress maps is also consistent with formative-assessment research which suggests that in order to improve learning, teachers should discuss with pupils the purpose of their learning and provide feedback that will help the learning process; encourage students to judge their work by how much they have learned and the progress they have made; help students to understand where they are in relation to learning goals and how to

make further progress; and give feedback that enables students to know the next steps and how to succeed in taking them. Each of these strategies is facilitated by the use of a progress map.

Summary

Significant advances have occurred in recent decades in methodologies for assessing student learning. These advances can be understood in terms of advances in

measurement theory and in our understanding of learning itself. Central to modern approaches to assessment is the construction of research-based assessment and reporting frameworks in particular domains of learning. These frameworks capture and make explicit the nature of progress within a domain and provide frames of reference for monitoring learning across the years of school. They support teachers in identifying and working from individuals' current levels of knowledge and understanding. Consistent with current understandings of learning, these frameworks are most useful when they describe progress toward deeper conceptual understandings of subject matter. Empirically based reporting frameworks also play an important role in the communication of students' levels of achievement and progress and in supporting learners to monitor their own learning.

The key features of these frameworks (or progress maps) are that they:

- represent progress or learning as a continuous process (i.e., occurring on a continuum) across the years of school;
- describe the direction and nature of progress within a domain (i.e., what it means to learn or develop);
- provide a framework for monitoring growth and change;
- are research-based (i.e., are developed from empirical studies of how students learn);
- provide a frame of reference for monitoring and describing progress independently of the instruments or methods of assessment used; and
- provide a shared basis for describing and communicating achievement and progress.

Students' Rights in Assessment and Evaluation

J Gardner, Queen's University Belfast, Belfast, Northern Ireland

© 2010 Elsevier Ltd. All rights reserved.

If rights are interpreted strictly as legally supported entitlements, enacted through statute, then this article should probably end at this point. As far as we are able to determine, there are no specific rights for students in relation to the assessment or evaluation of their learning in any nation's legislation. (Arguably, the terms assessment and evaluation are nuanced in meaning but for the most part, assessment will be used in the article to relate to any process designed to appraise student learning.) However, there do exist educational principles, widely endorsed standards and codes of practice, and at least one legally binding set of international articles that can be used to underpin a discussion of students' rights in assessment.

Most jurisdictions have education-related rights based on statutory or common law, which may apply to assessment contexts depending on the circumstances. Some of these rights have considerable case law, most notably in the US and to a lesser extent the UK, Europe, and Australasia. They cover issues such as discrimination (numerous instances of disability, race, and gender actions over the past half century), parents' versus children's rights, free speech on campus, and youth culture. However, the most amenable measures, which afford at least the potential for legal protection of students in contexts involving assessment, are espoused under two internationally respected codes: the Standards for Educational and Psychological Testing (AERA *et al.*, 1999) and the Code of Fair Testing Practices in Education (JCTP, 2004). A third axis of potential protection derives from two articles of the United Nations Convention on the Rights of the Child (UNCRC, 1990), namely articles 3 and 12. These standards, code, and articles are discussed below, but first it is worth outlining why students should have the right to a greater say in the assessment of their learning.

Purposes of Assessment

Assessment can be argued to have many purposes, roughly positioned along a spectrum that ranges from the ad hoc question-and-answer sessions of teachers and students in classrooms to the formal examination style of assessment that tests students' levels of achievement after a period of learning activity. The former is generally located at what is called the formative end of the spectrum, where the purpose is primarily to provide support for students' learning, while the latter is generally located at the

summative end of the spectrum, where the purpose is primarily to identify a measure of the students' learning.

Assessment as Support for Learning

Over the past 10–15 years, there has been a growing awareness that the primary role of assessment should be to support learning. This realization is emerging as the result of a number of key developments, most notably the rise in importance of formative assessment, or assessment for learning as it has become known. A growing body of research-informed theory and knowledge has been accumulating in the field of formative assessment in relation to its practice and implications for policy (Gardner, 2006). In common with pedagogical approaches such as dynamic assessment and dialogic teaching, assessment used as support for learning promotes a variety of processes involving increased student participation and their owning of the learning activities. These include: sharing in the process of identifying learning objectives and success criteria between the teacher and the students; the development of peer and self-assessment; effective questioning, listening, and feedback techniques; and a conscious determination on the part of the teacher to recognize and affirm the full range of student achievement. Such processes promote the students' voice in their learning and assessment, while seeking to maximize engagement, not just with the lesson activities and content but with each other, with the teacher, and with the learning process itself.

The theory of formative assessment eschews the traditional didactic model of passive learners and directive teachers, instead giving the students their say in important aspects of their learning and its assessment. The argument draws on widespread evidence that formative assessment approaches can contribute to higher levels of student motivation, achievement, and participation.

Assessment of Learning

At the other end of the assessment spectrum, assessment of learning, which is generally summative in design and intention, largely continues to illustrate the phenomenon of doing to rather than with students. Such summative assessments may have several purposes but generally speaking they come at the end of a period of learning

(end of semester, end of year, etc.), are formal compared to classroom assessments, and purport to be objective and trustworthy. The underlying traditions of assessments for summative purposes include isolating students from sources of advice, support, or knowledge, and requiring them to address a set of tasks (questions, essays, problems, etc.) in time-bound circumstances, usually by means of pen-and-paper tests. Such conditions do not readily enable students to participate in the design or the content of the assessment. However, once the work is assessed, the students do enjoy some widely accepted entitlements, including specified circumstances in which they can seek to have grades or scores reviewed. In most national-education systems today, the main purposes of summative assessments may be summarized under two headings: accountability and credentialing.

Accountability Purposes

There is a variety of purposes to which assessments may be put and the most topical are arguably those that serve accountability. Aside from the traditional accountability of learners (how well they have performed), the last couple of decades has witnessed vigorous programs in the US and UK that incorporate the assessment of student learning to hold teachers, schools, and school authorities to account. One of these, the hugely important No Child Left Behind Act (NCLB) 2001 in the US, is silent on students' rights or perspectives on any aspects of its processes or impact, including assessments, though parents' rights are exhaustively detailed and secured. It has been in operation for 6 years without any noticeable attention to the students' perspectives on its processes or impact. The US NCLB and the UK Making Good Progress programs are typical of many recent educational policy developments around the world, inasmuch as they set targets for schools, based on the dubious proposition that testing and increased accountability raises standards. NCLB has attracted from educationalists who see it as damaging to its main disadvantaged target groups and to individual students (e.g., Houston, 2007; Nichols *et al.*, 2005).

It is only a small step from local accountability to making whole nations accountable for the success of their education provisions through, for example, international comparative programs such as the Trends in International Mathematics and Science Study (TIMSS) and the Programme for International Student Assessment (PISA). Almost without exception in these cases, the students are the cannon fodder in a battle between policy-makers and the school communities they oversee. They have next to no voice (except perhaps through the ventriloquism of their advocates) and precious little in the way of rights. Houston (2007), for example, claims that one of the deadly sins in the US NCLB is the "subjecting

of children to days of examinations annually, with the time taken away from instruction" while Skidmore (2003: 34/35) in the UK cites the statistic that "... an average pupil [in England] will now take 70 exams by the time they finish school [at 16]." In none of these circumstances has the student any rights to constructive participation in, for example, contributing to the identification of assessment criteria or design of assessment items and tasks. They are merely the subject of the tests.

Doing all of this to students has considerable cost implications. For example, the UK Association of College and School Leaders claims that many schools in the UK are spending more on examination fees than on learning resources, and that costs for examinations have risen by 51% in the past 3 years.

PriceWaterhouseCoopers (PWC, 2004) has modeled the examinations system in England (ranging across a wide variety of testing programs) and reported that in the year 2003–2004, its direct cost was £370 million with an additional £240 million on time costs, but excluding teachers' time in their assessment-support activities. There were also huge environmental costs in, for example, the distribution to test centers of 4.2 million test papers, 80 000 packages, and 237 million A4 sheets (Durant, 2003). In the US, Wallis and Steptoe (2007) estimate that the costs of independent state testing programs in the US (separate to National Assessment of Educational Progress (NAEP) testing) is in the region of US\$600 million.

Although the costs of external assessments may give cause for concern, the justification for such a huge investment in testing appears to be its perceived reliability. What, then, if external tests are not as reliable as the confidence in them implies? Research shows that systemic errors arising from the difference between students' observed score on specific test-taking occasions and their true score, as would be determined by an infinite number of test-taking occasions, can have considerable impact on results. These standard errors of measurement can cause an astonishing degree of misclassification in high-stakes testing (Black and Wiliam, 2006). In 2006, some 65 000 UK General Certificate in Secondary Education (GCSE) results were appealed and over 14 305 were regraded. Though a small percentage of the huge number of individual examinations taken (6.5 million), the fact is that many more students were likely to have been misgraded but they either did not know this or were unaware or did not take up their right to a review.

The most important observation in this situation is that these students exercised their right to request a review of their grading. This right has been offered by the UK examination authorities to students for some time. However, to assume that such a right is granted primarily from a natural-justice perspective would probably be an overly generous analysis. Newton and Whetton's (2002) four objectives for student appeals illustrate that the right of

appeal has less of a rights perspective than a pragmatic purpose. They identify appeals as serving a measurement objective, which is designed to maximize the measurement accuracy of the test in question (i.e., more accurate grade attribution) and a political objective, which is intended to safeguard public and professional confidence (i.e., the “if we find a mistake, we fix it!” assurance). There is also an educational objective for student appeals, one of contributing to teachers’ professional development by sharing the outcomes and reasons for appeal decisions. Finally, there is a tip of the hat in the direction of students’ interests with the objective of aiming to minimize any negative psychological consequences for them.

Credentialing Purposes

On an individual level, the credentialing purpose of assessment, that is, the award of qualifications in academic or vocational settings, is perhaps the most pressing for many students. Test programs that lead to qualifications or credentials are generally taken by students because they need them to demonstrate that they have a certain set of skills or that they have the necessary qualifications to progress to the next step in their careers. For some years now, qualifications-oriented programs have been expanded to include key skills (sometimes known as basic or transferable skills) such as literacy, numeracy, information technology, and working together. The concept of twenty-first-century skills is also gaining ground, for example, Baker’s “... adaptive problem-solving, risk assessment, managing distraction, self-management and changeable roles” (Baker, 2007). Such skills are simply not being assessed properly at present, if at all, and much needs to be progressed before students can avail of their entitlement to valid and reliable assessment in important new areas of learning.

The pursuit of qualifications may also have the objective of seeking admission to a college or university course, to a selective school or to the world of employment. As such they are high-stakes tests or assessments and it is entirely reasonable for students to expect and indeed demand accurate and valid assessments of their performance. To this end, two codes of good practice, the Code of Fair Testing Practices in Education (JCTP, 2004) and the Standards for Educational and Psychological Testing (AERA *et al.*, 1999), have been widely endorsed as guides to good assessment practice.

Writ large in the American Educational Research Association (AERA) standards is a recognition of the perspectives of the different stakeholders in assessment contexts; from parents, teachers, and students through to the test developers and those who use them for assessment purposes. Most importantly, for our purposes, they also provide a comprehensive overview of the rights and

responsibilities of students (or test-takers as the standards more precisely define those who are assessed) whether in educational, legal, or employment contexts. For example, the first reliability standard, Standard 2.1 (S 2.1) states that:

... estimates of relevant reliabilities and standard errors of measurement or test information functions *should* be reported (our emphasis) (AERA *et al.*, 1999: 31).

It would seem reasonable that students should be able to determine the accuracy of any measurements of their performance, but in some significant instances, most notably the formal assessments of school students of the UK, the examination authorities are silent on the technical performance of the tests. Examination processes remain arcane with little or no information being made available in relation to reliability or validity, and no recognition of the rights of students to have access to this type of information. Yet, as we mention above, reliability is demonstrably a problem.

The large majority of the 264 standards are characterized in their language by the use of the word *should*. If this was the imperative *should*, and if there was a means by which the standard could be enforced (which there currently is not), then they would underpin legally protected student rights. However, there is little prospect of them being formally enshrined in law and it will likely remain an advisory *should*. The term *rights* is therefore something of a misnomer, and its substitution by a term such as *expectations* is arguably more accurate. Although not immediately obvious, the language of the standards is quite circumspect, carefully written to avoid any charge of being dogmatic or any potential of being used inappropriately, such as might be the case in attempts to override professional judgment. In situations in which assessments are being subjected to legal scrutiny or challenge, the standards are crystal clear about their advisory role: “... the intent of the Standards is to offer guidance for those judgments” (AERA *et al.*, 1999: 4).

The standards may stop short of speaking to legally enforceable rights but they are no less important in informing professional judgment and in their advocacy of fair and good practice (see, e.g., Camara and Lane, 2006). Among the instances of good practice in seeking to protect student interests and rights, are those standards that specifically address issues of information, consent, privacy, and appeals. For example, the standards articulate the view that if any information about an assessment is given to any candidate, it should be given to all of them (S 8.1). The information should cover all important aspects of the assessments including the intended use of the results, scoring criteria, confidentiality, re-sits, and the release of results (S 8.2). The consent of the student to be assessed is seen as a major principle of procedural propriety, though several potential exclusions are offered: when

the testing is mandated by government; when the testing is a routine part of school activities; and when consent is obviously implied. For example, consent may be assumed in an employment-selection context when the act of applying is deemed to include consent to undertake any assessment that is a part of the process (S 8.4). There should be an entitlement to have the privacy of individuals' results maintained (S 8.5) and secure arrangements for storage of the results (S 8.6). In decision situations, the student should be entitled to receive details of the results and scores, and of their interpretation (S 8.9). Such information should also inform students of any recourse to appeals, challenges, and reviews (S 8.10).

While one whole chapter (chapter 8) of the standards is given over to the rights and responsibilities of test-takers, the other chapters also contain standards that speak to students' rights. For example, if the integrity of a test score is challenged, the student should be informed of any rights to appeal and to have legal representation (S 11.11). Standard 13.14 also states that information on the extent of possible misclassification and errors in measurement should be released.

Much of the intention behind developing the standards was to ensure reliable, fair, and valid testing of students and others, particularly in high-stakes settings, but they are nonetheless daunting for the average student, parent, or person who is not *au fait* with assessment terminology. As a means of making the underpinning principles of the standards more accessible, the Joint Committee on Testing Practices (JCTP) issued their 1988 Code of Fair Testing Practices in Education. This was updated in 2004 and "...applies broadly to testing in education (admissions, educational assessment, educational diagnosis, and student placement)" (JCTP, 2004: 2).

In essence, the JCTP code addresses the importance of students (test-takers) having the fullest information possible, including what rights they may be granted in terms of appeals, having their scripts returned, or being able to take re-sits. As with the standards from which they are derived, they are also advisory. However, in combination with the standards they present a formidable array of widely accepted good practices in assessment, to which most courts and legally constituted tribunals will have due regard.

United Nations Convention on the Rights of the Child

As mentioned above, the United Nations Convention on the Rights of the Child is the third axis of possible protection for students' rights in assessment, or at the very least those students who are under 18 years of age, which is the definition of the child under the Convention. At first sight, this might appear an unlikely bastion for

students' rights in assessment, focusing as it does on issues such as children's fundamental rights to life, freedom from abuse, and from recruitment to armies. Ratified by 192 countries, with the remaining two as signatories (the US and Somalia), courts have less leeway to reject rights actions that arise under the relevant articles of the Convention. Aside from the education-specific articles such as 28 and 29, which respectively assert the right to primary education and to the development of personality and talents, the key articles for our purposes are:

1. *Article 3.* In all actions concerning children, whether undertaken by public or private social-welfare institutions, courts of law, administrative authorities, or legislative bodies, the best interests of the child shall be a primary consideration.
2. *Article 12.* States/Parties shall assure to the child who is capable of forming his or her own views the right to express those views freely in all matters affecting the child, the views of the child being given due weight in accordance with the age and maturity of the child.
3. *Article 3.* This has the potential to call into doubt the legality of the testing regimes currently holding sway in the US and England (not, it should be noted, in the three other UK home countries, Scotland, Northern Ireland, and Wales. In these nations, much of the London-led accountability testing has been abandoned as counter-educational by their devolved governments). Many commentators have called the preponderance and nature of the testing into serious question and some researchers are beginning to bring a United Nations Conventions of the Rights of the Child (UNCRC) lens to bear on the issue (e.g., Yates, 2006). Clearly there is an argument that state testing programs in the US, and the national-curriculum tests of England, are not in the best interests of the young students concerned. Probably more to the point, however, is the tenuous validity (and ethical basis) of using such tests of students' learning for a purpose that is some way removed from their individual learning and progression, that is, school and state accountability.

Article 12 brings the matter of assessment propriety into particular focus. High-stakes tests are so called because they have the potential for considerable impact, whether positive or negative, on students' educational or career choices. More often than not, however, the students concerned have little say either in formulating or responding to any aspect of the major decisions that directly affect them and which arise from such tests. The extent to which re-sits are offered, actual annotated test scripts are returned for scrutiny, information on scoring is shared, or feedback on performance is offered, is generally in the gift of the examiners – and not an established right of the students. The AERA Standards and JCTP Code set out clearly what should happen and it is possible that the UNCRC will

provide a legal platform from which to challenge the more arcane of assessment practices today. However, one major obstacle stands in the way – the special place given to academic judgment.

Academic Judgment

Unless there are procedural or technical grounds for challenging a grade or score, it is most likely that students appealing the assessment of their performance in a test will face the dictum, especially in higher education institutions, “We cannot accept challenges to academic judgment.” For example, the UK’s Quality Assurance Agency (with a remit for the quality assurance of teaching and learning in UK universities and colleges) say simply that “[Since] most institutions do not allow appeals against the exercise of academic judgment . . . it would therefore be helpful to define what constitutes an academic judgment” (QAA, 2008: 7). It defines an appeal as “. . . a request for a review of a decision of an academic body charged with decisions on student progression, assessment and awards” (QAA, 2008: 4). Another body, the Office of the Independent Adjudicator for Higher Education (England and Wales) similarly states: “We cannot look at a complaint if . . . it relates to a matter of academic judgment” (OIAHE, 2008) yet it does allow what it terms academic appeals. The adjudicator can recommend compensation and in the examples of the 32 completed cases provided on the website, compensation payments of up to £9000 for students are recorded. Although these are clearly not court-of-law judgments, they are beginning to form a body of case law in the context of university students’ rights in the assessment of their performance.

Disbarring appeals against academic judgment is not a simple expedient on the part of examination authorities, whether university boards of examiners or major testing agencies. Judgments of student performance, other than the purely correct/incorrect dichotomies of aspects of some disciplines such as mathematics, are generally supported by processes such as those that promote inter-judge (inter-rater) reliability. An example of this process is known in the UK as moderation, in which examiners’ grades and scores are checked and calibrated by other examiners. Agreement trials are processes in which a group of examiners take samples of student scripts and grade them together, aiming to develop a connoisseurship among the examiners on the standards to be applied. There are also systems of double marking (where two examiners independently grade the work) and anonymous marking (to ensure that knowledge of the student does not influence the examiner’s grading). The purpose of all such procedural devices is to ensure that the assessments are as reliable as possible and executed fairly across the

test-taking group. Notwithstanding these efforts, however, much of the process remains largely hidden and unknown to the student. Disappointment with their grading will often prompt students to appeal, to be told that only technical or procedural grounds are allowed.

Courts for their part are also notoriously wary of becoming involved in challenging the internal judgments of schools, universities, or examination agencies. Unless there is *prima facie* evidence of malpractice, which is amenable to statutory or common law redress (e.g., some form of discriminatory practice), they will often not proceed. Even if there is an assessment appeal purporting to be a contravention of UNCRC Article 3 or 12, the prospect of a case coming down to the consideration of the reliability or validity of an academic judgment may well jeopardize any potential finding for the student concerned, specifically because it is considered so difficult to mount an effective challenge to academic judgment.

Summary

Students’ rights in relation to the assessment of their learning or performance do not specifically exist in legislation in most jurisdictions. However, the long-standing and highly respected AERA and JCTP guidelines enshrine many expectations for fair treatment. Arguably, these have the intention of prescribing entitlements or rights and the rationale seems eminently reasonable for expectations such as receiving academic information on tests (e.g., the curriculum covered and assessment criteria), receiving technical information on tests (e.g., reliability and validity), having annotated scripts returned, having recourse to appeals, and having opportunities to re-sit a test. Two main factors seem to be in play: a keen sense of natural justice among educators and an increasing academic and professional understanding of the extent to which uncertainty in scores undermines the pursuit of absolute measures of performance.

As time goes on, the hope must be that increased compliance with the AERA Standards and JCTP Code will reduce the potential of unfairness in treatment or outcome in assessment of students. But when needed, there is the increasing prospect of legal strengthening of students’ rights, especially in high-stakes testing. This will most likely occur through bringing to bear national instruments such as the Bill of Rights or international treaties such as the UNCRC, both of which have seen considerable impact in contexts of discrimination in education over recent years.

Summative Assessment by Teachers

R Daugherty, Cardiff University, Cardiff, Wales, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Teachers routinely sum up what their students have learned. They cannot expect to be able to move students on in their learning, either individually or as a group, if they have not established where those students have reached. The skill of summarizing is therefore integral to instruction and to informing instructional practice.

Teachers sum up in a multiplicity of ways, from an informal comment on a particular piece of work to a formal grade generalizing about overall performance. What marks out such summing up as summative assessment is not the extent of the formality or of the generalization but the purpose or purposes for which it is undertaken. Where the teacher is making a judgment that is part of a dialog between teacher and student to help the student learn more effectively that summing up is part of the process of formative assessment. If, however, the teacher's judgments are directed toward a record of student performance that is to be communicated to others, within or beyond the school, we are into summative assessment – evaluating learning in ways that are determined by the needs of others for evidence of student performance.

Assessments designed to meet summative purposes may sometimes have formative spin-offs; teachers and students can adapt subsequent learning to take account of what such assessments have revealed. But the form those assessments take and the approach of both teacher and student to them will reflect the needs of the user(s) for the performance data that emerge from them.

There are numerous possible reasons why information about the performance of students might be needed by someone other than the teacher and the student. These purposes will be referred to here in three broad categories:

- reporting on the individual student to other teachers in the same school, to another school, or to a parent/guardian;
- reporting on individual performance as part of a process leading to the student being awarded an external qualification; and
- reporting on the performance of groups of students to supply aggregate data which managers of the school system will use to monitor the performance of teachers and schools.

Each category places particular demands on the way the evidence of performance is generated, evaluated, and reported. The school and its teachers have to be able to

respond to needs as diverse as a parent wanting to know how his/her child progressing, an agency managing a national qualification that is awarded to many thousands of students, and a school district monitoring the performance of the schools for which it is responsible.

One definition of summative assessment by teachers, precluding the possibility of teachers assessing the performance of students other than those they have taught, is:

The process by which teachers gather evidence in a planned and systematic way in order to draw inferences about their students' learning, based on their professional judgment, and to report at a particular time on their students' achievements (Assessment Reform Group, 2006: 4).

In the article, discussion of the teacher's role in summative assessment extends beyond systems of assessment in which teachers are making judgments about their own students. The above definition is, however, helpful in highlighting four crucial features of summative assessment by teachers:

- it is systematic, occurring within a system;
- it requires teachers to draw inferences from the evidence they have of student learning;
- it calls for teachers to exercise their judgment; and
- it involves some form of report on student achievement.

It should also be noted that the systems, inferences, judgments, and forms of report can be expected to be purpose specific; a teacher will be responding concurrently to several different sets of requirements for data about student performance. What is needed by the student's parent will make demands on the teacher's record-keeping, judgment, and reporting that are different from, for example, the requirements of the school's monitoring procedures or of the agency managing a national qualification. For many teachers it is the within-school procedures that make the most frequent demands on them to sum up student performance. However, it will be on the other two categories – the award of external qualifications and the supplying of data for system monitoring – that this article focuses.

Why a Role for Teachers?

The case for teacher judgment contributing to the way student performance is evaluated, whatever the use that is to be made of the evidence thus generated, has been well

rehearsed. In principle, it rests on the argument that teachers can sample the range of a student's work more fully than can any assessment instruments devised by an agency external to the school, thus enhancing both the reliability (more evidence) and the validity (a wider range of evidence) of the assessment. Various interpretations in different cultural contexts, this argument has fueled the case for performance assessments in the USA (Resnick and Resnick, 1992), for assessment by teachers in high school qualifications in the UK (Wilmot, 2004), and for reliance on teacher judgment in school-based assessment at the end of secondary school in Queensland, Australia.

Broadfoot (1995) interpreted the increased use of performance assessments as part of a broader international trend with five main elements:

- greater reliance on formative, learning-integrated assessment;
- a commitment to improving teacher expertise in assessment;
- increasing emphasis on validity in relation to the full range of curriculum objectives;
- increasing emphasis on describing learning outcomes in terms of specified standards; and
- increasing emphasis on using assessed learning outcomes as an indicator of the quality of educational provision.

It is worth noting here that the advocacy of teachers having a role in summative assessments is based on the teacher being able to draw on a wider range of evidence available (rather than a small, time-limited sample) and being better placed to draw inferences from the evidence (through familiarity with what students' work reveals about their learning). It is not in essence a matter of the assessment instruments that are deployed. For example, both the external agency and the teacher may well draw inferences from test-based assessment instruments though, for practical reasons, the external agency will necessarily be more dependent on such instruments. To discuss summative assessment by teachers in contradistinction to external tests/examinations is to conflate the who of judgment with the how of assessment procedures.

If the arguments in favor of the teacher's role in summative assessments are so persuasive, then that way of assembling evidence and drawing inferences might be expected to have a prominent place in systems of assessment across the globe. Some of the reasons why this has not occurred will become apparent from a review of practice in a range of contexts.

Summative Assessment by Teachers in Practice

There is enough experience from different countries of summative assessment of student work by teachers within

large-scale systems of assessment for some conclusions to be drawn about its use in practice. Three case studies are briefly summarized here as a prelude to the discussion being broadened and to identifying recurring themes.

Portfolio Assessment in a State-Wide Assessment Program: Vermont, USA

Disillusionment with models of state-wide testing that relied on multiple-choice test instruments led a minority of US states to experiment in the 1980s and 1990s with various forms of performance assessment. One such form is the assessment of a portfolio of student work, sampling a student's performance more fully than either multiple-choice or constructed response tests presented under standard conditions. In this form of assessment, the work to be judged is accumulated during a course of study, allowing for greater diversity both in the individual student's response to the tasks set and in the conditions under which it is completed. Maintaining a degree of standardness that should, in principle, make consistent judgment possible across a large student cohort is achieved partly through a task specification that is common to all and partly through rules for scoring the portfolios.

The original plans for state-wide assessment in the state of Vermont gave portfolio assessment in the two assessed subjects (mathematics and writing in grades 4 and 8) equal status with the test-based assessments of those subjects. Students and teachers selected what they judged to be the best pieces of work for each student while also taking account of requirements for specified types of work. For state-level reporting, after early experiments with teachers scoring their own students writing portfolios, the portfolios were scored by teachers other than the students' own.

There were marked disparities in the scoring of portfolios in the early years of the Vermont program. Subsequent refinements in the rubrics and in the training of teachers achieved relatively high correlation between scorer ratings in mathematics, with improved but lower levels of consistency in the scoring of writing. Rater inconsistency was not, however, the largest source of unreliability in the scoring of portfolios. From the evaluation of the early implementation of the Vermont program, it was apparent that the sampling of tasks contributed substantially to the unreliability of scoring of the mathematics portfolios; different selections of tasks would have resulted in substantially different ratings. Another variable in the compiling of portfolios was the extent to which teachers provided assistance to students, including whether students were encouraged to revise the pieces of work that would be selected for inclusion.

The conclusions drawn by Koretz (1998) from his review of the evidence from four large-scale programs using portfolio assessment in the USA are not encouraging:

Portfolio assessment has attributes that make it particularly appealing to those who wish to use assessment to encourage richer instruction – for example, the ‘authentic’ nature of some tasks, the reliance on large tasks, the lack of standardization, and the close integration of assessment with instruction. But some of these attributes may undermine the ability of the assessments to provide performance data of comparable meaning across large numbers of schools (Koretz, 1998: 332).

Coursework Assessment in a National Qualification: The General Certificate of Secondary Education, England

The General Certificate of Secondary Education (GCSE) was established in the mid-1980s as a subject-based national qualification for students at age 16 in England, Wales and Northern Ireland. Its main rationale was that the high-status qualification that it replaced, O level, had relied too much on time-limited written examinations which prioritized a narrow range of academic attainments. The new qualification, it was claimed, would recognize a wider range of attainments; it would assess not only student performance in written examinations but also what students know, understand and can do. In short, it would be more valid.

Coursework assessment was to be the means of achieving this goal, building on the experience of in-course assessment that had been gained through the lower-status qualifications that were, along with the O level, replaced by GCSE subject certification. The arguments for teachers contributing to summative assessments of their students were accepted and signed up to by all the main interest groups, including the Conservative government responsible for implementing the new qualification. However, it remained unclear what was actually meant by coursework assessment and how an acceptable level of consistency would be achieved in the summative assessments for which teachers would be responsible.

In the event, each of the several agencies responsible for awarding the new qualification put in place its own arrangements, lightly regulated by the national organization overseeing the examination. The activities encompassed under the umbrella term of coursework were extraordinarily diverse, from portfolios in art and English to laboratory tasks in science but also including a proliferation of activities in minority subjects that were also scored by the students’ own teachers. In the overall GCSE grade, the notional weighting accorded to coursework ranged from as low as 10% to 100% in one high-profile scheme in English. The only system-level attempt to enhance consistency of teachers’ practice and of teacher judgment was a national (but not compulsory) scheme of

training for one teacher from each school in the ten most popular subjects, supported by publication of guidance materials.

Within a very short time, media reports of students plagiarizing the work of other students, parents completing their children’s work for them, teacher bias, and sundry other indefensible practices undermined public confidence in the new qualification. The GCSE was always going to find it difficult to match the respect that had been accorded to the O level, an examination tailored to what were assumed to be the academic needs of the minority of students who attended selective secondary grammar schools. However, those responsible for its implementation had failed to think through, plan for, and regulate effectively a qualification that would depend substantially on tens of thousands of teachers in over 100 subjects managing and scoring work undertaken by their own students.

An initial phase of reduction in the reliance on coursework for the award of GCSE grades, coupled with tighter regulation at national level, quickly followed in the early 1990s. A second phase, abandoning the term coursework and further limiting the role of teachers in contributing their judgment to the award of the qualification, was implemented from 2009. The new controlled assessments would be designed to ensure an acceptable level of consistency in the setting, taking and scoring of in-course tasks.

Continuing concerns about the reliability of teachers’ assessments of individual students were not the only reason for coursework assessment being abandoned. The GCSE had been introduced as a qualification for individuals to aim at. Twenty years on, with governments in England as elsewhere in the world using data from a range of sources to monitor system performance, GCSE grades aggregated across cohorts of students had become the main indicators of the performance of high schools in England. High school teachers were not only being expected to contribute to the grading of their students, they were also participating in supplying the data on which their own, and their school’s, performance would be judged.

National Monitoring of Educational Achievement: New Zealand

Some national education systems rely on a sample of performance data collected for that purpose for the monitoring of system performance. Other systems analyze and interpret data obtained from every student in the selected cohorts. For example, England abandoned its sampling system, the assessment of performance unit (APU), in the late 1980s in favor of using data on every student in the cohort gathered either from national-curriculum assessments at ages 7, 11, and 14 or from the grades achieved by students in national qualifications at ages 16 and 18.

A national system of sampling student performance in which teachers have a central role is New Zealand's National Education Monitoring Project (NEMP). Each year, about a quarter of the areas within the New Zealand Curriculum Framework for children in years 4 and 8 are targeted by a range of tasks designed to elicit students' attainments through approaches that interest and stimulate them. These tasks are administered to a sample of about 2.5% of the two cohorts by teacher administrators seconded to work in pairs assessing children in several schools over a 5-week period.

The students' responses are forwarded to be marked centrally. Teachers are also recruited at that stage in the NEMP to mark the tasks that require higher levels of professional judgment. Evidence of performance is not confined to the students' written responses to tasks. By 2006, two-thirds of the evidence of student attainment was in the form of videotapes of the interaction between student and teacher administrator, allowing for a rich analysis of both process and task achievement.

Several features of the role of teachers in the NEMP are worth highlighting in the context of this review of summative assessment by teachers:

- Only a selected group of teachers is engaged either in administering or in marking students' work. By giving priority in each year's selection as teacher administrators to teachers who have not previously been engaged as teacher about 5% of primary teachers had undertaken that role over the first 12 years of the NEMP.
- There is at least as much focus on how the tasks are administered as on how they are marked, ensuring close scrutiny of how the evidence of attainment has been obtained.
- The teachers who manage the task administration and those who mark the students' responses are trained; teacher administrators undergo a week of specialist training.
- Substantial gains in professional learning are reported (Gillmore, 2002) for those teachers.
- Teachers are engaged in managing and judging the performance of students on curriculum-related tasks but, crucially, not the work of the students they teach or of other students in the schools in which they are employed.

Overview

Reference to only three of the many examples that could have been quoted runs the risk of distorting what emerges about the role of teachers in large-scale systems of assessment. For example, more than 30 years experience in the Australian state of Queensland of school-based assessment at the end of secondary school paints a more positive picture of teacher judgment having a central role in the award of a qualification. On the other hand, 20 years

experience of a national-curriculum assessment system in England has shown that, when the stakes are high and no more than token recognition is given to the judgment of teachers, the role of teachers as assessors in national systems can become peripheral (Whetton, 2009).

A systematic review of the evidence of reliability and validity in assessment by teachers for summative purposes (Harlen, 2004) brought together evidence from a range of academic studies of the practice of summative assessment. Several of the findings from that review point to ways of enhancing the contribution of teachers to the judgments made about large cohorts of students:

- The low reliability of portfolio assessment where tasks are not closely specified, as was the case in Vermont, argues for closer task specification.
- Clear specification of the criteria by which performance is judged can also improve reliability.
- The clearer teachers are about the goals of students' work, the more consistently they apply the criteria used to judge performance.
- Where teachers are required to assess their own students, steps need to be put in place, through training, to minimize bias in teacher judgment and, through monitoring outcomes, to detect malpractice.

As is inherent in any review of relevant research, the systems of summative assessment by teachers included in Harlen's review varied greatly in many respects: teacher expertise; the training available; whether or not teachers are judging their own students; and the way teacher judgments are moderated. The contexts in which teachers were making judgments of student performance were also diverse: different purposes (including qualifications for individual students, system-wide monitoring and holding teachers and schools to account); different types of demand for performance data; and the degree of trust accorded to teachers' professionalism. As Madaus and Kellaghan (1993: 459) noted in their observations on experiments with authentic testing in England, the arguments for teachers to have a role in large-scale systems of summative assessment must be evaluated in relation to two realities:

First, there are many practical, technical and infrastructural issues that must be resolved before such techniques can safely be deployed as policy instruments on a large scale in schools. Second, claims about the positive effects of such techniques have to be examined in light of how the results will be used.

Summative Assessment by Teachers: A Process

The teacher drawing inferences from evidence presented by a student is only one stage in a process that has several

key components. To understand summative assessment by teachers, we need to understand how each stage plays its part in the overall process.

Task Specification

A task must have been completed if the student is to present evidence on the basis of which a performance judgment can be made. This is equally true when the student is responding to a question in a test but that test question is notionally the same for every student in the cohort. However, to define closely the nature of the task(s) to be undertaken by each student in a system of summative assessment by teachers would be to compromise its potential to be more valid than a system that is wholly dependent on evidence from the student's performance in a test.

The tasks should, in principle, reflect the educational outcomes of the course of study. If speaking a language is an integral part of learning it, then an assessable task will call for oral proficiency to be demonstrated. If practical skills in the laboratory are valued outcomes from a course of study in science, then laboratory skills should be assessed. Systems of summative assessment by teachers open up a wider range of task possibilities but do not preclude the use of test-based instruments.

Amidst that diversity there needs to be some commonality of tasks across the whole student cohort. For the designers of systems of summative assessment, there is a delicate balance to be achieved along a continuum from precise task specification to loose guidelines. It is possible within a framework of specified tasks, as the New Zealand monitoring project illustrates, to offer students considerable scope to show what they are capable of.

Task Conditions

For a student to produce her/his best possible response to a given task, there will need to be some flexibility allowed in the conditions under which the task is completed – time to plan, to revise drafts, or to access relevant information. Two main threats to the validity and reliability of the outcomes can arise from that flexibility. One is that the conditions under which the students across the cohort have completed the task are too variable for their performances to be judged fairly. The other is that the openness of conditions under which the work was completed will have resulted in much or all of it not being the work of the student in whose name it is submitted.

Once again there is a delicate balance to be achieved by system designers. Students may be required to complete tasks under supervision and with minimal support but where would be the potential in those conditions for the student to produce a best performance across a range of curriculum goals? On the other hand, as with the nature

of the tasks themselves, if the conditions under which those tasks are completed are too variable, the outcomes will be, and will be seen to be, unreliable.

Which Teachers' Judgments?

Discussion of the merits of summative assessment by teachers has sometimes been clouded by a lack of clarity as to which teachers are called upon to judge student performance. There are three possible answers to that question:

- a teacher who has also been responsible for setting and managing the work that is to be judged (the GCSE example above);
- a teacher working closely with the teacher who has set and managed the work, possibly in the same school (the Vermont portfolios example above); and
- a teacher whose workplace is equivalent to, but entirely separate from, the school in which the work they are judging was undertaken (the New Zealand NEMP example above).

For teachers in the first of these categories, their knowledge of the students concerned could enable them to make more appropriate inferences from the evidence than would be possible for a teacher who did not know those students. On the other hand, there is also evidence from research (Harlen, 2004) of bias in judgments by a student's own teachers, much of it unintentional. In the third category, the rationale for teachers judging student performance is that they are drawing upon the professional expertise they bring from their own classroom experiences.

Criteria and Performance Standards

Any judgment of student performance will involve the application of criteria to match the available evidence against expected standards of performance. The criteria identify the critical features of the student's work, the standards identify the level(s) of performance against which that evidence is to be judged. As Sadler (2009: 160) explains it:

Divergent works are typically complex, in the sense that their quality can be explained only by reference to multiple criteria, possibly including some that are abstract in nature . . . A *criterion* refers to a property, quality, characteristic or attribute of a student response. It is distinct from a *standard*, which refers to a particular degree or level of quality.

In a straightforward marking rubric for a test in which the person scoring the test is not expected to exercise her/his own judgment, the criteria may remain implicit and the performance standards may be expressed only in terms of an overall cut-off score.

But for a more sophisticated judgment of less straightforward evidence, such as that in a set of portfolios, it is essential to make the criteria as explicit as possible and to show how the performance standards can be operationalized. Experience from systems that have relied, at least in part, on teacher judgment has shown that the involvement of teachers in the generation of criteria and in shared interpretations of standards can, over a period of time, enhance both the validity and reliability of outcomes.

What Inferences

Once the tasks specifications, task conditions, criteria, and performance standards are in place, it may sound deceptively easy to say that teachers will then be able to draw inferences from the available evidence of student performance. But what kind of inferences are they expected to draw and to what purpose? It is one thing for a classroom teacher to grade the performance of each student for internal monitoring within a school but quite another for a teacher to draw inferences that will be used to determine whether a student is awarded a national qualification.

The translation from evidence via inference to the reporting of performance can take many different forms. It can result in a numerical score, a grade, or a profile of the attributes that the work has displayed. Even within the same system, the form of the inferences teachers are expected to draw from the evidence can be radically changed. The teacher assessment element in national-curriculum assessment in England moved on from compartmentalized judgment in terms of statements of attainment and attainment targets to an expectation that teachers would make holistic best-fit judgments, matching any available evidence of student performance to multifaceted levels of attainment. There is evidence from a number of contexts of significant variability in the way teachers draw inferences and make judgments, suggesting a need for research into the deep structures of teacher judgments and the underlying conceptualizations.

A Systematic Approach

The definition quoted at the beginning of the article drew attention to the fact that, as with any large-scale arrangements for assessing the performance of students, a system must be in place within which those stages in the process of assessment can be operationalized. The structures and procedures within that system will need to be fit for purpose. Experience of summative assessment systems in which teachers have an active role suggest that there are several aspects of system design that are critical to the system being fit for purpose.

1. *Explicit procedures for each stage in the process.* It might seem obvious from the previous section of this article that the answers to the system design questions referred to there would be decided and communicated to the teachers involved in advance of implementation of a new assessment system. That there are many instances of this not being done suggests that the subtleties and complexities of enabling teachers to contribute their judgments to large-scale systems of assessment have often not been recognized. For example, initial planning at the national level for the teacher-assessment element of national-curriculum assessment in England consisted of little more than pamphlets that were long on generalization and short on practical suggestions.
2. *Teacher expertise.* Systems of assessment where the teacher has a role in setting and managing the tasks, as well as in drawing inferences from, and making judgments about, students' responses, place considerable demands on teachers' expertise. The teachers involved will bring to that work what they have learned from their training and their experience; to varying degrees, each teacher will have a generic guild knowledge of assessment. If the system depends on the assessment expertise of every teacher across a whole student cohort (about 600 000 students for national-curriculum assessment in England), that is a lot of variability. The problem is reduced, as in the case of the NEMP in New Zealand, where fewer teachers are involved and where they are selected on the basis of the level of expertise they possess.
3. *Teacher training and support.* Whatever expertise teachers bring to their role(s) there will be a need for system-specific training and support. That training may take the form of induction into the system as a whole and ongoing support as the system evolves or it may be targeted at perceived problems such as inconsistency or bias in teacher judgments. For a system of summative assessment by teachers to operate efficiently, all of those forms of training – initial and ongoing, generic and targeted – need to be in place. It is also the case, as was noted earlier, that teachers are likely to fulfill the roles allotted to them more effectively if they are active participants in, rather than passive recipients of, training and support.
4. *Quality assurance and quality control.* The quality of the outcomes from any system of assessment can in principle be enhanced by quality-assurance arrangements to establish confidence in the procedures and judgments. It will also need to be reinforced by quality-control arrangements to check that those procedures and judgments are resulting in assessed outcomes that are fit for purpose. Both quality and assurance and quality control depend on moderation procedures designed to produce consistency across assessors in qualitative judgments of student performance.

A range of approaches to moderation, in particular social moderation through interaction among participants in an assessment system, is discussed more fully elsewhere in the encyclopedia. Maxwell helpfully characterizes the distinction between assurance and control as moderation for improvement (through professional development) versus moderation for accountability (quality control). This aspect of a system of summative assessment by teachers is crucial to the system's effectiveness and Maxwell refers to no fewer than 12 factors to consider in designing moderation processes.

Conclusion

These examples of summative assessment by teachers in practice show that the social and cultural context is a crucial factor in ensuring successful implementation of a system of assessment. In the USA, Shepard (2000: 4), after reviewing how conceptualizations of assessment evolved during the twentieth century, concluded that there had been:

... consistent theoretical frameworks in which conceptions of 'scientific measurement' were closely aligned with traditional curricula and beliefs about learning.

In the decade following Koretz's (1998) review of portfolio assessments, the role of scientific measurement has been reinforced by the US federal government's No Child Left Behind program.

In contrast, the government of New Zealand has since 1994 entrusted the monitoring of student performance in its schools to teachers seconded into their roles as administrators and markers. There are other examples too of countries, for example, Scotland (Hutchinson and Hayward, 2005) and Wales (Daugherty, 2009), where teachers are trusted to judge the performance of students, including their own students.

Within any one context, there are also technical dimensions to systems of assessment by teachers for summative purposes. Some of the examples referred to here have had serious, sometimes fatal, design deficiencies. The five stages in the process and the four aspects of a system of summative assessment by teachers that were discussed in the two preceding sections of this article offer a checklist for system designers. In their discussion of threats to the valid use of assessments, Crooks *et al.* (1996) proposed a model of a chain with eight links, from administration of the task through to impact on the student and others. Validation in any system of assessment, not only one in which teachers are responsible for some of the links, requires careful consideration of the strength of each link (Crooks *et al.*, 1996: 269).

Commentators on the conceptualization and practice of student assessment (e.g., Resnick and Resnick, 1992; Broadfoot, 1995; Shepard, 2000; Harlen, 2007) have

typically interpreted recent international trends as being in the direction of greater reliance on the judgment of teachers. That interpretation may underestimate the contradictory pressures that are associated with demands for measures of system accountability, both within and across national-education systems. Even in Australia, a country where all six state-education systems have developed standards-referenced, teacher-based procedures, there are tensions between those systems and federal government requirements for test data to enable comparisons of performance against benchmark standards (Cumming and Maxwell, 2004). In Japan, a perceived crisis in school standards, fueled by the country's ranking in international comparative studies of achievement (Tsuneyoshi, 2004) and the inadequacy of the data available on student performance at the level of schools and districts, led to the reintroduction of national tests in 2007. The conflict that is inherent when teacher judgment has a role in summarizing student performance and the performance data then used for system accountability purposes was highlighted in a review of large-scale assessment systems in seven countries:

... while many systems rely on teacher judgment for assessments that are high stakes for students, there are ... no systems that rely on teacher judgment for assessments that are high stakes for teachers (Black and Wiliam, 2007: 11).

Summative assessment by teachers can and does have a role in large-scale systems of assessment. In a social and cultural context where teachers are trusted to exercise their judgment of student performance, there are two essential features if such systems are to be designed and implemented effectively. First, the role that teachers have in a system must be compatible with the use(s) that will be made of the student-performance data produced by that system. Second, a sophisticated infrastructure is required if large-scale systems are to realize the potential benefits, in terms of both validity and reliability, of extending the involvement of teachers beyond the use of their judgment for internal reporting purposes.

The Multiple Purposes of Assessment

P E Newton, Cambridge Assessment, Cambridge, UK

© 2010 Elsevier Ltd. All rights reserved.

Anyone planning to invest in a new vehicle ought first to have a good idea of what they are going to use it for. If the foremost desire is to cruise in style along winding roads, then a Harley Davidson motorcycle might fit the bill. If, instead, the major concern is to transport colleagues, tools, and the odd animal across country fields, then a four-wheel-drive utility vehicle might be much more appropriate. In just the same way, those who design vehicles need to start by considering transportation purposes, as do those who review them.

Designers, users, and evaluators of educational assessments also need to start by considering purposes. Just as it would be daft to try to use a bicycle to cross a desert, it would be daft to try to use certain forms of assessment for certain kinds of purpose. Strangely, though, when it comes to educational assessment, people often fail to appreciate this point.

What Is an Assessment Purpose?

Admittedly, it can be confusing to discuss the multiple purposes of educational assessment, since there are multiple levels at which these can be envisaged. At one level, the purpose of assessment might be to generate a particular kind of judgment, result, or outcome (e.g., a pass or a fail, a grade linked to a performance descriptor, or a percentile rank). At another level, the purpose might be to bring about a particular kind of social or educational impact or consequence (e.g., to motivate learners to work hard, or to cause teachers to align their teaching with a specific curriculum). At yet another level, the purpose might be to support a particular kind of decision, process, or action (e.g., to select the best candidate for a job, to guide subsequent teaching and learning, or to monitor educational standards over time).

All of these three levels – result, impact, and decision – need to be borne in mind by users, designers, and evaluators alike. However, in keeping with the emphasis in the literature, and with its centrality to theory and practice, the remainder of this article focuses upon assessment purposes at the decision level: the decisions, processes, or actions for which assessment results are used.

What Does It Mean to Be Fit-For-Purpose?

Fit-for-purpose is a phrase that is often used when discussing whether or not something can be expected to

function effectively. In the world of educational assessment, fitness-for-purpose is closely related to the concept of validity. This validity is broadly interpreted to embrace any form of evidence which bears upon the adequacy and appropriateness of inferences from results in relation to a specified use (e.g., Messick, 1989; Kane, 2006).

Inferences from exactly the same set of assessment results might be fit (i.e., valid) for certain purposes, but unfit (i.e., invalid) for others. This might seem counterintuitive, but it is fairly straightforward to explain. It depends upon factors such as the following:

- the kind of inference drawn from results (e.g., results from a single test might be interpreted either in terms of attainment in relation to a specific curriculum, or in terms of potential to succeed in a related course at a higher level, and the adequacy and appropriateness of inferences drawn will differ accordingly);
- the form of the inference drawn from results (e.g., results in the form of an overall grade might be appropriate for placing students in suitable educational programs, but inappropriate for identifying individual teaching and learning needs); and
- the accuracy of the inference drawn from results (e.g., results from a single test might be quite accurate in identifying those who have failed to achieve basic proficiency, but quite inaccurate in distinguishing excellent students from very good ones).

In short, decisions made when designing an assessment instrument, process, or system will secure the validity of inferences in relation to certain purposes, but will threaten the validity of inferences in relation to others (see AERA/APA/NCME, 1999, Standard 13.2 comment).

How Many Assessment Purposes Are There?

There are very many different kinds of decisions, processes, or actions that result from educational assessments might support. They might, for instance, be used:

1. to decide whether students are making sufficient progress in attainment in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (student monitoring);
2. to identify students' proximal learning needs, guiding subsequent teaching (formative);

3. to judge the social or personal value of students' achievements (social evaluation);
4. to clarify the type and extent of students' learning difficulties in light of well-established criteria (diagnosis);
5. to determine whether students meet eligibility criteria for special educational provision (provision eligibility);
6. to identify students who differ significantly from their peers, for further assessment (screening);
7. to segregate students into homogeneous groups, on the basis of aptitudes or attainments, to make the instructional process more straightforward (segregation);
8. to identify the most suitable courses, or vocations for students to pursue, given their aptitudes (guidance);
9. to identify the general educational needs of students who transfer to new schools (transfer);
10. to locate students with respect to their position in a specified learning sequence, to identify the level of course which most closely reflects it (placement);
11. to decide whether students are sufficiently qualified for a job, course, or role in life – that is, whether they are equipped to succeed in it – and whether to enrol them or to appoint them to it (qualification);
12. to predict which students – all of whom might, in principle, be sufficiently qualified – will be the most successful in a job, course, or role in life, and to select between them (selection);
13. to provide legal evidence – the licence – of minimum competence to practice a specialist activity, to warrant stakeholder trust in the practitioner (licensing);
14. to provide evidence – the certificate – of higher competence to practice a specialist activity, or subset thereof, to warrant stakeholder trust in the practitioner (certification);
15. to identify the most desirable school for a child to attend (school choice);
16. to decide whether institutional performance – relating to individual teachers, classes or schools – is rising or falling in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (institution monitoring);
17. to identify institutional needs and, consequently, to allocate resources (resource allocation);
18. to identify institutional failure and, consequently, to justify intervention (organizational intervention);
19. to evaluate the success of educational programs or initiatives, nationally or locally (program evaluation);
20. to decide whether system performance – relating to individual regions or the nation – is rising or falling in relation to expectations or targets; and, potentially, to allocate rewards or sanctions (system monitoring);
21. to guide decisions on comparability of examination standards for later assessments on the basis of cohort performance in earlier ones (comparability); and
22. to quality adjust education output indicators (national accounting).

This is not an exhaustive list, but it helps provide a sense of the number and range of different kinds of decisions, processes, or actions that can be identified. Furthermore, the distinctions drawn above are illustrative rather than definitive, using labels which have been informed by the literature, but not necessarily circumscribed by it. This is for a range of reasons, including the following:

- a tendency for different names to be used for the same purpose; for example, Chauncey and Frederiksen (1951: 109) used articulation instead of the more common placement;
- a tendency for the same name to be used for different purposes; for example, Nitko (1989: 455) described as diagnostic what many would describe as formative;
- a lack of precision in applying the terminology; for example, certification is sometimes used vaguely, as though to imply the process of summarizing end-of-course attainment (e.g., Sadler, 1989), but sometimes far more precisely to refer to a specific professional purpose (e.g., AERA/APA/NCME, 1999); and
- the identification of novel purposes; for example, comparability and national accounting (see Newton, 2007, for further details).

Is It Useful to Classify Assessment Purposes?

It is fairly easy to develop schemes for classifying assessment purposes. For instance, those up to purpose 14 (above) relate primarily to individuals and are based upon individual results, while those from 15 to 22 relate primarily to larger entities (such as schools, examination cohorts, or nations) and are based upon aggregated results. Equally, though, the same 22 purposes could be classified in an entirely different manner, as illustrated by the following scheme:

- personal decisions, made by students and parents (e.g., social evaluation, guidance, school choice);
- educational decisions, made by teachers and psychologists (e.g., formative, diagnosis, screening, placement, transfer, and segregation);
- administrative decisions, made by gatekeepers (e.g., provision eligibility, qualification, and selection);
- managerial decisions, made by those supervising and directing performance (e.g., student monitoring, institution monitoring, system monitoring, resource allocation, and organizational intervention);
- endorsed decisions, made by consumers (e.g., licensing, certification);
- technical decisions, made by technicians and analysts (e.g., comparability, national accounting); and
- evaluative decisions, made by researchers (e.g., program evaluation).

As it happens, most writers who have discussed assessment purposes in any depth have provided their own version of a classification scheme (e.g., Cook, 1951; Findley, 1963; Bloom *et al.*, 1971; Millman and Greene, 1989; Nitko, 1989; Hopkins *et al.*, 1990; Mehrens and Lehmann, 1991; Black, 1998; AERA/APA/NCME, 1999; Pellegrino *et al.*, 2001; Schmeiser and Welch, 2006; Gronlund, 2006). This, in itself, seems to cast some doubt over the utility of the exercise. In an ideal world, a classification scheme might help the reader to understand how certain kinds of purposes are associated with certain forms of assessment. But the reality is simply not that straightforward and the many classification schemes in existence seem to provide little more than relatively arbitrary and contestable groupings which lack obvious utility.

While both Millman and Greene (1989) and Schmeiser and Welch (2006) have noted the lack of a universally accepted scheme, Newton (2007) went a step further by claiming that classification schemes can sometimes do more harm than good. Having noted an increasingly common distinction between formative, summative, and evaluative purposes, he suggested that the distinction between formative and summative is spurious and that the distinction between summative and evaluative is trivial. To explain this first claim, the term ‘formative’ describes a decision-level purpose (and might be compared with others like ‘student monitoring’ and ‘diagnosis’); while the term ‘summative’ describes a judgment-level purpose (and might be contrasted with others like ‘descriptive’). To explain the second claim, the only difference between summative and evaluative, as the distinction is typically drawn, is that the former concerns results for individual students while the latter concerns aggregated results, which seems to be a fairly superficial difference. Most importantly, he suggested that making such broad-brush classifications can mislead policymakers, users, and stakeholders into inappropriate inferences, by implying that there might be deeper functional similarities between similarly classified purposes. For instance, it can mislead them into thinking that similarly classified purposes can be supported by the same assessment instrument.

Instead of seeking simplifying schemes, it may be more helpful to think of each purpose as a category in itself. Emphasizing differences between and even within purposes helps to foreground the necessity of tailoring assessment design to assessment purpose.

Tailoring Assessment Design to Assessment Purpose

Even within the same category of purpose, there are often subpurposes which necessitate very different assessment-design decisions. Program evaluation is a good case in point. As explained many decades ago: “If you wish only

to know how well a curriculum is achieving its objectives, you fit the test to the curriculum; but if you wish to know how well the curriculum is serving the national interest, you measure all the outcomes that might be worth striving for” (Cronbach, 1964: 243).

Similar within-purpose distinctions could be made for many other uses. This explains why the national monitoring system which operates in New Zealand is quite different from that which has been operating for many decades in the USA. In New Zealand, the National Education Monitoring Project was intended to be of particular use to teachers and curriculum designers; and, consequently, it was designed to report at the level of individual tasks and small clusters of tasks. In the USA, although originally reporting at the level of individual tasks, the long-term trend National Assessment of Educational Progress was specifically redesigned to be of particular use to policymakers and stakeholders, subsequently reporting only at the overall subject level. Within-purpose distinctions also explain why Nitko (1989: 455) was able to identify five different categories of diagnostic test and their correspondingly divergent technical characteristics.

In exactly the same way, between-purpose distinctions highlight different assessment-design implications. Thus, Millman and Greene (1989: 338) illustrated how assessments designed for program evaluation might differ from those designed for other purposes, such as student monitoring, by:

- targeting learning objectives beyond those specific to the course;
- employing item formats unfamiliar to those following the course;
- allocating different items to different students, to sample learning objectives thoroughly; and
- scoring by learning objective, rather than overall.

This kind of assessment would not even report at the level of individual students, let alone allow a user to monitor student progress in relation to a specific course of instruction.

To illustrate the point further, an assessment intended to support student monitoring ought to be designed according to criterion-referenced principles, rather than to norm-referenced ones; which would not be necessary if only a selective purpose needed to be served (e.g., Thorndike, 1971). Similarly, when results are to be used for purposes with high stakes – such as qualification, selection, or licensing – all aspects of the assessment system need to be designed with test security in mind; from identity checking at the test center to the disposal of completed test scripts (e.g., Millman and Greene, 1989; Schmeiser and Welch, 2006). Such considerations simply do not apply when results are used only for low-stakes purposes, where cheating does not present a significant threat to validity.

Can a Single Assessment Support Multiple Purposes?

Although it might seem possible to use outcomes from a particular assessment instrument, process, or system for a range of disparate assessment purposes, not all of these uses may prove to be defensible. The problem – a classic problem of assessment – lies in determining the appropriate cut-off point between defensible and indefensible.

To illustrate the point, it might be considered indefensible to use an assessment designed principally for system monitoring, and based upon a matrix-sampling approach, for student monitoring. This is because system monitoring tends to emphasize overall content validity at the expense of reliability for individual students. To design an assessment system which thoroughly sampled both curriculum-learning objectives and assessment formats, it would be necessary to allocate different task blocks to different students and to link the results statistically. In theory, if the task blocks were long enough, reliability for individual students would not need to be sacrificed and it might be defensible to report results at multiple levels. In practice, though, if the task blocks were constructed to be long enough, the complexity, expense, and goodwill required to administer the assessment would probably render it unmanageable. So pragmatic compromises tend to be made and results from assessments based on matrix-sampling are generally not reported back to students or to their schools.

It will often be possible to identify a variety of reasons why results from a particular assessment might be considered indefensible for certain uses. One such reason might be that the inferences drawn are of an inappropriate kind. Linn (1989: 7) cited the case of *Larry P. versus Riles*, which concerned the use of intelligence tests to place (predominantly black) children in special classes for the educable mentally retarded. This practice might be considered defensible if it were possible to infer, from performance on such tests, the potential to benefit educationally from segregation. That this inference could not be validated supported the legal decision which prohibited the practice. Although the possibility of drawing valid inferences concerning intelligence was not in question, the possibility of drawing more-distant inferences was.

Perhaps the most common reason for limiting the use of results to specific purposes concerns accuracy – when results which are sufficiently accurate for one purpose are insufficiently accurate for another. This is often attributable to compromises during the assessment-design stage. As noted above, system monitoring assessments typically sacrifice reliability of results for individual students, for reasons of manageability and cost effectiveness. If a system-monitoring assessment were to be designed also to report results for individual students, then it would need, in effect, to be over-engineered for the purpose of system monitoring.

This reasoning is relevant to the debate over whether a single assessment system can effectively support both formative purposes and other purposes too. On the one hand, it does seem theoretically possible to use the same assessment evidence to generate low-level micro-inferences for formative purposes and high-level macro-inferences for other purposes – just as long as the original evidence base is sufficiently comprehensive, structured, and detailed (e.g., Findley, 1963; Harlen, 2006). On the other hand, a single assessment system designed to this specification would probably turn out to be both over-engineered for formative purposes (in terms of comprehensiveness and structure) and over-engineered for other purposes too (in terms of detail). In circumstances like this, it can actually turn out to be more manageable and cost effective to develop separate assessment systems, each tailored to their intended uses of results and each with their own compromises and trade-offs.

Maybe, though, we should look optimistically to the technology of the future for genuinely multifunctional, cost effective, and manageable assessment solutions (e.g., Pellegrino *et al.*, 2001: 284).

Dealing with Multiple Assessment Purposes

The USA *Standards* document (AERA/APA/NCME, 1999) provides some sensible practical guidance on how to deal with multiple assessment purposes, for example:

- A rationale should be presented for each recommended interpretation and use of test scores, together with a comprehensive summary of the evidence and theory bearing on the intended use or interpretation (Standard 1.1).
- The test developer should set forth clearly how test scores are intended to be interpreted and used (Standard 1.2).
- If validity for some common or likely interpretation has not been investigated, or if the interpretation is inconsistent with available evidence, that fact should be made clear, and potential users should be cautioned about making unsupported interpretations (Standard 1.3).
- If a test is used in a way that has not been validated, it is incumbent on the user to justify the new use, collecting new evidence if necessary (Standard 1.4).

Unfortunately, recommendations such as these have implications that are not always palatable to measurement professionals (e.g., Green, 1998). For a start, the responsibilities assigned to test developers, publishers, and users are contestable. Given that any particular test might potentially be used to generate inferences in support of a range of purposes, should test developers and publishers really be expected to provide validity evidence in relation to all of them? If not, then how exactly ought the list to be restricted – to one principal purpose? And, while it may, from a theoretical perspective, be incumbent upon users

to justify new uses, how practical a recommendation is this? Particularly, when the user group extends beyond those professionals with formal responsibility for assessment to stakeholders like parents and many employers.

The situation becomes more complicated still when test developers are required to produce tests for sponsoring agencies, like regional or national governments. Often, policymakers responsible for commissioning the development process will have limited understanding of the challenge of multiple purposes and may need to be disabused of the false belief that a single assessment system can support a multitude of disparate purposes. This may not be easy to do, especially if the policymaker has already earmarked a limited budget for developing the new system.

Hopefully, the responsible test developer will begin by helping policymakers to identify the purposes they consider most important to support, and those which it will be less possible to support. Ideally, the developer would encourage the policymaker to prioritize between desired purposes, and orient the development process to the principal purpose or purposes. However, ensuring that these principal purposes are made explicit for all users and stakeholders to see may prove less straightforward. Moreover, either during the development process or as years go by, ensuring that there is no unannounced drift or accumulation of assessment purposes may prove harder still to prevent. Finally, there is a clear tension for policymakers who are both responsible for publicizing the limitations of their assessment systems in relation to specified assessment purposes and accountable for the success of those systems as mechanisms for organizing and informing a fair society (see Newton, 2005).

The challenge of multiple assessment purposes is not simply technical, but social and political. It requires full and frank debate between developers, policymakers, users, and other stakeholders. All parties need to recognize that a single set of assessment results may not be capable of supporting a range of disparate uses of results. And all parties need to recognize that, when an assessment which has been designed for one specific purpose is used for another, the consequence will be a larger number of incorrect assessments and bad decisions than might otherwise have been the case.

Glossary

Associationist epistemology – The theory of knowledge and learning in which knowledge is defined as a collection of established facts and generalizations.

Embedded assessment – The teacher judgments made in the course of classroom interactions with students.

External assessment – The standardized tests or exams are administered under controlled conditions.

Formative assessment – An embedded, diagnostic assessment.

Interpretive epistemology – The theory of knowing and learning in which learners work to establish meaning, and competing interpretations are considered by a community of learners.

Tracking (also called grouping, setting, or streaming) – The policies in which students of different abilities are placed in different track groups, sets, or streams which receive instruction that proceeds at different rates and may involve different content.

embody an interpretive theory of knowing and learning in which learners work to establish meaning and competing interpretations are considered by a community of learners. These two dimensions of assessment are far from perfectly correlated with one another – interpretive epistemologies can be used in external examinations, for example; and associationist epistemologies can produce engaging classroom discussions. This leads to considerable confusion as educators and psychometricians discuss the role of assessment in adaptive teaching. We examine the two-dimensional assessment space defined by the external-embedded and the associationist-interpretive distinction, showing how goals of reliable measurement and agile response to individual students can sometimes conflict.

Diagnostic Assessment: From Tracking and Sorting to Classroom-Based Adaptation

Early attempts to adapt classroom instruction to individual differences generally led to grouping, tracking, and streaming policies in which students of different abilities were placed in different tracks or streams. These students received instruction that proceeded at different rates and that often involved radically different curriculum offerings. Tests and assessments were intimately involved in this process of instructional sorting – from Alfred Binet's individually administered intelligence quotient (IQ) test to later group-administered aptitude and achievement tests. Tests were routinely used by schools, either as admission screens or as a means of placing students in the appropriate classes or courses within an institution. Group tests found widespread applications beyond classroom walls as well, such as the US Army's use of IQ tests to channel recruits into different specialties.

These macro-strategies of sorting and streaming placed assessment external to the classroom and became the domain of a separate profession of psychometrics. They were based on widely held beliefs among scholars and education professionals that different scores on placement and sorting tests reflected fixed differences in ability, and that sensible adaptation to these differences in ability would probably require not just slower rates of instruction, but different ways of teaching, and perhaps even different content.

Introduction

With the advent of compulsory public education, for most modern societies came efforts to adapt instruction to students. Strategies for adapting have ranged from external assessments of abilities and knowledge in which standardized tests or exams are administered under controlled conditions to deeply embedded teacher judgments made in the course of classroom interactions with students. External assessments provide reliability and replicability, but standardization along with delays in the cycle of testing and feedback can limit their pedagogical utility. Embedded assessments are tuned to the instructional moment, but usually require highly skilled teachers and may be subject to biased judgments. Assessments also differ in their epistemological assumptions. Some are based in an associationist theory of knowledge and learning in which knowledge is defined as a collection of established facts and generalizations. Others attempt to

Starting in the mid-1960s, a number of psychologists began to suggest that intelligence and aptitude were far more malleable than earlier theories had assumed (Glaser and Resnick, 1972). It soon became clear that tracking and streaming were *de facto* denying many students the opportunity to learn more cognitively demanding curricula that they might, with appropriate adaptations and perhaps some extended learning time, be able to learn successfully (Oakes, 1985). Evidence also grew that students of color and language minorities were being disproportionately assigned to special-education categories that isolated them from cognitively demanding instruction.

In response, educators began searching for ways to adapt instruction within heterogeneous classrooms. To guide such adaptive teaching, many scholars and theorists proposed embedding brief evaluative or stock-taking observations within instruction. Not surprisingly, the psychometrics profession sought to respond by developing practices of assessment that would support the ongoing adaptation of instruction. They distinguished between formative (i.e., embedded diagnostic) assessment and summative (i.e., external, evaluative) assessment.

Glaser (1963) proposed that tests should be designed so as to produce information not just on how an individual student ranked within a class but also what, specifically, had been learned. Bloom (1969) advocated the use of formative evaluation:

to provide feedback and correctives at each stage in the teaching-learning process. By formative evaluation we mean evaluation by brief tests used by teachers and students as aids in the learning process. While such tests may be graded and used as part of the judging and classificatory function of evaluation, we see much more effective use of formative evaluation if it is separated from the grading process and used primarily as an aid to teaching. (p. 48)

Toward the end of the 1980s, two substantial articles reviewed the impact of classroom-assessment practices on students and their learning. One (Natriello, 1987) used a model of the assessment cycle, involving purposes, setting of tasks, criteria, and standards, evaluating performance and providing feedback. The author concluded that much of the research reviewed was largely irrelevant because of weak theorization, resulting in the conflation of key distinctions (e.g., the quality and quantity of feedback).

The second review (Crooks, 1988) had a narrower focus – the impact of assessment practices on students. This author suggested that the summative function of assessment predominated, and that little attention was paid, either in research, or in the practice of educators, to the potential of classroom assessments to assist learning.

The view of assessment as a separate process from teaching continues to dominate approaches to the use of assessment in the support of learning. A review of research by Bangert-Drowns *et al.* (1991) focused on the

effects of feedback in what they called test-like events (evaluation questions in programmed learning materials, review tests at the end of a block of teaching, etc). Throughout this strand of research, the assumption is that assessment is a related, but separate process from teaching; and that assessments need to be psychometrically sound in order to allow valid inferences about students to be made; but that we should explore the potential for these assessments to do double-duty by also being instructionally supportive. It should be noted that this characterization extends also to the experiments with authentic or performance assessment in the 1980s and 1990s (see, e.g., Koretz, 1998), and to more recent work on student-involved classroom assessment (Stiggins, 2001). The emphasis has been on trying to make assessments that are primarily designed to support a summative function to function formatively as well. Most recently, the Commission on Instructionally Supportive Assessment in the US explored the possibilities for tests used primarily for purposes of accountability also to provide information useful to teachers in their teaching (Popham, *et al.*, 2005).

Over the last 20 years, there has been a strand of work on formative assessment that seeks to examine the real-time classroom-evaluation processes used by teachers not only as aspects of teaching, but also as particular kinds of assessment (Sadler, 1989; Black and Wiliam, 1998). Rather than seeking to make existing assessments support learning, this work has explored how an assessment perspective on certain aspects of teaching might illuminate, and improve, learning (Wiliam and Thompson, 2007).

Accountability Assessment: From End Results to Data-Based Management

Even as some psychometricians have been turning attention to formative assessment, large-scale summative testing has come to exert substantial pressure on teachers and classrooms. Test-based international comparisons of academic achievement are eagerly reported in many countries, and these motivate lively and often quarrelsome debates about how to increase school achievement results. In some countries, schools are held accountable for achievement gains, with varying positive and negative incentives attached to schools' test results. The end-of-course external assessment results are increasingly becoming requisites for promotion and graduation from one level of schooling to the next, thus attaching important consequences to test performance.

The comparative and accountability tests now in wide use were not designed to guide adaptive instruction although tests used in these evaluations can have a distinct influence on the nature of instruction – despite rhetoric in some countries that claim that the tests are curriculum neutral. Teachers work to prepare students to do well on

school-leaving exams, and even on yearly tests that carry important consequences – as in the current American accountability system. In addition, psychometric criteria of reliability and generalizability, along with cost, often drive out assessment of interpretation, problem solving, and reasoning.

The line between embedded and external assessment is blurred when tests designed as external measurement instruments are used as interim assessments to check on progress through an externally mandated sequence of learning topics. This use is current now in several countries with test-based accountability policies. Evidence suggests that unless the interim tests closely match the intended curriculum, tests over time come to trump curriculum as schools and teachers focus increasing attention on teaching to the test.

Truly diagnostic tests, aimed at adaptive instruction, should examine the units or modules of instruction in the classroom. The information such tests yield is intended for a very local audience – the teacher and even students themselves. Assessment results are meant to be used to guide the very next bit of instruction. Thus, if an error in judgment is made, it can be corrected quickly and with no important long-term impact on student-learning opportunities. This means that psychometric criteria for large-scale external assessments need not drive out attention to the details of content and performance that are essential in diagnostic assessment. To be useful to teachers and students, embedded assessments should be tightly linked to the specifics of curriculum – what is taught. Teachers – rather than administrators or accountability monitors – are the people who need to see the data quickly. Indeed, to an outside observer, embedded diagnostic assessments may not appear to be assessments at all but rather part of the teaching process.

Epistemologies of Learning and the Nature of Assessments

Especially strong tensions arise when assessments intended to assist teachers in adapting instruction to their students do not share the same epistemological assumptions as the curricula teachers are attempting to implement. Most of the evaluation and accountability tests in the US today are based on epistemological assumptions of the early twentieth century. Major developers of educational psychology, such as E. L. Thorndike, who is arguably the father of standardized testing, worked from within the associationist theory of learning. To know something, for Thorndike and his colleagues, was to have a mental collection of many separate associations and the ability to call up these associations quickly and accurately. Thorndike's influential book on *The Psychology of Arithmetic*, published in 1922, listed hundreds of individual

associations that people who knew arithmetic would need to hold in their heads. The best form of teaching, it followed, was well-designed practice of all the many associations that constituted a given body of knowledge.

The appropriate form of testing, given the associationist definition of knowledge, were short items that examined which associations a student had mastered and which needed further study. Associationist testing initially began as collections of short-answer (often single-word) constructed responses, but with the advent of machine scoring, multiple-choice testing took over. With this type of testing as the dominant form of summative evaluation, it was a logical step to try to create formative tests that were essentially subsets of the larger summative evaluation.

From the 1960s onward, however, psychology and cognitive science were giving us a new view of knowledge and skill with profound implications for what to teach and how to assess. These new interpretive theories of learning and knowing range from Piagetian constructivism, to cognitive science's focus on mental models and problem solving, all the way to sociocognitive theories that place learning in the nexus of social interaction as pairs or groups of people work to align their understanding. In all of these theories, knowledge is the result of sense making by learners. To know something is to have constructed a web of understanding that links individual associative bits into structured schemas that are used in reasoning and in acquiring new knowledge. The learner is understood to be an active constructor of knowledge, bringing to bear existing, often schematized, knowledge on new problems. Learning, even of simple material, is thus an interpretive process. Readers, for example, do not just extract a mental copy of what they read; they build a mental model of the situation described by the text (Kintsch, 1986); they question the author's intent (Beck and McKeown, 2001) in order to understand the text's meaning; they construct self-explanations that tell them how elements are linked and why things work the way they do.

With the cognitive revolution in psychologists' understanding of knowledge, which brought a focus on instruction for understanding, meaning making, and the creation of explanations, new forms of teaching have been developed. Students work on tasks and problems that are designed to engage their meaning-making capacities. These often involve both collaborative work with other students, and structured, teacher-led talk as integral parts of the learning process. In classrooms that are engaging in this kind of learning activity, the use of tests matched to the coming end-of-year summative assessment may disrupt teaching rather than support it. Recognizing this, many assessment specialists, along with teachers, have called for types of formative assessment that would better match the new forms of pedagogy they were trying to implement.

Embedded Assessment in Two Epistemologies: Classroom Talk as Diagnostic Testing

Each of the epistemologies we have discussed – the associationist and the interpretive – gives rise to a distinctive set of classroom practices. We might call them signature pedagogies – pedagogies that can be recognized by a small set of classroom moves that signal quite different expectations of how students learn. The differences can be seen to some extent in the tasks students are assigned; but they are most clearly evident in the nature of the conversations about the content embedded in the tasks. These conversations are simultaneously diagnostic and evaluative.

From Catechism to IRE: Associationist Teaching and Assessment

Much of associationist classroom instruction, at least in Western societies, takes its origin in early forms of religious education in the Christian church. Protestants first, and then Catholics, developed a form of basic instruction that proceeded in oral question-and-answer form – known as catechism. Children (and neophyte adults) were asked a set series of questions and were expected to provide standardized answers.

As mass schooling developed, the catechism form moved into the secular classroom.

The content changed (now to include basic arithmetic, a broader range of texts for reading, attention to spelling and correct grammar as the public definition of literacy enlarged to include written composition, and nationalist history), but the form of classroom interaction remained remarkably constant. In reading, history and geography and science, students were assigned a brief text to read – perhaps during class, perhaps overnight as homework – and were then quizzed by the teacher with a series of questions that checked out whether each student had read and remembered what the text said. Arithmetic was similar: a set of calculation problems to solve and a classroom check on whether answers were correct. The classroom check might be in the form of a written quiz, a review of homework, or an oral question and answer: questions by the teacher, answers by the student. Teaching was a matter of setting a task and evaluating how students performed the task. Sometimes a teacher was called upon to explain or to tell students about concepts or events that textbooks had not yet caught up with (with more extended teacher talk as students grew older – right up to the college lecture hall). But evaluation of bite-sized bits of information was the most common form of teaching in schools.

The catechism form is still with us in what we now know as standard recitation teaching. In 1979, Hugh Mehan, aiming to provide a structured account of the

first-grade teaching that he had observed in elementary-school classrooms, described a standardized sequence that came to be known as the I–R–E sequence (Mehan, 1979). The teacher initiated (I) a three-step exchange. The student, who might be a volunteer or someone picked by the teacher, responded (R). The teacher then evaluated (E) the student's response, either accepting it as correct or indicating that a different answer was needed.

Characteristic of IRE, as of catechism, is the assumption that what students are to learn is a prespecified set of facts or explanations. It is understood that the teacher already knows the answers – in fact, it is the preestablished set of questions and answers that defines what is to be learned. In IRE conversations, the students' job is to provide the answers expected by the teacher. The teacher's job is to find a student who can provide the expected answer in order to keep the instructional conversation on track and on time. Assessment is undetachable from the act of teaching, which in turn is composed of a string of rehearsals of the proper questions and proper answers.

In their book on the teaching gap, Stigler and Hiebert (1999) describe standard American teaching of mathematics as very close to this catechism approach. In a prototypical lesson, the teacher provides a set of arithmetic, or algebra, problems to be worked. The students are expected to solve the problems at home or during in-class work periods. During the subsequent class period, a review of homework is conducted (a form of micro-assessment). This review, conducted largely in the IRE form, identifies right and wrong answers to the problems, but there is little discussion of why the answers are right, or of what alternative solutions might have been considered. This recitation form of teaching is standard practice in other subject matters as well. For example, students might be expected to read a chapter in a history book and be prepared to respond from memory to a series of questions posed by the teacher the next day.

Multiple efforts underway now use various forms of technology to expand the power of IRE teaching to diagnose where each individual is in the process of learning the expected set of knowledge components and procedural skills. For example, students can use wireless handheld computers (personal digital assistants or PDAs) to respond to teachers' multiple-choice or short-answer questions and the teacher can receive almost instantaneously a summary of responses. The teacher can then adapt the next piece of a lecture or other presentation to the average knowledge displayed by the class; and can also pick out specific students who may need individual tutoring in order to keep up. Going even further into a technology-based future, today, there are already available sophisticated computer tutors that use a highly interactive combination of problem presentation and solution elicitation to tailor a substantially personalized form of

instruction in which students' steps of reasoning and explanation are immediately evaluated by the computer. Depending on the outcome of the evaluation, the tutor may silently wait for further reasoning, provide corrective feedback, prompt for an alternative strategy, or provide a new problem to address a knowledge growth need (e.g., Koedinger and Aleven, 2007). Interactive computer tutors in use in schools today monitor student reasoning and explanation to provide deeper assessment and learning support beyond simple practice of facts and associations. We are also coming closer to the day when computer-student interactions can be used to provide formative assessment of student-learning strategies. As this happens, computer-based instruction may also be able to support interpretive learning.

Communities of Learners: Interpretive Teaching and Assessment

The classroom conversation takes a very different form in classrooms based on interpretive epistemologies. Over the past two decades, research has accumulated on how discussion methods are used in classrooms and why such discussion may support learning of important school subject matter as well as the process of reasoned participation (Michaels *et al.*, 2007). This research – blending sociology, linguistics, and psychological strands of educational research – has repeatedly demonstrated the role of certain kinds of structured talk in learning with understanding. The discourse focuses on understanding and explanation, and admits multiple student solutions to the classroom discussion.

We can turn once again to the teaching gap book for an interpretive pedagogical image, this one based on the typical Japanese mathematics classroom. Variants of this approach have appeared in many countries in the past 15–20 years, and can now be said to constitute an emergent signature pedagogy for interpretive teaching and learning.

As in associationist teaching, the process begins with the teacher assigning a task for students to work on. The task for an interpretive mathematics lesson typically describes a situation that needs to be mathematized by the students. That is, variables have to be identified and their relationships understood even before specific quantities come into the discussion. Typical tasks for this form of instruction have more than one route to solution, although there is no compromising on the need for finding mathematically correct answers through different routes.

Once the task has been set out, there follows a period of individual and small group work in which students develop candidate solutions to the problem. It is typical at this time for teachers to move around among students, keeping everyone focused, and sometime suggesting an approach to a group that has reached a dead end in their thinking. This is also a time when the teacher can make

mental notes of what the thinking of groups and individuals is. This work period is thus a privileged moment for embedded assessment.

Next, there is a teacher-led whole-class session in which solutions are presented to the whole class by students. This is followed by class discussion of the validity of solutions and of interrelations among suggested solutions. During this time, the teacher uses a number of talk moves in which individuals are asked to elaborate their own ideas or those of other students. Several of the most common moves are shown in **Table 1**.

In this form of carefully guided discussion students' ideas may be challenged – by the teacher or by other students – but a developed set of norms for classroom discussion insure that talk remains accountable to the community, to appropriate forms of reasoning, and to the specific knowledge that is under discussion.

This form of interpretive discussion represents a large change from recitation or catechism – even as it contains a large measure of teacher direction, and hence occasion for embedded assessment of student knowledge. But what counts as knowledge is expanded, the chunks to be learned and talked about are larger; there are more occasions for the teacher to be surprised by students' understanding (and misunderstanding), and it is clear that there is more at stake than finding the single answer that the teacher is looking for. The teacher is not simply searching for a succession of right answers to simple problems or steps within a larger problem. The opportunities for assessment are embedded in the learning activities, and it is difficult to imagine separating them out as individual test items.

Table 1 Characteristic talk moves

<i>Talk-move action</i>	<i>Prototypical form</i>
Revoicing	"So let me see if I've got your thinking right. You're saying XXX?" (With time for students to accept or reject the teacher's formulation)
Asking students to restate someone else's reasoning	"Can you repeat what he just said in your own words?"
Asking students to apply their own reasoning to someone else's reasoning	"Do you agree or disagree and why?"
Prompting students for further participation	"Would someone like to add on?"
Asking students to explicate their reasoning	"Why do you think that?" or "How did you arrive at that answer?" or "Say more about that."
Challenge or counter example	"Is this always true?" "Can you think of any examples that would not work?"

Adapted from O'Connor, R. and Michaels (in press). How (well structured) talk builds the minds. In Sternberg, R. and Preiss, D. (eds.), *Pathbreaking Discoveries in the Learning Sciences*.

Conclusion

In this article, we have suggested that strategies for adapting instruction to the needs of students range from formal external, standardized assessments to informal teacher judgments deeply embedded in day-to-day classroom practice. These strategies also differ in the epistemological assumptions underlying the assessment, with some grounded firmly in an associationist theory of knowledge, while others embody an interpretive theory of knowing and learning. We have argued that distinguishing clearly between these two aspects of assessment defines a two-dimensional assessment space (external-embedded and associationist-interpretive) that shows how conflicts can arise between the goals of reliable measurement on the one hand and agile response to individual students on the other.

Assessment Conversations: Reading and Writing Conferences with Students and with Parents

Defining the Territory

In exploring this aspect of assessment it has to be recognized that we quite soon come up against problems of terminology: these assessment events are variously referred to as conferences, consultations, discussions, or interviews. For the purposes of this article we will refer to them all as assessment conversations, a term that has already been used in another context by Johnston (2003).

All of these terms suggest some kind of formalization of classroom talk, the making of a special occasion for teachers to discuss students' progress in reading/writing or literacy with them – either in groups or, more commonly, with individuals. Sometimes assessment conversations may be held with students' parents, or sometimes conversations with students may include their parents.

Assessment conversations are often recorded in some way and the record becomes part of a teacher's ongoing assessment, or of a final overall assessment.

Purposes and Principles

In the field of literacy, there can be several purposes to this quite well-known but underdocumented practice.

In relation to conversations with students these may include:

- enabling the teacher to find out more about students' views of literacy and attitudes to literacy, both in general and in relation to their own work;
- enabling teacher and student to discuss the student's home literacy experiences and linguistic range;
- enabling the teacher to find out more about a student's literacy work by observing their approach to a literacy task (e.g., reading a text and discussing it);
- reviewing a student's reading or writing with them and evaluating their progress as a reader/writer; and
- encouraging students in reflection, making them more conscious of their own progress and of their strengths and needs

The purposes of assessment conversations with parents may include:

- enabling the teacher to find out more about students' home literacy experiences and attitudes to literacy;
- promoting discussion between teacher and parent of different aspects of students' home/school literacy; and
- reviewing students' reading or writing with their parents and evaluating their progress as readers/writers.

History of this Practice

There are a number of antecedents that may have contributed to the development of assessment conversations in literacy:

1. *Case studies in literacy research.* The use of case study in qualitative research in literacy has demonstrated how much can be learned about students' literacy development by observing them and talking to them about their reading and writing. Important studies such as Fry's (1985) *Students Talk about Books: Seeing Themselves as Readers*, *Inquiry into Meaning* by Chittenden *et al.* (2001), and Hugh and Crago's (1983) *Prelude to Literacy* have documented students' individual paths of literacy development and revealed their personal constructs of literacy.
2. *The analysis of reading strategies.* Miscue analysis was developed by Goodman (1973) in the late 1960s as a way of looking inside students' errors or miscues in the oral reading of a text. The Running Record, developed by Marie Clay in 1972, is essentially another type of miscue analysis, but is more suitable for younger children beginning to read. Both of these assessments involve teachers in listening closely to students' reading and recording/analyzing their errors as a guide to their characteristic behavior as readers; they are sometimes followed by conversations with the student about the text or about their reading in general.
3. *Classroom observation or kid watching.* Assessment conversations form part of a general approach to assessment in the classroom that includes the informal observation of children's reading and writing behavior. Teachers in the early years have been at the forefront of using child observation as a means of understanding and documenting students' learning. In the 1980s, teachers of older students began to observe students more systematically, recording their observations and reflections on what they were finding out about students' patterns of learning. Yetta Goodman coined the term kid watching to describe this kind of informal observation in 1978, and has written extensively about it since (Goodman and Owocki, 2002).
4. *Writing conferences.* A writing conference is a face-to-face discussion of a text between the student author of the text and their teacher. The term first came into general educational use through Graves' (1982) work in the late 1970s on students' writing processes, detailed in his book *Writing: Teachers and Students at Work*. Graves and his associate Lucy Calkins (1994), author of *The Art of Teaching Writing*, developed the use of writing conferences as a way of moving students on in their writing. This kind of interaction can be viewed as formative assessment; it allows teachers both to evaluate students' progress and to help them to develop their writing.

Conferences and Conferencing

Assessment conversations in literacy are sometimes known as conferences. Although this term – perhaps borrowed from parent–teacher conferences – came into use mainly in relation to writing, it is also used in relation to reading. Reading and writing conferences are usually informal, one-to-one conversations between teachers and students to discuss students' work. In this context, the word conference is sometimes used as a verb as well – to conference can mean to conduct writing or reading conferences with students.

Reading and writing conferences can range along a continuum from informality to formality. At the informal end of the continuum, teachers can drop by while children are writing and ask "How's it going?" (Anderson, 2000). This can lead to an informal conference in which teacher and pupil discuss the progress of a particular piece of writing. At this end of the continuum, the conference is as much a part of the everyday business of teaching as an informal assessment. Lucy Calkins, the American educationalist who has developed the workshop approach to teaching writing most fully, always includes mini-lessons in her approach to conferences.

However, informal conferences do not have to involve direct teaching; they can be opportunities for teachers to observe a child's literate behavior in some depth, in order to assess her/his needs and plan future teaching and learning activities. Therefore, a reading conference can take a form as simple as a child reading and discussing a picture book with the teacher, while the teacher notices and records all that she/he can observe about the child's approach to the reading and the text.

At the more formal end of the continuum, teachers can organize times for individual conferences with students to discuss their literacy progress, perhaps with special reference to their writing folders or reading journals. Conferences of this kind can provide valuable information about pupils' attitudes to their own literacy learning and can also involve discussions of their home literacy experiences, the range of those experiences, their personal tastes, and the social nature of their literacy – the involvement of family members in their learning. A record of language/literacy conference with a child is as follows:

'What Is A Ghost Going To Do' is D's favourite book. 'I like to be able to read so I can read stories to my sister, I sometimes make up stories to tell her. I'm not that good a reader 'cos sometimes I forget the words, I don't know them. I ask my sister and she gives me a clue. I read at home every night.' Given the choice D would watch television rather than read. 'I make up ghost stories and copy from books – my mum helps with spellings. My best bit of writing was when I wrote about the tele programme Dungeons and Dragons. Sometimes I'm a bit lazy with

handwriting and I chat too much but sometimes it's OK' (Barrs *et al.*, 1988).

A well-conducted individual literacy conference is an opportunity for a child to engage in self-assessment and to reflect on her/his own progress. But the way that children assess themselves as literacy learners will reflect the discourse of their classrooms. Johnston (1992), in discussing evaluation through interviews, observes that "It is probably worth noting that the kind of interaction you set up in interviews about books and about writing will form the basis of those interviews that take place between students." Conferencing helps to establish a classroom discourse in which listening to others and reflecting with others is normal.

Assessment Conversations as Part of Informal Assessment Systems

Assessment conversations form part of a range of techniques and practices that teachers now have at their disposal for evaluating students' literacy progress. These ways of assessing are sometimes collectively called informal assessment or authentic assessment. What they have in common is the fact that they are carried out in the classroom, in the course of normal classroom activities, and recorded by the teacher. These assessments are formative; they help the teacher to assess students' strengths and needs, and they support further planning.

Such informal assessments include teachers' diaries and anecdotal records, running records and miscues, reading records, reading and writing journals, the analysis of writing samples, and conferences with students about their reading/writing. Some of these practices are more highly structured, others less so. At best, they work together to give a full and rounded picture of students' progress, based on their daily behavior in normal classroom contexts rather than in test situations.

Effective teachers often include these informal assessments in their normal classroom practice. The survey conducted by Medwell *et al.* (1998) into the effective teaching of literacy in the UK suggested that a group of 228 teachers whom they had identified as effective practitioners were less likely than their validation (control) group of 71 teachers to rely on tests for their assessments in literacy. Instead, they were much more likely to use assessment techniques, such as marking, error analysis, and observation. When given a list of approaches to assessment in literacy and invited to add more, the effective teachers added a further 55 approaches, which included reading conferences – mentioned by 20% of those responding (but only by two of the validation teachers).

There have been relatively few attempts to fully incorporate informal assessment techniques into an official

system of assessment. Although many national and state systems (e.g., Florida, Kentucky, Ontario, and Tasmania) have recommended the use of a range of informal assessments as a part of a wider system of assessment, not many have attempted to blend these practices into a coherent whole.

Fewer administrations still have made assessment conversations part of such a system. This is not surprising: assessment conversations are a relatively unstructured form of assessment and depend heavily on a teacher's sensitivity and responsiveness in conducting a discussion with a student. Because these conversations are one-to-one events, they also take up substantial teacher time. The hesitancy around the use of assessment conversations in official systems means that there are few guidelines about how to conduct assessment conversations, either with students or with parents.

Often, early-years practitioners lead the way in making conversations with children and with parents a key part of an assessment system (Smidt, 2005). The New Zealand *Learning Stories and Teaching Stories* research report (Carr *et al.*, 2000) emphasized the necessary complexity of assessment in the early years and the importance of taking into account:

The funds of knowledge children bring to school, and the advantage to which they might be turned for literacy development, the languages the child brings and his or her ability to transfer one to the other, the permeability of classroom interactions around print to the language(s) and patterns of interaction in the child's home, the child's understanding of literate activity... what he or she can know and do under which circumstances....

In order to capture the complex nature of this learning, the project placed narrative assessment, including teachers' observations, transcripts, photos, children's work, and children's and parents' comments at the heart of its approach to assessment. Learning stories document children's engagement in learning experiences and are presented in children's portfolios for children, families, and teachers to read and discuss.

In the UK, the Primary Language Record (PLR; 1988) included conversations with both students and parents at the beginning and at the end of each school year. This practice provides teachers with information about children's home literacy and linguistic experiences early in the year, and encourages the review of children's progress over the course of the year. Assessments that derive from or are influenced by the PLR generally include both student and parent conferences. Following is a record of discussion between child's parents and the class teacher:

M. thoroughly enjoys reading, reading every evening. She selects books from school as well as the Public Library. She reads to her mother at the weekend. M. writes a lot

too, writing about special events and outings. She enjoys drawing cards and makes her own books. Loves to paint and draw.

M. is busy all the time helping her mother in the house. She enjoys some television, mainly Indian films. M. speaks Panjabi at home and is a fluent speaker. She enjoys maths at home and using text books from the library. (Ellis, 1993).

Conversations with students and with parents give teachers more insights into students' linguistic and cultural experiences and the implications for their literacy learning. They help teachers to see how they could plan their teaching better, and how students could be better supported in the classroom. In addition, assessment conversations can establish a dialog between teachers, students, and parents, which makes for better working relationships and better learning.

Links with Self-Assessment and Peer Assessment

One of the purposes of holding assessment conversations with students is to develop their confidence, their ability to reflect on their own learning, and their capacity for self-assessment. Such conferences require students to review their work and consider what they have already learned – they encourage self-evaluation. They make students more conscious of the learning strategies that they are using, and help them to become aware of their use of unhelpful or negative strategies.

The development of students' ability to discuss their learning and their understandings is an essential component of self-assessment. The UK-based Assessment Reform Group (2002) has for some years been promoting assessment for learning, as distinct from the assessment of learning, and has articulated ten research-based principles which characterize assessment for learning. These include:

Principle 9: Independent learners have the ability to seek out and gain new skills, new knowledge and new understandings. They are able to engage in self-reflection and to identify the next steps in their learning. Teachers should equip learners with the desire and the capacity to do this for themselves through developing the skills of self-assessment (Assessment Reform Group, 2002).

Assessment conversations provide an ideal opportunity to help learners to develop and practice these skills.

Links with Portfolio Assessment

Assessment conversations are sometimes structured by being based on a student's portfolio, and then they form part of portfolio assessment. Discussions between teacher

and student are generally seen as being a vital component of portfolio assessment.

In portfolio assessment, students make a collection of samples of their work over an extended period – the principle of compiling a portfolio is sometimes expressed as: collect, select, and reflect. Student-kept records of reading and other evidence of learning can be included in a portfolio. Teacher observations and notes on conferences can also form part of the portfolio. Every aspect of keeping a portfolio, from the initial selection of work to the review of the final collection, can be discussed with teachers and/or with other students. In the process, students' awareness of the development of their work – its range, variety, and its relation to key criteria – is enhanced. Several authorities on portfolio assessment, including Roberta Camp, Ellen Krogh, and Val Klenowski, have commented on the basis for dialog that portfolios offer and how they make learning more visible (Camp, 1998; Klenowski, 2002).

Portfolios can be used to support peer assessment, where students review their work together. Portfolio assessment can also involve parents; portfolios can be shared with parents at regular parents' evenings or parent-teacher meetings. More ambitiously, parents have sometimes been involved as partners and stakeholders in portfolio assessment, and assessment conversations around the portfolio have been conducted as three-cornered discussions between parent, student, and teacher.

Assessment Conversations with Parents

Assessment conversations with parents can go further than the discussion of students' portfolios. They can contribute to the establishment of links with homes that will support students through their school careers. Schools can also benefit hugely from parents' knowledge of their children's home literacy experiences, their interests, and their approaches to learning. This knowledge can complement teachers' own observations of students' school learning, and help them to arrive at more-informed judgments of their literacy progress.

However, some parents feel disenfranchised from school settings, and some schools do not do enough to reach out to parents who did not have good school experiences themselves. Gaitan (2001) has documented the difficulties that parents can experience in participating fully in their children's education and has explored the particular issues that affect bilingual Latino children's literacy achievement. She argues that interactions between Latino parents, and between parents and school staff, are more than usually important to children's progress; they enable parents to understand the system and begin to make their viewpoints heard, and can affect practice in schools.

Teachers are not always sufficiently well prepared by their training to conduct effective parent-teacher

conferences. A national study of teacher-education programs in the USA found that in most universities parental involvement was not a required course for trainee teachers. Although classroom teachers assert that working with families is important to children's positive school outcomes, they receive little formal training and preparation to work with parents.

In her book *The Essential Conversation*, the distinguished African American educationalist Sara Lawrence-Lightfoot (2003) analyses the tensions that can exist when parents and teachers come together in the parent-teacher conference, but argues that effective and authentic dialogs in this setting are both possible and necessary for children's achievement in school. She views the student as the missing link in the parent-teacher conference and advocates the inclusion of children as full participants in the conference.

Some pioneering classroom teachers arrived independently at the belief that parent-teacher conferences would have more meaning and be more effective if the child/student were involved. In a self-study of her professional practice, an Alaskan elementary teacher, Terri Austin, has described how she moved to student-led conferences with parents:

I created student-led conferences as a result of seeing students negated in the assessment process. They virtually had no voice in any step of the traditional reporting. Now at the end of each quarter, my students prepare a portfolio of work that best represents them as a learner. The student and I review the portfolio and complete the report card together. On one evening, all the students and their families come for our conference night. The student leads their own conference, showing their work and answering parent questions (Austin, 2000).

In recent years, student-led conferences have begun to be part of more general practice. Schools find that preparing for the conferences helps students to be more reflective and more effective learners. They do not always supplant traditional conferences, but can supplement them (Hiatt-Michael, 2001).

Whether or not students are included in parent-teacher conferences, the student is always the center of the conversation. It is particularly important that such important conferences should be true dialogs in which all parties can share their perceptions, stories, and their concerns. If the conference is open and interactive, issues may surface that will help both parents and teachers to support children better.

Recent Developments in Assessment Conversations

Conversations between students and teachers are the essential stuff of teaching and learning. Applebee (1996),

in his book *Curriculum as Conversation*, has argued that we should design curriculum around "domains for conversation" and then help students enter these conversations "seeking not consensus but understanding difference, the willingness to listen, and the ability to disagree."

This article has argued for assessment as conversation – if students' perspectives on their own learning are to be taken fully into account, assessment also must be designed to include conversations and conferences between students, parents, and teachers. This last section looks at two recent developments in assessment that give full weight to conversations between students and teacher-evaluators.

The Learning Record

The Learning Record is a technology-based development from the print-based California Learning Record, which was in turn adapted from the UK PLR (1988). The international collaboration between the UK originators of the PLR and the developers of the Learning Record in California and in the University of Texas at Austin dates back to the late 1980s.

Regular conversations between teachers and children, and between teachers and parents, were an integral part of the original PLR and of the Learning Record in California. This emphasis on the involvement of children and their parents contributed to the reputation of the Learning Record as an assessment responsive to bilingual children and to cultural difference. The Learning Record lends itself readily to use with bilingual children and has been translated into Spanish. A paper on its use with deaf and bilingual children (Allen, 2005) can be found on the website of the University of California's Linguistic Minority Research Institute.

Between 1988 and 1994, the Learning Record became the only alternative assessment approved by the California State Department of Education as an alternative to standardized testing. It also became the first initiative in the history of the Bureau of Indian Affairs (BIA) that was supported both by BIA officials and tribal elders. In a series of countrywide moderations attended by BIA and California teachers (1999–2004), it achieved an inter-rater reliability rate of 90–92% – a consequence of thorough professional development and clear, shared descriptions of progress (Hallam, 2001). The Learning Record has been strongly endorsed by the US organization Fairtest.

A later version of the Learning Record was originally designed as an online portfolio and this form was used by hundreds of teachers and students at 14 institutions of higher education in the USA. However, it has now been redesigned – as part of a drive to radical simplicity – and has become a stand-alone Word version of the record. In this version, it can be accessed and transferred from the Learning Record website, administered by Dr. Margaret

Syverson at the Department of Rhetoric and Writing, University of Texas at Austin.

In its current form, the Learning Record is an essentially dialogic record. It is an evidence-based assessment in which information is collected by the student and organized, using a simple Word or Rich Text Format (RTF) document linked to a selection of their work. The student's commentary on this evidence of their learning is an integral part of the portfolio.

The assessment of the record takes place as students discuss their progress with their teacher – either in a face-to-face conversation or an online one. The eventual negotiation of a grade, based on the evidence provided and on clear, shared criteria, is part of this dialog. Students are paired to read and discuss their learning records in a peer moderation process. Examples of students' records and their commentaries, of teachers' responses, and of the moderation discussion process can all be found at the Learning Record website.

Assessment Conversations in the New Zealand Education Monitoring Project

The New Zealand Education Monitoring Project (NZEMP) is one of the most developed forms of national monitoring, and one of its interesting features is the fact that it employs specially trained teacher administrators to conduct assessments. Among the task approaches used is a one-to-one interview with a teacher, with the whole session recorded on videotape, and scored centrally by a team of assessors.

A serious effort is made throughout the NZEMP to engage students, both through the content and design of the actual tasks and through the involvement of the teacher administrator. One of the key aims of the NZEMP is to gain information about students' attitudes to learning as well as their factual knowledge and concepts. A remarkable feature of the project is the way in which, following the assessments, students are asked to evaluate the tests, saying which they most enjoyed doing (Crooks, 2007).

The teacher administrator aims to create a genuinely communicative situation in which the student responds to her directly and personally. For instance, in the *Whaka-boaboa* (personal introduction) oral presentation task, reported in Reading and Speaking Assessment Results 2004, the teacher first invites the student to introduce him/herself. After this, the teacher introduces her/himself and then encourages the student to say more: "Is there anything else you would like to tell me about yourself?" This task is videotaped and then scored centrally, with assessors considering the content of the student's personal introduction and its presentation (organization, clarity, fluency, and overall effectiveness).

The one-to-one reading assessments include a retelling, with the teacher as a receptive audience. Another reading assessment, *Favourite Book*, presents students with pictures of children reading and simply asks the student to think of a book that they really enjoyed and tell the teacher administrator as much as they can about it. Although the task is a standard one, the benefits of having an encouraging listener in a one-to-one assessment situation like this are obvious.

The NZEMP also includes a range of group assessments and Terry Crooks, the co-director, describes why these are an important part of the assessment system:

From the outset, we were aware that much classroom learning takes place in groups, and that interpersonal attitudes, communication skills, and group problem solving processes would appropriately be assessed through the use of group tasks. Groups provide an appropriate context for some listening, speaking, drama, and musical performance activities, as well as for areas where debate and discussion are appropriate (such as social studies). A further strength associated with the use of group tasks is that collectively a group can undertake substantial tasks that would be beyond the capabilities of some individual group members. . . NZEMP team tasks are administered to groups of four children, who work on each task for 10 to 20 minutes while their work is facilitated by a teacher and recorded on videotape.

To reduce the reading load for students, many of the tasks are presented through audio or video clips.

The NZEMP has taken the idea of assessment conversations, both between teachers and students and between groups of students, a long way. It recognizes that the social context of assessment strongly influences what students are able to do, and sets out to provide supportive interpersonal contexts in which to assess children's learning. One of its most innovative features is that children are asked to evaluate the tasks they have undertaken, and to say whether they enjoyed them – these responses are taken into account in the design of future tasks.

The Validity of Assessment Conferences

Johnston and Yanoff (2002), in an article on early childhood assessment and family literacy, draw attention to the concept of consequential validity in assessment. Assessments which feed back positively into classroom practice are greatly to be preferred, they say, to narrow assessments that diminish the curriculum:

We have to think about the learning community – how assessment practices affect the teachers, parents, children, and families involved. (Johnston and Yanoff, 2002)

The consequential validity of literacy conferences with students and with children is high. As teachers take into

account learners' perspectives and self-evaluations, as they involve parents in dialog about their children's progress, they are recognizing the complex and personal nature of literacy learning and making strong links with children's families and cultures. In addition, they are discovering more about the sense that their students are making of school literacy; discoveries which can help them to reshape their curriculum and their teaching.

Assessment: Pre-service and In-service Teacher Education

A Davies, Classroom Connections International, Courtenay, BC, Canada

© 2010 Elsevier Ltd. All rights reserved.

Elizabeth and her high school colleagues had a problem. Numerous ninth-grade students were not academically ready to learn what needed to be learned. They teach at an urban high school of 2500 students that serves students from a large area including four housing projects. This means working with students who may enter ninth grade with behavior plans, identified learning deficits or identified as students with special needs, including English Language Learners.

While working with these students over time, a variety of interventions were tried teacher by teacher and student by student. While there was some success, there wasn't enough. Elizabeth and her colleagues expanded their informal conversations to include the school leadership team. They talked about what they wanted for these students. They came to agreement on what success would look like. Together, as they considered what had worked and what hadn't, a possible solution emerged.

Now a larger intervention is being tried by more teachers under the umbrella of a school-wide effort to help every student be successful – “whatever it takes.” New ninth-grade students identified as being at risk by their eighth-grade teacher are put into a special team for 1 year. The teacher to student ratio has been reduced because classes are taught by a team – one regular education teacher and one teacher qualified in special education methods. These students need the skills to learn and are given extended time to learn them. As part of this intervention teachers are deliberately using assessment for learning to support success for all students. This larger intervention isn't perfect but thus far it is working better than the previous patchwork of small interventions tried by a few teachers. Informally day-by-day and formally during the year and at the end of the year, student successes and challenges are reviewed. Then, based on the qualitative and quantitative data, the intervention is adjusted and renewed.

With a growing recognition of the complexity of teaching and learning, the term ‘professional learning’ has emerged to replace ‘teacher training’ to describe the ongoing education of teachers and other educators. The example above describes a continuous assessment for learning cycle that engages teachers in professional learning that leads to increased student learning and achievement. It is learning that arises from the needs of students under the district and state commitment to success for all learners. Results are documented by informal and formal qualitative and quantitative data (feedback)

collected continuously. It is supported through ongoing reflection and collaboration with colleagues. Over time, the feedback feeds forward to more learning as teachers reflect and review student evidence and help students set new goals that lead to further action and learning. This is professional learning supported by assessment for learning that is embedded in the work of schools and the professionals who work within them.

The focus of this article is on supporting educators to learn about classroom assessment through engagement in assessment for adult learning. It is important for educators to learn about and be able to use effective classroom assessment to both support learning and evaluate student progress and achievement. Second, it is important that educators be able to apply these practices for student learning. Third, educators need to experience and be supported to use assessment for learning during professional learning opportunities. This is illustrated through a series of vignettes, a description of the acquisition of essential skills and understandings about classroom assessment and a consideration of professional learning from an assessment for learning perspective. This learning needs to occur during preservice education and throughout an educator's career given continuous curricula renewal, changing student needs, and evolving community expectations. This perspective complements the work of Darling-Hammond *et al.* (2009) in a review of research related to professional learning and Timperley and Parr's (2004) research showing the need for evidence-based professional learning. Further, it is supported by research that demonstrates the importance of initial and ongoing teacher training in the area of classroom assessment (James *et al.*, 2007).

Classroom Assessment

Preservice and in-service educators need to learn about classroom assessment: research, theory, and practices. Research in the area of classroom assessment is comprehensive and shows that the way to support more learning is through increased formative assessment that involves learners in the assessment process (Crooks, 1988; Black and Wiliam, 1998; Hattie and Timperley, 2007). There are four areas of research that support work in this area: motivation, classroom assessment, feedback, and summative evaluation. Each area is linked to classroom assessment practices that support student learning.

Research: Motivation

Educators report, and research confirms, that when learners are involved in the assessment process, they:

- engage in learning,
- develop a sense of ownership and commitment to their learning, and
- make choices about what to focus on next in their learning.

When the focus is on learning and performance (rather than evaluation and judgment), learners are more likely to be intrinsically motivated and encouraged to take risks that challenge and expand their learning. When feedback is specific and descriptive, learners are more likely to remain focused on learning and make informed choices about what to do next. When learners make choices about their learning, achievement increases; when choice is absent, learning decreases. The use of rewards of any kind – marks, grades, and evaluation – can result in learners being de-motivated and less willing to take the risks needed to learn. While at times summative evaluation may be required, it is important to try to keep the feedback as specific and descriptive as possible (rather than evaluative) in order to support learning (Covington, 1992; Dweck, 2000; Hattie and Timperley, 2007).

Research: Classroom Assessment

Research shows that when learners are involved in the assessment process, they learn and achieve more. When learners are involved in their own assessment – co-constructing criteria, self-assessing in relation to criteria, giving themselves information to feed forward their learning, collecting, and presenting evidence of their learning, and reflecting on the strengths and needs that are revealed – motivation and achievement increase. Learners are able to set informed and appropriate goals when they apply feedback to feed forward into learning. When learners are involved in their own assessment, mistakes become information or feedback to use to adjust what they are doing. When learners pay attention to mistakes in their learning and identify ways to improve, they learn. This is self-assessment. Self-assessment can provide feedback information to inform and further the learning. This kind of feedback/feedforward information is essential for learning (Black and Wiliam, 1998; Crooks, 1988; Hattie and Timperley, 2007).

When learners are involved in the assessment of their work, they consider their own strengths and the areas they need to improve. By doing so they have the opportunity to make the most of their strengths and correct or compensate for their weaknesses. This leads to greater learning success. Black and Wiliam (1998) put it this

way, “The research reported here shows conclusively that formative assessment does improve learning. The gains in achievement appear to be quite considerable, and as noted earlier, amongst the largest ever reported for educational interventions” (p. 61).

Research: Quality Feedback for Learning

There are two general categories of feedback: specific, descriptive feedback and evaluative feedback. Each has a different impact on learning. Specific, descriptive feedback comes during as well as after the learning. It is formative. It says what is working and what needs to be adjusted or changed. It provides information about what needs to be learned next or done differently – it feeds forward to more learning. This kind of feedback is easily understood by learners and relates directly to their learning. It is specific so performance can improve. It is often given in comparison to models, exemplars, samples, or descriptions.

Evaluative feedback often comes at the end of the learning. It is summative. It tells the learner how she or he has performed compared to others (norm-referenced assessment) or in relation to what was to be learned (criterion-referenced assessment). Evaluative feedback is communicated using letters, numbers, checks, or other symbols; it is encoded. Learners who receive evaluative feedback usually understand whether or not they need to improve. However, unless learners can decode the evaluative feedback, they may not have enough information to understand what they need to do differently in order to improve. Researchers report that letter grades and other symbols that communicate evaluative feedback can have a negative effect on learning. The negative effects are most pronounced with low-achieving students. Learners with poor marks are more likely to see themselves as failures. Learners who see themselves as failures are less likely to succeed as learners (Butler, 1988; Hattie and Timperley, 2007).

Research: Summative Assessment

Summative assessment – evaluation – comes at the end of learning, while formative assessment provides information and support during the learning. Summative assessment aims to evaluate what students know, can do, and can articulate at a given point in time. This evaluation is reported verbally or in writing to others. Summative assessment is more reliable and valid when evidence of learning is collected from multiple sources over time and when the evidence is examined in light of quality expectations or achievement indicators. Summative

assessment, at the classroom level, is based on evidence collected both during the learning by students and teachers as well as evidence collected at the end of learning. Evidence of learning may include observations of students engaged in the process of learning, products students create, test results, and student articulations of their understandings as evidenced through sources such as teacher notes, student self-assessments, or recordings of discussions. Anything students do, create, or articulate is potentially evidence of learning. It is important that evidence of student learning be in relation to clear learning targets, be of high quality and free of bias (James *et al.*, 2007; Stiggins, 2007). In recent years, there has been growing concerns regarding the quality of teacher-made tests and the appropriate use of external examination results in summative assessments (ARG, 2006). It is important that educators learn how to use tests and the information they provide appropriately.

Summative evaluation requires sufficient evidence that the intended learning has been achieved. In the past, the assumption has been that such evaluation was best done externally – with tests and other forms of evaluation created and monitored by outside sources. What research has revealed, however, is that when teachers are involved in becoming assessment literate and engaged in a conscious development and application of consistent criteria for summative evaluation, valid and reliable summative evaluation of the learning are more likely to result. Further, when clearly specified criteria that describe progressive levels of competence and procedures are developed and used to judge student work for evaluation purposes, teachers are more able to reliably assess a greater range of classroom work. Looking at a greater range of student work as they apply shared criteria increases the validity of professional judgments (ARG, 2006; Sadler, 1989). It is important that classroom teachers understand the role of external evaluations in terms of:

1. how the information is used to impact classrooms and education practice;
2. informing teachers' understanding of the effectiveness of classroom programs and instructional techniques;
3. providing information concerning trends and patterns with regard to indicators such as student learning, student achievement, evolving needs of learners, and changing emphasis of curricula; and
4. informing system-level decision-making so appropriate supports and resources can be provided.

In summary, when preservice and in-service educators learn about classroom assessment research, theory, and practices, they are better able to support student learning through assessment. Educators can then thoughtfully employ classroom assessment practices such as:

- setting clear learning targets;
- using samples to show quality and possible pathways to success;
- co-constructing criteria about important products, processes or other evidence of learning;
- engaging students in reflection, self-assessment, and peer assessment using a common language;
- ensuring that they give themselves and receive from others specific descriptive feedback;
- collecting ongoing evidence of their learning;
- preparing collections of evidence to show proof of learning; and
- involving students in communicating proof of learning to an audience.

When students are involved in creating and collecting evidence of learning in relation to clear learning goals, they have a greater opportunity to show proof of learning and use the language of assessment. When they communicate proof of learning to others using the language of assessment they inform others, receive feedback, and can consolidate plans for next steps. Lastly, teachers themselves also collect evidence of learning from multiple sources over time in relation to clear learning goals. When it is time to report, teachers engage in a process of summative assessment – evaluation – that involves professional judgment.

Professional Adult Learning

Classroom assessment research, theory, and practices, while important foci for professional learning, have opened new possibilities for helping adults engage in learning themselves. In this section, research regarding effective professional learning is described, and then assessment – as a vehicle for adult learning – is detailed.

Ongoing research related to adult learning demonstrates that they need to be engaged in their learning in a variety of ways, both alone and with others. Efficiencies cannot be gained by doing the same thing, at the same time, and in the same way (Darling-Hammond *et al.*, 2009). Research has also shown that adult learning experiences that result in lasting changes to beliefs and practices that make a difference for student learning are multifaceted and occur over time (Timperley and Parr, 2004). Professional learning may focus on classroom teachers, school or district leaders, or any certificated adult who supports students or the adults who work with them so in this article the term adult learning (not training) is used. It is essential that professional learning in the area of assessment not be limited to teachers. Teachers who are most successful in implementing assessment for learning are supported in their learning by school leaders (James *et al.*, 2007). Further, when school and district leaders use

assessment for learning strategies in their work in schools, implementation success is enhanced.

Research has shown that in different educational contexts adult learning is supported when it:

- is purpose-driven and related to overall vision;
- engages learners so they learn by doing and provides for learning to emerge through interaction with others;
- involves adult learners in learning alongside colleagues in response to personally identified needs, concerns, or issues;
- is supported by reflection and focused conversation with the larger community;
- results in sustained commitment and re-commitment to improving their teaching habits since change – learning – necessarily occurs at the individual level;
- invites us to learn from others whose knowledge, expertise, and wisdom we respect, with learning being embedded in apprenticeship-like experiences that acknowledge the complexity of the work; and
- is continually informed by evidence (quantitative and qualitative) about student learning from students, from self, others, and the system that feeds forward to new learning and new actions (reflective feedback).

Professional Learning

Assessment for learning needs to be an essential part of any professional learning initiative because it helps adult learners understand what success is, have a common language to use with one another, as well as monitor and make adjustments in response to ongoing assessment information. When assessment is used to guide adult learning in the same way that classroom teachers use assessment for learning to guide and support student learning, effective research and experience-based practices are modeled while ongoing learning is supported. Assessment for learning supports the learning of educators as they:

- are involved in co-constructing criteria which lead to clear learning goals, shared understanding of success, and a common language;
- give and receive specific, descriptive feedback about the learning – during the learning – for themselves and for others through increased self- and peer assessment in relation to the criteria;
- collect, select, reflect, and communicate evidence of their learning;
- set realistic and manageable goals for next steps; and
- engage in providing evidence of their own learning in preparation for performance reviews.

In the following section various aspects of assessment for learning practices are described and their application to adult learning articulated: co-constructing criteria, specific feedback, evidence of learning, and summative assessment.

Co-Constructing Criteria

Ms. C. meets with teachers and co-constructs criteria around what's important when setting criteria with students. The teachers then reflect on their own practice, self-assess, and set goals for involving their own students in setting criteria. Teachers then set criteria with their students and later share what they did with one another, explaining what worked and what didn't work. They then set goals and return to fine-tune the process of co-constructing criteria.

Criteria define and describe evidence or proof that demonstrates learning and achievement. When adult learners are involved in co-constructing criteria about key processes or products related to classroom assessment, important ideas are made explicit to all learners in language that they share and understand. They begin to gain the knowledge they need to make decisions to help close the gap between where they are in understanding how to support students and where they need to be. The process of co-constructing criteria provides adult learners with opportunities to confirm, consolidate, integrate new knowledge, and make better choices for next steps. Adult learners also have opportunities to share their ideas and check their personal theories. They not only witness a key process being modeled, they experience it and, as a result, are better prepared to engage their own students in similar ways.

Professional development leaders sometimes choose to use samples and models to inform the criteria setting process. Adult learners are more likely to understand what success is when it comes to classroom assessment when they can examine samples of work, watch video footage that illustrates key concepts, listen to teachers and other educators describe their practices, or visit classrooms to watch classroom assessment in action. Samples are useful to help adult learners understand:

- the attributes of quality classroom assessment;
- development from novice to experienced to expert; and
- different ways to adapt what is being learned.

When adult learners are engaged in discussion with professional development leaders about the learning expected before an activity or task and then co-construct criteria, the conversation clarifies options, highlights possible pathways to learning, and shares learning information across the group. Knowing what they are learning and what must be present in their work gives adult learners the information they need to keep themselves on track.

Giving and Receiving Specific, Descriptive Feedback

A whole school faculty co-constructed criteria around quality classroom assessment prior to district staff conducting a

walk-through to observe students and teachers at work. When the guests arrived to look for evidence, classroom doors had signs highlighting what part of the classroom assessment process could be witnessed. The signs said, “As you walk through my classroom, please notice that we are...”. Teachers also used the criteria to assist their own self-assessment and provide feedback to each other as they work to improve classroom assessment.

Specific feedback is important for learning. Each time adult learners reflect on their learning using co-constructed criteria, they are better able to articulate their learning and give themselves and others specific, descriptive feedback that will feed forward the learning. Quality feedback gives adult learners specific information they need to adjust or change what they are doing so they can learn and do better. When adult learners are assessed during the learning and evaluated at the end of the learning, they have time to practice and extend their learning; and, they learn more.

Multiplying good-quality feedback leads to more learning for adults. The learning brain needs continuous feedback – much like a fish needs water. The amount of specific, descriptive feedback that feeds forward to more learning is increased when sources of feedback are increased. Consider the co-constructed criteria described earlier. Adult learners can use the language of criteria to give themselves and others specific information to improve. They can observe their peers and give specific feedback, analyze professional practice, and select two elements that are powerful and something specific that could be done to improve their own practice.

Collecting, Selecting, Reflecting, and Presenting Evidence of Learning to Others

School leadership teams meet as part of a long-term ongoing commitment to improving quality classroom assessment. They commit to working with their colleagues and collecting evidence of learning. At the beginning of each session and at the end of each year members bring evidence of learning forward to share with others. They also set goals for the next learning period.

It is important to collect evidence of the impact (or not) of a professional learning initiative. Everything a learner says, does, or creates is potential evidence of learning. Professional development leaders involve adult learners in collecting proof of their learning. Involving adult learners in collecting, selecting, reflecting, and presenting evidence of learning is important because:

- Adult learners have an opportunity to affirm their understandings as they select evidence of learning to

show others. This helps them reflect on what has been learned.

- Adult learners have an opportunity to articulate what they have learned and what they still need to work on. The process of articulating what has been learned and considering how best to communicate it to others helps the learner learn more.
- When adult learners show evidence of learning to an audience of peers, they receive feedback and recognition for their learning and everyone has an opportunity to learn more.
- When evidence of adult learning is collected from a variety of sources over time and examined in terms of patterns and trends, the reliability and validity of the findings is increased.

Adult learners vary in terms of their background experiences, knowledge, and skills (inherent and learned). They require different kinds of input and levels of support in order to learn. Often adult learners need different learning paths and different evidence is created along the way. As a result, the collection of evidence of learning becomes increasingly complex because learners produce different kinds of evidence to show that they have met the criteria.

Once adult learners have collected evidence of their learning, a next step shows their evidence to others since the presence of others influences what and how we present. Performance reviews that involve learners in communicating evidence of their learning assist adult learners to step back and reflect – to assess what they are doing and reexamine their current practices. Some of the ways adult learners present evidence of learning include sharing student work samples, professional portfolios, or postings online. No matter what the format, it is important that adult learners identify what has been learned, what the evidence shows, and ask for specific feedback that can help them frame their own next learning steps.

Selecting Next Steps to Feed Forward Learning (Goal Setting)

Ms. G. uses protocols to support adult learning by providing feedback for their work and to their peers. Some of the teachers with whom she has worked have further adapted the protocols for work with their students to improve feedback/feedforward. Students insist on receiving good-quality feedback that helps their learning improve.

When adult learners self-assess using co-constructed criteria, they come to understand what they have learned. As they reflect and present evidence of learning to others, they identify possible next steps needed for their

continued learning. This is feedback that feeds forward into further learning for adults. Goal setting is simply the process of deciding what feedback to take forward as next steps. Next steps are realistic, manageable goals in relation to co-constructed criteria. Research and theory indicates that closing in on a goal triggers a part of the brain linked to emotions, motivation, and learning (Csikszentmihalyi, 1997). When professional development leaders ask adult learners to reflect and set realistic, manageable goals for learning in this way – to look at what they are doing well and what they need to improve in relation to co-constructed criteria – they help them prepare to learn more.

Summative Assessment: Assessment of Learning

In order to bring alignment to a system-wide initiative at the secondary school level, district leaders revamped the performance review system so as to mirror the classroom assessment process. Educators were asked to set professional learning goals, collect evidence of their learning from multiple sources over time, and meet with their supervisors to consider their strengths, areas of learning needs, and to set goals for next steps.

As professionals learn more about summative assessment, it is important that they engage in processes to inform their professional judgment since professional judgment is a key aspect of summative assessment. Here are a few of many possible examples of educators engaged in processes of summative assessment:

- Engaging in the process of moderation of student work in relation to co-constructed criteria is a key element.
- Using structured learning protocols to give oneself and one's colleagues specific feedback.
- Using protocols to engage groups of educators in examining student work to enhance common understandings of the quality required to meet achievement indicators.
- Involving adult learners in showing proof of their own learning through collecting evidence of learning from multiple sources overtime in relation to shared criteria and using that evidence in the performance review process.

Complex learning systems collect evidence – feedback information – from adult learners as well as consider a wide range of other data from a variety of sources over time. Significant learning – whether individuals or systems – takes time. Data collected from yearly achievement tests, for example, will not provide immediate evidence. Evidence has to be based on more sensitive data. Consider the marketplace. Economists use leading and

lagging indicators to help explain how change occurs. Education research shows that increased student learning and achievement (lagging indicator) follows powerful professional learning (leading indicator). External examinations are an example of a lagging indicator. Classroom assessment evidence of learning provides leading indicator information.

While it is critical that professional learning result in increased student learning and achievement, the demand for immediate results is unrealistic as it does not give adult learners time to adapt ideas for their students and their context nor systems time to align their policies, regulations, and practices. In order for adult learning to be successful, it needs to be ongoing, sustained, and connected to other aspects of change in the school community.

Professional learning that supports and sustains life long, independent, self-directed learners draws upon educators' strengths, communicates self-worth and capability, and views participants' individual differences as a value-added benefit to the group. Professional learning that works is purposeful, grounded in work with students, relevant to the adult learner, and uses assessment for learning to initiate and sustain learning that makes a difference for adults and then students over time.

Classroom Assessment in Policy Context (Australia)

J J Cumming, Griffith University, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

The one certainty about education policy is constant change. Charting educational practice within policy is fraught with difficulties. Certainty of practice at a point in time can change through legislative action, public pressures, and financial restrictions. This article describes the commonalities of Australian classroom assessment policy and practices that have emerged from the vagaries of cultural practice to be recognized as the standards of practice expected across the nation. Necessarily included in the discussion are the policy directions emerging in the twenty-first century that may or may not reach maturity, and may or may not affect the basic principles underlying classroom assessment in Australia.

Purposes of Classroom Assessment in Australia

Classroom assessment in Australia serves many purposes, both to chart student progress in learning and to provide the basis for reporting and accountability. A review of future schooling states:

[t]he primary purpose of assessment is for use in providing teachers with the information they need to improve each student's results and parents with information on their child's progress (Federalist Paper 2, Council for the Australian Federation Steering Committee, 2007).

Classroom assessment is valued in Australia for the scope it provides to teachers and students to engage in rich and complex curriculum and assessment activities, increasing the likelihood of knowledge transfer to settings beyond school. As one curriculum authority notes, "assessment tasks such as independent research projects and major works are likely to be the most challenging learning" students will undertake (Board of Studies (NSW), undated).

The international focus on assessment for learning (Assessment Reform Group, 1999) is clearly compatible with the Australian philosophy that assessment is to improve student learning. In most Australian classroom assessment contexts, distinctions between formative and summative assessments are not a major focus. Assessment of learning is ongoing, with summative assessment a point-in-time summary of the student's achievement for reporting, drawing on both formal and informal assessment data (Assessment Resource Centre, NSW Board of Studies).

Classroom assessment in Australia, then, is firmly focused on enhancing student learning. Moreover, Australian education policy endorses the principle of inclusivity – schools are a microcosm of society. Classrooms include children with differing levels of academic achievement, abilities and disabilities, and sociocultural and language backgrounds.

Policy Influences in Australian Education and Classroom Assessment

Inclusivity and Diversity of the Classroom

Australian education has long catered to students with special needs, originally in special schools. However, Australian policy during the last decades of the twentieth century and early twenty-first century endorsed inclusion of all students, to the extent possible, within regular classrooms, with legislated equitable practice established by the Disability Standards for Education 2005 (Cth), including curriculum and assessment design to allow all students to demonstrate their knowledge and achievement (s 6.3). Students generally attend specialist schools by parental (and student) choice. Otherwise, regular schools across all levels of schooling are expected to provide appropriate support for students with intellectual disability and/or physical impairments.

Australian classrooms also reflect our multicultural society. Students from migrant and refugee backgrounds enter school at all ages, often with limited or no English-language skills. In New South Wales, more than one in every four students is from a non-English-speaking background, that is, a language other than English is spoken in the home.

Not only do students within a classroom represent a broad range of abilities and linguistic and cultural backgrounds, but Australian schools are also socioculturally and geographically diverse. While most Australians live in coastal regions, many children live in rural or isolated areas, attending very small schools.

The diverse nature of classrooms has impact for classroom assessment. Assessment guidelines published by the Australasian Curriculum, Assessment and Certification Authorities (ACACA, 1995), while primarily focused on assessment for high school certification, provide principles for good practice across all levels of education. Schools are expected to reflect and respect student diversity, and to value different knowledge and experience (ACACA, 1995: 1).

As knowledge, particularly early knowledge, develops within cultural contexts, Australian schools are encouraged to modify their curriculum, learning and assessment practices, even in the final years of schooling (QSA, undated), to reflect and integrate with their communities, in order to promote effective learning and engagement.

Consideration of diverse ways and means of learning, as well as identifying and supporting communities to integrate their own cultural content into the curriculum, must be taken into account. The NTCF (Northern Territory Curriculum Framework) provides scope for learners to demonstrate outcomes within a range of contexts, including localised contexts. For example, Two-Way learning emphasises the importance of locally developed learning programs that uphold the values and learnings of particular communities (DEET(NT), 2007: 1).

Assessment is also expected to incorporate a range of instruments, under a range of conditions, in a variety of modes, to meet the needs of different learners, and facilitate student demonstration of achievement rather than creation of barriers due to the form of the assessment (ACACA, 1995: 3). This expectation further facilitates the design of different forms of assessments to suit students with special needs or diverse cultural backgrounds.

Within this framework of diverse classrooms and communities, the expectation is that Australian teachers will be able to identify students' knowledge backgrounds and needs, cultural and linguistic diversity, and plan appropriate learning activities and a variety of assessments to chart learning. Australian teachers are given considerable responsibility to plan student learning and assess students' progress, including assessment for end-of-schooling certification. A fundamental principle underpinning this responsibility is that education systems and communities in Australia respect teachers' professional capacity (Cumming and Maxwell, 2004). However, regard for, and expectation of, teacher professionalism occur in a highly structured educational environment managed through a range of national and state and territory policies.

Professional Standards for All Teachers

The second major policy context for Australian classroom assessment is the expected standard of teacher professionalism. All states and territories in Australia, except one, require school teachers to be registered or accredited through a state or territory authority. At the time of writing, the remaining territory (the Australian Capital Territory (ACT)) was finalizing registration processes.

Registration requirements generally specify personal suitability to teach (a fit and proper person) and 4 years of formal tertiary (university) training in an accredited teacher program, in conjunction with studies in discipline

areas in one or two areas for high school teachers. Teachers may also become specialists in special needs, or areas such as music, languages, or physical education.

Teacher registration authorities establish accreditation guidelines for teacher education program content and structure, including specified periods of practical experience with school mentors. Authorities elaborate professional teacher standards across skill levels, from graduate to advanced, and may require ongoing professional development for registration retention.

Classroom assessment knowledge is identified by the authorities as an integral component of quality teaching and hence required in teacher-education programs. For example, in Tasmania, a commencing teacher is expected to know how to develop a teaching sequence and "assess, plan and teach for the learning needs of a range of students" (Teachers Registration Board, 2007). In Queensland, new graduates should be able to:

- identify and apply learning experiences that incorporate flexible individual and group learning, teaching, assessment and 'have a sound fundamental knowledge of ...'
- effective ... assessment strategies and resources where ICT is embedded (and)
- authentic literacy and numeracy assessment strategies for gathering information and making judgements about students' language, literacy and numeracy development (Queensland College of Teachers, 2007: 10–11).

The expected assessment skill requirements are clearly demanding. Criticism has occurred regarding the extent to which such assessment skills are realized for new teachers (House of Representatives Standing Committee on Education and Vocational Training, 2007: 8). However, such concerns may be more indicative of high expectations of beginning teachers by the Australian public, than lack of appropriate novice skill level.

Control of Schools and Prescribed Curriculum

The third and fourth policy contexts influencing Australian classroom assessment are state and territory syllabi or curriculum frameworks, and regulation of schools, respectively. State and territory government authorities (often tripartite representing government, independent, and Catholic-sector interests) develop syllabi in numerous discipline areas, providing general but official guidelines on topics for instruction.

Two-thirds of Australian students attend government schools with the remaining one-third attending nongovernment schools, both secular and nonsecular. Schools and instructional programs are regulated in two ways in Australia. First, all schools receive federal funding, either directly or through funding to the state or territory government. Federal funding provision legislation specifies a

range of school requirements, using the power of the purse (Schools Assistance Act 2004). While nongovernment schools were less monitored by such legislation until the 1990s, legislative control gradually increased. By the twenty-first century, legislative requirements paralleled those for government schools.

The second mechanism for controlling schools occurs at the state or territory level. To operate, schools must meet accreditation and registration criteria under relevant state or territory legislation, including teacher qualifications, resources, capacity to maintain the health and safety of students, and, most importantly, “curriculum (including the framework of the curriculum and the principles on which the curriculum is based) (that) meets the curriculum requirements for students attending government schools” (Education Act 2004 (Tas), s88(6)(c)). Thus, all schools, both government and nongovernment, must use curriculum developed or recognized by their relevant curriculum authority.

Breadth of syllabus, dimensions and progressions, and classroom assessment

In Australia, syllabus frameworks in general separate into two levels. The first framework, from kindergarten/preparatory year to year 10 (K-10), focuses on key learning areas identified in a national agreement, the Adelaide Declaration (MCEETYA, 1999). Eight key learning areas were endorsed for the compulsory years (generally 6–15 years inclusive) – the arts, English, health and physical education, languages other than English, mathematics, science, studies of society, and environment technology. The second framework of syllabi addresses the senior secondary years leading to high school graduation and certification. Senior students select study areas, typically studying five or six subjects.

K-10 syllabi and classroom assessment

Using the K-10 syllabi, schools are expected to plan and integrate assessment across classrooms, years of schooling, and curriculum. In Western Australia, each school is required to have a whole-school assessment policy, consistent with the ACACA guidelines. Other states and territories incorporate the ACACA guidelines in advice to schools about good assessment practices.

Syllabi developed across Australia emphasize the interconnectivity of teaching, learning, and assessment. Therefore, it is difficult to talk about classroom assessment independent of curriculum contexts. During the last decade of the twentieth century, building from initial attempts to develop a national curriculum, states and territories endorsed outcomes-based frameworks for K-10 syllabi, outlining curriculum topics and charting development across levels of proficiency. Outcomes-based syllabi describe performance criteria and knowledge bases to be achieved by a student. The principle is that a student progresses when they have mastered a level, independent

of their year level in school, or the progress of their classroom peers.

Teachers are expected to use outcomes-based syllabi and descriptors of achievement to design learning activities and assessments that enable students to develop and demonstrate the target outcomes. Best practice addresses both multidisciplinary outcomes and multiple levels. Students work alongside one another to attain different learning goals extending their previous achievements. Reports to parents describe the level of achievement attained by their child and the type of skill the child has demonstrated.

The concept of outcomes-based syllabi and assessment is familiar. The same principle underpins grading in many sports, such as the martial arts and gymnastics. Students attain a skill level, learn a new repertoire, are assessed in performance, and, if successful, attain a new level of achievement. The motivation is the advancement, and self-improvement against specified standards, with the learner assessed when ready, and the repeated failure experienced by many in traditional school examinations avoided.

Although outcomes-based syllabi had yet to be fully realized in Australian classroom practice, by the turn of the twenty-first century they started to fall from favor. Reasons included media barrage for a return to the basics, and simpler reporting to parents. The outcomes-based syllabi did have two, possibly fatal, flaws. A syllabus should provide general guidelines for topics and sequences of instruction. However, outcomes-based syllabi became very detailed. While such detail could have been helpful for teachers for planning assessment, the volume of information across eight subjects and multiple levels overwhelmed many. Teachers were inadequately prepared to develop holistic, integrated learning and assessment activities, with the default adoption for many a checklist approach and questions such as how many times a child had to demonstrate achievement of a skill – 1 time? 3 times? 10 times? – to be assessed as having met a level (Cumming *et al.*, 2006). More professional development and support materials may have addressed these issues.

The second flaw was that the detailed reporting to parents was often couched in educatese, that is, the language used by educational professionals to describe a learning outcome to each other, rather than language parents could understand.

Senior schooling curriculum and classroom assessment

Australia is noted internationally for its use of classroom assessment for high-stakes assessment. Again, centralized syllabi guide classroom instruction and assessment. Across Australia, school graduation certification and achievement reports are based on a mix of classroom assessment and external-curriculum-based examinations. For example, in

Western Australia, classroom assessments in some subjects are weighted equally with external examinations for tertiary entrance purposes. However, with the raising of compulsory education years in that state to 17 years of age, not all students will be undertaking programs of study for university entrance, and many may never be required to take an external examination. In Victoria, the weighting of school assessments versus examinations varies according to the nature of the subject, with areas with high practical components, such as art, having higher school-based weighting. For most subjects, the weighting is 50–50. Queensland and the ACT differ from the other states, as final certification of achievement is based solely on classroom-based assessment and achievement.

Classroom-based components of assessment for high-stakes certification operate within a system of central governance. Relevant curriculum authorities monitor classroom assessment programs with subjects studied for university entrance monitored most extensively. In Queensland, samples of student achievement are monitored against the descriptors of levels of achievement in the syllabus (moderation) to provide comparability across schools.

Across Australia, classroom assessments in the senior years are expected to follow the ACACA guidelines (ACACA, 1995: 3) that good assessment practice requires “explicit, clear, unambiguous criteria declared in advance”: the provision of information to students outlining the curriculum framework in a subject; the assessment activities that will be completed and evidence that an appropriate range of assessment modes will be used; how these assessments will be weighted toward an overall grade; and guidelines for the criteria and standards to be used for assessment. Australian classroom assessment generally endorses criteria-referenced assessment (Sadler, 1987), with assessments against descriptors of performance rather than relative to other students.

It should be noted that in addition to university prerequisite and general subjects, students in high school in Australia may study vocational training subjects, either alone or as part of recognized certification. While partnership with training providers may occur, school teachers with appropriate qualifications may both instruct and assess students, using a competency-based approach, against competencies outlined in national training packages. This area of classroom assessment is beyond the scope of this article.

Ensuring student work is their own

When classroom assessment is used for summative purposes and high-stakes assessment, concerns are raised regarding assurance that work is the student’s own, often argued as a reason against using classroom assessment for such purposes. A further issue is the balance between acceptable teacher guidance and formative assessment during the development of student’s work, and its

summative assessment. Curriculum authorities and schools in Australia have developed a range of strategies to address these concerns. For example, the Senior Secondary Assessment Board of South Australia (SSABSA) Supervision and Verification Policy suggests close monitoring of and discussions with students during the production of the work, undertaking some components of assessment tasks in class (particularly for larger activities), team work, and developing new assignment activities regularly. In New South Wales, a program for teachers and students, All My Own Work, takes an ethical education stance about the issue, to raise student awareness about scholarly activity and plagiarism.

Initiatives to assist professional practice in classroom assessment

Current education and policy agendas have highlighted the need to provide ongoing professional development support for teachers. While external accountability regimes can have negative impact on the breadth of classroom curriculum and assessment practice, they do draw attention to the need for teachers to collect evidence on student progress. Teachers’ intuition or internalized knowledge of a student is no longer sufficient – reportable information is necessary, whether formal or informal such as classroom observation notes, practiced very successfully in early years of schooling.

Work to enhance teacher assessment knowledge and practice is ongoing, including seminars and workshops around Australia. Exemplary assessment activities, often cross curricular with technological foundations, are available through websites for use and modification. These activities identify syllabus components, often providing criteria and standards or rubrics for assessing student work and student work to exemplify different standards. A major goal of such work is not just to offer professional development, but also to provide teachers with greater assurance regarding the reliability of their judgment of students’ achievement and performance relative to other students in the state or territory – especially valuable to teachers in remote areas. However, the weakness of the assessment-sharing activities to date is the focus on summative assessment and grading of student performance but with limited scope for providing feedback to teachers to help to improve student learning, and the imposition of tasks that may not be embedded within the curriculum and context of the classroom.

Increasing Federalization of Curriculum and Classroom Assessment

A major (fifth) policy direction influencing classroom assessment in Australia for the twenty-first century is increasing federalization of both curriculum and classroom assessment. The Commonwealth of Australia was

created as a federation of states in 1901, under a Constitution that promoted both the common good of the nation, the Commonwealth, while ensuring the rights of states to manage their own affairs. While areas were identified in the original Constitution as the responsibility or reserve of the states, education was not mentioned. Unlike constitutions of some other nations, the Australian Constitution is not interpreted as giving reserve powers to states for matters that are not explicitly allocated in the Constitution, although the Australian government may not legislate to interfere in the policymaking powers of a state (Engineers case).

While there are ongoing contestations about increasing federalization of education, the ministers of education for each state and territory have been in agreement that national goals of education and curriculum are desirable since the Hobart Declaration of 1989, revisited in the Adelaide Declaration that identified the eight key learning areas.

Concerns about the crowded curriculum and reemphasis of basic areas of learning such as literacy and numeracy, especially in the early years of schooling, led to reconsideration of these key learning areas by the state and territory ministers. New discipline areas under consideration to replace the key learning areas include English, maths and science (including physics, chemistry, and biology), languages, humanities and social sciences (including history, geography, and economics), the arts (performing and visual), health and physical education, and cross-disciplinary learning areas (technology including information and communication technology (ICT) and design, civics and citizenship, and business). Such new policy directions do not apparently reduce curriculum but the weight accorded to different discipline areas would change from year to year.

Further national agreement has occurred through national statements in English, mathematics, science, civics and citizenship, and ICT (MCEETYA, 2007a) that states and territories have incorporated in syllabi, referred to as essential learnings but with some interpretative differences. However, the national statements are linked to mandated national testing (through the funding provisions), and the latter more than the former may have most impact on classroom teaching and assessment.

While outcomes-based syllabi were being challenged in public forums, the Australian Government intervened for the first time in classroom assessment practice, mandating that all schools must report student progress twice yearly to parents, in “plain language,” and “relative to the performance of the child’s peer group at the school” (Schools Assistance Act 2004, ss13, 22). Regulations further stipulated that such reports must include “an assessment against achievement levels or bands defined by the education authority or school,” in bands that “must be labelled as A, B, C, D, E (or an equivalent),” “clearly

defined against specific learning standards,” and must include, for each subject, “the child’s achievement relative to the achievement of the child’s peer group at the school by at least quartile bands” (Schools Assistance Regulations 2005, ss 2.3, 3.3).

As noted, school funding is contingent upon legislative compliance. Although the Tasmanian State Government indicated initially that it would not comply with the reporting regulations, report formats deemed to meet the guidelines were developed and a compromise reached. School sectors with strong commitment to nurturing the individual student in a positive manner, such as the Catholic sector, were also critical of the new peer-comparison requirement. However, school systems can meet the requirements using the outcomes-based syllabus assessment framework. Some schools address the quartile regulation by providing information on the percentage of students achieving each of the A–E levels (Catholic Education Archdiocese of Brisbane (undated)). Reporting on quartiles against peer group poses more challenges for the many small rural schools in Australia, where total enrolment of children across all primary school years may number fewer than 25 students, and each year level may be represented by only one or two children.

Classroom Assessment and External Assessment in the K-10 Years

The final (sixth) policy context affecting classroom assessment in Australia is the balance and impact of external versus classroom assessments of student achievement across the years of schooling. From the mid-1960s to late twentieth century, with the exception of a year 10 certificate in New South Wales, student assessment and reporting in the compulsory years have been classroom based.

In the first moves toward national collaboration, the Adelaide Declaration, the states and territories agreed to assess and report literacy and numeracy achievement against nationally developed literacy and numeracy benchmark standards for years 3, 5, and 7, initially on a sample basis but becoming cohort testing. By 2007, further agreement was reached that common national assessments would be used. Such tests apparently make little intrusion into classroom assessment practices. States and territories have in general avoided school league tables, pointing to the diversity of classrooms and school contexts. However, new federal legislative requirements for public reporting have exerted pressure on schools and internal pedagogy and assessment practices. Evidence is emerging of the negative effects, noted in other nations, of reduction in the breadth of classroom instruction and assessment practices, and teaching to the test (Cumming *et al.*, 2006).

External monitoring of student performance is increasing. In conjunction with the literacy and numeracy testing

at years 3, 5, 7 and 9, national testing will be implemented in ICT literacy at years 6 and 10 and science literacy in year 6 (MCEETYA, 2007b). Over time, these programs of external monitoring must impact on classroom assessment practices in Australia.

Future Challenges

Classroom assessment in Australia provides a quality of practice and sophistication that can be taken for granted. However, even within this context of practice, four areas offer new or increased challenges.

Increasing Student Diversity in the Senior Years of Schooling

As noted earlier, an area of challenge for the future for senior schooling is the goal of increased school retention. Approximately two-thirds of the potential year level (67%) complete the final year of schooling, year 12, a retention rate that has been consistent for a decade. A further 15% complete year 12 equivalence through other education (MCEETYA, 2006). Increasing the age of compulsory education (or training or employment) will require an increase in study options to address the needs of all students. Increasing diversity in senior schooling will require considerable change in the assessment knowledge and practices of teachers who have previously worked within narrower discipline studies and with cohorts of students academically motivated by the goal of university entrance.

Diagnosis of Special Learning Needs

An area of classroom assessment needing attention is diagnostic assessment, the ascertainment of specific areas of need or learning difficulties, as opposed to formative assessment to shape student progress. The corollary of inclusive practices is that classroom teachers encounter students with diverse learning needs, many of whom may have learning difficulties or disabilities that have not yet been identified. If a teacher considers the student has a special need, the student is referred to a specialist for assessment. The critical issue is that classroom teachers need to identify when such a referral should occur. Evidence of lack of knowledge to do so is emerging through the law courts. Legal challenges are already occurring in Australia and the United Kingdom by students whose disabilities were not appropriately diagnosed in time to provide intervention.

The extent to which teachers are provided with support and guidance in this area of classroom assessment is still limited. Special instructional programs in early reading and

mathematics that often incorporate ongoing diagnostic and formative assessment activities are in place in schools. In Queensland, the Year 2 Diagnostic Net provides a structured interview and resources for teachers to individually assess students' strengths and needs in literacy and numeracy. Initially, all students were assessed. However, the Net is now used for students believed to be at risk, negating its effectiveness in identifying students who might otherwise escape teacher notice and the Net. Victoria is undertaking work in this area with an online interview in mathematics to assist teachers to identify students' strengths and needs in this area (DEECD, undated).

The Role of Technology in Classroom Assessment

The expectations that teachers maintain comprehensive records of student assessments against curriculum outcomes or essential learnings, the use of portfolios to record students' work across the years of schooling, and comparative reporting of student achievement to parents have placed considerable demand on teachers to maintain records and materials. States and territories, and government and nongovernment sectors, are using technological resources to assist teachers. Electronic records, the provision of exemplars previously discussed, and online recording of student outcomes are some of the technological solutions in progress, and which can be expected to expand exponentially in the twenty-first century.

Assessing All Goals of Learning

State and territory syllabi fulsomely articulate learning goals that are not just content based but also directed at what has previously been called the affective domain. All Australian education authorities aim to develop lifelong learners with skills in learning how to learn, effective Australian and global citizens, critical thinkers and problem solvers, and persons with resilience and a range of other personal characteristics – incorporating what have been referred to as conative knowledge (Snow, 1989), personal learning (Cumming, 2001), or learning power (Broadfoot, 2007). While regarded as an essential component of the K-10 syllabi, this area has yet to be developed across all states in classroom assessments and reporting. The Victorian Department of Education has developed frameworks and assessment tools for personal learning that give the fullest guidance to teachers. Given endorsement in the goals of education for the twenty-first century of the principles espoused in conative and personal learning, assessment in this area is a challenge to come. The classroom assessment practices of Australia provide the most opportunities for such an assessment reform to occur.

Conclusion

Classroom assessment in Australia is regarded as a fundamental dimension of education: to help students, identify needs, promote further learning, and to report achievement. Teachers are trained professionals who make judgments about student performance within a structured environment of syllabi and with increased central governance, as assessments become more high stakes. The benefit of classroom assessment approaches in Australian schooling has been the breadth of learning and performance facilitated by classroom assessment. Differences among the states and territories do occur. These can be seen either as detrimental to Australian national unity and cohesion, or as laboratories that enable experimentation with curriculum and assessment. The latter view allows best practices to be identified and used in other states. However, when state and territory assessment practices are examined, strong commonalities emerge. A watching brief for classroom assessment in Australia during the twenty-first century will be the impact of increasing federalization of curriculum, and testing, on what have been to date highly student focused and enriched classroom assessment practices with successful learning outcomes.

Classroom Assessment in Policy Context (England and France)

M Osborn, University of Bristol, Bristol, UK

M Raveaud, Université du Maine, Le Mans, France

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Assessment is a social practice and social product that entails a conception of learning and of the learner. It is value laden and socially constructed (Broadfoot *et al.*, 2001). In this article, we compare assessment policy and practice in two countries with very distinctive educational priorities and traditions, England and France, to illustrate the extent to which classroom assessment is culturally situated and closely linked with the key values of an educational system (Planel *et al.*, 2000).

The article contrasts the policy context in England and France, and draws upon comparative empirical research on assessment practice in both countries. It points not only to a shared experience of a gap between policy and practice, but also to the cultural embeddedness of assessment practice.

The Policy Context for Assessment in England and France

The article assumes that the English policy context will be more familiar to readers (Gipps *et al.*, 1995; Scott, 2007). This is therefore outlined briefly while more space is given to describing the context in France.

England

Currently, in England, all pupils of years 2 (approximately 7 years old) and 6 (approximately 11 years old) in primary school are assessed through statutory assessment involving teacher assessment (TA) and a combination of standard tasks and/or tests.

In addition to statutory assessment, ongoing assessment by teachers has become a more overt feature of classroom life in England. The PACE (Primary assessment, curriculum, and experience) study which studied teachers, schools, and classrooms over 6 years of reform from 1989–95, found that the majority of teachers believed that assessment was the aspect of their practice and skills that had changed most significantly following the continuous policy changes of the last 20 years (Osborn *et al.*, 2000; Pollard *et al.*, 2000). The introduction of more rigorous assessment of subject knowledge as specified by the national curriculum, introduced by the Education Reform Act (ERA), 1988, represented a move

in the direction of more overt and explicit assessment. Many teachers hoped to be able to develop their required TA as formative assessment and to build it as an integral part of their classroom practice. However in the early days of the reforms, the scale and complexity of the record keeping and evidence gathering required, threatened to overwhelm teachers and Gipps *et al.* (1995) reported that TAs remained intuitive rather than being evidence based. In addition, the requirement for teachers in years 2 and 6 to aggregate their assessment for each attainment target, for each child, into a national-curriculum level, which was to be reported alongside each child's scholastic aptitude test (SAT) results, was seen as an attack on teacher professionalism (Osborn *et al.*, 2000).

Virtually all schools in England have explicit assessment policies and teachers are encouraged to collect the following for each child in their class: individual reading record; individual maths record; child's grouping for maths/English and other subjects; an individual portfolio containing samples of a child's work; TAs plus task or test results; and national-curriculum summary record, showing work covered and individual progress. While much of this evidence would have been collected prior to the ERA, the records became more detailed and more directly tied to national curriculum attainment targets as the PACE study progressed. With the increasing age of pupils and pressure of national testing, there was also a decrease in the use of more formative approaches to assessment, such as listening and observing, and an increase in activities, such as marking work and recording, and regular classroom tests. The PACE study (Pollard *et al.*, 2000; Osborn *et al.*, 2000) and the research of Gipps *et al.* (1995) suggest that there is much evidence that teachers have developed increased skills and confidence in their assessment practices. However, the PACE data also showed that although the national tests may be accommodated by teachers, the effect on classroom practice is profound. Besides the more obvious sessions of revision and teaching to the test which were observed in year-6 classes, there was also increasing evidence of a wash-back effect which reached into year groups that were not immediately involved with the tests. This appeared to be diminishing the opportunities for teachers to work in a way that enabled them to develop the whole child and address the social concerns of parents and the wider society.

Paradoxically, while British government policy was moving in the direction of more overt, explicit, and

summative assessment, similar to a traditional French model, French policy discourse appeared to be moving toward a more traditional English emphasis although changes in practice did not necessarily follow.

France

As in England, policy discourse in France has adopted research-based categories distinguishing summative and formative (in which case the French official terminology is diagnostic) assessment.

The French policy context has been characterized by a top-down drive toward diagnostic assessment as part of a wider trend to use assessment – not only of students but also of systems, of management procedures, of institutions – as a form of governance in an increasingly decentralized education system. Assessment, particularly summative assessment, has traditionally had a very high status in French education. However, the two major education acts passed recently (*Lois d'orientation* of 1989 and 2005) have attempted to introduce a culture shift from summative to diagnostic/formative assessment. While they stem from opposed political views (left-wing government in 1989, right-wing in 2005) with diverging views about the missions and management of the education system, both resort to diagnostic assessment as a tool to identify student needs, and thus ultimately improve the education system and increase school effectiveness.

Pedagogically, these reforms have contributed to making differentiated teaching possible and to providing (or imposing) tools for diagnostic assessment. For instance, curricular aims, traditionally set out as annual goals, have been restructured into triennial cycles to encourage a degree of differentiation in teaching instead of making pupils repeat a year. Formative assessment tools have been supplied by the Ministry, complete with keys for

analyzing their results, to encourage teachers to plan their teaching according to students' needs. A pool of such resources is available online for all levels, and national compulsory evaluations for 8-year-olds and 11-year-olds are carried out at the beginning of a new cycle. **Table 1** summarizes major reforms in this attempt at a culture change and their expected impact on classroom practice.

So far, these top-down initiatives appear to have had little impact on classroom practice as described in academic research and inspection reports (IGEN-IGAEN, 2005). Traditional practice remains largely unchanged in France despite research pointing to the limits of summative assessment as practiced in the French context. For instance, the pedagogical benefit of repeating a year has been called into question. Similarly, pseudoscientific annual results expressed as averages out of 20 remain the basis for determining whether a pupil should be held back a year despite evidence that grading varies depending on factors such as the teacher carrying out the assessment, the order in which papers are marked, pupil characteristics such as gender or sociocultural background, school and class variables. Classroom-assessment practice in France typically continues to focus on subject-specific aims in 97% of cases rather than cross-curricular aims (31%), with assessment of knowledge (84%) taking precedence over that of skills and attitudes (29%), and it remains under the control of the class teacher with little collaborative planning, coordination, or sharing of resources with colleagues, and an equally infrequent use of resources such as the Ministry's pool of tests (*banque d'outils*) (Ministère de l'Éducation Nationale, 2005a).

Teaching practice in France has proved largely resistant to policy-led changes, due to a culture of summative assessment rooted in a strong consensus regarding the educational and cultural values underlying the aims and practice of classroom assessment (Broadfoot *et al.*, 2001;

Table 1 Policy reform in France and intended impact on classroom practice

Year	Reform	Intended impact
1989	<i>Cycles</i> : restructuring the national curriculum into cycles (key stages) instead of setting annual targets	Allows for a degree of pedagogical differentiation, maintaining common goals to be reached by all pupils, but within 3-year cycles
1989	National compulsory evaluations with formative aims at ages 8 (CE2) and 11 (6 ^e), carried out at the beginning of a new cycle	Top-down introduction of compulsory formative-assessment tools, complete with feedback mechanisms for teachers to plan their teaching accordingly
2005	<i>Socle commun</i> : lists the knowledge, skills, and attitudes that each child must be equipped with, by school-leaving age	Change in relevant assessment: replacing averages with a binary notion (acquired or not) that excludes compensation between knowledge of one notion and ignorance of another
2005	<i>Banque d'outils d'aide à l'évaluation</i> : a pool of formative assessment resources set up by the Ministry for all levels of compulsory schooling	Resources and guidance including tests and analysis of student responses so as to identify the areas of knowledge and skills that have not been acquired
2005	<i>Programme personnalisé de réussite éducative</i> (PPRE): students are entitled to personalized support programs if they appear likely to fail to meet end-of-cycle targets and to acquire the <i>socle commun</i>	Cross-disciplinary remedial or preventive approaches based on assessment to identify target students, set up their PPRE and monitor progress; partnership between various education, social, and healthcare actors

Planel *et al.*, 2000). While policy stresses formative assessment to plan teaching using pedagogical differentiation to remedy individual students' identified weaknesses, dominant teaching practice relies heavily on summative assessment expressed as grades that are perceived as an objective measurement of student performance against standard curricular aims that are identical for the whole class and based on the national curriculum rather than previous student attainment (Raveaud, 2004). In other words, teachers tend to make little use of new statutory possibilities for classroom autonomy and remain attached to the tradition of universalism and national uniformity in teaching, perceived as a safeguard against arbitrary treatment of students. French teachers resist longitudinal monitoring of student progress and the transmission between classes or cycles of student profiles, as such mechanisms are considered as giving students a criminal record (IGEN-IGAEN, 2005: 54) that could lead to perpetuating prejudice.

Comparing National Assessment and Classroom-Assessment Practice in England and France

This section considers similarities and differences in both the national tests and in classroom-assessment practice in England and France. In both countries, there is evidence of discrepancies between the aims, content, and ideology of national policy discourse and of national tests and actual classroom practice. For example, while in France the emphasis of policy discourse is on the use of national tests for diagnostic evaluation for teaching purposes, in England the aim of national testing is to monitor and evaluate output and to raise standards through market competition between schools. As we saw earlier, in France,

national assessment policy has had little impact on classroom practice, whereas in England, most teachers believe that they have changed their practice in terms of assessment more than in any other area. In the PACE and STEP (Systems, teachers and education policy) studies, 84% of teachers said that they had given assessment skills more importance following reforms as against 69% of French teachers. Almost one-third of French teachers felt that their practice had not changed at all, following reforms (Broadfoot *et al.*, 2001). In England, there is also considerable concern about washback effects of national testing on classroom practice and on teacher and learner perceptions (Scott, 2007).

Table 2 summarizes the key areas of difference in the English and French national tests at the end of primary and beginning of secondary schooling.

So although there are similarities between the aims of the two countries in terms of their prioritizing of educational outcomes and the monitoring of the progress of the reforms they have introduced, there are also key differences in their educational ideologies. The introduction of national testing caused much tension between politicians and professionals in England, whereas in France there appeared to be greater consensus between policymakers and professionals about testing, reflecting the traditional values of universalism. The 1988 ERA in England, which introduced national testing, reflected a fundamental change toward the marketization of education where schools would compete for clients. The *Lois d'Orientation sur l'éducation* of 1989 and of 2005 were less politically charged and did not represent such a major shift (Broadfoot *et al.*, 2001). In both theory and practice, French national testing is more directly supportive of professional educators and the French national tests were designed to guide teaching and learning while the English tests functioned more for purposes of accountability and influencing the curriculum and teaching at a time when the

Table 2 The key areas of difference between English and French national tests at the end of primary/beginning of secondary schooling

	England	France
National test aims and uses	Monitor and evaluate output, indirectly raise standards through competition between schools	Diagnostic evidence for teaching purposes over time, consideration of trends over time, awareness of socioeconomic variables
Relationship between curriculum and test	Matching width, approach, and differentiation	Matching a narrower but deeper curriculum; matching uniform level and subject compartmentalization
Test structure; administration and marking	Differentiated, individualized approach, more subjective marking	Uniform structure, more objective marking
Relationship between test and learning	Matching open and more experimental approach; matching emphasis on ability	Matching more closed, formulaic, and abstract approach; matching emphasis on knowledge and skills learnt

From Planel, P., Broadfoot, P., Osborn, M., Sharpe, K., and Ward, B. (2000). National assessments: Underlying cultural values revealed by comparing English and French national tests. *European Journal of Education* 35(3), 363.

government was seeking to carry through its educational reforms.

These comparisons and those that follow were carried out as part of a series of research projects conducted in both France and England since the 1980s. These include the Bristaix project that ran from 1984 to 1987, the PACE project that ran from 1989 to 1997, the STEP project (1992–93), the Quality of education systems transnationally (QUEST) project (1996–98), and the Education and national culture: A comparative study of attitudes to secondary schooling (ENCOMPASS) project that ran from 1998 to 2000 (Broadfoot *et al.*, 2000; Osborn *et al.*, 2003; Raveaud, 2006). These various studies embraced both teachers' and pupils' perspectives, policymaking, and classroom practice in England and France. They were linked by the use of a comparative approach to illuminate key features of the teaching and learning process and focused particularly on the impact of the educational policy change in both countries and the challenge these posed for teachers to change, in more or less fundamental ways, their professional perspectives and ways of working. This article draws upon all of these to illuminate cultural influences on the meaning and practice of assessment as perceived by both the teachers and the pupils in the study with the aim of demonstrating the relativity of this aspect of classroom experience. In particular, the QUEST study used specifically devised literacy and math assessments as well as interviews, questionnaires, and observation to establish the ways in which pupils' performance differed from one country to another and to explore the pedagogical and cultural reasons for those differences. The study aimed to analyze the significance of national differences in teaching and learning in England and France and to compare pupil perceptions of learning and assessment.

The study found that the underlying national attitudes and traditions were, to a certain extent, resistant to change. Despite reforms that brought more control to the center in England and attempts to create more diversity in France, the English system continued to be characterized by individuality and diversity, while the French system remained a centralized, bureaucratic structure.

Thus, although the *loi d'orientation* (1989) in France was introduced to promote a more child-centered approach to education and aimed to increase school autonomy in the organization of learning, the classroom practice we observed had not fundamentally changed. The focus of lessons in France was still on the acquisition of skills to standardized national levels, a transmission style of teaching, and moving the class forward as a single unit. The French classrooms we observed were work centered and relatively formal. Teacher expectations of performance were explicit and children knew precisely how well they were doing on the basis of the regular, public allocation of marks. Poor performance in class could mean public disapproval and even humiliation by the teacher. Pupil

satisfaction was often linked to evidence of academic achievement and pupils were motivated to try harder. Pupils were able to discuss their progress or lack of it in an articulate way and were aware of reasons for their success and failure. Academic success was seen by both teachers and pupils as closely linked with effort, which may also account for the continuing practice of holding students back a year rather than differentiating teaching to deal with the range of attainment in the classroom.

In contrast, English primary education was informed by a continued concern for the whole child and for the school as a community. There was an emphasis on trying to make learning fun and on a broadly based curriculum but this very focus on the whole person led to a tendency both for teachers to judge pupils in terms of their personal and social characteristics and an innate level of ability, and for pupils to develop an identity as a learner on those terms (Broadfoot *et al.*, 2000, 2001). Although English primary teachers emphasized a positive and pupil-centered evaluation of performance and tried to minimize the effects of overt, categorical assessment, many English primary pupils were less motivated and positive about school than their French counterparts.

Overall, the QUEST study found that, despite some recent convergence between the values underpinning the French and English systems, English pupils are still expected to reach widely varying levels of attainment which government policy discourse sees as reflecting their innate ability. In contrast, French pupils are expected to strive to achieve a common level of attainment and this achievement is seen as reflecting the amount of effort they are prepared to exert. This emphasis on common rather than differentiated learning outcomes has an impact on assessment criteria. When we compared French and English teachers' approaches to assessing children's writing (Osborn and Planel, 1999), we found that French teachers expected correctness and conformity to a predetermined plan, while teachers in England looked for creativity and divergence and emphasized process rather than product. French teachers tended to make greater use of negative language and sanctions, using finite marks where English teachers made open-ended comments.

These findings were echoed in the research carried out by Raveaud (2006) with younger children in England and France. Observations were carried out in 15 classrooms of pupils aged 4–6, between 1998 and 2001, and continued in 2007–08. Assessment practice in these classes confirmed the culturally situated nature of key educational concepts, and acted as a lens revealing different priorities in the English and French education systems (Raveaud, 2004). One example shows the extent to which the notion of a mistake is socially constructed, for instance, when children are learning to write. In the classes observed in England, in parallel with an emphasis on spelling, much writing was linked to communication and

expression, whatever the pupils' degree of competence in spelling. Many emergent writing strategies were encountered, where young children wrote the sounds they heard, leaving out the parts of difficult words they could not identify. In this way, a high-attaining 4-year-old wrote "The b- is in a b- h-as n in l- to go on a l-" (The butterfly is in a butterfly house and likes to go on a leaf.). This method was compatible with the national curriculum which, despite a concern with spelling, states that pupils should be taught to write familiar words and attempt unfamiliar ones (DfEE/QCA, 1999: 48).

By contrast, French pupils were given fewer opportunities to write their own texts: they are intended to spell words correctly as soon as they start writing so that they do not memorize mistakes. Opportunities for creative writing are limited in French children's early schooldays, until they have mastered enough spelling and grammar to enable them to produce correct texts. Until then, much writing consists in copying from the blackboard or from a book, in line with the French curriculum: "until basic skills (forming letters, mastering the main rules of spelling) have been acquired and become automatic, it is difficult for the child to concentrate fully on more delicate tasks such as ordering information, structuring a text or composing their own sentences" (Ministère de l'Éducation Nationale, 2002: 87). As a result, what would be considered as a mistake in French classes was tolerated, if not encouraged, in English infant classes where pupils gradually built up their own understanding of sound-symbol relationships. The emphasis shifted from the outcome of a task to the act of learning, highlighting the product or the process of learning.

The form and scope of assessment also differed. While teachers in both countries gave oral and written feedback to pupils, French teachers were more likely to limit the written component of assessment to a grade, while English teachers favored comments not only on cognitive outcome but also on efforts, progress, and neatness. These factors were also taken into account in French classes, but only orally. The mark was conceived as a measurement of work against an absolute norm that could not be relative to an individual child's efforts or prior attainment, whereas English schools sought to reflect the stage reached in the development of pupils' learning. The French notion of an external, criterion-referenced standard of attainment gives way to a more diffuse evaluation akin to Bernstein's invisible pedagogy where a pupil's behavior and dispositions are taken into account, thus laying open more of the child to the teacher's assessing eye.

Some of these dimensions of difference found in these studies are summarized in **Table 3**.

It is striking that in some of the dimensions identified here, the policy discourse in each country appeared to be shifting each education system closer to the other,

Table 3 Dimensions of assessment

	<i>England</i>	<i>France</i>
Emphasis on	Process of learning	Product of learning
Assessment reference	Relative to child's attainment	Absolute, criterion-referenced
Classroom-assessment tasks	Frequently differentiated by attainment	Identical for all
Form of written assessment	Comment	Mark, grade
Dimensions taken into account	Prior attainment, effort, neatness	Cognitive outcome
Institutional stakes for students	Grouping, occasionally setting	Repeating a year (redoubler)

Adapted from Broadfoot, P., Osborn, M., Planel, C., and Sharpe, K. (2000). *Promoting Quality in Learning: Does England Have the Answer?* London: Cassell.

although the classroom practice observed held closer to the original dimensions and was more resistant to change.

Teachers' response to assessment in the two countries has also been very different. As Alexander (2001) argues, while teachers in many countries talk about assessment, it is above all in England that teachers see what they call the burden of assessment as oppressive and alienating. As he puts it, following the reforms of the late 1980s and 1990s, teachers in England found assessment burdensome "because it was outside their control, because it had been imposed on them in a form and at a time that they were not in a position to question" (p. 372) and because it had become heavily politicized.

Although there is evidence that teachers in England now feel more at ease with the current assessment requirements, it is still the case that there has been concern among educators and parents with what is seen as the overassessment of children and a possible link with anxiety, unhappiness, and a loss of motivation in learning. Certainly, the PACE study (Pollard *et al.*, 2000) found that children's feelings about testing became increasingly negative as they progressed through school with a peak in year 6 at the key stage-2 tests. Currently, schools and teachers are under pressure to demonstrate constant improvement in performance as a result of target setting and due to parental pressure, Office for Standards in Education (Ofsted) inspections, and publication of results (Osborn *et al.*, 2000; Scott, 2007). As James (2000) notes, the pressure on schools and teachers is far from accidental but is a form of intentional washback based on the expectation that the publication of league tables of performance would lead to open competition for students and push schools to improve. Teachers in England feel that their work

is evaluated more by the test results than by their TA. As one of the teachers in Scott's (2007) study argued:

I think most people look at the test results. I don't think they give two splodges of marmalade for what I put. . . . at the end of the day it's like 74% of people passed their test and got at least a Level 2 rather than me saying well, I think he can do (such and such) (Scott, 2007: 37).

In contrast, teachers in France generally feel positively about assessment and share similar goals. Ninety-five percent of secondary school teachers agreed that the purpose of assessment is to measure students' attainment, with 20% only using it as a decision-making tool (Ministère de l'Éducation Nationale, 2005b). It is also the case, as the following quote from the QUEST study illustrates that there has been little compulsion to change their assessment practice in the classroom. A typical comment from a French teacher was

Les ministres passent, les enseignants restent et évoluent à leur rythme. (Ministers (of education) come and go: teachers stay and change in their own time.)

Or:

Il y a les belles idées; et il y a ce qui se passe en classe. (There are beautiful ideas and there is what happens in class.)

Two factors, however, have led to a growing diversity in assessment practice over the past decade. The first is related to student characteristics: in underprivileged schools where academic achievement tends to be weaker, there is evidence of teachers adapting their academic goals, methods, and assessment practice, for instance, by lowering academic standards so as to avoid failure on a massive scale, or by taking into account relational dimensions and not only cognitive outcomes. Second, changing teacher characteristics have led to renewed ethical references shifting away from egalitarian principles and a strict republican ethos toward more student-centered concerns. What change has been observed in classroom practice in France may be more strongly related to these two factors than to top-down policy reforms.

Conclusion

The purpose of comparing these two assessment cultures has been to demonstrate the cultural situatedness of assessment beliefs and practices. As Broadfoot argues, in a sense the French system has had to move toward the mode of control traditional in English education, and central to the efficacy of these changes has been a very substantially increased role for assessment of students, of

schools, and of the system as a whole. Assessment is an inevitable feature of both classroom life and of institutions and educational systems as a whole. It is one of the most powerful forces shaping learning but we should not lose sight of the extent to which it is a social, culturally embedded process and will thus vary considerably from one educational culture to another. The article has emphasized the differences as well as the similarities of assessment approaches taken by the two education systems with differing values and priorities and the impact of this on teaching, learning, and pupil identity. The English education system, even after the 1988 ERA, takes a wider view of the pupil than does the French system, informed by the republican model of social justice that requires assessment to be conceived, as far as possible, as an objective, universal measurement. Such cultural differences in educational values are conveyed to pupils through varying assessment discourses and practices, and lead to differing pupil expectations of the learning process. The "effective harnessing of assessment to promote learning" (Broadfoot *et al.*, 2001: 59) depends on our understanding of the way in which assessment conveys these cultural messages and of the effect this has on learner identity.

Classroom Assessment in Policy Context (French Sources)

D Laveault, University of Ottawa, Ottawa, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

The increased recognition of the impact of better and more efficient classroom-assessment practices on student learning has led government and local administrations to develop policies on classroom assessment to capitalize on its benefits. Such policies are varied and depend on national and local context. French sources are used in this article to report on how policy decisions have influenced classroom assessment to enhance its quality and use. French sources used here are limited to four countries which share French as an official language of instruction and which have contributed several scientific publications on the subject: Belgium, Canada, France, and Switzerland. All four countries are part of the same international organization, *l'Association pour le développement des méthodologies en éducation* (ADMEÉ) and share the same scholarly journal *Mesure et évaluation en éducation* (MÉEÉ). Both have contributed to the scientific exchange of information among the four countries and to the development of some distinct perspectives on classroom assessment.

Four main issues seem to have shaped the way educational policies influence classroom-assessment practices and have emerged as crucial in French sources in the context of school reform and in the consequent renewal of classroom-assessment practices:

1. the impact of competency-based programs on classroom assessment;
2. the priority on the formative function of classroom assessment;
3. the communication of classroom-assessment results;
4. the influence of standards and external testing on classroom assessment.

Before addressing each of these issues, some clarification about the meaning of French sources and classroom assessment is necessary. This will help us understand the terminology and the scientific context and background associated with classroom assessment in French-language publications.

French Sources

Each country's governing jurisdictions have addressed classroom-assessment issues through their own system of rules and laws. International comparisons are thus dependent on each country-specific context and should be interpreted with great care. On the one hand, Belgium, Canada, and Switzerland have more than one official

language and are highly decentralized federations. In these countries, education is under the state or other local jurisdictions. On the other hand, France is a republic with a single official language and a lot of decisions on education are centralized at the national level. Each country or jurisdiction posts its policies and the approved classroom-assessment material on the Web (see list of websites).

A few comparative studies among those countries have started to emerge within the last 10 years, especially in the context of the ongoing school reforms. Such reforms have presented classroom assessment with important challenges and have contributed to the publication of an important documentation. Several of these publications include references in both French and English. A study of the references cited in papers published in *Mesure et évaluation en éducation* from 1999 to 2005 (Laveault, 2006) revealed that 41% of the references came from English sources as compared to 46% from French sources. The most frequent sources reported were scholarly journals in English (26%) followed by books published in French by European editors (23%). References to scholarly journals in French accounted for no more than 12% of total references.

The previous statistics tend to show that French sources refer to English and French sources in almost equal proportions. Among European authors, books are the most important vehicle of publications in French. Forty percent of the references from European authors originate from books. Such statistics are also indicative of the scarcity of French scholarly journals in the field of educational assessment.

Classroom Assessment: French and English Meanings

Classroom assessment is best translated in French as *évaluation en salle de classe*. The French word *évaluation* has two possible translations in English: assessment and evaluation. This should be taken into account when reading directly from French sources. Scallon (2004) imported the word assessment into French. Such a practice is not widespread, but is symbolic of the need to differentiate the timely operation of professional judgment (evaluation) from the more global task of collecting and organizing a large volume of information and appreciations on student achievement (assessment). This conceptual

distinction is in line with English definitions of the term assessment and has taken on an increased significance with the renewal of classroom-assessment practices which have occurred in the context of school reform. While assessment and evaluation may be differentiated conceptually, they may not be or need not be in actual practice. Most representative of this issue is the growth of competency-based classroom assessment where assessment can hardly be separated from instruction and the complex situations which are developed for student learning.

The Impact of Competency-Based Programs

Competency-based programs of studies have come to replace learning objectives defined in terms of measurable and observable outcomes in Belgium, France, Canada (Québec), and Switzerland. Although the definition of what is meant by competency may not be exactly the same in each country, they all involve the capacity to act effectively by mobilizing an integrated set of resources (knowledge, skills, and attitudes) to work out a family of situations. Such curriculum developments have been highly influenced by the French socioconstructivist theories which emphasize the central role of the student and social interactions in the construction of knowledge. Such changes in program descriptions have had a strong impact, from the standpoint of both the curriculum developer as well as the teachers' and students' classroom-assessment practices. They have resulted in program descriptions of disciplinary and cross-sectional competencies which provide teachers with more holistic and situated descriptions of learning acquisitions.

From the perspective of curriculum development, the description of competencies has required innovative ways to organize a program of studies while trying to maintain a certain level of alignment with teacher's classroom assessment (Jonnaert and Masciotra, 2007). Important distinctions have been made by Le Boterf (1994) to define more precisely what a competency is and what it is not. Though the notion of competency involves some form of mobilization, integration, and transfer of knowledge and skills, it is not limited to any one of these conditions. It is not to be confounded with terminal objectives of a program or with objectives of knowledge integration. Finally, competencies are inferred not only from the resources to be mobilized but in the sequence of actions necessary to mobilize such resources in the appropriate situations.

From the teachers' perspective, the interpretation of a competency-based program requires that they develop a clear understanding of the way competencies are developed and assessed throughout the curriculum. The notion of family of situations introduced by Roegiers (2004) is central to this goal. It requires teachers to think of a set of

problems, complex assessment tasks, or projects that will have students mobilize the same pool of resources in a variety of meaningful situations. Such complex tasks will involve one or more competencies and will present students with situations they have not yet encountered. To demonstrate their competencies, students may use different procedures or exhibit diverse productions, performances, or answers.

The focus of competency-based programs on complex tasks or situations has a profound impact on the way teachers conduct assessment. Competencies can hardly be treated separately from the learning context or from the situations which will be used to infer them. Consequently, complex assessment tasks or situations require some form of harmonization between instruction and assessments procedures used to support learning and certify competencies. They will also involve students to a greater extent. Here is a short description of the changes in assessment practices which occur at each step of the evaluation process of competencies.

1. *Planning.* Planning assessment of competencies requires the appropriate selection of a series of complex learning situations that will provide an adequate coverage of the program along a continuum of progression. The sampling and sequencing of situations must be suitable for gathering relevant information to allow teachers to make a decision on how to support or recognize a competency. Descriptive scales are used to inform teachers of what are the major stages of a student progression on a continuum. They also provide teachers with benchmarks on what are the key features and final outcomes which are the targets of a cycle of training (Ministère de l'éducation, 2006).
2. *Information gathering and interpretation.* To support and render account of competency development, teachers observe students' performance in a variety of situations, on more than one occasion and use diverse assessment instruments. Grids are often used to help teachers collect and code observations on students' performances or productions. They also assist teachers in interpreting their observations when such grids refer to evaluation criteria which are formulated in the curriculum. Such tools are provided to reduce teachers' subjectivity or bias in the case of summative evaluation or to regulate students' progress through appropriate feedback and intervention in the case of formative assessment. When such grids are adapted for students' use, they help teachers communicate the evaluation criteria. Students may thus be involved in multiple forms of assessment that assist them at all critical steps of their work and ultimately will contribute to set individual targets for personal improvement. Occasionally, gathering data through quizzes or tests will help find out whether students' difficulties results from a lack of skill or knowledge or from the incapacity to

mobilize such resources appropriately in a specific context. The same result may be accomplished by repeating observations in different contexts where the level of guidance is varied. The three-step assessment design developed by Rey *et al.* (2003) is a good illustration of an assessment practice where teachers may determine whether a student's difficulty derives from problems in (1) the mastery of basic procedures; (2) the capacity to select the appropriate one; or (3) the capacity to combine several of them in the appropriate context.

3. *Judgment and decision.* Teachers' professional judgment plays an important role in supporting students' learning and in making decisions concerning students' progressive acquisition of a competence. It is based on the information gathered on students' achievements and on various guidelines regarding what should be recorded and how it should be organized and reported. Scallon (2004) has shown that depending on the type of continuum used to collect data on students' achievement, teacher's judgment may take different forms. It could have a bearing on the student's ability to achieve increasingly complex tasks or on the capacity of the student to perform to standards with varying degrees of autonomy. Teachers' professional judgment is also required to weight the relative importance of each different competency in rating or marking students' work. Competencies may be considered of equal importance or not and compensation among competencies may be permitted or not. Policy directives assist teachers on such matters through the criteria and outcomes specified in the curriculum or through general guidelines indicating what values and principles should be taken into account (Ministère de l'éducation, 2003). To reduce personal subjectivity in teachers' interpretations, criteria and performance standards may be exemplified in a variety of government publications such as scales of competency levels, exemplars of students' performance, or generic evaluation grids. Mandatory or optional diagnostic assessment tools may also provide teachers with indications as to whether their own appreciation of students' work is properly aligned with the curriculum performance standards (IGEN, 2007; Rey *et al.*, 2003).

On certain aspects, classroom assessment of competencies still raises important questions on the notion of learning progression or developmental trajectory (Tardif, 2006). The implementation of cognitive models into developmental scales of progression requires deep knowledge of how a competency is learned. Other important questions also concern how teachers use their professional judgment to certify students through retrospective judgment or decision algorithms. Consequently, the way teachers use their professional judgment is the object of increased study.

The Formative Function of Classroom Assessment

The new programs of studies developed in the French countries all emphasize the major role of formative assessment in one form or another. Such an emphasis is not new since formative assessment practices have long been associated with values of differentiation of instruction and equal opportunities for learning for all students. The introduction of competency-based programs, however, has required a redesign of the instruments of formative assessment and the inclusion of additional methodologies to gather information on student learning. Such a renewal had already been prepared for years as several papers and books had already been published in French on formative assessment.

Following an extensive review of the French-language publications, Allal and Mottier Lopez (2005) have concluded that it has contributed to an enlargement of the conception of formative assessment. In such an enlarged perspective, highly influenced by constructivist theories of learning such as Piaget's and Vygotsky's, a much greater emphasis is placed on the regulation of cognitive and motivational processes occurring in learning. Still another direction of enlargement occurs when formative assessment is used to inform teacher planning of future instructional activities. It thus goes beyond remediation that directly benefits the students and includes regulation of teachers' future instructional activities to the point where decisions on instructional strategies and assessment are closely related.

The concepts of regulation and self-regulation have largely contributed to redefine formative assessment as an object of study in the French-language publications. External regulation (by the teacher, by the test, by remedial materials) is "redefined as scaffolding that assists students' development of self-regulation" (Allal and Mottier Lopez, 2005). Classroom assessment is thus considered as an instrument in developing students' autonomy in learning through procedures of self-assessment, reciprocal peer-assessment, and joint teacher–student assessment. New methods of student involvement in assessment are emphasized to such an extent as to include motivational regulations in addition to cognitive and metacognitive regulations.

The work of French researchers has led to an increased diversity in the ways of carrying out formative assessment. A lot has been accomplished at the theoretical level, but very little has been published on the verification of the impact of formative assessment on student learning. In the light of the new curricula based on competencies, the French-language work on formative assessment is in need of considerably more empirical research.

Classroom Assessment as Communication

Competency-based programs of studies have brought in several changes in classroom assessment that have

required innovative ways of reporting students' results. The performance on a complex task may require knowledge and skills derived from several subject matters such as mathematics, sciences, and writing as well as from more global competencies which are not linked to a single subject matter such as cross-curricular competencies in Quebec or the common base of knowledge and skills in France. This makes reporting students' progress through subject-matter content areas most difficult and somewhat artificial. Furthermore, students' learning progression involves both qualitative and quantitative changes which can hardly be summed up on a single scale.

Through a comparative study of different report-card systems in France, Quebec, and the French regions of Belgium and Switzerland, IGEN (2007) has listed a series of conditions for the effective use of report cards and communication of students' results and has made recommendations which extend well beyond the context prevailing in France:

1. Report cards should serve a clear purpose: either report on the best way to follow-up on a student's learning progression or to summarize student's achievement at certain period in time. Different report cards may have to be developed to serve distinct purposes.
2. Report cards do not need nor can they report exhaustively on the very fine details of a learning progression. To assess competencies require that a delicate balance be found between expected competencies and the whole set of resources associated with them. Decisions should be made as to what competencies and resources should be reported as priority and how they should be structured in the report card.
3. The same report card system cannot be used for both internal and external communication. The way information on students' achievement is conveyed depends on the intended recipient of the communication: parents or tutors, students, or other teachers or professionals.

Recent experiences with various forms of report cards have shown the difficulty of transmitting useful information on both qualitative and quantitative changes occurring in competency development to different stakeholders and for multiple purposes such as guidance, certification, and regulation of learning. Cross-sectional competencies have been found especially difficult to report on. They raise questions as to who should assess them and how, especially when such competencies may be acquired in disciplines taught by different teachers and validated in contexts which are not necessarily identical to the situations used to learn them. More development is required to build efficient report-card systems which articulate and coordinate several sources of information, at different times and for different purposes.

The Influence of Standards and External Testing

French countries have echoed the global world trend for a better monitoring and accountability of school systems. They have all developed some form of external testing to inform decision making at different levels of the school system. Such initiatives, however, are not translated in the same terminology as in the English publications. For instance, French countries which have tried to import the concept and word standards have been confronted with its multiple English definitions and interpretations. As Mons and Pons (2006) have shown, standards of evaluation policies are often shaped locally to take into account and weight differently, notions such as school efficiency, student learning progress, accountability, responsibility on one side, and the structural characteristics of the national systems such as the level of centralization, the multicultural nature of the country, the relationship between teachers' union and school administration, to name just a few.

A review of French sources by Mons and Pons (2006) shows that external tests may have both desirable and undesirable effects on classroom instruction and on classroom-assessment practices. To really have a positive impact, such external evaluations must be part of a *culture d'évaluation* (culture of evaluation) where decision making and management at all levels of the school system value the collection of data and its use to plan school improvement. Such a culture of evaluation provides teachers with formative opportunities to work collaboratively, reflect on the efficiency of their instructional practices, on their shared understanding of the curriculum, and on the best ways to use it to assess students' learning acquisitions (Demailly, 2001).

National Education Inspection–National Education and Research Administration Inspection (IGEN–IGAENR) (2005) have also observed that the introduction of new standardized tests in France have had an almost immediate impact on what is taught and assessed by teachers. The introduction of geometry as part of the grade 6 diagnostic test was sufficient to reactivate the teaching of this strand of mathematics which had been neglected for some time. The authors conclude that external forms of testing do not need to be related to high stakes to have an impact. They warn, however, that the introduction of new tests may have both, a dynamic effect, such as in the previous case, or a reductive effect when such tests validate a limited number of competencies mentioned in the program of studies.

Both the assessment of students' individual learning and teacher's instructional methods will benefit if assessment comes from a variety of sources and uses a diversity of strategies. External evaluations, however, should not be limited to multiple-choice tests or easily measurable learning acquisitions. There is a general apprehension as to whether such standardized tests can measure students' competencies as efficiently as with classroom-authentic

and complex assessment tasks. The development of large-scale standardized tests to assess competencies has presented test builders with important challenges such as duration of such tests, the authentic nature of the complex task or situation, and the capacity of students to mobilize extracurricular and out-of-school learning acquisitions.

Conclusion

The notion of competency has captured and crystallized a long-term interest relayed in French-language publications on the cognitive and developmental processes in student regulation of learning and on the role of formative assessment to involve both teachers and students in these processes. Such interests are inherited from the French constructivist models of learning and teaching and the notion of competency fits well within these models.

French-language publications on classroom assessment have contributed to show how it is closely interrelated with teaching and learning to the point of it being difficult to differentiate when assessment involves complex learning situations. This high degree of interrelationship is also evidenced by the domino effect which the introduction of competencies in the curriculum has had on all aspects of classroom-assessment practices, from planning assessment to the report of results.

Due to the high degree of interconnectedness of classroom assessment with the multiple facets of student learning, each country's policies have tried to maintain a certain coherence and alignment between the expectations of the program of studies and classroom-assessment practices. This has been translated with various degrees of success into materials linked to competency-based programs of studies. Such materials ranged from ready-to-use complex learning situations to diagnostic instruments of competency development. Descriptive scales and exemplars of student performances are also used to provide teachers with a better understanding of students' learning progression, a central concept in the assessment of competency development.

In actual practice, classroom assessment is much less coherent than what it is intended to be. A separate look at each country would reveal different kinds of problems in the implementation of competency-based assessment in the classroom depending on national priorities, the political and social situation of each country, and the mere resistance to change. External assessments have been introduced to monitor and regulate the effect of policies on the school system. The consequential validity and, especially, the side effects on classroom assessment are still being debated upon and are a matter of concern.

The difficulties in implementing appropriate assessment practices also result from a shortage of empirical research in the field. A few comparative studies among

French countries have started to emerge and it is expected that their results will increasingly contribute to inform policy decisions. In the meantime, French sources will continue to refer to English publications to complement the knowledge base on classroom-assessment practices. In the past, such combinations of sources have been very stimulating and led to original syntheses. They, however, require being appropriately adapted to each national context. Moreover, they make the case for an increased attention to empirical validation even more compelling.

Classroom Assessment in Policy Context (Hong Kong)

D Carless, University of Hong Kong, Hong Kong, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Confucian-heritage culture – Those societies which subscribe to the tenets of Confucian thought.

School-based assessment – Assessments taken by students within the school, marked by their teachers and counting as part of the external examination score for the subject.

Washback – The phenomenon whereby due to the influence of a test, teachers, and/or students do things that they would not normally do.

The potential of classroom assessment to enhance student learning has, in recent years, attracted considerable attention in the main Anglophone countries. Learning-oriented assessment has been less established in jurisdictions that share a Confucian-heritage culture (China, Hong Kong, Japan, Korea, Singapore, and Taiwan) and are usually considered to be highly test-driven. Such examination-oriented systems may be due in part to high expectations of parents for the academic success of their offspring and the residual influence of the Chinese imperial examination system. The intense pressure and potentially negative social impacts of highly competitive examination-oriented systems in East Asia have been much discussed. Pong and Chow's (2002) portrayal of the pressures exerted on Hong Kong youngsters contains a distressing depiction of the risks of heaping examination stress on vulnerable teenagers. More positive images arise from the seminal work of Biggs (1996) who elaborates the paradox of the Chinese learner in that large class sizes, transmissive teaching, and test-dominated education can still lead to successful deep learning outcomes. A further positive performance indicator is that Hong Kong students generally perform well in international tests of achievement, such as TIMSS (Trends in International Mathematics and Science Study) and PISA (Programme for International Student Assessment).

Within such examination-oriented systems, the prospects for classroom assessment in East Asia might seem unpromising at first sight. A more positive outlook arises from Hong Kong's historical position as a combination of Eastern and Western influences and so there might be greater potential for formative approaches to assessment than in neighboring economic success stories, such as Japan or South Korea. There are grounds for believing that there is scope for classroom assessment to embed

itself in the Hong Kong context and a number of relevant policy initiatives have manifested themselves in recent years. The aim of this article is to review the prospects for classroom assessment in Hong Kong with developments divided into those in the primary sector (students aged 6–11 years old in years 1–6) and those in the secondary sector (students aged 12–18 in years 7–13). Each section includes both policy and implementation perspectives, mindful that there are tensions and contradictions between policy intentions and actions, as teachers re-interpret, subvert, or ignore policy prescriptions. This can particularly be the case when policy borrowing from overseas fails to account adequately for local contextual factors.

Assessment Developments in Primary Schools

Primary schooling in Hong Kong has traditionally been textbook dominated and test driven with school communities attaching great importance to indicators of academic achievement, such as textbook completion, homework, test scores, and report cards. Testing from an early stage is emphasized as preparation for future competition and selection through high-stakes examinations. From the age of 6 years, primary school students experience multiple tests and examinations in each school year. Within this test-dominated setting, two significant policy initiatives related to classroom assessment in the primary sector are: the target-oriented curriculum (TOC) in the period 1993–99 and the promotion of reforms related to learning to learn; and assessment for learning, from around 2000 until the time of writing. These two initiatives are discussed below.

Assessment Reform in the TOC

TOC was a radical and wide-ranging reform that sought to transform curriculum, pedagogy, and assessment through multiple components, including targets, tasks, and criterion-based assessment. It is probably fair to say that although there were pockets of encouraging developments, an overall judgment would indicate that TOC was overambitious in scope and failed to achieve the fundamental changes its adherents sought. Here the focus is only on the assessment aspects of the TOC reform. The TOC framework document, developed by Clark *et al.* (1994), sets out what they saw as the main problems with assessment in Hong Kong:

1. too much assessment involving gap-filling and multiple-choice questions;
2. a focus on the ranking and sorting aspects of assessment;
3. lack of integration of assessment with the curriculum; and
4. Failure to assess what is important in learning rather than what is easily assessable.

The proposed solutions tended to be more at the level of exhortations rather than concrete practical strategies and included pleas for: greater use of criterion-referenced assessment; more attention to formative assessment and student improvement over time; and the development of records of student achievement.

Evaluation reports indicated that the assessment aspects of TOC were the most difficult to reform and proved most problematic for teachers. Morris *et al.* (2000) reported resistance to TOC-assessment processes in that teachers held a set of interlinked beliefs, which involved a preference for objective, reliable, formal assessments, and doubts about the feasibility of formative assessment. Teachers did not see assessment as something which would involve their professional judgement and had a reluctance to assess through any means which might be regarded as nonobjective. Formative assessment in TOC became associated with the recording of data about learners, with teachers not having the time, skills, or support necessary to feed back this data into the classroom. Teachers reported doing extra work in collecting assessment data and became frustrated as they realized this was not contributing to enhanced pupil learning. The combination of increased paperwork through record-keeping and a system which was both misunderstood and not congruent with teacher beliefs resulted in formative assessment being considered by teachers as the most problematic and unpopular aspect of the TOC reform.

TOC classroom assessment was further hindered in view of the failure to reform the complex secondary school-selection processes at the end of primary schooling, whereby internal school tests in years 5 and 6 are scaled against a standardized test. It became apparent that neither the system, nor educational stakeholders were ready for the kind of assessment system envisaged by TOC. As a central plank of government educational policy, TOC was beginning its decline by the time of the retrocession to mainland China in 1997 and began fading out as the incoming postcolonial government sought to make its mark. Challenges in the implementation of formative classroom assessment were one of the factors in the eventual abandonment of the TOC reform.

Learning to Learn, Assessment for Learning and Basic Competency Assessments

It was acknowledged that TOC had done little to modify the prevailing examination-oriented culture. A number of TOC principles or concepts were however, repackaged as a new curriculum reform was launched at the turn of the

millennium under the theme of learning to learn. Following contemporary terminology in the UK and elsewhere, the nomenclature formative assessment was changed to assessment for learning. The Education Bureau made a number of recommendations for the development of assessment for learning, including the following:

1. the development of more diversified modes of assessment and a reduction in tests and examinations;
2. opportunities to do assessment collaboratively with students or encourage students to carry out peer or self-assessment;
3. sharing with students the goals of learning, so that they can recognize the standards they are aiming for; and
4. the use of assessments which probe higher-order thinking skills, creativity, and understanding rather than rote memorization of facts.

Within this policy context, Carless (2005) discusses two case studies of progressive teachers implementing assessment for learning, mindful that scaling up of these experiences is likely to be difficult. He proposes a multi-level model of factors impacting on the implementation of assessment for learning in Hong Kong, comprising three components: teacher factors, including attitudes toward and understanding of assessment for learning; microlevel school factors, including internal resources, support from management, and collaboration with colleagues; and macrolevel societal factors, including the wider reform climate, educational culture, impact of relevant governmental agencies, and washback from high-stakes testing.

A further subcomponent of the learning-to-learn reforms relates to the introduction of basic competency assessments for the three main subjects of mathematics, Chinese, and English. Basic competencies are the essential knowledge and skills or basic standards required by students in relation to the learning targets and objectives set out in the curriculum for each key stage. Progress toward the basic competencies is monitored through a territory-wide system assessment (TSA) administered by the government at primary three (first conducted in mid-2004) and primary six (first conducted mid-2005), comprising paper-and-pen mode with an oral-assessment component for the two languages. Its stated purposes are to provide feedback to schools about their standards in the three key subjects so that schools can draw up plans to increase effectiveness in learning and teaching.

The government claims that the TSA is low stakes in nature and this is true for students because no individual student grades are made available. For schools and teachers however, it is generally interpreted as high stakes because it indicates how well schools are performing. In a context with a low birth rate, competition for students and associated threats of school closures, the TSA exerts pressure on teachers, which is then transmitted to students.

Table 1 Percentage of students achieving basic competency levels

<i>Subject and year level</i>		<i>Percent achieving basic competency</i>			
		<i>2004</i>	<i>2005</i>	<i>2006</i>	<i>2007</i>
Chinese language (listening, reading, and writing)	Yr 3	82.7	84.7	85.2	84.9
	Yr 6	–	75.8	76.5	76.7
	Yr 9	–	–	75.6	76.2
English language (listening, reading, and writing)	Yr 3	75.9	78.8	79.4	79.5
	Yr 6	–	70.5	71.3	71.3
	Yr 9	–	–	68.6	69.2
Mathematics	Yr 3	84.9	86.8	86.9	86.9
	Yr 6	–	83.0	83.8	83.8
	Yr 9	–	–	78.4	79.9

Adapted from government press release: <http://www.gov.hk>.

The government documents tend to reinforce this by stating that monitoring of the extent to which individual schools attain the basic standards in key learning areas is premised on the need for accountability. The TSA seeks to incorporate both summative (overall assessment data about school performance) and formative (information which can feed back to teaching) functions. The reality, however, is a focus on statistics when results are published. **Table 1**, for example, illustrates the percentage of students who have reached the basic competency standard. It indicates an initial improvement, perhaps as teachers and students become familiar with the test format, and then evidence of tapering off in 2007.

In terms of the formative function of TSA, schools are provided with data which summarize the performance of their students on different test items. Teachers find it difficult to channel this raw feedback into classroom practice. A consequence of the emphasis on statistics and the difficulty of making formative use of the data is to reinforce the prevalent notion in Hong Kong that almost all tests are perceived by stakeholders as high-stakes and formative assessment tends to be drowned by the power of summative assessment. The use of standardized assessment data to inform teaching and learning still needs further development if its formative potential is to be realized.

Assessment Developments in Secondary Schools

Secondary schools in Hong Kong tend to be even more examination oriented than primary schools, as students work their way toward the key selective public examinations at the end of years 11 and 13. Years 10 and 11 are often characterized by drilling, rote learning, examination tips, and repeated study of past papers or examination-practice

exercises. A narrowing of the curriculum results from the tendency to disregard anything that is not directly examination related. Given the importance of the major public examinations, TSA (at secondary 3, year 9) seems less influential than in primary schools.

Unlike in the primary sector, where initiatives such as TOC or assessment for learning can be adopted, tinkered with, or ignored, changes to high-stakes examinations in the secondary sector have an immediate impact on classroom practice, particularly as teacher effectiveness is principally judged by examination results. In line with the understanding that one of the principal influences on what goes on in the classroom is the nature of high-stakes tests, most examination changes in Hong Kong during the last 20 years have had the aim of promoting positive washback on classroom pedagogy. Washback can be defined as the phenomenon whereby because of a test, teachers and students do things that they would not normally do. Washback studies have been a particular feature of assessment research in Hong Kong, particularly with respect to English language, one of the key subjects in the school curriculum. Cheng (2005), for example, studied the impact of changes to the 1996 English language Hong Kong Certificate of Education Examination (HKCEE) taken at the end of year 11. These changes were premised on the aim of improving students' English communication skills and encouraging a more communicative orientation to language teaching. Cheng argues that washback works quickly and efficiently in bringing about changes in teaching materials, which is due largely to the highly adaptable and commercial nature of Hong Kong society, and slowly and with difficulties in terms of the methods teachers employ.

Two current developments should also be noted. First, the Hong Kong Examinations and Assessment Authority HKEAA (2006) with effect from 2007 is moving from norm-referenced to standards-referenced reporting with grades of A–F being replaced by levels 1–5, with the top-scoring students within level 5 being awarded a 5*. Under the standards-referenced approach, the standards are held constant and the percentage of students being awarded a given level varies according to the proportion of students meeting the defined standard. Key aims are to allow students to gain recognition for what they know and can do, and reduce the number of students who are currently awarded unclassified grades and hence no recognition of their learning. It is also hoped that transparent standards with associated criteria and exemplars can be useful in illustrating to students targets and areas for improvement. This aspect is congruent with the role of learning intentions and explicit criteria in classroom assessment.

Second, Hong Kong is moving from 7 to 6 years of secondary schooling with 4-year undergraduate degrees to align itself with mainland China and North America. As part of a new senior secondary (NSS) curriculum,

instead of two high-stakes external public examinations, – HKCEE at the end of year 11 and Hong Kong advanced level examination at the end of year 13 – from 2012 onward there will be one qualification, a new Hong Kong diploma of secondary education (HKDSE) at the end of year 12. It is hoped that moving from two examinations to one will reduce the amount of time preparing for and taking examinations and thereby increase the time available for student learning. The overall aim of the assessment change is to assess a wide range of outcomes relevant to the aptitudes, needs, and abilities of the entire cohort of students eligible for the HKDSE. Each student would also have a learning profile to record their main achievements during the process of senior secondary school. One school of thought is that the HKDSE may reduce pressure on students as there is only one instead of two public examinations for secondary school students. A contrary viewpoint is that having only one high-stakes examination process actually intensifies the pressure on students. A further feature of the HKDSE is that a proportion of marks is being awarded for school-based assessment in all subjects, thereby bringing classroom assessment a higher profile. This development is discussed below.

School-Based Assessment

The most significant and longstanding classroom assessment initiative in the secondary section is the promotion and development of school-based assessment (SBA). SBA in the Hong Kong context refers to in-school assessments graded by teachers and contributing around 15–25% of the marks to the HKCEE or HKDSE. The earliest manifestations of SBA date from a teacher assessment scheme (TAS) for science subjects, initiated from the late 1970s onward. Motivations for SBA include: the potential for assessing a wider range of achievements than through examinations; involving teachers and students more actively in the processes of external examinations; facilitating student improvement over time; and not determining students' academic standard by a single examination. As indicated above, this and other assessment innovations have been generally motivated by the need to temper the negative impact of examinations on classroom practice.

Benny Yung Hin-Wai's research into practical work in science for the TAS has developed particularly useful insights into the challenges of combining both summative and formative functions of assessment. In TAS/SBA, teachers need to award a grade for certification purpose and also provide feedback to students for ongoing learning purposes. This represents a tension which Yung (2001) analyses using the metaphors of policeman and companion to illustrate Hong Kong teachers' conceptions of assessment. The former saw the teacher adopting a picky and fault-finding attitude as represented in the following quotation, "I had to behave like a policeman who had to grasp every chance to give out the assigned

quota of illegal parking tickets in order not to be scolded by his superiors" (Yung, 2001: 254). The latter was represented by a teacher who upheld his beliefs that the teacher's role was to assist students' learning and that the process of awarding an examination grade should be of subsidiary importance to that goal. As Yung acknowledges, the teachers in his study did experience challenges and confusion concerning formative and summative uses of the same set of evidence; illustrative of challenges also found elsewhere in reconciling formative and summative functions of assessment.

Yung also discusses the crucial issue of fairness and describes three views of fairness exhibited by the case-study teachers in his research: fair in the sense of assessing students reliably; fair in terms of not jeopardizing students' chances of learning the subject matter; and fair in the sense of not depriving students of opportunities to receive a well-rounded education. Yung concludes by suggesting that the educational benefits derived from the TAS are at a cost to reliability. The evocative subtitle of Yung's (2006) recent book *Fairness and Fear* reinforces these issues and the pressures of assessment for both teachers and students.

SBA is currently being expanded to all subjects of the curriculum within various timeframes with statistical moderation being used to enhance the reliability of teacher grading. The subject of English has been a particularly high-profile example of SBA. Early progress indicates some positive impacts on students in terms of engaging with assessment criteria and having the explicit opportunity to improve over time, balanced by concerns about increased workload in preparation for SBA. Teachers' responses vary and concerns are mainly focused on the pressures of being responsible for part of the public-examination score; the issue of fairness and interrater reliability; and the heavy workload accruing from SBA preparation, scoring, moderation, and attendance at training programs.

The extent to which SBA can operate fruitfully in a Confucian-heritage culture setting is still open to question. There remain a number of societal barriers to its successful implementation: a preoccupation with reliability and fairness at the expense of validity; lack of understanding, and few well-publicized local models of formative assessment; and a societal perception that teachers cannot be trusted to grade their own students fairly. The following comment of Pong and Chow may still carry some validity, "the highly selective nature of examinations has forced examiners to put fairness and objectivity of marking above all other concerns" (Pong and Chow, 2002: 143).

Summary

This article has focused on assessment developments in Hong Kong primary and secondary schools. Hong Kong

represents an interesting case in which global trends (assessment for learning; learning to learn; school-based assessment) meet a traditional competitive test-driven culture dating back to the Han dynasty. In primary schools, despite some pockets of good practice, classroom assessment is still struggling to become firmly embedded. In secondary schools, SBA has been and will remain to be a crucial topic and one which is likely to generate much discussion or controversies. The new HKDSE and standards-referenced reporting are also issues which are likely to be extensively debated in Hong Kong in the years to come. The high demands for education from parents, the public, and employers, allied with perennial concerns about perceived falling standards continue to put pressure on government, schools, teachers, and students.

The prospects for classroom assessment to become a positive force in Hong Kong remain unclear. In an examination-oriented system, a contextually suitable version of classroom assessment would need to acknowledge the power and dominance of summative assessment. Developing formative learning power from in-school and external tests might be a useful way of developing productive synergies between summative and formative functions of assessment. SBA also has the potential to develop a stronger interface between examinations and productive student learning but still faces the barriers of societal values and teacher resistance. For these potentials to be realized, there remains a pressing need for the enhancement of assessment literacy through teacher development and an associated program of collaborative classroom-based research.

Classroom Assessment in Policy Context (New Zealand)

T J Crooks, University of Otago, Dunedin, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

New Zealand has an area similar to that of Japan or the British Isles, but a population of about 4.3 million people. About 70% are of European origin, predominantly from the British Isles. The indigenous Maori population makes up about 15% of the balance, with substantial percentages also from other Pacific Islands and Asian countries.

School attendance is compulsory in New Zealand from age 6 to 16. However, it is normal to enrol children in early childhood care and education well before their fifth birthday, to enter them into the school system on or soon after their fifth birthday, and to continue their formal education past their 16th birthday. A majority proceed into some form of tertiary education.

Primary schooling (years 1–8) usually starts at age 5 and lasts 7.5–8.5 years. Secondary schooling normally lasts for up to 5 additional years (years 9–13). More than 80% of students remain until year 12, and almost 60% remain until year 13.

The most common patterns for schooling, in decreasing order of student numbers, are:

- approximately 6 years in primary school, 2 years in intermediate school, and up to 5 years in secondary school;
- approximately 8 years in primary school and up to 5 years in secondary school; and
- approximately 6 years in primary school and up to 7 years in a secondary school that includes years 7 and 8, as well as years 9–13.

The focus here is on classroom assessment in New Zealand schools. Crooks (2002) has written an overlapping but more wide-ranging review of assessment in the New Zealand school system, while Carr (2001) has given an extensive description of recent developments in assessment practices for early childhood education in New Zealand.

School Curriculum Policy

Prior to 1990, school curricula evolved slowly, with leadership from experienced specialists in the national Department of Education and extensive involvement of teachers in developing successive drafts and trying them with students. The syllabi that resulted from this process were not highly prescriptive, but commonly were accompanied by custom-developed resources that teachers could use. In 1991, a new government and minister of education introduced sweeping changes modeled on the

curriculum and assessment changes made in the late 1980s in England and Wales. These changes have substantially influenced classroom assessment practice.

Working groups of curriculum experts and teachers identified several strands for each curriculum, and within each strand a substantial number of achievement objectives. The objectives were then placed into eight levels, representing the planned progress of students over their years of primary and secondary education. The first five levels were spaced approximately 2 years apart, with the last three levels each intended to represent 1 year of normal progress. The details for each curriculum area were described in separate volumes: one each for mathematics, science, English, technology, social studies, health and physical, education, and the arts. Special versions of each of these were developed for students learning in Maori-language immersion programs, and additional volumes were prepared for the teaching of languages other than English.

These curriculum changes saw a considerable tightening of curriculum and assessment expectations for schools and teachers. Pressure to implement the fairly detailed structures of the new curricula – with their strands, levels, and achievement objectives – largely has come through the reviews of schools conducted by the Education Review Office (a school inspection agency), supplemented by nationally funded but regionally implemented professional development contracts focusing on each new curriculum document. Many primary school teachers were quite overwhelmed trying to cover the full range of achievement objectives, and, toward the end of the 1990s, changes to the national education guidelines for schools offered greater flexibility in curriculum implementation, particularly for the first 4 years of school, where renewed priority was given to literacy and numeracy.

There has been significant debate about the merits of these curriculum changes. On the one hand, they were seen as helping teachers by offering them more structured guidance for their teaching and increasing continuity of learning programs for students moving between schools. On the other hand, many teachers felt that they and their students were on a treadmill of curriculum requirements, that the large list of achievement objectives encouraged shallow rather than deep learning, and that the loss of the trust and creative freedom that teachers previously enjoyed undermined their sense of professionalism.

Late in 2007, after a 4-year gestation, a revised, integrated curriculum document was released. This maintained the

general structure of the previous curriculum, with its strands, levels, and achievement objectives, but considerably streamlined it into a single volume with fewer and broader objectives. Schools are encouraged to develop their own curriculum plans within the broad national framework.

School Assessment Policy

In New Zealand, assessment of individual students in schools predominantly has been viewed as a responsibility of their teachers. Where standardized tests have been used in schools, it usually has been in a low-stakes manner, offering teachers additional information on which to make their judgments.

The main exception to this has been assessment for national qualifications in the final 3 years of secondary education. These use a mixture of national examinations and teacher assessments, with inter-teacher moderation procedures for the latter that are intended to achieve greater national consistency of standards.

Until the late 1980s, formal assessment and reporting in New Zealand schools were predominantly norm referenced, emphasizing the relative performance of different students. There is now widespread acceptance of the arguments for criterion-referencing or standards-based assessment (as it is commonly called in New Zealand), which is now integral to the national curriculum and qualifications. However, many teachers who have found the arguments for standards-based assessment convincing have struggled to develop practices consistent with the goal.

The basic structure for assessment of students in New Zealand schools from 1993 to 2007 was set out in *The New Zealand Curriculum Framework* (Ministry of Education, 1993). It stated that:

The primary purpose of school-based assessment is to improve students' learning and the quality of learning programmes. Other purposes of assessment include providing feedback to parents and students, awarding qualifications at the senior secondary school level, and monitoring overall national educational standards. Assessment also identifies learning needs so that resources can be effectively targeted (p. 24).

The emphasis on the use of assessment to improve learning and teaching has been maintained and strengthened in the 2007 version of *The New Zealand Curriculum* (Ministry of Education, 2007):

The primary purpose of assessment is to improve students' learning and teachers' teaching as both student and teacher respond to the information that it provides. With this in mind, schools need to consider how they will

gather, analyse and use assessment information so that it is effective in meeting this purpose.

Assessment for the purpose of improving student learning is best understood as an ongoing process that arises out of the interaction between teaching and learning. It involves the focused and timely gathering, analysis, interpretation and use of information that can provide evidence of student progress. Much of this evidence is "of the moment". Analysis and interpretation often take place in the mind of the teacher, who then uses the insights gained to shape their actions as they continue to work with their students. (p. 39).

In describing the key features of good assessment, the new document states that effective assessment benefits students, involves students, supports teaching and learning goals, is planned and communicated, is suited to the purpose, and is valid and fair (p. 40).

Classroom Assessment of Students in Primary Schools

For the purposes of this section, the term primary schools includes schools specializing in the education of early adolescents (intermediate and middle schools).

Most of the assessment in New Zealand primary schools can be described as assessment for learning (formative assessment). This is focused on enhancing student development, and often involves relatively unstructured interaction between student and student or teacher and student rather than planned formal assessment events. A few well-timed words, an insight shared, or shared enjoyment of notable achievement may have a lasting beneficial impact. Much of the assessment in New Zealand primary schools is of this nature, because teachers spend a lot of their teaching hours walking around their classes and monitoring and guiding the work of their students. More formal assessment of work done in class or for homework also focuses mainly on providing feedback rather than on accumulating marks or grades.

Assessment for learning is thus an integral part of teaching and learning, and appears to have more affinity to good teaching practice than to the usual prescriptions for good practice in assessment of learning (summative assessment). The goal of the latter is to provide a trustworthy, clear, and up-to-date picture of a student's current capabilities or attitudes, progress over time, or further growth needs and potential. Summative assessment in New Zealand primary education is evident mainly in reports to parents about their children's progress and in school-wide monitoring of student achievement by principals and boards of trustees.

When the curriculum documents described earlier were released during the 1990s, each listing a large number of

achievement objectives classified into levels, the Ministry of Education and the Education Review Office encouraging the use of these objectives and levels in teachers' assessments of students. A common early response from teachers and schools was to develop detailed lists of the achievement objectives, tabulate these alongside the names of all children in a class, and record in the resulting table whether or not each child appeared to have met the objectives.

Several things soon became apparent to teachers and researchers:

- Because of the large number of objectives, a teacher's judgment for one objective might be made on the basis of just one task, yet many tasks could be developed for each objective and students could be expected to perform differently on different tasks.
- Children who could do a particular task on one day often could not do that task or a very similar one the next day.
- Trying to complete this process for all of the achievement objectives in the primary school curriculum for a particular class was overwhelmingly time consuming, and threatened the quality of teaching by fragmenting the teacher's educational focus.
- There were major difficulties in summarizing student performance by aggregating across achievement objectives in a curriculum strand or whole curriculum area, because student performance varied markedly across objectives and strands.
- Different teachers applied quite different standards in judging whether or not an objective had been met or a level achieved.
- The gap between adjacent levels (2 years of normal progress) was too large to give a satisfying sense of progress.

There have been varied responses to these dilemmas from teachers, schools, and professional development consultants. Some tried to make assessment decisions more straightforward by subdividing each objective into a number of more specific outcomes, making their assessment easier but exacerbating the other difficulties by, in effect, increasing the number of objectives. Others subdivided each level into finer divisions, making evidence of progress more attainable but not resolving the other issues. Still others concluded that while the sequences of achievement objectives offered useful guidance for program planning, the levels should not play a significant role in assessment and reporting. The reduced number of objectives in the 2007 version of the curriculum and the greater degree of choice that it offers to schools appear likely to reduce the emphasis on curriculum levels in teacher assessments and reporting.

New Zealand has not used achievement tests nationally for whole cohorts of primary school students. Reports

to parents have primarily focused on teacher judgments of what students do well, how much progress they are making, and what they most need to work on. This recognizes the extensive knowledge of students that primary teachers develop from more than 700 h of observations during a school year. However, there has been concern from some parents, education officials, and politicians that reports to parents on their children's progress have tended to accentuate positive aspects (areas of good performance and good progress) and minimize comment on less positive aspects. This has been used as an argument for introducing national testing, with proponents suggesting that national test results would give parents a true picture of their children's progress within their national age cohort. To date, however, national testing has been rejected on the grounds that it could be expected to do more harm than good. While teacher judgments remain central in reporting student progress, there is increasing support for using professionally developed assessment resources (such as nationally standardized tests) to further inform their judgments.

Compared to many other countries, New Zealand has not made heavy use of standardized tests in its primary schools. Where they have been used, the results often have not been passed on directly to parents, but used as additional evidence for teacher decision making.

The most pervasive standardized technique has not been a test, but rather a means of monitoring the progress of student's oral reading skills: the running record (Clay, 1993). This technique is very widely used in the early primary school years, and to a lesser extent in the later primary years. At about age 6, a year after most children start school, many students have been assessed for their reading development through the use of the Observational Survey (Clay, 1993). In many schools, this has helped to identify the weakest readers for personalized reading recovery tuition.

At more senior levels (mainly year 4 upwards), many schools since the early 1970s have made annual use of the Progressive Achievement Tests (covering listening comprehension, reading vocabulary, reading comprehension, mathematics, and study skills). Although this testing is a well-established practice, schools have varied widely in how much use has been made of the results. In many cases, the scores have had little impact on teacher decision making and reporting. New, more sophisticated versions of these tests are now being released. These use item response modeling and provide a range of reports, at individual student and class level, designed to give teachers and principals more insight into the performance and learning needs of students.

Since 2000, the government has been funding the development of Assessment Tools for Teaching and Learning (asTTle), designed for assessing reading, writing, and numeracy in both English and Maori, predominantly with

students between years 4 and 11. These are currently available in CD-ROM format, but an Internet-based version is currently being developed. They are based on banks of nationally normed items, calibrated through item response modeling, together with software to assemble tests and print reports in several easily understood graphic formats. The reports are intended to identify strengths and learning needs for individuals and groups of students, and to compare the performances of individuals and groups to selected norms. Through task-selection criteria, tests can be tailored to the preferences of particular schools or teachers, for instance, by selecting particular curriculum strands to focus on and emphasizing easier or harder items. Results can be viewed by curriculum level and compared against a variety of norms, such as students attending similar schools. Ideas for the next instructional steps based on the patterns of responses are available online.

An ongoing project that commenced in 1993 has involved the development of Assessment Resource Banks. These now contain about 3600 assessment resources (tasks) for mathematics, science, and English, predominantly suited to students in years 4–10. Many of the tasks use multiple-choice or short-answer formats, with smaller numbers involving extended written answers or practical science activities. Marking guides are included. The resources have been normed on nationally representative samples and are coded by curriculum strand, levels, response format, and other features such as task difficulty. They can be accessed and searched through the Internet.

Between 2000 and 2004, the Ministry of Education funded the development of exemplars of student performance in many areas of the national curriculum, from early childhood education through to lower secondary school. These are nationally moderated, annotated examples of student work that are designed to help answer the question “What do we mean by quality work?” They aim to assist teachers to choose appropriate criteria for evaluating student work, understand which aspects are of particular importance, and, therefore, focus ongoing teaching and guidance more effectively.

In addition to funding the development of these assessment resources to help classroom teachers make better-informed judgments about student achievement, the Ministry of Education has also devoted substantial resources to assessment-focused professional development programs for teachers. Since 1995, school-based programs on ‘assessment for better learning’ and, more recently, ‘assess to learn’ have been offered throughout the country. The main focus of these has been to further develop the formative assessment practices of individual teachers, but more recently there has also been emphasis on the use of assessment data collaboratively by clusters of teachers or by all staff at a school. The latter approach is supported by some research evidence, suggesting that

individual teachers can best be helped to deal with teaching and learning issues in their individual classrooms by engaging the collective skills, ideas, and insights of a group of teachers to review the available assessment information and discuss desirable next steps.

In summary, assessment in New Zealand primary schools is predominantly low-stakes assessment focused on monitoring students’ learning and improving learning through direct feedback to students or adjustments to teaching programs. Written or oral reports to parents can be seen as complementing the formative role by giving guidance to parents and students, while also having a comparatively low-stakes summative role. A substantial range of standardized tests and resources is now available, but New Zealand does not have whole-cohort testing in its primary schools.

Classroom Assessment in New Zealand Secondary Schools

While some secondary schools begin at year 7, a majority have students in years 9–13. Most of the students in years 11–13 are seeking to earn credits toward national qualifications, and the high focus on the assessments for these qualifications has a major influence on assessment practices throughout secondary schools. In this section, the general character of assessment in years 9 and 10 is described briefly and subsequently assessment for qualifications in years 11–13 is discussed more fully.

The most notable differences between assessment in primary schools and assessment in secondary schools involve the timing and forms of feedback and the use of marks or grades. In primary schools, and particularly the earlier years, the majority of teacher feedback is given while work is in progress and work is not generally returned with marks or grades on it. Teachers keep records of their observations and judgments about some of the work done by the student, but these are not usually numerical, and they are not mathematically aggregated to produce end-of-term or end-of-year marks or grades. By years 9 and 10 in secondary school, students usually have different teachers for each subject. Much of the feedback that students receive comes on completed work, and it usually includes formal marks or grades. Significant pieces of work are marked and these marks accumulated in a grade book, so that they can be aggregated to produce a cumulative mark or grade.

For much of the last century, secondary schools produced written reports to parents that give, for each subject, a cumulative percentage mark, a grade and/or place in class, and a fairly brief written comment. About 20 years ago, national efforts were made to introduce a form of standards-based assessment into secondary

schools. Several (usually 5–7) important learning goals were identified for each subject and year level, and for each of those goals a descriptive scale with about five levels was developed to describe levels of development or performance. For instance, in year 12 physical education, one of the goals was knowledge of exercise physiology. The performance levels associated with this goal were that the student:

1. can identify the physiological body systems;
2. has a basic knowledge of physiological body systems;
3. has a basic knowledge of physiological changes in body systems in response to exercise and knows how to apply this;
4. has a broad knowledge of physiological changes in body systems in response to exercise and applies this to familiar activities; and
5. demonstrates a clear understanding of the physiological changes in body systems in response to exercise and applies this in new and different activities.

Many secondary schools have adopted variants of this approach for use in years 9 and 10. Within this approach, each assessment task involves one or more of the learning goals, and students receive feedback in terms of the levels of those goals. Many teachers find that this approach helps them to be precise in setting tasks for students and allows students to become more skilled at assessing their own work against the goals and performance levels. At the end of each school term or year, parents receive reports in which a level has been assigned to each goal, a generic description of that level is provided, and often a more specific or personal comment added.

For more than 50 years, students in years 11–13 (the final 3 years of secondary school) have attempted national qualifications through national end-of-year exams, moderated school-based assessments, or a combination of both. The precise form of these assessments has changed several times over the 50 years, while the percentage of students remaining in school until years 12 and 13 has risen dramatically in the last 20 years. A brief account of those changes is given in Crooks (2002).

The current form of qualifications for years 11–13 is a series of National Certificates of Educational Achievement (NCEAs). Students can attain these certificates by gaining credit on Achievement Standards or Unit Standards. Most established secondary school subjects are subdivided into several (usually five to eight) achievement standards, each of which has three passing levels (achieved, merit, and excellence) and a specified number of credits toward an NCEA for those who pass the standard. In addition, there are unit standards, which are assessed on a pass/fail basis, each with a specified credit value. Unit standards are most commonly used for more vocational subjects, but are also available as alternatives to

achievement standards in many secondary school subjects. Schools vary in the extent to which they allow or encourage use of unit standards rather than achievement standards. A recent government decision that NCEAs can be awarded with overall merit or excellence if 50 or more of the required 80 credits are gained at the specified level appears likely to encourage more use of achievement standards rather than unit standards in subjects where both types are available.

About half of the achievement standards are assessed through national examinations held late in the school year (external assessment). The remaining achievement standards and all unit standards are awarded through teacher assessments conducted within schools (internal assessment). These two alternatives have clear implications for classroom assessment practice. For externally assessed standards, classroom assessment is largely assessment for learning, with teachers trying to help their students prepare well for the national examinations. For internally assessed standards, classroom assessment is a complex mixture of assessment for learning and high-stakes summative assessment. Teachers need to walk a delicate line between their mentor and assessor roles. In most cases, this line is partly established by having quite formal assessment events for awarding the standards, so that the remainder of class time can be focused on helping the students to prepare for the assessments. The more tricky aspect is that the teachers usually know the details of the assessments tasks that will be used, and have to decide how specifically to prepare the students for those tasks. To help ensure national consistency in the assessment of internally assessed standards, there are nationally supervised processes for moderation of the internal assessment tasks and their marking, but the extent and effectiveness of this moderation remain a matter for substantial debate. At its best, moderation can be a valuable source of professional development for teachers.

Classroom Assessment in Policy Context (Sub-Saharan Africa)

S J Howie, L Zimmerman and K Draper, University of Pretoria, Pretoria, South Africa

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article focuses on the policy and practice pertaining to assessment in schools from the sub-Saharan region. In particular, the case of classroom assessment in South Africa is presented in some detail, while information and examples are also provided from other countries such as Botswana, Ghana, and Tanzania. As a starting point, it is first necessary to contextualize classroom assessment by providing an overview of issues that continue to play a role in education in sub-Saharan Africa (SSA).

SSA's population of more than 694 million people is one of the poorest (41.1% of people lived on less than US\$1 or US\$2 a day in 2004 (World Bank, 2008a)) and most underresourced regions of the world with some of the highest illiteracy rates, highest exclusion of females from education, and the lowest access to education. The average life expectancy is 46 years, compared to 78 years in developed countries (EFA, 2007: 228). The gross national product (GNP) per capita is the lowest of all the world's regions at US\$601 (compared to US\$1416, the next lowest) (EFA, 2007: 229). The adult literacy rate stands at 61% compared to 77% of developing countries and 99% of developed countries (EFA, 2007: 236). Poverty and substandard living conditions prevail throughout the region, exacerbated by violent civil and tribal conflicts. As a result, access to and the quality of education offered to children, vary greatly within and between countries in the region. Vast inequities characterize the region with children from the richest (20%) of the households having on average, more than 11 times the chance of reaching grade 9 than those from the poorest (40%) of households (Lewin, 2004 in World Bank, 2008a).

Access to education in SSA was strongly emphasized after the 1990 World Conference on Education for All (EFA) in Jomtien, Thailand, particularly with the move to provide universal primary education. Nonetheless, the gross enrolment rates for this region are the lowest in the world. The primary education gross enrolment ratio for SSA is 79% with the next lowest being the Pacific region at 94% (EFA, 2007: 268). In contrast, the gross enrolment ratio for secondary education in SSA is 36% compared to the next lowest region at 64% (EFA, 2007: 292). Across Africa, gross enrolment rates for secondary students vary below 20% and above 80%, with Botswana having one of the highest transitions from primary education to secondary (almost 100%) (Bregman and Simmonet, 2004; in World Bank, 2008b: 5).

In SSA, an estimated 86 million children are of secondary school age; however, approximately 63 million are estimated to be excluded from school (Bregman and Simmonet, 2004 in World Bank, 2008b: 5).

The curriculum structure also varies across SSA as seen in Table 1. Primary education varies between 6 and 7 years for the five countries listed, while secondary education ranges from 5 to 6 years.

Types of Assessments Undertaken in SSA

There is a paucity of literature and research emanating from the SSA region on assessment practices in general and classroom-assessment practices in particular. Countries conduct and participate in a range of assessment activities across the regions. These include national and international assessments, external examinations, continuous assessment, and traditional and alternative forms of assessment in the classroom. In this section, the first three are briefly described.

National and International Assessments

While national examinations have long been prevalent in African education systems, national assessments are a relatively new occurrence. National assessments are designed to describe achievement levels of an entire education system or a clearly defined part of it via collection of school-level data. Four major categories of national assessments have been identified in Africa. Three have involved similar activities in several countries. These are the monitoring learning achievement (MLA) project; the Southern Africa Consortium for Monitoring Educational Quality (SACMEQ), which has been implemented twice thus far and is about to be undertaken for a third time; and the *Programme d'Analyse des Systèmes Educatifs des Pays de la CONFEMEN* (PASEC). In MLA I, in which 40 African countries participated, grade-4 learners were assessed in literacy, numeracy, and life skills. In MLA II, in which 11 African countries took part, grade-8 learners' performance in mathematics and science were assessed (Kellaghan and Greaney, 2005).

At least 20 countries in Africa have participated in large-scale assessments through major international studies organized under the auspices of the International Association for the Evaluation of Educational Achievement

Table 1 Curriculum structure in five countries of sub-Saharan Africa

<i>South Africa</i>	<i>Botswana</i>	<i>Ghana</i>	<i>Tanzania</i>	<i>Senegal</i>
Basic education 9 years	Basic education 10 years	Free compulsory universal basic education	–	–
Foundation phase 3 years	Primary lower level 4 years	Primary education 6 years	Primary education 7 years	Primary education 6 years
Intermediate phase 3 years	Primary upper level 3 years	–	–	–
Senior phase 3 years	Junior secondary 3 years	Junior secondary 3 years	Junior secondary 4 years	Junior secondary 4 years
Further education and training 3 years	Senior secondary 2 years	Senior secondary 3 years (to become 4 years)	Senior secondary 2 years	Senior secondary 2 years

Adapted from World Bank (2008b). Curricula examinations and assessment in secondary education in Sub-Saharan Africa. World bank working paper No.128. Washington: World Bank, p 16.

and the SACMEQ (see Howie, 2008). The last decade has seen a significant increase in the number of studies and in particular, an increase in the number of African countries participating in international studies:

- South Africa was the only African country to participate in Trends in International Mathematics and Science Study (TIMSS) 1995 whereas in 1999, they were joined by Morocco and Tunisia and then in 2003, Botswana, Egypt, and Ghana joined South Africa, Morocco, and Tunisia.
- A voluntary grouping of 15 ministries of education in Southern and Eastern Africa, together with the International Institute of Educational Planning (IIEP) in Paris, cooperate to carry out educational policy research (SACMEQ). Between 1995 and 1998, eight of these ministries participated in SACMEQ I by collecting information on educational inputs, human and material resource allocation, and the literacy levels of grade-6 learners. Teachers were also assessed except in South Africa and Mauritius. From 1999 to 2002, Botswana, Kenya, Lesotho, Malawi, Mauritius, Mozambique, Namibia, Seychelles, South Africa, Swaziland, mainland Tanzania and Zanzibar, Uganda, Zambia, and Zimbabwe participated in SACMEQ II (Kellaghan and Greaney, 2005: 279–280).
- South Africa and Morocco participated in the second study of the Progress in International Reading Literacy studies (PIRLS), 2006. Morocco previously participated as the only African country in the PIRLS, 2001.

Public (External) Examinations in SSA

Public or external examinations have played a major role in modern education in African countries. These examinations may be administered at the end of primary schooling when students are assessed in the major subjects of the curriculum; after 2–3 years of secondary school usually in a wider range of subjects; and at the end of secondary school. In secondary education, these examinations have played a key role in determining the implemented

curriculum in schools and also acting as gatekeepers to schools and providing an evaluation of students at school exit which is likely to have important consequences for their further education and even life chances (Kellaghan, 2004).

In South Africa, as in many other SSA countries, the final year of schooling is dominated by the high-stakes National Senior Certificate (NSC) exam. As with the previous so-called matric examination, the examination is perceived to have various roles. For instance, it is seen by many as a gatekeeper to employment and higher education and is held in high esteem by members of the public as it represents an indication of achievement. In SSA, examination results need to be interrogated. In Tanzania, the pass rate is high but the University of Dar es Salaam has developed its own examination tests because the quality of school-leaving students is not considered at par with the examination results (World Bank, 2008: 60).

In addition, inadequacies in the quality of public examinations in Africa have been identified (Kellaghan and Greaney, 2005). Most examinations take the form of the paper-and-pencil variety ignoring areas of knowledge and skill, which although often specified by curricula, cannot be measured by these tests. A high emphasis is placed on cognitive skill in these tests with little on practical skills. In some instances, these examinations also focus on low taxonomic skills such as recall and recognition of factual content, rather than more advanced higher-order skills such as synthesis of information or application of knowledge. These examinations may also contain little reference to everyday life outside of school and the quality of the examination questions is often poor. Another key factor in less than optimal performance in these examinations for many African learners, is a lack of proficiency in the language used for testing (Kellaghan and Greaney, 2006).

Continuous Assessment in SSA

Examinations only allow for a limited measurement of certain skills and knowledge. Countries in SSA acknowledge the need for a wider range of assessment practices,

using a variety of tools and strategies to assess learning progress. This model of assessment is generally referred to as continuous assessment or CASS. CASS is criterion-referenced and allows teachers to continuously monitor the progress of their learners over time through cumulative judgments.

In **Table 2**, the emphasis in assessment was found to be on CASS in the early phase of language education in South Africa, Botswana, Ghana, and Tanzania. No formal assessments such as tests are used, except in Ghana. The general approach is informal assessment with teachers observing learners' language performance in speech and writing. In Tanzania and in Ghana, CASS is practiced as the continuous evaluation of subject content covered (norm-referenced tests) with its main purpose being to promote students through periodic tests to the next educational level or class. Tanzania has now included a 50% CASS in the final examination (HSRC, 2008). The role of CASS in South Africa will be considered within the realms of the overall policy on assessment.

Assessment Policy and Practice in South Africa

The end of apartheid in the early 1990s and the emergence of a democratic South Africa after the first democratic elections in 1994 resulted in significant changes in education policy. The fundamental framework of the Department of Education was set out in the first White Paper in 1995: Education and Training in a Democratic South Africa after which a number of policies were promulgated for implementation in school. Thus developments in education and assessment policies in South Africa can be discussed in two distinct phases since the end of apartheid in 1994 (Lubisi and Murphy, 2002).

Table 2 Assessment types found in grades 1–3 for language assessment

	<i>Assessment</i>		
	<i>Continuous/formative</i>	<i>Portfolio/assignments</i>	<i>Summative/tests</i>
South Africa	Yes	Yes	No
Botswana	Yes	No	No
Ghana	Yes	Yes	Yes (tests and CASS)
Tanzania	yes	No	Yes

From Human Sciences Research Council (2008). A review of the curriculum documents for English second language learning in Grades 1–3 in twelve African countries. *Report Prepared for Maskew Miller Longman*. Pretoria: Human Sciences Research Council, p 7.

Curriculum 2005

The systemic transformation in the schooling system started in 1996 with the introduction of Curriculum 2005 (C2005), introduced to teachers in 1998. It was so named because after its introduction in 1998, a planned phasing-in of the curriculum was expected to result in all school grades up to grade 12 implementing the new curriculum by 2005, a timeframe that later proved to be unmanageable. The new curriculum model drew upon a number of ideas and trends in the international arena, shaping them to fit local conditions (Botha, 2002: 362). This curriculum was guided by principles of outcomes-based education (OBE) (Spady, 1994) which the new government had undertaken as a central feature of its educational-reform plan.

OBE is a learner-centered approach that emphasizes what the learner should know, understand, demonstrate, and become. Teachers and learners focus on predetermined results or outcomes which must be achieved by the end of each learning process. The idea of critical cross-field outcomes is fundamental to this model, and these are subdivided into seven critical and five developmental outcomes, which give prominence to the cultivation of cognitive capacity (Lombard and Grosser, 2008).

As part of this educational-reform process, the school system was restructured. **Table 3** illustrates the old and new structures since the introduction of C2005.

The old structure was based on a primary–secondary division while the new structure is based on a division between the general education and training (GET) phase from grades R (reception year) to 9 and the further education and training (FET) phase from grades 10 to 12. The FET band was designed to diversify curricula beyond traditional concerns for tertiary education. Learners in this phase of education can choose options that may prepare them for higher education, vocational

education, careers, and self-employment (Lubisi and Murphy, 2002). **Table 4**, illustrating the exit points for South Africa compared to three other SSA countries, is shown below.

The rapid and dramatic change to the curriculum and so many parts of the education system highlighted the weakness in C2005 and in 2000, a review committee was appointed (Chisholm, 2000). Chisholm (2007) observes that C2005's "... original formulations were clothed in a complex framework of outcomes that provoked a range of criticisms drawing attention to the behaviourist underpinnings, excessive assessment requirements, and difficulty of implementation in under-resourced contexts with poorly-trained teachers," the review led to the conclusion that it made little difference to what actually happened in classrooms. Well-resourced schools were thought to be better able to adopt learner-centered approaches and new assessment methods than poorly resourced schools. There were complaints about the language used, excessive paperwork related to new forms of CASS and expectations that were too complex. A revision was therefore proposed and accepted (Chisholm, 2007: 298).

The Revised National Curriculum Statement

In 2002, a new curriculum, the revised national curriculum statement (RNCS) was issued. The fundamental principles of C2005, that is OBE, remained the same. It covered education for grade R (reception year) to grade 9 together with a draft version of the new suggested curriculum documents for grades 10–12. The RNCS introduced a more streamlined and less-technical curriculum. The RNCS was implemented in schools in 2004 for the foundation phase (grades R–3), 2005 for the intermediate phase (grades 4–6), and then 2006/7/8 for grades 7, 8, and 9. The new national curriculum statement (NCS) was introduced in the FET phase in 2006 with the first cohort of -grade-12 pupils writing the NSC in 2008 (Lubisi and Murphy, 2002).

Current National Assessment Policy in South Africa

The prominence of assessment in South Africa emerged particularly in the late 1990s as teachers grappled with the

new (and alternative) vision on assessment as stated in the new curriculum documents. According to the RNCS, assessment is still the continuous planned process of gathering information on learner achievement as it was in C2005, based on the principles of OBE. Outcomes-based assessment (OBA) (authentic assessment) is practiced (Combrinck, 2003). This approach is aimed at clarifying what learners are expected to achieve and assists the process of learner assessment by placing assessment standards at the center of the assessment process in every grade. The assessment standards describe the level at which learners in each grade should demonstrate their achievement of the learning outcomes as well as the ways of demonstrating their achievement. OBA is a move from a summative norm-referenced approach to a formative criterion-referenced approach, hence the shift to CASS which is a formative continuous model based on the principle of authentic assessment that encompasses group or individual projects, portfolios, and performance-based assessment (Combrinck, 2003).

CASS in South Africa was intended to be used for formative and diagnostic purposes within the classroom. South African CASS should be based on tests, classroom interaction, project work, investigations, and assignments. The use of learner portfolios is part of the strategy of CASS. Evidence of learners' work is filed and used as a means to determine progress or promotion to the next grade. The portfolio is used to track progress, growth, and learner achievement with regard to expected outcomes, create an opportunity for the learner to reflect on his/her growth and set goal for self-development, and inform teachers' planning as well as intervention strategies. The South African basic education examination consists of 75% CASS, and 25% so-called common-task assessment (CTA), a standardized external examination written by grade 9 learners in all government-funded schools. The inclusion of CASS is often problematic when it comes to grading. CASS marks are usually far above the final examination marks of students indicating that there is a problem. Most often, the CASS marks are statistically moderated by the national quality assurance body for the national examinations body, to bring them in line with the final examination results. However, students passing examinations are widely reported as lacking in basic reading, writing, and mathematical skills.

In South Africa, assessment in the NCS is an integral part of teaching and learning and should be part of every lesson to complement learning activities. In addition, teachers should plan a formal year-long program of assessment. Together, the informal daily assessment and the formal program of assessment should be used to monitor learner progress through the school year. South Africa has adopted a policy of CASS in the form of informal daily assessment together with the formal program of assessment. These assessment approaches should be used in

conjunction to develop learners' knowledge, skills, and values; assess learners' strengths and weaknesses; provide additional support to learners; revisit or revise certain sections of the curriculum; and motivate and encourage learners.

Classroom Assessment Under the RNCS (GET) and NCS (FET)

Before the introduction of C2005, assessment in South African schools was considered a straightforward process of testing pupils' ability to reproduce information that was presented to them through a content-based curriculum. The first years of the change to an OBE approach required teachers to use forms of criterion-referenced assessment to monitor pupil progress which stated learning outcomes which pupils had achieved. Before teachers had become competent at using this assessment system, the RNCS guidelines shifted to a standards-referenced approach which required of teachers to make qualitative decisions on frames of reference on different levels of achievement, an activity foreign to many South African teachers (Vandeyar and Killen, 2006).

Assessment within an OBE approach, now focuses on the achievement of defined outcomes, referenced against pre-defined criteria. A variety of tools and strategies are used with the aim of encouraging lifelong learning skills. Classroom assessment is based on a program of daily assessment tasks as well as a year-long formal program of assessment (see **Table 5**). The daily assessment tasks take place in the classroom with learner progress being monitored during learning activities. This informal daily monitoring of progress can be done through question-and-answer sessions; short assessment tasks completed during the lesson by individuals, pairs, or groups; or homework exercises. These tasks can be marked by the learners themselves and this allows learners to learn from and reflect on their own performance. The results of the informal daily assessment tasks do not have to be formally recorded.

South Africa's school assessment policy is guided by the *National Protocol on Assessment for Schools* in both GET and FET and training band (grades R–12) published 21 October 2005 by the Department of Education.

Table 5 Weighting assigned to various forms of assessment in grades 10–12 in South Africa

	<i>Daily assessment tasks</i>	<i>Formal program of assessment</i>	<i>External formal examinations</i>
Grade 10 and 11	25%	75%	none
Grade 12	none	25% (moderated)	75% (examination)

All schools are expected to implement this national protocol on assessment from January 2006. It was written within the frameworks of the outcomes-based national curriculum statements (grades R–9 and grades 10–12) and provides schools with a regulatory framework for the management of school assessment records and basic requirements for learner profiles, teacher and learner portfolios, and report cards. The protocol gives guidelines for recording and reporting assessments (see **Table 6**).

Assessment is viewed as an integral part of teaching and learning to be incorporated into all levels of planning. Assessment standards stated in the RNCS (2002) define the minimum requirements for achieving the stated learning outcomes for a grade and for a learning program or learning area. These assessment standards “describe the level at which learners should demonstrate their achievement of the learning outcome(s) and the ways (depth and breadth) of demonstrating their achievement.” The assessment standards are also designed to show how conceptual progression will occur in a learning area. The goal of the assessment standards is to help teachers know when learners have achieved a learning outcome; to show the minimum levels which learners should achieve in a specific grade; and to show learners’ level of achievement and progress in a specific grade (DoE, ND, p. 8).

A Final Word

It is apparent that the same problems with classroom assessment that are reported in the international literature (Kellaghan and Greaney, 2005) have also been observed in the African context which means that in Africa, the quality of teachers’ assessment practices is seen to be deficient in many ways. Prevalent assessment procedures in African classroom contexts, including South Africa, have been attributed to the nature of the teaching and learning situation in which teachers are often dominant and learners are passive. Other explanations for inadequate existing assessment practices include large class sizes, poorly qualified teachers, poor facilities, and a shortage of learning materials and storage. The use of drill exercises, recitation, and mock examinations in preparation for public examinations have also been cited as a potential cause of poor assessment procedures (Kellaghan and Greaney, 2005). Teachers too, tend to use poorly focused questions, questions requiring short answers drawing on factual knowledge and as a result, questions may lead to repetition and recall instead of reflection and application of knowledge and skills. Another difficulty may be the inability of teachers to use strategies and procedures designed to develop students’ higher-order cognitive skills (Kellaghan and Greaney, 2005).

In South Africa, despite changes to the curriculum policy for assessment, research reveals that teachers may be either unwilling or unable to change their assessment

practices (Vandejar and Killen, 2007). Although government educational-policy changes were aimed at redressing past inequalities in educational provision, they have not necessarily resulted in major changes at classroom level with some teachers still applying the same pedagogical practices they used a decade ago. It appears as if entrenched assessment practices may be hampering the government’s transformation plans (Vandejar and Killen, 2007). If it is accepted that all pedagogical acts are influenced by teachers’ conceptions about teaching and learning and the processes and purposes of assessment, then these conceptions may also be barriers to change in practices. One of the strongest influences on teachers’ conceptions of assessment is their understanding of their subject(s), which is an ongoing difficulty in South Africa because many non-White teachers were trained during the apartheid era under a teacher-education system which left them poorly trained and underqualified. The apartheid education system emphasized content, conformity, and high-stakes summative assessment and, as it is difficult to change teachers’ conceptions of practice, it is not surprising that ideas of assessment, founded on learner and school accountability, still abound (Vandejar and Killen, 2007). In a small exploratory study, Vandejar and Killen, (2007) found that teachers may be struggling with OBA and may still hold conceptions of assessment resulting from policies and practices that are no longer relevant, that is, practices that were used prior to 1994. In South Africa, concerns have been raised about teachers’ ineffective teaching methods, weak subject knowledge, and misunderstandings of the demands of the curriculum (Fleisch, 2007) which no doubt incorporate difficulties with assessment practices too. Indeed, teachers’ difficulties with classroom assessment and reported assessment practices are indicated as issues of continued concern (Vandejar and Killen, 2007; Moloi and Strauss, 2005).

While education policy in Botswana (Revised National Policy on education, 1994) recommends the use of criterion-referenced assessment, teachers still commonly use norm-referenced testing which largely test knowledge recall. End-of-term school-based examinations are used for ranking pupils according to performance. Senior secondary results are typically used to stream students into science or humanity streams, depending on performance in the examinations. In 2006, only terminal examinations were used in secondary education but practical work, project work, CASS with criterion-referenced testing are expected to complement the terminal examinations over time. However, in Botswana, many teachers lack sufficient skills in assessment to develop their own tests and examinations and often resort to copying other tests and examinations. This means that teachers in Botswana as well, have still to adopt and implement real-CASS practices (SEIA, 2008).

If the implementation of a new curriculum demands new forms of assessment but the implementation of the assessment strategy lags behind, there is little change of

curricula changes making their way into the classroom. The example of South Africa reveals this as a serious challenge but this is a problem across SSA where there is a lack of alignment between the intentions of the curriculum and the quality of assessment.

Combrinck (2003) asserts that in implementing OBA, certain factors need to be in place for the new assessment approach to be successful:

1. an adequate in-service training program;
2. a support system for schools and teachers in implementing the new approach; and
3. a clear school assessment policy that addresses all aspects of assessment including a policy on cultural diversity.

There are a number of logistical and practical problems, such as the lack of clear assessment instruments

and marking schemes in the hands of teachers and these are persistent problems in assessment reform. Coupled with the practical problem is that regardless of the quality of assessment protocols and tools, the high incidences of learners being assessed in languages other than their vernaculars across Africa, languages in which in many cases they are not educationally proficient, will continue to impact negatively on learner outcomes and the quality of educational output across Africa.

Moderation of Student Work by Teachers

G S Maxwell, Brisbane, QLD, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

External assessment – An assessment designed and managed by an agency outside schools, as with public examinations and standardized tests.

Internal assessment – An assessment designed and conducted by teachers within a school.

Moderation – A process for producing consistency across assessors in qualitative judgments of student performance or achievement.

Standards – The representations of the quality of achievement or performance that needs to be demonstrated for awarding particular grades, ratings, or score ranges.

Definition

Moderation is a process for producing consistency across assessors in qualitative judgments of student performance or achievement. It is especially relevant to teacher assessments (teacher-managed or school-based assessments) where results are expected to be comparable across teachers and across schools. However, it can be relevant to any situation involving multiple assessors (perhaps across multiple sites or observations) where judgment is required concerning performance quality.

Moderation contributes to quality assurance of assessment procedures and outcomes. Quality assurance, in its broadest sense, refers to processes for establishing confidence in the quality of procedures and judgments. Confidence is always a matter of degree. More rigorous processes are required where the stakes are higher and more confidence is needed. Where less confidence can be tolerated, processes can be less rigorous. This means that moderation procedures need to be tailored to the context.

Quality assurance sometimes refers more narrowly to processes for encouraging or approving practices that are assumed to produce desired consequences, without necessarily checking that they do. Checking on the outcomes can be characterized as quality control, which means reviewing, and where necessary adjusting or correcting, the outcomes (Harlen, 1994). That is, moderation as quality control involves checking assessment procedures and outcomes to ensure that there is consistency in the judgments (student results) before they are used or reported.

Typically, quality control is embedded within broader processes of quality assurance – that is, supported by other aspects of quality assurance (maybe all seen as part of the moderation process) such as assessor training, program approval, and implementation monitoring (Daugherty, 1994).

This distinction may also be characterized as moderation for improvement (through professional development) versus moderation for accountability (quality control) (Maxwell, 2002). The former develops the capability of teachers to undertake appropriate assessments and make consistent and comparable judgments. The latter provides official confirmation of results that are reported or used publicly. Clearly, each can complement the other: quality control can contribute to improvement in future assessments through the feedback it provides to assessors; professional development can provide the competent assessors needed for producing consistency.

How much emphasis to place on quality control depends on how the assessments are used, their public visibility and their status. High-stakes assessment, that is, assessment with external consequences – such as selection decisions (individual consequences), professional certification (public consequences), or resource allocation (institutional consequences) – demands more consistency and therefore greater quality control. Where the consequences are less public and more diffuse – such as classroom assessments that do not contribute to public reporting or student certification – the aim may be to raise assessment quality and consistency in the longer term through professional development processes rather than expect substantial consistency in the short term. In many situations, this is more realistic, affordable, and effective, especially where the emphasis is on formative assessment.

Situations Where Moderation Is Applicable

Moderation is relevant to all levels and types of education and training. It is also potentially relevant to other judgment situations such as workplace assessments, case-work assessments, and quality audits – wherever application of consistent standards across multiple assessors and/or multiple sites is important for fairness and equity or the promotion of consistent high-quality professional judgments.

Some illustrative situations are school-based end-of-secondary-school certification, other school-based assessments, vocational training assessments, and university course assessments, which are discussed below.

School-Based Certification (High Stakes)

Moderation has been keenly identified with school-based (that is, teacher-directed) assessments contributing to state-awarded (provincial or national) certificates in secondary school (high school). The aim of school-based assessment is improved validity through use of an expanded range of assessments, authentic performance assessments, multiple assessments over time (continuous or progressive assessment), and achievement portfolios. For public certification, equity considerations require consistency and comparability across teachers and schools. Otherwise confidence in the certificate is compromised. This is especially important where selection decisions, such as for higher education, are based on the certificate (ACACA, 1999).

The Australian state of Queensland has since 1972 implemented and refined a system of moderation for high-stakes school-based assessments at the end of secondary school (Maxwell, 2007; QSA, 2006). Some other Australian states also have moderation processes for school-based assessments at the end of secondary school but only Queensland and the Australian Capital Territory (ACT) are entirely school based with no external examinations (apart from a core skills test – see later). High levels of comparability have been achieved in Queensland (Masters and McBryde, 1994; QSA, 2000–2007) and the system enjoys public confidence.

Moderation in such situations is directed at comparability of grades reported against a particular subject label (such as Physics or French). In Queensland, such subjects have a syllabus (content standards) and grading standards (performance standards). Schools submit their teaching and assessment programs for approval by a central agency (Queensland Studies Authority) that manages between-schools moderation processes and issues the Queensland Certificate of Education. This system allows flexibility for schools to design their own assessment programs within an overall framework of curriculum expectations and achievement standards. Other systems may allow less flexibility, for example, by imposing common assessment tasks. In all cases, successful moderation requires some way of establishing common expectations and standards against which student performance (achievement) can be judged.

Other School-Based Assessments (Low Stakes)

At all levels of education, there are situations where assessments are set and/or conducted and/or marked by

teachers and where consistency in the reported results is desirable. For example, student progress reports should reflect consistent application of standards among teachers within the school. School districts might want also to see consistency in reporting across schools within the district. Moderation processes can contribute to raising the quality of teacher assessments and developing both within-school and between-school consistency in teacher judgments (Daugherty, 1997).

Some systems impose common assessment tasks at particular year levels. Other systems involve centrally determined assessment specifications and performance standards but not prespecified assessment tasks. Assessments may also be marked in the schools by the teachers or marked centrally by specially selected marking teams. Central markers can be closely monitored. On the other hand, local marking can enhance teacher professional growth and development. The specifics of moderation, including whether assessment is centrally set or open and whether marking is central or local, have to be worked out in the political, social, and institutional context and depend on the purposes, uses, and consequences of the assessments as well as the amount of consistency expected. Recent enactments of moderation-supported teacher assessments in schools can be found, for example, in England, Scotland, Wales, and Australia.

Vocational Training Assessments

National vocational training systems, such as those in England, Scotland, Australia, New Zealand, and South Africa, have developed vocational-qualification frameworks based on workplace skills. Performance expectations for different levels of expertise, typically expressed as competency requirements, are specified and assessed through *in-situ* workplace observation. Quality assurance tends to focus on front-end-delivery requirements for each training organization, such as proper training of assessors. In some countries, there is support for consistency of assessment judgments through verification or validation processes. These processes involve mandatory checks on the appropriateness of the assessment processes and judgments – for example, through site visits by external verifiers appointed by the qualifications agency or an industry-training body. Alternatively, there may be encouragement of voluntary participation in assessor networks that support the development of common understanding and application of the competency requirements. These networks allow assessors to share and compare their assessment processes and judgments with other assessors. External verification and assessor networks are instances of assessment moderation even if not so labeled. Other possibilities deserve more deliberate attention (Maxwell, 2001).

University Course Assessments

Universities worldwide are increasingly concerned about improving the quality and consistency of their assessments as part of their overall teaching and learning strategies. In the UK and Denmark, universities engage external examiners as part of their quality-assurance processes for assessment; the aim is to maintain national consistency of standards among universities although there is ongoing debate about their purpose and function and the need for a broader participatory process. External examiners are essentially external moderators. Internal moderation is beginning to emerge in the practices of UK universities, encouraged by the *Quality Assurance Agency Code of Practice* (QAA, 2006) which references moderation.

Australian universities use external examiners only for higher-degree theses, but most have specific policies on moderation for course assessment; these policies typically include a role for moderators (external to the course but not necessarily the university) to review and approve course assessments. More generally, most Australian universities now encourage internal moderation processes for developing consistency in assessment of students, especially for large classes with several markers but also for coherence of assessments across courses within the same degree program. Such practices are recent, uneven, and evolving (DEST, 2002: paragraphs 146–150).

Social Moderation versus Statistical Moderation

Linn (1996) makes a distinction between social moderation and statistical moderation. The former involves personal comparison and alignment of assessor judgments (review and coordination of teachers' ratings of student products, p. 102) whereas the latter involves statistical scaling of the results of each group of students against that group's performance on an external anchor test or examination. These have different purposes and effects and it may be confusing to refer to both as moderation. Social moderation (including the consensus moderation discussed by Linn) is the focus of discussion here. Social moderation is concerned with the direct apprehension and comparison of standards (standards referencing) whereas statistical moderation is a norm-referencing strategy. That is, in social moderation, the codes for ratings of performance (often expressed alphabetically rather than numerically) are tied to performance levels or standards. In statistical moderation, the ratings are assumed to have only relative meaning (ordinal and perhaps equal-interval scaling) and hence can be arbitrarily adjusted to match another distribution without losing their meaning.

Statistical moderation may be better called scaling or linking. Linn (1996) notes the two forms it typically takes:

scaling of internal (teacher assessed) scores against external (public examination) scores through distribution equating; and scaling of scores in different subjects against a measure of general academic achievement (in Queensland a core-skills test). The latter is done to produce an appropriate aggregation of results across subjects taken in different combinations by different students. Both depend on an appropriate match between the external measure and the internal measures and this requires careful delineation of the relevant construct (Maxwell, 1996; Newton, 2005). The focus of the discussion here is social moderation.

Moderation as a Participative Process

Social moderation is a participative process that treats assessors professionally. Moderation can be framed as a normal and positive consultative process that values consensus and builds confidence rather than as a corrective activity that compensates for presumed inadequacies or mistakes of the assessors. Arbitrarily overriding and adjusting the grades, levels or scores awarded by an assessor can undermine professional responsibility and confidence. Professional engagement is strengthened by dialog and negotiation to arrive at consensus. Even so, in high-stakes assessment, external moderators or panels may have greater power in any negotiation. How far a certifying agency chooses to go in forcing the issue depends on how high the stakes are and how much responsibility it wishes to accept for the assessment judgments. In school-based assessments, there is shared responsibility between certifying agency and schools and the certifying agency cannot usually verify directly all of the assessments. Moderation typically provides a feedback loop to advise the assessor. In the moderation processes for the Queensland Certificate of Education, checks are made on whether advice is heeded and further negotiation may be necessary before the results are approved (Maxwell, 2007).

Moderation as a Proactive Process

The aim of moderation is typically represented as delivering comparability across all the assessment results (grades, ratings, levels, and scores). Sadler (1986) argues that comparability has two meanings:

- the results must be compare-able, that is, able to be compared, and
- achievements reported by the same code (grade, level, or score) must be equivalent in terms of the standard they represent.

Assessments are compare-able only if they assess common qualities, characteristics, or criteria. Equivalence requires consistency in the application of common standards

so that all performances awarded the same grade are in fact at the same standard.

Delivering comparability implies action before judgments are final, not simply checking whether they were satisfactory afterward. This means that moderation needs to be a planned proactive process covering all phases of assessment: before (at planning phase), during (while assessments are administered and marked), and after (before the results are reported, while there is still time to amend them). In addition, there could be a follow-up evaluation of the whole process to confirm that comparability was achieved (to a satisfactory extent) and provide feedback into the next round of assessments (to strengthen and improve comparability in future) as with *post-hoc* random sampling in Queensland (QSA, 2000–2007).

Achieving Consistency in the Application of Standards

Consistency in the application of common standards is more likely if those standards are explicitly stated and exemplified. Clarification of the standards is the key activity in moderation. However, no matter how apt the standards statements and exemplars, assessors can and will interpret them differently. Moderation is directed at aligning assessors' different understandings and judgments of the relevant standards to produce shared interpretations.

In the before phase of moderation, the focus is on assessor training. This includes explanation and discussion of the performance standards (and in some cases the collaborative design of those standards). It also beneficially includes discussion focused on exemplars of the standards, either deliberately designed or drawn from previous assessments undertaken by similar students in similar circumstances. Where the assessors design the assessments themselves, as in school-based assessment designed by teachers to fit local circumstances, training is also necessary in assessment design. In some cases this training might lead to formal certification of the assessors as being qualified to assess, as is required in some vocational training systems. In school-based assessments designed by teachers, training might be followed by submission and approval of an assessment plan, including example assessments and supporting documentation, before the assessment plan is enacted. In addition, external moderators or moderation panels need to be trained both in the standards and in the role they are expected to adopt.

In the during phase of moderation, the focus is on fine-tuning assessor judgments, trouble-shooting any concerns and problems and making sure that assessors stay on target, that is, setting up conditions that support consistency among the assessors. This could involve joint

marking of a small sample of assessments early in the marking process to provide initial orientation, or periodic meetings to consider borderline or unusual cases, or more formal procedures at particular stages of the marking. The longer the delay in checking for consistency, the more difficult it is to rectify any misapplication of the standards. In large-scale school-based assessment, complex management systems may be necessary to develop consistency at three levels: within schools; between schools within a district or region; and between districts or regions.

In the after phase of moderation, the focus is on final validation or verification of student results so that they become official. This is only relevant when there is official reporting on an authorized certificate or transcript of results. Final validation or verification may involve further negotiation between an external moderator or moderation panel and an assessor over whatever adjustments are deemed necessary to establish comparability. Sufficient time has to be allowed for this, but the process might begin while assessments are still being marked, allowing early identification of problematic assessments. Successful negotiation also requires goodwill on both sides. Any breakdown in negotiation can be costly in time and resources, especially in large systems. There is usually no time to re-mark large numbers of assessments.

Factors Affecting Moderation Design

Moderation processes are tailored to the circumstances. Factors to consider in designing moderation processes include the following:

- locus of authority: whether local (e.g., school), central authority (e.g., state), or shared;
- Layers: how many layers must be managed (e.g., school, district, and state)?
- Stakes: higher stakes (e.g., assessments used for selection or placement) demand stronger moderation (tighter comparability)?
- Risks: what are the consequences of lack of comparability (personally for students or publicly for education authorities)?
- Size: how many students, but more especially how many assessors?
- Time and timing: are there set timelines to manage?
- Dispersal: how geographically or institutionally dispersed are assessors (making communication, meetings, and/or visitation more difficult)?
- Scope: single task or multiple tasks; standardized tasks (e.g., written examinations) versus situated tasks (e.g., work based); common task (centrally set) versus tailored or individualized tasks (locally set and therefore different across locations and students); projects, presentations, or portfolios?

- Tolerance: latitude in public acceptance – put most effort where comparability is most needed;
- Logistics: larger systems require more management (e.g., training moderators, assembling panels, transporting portfolios, and developing IT communication);
- Cost benefit: is it affordable; does the benefit warrant the cost?
- Professional capacity: how skilled are the assessors; can they be up-skilled; do the moderation processes contribute to long-term skills development?

Some Specific Moderation Processes

The following discussion is divided into weak quality control and strong quality control. The former is typically considered sufficient when the stakes are low but the latter necessary when the stakes are high. However, weak and strong (just as low and high) are relative concepts. Therefore, weak and strong quality control are best seen as two ends of a spectrum of possibilities allowing potential mixing of approaches.

Weak Quality Control (Low Stakes)

Assessor meetings (consortium moderation)

These can be group meetings based on communities of interest (course, school, and district). There might be a nominal leader to chair the meetings and ensure balanced participation. The purpose is to share understandings of the relevant performance standards and their application to examples of student performance brought by the participants and put on the table for consideration. The focus is on learning from each other and convergence toward common understandings of standards. This can improve comparability within the group. Assembling different groups on different occasions can create more widespread convergence over time.

Assessor partnerships and conversations (moderation exchanges and networks)

Partnerships can be small groups, perhaps just pairs, based on proximity or similarity. Relationships can be formal (requiring reporting) or informal (emphasizing mutual support). The aim is exchange of assessment practices and convergence of viewpoints on standards, again in relation to specific examples of student performance. This is sometimes extended to voluntary assessor networks and communities of practice that encourage wider sharing and dissemination of assessment ideas and practices.

Self-audit and self-moderation

Many quality-assurance processes involve self-audit. This is always a necessary first step. For example, in student

assessment, there is no point in moderating between schools if schools are internally incoherent in their practices. External moderation assumes internal consistency, that is, assumes that there is consistency across all assessors within the school. Similarly, moderation between assessors assumes that each assessor is internally consistent, that is, applies standards consistently across all the assessed performances. This is especially relevant where there are many scripts or portfolios that can take several sessions to mark. Later ratings should be checked for consistency with earlier ratings; performances given the same rating should be checked for their comparability. Assessor consistency is not only important for fairness and equity among those students; it is a prerequisite for consistency with other assessors.

Strong Quality Control (High Stakes)

Group (consensus) moderation

Where the group of assessors is small and self-contained (e.g., assessors for the same subject or course within a school or university), the group may take collective responsibility for quality control among themselves, perhaps under the direction of a coordinator. The aim is comparability across the group achieved through consensus. Where assessors have latitude in setting the assessment tasks, task equivalence has to be designed and agreed upon before assessment begins and clear understandings reached on the common performance standards to be applied. Where external approval or intergroup comparison is required, group moderation may be accompanied or followed by external expert or panel moderation.

Expert moderation

Expert moderation can be both internal and external to a school or institution. It can supplement or replace group consensus. The role of an expert moderator can vary from offering an independent viewpoint (advisory) to requiring compliance (regulatory). In large systems (e.g., in state-wide between-school moderation) teams of moderators may be needed. Moderators may conduct site visitations for observation and discussion with assessors and/or may review samples of performance evidence. Moderators provide feedback to the assessors on all relevant aspects of the assessments, but especially on ratings against the defined performance standards. Action may be requested and negotiated (e.g., adjustments to ratings). Success depends on the competence, skills, and authority of the moderator(s). The moderation team itself will need moderation (perhaps group moderation).

Panel moderation

Panel moderation can replace external moderators and fulfill the same function. The constitution, management, and operation of panels are matters for thoughtful design.

Typically, chairs and members of panels are selected from the most skilled and experienced assessors, making this a form of peer moderation. Scripts or portfolios may be formed into batches for allocation to subgroups of panelists (perhaps only two members per subgroup in a mixed design). Small differences of judgment within a chosen level of tolerance may be averaged. Larger differences require discussion and resolution within the subgroup, with the panel chair arbitrating difficult cases. In large multidistrict systems, district panels themselves need to be moderated.

Issues and Alternatives

The issues related to moderation and the alternatives offered can be summed up as below:

- A certain level of trust is necessary for successful moderation. Assessors are assumed to be professionally competent and ethical. In some situations, persistently incompetent and unethical assessors can be replaced. In other situations, for example, where assessment is continuous or *in situ*, assessors are integral. In general, provided assessor judgments are respected, moderation can provide powerful professional development and therefore strengthen trust. A balance must be struck between trust and surveillance.
- Moderation consists essentially of a series of feedback loops to improve overall quality and consistency of assessment processes and judgments. Feedback is usually based on a sample of assessments. Most assessments are not reviewed. Moderation involves negotiation and agreement on standards in relation to the sample. The assumption is that assessors will then apply those agreed standards to all the other assessments. Sometimes assessors are asked to demonstrate that they have done this but options for final validation are usually limited.
- Sampling can be random or deliberate and chosen internally or externally. Being deliberate is more efficient since it can cover the range of performance and include mid-grade and borderline cases. Atypical or unusual cases are sometimes instructive and assessors may want to seek guidance on them, while noting their atypical or unusual characteristics. In general, typical cases may be more helpful for exemplifying general standards.
- With external moderation (expert or panel) a choice must be made between blind re-marking and confirmatory review. The latter is usually more practical; keeping scripts free of assessor marks and comments is often unrealistic. The question is then whether the moderator agrees with the assessor's judgment. The moderator looks for the evidence to justify that judgment. This lays a better basis for negotiation through professional respect rather than a clash of judgments.
- Moderation emphasizes consensus, that is, averaging judgments is a weak alternative that leaves different interpretations and applications of standards unchallenged and unresolved; besides, negotiation allows standards to be discussed, clarified, and aligned, generating greater transparency and consistency into the future.
- Reaching for agreement encourages and strengthens professional engagement. A choice sometimes must be made between accepting assessor judgments at face value versus substituting the moderator's judgment for the assessor's. The latter may sacrifice long-term for short-term benefits and is best limited to exceptional cases such as recalcitrant assessors with whom agreement is unattainable.
- Once agreement is reached, some form of follow-up may be necessary. This might involve assessor sign-off that agreed actions have been taken. Alternatively, there might be further monitoring of those actions, such as through additional moderation. Clearly, the extent of follow-up depends on time and resources.
- What constitutes successful moderation will vary. Long-term refinement and improvement depends on asking *post hoc* whether the implemented moderation processes served their purpose and had desirable consequences. Such a review can be informal (e.g., by discussion) or formal (e.g., by systematic research).
- Little research has been conducted on moderation even though moderation practices are now widespread and becoming accepted as part of normal educational practice. More research is needed to establish a more extensive and systematic body of knowledge on the varieties of moderation practice, the rationales and circumstances of their adoption, and their effects and effectiveness.

School Policies and Practices to Support Effective Classroom Assessment for Learning

D Pedder, University of Cambridge, Cambridge, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

At root, what makes assessment educational is the use of assessment information for supporting improvements in learning by teachers and their students. The classroom assessment strategies that teachers develop to support learning are commonly known as formative assessment or assessment for learning (AfL). Five broad classroom strategies commonly associated with formative assessment or assessment for learning are sharing; learning intentions and success criteria with learners so they understand criteria of quality; developing classroom talk, questioning and learning tasks that elicit evidence of learning; giving feedback that identifies strengths and weaknesses and helps learners know what to try next to move forward and improve; and providing opportunities for peer- and self-assessment so that learners can eventually develop and apply the four other strategies in this list and become autonomous learners and sources of learning support for one another. Indeed, a central underlying core principle reflected in assessment for learning is its value for promoting learning autonomy (James *et al.*, 2007). More specific practices and techniques have been developed for realizing the five broad AfL strategies listed above in different classroom contexts, and these are discussed further in Wiliam (2007).

In understanding how teachers develop and use different classroom assessment strategies and practices in different contexts, it is always important to ask how they manage to do so in ways that reflect the underlying core principles of using classroom assessment to improve the quality and autonomy of students' learning. It then becomes useful to ask whether teachers' use of the five broad AfL strategies in classroom lessons brings them to a genuinely closer appreciation and fuller understanding of their students' learning and orientations to learning to (1) support it better and (2) provide more scope for their students to exercise and develop increasing autonomy and responsibility in their learning. For example, do teachers observe their students' learning as it happens in classroom lessons? Do they focus on what their students are learning and also on how they are learning? Do they provide opportunities for their students to assess their own and one another's learning? Do they help their students to plan appropriate ways to take their learning forward? And then, do teachers widen the scope for their students to take on more responsibility in deciding or negotiating learning objectives and in assessing their own and one another's learning?

Related to these questions on how broad classroom assessment strategies can be realized by teachers in specific classroom contexts and in ways that remain true to the original precepts and values of assessment for learning, there are also questions about the scalability of effective classroom assessment. These questions relate to how AfL can be embedded beyond the practices of small pockets of committed advocates. For example, how can knowledge of effective classroom assessment be developed by a teacher for use with students in all the different classes he or she teaches? How can transfer of expertise and know-how be spread across all teachers within a school and across schools throughout entire school systems? Also, what school systems and practices support the development and transfer of such expertise? In short, on what scale can effective classroom assessment that supports improvements in learning be incorporated into classroom practice within schools and between schools throughout entire school systems?

Earlier small-scale experiments indicated powerful effects of a number of classroom assessment interventions, but the problem of scaling up these innovations across all schools and teachers remained. The Learning How to Learn (LHTL) project in the United Kingdom (see James *et al.*, 2007) is the main large-scale longitudinal study that was designed from the outset to understand and support development of the organizational conditions that would enable such scaling up of effective classroom assessment practices. There is, therefore, extensive reference to this project throughout this article.

In addressing these questions, it is important to recognize sources of complexity and challenge involved for teachers and students when asked by researchers and policy makers to incorporate assessment into their everyday classroom practices. This is the focus of the next section. In the light of these complexities and challenges, later sections consider what school practices and policies are needed to support development and embedding of effective classroom assessment practices to scale.

Sources of Complexity and Challenge in Enhancing the Use of Effective Classroom Assessment

The Classroom Environment

One source of complexity and challenge that shapes any kind of classroom practice, including classroom assessment,

is the nature of the classroom itself as a place in which teaching, learning, and assessment take place. McIntyre (2000: 98) suggests that the sustained high-quality oral and/or written interactions involved in effective formative assessment so adds to the complexity of classroom teaching as to make it a quite impracticable option for teachers. He refers to six features of this complexity: the multidimensionality, simultaneity, immediacy, unpredictability, publicness, and historical embeddedness of the demands made on teachers in classroom lessons. McIntyre (2000: 99) goes on to ask how far the advice and guidance to teachers from researchers such as Black and Wiliam (1998) and Torrance and Pryor (1998) about using formative assessment in classrooms takes sufficient account of the complexity of classroom life and of the sophisticated ways in which expert teachers have learned to work effectively in classrooms through rigorous prioritization, simplification, and intuitive decision making. Fairly low uptake of assessment for learning practices has been reported by James *et al.* (2007). Decisions by teachers not to build regular high-quality formative interactions with individuals or small groups into their classroom lessons might well be due to constraints of the classroom as an environment in which teaching and learning take place.

However, over the past 10 years, researchers have been designing research and development projects on the belief that, despite such complexities, teachers can build assessment for learning into their everyday classroom practices so long as they are supported appropriately in doing so. These researchers believe that integration of AfL or formative assessment within normal everyday classroom practice is possible because all aspects of student activities during classroom lessons carry some potential for informing teachers and students about current levels of understanding. When AfL strategies are successfully integrated into routine classroom practice, the boundaries between teaching, learning, and assessment become blurred. As James (1998: 172) argues, the aspiration is that assessment should become fully integrated with teaching and learning, and therefore part of the educational process rather than a bolt-on activity. Since then, research and development projects such as those undertaken by Black *et al.* (2003), James *et al.* (2007), Thompson and Wiliam (2008), and Wiliam (2007) have actively supported groups of teachers and schools in using and improving assessment for learning as part of their everyday practice in classrooms.

Changes in Teachers' and Students' Conceptions of their Classroom Roles

A second and related source of complexity and professional challenge in enhancing the use of effective classroom assessment relates to changes in teachers' and students' conceptions of their classroom roles. An important thread

that runs through the LHTL project data (James *et al.*, 2007) is that important shifts in the roles of teachers and students, and their conceptions of those roles, are needed if the promotion of learning autonomy through the development of AfL is to become a reality in classroom lessons. A central feature of any AfL approach is that students are actively supported by their teachers in taking increased responsibility for their own and one another's learning. This increased responsibility is encouraged when learning itself becomes established as an explicit and critical focus of classroom talk through, for example, discussing with students what to try next to improve, negotiating learning objectives with students, or supporting students to clarify their understandings of success criteria. As learning becomes more explicit and visible, learners are helped to become more conscious of the how and the why of learning as an invaluable support for developing more effective strategies and increasing learning autonomy. To make this a reality, new understandings and perspectives need to be developed among teachers and students about each other and, therefore, about the nature of learning and teaching. Furthermore, new attitudes to and practices of learning and teaching, shaped by explicit and critically reflective modes of participation, need to be acquired and developed.

This shift in emphasis in the roles and relationships of teachers and students is not trivial and further complicates teachers' work in an already complex classroom environment. Teachers are challenged to change the way they see their role: from prescribing what tasks students perform to a kind of orchestration of the learning itself (James *et al.*, 2007: 217). Similarly, there is a perspective shift involved for students as they are challenged to take on an expanded role in classroom lessons. Students as well as teachers have an explicit role in instigating classroom teaching and learning. They are not merely the objects of their teacher's behavior, but animators or co-constructors of their own effective teaching and learning processes. As such, AfL challenges teachers and students to develop conditions of trust and norms of participation that are conducive to the kinds of power-sharing that support pupils to move much closer to decision making that influences the conditions of their classroom learning.

In the next section, we move beyond the individual classroom and ask what is involved in encouraging and supporting scaling up of AfL practices within and between schools.

Fidelity and Flexibility

As more teachers adopt and adapt AfL approaches, a third source of complexity and challenge lies in striking an appropriate balance between what Thompson and Wiliam (2008) refer to as fidelity and flexibility. How, they ask, can teachers adapt AfL practices to local opportunities in different classroom contexts while at the same time

remaining true to the core principles and theory of action that underpin AfL? In their various classroom contexts, teachers need to be flexible in their development and adaptation of AfL strategies (as with any strategy they decide to work into their practice) to recognize, take advantage of, and then optimize opportunities for promoting high-quality learning.

This tension between flexibility and fidelity was evident in the reported experiences of teachers in the LHTL project (James *et al.*, 2007). From analysis of large-scale survey data from this project, three groupings of teachers' classroom assessment practices were identified and these are summarized in **Table 1**.

Measures of the value teachers placed on different classroom assessment practices were compared with their reported levels of practices. The LHTL project data show that teachers tend to place highest value on making learning explicit, and these high values were in line with similarly high levels of reported practice. However, the majority of teachers in the project (about 80%) struggled to bring practice into line with values with regard to promoting learning autonomy and performance orientation. Levels of reported practice for promoting learning autonomy were significantly behind their values, whereas levels of practice reported for performance orientation were significantly ahead of their values.

These survey findings are reflected in the interview and classroom observation evidence from the same project reported by Marshall and Drummond (2006). They report genuine difficulties faced by teachers as they attempted to transform classroom cultures through the use of AfL strategies aimed at promoting pupil autonomy. They found only about a fifth of the lessons they observed captured the spirit of AfL – assessment practices with an explicit orientation to the promotion of learning autonomy. Many teachers felt constrained by a policy context that encouraged rushed curriculum coverage, teaching to the test, and a tick-box culture.

What is clear from these different data sets is that in attempting to develop classroom assessment practices, teachers struggle to realize their values in practice with

regard to both the promotion of learning autonomy and performance orientation. At the heart of implementation is this struggle to resolve the tension, discussed by Thompson and Wiliam (2008), between fidelity to core principles and flexibility in contexts of constraint. In developing classroom assessment practices, teachers are constantly balancing and aiming for synergy between learning and performance orientations. These tensions are an important source of complexity in scaling up genuine AfL approaches to classroom assessment in classrooms, schools, and networks of schools throughout systems.

The main argument so far is that if teachers are to build genuine AfL approaches to their classroom assessment practices, changes are needed in their assessment values and their conceptions of classroom roles. Changes are also needed in the role conceptions of their students. This, together with the complexity of the classroom itself as a place in which to teach, learn, and assess, represents a set of significant professional challenges and cultural shifts for both teachers and students. Therefore, if teachers are to sustain support for high-quality learning through their adaptation of AfL in multiple school and classroom contexts, then they need to continue learning and be encouraged and supported to do so by schools with a culture and commitment to teachers' professional learning (Pedder *et al.*, 2005; Pedder and MacBeath, 2008).

The Importance of Teachers' Professional Learning for the Development of Effective Classroom Assessment

What kinds of professional learning then are most conducive to the development of assessment for learning practices in classrooms? This is a question posed by James and Pedder (2006) with reference to the LHTL project. Four main groupings of teachers' professional learning practices were identified through analysis of the LHTL survey data (Pedder *et al.*, 2005) and are presented in **Table 2**.

The most striking finding from analysis of the LHTL survey data was the importance of the inquiry group of

Table 1 Teachers' classroom assessment practices: Factors and definitions

Promoting learning autonomy	Widening scope for pupils to take on greater independence over their learning objectives and the assessment of their own and one another's learning
Making learning explicit	Eliciting, clarifying, and responding to evidence of learning; working with pupils to develop a positive learning orientation
Performance orientation	A concern to help pupils comply with performance goals prescribed by the curriculum through closed questioning and measured by marks and grades

Table 2 Teachers' professional learning practices: Factors and definitions

Inquiry	Using and responding to different sources of evidence; carrying out joint research and evaluation with colleagues
Building social capital	Learning, working, supporting, and talking with one another
Critical and responsive learning	Reflection, self-evaluation, experimentation, and responding to feedback
Valuing learning	Valuing their own and their students' learning

teacher learning practices. This group of practices reflects a range of research-informed, classroom-based approaches to collaborative teacher learning, and it is these that were most directly and powerfully associated with promoting learning autonomy and making learning explicit dimensions of classroom assessment. This association suggests that teachers' uses of and responses to different sources of evidence (from more formal research and their own enquiries) together with their collaboration with colleagues in joint research and evaluation activity are important for the development of assessment practices that lead to autonomous, independent, and active learning among their students.

Classroom-based teacher research and inquiry is not only an important strand of teachers' continuing learning and sustained critical reflection but also an important factor in helping teachers to enhance the ways they support students develop independence and autonomy in their learning. In fact, as James and Pedder (2006) argue, teachers who are prepared to engage in the risky business of problematizing their own practice, seeking evidence to evaluate to judge where change is needed and then to act on their decisions, are thus engaging in assessment for learning with respect to their own professional learning. Helping students to do the same with respect to their learning becomes less challenging because teachers are familiar with the principles and processes through inquiry into their own practices. In other words, they are well on the way to conceptualizing, developing, and valuing expanded roles for themselves and their students in teaching and learning.

Collaborative classroom-focused inquiry can take many forms. Teachers can visit one another's lessons and have focused conversations about what took place and how practice can be further refined. Teachers can consult their pupils about what they do that is helpful or not for supporting their students' learning (e.g., Rudduck and McIntyre, 2007). Research Study Lessons or Lesson Study represents a more formal approach to collaborative professional learning pioneered in Japan and developed in England by Dudley. Thompson and Wiliam (2008) report the centrality of teacher learning communities as opportunities for knowledge creation and transfer of AfL expertise and for sustained reflective practice.

A collaborative classroom inquiry orientation helps teachers develop subject content knowledge and find ways of applying it appropriately as they realize broad AfL strategies as specific and increasingly refined practices in particular subject and classroom contexts. Thompson and Wiliam (2008) argue that well-developed content knowledge is a necessary precondition if teachers are to ask good questions, interpret responses of their students, provide richly formative feedback that focuses on what students can do to improve, and adapt their teaching to developments as they unfold in lessons, based on the information they are gathering about their students' understanding of particular content.

Similar findings related to the importance of classroom-based professional learning in specific subject and classroom contexts have been replicated in a number of other research and development studies such as the King's-Medway-Oxfordshire Formative Assessment project in the United Kingdom (e.g., Black *et al.*, 2003); Classroom Assessment as a basis for Teacher Change project in the Netherlands and the United States (e.g., Dekker and Feijs, 2005); the Assessment is for Learning project in Scotland (e.g., Hutchinson and Hayward, 2005); the Keeping Learning on Track programme in United States (e.g., Thompson and Wiliam, 2008); and a number of case studies involving Canada, Denmark, England, Finland, Italy, New Zealand, Australia, and Scotland as part of the OECD study of formative assessment (e.g., Sebba, 2006).

Given the importance of collaborative, classroom-based professional learning and inquiry for fostering effective classroom assessment, it is vital that teachers sustain such learning at the center of their practice. In the next section, we turn to the question of what school policies and practices support and encourage teachers to continue learning together in these ways as a basis for advancing classroom assessment.

School Policies and Practices to Support Promotion of Effective Classroom Assessment

A guiding assumption of the LHTL project (see Pedder and MacBeath, 2008) was that schools that get to know themselves better, that approach pedagogy with a more informed grasp and critical understanding, and with an enhanced disposition to discern the integral connections between learning in classrooms, schools, and networks are best placed to support teachers and students in developing effective classroom assessment. At the heart of school policies and practices that support promotion of effective classroom assessment is school self-evaluation (e.g., MacBeath, 2006) and organizational learning. Schools that develop double-loop approaches to organizational learning adopt a critical stance to prevailing school routines and raise questions such as what are we noticing about the process of our learning as a school? Also, how can we learn more about ourselves as a learning community? Core values and assumptions are brought to the surface, and defensive routines and barriers to learning that are resistant to change are acknowledged in a climate of openness and willingness to critically reflect and respond at all levels of the school organization. The importance of organizational learning processes to promoting effective classroom assessment, and the teachers' learning that is a necessary condition for it is also recognized in Scotland's Assessment is for Learning project (e.g., Hutchinson and Hayward, 2005). However, the

organizational processes and cultures of support tend not to have been emphasized in the design of this and other research projects. The LHTL project is an exception; therefore, consideration of school policies and practices to support promotion of effective classroom assessment rely on insights from that project.

We have seen that teachers' collaborative classroom-based professional learning and inquiry embody assessment for learning processes of sustained critical reflection and self and peer assessment as a basis for reexamining and taking forward professional practices and values. Similar processes can be realized organizationally. Schools that are committed to self-evaluation through deep critical inquiry and continuous double-loop organizational learning enact assessment for learning processes and practices at the level of the institution. Schools that have well-developed systems and practices for learning critically in these ways lay the basis for development of the kinds of culture and institutional environment in which teachers become more collaborative and critically reflective in their learning and practice, while encouraging their students to do the same: to become more reflective and critical with regard to their own and one another's learning through, for example, effective classroom assessment practices.

Analysis of the LHTL survey data leads to the identification of four groupings of school leadership systems and practices as given in **Table 3** (Pedder and MacBeath, 2008).

Analysis of relationships between school practices and systems, teachers' professional learning, and classroom assessment practices through the LHTL survey data provided the basis for developing a model of the organizational conditions that foster successful promotion of assessment for learning in classrooms (see **Figure 1** below). This model shows empirical links between classroom assessment practices and the organizational conditions that support wider uptake of those practices within and across classrooms and schools (see Pedder, 2006).

A striking feature of this pattern of relationships is that organizational strategies such as developing a sense of where we are going, supporting professional development, and auditing expertise and supporting networking have an indirect influence on promoting learning autonomy and making learning explicit. In other words, school leadership practices and systems do not have a direct impact on classroom assessment practices; they are mediated by the inquiry group of professional learning practices. This points to the importance of school leaders focusing on school strategies that help teachers develop collaborative classroom-based, research-informed approaches to professional learning. The model also suggests that an emphasis on performance-oriented classroom assessment is disconnected from both professional and organizational learning.

Principal and senior leader interview accounts (as part of the LHTL database) focused on resolving tensions

Table 3 School leadership systems and practices: Factors and definitions

Deciding and acting together	Involving staff in decision making and using their professional know-how in the formulation and critical evaluation of school policy
Developing a sense of where we are going	Clear communication by senior management of a clear vision and the fostering of staff commitment to the whole school, based on good working knowledge among staff of school development priorities, which they view as relevant and useful for learning and teaching
Supporting professional development	Providing formal and informal training opportunities so that teachers, for example, can develop skills to assess their pupils' work in ways that move them on in their learning and to observe learning as it happens in the classroom
Auditing expertise and supporting networking	Information is collected on practices that staff themselves think they do effectively and on informal teacher networking in which they play an active role; teachers are supported in sharing practice with other schools through networking

between a performance-oriented policy environment and the support provided for the development of learning-oriented classroom assessment practices. Principals varied in the degree to which they embraced or critiqued this policy environment, differing in their perspectives along a continuum from compliance to subversion (see MacBeath, 2008). It was clear from school leaders' accounts how deeply embedded in thinking and practice the performance levels and attainment targets were. The prevalence of language related to targets and levels, monitoring, standardization, and consensus contrasted sharply with the absence of terms such as dialog, dissent, disagreement, or conflict. It seemed as if these forms of interaction were viewed as negatives to be avoided, and not part of a discourse among professional colleagues through which decisions about a sense of where we are going or acting together could be made.

Schools differ in the leadership approaches adopted for embedding effective classroom assessment. Swaffield and MacBeath (2006) distinguish between a structural and a cultural emphasis in the leadership strategies developed at different schools. Although all LHTL schools used both structural and cultural approaches to embedding effective classroom assessment, the conception of change described by some principals could clearly be located within a structural approach. These principals emphasized clearly

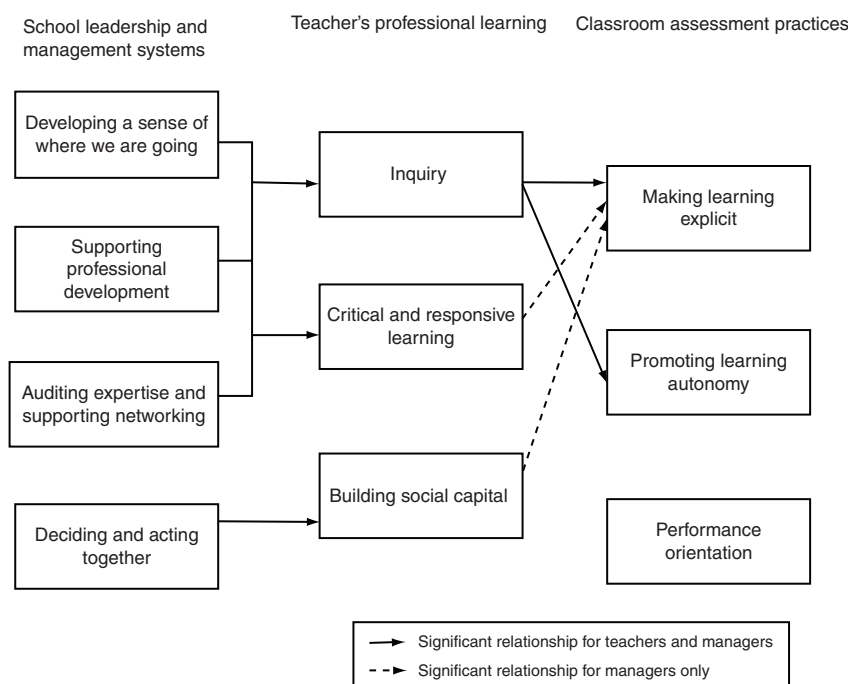

Figure 1 Organizational conditions that foster successful promotion of classroom assessment practices.

defined organizational structure with identified roles, linking mechanisms between roles and clear communication patterns. Specific tasks were identified with explicit lines of authority leading, within a traditional school hierarchy of responsibility, to a downward flow of decision-making from senior leadership to classroom teachers and classroom assistants. Other heads envisaged embedding more in terms of a cultural shift in which values and systems of belief change over time, through persuasion and support. Changing cultures for these school leaders required an extensive time frame; the use of a horticultural metaphor was common; change was portrayed as an organic growth and nurturing process. The term bedding in was used to describe a settling down of ideas and practices into new soil where they take root over time and with watchful tending. A culinary metaphor was another common evocation of processes of cultural change. Senior leaders spoke of the bubbles in the oil, assessment for learning was constantly bubbling away. Embedding was viewed as a slow simmering – a constant informal presence in the background of school life.

In practice, however, there was a great deal of common ground among schools in the adoption of strategies for embedding assessment for learning throughout the school. Committed leading teachers were used to move classroom assessment forward. Senior leaders made constant reference to the thinkers, the innovators, the change agents, and the champions as key advocates involved in fostering a climate of change. Commonly, these key personnel occupied a middle leadership role. Other schools, however, set up cross-departmental teaching and learning groups or

working parties to develop and test practical classroom assessment ideas, devise policies and feedback to senior leadership teams, and lead professional development. See MacBeath, 2008; James *et al.*, 2007 for further discussion of these aspects of leadership and organizational approaches to enhance the use of classroom assessment. What is clearly suggested from the LHTL project is that there is no simple formula and no single leadership model for promoting and embedding effective classroom assessment for learning in schools.

Conclusion

Schools that are serious about supporting teachers as they build authentic assessment for learning practices and values into their classroom routines are, at the same time, serious about promoting learning at all levels of the school organization. This is a key argument running through the research considered in this article. Teachers and school leaders as well as students go to school to learn. These schools are likewise serious about the need to support teachers and students in transforming their relationships and roles – a necessary condition if the development of classroom assessment is genuinely to be a collective endeavor and to genuinely support advances in the quality of both teachers' and students' learning. This much is clear from the LHTL project. But fundamental changes are needed, and not just in the classroom. To remain at the cutting edge of innovation in classroom assessment, and to ensure all school members have

genuine opportunities to contribute to its development and promotion, a school is invited to seek ways of broadening its organizational perspective by first asking the question, what a school needs to become to transform relationships and the learning of its members. And this question involves schools and everyone associated with them in continuously reflecting on what a school can be.

The rationale for schooling, that schools and classrooms exist to serve the learning needs of their pupils, can carry assumptions of dependent relations, which is to say that in the school community there are those who do things for others and those who have things done for them by others. And this is a common trend in performance-oriented assessment cultures. For example, it might be assumed that there is a division between teachers – those who teach pupils – and pupils – those who learn from their teachers. However, what might be involved in a richer, more expansive understanding of school relationships that goes beyond this strict division of labor between teachers (those who teach) and pupils (those who learn)? A new definition of schooling is needed in which schools recognize in each member of the school community something of value for the learning and social development of all members. In this sense, the school certainly exists for the sake of all members of the school community but not on the basis of a dependent model of service that dictates that there are professionally qualified teachers who teach and students who learn from their teachers.

New frames of school that are more in line with the transformational and collective potential of assessment for learning go beyond potential and actual divisions between agents and recipients of service – those who do and those who are done to. An alternative vision can be articulated and developed in a school on the basis of autonomy, interdependence, and human capacity for independent learning and transformation. Such a vision is highly inclusive: an all-members-as-subject vision. Research discussed in this article provides powerful evidence to suggest that assessment for learning practices and values, with their focus on the promotion of learning autonomy and making learning explicit, offer one powerful set of professional orientations and practical starting points for realizing such a vision.

However, the persistence of performance-oriented models of assessment continue to risk shrinking human agency and capacity to a narrow range of achievement, mode of development, and participation, and it can entrench teachers and pupils in traditional roles of doers and done-to which ill prepares them for active citizenship and lifelong learning. A preoccupation with league tables and test results has all too frequently led schools to narrow their organizational perspective in ways that limit scope for nurturing agency and a genuine responsiveness to the capacities of all members. Hence, the realization of the all-members-as-subject vision is frustrated.

What is it then that an assessment for learning perspective brings which helps a school move closer to this inclusive and participatory vision? At the heart of such a vision is a model of learning and achievement that belongs both individually and collectively to teachers and pupils as agents, connected to choices they make and directions they decide in their own and one another's learning. Learning is not defined for students or for teachers by the power and external constraints of someone else or by school or by some other body or authority. Predominantly students and teachers are accountable to themselves and those in their milieu for their learning and the relationships which underscore that learning. They, as subjects, take responsibility for their actions and choices with others. This is both a collective and an individual responsibility because learning practices are embedded in the lives of others and as such constitute a corporate practice in the common life of the school. But ultimately an individual's learning is something that fulfills the life of an individual agent and thus it is easy to forget that learners are not only accountable to one another but also to themselves.

Such learning and fulfillment can never be reduced to a curriculum and testing package provided or delivered to a learner by another. Nor can it be defined by school for learners. It is shaped through negotiation, dialog, conversation and consultation. There is co-construction and joint discovery by agents with other agents. Freedoms and agency flow together in joint enterprises of learning, assessment, and inquiry. In this sense, it is not the school's job to provide learning and fulfillment. It is not about someone else's responsibility for my learning. But it is the school's job to release teachers and pupils from any restrictive organizational constraints or barriers that prevent a flourishing, a shaping, and a discovery of what can be learnt and developed with others in the school community. And this is the challenge of developing school conditions conducive to the development of classroom assessment that supports genuine improvements in learning.

A school that develops such conditions then becomes a place where members are not relieved of burdens of choice, decision making, responsibility for their own and one another's learning, and the struggle to become an agent. A school does not exist to make people passive. Therefore, the school as an institution serving the needs of pupils becomes an inadequate institutional arrangement for the educational flourishing that can take place in schools. A better characterization of school centers on it as a place that fosters learning in terms of students' and teachers' agency being released – in consultation and negotiation, conflict and harmony, joint decision making and inquiry. Assessment practices that emphasize formative processes have been found to engender such a release of agency and organizational renewal in a small number of schools. Embedding and scaling up such practices organization- and system-wide remains the long-term goal. Consideration of

the research suggests that finding appropriate strategies involves collaborative experimentation among teachers and students and a great deal of adaptation to context – the kind of challenge to which the distinctive professional expertise of teachers is so well suited.

Glossary

Backwash effect – The effect, intentional or unintentional, that testing and other assessment practices have on the behavior of teachers and learners. Positive backwash has a beneficial effect, while negative backwash is detrimental.

Formative assessment – An assessment that takes place during the teaching/learning process for the specific purpose of providing developmental feedback so that teachers and learners can adjust their plans for future learning and, hence, improve outcomes. An alternative term is assessment for learning.

High-stakes assessment – A high-stakes assessment is where individual candidates stand to gain or lose much according to their results. For example, in Armenia, young men who do well in the university selection exams win financial support for their further studies, while those who fail have to enter military service. Here, the stakes for candidates are extremely high.

National assessment – An assessment exercise carried out to determine average national educational standards in a particular curricular domain at a particular stage of education. Usually this involves testing a relatively small, but representative sample of students from the cohort.

Summative assessment – An assessment that takes place at the end of a learning activity or program for the specific purpose of judging and reporting a student's overall achievement.

Value-added modeling (VAM) – This predicts the likely educational outcome for an individual student by applying a statistical model to current or past test scores taking into account a range of background characteristics for the student concerned. By comparing actual outcomes, as measured by tests, with predicted outcomes the effects of individual schools or teachers can be estimated. Where the actual outcome exceeds the predicted outcome by a significant amount, we conclude that the school or teacher has added value.

dramatic shift. Within 10 years of the fall of the Berlin Wall in 1989, Germany was reunited, the Soviet Union and the Yugoslav Republic had collapsed, and other aligned nations in the region had, to a greater or lesser extent, broken free of restrictive ideologies and authoritarian rule. Throughout Central, Eastern, and Southern Europe, newly independent republics were free to rebuild their national identities and formerly closed states were suddenly open to the Western influences from which they had long been isolated (**Table 1**). In these countries, political parties, special-interest groups, and the wider public debated two key issues: how to generate economic growth in a competitive global market and how best to bring about desired social and political reforms. These internal voices were joined from outside by international development banks, multinational agencies, and numerous nongovernmental organizations (NGOs) – each keen to promote its own economic model or recipe for social change.

From the outset it was apparent that the reform of education would have a major role to play in both areas. If a country is to succeed in a fiercely competitive open market, the knowledge and skill levels of all young people, not just those of a small elite, must be raised and made more relevant to an increasingly technological world. At the same time, an open, civil society has far more chance of being sustained where students have the competencies and confidence necessary to question long-established orthodoxies and where they are given the opportunity to propose alternatives freely. As a consequence, policymakers across Central and Eastern Europe (CEE), the Commonwealth of Independent States (CIS), and the Baltic States sought to transform not only the structure and management of their education systems, but also the content of the curriculum and its delivery in schools. Many of the models considered were those operating in the West where, over a period of 25 years, the crucial role of assessment in measuring, monitoring, and raising educational standards had been firmly established and subsequently incorporated into sophisticated national assessment and qualification frameworks and rigorous international studies of learners' achievements.

Against this background, three main themes related to educational assessment emerged:

1. the reform of examination and qualification systems – especially at the secondary/tertiary interface;
2. the development of new national standards for educational outcomes and mechanisms for monitoring them and comparing them with international norms; and
3. the introduction of new approaches to classroom assessment in order to enhance learning.

Context

In the late 1980s and early 1990s, the European order which had prevailed since the end of World War II underwent a

Reform of School-Leaving and University Selection Examinations

Assessment of students in the CEE/CIS region was, and to a great extent remains, a task delegated to schools. Teachers are required to use a variety of methods to assess students regularly throughout the academic year, but they are given much freedom in the choice of assessment tasks and the way in which they set standards. Approved methods include teacher-made tests and control works – a term from the Soviet period for classroom tasks specifically set for assessing student achievement. In addition, and in contrast to Western practices, formal oral examinations remain common throughout basic and secondary education. For each assessment, student performance has traditionally been reported on a simple numerical scale of either five or ten points. For example, on the five-point scale, 1 is considered a failing score, 2 as satisfactory, and 5 as excellent. On the ten-point scale, 4 is the minimum passing score and 10 is considered a perfect score. At the end of each year, numerical scores from all assessments in a particular subject are combined to give an overall mark. At the end, for example, of secondary education these school marks are noted on the student's diploma where results from any formal, centralized examinations may also be recorded.

Prior to 1990, any centralized examinations used in the region bore little relation to the highly sophisticated, external examinations common throughout Western Europe. Ministries of Education allocated few human, physical, or financial resources to the production and delivery of examinations. For example, in Romania, a single ministry official worked largely in isolation, preparing question papers for the baccalaureate examinations taken at the end of secondary education. The question papers were, as a rule, constructed using items from previous tests and approved textbooks. Master copies of tests were duplicated for distribution to schools where, at the appointed time, teachers would copy the questions on to blackboards for the students to answer. Teachers then evaluated (marked) the responses of their own students; however, since it was assumed that

all teachers would be familiar with the correct answers, detailed marking criteria were not provided.

An alternative model, still used in Serbia, involved the publication of all possible examination tasks in advance. This open item bank was widely available at very low cost so that students could prepare, or be prepared by teachers and tutors, in advance. On the day of the examination, the numbers of the tasks selected for testing were announced on national radio. Students wrote their answers to the chosen tasks and these were then marked and graded by their teachers.

Such examinations were extremely cheap and generally secure, but they encouraged rote learning and did not promote the development of higher skills in the classroom. In addition, because conditions for taking the test were not uniform and there was no mechanism for standardizing marking, the results were too unreliable to be used for comparing standards or selecting students for further education. For example, it was found that the results awarded by teachers to students in disadvantaged schools in remote rural areas were not dissimilar to those of students attending the most prestigious urban schools. In addition, disproportionately large numbers of students were awarded perfect scores, making it impossible for higher education institutions (HEIs) to select the most able students (Bethell and Zabulionis, 2000). As a result, university faculties set, and in some countries continue to set, their own selection examinations. Such bifurcated systems, where school leaving examinations have no formal link with university selection procedures, lead to several problems. First, the powerful backwash effect of university admissions tests tends to undermine the central position of the national curriculum in schools. Students approaching the end of secondary education direct all their efforts toward preparing for the entrance examinations of their preferred faculties. In some cases, schools simply suspend teaching programs toward the end of the year to enable students to practice for the selection tests. Where competition for university places is particularly fierce and where the stakes associated with success and failure are high, private coaching for university entrance tests becomes commonplace – and a problem for ministries of education, parents, and students. In some countries, the perception, and perhaps the reality, is that unless a student has paid for private coaching from a university tutor, their chances of success in the entrance examination is minimal. Where such tutors have the opportunity to influence selection decisions directly either as markers of written answers or as members of evaluation panels for oral examinations, prevention of corruption becomes extremely difficult and public confidence is undermined.

In order to eliminate the pressure on students (and their families) of having to sit multiple exams in the same subject at different locations, and to reduce the perceived

levels of corruption in the allocation of university places, politicians and educators sought to introduce new examination systems at the school/university interface. Two alternative approaches have been used. The first, adopted by several CEE and CIS countries, was to develop a centralized examination system based on the European baccalaureate model. In this case, the majority of school leavers take formal examinations in compulsory subjects (usually the national language and mathematics) and a number of optional or elective subjects. The results are used for two purposes: certifying achievement in a school-leaving diploma and selecting candidates for places in institutions of higher education. The second approach was to introduce a single, centrally controlled university entrance examination system to replace the multiplicity of entrance tests set by the various university faculties. Here, the general model is more closely related to the system of standardized, objective tests used in the United States and in Turkey.

The first transitional country to introduce radical examination reforms was the former Yugoslav Republic of Slovenia where, in 1989 the Ministry of Education recommended that a centrally controlled Maturity (*Matura*) examination system should be introduced to serve both as a school-leaving qualification and as a passport to university (Gabršček, 2001). To achieve this, a National Matura Commission was established to determine the principles, rules, and procedures for the new examinations. After much deliberation, the model chosen was one based on the International Baccalaureate and much influenced by the A-level examinations of England. The compulsory subjects were mother tongue, mathematics, and a foreign language. In addition, students were to choose two elective subjects from a prescribed list. In order to pass *Matura*, and hence be eligible to compete for a place in an institution of higher education, candidates had to achieve at least a minimum pass in each of the five subjects taken.

Administering high-stakes examinations on a national scale requires far more resources than operating a decentralized system where much responsibility is delegated to schools. In Slovenia, this challenge was met by establishing an independent National Examinations Centre. This is responsible for setting question papers, printing and distributing examination materials to schools, organizing the marking of student scripts, and processing the results. The costs associated with accommodating, equipping, and staffing such an organization are considerable. In most CEE/CIS countries, these costs are met from the state budget for education.

Slovenian reforms were generally considered a great success and they influenced policymakers throughout the region. The World Bank, the European Union, and other international agencies have been keen to provide financial support for similar reforms in CEE, the CIS, and the Baltic states. Typical projects have included the establishment

of new national assessment agencies, the training of assessment specialists and the development and piloting of new assessment procedures. Countries that have successfully adopted this model to date include Armenia, Estonia, Latvia, Lithuania, and Romania.

New Matura and Baccalaureate examination systems successfully address many of the educational challenges facing transition states. However, not only are they costly to operate, but it is also difficult to keep them secure because of their large scale and dispersed administration. Indeed, leakage, that is, the loss of a question paper in advance of the examination date, can be both expensive and politically damaging. In countries where competition for places in institutions of higher education is fierce and where the perception of corruption is high, maintaining the security of the examination is the first priority. In these cases, policymakers have favored the introduction of standardized university selection examinations based on the use of objective questions and automated scoring methods.

An early and extreme example of this approach can be found in Azerbaijan which was the first former Soviet republic to introduce a centralized examination built around automated systems and new technologies for admission to all institutions of higher education. The admissions testing system is conducted by the State Students Admission Commission (SSAC) which was established in 1992 under the control, not of the Ministry of Education, but of the president's office. Currently, about 90 000 students apply annually for approximately 25 000 places in HEIs. All students applying for each of the five specialties (i.e., medicine, mathematics, economics, humanities, and sociology) take their examinations on a given day. For example, in 2004 approximately 23 000 applicants for mathematics took their examinations on the same day. This required 20 variants of the question paper. For this group, results were issued within 7 days. (Compare this with Matura-type examinations which typically include constructed-response and essay questions. In this case, marking and the processing of results takes more than a month from the date of the examination.)

To achieve a high level of security both before and during the examination session, all variants of the test are produced from the large item bank that SSAC has built since its inception. The items in the bank are categorized by level of difficulty and the content/skill being tested. When a test variant is required, the information system selects items at random until the test's specification is met. No further human intervention is made to ensure secrecy. Answer sheets are marked by optical mark readers to remove all elements of subjectivity.

Azerbaijan's automated testing system meets its key objectives in that the admission system is standardized for all candidates and that corruption in processing tests is eliminated. However, critics argue that the use of objective

tests built from open item banks obviates the need for school students to develop higher skills and promotes rote learning and the use of private tuition. Indeed, it is estimated that over 80% of university applicants in Azerbaijan pay for private tutors or preparation classes at an average cost of about USD 200 (ESP, 2006).

Establishing and Monitoring Educational Standards

Formerly, the term standards was used in Eastern Europe to refer to the document setting out the content, duration, and objectives for a particular teaching program. The intended outcomes were not, in general, differentiated and so served as targets for all students. This was in contrast to the concept of educational standards prevailing in the West which, in recognition of the fact that there is a broad spectrum of student ability, described discrete levels of achievement or, in the case of England, a complete ladder of achievement targets against which the progress of each child could be judged. In the Netherlands, basic and higher levels of achievement were based not only on the judgment of experts but also on quantitative evidence gained through testing representative samples of students. Encouraged by the World Bank and other funding agencies, many transitional countries built the concept of graduated standards into their new curriculum frameworks and, most importantly, developed national assessment systems to validate and monitor the new standards – particularly in mathematics and native/state languages.

In all cases, a sample-based model was used. This was, to all intents and purposes, the model used both in international comparative studies of learner achievement and in well-established national systems such as the National Assessment of Educational Progress (NAEP) used in the United States since 1969. Conducting sample-based national assessments requires a high level of expertise in test construction, sampling, and statistical analysis. In particular, it requires the use of item response theory in calibrating items, linking tests, and developing achievement scales. Capacity in these fields was developed through technical assistance from international assessment agencies and by participating in international studies (see below).

The result of much investment is that many CEE/CIS countries now have assessment units with experience of running sophisticated national assessments and reporting the outcomes. However, the impact of these surveys is generally disappointing. Assessment specialists are frustrated that decision makers do not pay due attention to their findings and that educational policy is not influenced by the objective data that national assessments yield. One reason for this is that ministers of education

throughout the region are keen to use the results of testing to increase accountability. In particular, they would like to identify failing schools and teachers so that sanctions could be imposed. However, it is not possible to use sample-based results to produce a meaningful league table of schools or to detect inadequate teachers. These objectives can only be met by regularly testing every child and by calculating the value added by schools and teachers between stages of education as in the English system. While no CEE/CIS country has yet invested in developing such a system, there is increasing interest in using test results for accountability and some steps toward this are being taken. In the Krakow region of Poland, for example, the regional examination board is investigating the use of value-added models based on national examination results.

International Comparative Studies

On entering a more open Europe where it was intended that there should be greater freedom of movement for employment and study, many CEE/CIS countries were keen to compare their national educational standards with those of others by participating in international surveys of learner achievement. Early adopters included Bulgaria, Latvia, Lithuania, Romania, the Russian Federation, and Slovenia – all of which participated in the Third International Mathematics and Science Study (TIMSS) conducted by the International Association for the Evaluation of Educational Achievement (IEA) in 1995. This policy was strongly encouraged by international agencies and, in particular, by the World Bank which gave financial support through grants or through loans to countries embarking on education reform programs with assessment as a component. Such support allowed, for example, Moldova and Macedonia to join the next round of the renamed Trends in Mathematics and Science Study (TIMSS) in 1999.

In 2001, IEA conducted the first Progress in International Reading Literacy Study (PIRLS). This aimed to measure how well 9- and 10-year-olds read and to investigate the factors influencing reading achievement. This was seen as an important development and the CEE/CIS and Baltic countries that had taken part in TIMSS in 1999 also participated in PIRLS (Mullis *et al.*, 2003).

In a parallel development, the Organization for Economic Co-operation and Development (OECD) established its Programme for International Students Assessment (PISA) and conducted the first study in 2000. PISA looks at students nearing the end of compulsory education (15-year-olds) but, unlike TIMSS, focuses on the knowledge and skills needed in adult life rather than simple mastery of the school curriculum. Its assessment framework is based on four domains: reading literacy, mathematical literacy, scientific literacy, and the cross-curricular competence of problem solving. With its emphasis on competencies and

everyday contexts, PISA was seen by many transitional countries as being particularly relevant. As a result, Albania, Bulgaria, Latvia, Macedonia, the Russian Federation, and Romania were among the non-OECD countries that took part in a re-run of the study in 2001 (PISA+).

Prior to participation in such international studies, judgments as to national educational standards in Eastern Europe were often based on the performance of students in prestigious subject Olympiads. In these competitions, extremely gifted students demonstrated their advanced skills in, for example, mathematics and physics. The number of gold medals that a nation's students won was taken as a proxy for more general standards – unfortunately, the achievements of the few often flattered to deceive. For the first time, TIMSS and PISA allowed countries to measure with precision the average standards achieved by the complete student population and, on the basis of highly reliable data, to compare typical achievement with that of Western counterparts and regional neighbors. For most CEE/CIS countries, the results, particularly from PISA were, to say the least, disappointing. In PISA 2000, the Russian Federation and Latvia fell significantly below the OECD average, while Bulgaria, Albania, and Macedonia fell in the group of poorest performers with scores comparable to those of low-income countries in South America (OECD, 2003). In PISA 2003, Serbia's average mathematics score (432) placed it 33rd out of 40 participating countries (OECD, 2004).

Reactions to the results varied. Some countries were defensive, arguing that the unfamiliar test formats and the contexts in which the tasks were set placed their students at such a disadvantage that the results were misleading. Reactions in Albania and Serbia were particularly strong with the international results being decried and national reports being suppressed. However, in other CEE/CIS countries it has been accepted that the results of such surveys give a true picture of relative standards and hence indicate where new policies are required. Latvia, for example, has invested in major projects to raise national achievement – especially in mathematics and science.

Classroom Assessment Practices

Reform of high-stakes examinations, particularly those used for selecting candidates for universities, inevitably has the highest profile as far as politicians and the public are concerned. CEE/CIS countries have made unprecedented investments in implementing new assessment systems – the outcomes of which have often attracted media attention and resulted in controversy. This has, in many ways, overshadowed important developments in the day-to-day assessment of students in classrooms.

Prior to 1990, the classrooms of Eastern Europe were generally places where the teacher's role was to deliver the

approved curriculum in the prescribed manner to children who were expected to be passive learners. As countries became independent, old curricula were rejected and, in the interregnum, a space appeared where enthusiastic educators pressed for new approaches to teaching and learning. NGOs promoted their own programs and, in some cases, supported local initiatives for pedagogical reform. Two major themes emerged. First, there was a move toward active learning especially in kindergartens and early-years classrooms. Projects such as the Step-by-Step program, originally supported by the Soros Foundation and now maintained by a network of legacy foundations, promoted child-centered teaching with teachers and children as partners in the learning process. This and similar initiatives percolated upwards into the basic and secondary phases of education. Second, there was a reaction against the traditional emphasis on the memorization of facts and the ability to reproduce standard solutions to familiar problems. Curriculum developers and pedagogs argued for a curriculum and methodology that would encourage the development of higher-level cognitive skills, including independent critical thinking and the ability to solve problems in unfamiliar contexts – something where the PISA results of 2000 and 2003 had revealed significant deficiencies across the region (OECD, 2003).

As new outcome standards have been developed and more active approaches to teaching encouraged, complementary approaches to assessment have been proposed. These mirror recent and ongoing developments in Western education systems, and have the dual role of ensuring that teachers constantly monitor achievement through regular testing (i.e., assessment for reporting) and improving student achievement (i.e., assessment for learning).

At the primary level, there is much evidence of increased emphasis on judging performance against attainment standards defined in behavioral terms and helping young learners through increased use of diagnostic testing and remedial support. In Romania, for example, one of the first tasks of the new National Assessment and Examinations Service (established 1998) was to develop band descriptors, which described expected student performance at four levels in each subject of the curriculum. The intention was that these should serve as criteria against which teachers would judge and report the performance of each child. This was a radical departure from traditional practice in which teachers placed students on a numerical, 1–10 scale – a system which inevitably led to norm referencing with schools producing similar distributions of scores, regardless of absolute student achievement (Bethell and Mihail, 2005). In order to overcome the inevitable resistance to change, the Ministry of Education instructed all teachers of lower primary classes to report student achievement using comments, that is, statements related to the band descriptors, and to abandon the use of the 1–10 scale. This development may seem superficial to

some observers; however, in fact, it exemplifies a significant shift in approach to teaching, learning, and assessment, evidence of which can be found across the CEE/CIS region. First, it depends on a new interpretation of standards. Second, it focuses attention on the absolute rather than the relative performance of each student. Finally, assessment is seen as an integral tool in raising standards. In essence, it indicated a first, albeit small, step toward formative assessment to enhance learning.

Beyond the primary phase, as in the West, resistance to change is greater with secondary school teachers tending to be more conservative than their primary counterparts. In addition, high-stakes examinations at the end of secondary education exert a powerful backwash effect encouraging schools to focus on the use of summative tests to discriminate across the ability range in order to produce a rank order of students. Notwithstanding the above, there are initiatives to introduce new assessment procedures in many CEE/CIS countries.

One emerging issue is the perceived need of ministries to control teaching standards by requiring teachers to set regular and frequent written tests, oral examinations, assessed homework tasks, and other assessment exercises. In a throwback to earlier practices, student work on each assessment task is graded using traditional numerical scales and, at the end of the term or academic year, all results are combined using a prescribed formula. Such systems are based on repeated summative measurements (i.e., continuous assessment) and, as such, are a long way from the formative assessment they purport to promote. That having been said, many educators in the region are vocal advocates of true formative assessment as described by Black and Wiliam (1998) in *Inside the Black Box: Raising Standards through Classroom Assessment*. In particular, there is increasing emphasis on the use of tests for diagnostic purposes, especially for students making the transition from one grade to the next. In Armenia, for example, teachers have been provided with model diagnostic tests have been trained in setting similar assessment tasks and interpreting results. Progress here and elsewhere in the region is slow and limited, but this is not unexpected. Even in the relatively well-resourced classrooms of the West, high-quality formative assessment remains a distant goal and the number of teachers who, in Black's terms, have become pioneers remains limited.

Summary

Traditional approaches to student assessment, such as the value placed on oral examinations, remain strong in many parts of Central, Southern, and Eastern Europe. However, the reforms that transitional countries have put in place to make their educational systems more relevant to the modern world have incorporated significant developments in

the field of educational assessment. Perhaps the most visible signs of change are the numerous national agencies that have been established to administer high-stakes examinations. In particular, where new *Matura*, baccalaureate, or university selection examinations have been implemented, they have had a major impact on schools, teachers, students, and their families. Some of the reforms remain controversial but, at least in principle, they have increased equity by standardizing assessment procedures and setting uniform standards for all candidates.

Parallel developments, including the conduct of sample-based national assessments and participation in major international comparative studies, have yielded important objective data about the absolute and relative standards achieved by learners. At times, the results have been difficult for countries to accept, but many are now building on the lessons learned with the objective of closing the gap between their own results and those of, for example, their OECD counterparts.

Through these initiatives, educators throughout the region have been exposed to international best practice and the research upon which it is built. In particular, a much larger cadre of assessment professionals has been established – many of whom have benefited from technical assistance from some of the world's leading assessment agencies. As a result, the countries of the CEE, the CIS, and the Baltic States are now fully integrated into the international assessment community and, increasingly, are making their own contributions to the ways in which students are assessed.

Background and First Steps

Latin American educational systems arose in the nineteenth century, but the region's unstable situation delayed their development, in most countries, until the mid-twentieth century. By the 1970s and 1980s, education was obligatory only through primary (elementary) school. During this time, mandated education began to extend to the lower secondary (middle school) years. Even today, however, poverty in sectors of several Latin American countries prevents children from completing their primary schooling.

Two or three decades ago, the chief concern of educational policies was access to primary and lower secondary schooling. In some countries, this continues to be the priority, but student learning levels are gaining in importance, especially since the mid-1990s. In part, this is due to the low results among Latin American countries participating in international student-achievement assessments. It is also due to the economic globalization which demands attention to the preparation of future workers and citizens needed for a competitive society and effective democracy.

The development of standardized tests of school achievement began in the early twentieth century. Across the first-half of this century, this movement built momentum to the extent that teacher evaluations began to get integrated into standardized testing. The influence of these developments was felt around the mid-century in Latin America when some teachers were asked to prepare multiple-choice tests. They were asked to standardize their students' scores – known as grading on a curve – but since no special training was provided, the quality of teacher-made tests was poor. By 1960, standardized tests were used as entrance exams to high-demand programs in higher education in some schools at Mexico's National University, and the Technological

Institute of Monterrey began to use a Spanish version of the Scholastic Aptitude Test (SAT) – prepared by the Puerto Rican College Board. In 1968, the Colombian Institute for Higher Education Promotion (ICFES) was established to develop college-entrance exams. For primary and lower secondary education, the first large-scale assessments were conducted in Chile, Mexico, and Costa Rica.

Assessment Development since the 1990s

Previous efforts to develop student-assessment systems in Latin America were characterized by poor technical quality and low continuity. Thus, prior to the 1990s, accurate assessment systems did not exist. Efforts to this end were sporadic and incomplete. It was not until the 1990s that large-scale assessments were given increased importance. At the end of the first decade of the twenty-first century, more than half of the countries in the region have stronger assessment systems. Technical and organizational improvements have been made which translate into greater continuity of test administration and higher-quality data.

Argentina

In 1993, the Ministry of Education established the National Assessment System of Educational Quality to make National Assessment Operatives (ONEs). Initially, these were administered to students in the final year of primary and lower secondary schooling. Tests evaluated math and language. Later, they were extended to other grades and subject areas. The primary school assessments were

administered until 1999. In 1997, they began universal testing of the lower secondary level, which were repeated in 1998, 1999, and 2000. In 2000, the creation of the Institute of Educational Quality was approved. The serious economic crisis that struck this country prevented plans from advancing, and the ONEs intended for 2001 were not carried out.

Following the 2000–2001 period, crisis assessment was conducted in 2002 and 2003, and it was decided to administer tests – in the future – every other year. The exams were given in 2005, 2007, and 2009, under the direction of the National Division of Information and Evaluation of Educational Quality (DINIECE). Many of the nation's 24 jurisdictions administer their own assessments. In 2003, equating techniques were introduced and, in 2005, achievement levels were defined in relation with the Common Curricular Content. In 2009, all the students in the last year of secondary education were assessed (census-based), as well as a sample of ninth grade. The country is planning to switch to a 3-year cycle, with assessments of third and sixth grade students in a year, ninth and 12th grade in another, and a third year for analysis and dissemination of results.

Bolivia

In 1996, a System of Quality Measurement was established. In 1997, language and math achievement tests were administered to children in the third and sixth grades. In 2000, tests were administered to children in the first, third, sixth, and eighth grades, as well as in the 12th grade. With these results, a baseline was established as a reference for subsequent assessments. Tests in Quechua and Aymara – two native languages spoken by a large portion of the population, were developed. Following 2005, the unit in charge of assessments was dismantled and no testing has taken place since then.

Brazil

From 1990 to 1995, student samples attending the first, third, fifth, and seventh grades were assessed. During this time, the Basic Education Assessment System (SAEB) was initiated. In 1997, this institution was encompassed by the National Institute of Educational Studies and Research (INEP), which administers the National Secondary Education Exam and the National Course Exam – a college entrance exam known as *Prova*. Until 2001, samples of the fourth-, eighth-, tenth-, and eleventh-grade students were assessed every other year. The SAEB exams were redesigned in 2001. Revised editions included achievement levels and test equating to compare results over time. Other census-based tests have also emerged since 2005. The *Prova Brasil* is administered every other year to students in the fourth and eighth grades to assess language and math. Including more than 5 million children – all

students attending public schools in urban areas – results are available by school, municipality, and state. The *Provinha Brasil* seeks to measure emergent literacy at the end of the first grade. It is administered on a voluntary basis to children in public schools, where the results are processed. Several of the 27 states, such as Sao Paulo, Minas Gerais, and Parana, have developed their own assessments.

Chile

Chile had developed a true national assessment system prior to any other Latin American country. The first tests were administered to eighth grade students in 1968. A renewed interest in these tests emerged in 1978 with the redistricting movement and a step toward privatizing several public schools. The Ministry of Education entrusted the Catholic University with the system's development. In 1982, they began to administer the Tests of Performance Evaluation (PER) to students in the fourth and eighth grades. In 1988, the Educational Quality Measurement System (SIMCE) was established, which was absorbed by the Ministry of Education in 1995. Since the 1988 high stakes, universal tests have been administered every other year, alternating the grades. All the students are assessed in language and math. Tests in natural science, history, and geography are administered to student samples. In 1993, they administered tests to students in the 11th grade, and again in 1994, 1998, 2001, and 2003.

Since 1998 the item response theory (IRT) has been used for test equating between assessment years. In 2003, a committee of experts conducted a general evaluation of the SIMCE. Based on this, the ways in which assessment results are used were adjusted, but the assessment design remained the same. Achievement levels were instated in 2005. The tests are aligned with the Core Objectives and Minimum Obligatory Contents from the National Curriculum Standards, which define Progress Maps. From 2006, the tests are administered each year to fourth-, eighth-, and tenth-grade students. The SIMCE continues to have a strong impact because results are provided by school. Attempts are made to leverage the tests' potential and to use the results to develop policies that lead to the improvement of school quality.

Colombia

In 1968, the Colombian Institute for Higher Education Promotion (ICFES) was created to develop college entrance exams. In the early 1990s important educational reforms were undertaken and an interest in large-scale assessments emerged. At this point, ICFES was entrusted with test development for students in basic education. In 1991, language and math tests began to be administered to samples of students attending the third, fifth, seventh, and ninth grades. Social and natural science assessments were then developed.

In 1997, the Quality Division of the Ministry of Education and the ICFES launched the National System to Assess Educational Quality (SABER) – which sought to evaluate a longitudinal cohort of students with annual exams. This idea was later abandoned.

In 2002–2003, the first universal tests in reading, math, natural sciences, and civic competence were administered. The second round was during the 2005–2006 school year. Since 1998, IRT and test-equating techniques have been used. Bogota has their own assessments, and there are similar efforts in other regions. In 2008, the ICFES initiated an important effort to redesign its tests. The intention is to improve the technical quality and measurement precision of different curriculum areas – combining universal and stratified student samples in a multiyear cycle.

Costa Rica

The Institute for Research and the Improvement of Costa Rican Education (IIMEC), at the University of Costa Rica, began to administer large-scale tests in 1986 – with the endorsement of the Ministry of Education. This led to the creation of the National Center of Educational Evaluation in 1997. However, because assessment efforts could not be consolidated, national assessments are now administered by the Ministry. Universal assessments, in 1986, were administered to students in the third, sixth, and ninth grades in language and math. In 1987, 1990, 1996, and 1997, some of these grades were assessed, and in other subject areas as well. Currently, tests are administered to several grades, covering an array of subject areas. All children completing the ninth grade and secondary education (high school) are administered graduate exams which include all subject areas.

Cuba

The Evaluation System of Educational Quality began its development in 1996. The Central Institute of Pedagogical Sciences (ICCP), of the Ministry of Education, oversees the Quality Assessment Administrations. There are also provincial and local assessment units. From 1996 to 1997, language and math tests were administered to children attending the third grade in 100 schools. In 1999, sixth-grade students were added to the sample. Later, grades and the sample size have expanded, and the areas of natural science and history were added.

In recent years, some grades of technical/professional schooling as well as teacher training programs are being assessed in Cuba. These subsample assessments include reviews of math and language notebooks. In 2008, it was also planned to conduct assessments of special education. Achievement levels are used to report the results and produce briefs for several teachers, school administrators, and provincial supervisors. In addition to student

achievement, a socioeconomic indicator and other indices specify system efficiency, teacher performance, and school inspection.

Dominican Republic

Assessments began in 1991 with tests for fourth-grade students. In 1992, exams were administered to eighth-grade students, and to individuals attending a third term of adult education. In 1993, the last year of secondary education was included. From their inception, the tests are universal. Since 1994, they are administered annually to all students completing their final year of basic (eighth grade) and secondary (12th grade) education. The results of each student are combined with school scores to decide if the student will be permitted to continue to the following educational level. In 2009, the country is planning to create a new institution to develop a more comprehensive assessment system.

Ecuador

From 1996 to 2000, basic education assessment was carried out using tests developed by the National System for Academic Achievement Measurement, known as APRENDO. This was conducted by an external group of evaluators funded by the World Bank. They administered language and math tests to student samples attending third, seventh, and tenth grades. From 2001, the responsibility of testing was passed to the Ministry of Education, who continued to administer the same tests to the same grades. The APRENDO tests used the Classic Theory and equating methods of results over time. These tests were made public following each administration. In 2006, it was decided to substitute these tests with the National Assessment System – headed by the Planning Division within the Ministry of Education. Every 3 years, universal reading and math assessments will be administered in the fourth, seventh, tenth, and 12th grade. Natural and social science tests will be administered to samples in the seventh and tenth grade using a matrix design and IRT procedures.

El Salvador

The first tests – known as SABE – were administered from 1993 to 1996 as part of a project designed to strengthen achievement in basic education. Each year, language, math, natural science, and social science tests were administered to a national sample of students attending third through sixth grades and ninth grade. In 2001, the National Monitoring and Evaluation Division launched the National Learning Assessment System (SINEA) – which administers several achievement tests in various primary and lower secondary grades. In 2001, 2003, and 2006, the tests were

administered to student samples, and, in 2005 and 2007, they were applied universally. These tests contain defined achievement levels. The SINEA assumed the administration of the Learning and Aptitude Tests for Secondary School Graduates which, since 1997, were administered by the Simeon Canes University, and required to graduate from secondary schooling all over the country. Test scores contributed 20% of secondary graduates' final grades in 2005. In 2007, their weight increased to 25%.

Guatemala

From 1992 to 1996, the National Testing Center (CENPRE) of the Ministry of Education – with support of the US Agency for International Development – carried out their first assessments. In 1997, the University of the Valley of Guatemala assumed the tasks of the CENPRE and created the National System of Academic Achievement Measurement – later renamed the National Assessment Program of School Performance (PRONERE). From 1992 to 1996, it assessed children attending the third grade, and, from 1997 to 2001, children in the sixth grade. In 2004 – using a test called *Graduandos* – the PRONERE undertook new assessments of other primary grades, as well as of students finishing secondary schooling. In 2004, the University of the Valley administered *Graduandos*, for the first time, to students finishing secondary school. While results do not influence students' final grades, all students are required to take the test. In 2005, the Ministry of Education established the National Assessment and Educational Research System, within the General Division of Evaluation, Research and Educational Standards. The most recent tests include achievement levels, and seek to assess high-level skills; they are developed in Spanish and four native languages; results are available for all the schools – ranked by results considering students' socioeconomic status.

Honduras

From 1990 to 1994, the first large-scale assessments took place. This was part of the Program for Educational Quality by the National Pedagogical University, with support from United States Agency for International Development (USAID). In 1995, the Measurement Unit of Educational Quality was created by the National Pedagogical University. This office assumed assessment activities as assigned by the Ministry of Education. In 1997, the first test was given in Spanish and math to third- and sixth-grade students. In 1998, the second iteration of tests in the same subject areas was carried out, extended to second-, third-, fourth-, and sixth-grade students. Grades two through five were assessed in 1999 and grades three and six in 2000, 2002, and 2004.

Mexico

The Secretariat of Education launched initiatives, in the 1970s, which led to the creation of the Assessment Division. The first achievement tests were administered in 1972 as entrance exams to secondary schooling. By the end of the decade, tests were administered to the first samples of primary school students. Qualitative advances in testing administration did not occur until the early 1990s. In relation to an economic incentive program for teachers, called *Carrera Magisterial*, large-scale assessments were administered to students attending the last four grades of primary school, and the 3 years of lower secondary. The first administration was in 1993 to more than 4 million students. In 2005, the number approached 8 million. In 1991 – with support of the World Bank – the Program to Combat Educational Setback (PARE) was developed in four poor states, with student assessments. Similar programs continued, always with a student-assessment component. In 1996, an initiative to define curriculum standards was undertaken. Assessment instruments were developed, called the National Standards Tests. These were first administered in 1998. Until 2004, they were administered annually to national samples of primary school students. Since 2000, they were given to lower secondary school students as well.

In 2002, the National Institute for Educational Evaluation (INEE) was created, to develop independent assessments of the country's educational system. These tests have high technical quality and a wide distribution of the results – which contrasts with the previous practice of refraining to share test results publicly. As of 2004, the INEE developed Tests of Quality and Educational Achievement (EXCALE) using a matrix design. These cover the core curricular areas. EXCALE tests use multiple-choice and open-response items, and are administered to representative samples of students from all states within a cycle of four school years – successively assessing students in the ninth, third, and sixth grades, and the final preschool year (kindergarten). In 2006, the Secretariat of Education began to administer additional census-based exams (National Tests of Educational Achievement in School Centers (ENLACE)) during the four final grades of primary school and the last grade of lower secondary. In total, every year, more than 10 million students are tested. In 2008, students attending their final year of secondary school were tested for the first time.

Nicaragua

Nicaragua participated in a project by the Organization of Iberoamerican States (OEI) and the Central American Cultural and Educational Coordination (CECC) to establish standards for primary education – with an assessment component. In 1996, the Assessment Division of the

Ministry of Education began to administer tests from the APRENDE project. In 1999, the National Assessment System for secondary and basic education was created with support of USAID and United Nations Educational, Scientific, and Cultural Organization (UNESCO). Language and math tests are administered to samples of third- and sixth-grade students. The last administrations reported are from 2002 and 2006.

Panamá

Large-scale assessments can be traced to 1985. At the time, tests were administered to a national sample in a project led by the Organization of American States (OEA). In 1988 and 1992, the Ministry of Education carried out additional testing. In 1996, a National Assessment System for Educational Quality (SINECE) was established; samples of students of the third, sixth, and ninth grades were tested, and again in 1998, 2000, and 2001. In 2002, the National Direction for Educational Assessment was created and the National Assessment System was redefined as one for Learning Quality (SINECA). The methodological quality has been improved; in 2005, samples of students of third, sixth, and ninth grades were tested on Spanish, math, and natural and social sciences, and students at 12th grade on Spanish, math, and English. The first results were released on July 2006; later that year, a full report has been published – with analyses of the answers by content area and their association with contextual factors. A Plan for the Improvement of Learning has been defined.

Paraguay

In 1995, the Ministry of Education created the National Assessment System of Educational – process which administers exams to student samples. The first tests were given, in 1996, in language and math to sixth-grade students. In 1997, they were administered to third- and ninth-grade students, and, in 1998, to sixth- and 12th-grade students. From 1999 to 2006, students of one school grade were assessed each year, including grades third, sixth, ninth, and twelfth. Social science, natural science, and writing have been added. In 2001, an assessment of schools at risk was conducted.

Peru

The Quality Measurement Unit (UMC) was created within the Ministry of Education in 1996. Since then, six assessments have been conducted. The first four – from 1996 to 2004 – used student samples, while the final two were universal assessments. In 2006, universal assessments began with second-grade students. However, only 55% of schools and 44% of students were covered. In 2007, 91%

of schools and 80% of students participated in the testing, which included fourth grade students as well as those attending Quechua- and Aymara-speaking Intercultural Bilingual Education programs. In 2007, a longitudinal project began to follow a cohort beginning primary school until they finish the sixth grade in 2012.

Uruguay

The National Administration of Public Education (ANEP) established the Measurement Unit of Educational Results (UMRE) in 1995. In 1996, assessments were conducted for the first time. Universal administrations in language and math were given to sixth-grade students. Teachers administered these exams. Similar universal assessments were administered to sixth-grade students in 1999, 2001, and 2005. In 1998, third-grade students were also assessed, and, in 1999, ninth-grade students were tested. In 2001, linguistic competence and math were assessed at the start of primary school – using tests administered by teachers in kindergarten, and the first and second grades. This sort of assessment was repeated in 2007 among students attending the first grade. A universal, voluntary assessment was also administered to sixth-grade students.

In 2008, natural science content was added to previous assessments. Universal tests continue to be administered by teachers in each school. A control sample is used for test equating and research. The focus that distinguishes the work of the ‘Measurement unit’ remains in force; that is, efforts are made so that test results benefit teachers in all schools of the country. They are used in important training efforts. Evaluation results and test materials are counted as resources to improve teaching practice. The tests include multiple-choice and open-response items. A project was debated in 2008 to transform the Measurement Unit into an Evaluation Institute with greater autonomy.

Venezuela

The National Learning Assessment System was created by the Ministry of Education at the end of the 1990s. In 1998, a language and math exam was administered to a national sample of sixth-grade students. The instruments were developed with support from the Central University of Venezuela. This experience did not have continuity and, until 2008, no new assessments have been conducted.

Regional Participation in International Assessments

The First Study of the Latin American Assessment Laboratory of Educational Quality (LLECE) was promoted by UNESCO’s Latin American and Caribbean Regional Office (OREALC) in 1997. Argentina, Bolivia, Brazil,

Chile, Colombia, Cuba, Dominican Republic, Honduras, Mexico, Paraguay, and Venezuela participated in this project. Argentina, Brazil, Chile, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Guatemala, Mexico, Nicaragua, Panama, Paraguay, Peru, and Uruguay participated in the Second Study in 2006.

Increased interest in assessment is reflected in the growing participation in other international projects as well, particularly the Programme for International Student Assessment (PISA) studies by the Organization for Economic Cooperation and Development (OECD). In its first testing cycle, only Mexico – which was already a member of the OECD – and Brazil participated. A follow-up administration (PISA Plus) added Argentina, Chile, and Peru. These three countries did not participate in 2003, but Uruguay did – along with Mexico and Brazil. Argentina and Chile were integrated again in 2006, as was Colombia. In 2009, several more Latin American countries plan to participate.

Among Latin American nations, Chile has participated most in assessments conducted by the International Association for the Assessment of Educational Achievement: the Six Subjects Study in 1971, Institute of Advanced Legal Studies (IALS) in 1998, Trends in International Mathematics and Science Study (TIMSS) in 1998 and 2003, and Progress in International Reading Literacy Study (PIRLS) and the Civic Education Study (CivEd) in 2001. Colombia participated in TIMSS in 1995 and 2000, as well as in PIRLS and CivEd in 2001. Brazil participated in TIMSS in 2003. The IEA conducted a special administration of the civic education study for six Latin American countries in 2008. Regional cooperation has developed in relation to student assessment. Responsible parties for the administration of LLECE's Second Study met regularly from 2004 to 2008. They are now preparing the Third Study. The six countries participating in PISA 2006 have met regularly – together with Spain and Portugal – to prepare a joint report, published in 2009. This group supports countries participating in PISA for the first time.

Conclusion: Promises and Perils

Despite a late start and a shaky psychometric tradition, assessment systems in Latin America are consolidating and learning from international experience. Systems in Chile, Mexico, Brazil, and Uruguay already provide their educational authorities with information valuable to policymaking. Technical advances have been made in Argentina, Colombia, Ecuador, El Salvador, and Guatemala. Cuba's system – although very different from the others – demonstrated surprising efficiency according to results from the two regional assessment projects. Growing regional cooperation can contribute to the strengthening of the weakest systems.

On the other hand, two considerable perils are detected on the assessment horizon. The first – which is long standing – is the lack of continuity brought by political instability; its destructive effects are verified in decades passed. The second – a new danger to the region – is diminished educational quality as a by-product of inadequate understanding of the reaches and limitations of large-scale assessment. Indeed, the recent trend to conduct census-based assessments can have positive effects, but also negatives. There are no empirical studies on the subject, but qualified observers point out that the wrong practices of teaching to the test and poor instruction are increasingly present in several Latin American countries, following the implementation of census-based assessments with public results in the form of rankings of schools.

It was only a decade ago that few assessments existed in Latin America and, when administered, they produced results that were rarely distributed to the public. In sharp contrast, at present, testing has proliferated to the extent that it begins to tire the schools. Mass media fervently debates results – often with little knowledge of assessment complexity – and education authorities tend to take decisions based more on fads and political pressures than on solid knowledge.

In order for the promise of large-scale assessment to be realized, an objective vision of its real potential must prevail over superficial notions. It is essential to build teachers' capacity to do good classroom formative assessment, and to avoid the risk of poor replication of large-scale tests. Well-balanced assessment systems are needed.

Impact of Assessment on Learner Groups (Boys/Girls)

J Elwood, Queen's University Belfast, Belfast, Northern Ireland, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Assessment – An umbrella term that covers any practice that is used to make a judgment or evaluation of a student's learning. This judgment may be formative or summative and be made with the aid of tests, orals, practicals, portfolios, tasks, examinations, coursework, etc.

Bias – A term which indicates test items (or whole tests) that are discrepant and that may affect one group of test takers more adversely than another.

Differential performance – Different groups of test takers get different score levels on the same assessment either because of bias in the test or because of real differences in performance that may be the result of differing access to learning, resources, and/or educational opportunities.

Formative assessment – The assessment that is continuous throughout a course of study and through feedback supports the learning process.

Summative assessment – The assessment at the end of a course or program of study which, usually through a single grade or mark, describes the achievement obtained.

Validity – The extent to which an assessment dependably reflects the achievement being measured and the use to which the result is put.

Introduction

Research that is interested in the impact of assessment on learner groups of boys and girls considers differing views that promote various theoretical positions that help frame explanations and account for different performances by boys and girls on assessment tasks and tests.

At the core of these differing positions is how learning and the learner are viewed, how best to assess learning, and how assessment items and tasks interact with what the learner knows and understands. Moreover, how the learner interprets what is required from the task itself is also key, as well as those aspects of assessment tasks that may influence boys' and girls' understandings of what are necessary for a successful response. Furthermore, research exploring the social impact of assessment on learner groups is fundamentally concerned with the

role that gender plays in contributing to any differences in performance observed.

This article presents an overview of key research from this field that has a bearing on how we understand the complex range of influences and impacts that assessment has on the learning and achievements of boys and girls.

Assessment and Learning – Identifying Links

Current research in the area of assessment concerns itself with links that exist between our understanding of how children learn and assessment practice, with a focus on how the mode of assessment chosen aligns to a particular model of the learner and how the practice of assessment itself can be used as a tool to improve learning (see CERI, 2005; Wilson, 2004). In earlier investigative approaches, assessment researchers were less clear in their articulation of the model of learning that underpinned the assessment technique chosen. However, more recent studies have shown that one cannot consider systems of assessment and testing without acknowledging their relationship to the model of the learner they promote or wish to promote. Furthermore, there is a connection between learning and assessment within which the notion of gender in all its complexities needs to be considered. This is because how gender mediates learning has a profound impact on how students and teachers experience assessment practice and its influence on educational success.

Views of Learning and Links to Assessment

Within the literature on how children learn, there are many theories presented that consider what learning is and how it occurs (Murphy, 1998). These theories are varied, change in prominence over time, and are often contested. In reviewing these many theories of learning, writers tend to categorize certain types of theories and/or approaches to learning into larger groupings or families to help understand key themes and influences. For example, some categorizations bring together theories of behaviorism (where notions of learning are fixed and learning happens through transmission), theories of constructivism or social constructivism (where learning is seen as a social activity and learning happens through social interaction), and theories of socioculturalism (where learning is seen as something that happens within the social, cultural, and

historical contexts of students' lives) (Elwood, 2006; Murphy, 1998). In relation to work on assessment, different categories of learning have been associated with different approaches to assessment and how students' learning is evaluated. For example, assessment located within a traditional psychometric model is seen as something done to an individual to measure that individual's learning (the behaviorist influence), with underlying assumptions about the presence of psychological attributes that can be observed and evaluated through responses to test items.

More recent considerations of assessment practice see it as a social activity and promote assessment as something done with the learner, acknowledging that assessment is measuring learning that is acquired through the social mediation of teacher and students (the constructivist and social constructivist influence). Assessment within this tradition still attempts to check up on what the individual has learned even though they have acquired that learning through social interaction. Researchers who place emphasis on the complex interactions of gender and assessment, especially within classroom-based assessment tasks and practices, prioritize the cultural and social contexts within which assessment takes place and consider the gendered relationships between teacher and student, and student with student, as key in comprehending the impact and interaction of all this on girls' and boys' assessment outcomes (the sociocultural influence). Thus, how we understand how students learn has major implications for how we choose to assess them, how we understand their responses to assessment tasks, and how we consider gender in relation to the outcomes observed.

Assessment and Boys and Girls: Sex Group Differences and Fixed Notions of Learning

Assessment within a traditional psychometric model considers learning as an individual activity and something that the student acquires through instruction; learning gets stored within the student, and the act of assessment is to measure this stored learning and to check up on what a student knows. These views of the learner and how to assess them is aligned to a static view of gender, that is, as sex group (male or female). Thus, gender is seen as a fixed, dichotomous variable against which assessment scores can be analyzed and reported.

From the 1970s, much more educational research began to focus on, and take account of, sex differences in educational achievements. Within the field of assessment and testing, much of the early research into differences between boys' and girls' achievements on tests and assessments considered sex group of the candidate as a key variable in helping to understand differential achievement

and discrimination between learner groups in education more generally (see Gipps and Murphy, 1994; Willingham and Cole, 1997). The analysis of test data from a sex-group perspective has been helpful in the field of research into boys' and girls' achievements. The publication of national and international assessment results by sex group, alongside more detailed analysis of large-scale international assessment programs (OECD, 2004) and research evidence from other studies focusing on sex differences in performance on tests (Gipps and Murphy, 1994; Willingham and Cole, 1997) have shown distinct patterns of performance between males and females which are seen across different subjects, different ages, and different testing situations. To illustrate this point, a brief overview of male and female performance across large-scale assessment programs is given below.

Sex Differences on International Assessment Programs

In international tests of achievement, distinct patterns of performance for males and females across the subjects of language (native), math, and science have been identified. For example, in the assessment of English language across a number of studies, females tend to perform better than males in all main aspects of the subject, especially in reading and writing (Gipps and Murphy, 1994; OECD, 2004). The gaps in performance between males and females tend to show themselves in the beginning of primary school and continue to grow until females perform better than males to a significant degree by the end of compulsory schooling. In math, many international and cross-national surveys (OECD, 2004) show that on average males and females in the earlier stages of schooling perform similarly in math, but as age increases, males generally tend to outperform females, and by age 15/16, males achieve better performances in virtually all aspects of mathematics tested. In science, evidence from large-scale assessment programs at both cross-national and international level show that males perform better than females in science, but that the gaps in science are the smallest across the three subject areas (OECD, 2004).

Published data of male and female achievement on large-scale assessments has improved over the last three decades to the extent that we now have extensive datasets that provide information on how males and females achieve within subjects across a range of test types. Research in the field of gender and assessment has greatly benefited from this data, especially as much of it is disaggregated at a number of levels – the test as a whole, the test paper, the test item, and mode of response. Thus, we are better informed as to how males and females perform on various types of tests and assessments. These data have certainly enhanced our knowledge of differential performance as it allows us to monitor the results of different

groups across a range of tests and assessments and enables us to pursue questions of fairness and equity at a macrolevel.

Explanations for Differences

Reasons put forward to explain why such differences occur are often situated within a technical discourse of test development (e.g., test bias) and/or within a psychological cognitive discourse which positions psychological traits or characteristics of the male or female test taker as explanatory variables for the differences observed. In relation to test bias, the explanations presented are not unproblematic. This is mainly due to contradictions in definition, usage, and understanding of the term in relation to test and/or item characteristics as opposed to genuine group differences in test performance (see Goldstein (1996) for a review). While statistical procedures can be used to identify discrepant items in tests that can then be discarded in the aim of creating fair tests, such procedures tell us only about the difficulty levels of the items for different groups and tell us little about the construct being assessed (Gipps and Murphy, 1994). Items tend to have different meanings for different groups and items that do not fit a common pattern of response may simply be assessing a different attribute.

In relation to cognitive factors, many studies have addressed a variety of psychological characteristics as explanations for sex-group differences in educational achievement (Hyde, 2005). For example, the area of learning or cognitive styles has had varying popularity over the years as a way of explaining sex-related differences in performance. Research within this area has often positioned learning styles as fixed characteristics of learners that are innate (i.e., that boys or girls have particular learning styles) and that learning styles are responsible for how boys and girls respond to different assessment items and/or tasks and that curriculum and/or instruction should be adjusted accordingly to reflect these learning styles. However, Head (1996) shows quite clearly that learning styles are not fixed attributes and that individuals may show some flexibility in alternating between styles, adjusting them to cope with the situation in which the learning is being evaluated. What seems to have become more important over time is not so much that boys and girls have particular learning styles, but that they choose different learning styles and adopt different coping behaviors in learning situations which affect their opportunity to learn and the ability to show this learning to good effect.

Limitations of the Sex-Group Approach

While there are benefits to the types of data and research that have developed around treating gender as a sex-group variable there are also limitations to such approaches. One

such limitation is that the publication of sex-group differences in achievement on tests and assessments seems to attract little disagreement about the variable's dichotomous nature or that it is telling us something important about the test taker as well as the test itself. However, such data can only tell us what is happening in relation to male and female differences in performance, it can offer no explanation as to why such differences in performance occur. Thus, it becomes difficult to extract whether the differences observed are an artifact of the test item or whether there is fundamentally something more important going on in the educational experiences of boys and girls more generally.

A further limitation is that such an approach often accentuates differences that are small or of little significance. An alternative view is that there are far more similarities between boys' and girls' performances than differences. Hyde (2005: 581) has positioned this argument as the gender-similarities hypothesis where the notion of difference presents a negative and self-fulfilling model, whereas the notion of similarities positions males and females as performing similarly across most, but not all, psychological attributes, with any differences (of sizeable magnitude) being small in number. This hypothesis fits with a wide range of data for male and female performances in educational tests which show much more overlap between male and female performance with bigger differences (and variations in performance) occurring within female and within male groups. This also leads to consideration of variables other than (or as well as) sex of the test taker (such as ethnic group and/or social background) as having as much impact on learner groups as does their sex.

The traditional view of learning and assessment and sex group considered above is no longer helpful in understanding the complexities around gender and performance on tests and assessments. If we advocate that learning does not take place in isolation and that assessments are not socially neutral then we are forced to look beyond such fixed notions of these concepts to better understand gender differences in performance.

Assessment and Boys and Girls: Social Considerations of Gender, Learning, and Assessment Tasks

There is a considerable body of research in the area of gender and assessment that has taken seriously the limitations of the gender as sex-group-variable approach outlined above and has developed an alternative framework within which to consider the impact of assessments on learner groups (Elwood, 2006). In rejecting the notion of learning and assessment as fixed concepts, research within this alternative arena positions assessment and learning as

social activities that are socially generated and mediated. Furthermore, gender is seen less as a dichotomous variable against which results can be reported and more as a socially constructed category that has a much more complicated relationship to, and with, the practices of assessment; the consequences of which are manifested in differences in educational outcomes observed between boys and girls.

Influential movements within the assessment field over the last decade have advocated a reconsideration of the use and purpose of summative assessment, promoted the use of formative (or classroom-based) assessment to enhance students' learning, and championed a view of the learner that fits within a social constructivist theoretical position (James, 2006). Here, assessment is positioned as something that is done with the student to illicit clarification of students' current knowledge and understanding so they know where to go next in their learning. New forms of assessment (performance assessments, portfolios, coursework, and extended response items) have tended to reflect these shifting views of learning and achievement and have aimed to bring tests and classroom assessments into alignment. A consequence of this is that research has been able to focus on how the techniques and structures of assessment systems impact on learner groups and how different assessment and learning activities and processes contribute to differences in achievement.

Assessment Technique and Gender Differences in Performance

Research has identified several factors in the design, structure, and use of tests and assessments that contribute significantly to differences in performance between boys and girls (Elwood, 2005). Factors identified include: type and mode of item response; teacher-assessed components of qualifications (known as coursework or school-based assessment); different levels of assessment with restricted grade ranges within the same qualification (known as tiering); the use of real-life contexts in assessment items and tasks; and the sampling of subject content on test papers (see Gipps and Murphy, 1994; Willingham and Cole, 1997 for a detailed review).

For example, if we take the factor of teacher-assessed components of qualifications (i.e., coursework) there is a widespread perception (especially in the UK) that while such components generally benefit pupils, it is girls who gain from them most. Research (see Elwood, 2005) looked at whether teacher-assessed coursework accounts for the advantage that girls demonstrate over boys in end-of-school qualifications. In relation to differences in mean marks obtained on coursework components, it was found that in all cases, girls' mean coursework marks were higher than those of boys, and that these differences were statistically significant. However, teacher-assessed

coursework marks for girls tended to be slightly more bunched than those awarded to boys; there was also less variation in the marks awarded to girls than those awarded to boys. This bunching effect of coursework marks provided an interesting paradox; it indicated that coursework actually contributed more to the final outcomes of boys than it did for girls. If coursework marks are bunched and examination component marks spread more widely, then it is the examination component marks which determine the students' rank order and hence the final overall grade. Thus, the research showed that coursework had less of an influence on the final grades awarded to girls than to those awarded to boys.

Hence, different assessment components do not operate in practice in the same way for boys as they do for girls. This is an important point given the different attention paid by girls and boys to different assessment tasks, and teachers' perceptions of how different types of assessment contribute to the final success of boys and girls. The validity of different assessment modes is thus compromised by them operating in different ways from that intended. The social consequences of this are backwash effects into the curricula experiences of students; the negative consequence of which provide misrepresentations of boys' and girls' success. Therefore, the interaction of gender and assessment technique suggests that not all boys and girls are affected equally and fairly by similar types of assessment activity.

Limitations of Assessment-Technique Approach

There are limitations to the approach of focusing on the assessment systems or techniques used and their contribution to gender differences in performance. These limitations are connected to the ways in which focusing on the assessment technique and students' experiences of the technique does not allow for a consideration of the interaction between the two, nor does it allow for a more subtle understanding of how gender mediates students' experiences of subject knowledge(s), how these are encountered in classrooms, and how they are ultimately assessed. To move the work forward in a significant way, we need to consider how the social nature of assessment shapes the experiences of students and teachers, their perceptions of the subjects they teach and learn, and the ways in which knowledge(s) and understanding(s) are assessed.

The research outlined above does help in giving us a comprehensive picture of how different aspects of assessment activities (i.e., the test, the item, the task, etc.) influences the outcomes observed and how different groups of students perform across different subjects and contexts of learning. Thus, they do provide, at one level, important information about boys and girls as learner groups but tend to continue to see any differences in

performance as belonging to, and located within, the test taker when all technical aspects of the test have been accounted for. The research in this area has concerned itself with large-scale summative assessment (even that which is teacher assessed). Any such attention to gender and its interaction with formative assessment tasks and practices are less common as are any perspectives that consider problematic issues in classroom assessment. It is to these aspects of assessment and its impact on learner groups that we turn to next.

Future Directions

New interests in the field of gender and assessment are interested in the links between assessment and a view of learning and the learner that are situated within sociocultural theoretical understandings and the implications of such approaches for the understanding of how gender is integral to any consideration of assessment outcomes (Elwood, 2006; Moss, 2004; Murphy and Ivinson, 2004). The work within this field positions learning as a cultural activity that cannot be considered in isolation from the social and historical contexts within which it occurs and defines gender as a fluid, social construct that represents a set of cultural ideas, conventions, and norms within which boys' and girls' social beings are created and played out. Assessment within this view becomes a cultural artifact that only has meaning in relationship with and between the teacher and student and/or peer and the context in which it occurs; the outcomes are relational and cannot be abstracted away from the situation in which they were created.

Thus, to understand the achievements of boys and girls we need to consider these more essentially as relational to, and with, the interaction of learning with assessment practice. The relationships between teachers, students, their learning, and how this learning is assessed are entangled as are the gendered lives of students and teachers and their understandings of subject knowledge(s). All these factors come into play in comprehending how boys and girls learn and how this is represented in outcomes on assessment tasks and tests. From this perspective, to understand boys' and girls' learning through assessment, we need to see gender as located within the outcomes observed.

For example, research by Murphy and Ivinson (2004) considered how teachers present gendered messages to students, either consciously or not, about what it means to do well in a subject, and thus what is considered to be valued subject knowledge and equated with success. They acknowledge that boys and girls interact with these messages in different ways, that boys and girls themselves have different notions of what is relevant or what is of value to them, as well as different ideas about what are gender-acceptable things to be seen to know within the

contexts of socially constructed classrooms. They take the subject of English and an assessment activity of creative writing to illustrate their argument. Murphy and Ivinson (2004) outline an assessment task where boys and girls (aged 14/15) were asked to draft three openings to a novel using a range of genres, were given the opportunity to redraft pieces with the support of teachers and peers, and in some cases were asked to read aloud their paragraphs and receive oral feedback from teachers. It was through this latter part of the activity that different messages were given to students as to what constituted a good piece of writing – that is, the pieces that teachers choose to hear read aloud were considered of value and portrayed to students as the best type of writing. However, boys and girls both chose different genres within which to present their work and also tended to stick with genres that were seen (by them) as gender-appropriate (especially if reading aloud were part of the assessment). Thus, teachers' representations of good pieces of English writing (i.e., their social representation of good subject knowledge), which were those that were chosen to be read aloud, did not always fit with those genres chosen by boys (mainly) or girls in relation to the full nature of the task and the social contexts in which it was played out.

Thus, how teachers view success in the community of the subject, its conventions, forms, practices, and cultural settings can significantly influence their judgments of boys' and girls' abilities. These definitions of success are entangled with teachers' and students' experiences of learning; it is only by looking into these experiences of learning and the assessment of this learning we can obtain a more humble understanding of the impact of assessment on the learning of girls and boys.

Conclusions

This article explored the various research approaches and positions within the field of gender and assessment that attempt to help us understand the impact of assessment activities and practice on learner groups of boys and girls. Learning and gender are fundamental and interrelated concepts that interact with assessment practice in profound ways. As this overview has shown, how these concepts are viewed and defined will dictate how important they are seen to be in relation to assessment practice and the understanding of students' experiences of schooling more generally. If the move toward more formative assessment systems within national assessment programs continues, then consideration must be given to the socio-cultural contexts of classrooms and the relations between teachers and students where this learning takes place and is assessed. The gendered nature of students' lives and experiences do, and will, play significant roles in determining success in assessment outcomes.

Impact of Assessment on Learner Groups (Disabilities)

M Rouse, University of Aberdeen, Aberdeen, UK

Introduction

Few areas of education have seen changes as profound as those seen in the field of assessment and these changes are having a major impact on the education of children with disabilities and special educational needs. Many countries, especially in the English-speaking world, have enacted policies in which assessment plays a crucial role in attempts to improve standards and to ensure that schools are accountable for the attainment of all learners. These reform agendas are intended to raise attainment overall and to close the achievement gap between the highest- and lowest-performing students through the introduction of challenging curriculum content and achievement standards, systems of assessment that reflect the curriculum and accountability for the performance of all learners. In spite of claims that the reforms should be relevant for all learners, there was little mention of students with disabilities and special educational needs in the first wave of educational reforms. However, more recently, several countries have introduced reforms specifically designed to include such students and to raise standards for all children.

Although children with disabilities and special educational needs were not of central concern to policymakers when standards-based reforms were being formulated, the reforms have had a fundamental influence on their education and assessment. If the aim of these reforms is to raise the educational attainment of all learners, then some serious challenges must be faced, not least that children with disabilities, who may have been excluded from mainstream education and assessment in the past, will also be expected to achieve pre-specified academic standards. In the face of such a challenge, special needs education is undergoing a shift from a preoccupation with identification, resource allocation, and procedural safeguards, to a focus on outcomes and accountability. For example, in the United States, the President's Commission on Excellence in Special Education (US Department for Education, 2002) stressed that the special education must be judged by the outcomes achieved by each child. According to Nagle and Thurlow (2008), this recommendation fits well with the standards-based reforms already underway, specifically those specified under the No Child Left Behind Act (NCLB). In other countries too, questions are being asked about who should, and should not, be included in national systems of assessment and the extent to which national assessments might need to be adapted and modified if all students are to participate.

While the policy responses in various countries have been different, the tensions and implications associated with moving special needs education from a largely separate and highly specialized endeavor into a more inclusive system will be similar (Rouse and McLaughlin, 2007). Furthermore, many countries are looking at what is happening elsewhere, in part because of the impact of international comparisons of attainment and cross-national reviews of special needs education provision (OECD, 2005). Therefore, while this article is largely informed by developments in the English-speaking world, there is also relevance to other countries.

Standards-based reforms raise questions about the consequences of developing national/state systems of assessment that aspire to include all learners and whether new approaches and understandings about inclusive educational assessment might be challenging old assumptions and approaches to the assessment and classification of children with disabilities. In attempting to answer these questions, this article considers the ways in which changes in assessment policies and practices, together with other developments in classification systems outside education, have influenced basic assumptions and approaches to the classification of disability in education. It also examines the extent to which universal standards and common educational outcomes are possible, given the deeply embedded assumptions about human differences that pervade school structures and approaches to assessment.

Disability Classification in Education: Purposes

Before considering the impact of educational assessment on learners with disabilities, it is necessary to ask why some learners have been classified as disabled in the first place.

Historically, there were two main purposes for disability classification in education. The first purpose was to identify the children who might struggle in mainstream schools: those who would need to be placed in alternative forms of provision, such as special schools, or who might need additional help or support within a mainstream setting. It seeks to answer 'the who' questions.

The second purpose involves a more in-depth assessment of the nature and extent of the difficulty or disability. It seeks to answer questions about why some children have difficulties and what might be done about it. This process collects evidence using assessment tools and techniques,

by particular professionals such as school psychologists, in order to allocate a child to a particular category of handicap or disability. The intention here is to provide information that might lead to specific help tailored to the needs of such children based on a diagnosis of their difficulties.

Therefore, the identification and assessment of children's disabilities and educational needs have not only been an important element of selecting some children for alternative forms of provision, both inside and outside of mainstream schooling, but they also continue to be an important component of decisions about resource allocation and of informing pedagogical approaches.

Disability Classification in Education: A Historical Overview

Since schooling became compulsory, it was soon clear that some children did not easily fit into the schools that had been created and a system of sorting out these children was required. More than a century ago Alfred Binet was invited to devise the first tests to identify abnormal children who would need extra help or who would be too difficult to educate in mainstream schools. Subsequently, the Binet–Simon scale was developed for measuring intelligence of children. Since this time, the technologies of testing and systems of classification have changed, as has the language used to describe the children. For example, children are no longer described as imbeciles or subnormal, but many of the fundamental assumptions apparent in Binet's time still inform policies and practices. Underpinning these assumptions is a deep-seated belief that some children are normal while others are different. The distinction between normal and different (not normal) is based on two overlapping sets of assumptions, the first is quantitative, the second qualitative.

Quantitative assumptions are based on beliefs that abilities are distributed normally throughout the population according to the statistical laws of the bell-shaped curve. Thus, 2% or so of the population are located at more than 2 standard deviations below the mean (those typically scoring less than 70 on a standardized test of ability or attainment where the mean is 100 and standard deviation is 15). Such people were not only statistically unusual, but they were seen as not normal or indeed subnormal in the terminology used in the UK until the 1970s. Interestingly, about 2% have historically been placed in special schools in England and Wales.

Differences between the normal and different may also be understood as being qualitative. Some children's development or behavior may not be judged as meeting a set of pre-specified criteria thought to be normal within a particular cultural or educational context. Qualitative assumptions of normality are socially constructed and lie at the heart of many developmental and behavioral checklists. Using

such approaches with children who are not from the dominant cultural group is likely to lead to overrepresentation of minorities in special forms of provision and negative consequences resulting from low expectations.

Special education was built on the foundation of assessment practices designed to sort out children who were considered to be quantitative and qualitatively different. Nevertheless, the educational assessment of children and young people with disabilities has become a contested arena in recent years as long-held assumptions and practices about the nature and purpose of this task have been subjected to scrutiny and critique. For example, in the United Kingdom, there were attempts to move away from assigning children to categories of handicap following the Warnock Report (Department for Education and Science, 1978) to a broader concept of special educational needs. The identification of children's needs was to be made: "not in terms of a particular disability which a child may be judged to have, but in relation to . . . all the factors which have a bearing on educational progress" (Department for Education and Science, 1978: 3.6).

The process of assessment moved from being predominantly about allocating children to categories of disability to an individualized assessment of the child's strengths and difficulties based on an ecological perspective that recognizes disability and special educational needs result from an interaction between an individual's strengths and weaknesses and the environmental context.

Meanwhile, in the United States, the Individuals with Disabilities Education Act (IDEA) continued to use a framework for assessing entitlement to special education services based on the allocation of children to one of 13 disability categories. However, the President's Commission on Excellence in Special Education could find no firm practical or scientific reasons for supporting the existing classification of disabilities in IDEA (US Department for Education, 2002: 22) and suggested new ways of approaching this task. In other parts of the world too, assessment and classification have been changing in response to new understandings about why children have difficulties in learning. Yet, while the movement toward inclusive education has reduced the role of assessment in informing decisions about the placement of children in separate special schools and classes, old approaches to assessment and classifying children as disabled or having special education needs are still alive and well and are being used to justify why some children are not successful learners in schools.

Disability Classification: A Broader Perspective

The classification of disability involves a process of sorting people and collecting evidence in order to make

decisions about people's needs. This does not only occur in education, but it is also a process widely used in other human services, including employment, health, and social services. Disability classification systems have evolved across time within specific social, economic, and political contexts and crucially they exist within legal frameworks. They are used to inform decisions on a range of matters, including eligibility for services and benefits, and are often seen as playing important roles in equal opportunities and antidiscrimination policies (Pullin, 2008).

In education, this process is justified by arguments that it is in the best interests of these children (and the rest of the system) to identify them so that targeted extra help can be provided. It is argued that children have to be classified to protect their rights as part of the struggle for access and equity in education. However, a central dilemma is that attempts to help and protect children may have the opposite effect. By focusing on children's deficits as well as by classifying children as different, there may be unintended negative consequences. The philosopher Martha Minow has explored this dilemma when referring to the dilemma of difference, which results when people are classified as different so that they can be provided with legal protection and services designed to meet their needs, while at the same time recognizing that this very process involves imposing labels and potential stigma (Minow, 1990: 20). Such classification may also result in relocation to a different place where help may be provided but at the price of restricting opportunities to learn and lowering expectations. Thus, there is inevitably a trade-off between the benefits and the negative consequences of classification which manifests itself differently in different contexts, changing over time as conceptions of the common good and notions of difference shift (Pullin, 2008).

Although disability classifications systems are ubiquitous and are resistant to change, there have been challenges to old assumptions about human differences upon which they were constructed. More than 30 years ago, Nicholas Hobbs and colleagues began a major review of the classification and labeling of children in education. It demonstrated the complexity and ambiguity in classifying children, because while it may provide benefits, there are also risks. At that time, Cromwell *et al.* (1975) pointed out the need for regular review of the use of classification and labels to determine what purposes they are serving and injustices they might be creating.

In spite of such challenges, there are many questions that remain unanswered about the utility of educational classification systems as well as concerns about the negative consequences for those who are identified (Florian *et al.*, 2006). In a highly critical report, the President's Commission on Excellence in Special Education pointed out that current methods of identifying children with disabilities lack validity and that thousands of children are misidentified every year (US Department for Education, 2002: 8).

Significantly, assessment has been the predominant means through which additional resources and funding have been allocated to support some children's education. As more children were identified, there was an expansion of services and provision designed to meet special needs, with some countries seeing as many as a third of all children receiving additional support (OECD, 2005). The classification process was thought to be out of control. It was not transparent; it took too long and was consuming a disproportionate amount of professional time and energy (US Department of Education, 2002). The allocation of additional resources depended on a child's failure and schools were reluctant to demonstrate success for fear that any additional resources would be removed. Thus, assessment was at the heart of a system of perverse incentives that was not always working in the best interests of children.

At the same time, there has been movement from the assessment of deficits in individuals, an approach influenced by long-established medical approaches of the *Diagnostic and Statistical Manual of Mental Disorders-Text Revision* (DSM-TR) currently in its fourth version and the International Classification of Disease (ICD). The ICD developed from attempts to agree on a list of causes of death in the early part of the twentieth century and has evolved through ten versions to the ICD-10 (Classification of Mental and Behavioral Disorders), which contains clinical descriptions and diagnostic guidelines. Subsequently, the International Classification of Disability and Handicap (ICIDH) moved the focus from the causes to the consequences of disease and disability (Hollenweger, 2008). However, the ICIDH did not go far enough in acknowledging social and ecological models of disability. In response, there has been a shift to the assessment of a person's functioning within the environment in which they live and learn as can be seen in the International Classification of Functioning, Disability and Health (ICF; World Health Organization, 2001), which sees disability as the result of the interaction between the person and the environment (Hollenweger, 2008). The ICF is built upon an ecological perspective of disability and it has already begun to inform thinking about the assessment in educational settings because it can provide evidence linked to schooling, the curriculum, and teaching and is consistent with approaches based on dynamic and authentic assessment.

Nevertheless, the adoption of new approaches to classification is likely to be slow because even when the reasons for the establishment of old systems may no longer be relevant, complex systems are slow to change. Professional beliefs, commercial self-interest, and institutional inertia mean that approaches to assessment of disability are remarkably resistant to change, even when the original underpinning assumptions or purposes may no longer be relevant.

Assessment for Pedagogical Reasons

In one form or another, most countries have ongoing, formative assessment that is used to inform decisions about teaching and learning. Many of these approaches involve pupils and classroom teachers, are linked to the curriculum, and have been informed by the principles of assessment for learning. The benefits from using these approaches with children who have difficulties in learning are apparent and significant progress has been made in recent years in this regard in several countries (Watkins, 2007). However, in the field of special needs education, it is thought that more specific information about children's difficulties is required so that teaching can be matched to children's needs. In spite of the common-sense power of this argument, the usefulness of such approaches has been challenged. For example, in an extensive review covering 25 years of work, Ysseldyke (2001) has shown that there is insufficient evidence to support a diagnostic-prescriptive approach to teaching.

Assessing and Classifying Special Educational Needs: A Summary

For many years, the development of tests and diagnostic instruments was seen as a conceptual and technical challenge and the field of psychometrics developed to meet the demand for increasingly more sophisticated ways of sorting people out and diagnosing their needs. This grew into a multimillion-dollar industry and the products of this endeavor have had a profound influence on the development, not only of special education and disability classification, but also more broadly on schooling and systems of assessment throughout the twentieth century. Crucially, it has left a deep-rooted set of beliefs about human (dis)ability that continue to be used to explain and justify the educational failure of some children.

Including All Learners in National Systems of Assessment: The Impact on Students with Disabilities

Serious questions remain about how children with disabilities and special educational needs might be included in national systems of assessment and the extent to which state and national assessments might need to be adapted and modified if all students are to participate. In many countries, it has been recognized that some children may require assessment accommodation, such as additional time, a reader, large print, or alternative forms of response. The term accommodation is used to mean those changes that are not considered to alter the construct measured. Nevertheless, questions remain about who should decide which children are allowed such accommodations and the

extent to which such accommodations affect validity and reliability of test scores.

In England, flexibility within the national curriculum and its assessment systems have permitted children to be assessed outside of key-stage level and there are well-developed alternatives for children with severe cognitive impairments to work at levels below the starting point of the national curriculum on what are known as 'p' levels.

In the USA, the legislation requires states to annually assess the performance of all students in language, mathematics, and science against three levels: proficient, advanced, and basic. States have some flexibility; however, assessment must reflect the content standards, must measure the achievement of all children, and the results must be used to hold schools and school systems accountable for the achievement of all children. In part, this is carried out through setting annual adequate yearly progress (AYP) performance targets for individual schools and school systems designed to ensure that all children reach grade-level proficiency in reading and mathematics and science by 2014. AYP requires that not less than 95% of children with disabilities should be assessed. School districts and schools that fail to make AYP toward statewide achievement are subject to mandatory and increasingly severe sanctions aimed at getting them to meet state standards.

Despite the rhetoric that all children should take part in statewide assessments, the US Department of Education recognizes that it is not appropriate to measure all children with disabilities against grade-level achievement standards and that not all can participate in normal statewide assessment. States have been granted the flexibility to measure the achievement of children with the most significant cognitive disabilities against alternate achievement standards and to develop assessments based on alternate or modified achievement standards.

Interestingly, some unintended consequences are becoming apparent. Nagle and Thurlow (2008) suggest that children with disabilities are increasingly being described by the type of assessment they take; by the achievement standards against which they are measured and by the proximity of their score to the level deemed as proficient and that the established disability categories are less relevant than previously. The current regulations defining how students with disabilities will participate in state assessments may have unintentionally created a new categorization system: those children with disabilities, who are held to grade-level achievement standards, take the regular assessment, with or without accommodations, and those children who are held to alternate or modified achievement standards and take an alternate form of assessment. The practice of labeling children by their performance level encourages schools to engage in what Gillborn and Youdell (2000) in England and Booher-Jennings (2005) in the US refer to as educational triage, a process in which schools make judgments about where to target the

extra help. The evidence from Gillborn and Youdell (2000) is that extra help is provided for those students who are within reach of the passing grade to ensure that the school reaches its specified targets. Interventions are not provided to students who are either clearly proficient or unlikely to pass even with extra help.

There is considerable evidence that schools are focusing their resources on children who are just below the proficient level. Schools concentrate on the almost-passing children because they have a chance at moving them over the proficiency bar and improving their chances of making AYP (Booher-Jennings, 2005). Research conducted by the Educational Policy Reform Research Institute (Nagle and Thurlow, 2008) supports this contention. Practitioners involved in their research indicated that they concentrated their resources on these children, regardless of whether the child has or does not have a disability. Teachers and administrators indicated that they had a range of initiatives in place to improve the achievement of these children as the children who are unlikely to pass or are well within the basic range, may be perceived as lost causes and marginalized. It seems as though teachers do not believe that they can raise their performance and that there was no point in helping them because such students have already reached their potential. Thus, current systems of high-stakes accountability may be leading to new systems of classification based on whether children are deemed to be worth helping.

In the both England and the USA, national systems of assessment have created new dilemmas in which individuals and schools may be using disability classification to gain advantage. For example, individuals and their parents may have incentives to acquire a disability or special needs status if the benefits (such as additional time on tests) are thought to outweigh the potential costs of any stigma associated with the label. One of the most problematic aspects of this search for relative advantage can be seen in the huge increase in requests for modified assessment arrangements to compensate for dyslexia and other disabilities. In addition to bringing advantage to individuals, it may be to the advantage of schools if children are classified as disabled or having special educational needs if it means that accountability standards are lowered, or the conditions under which the assessments are taken are more favorable. This trend raises complex questions about fairness, equity, and equal opportunity (Pullin, 2008) as well as threatening the validity of the assessment process.

Conclusion

This is a time of great change and uncertainty for state/national systems of assessment and for disability

classification in education. A number of challenges face systems of assessment as they struggle to include students who are currently excluded from participation. If assessment systems are primarily for accountability purposes, then they will distort the ways in which schools view learners who may find it difficult to achieve the pre-specified standards. Equally, if an important purpose of assessment is to sort children out, then many will continue to be excluded. However, if national systems of assessment can be developed in which all learners can demonstrate their achievements, then we will be not only on the way to having an inclusive framework for assessment but also one of the fundamental purposes of disability classification will be redundant. However, while deep-seated assumptions about the so-called normal distribution of human abilities remain, it is unlikely that children with disabilities and special educational needs will be able to participate in national assessment without reinforcing notions of failure for children, teachers, and schools.

Nevertheless, the nature and purpose of disability classification in education is changing from a focus on deficits in individuals to one that acknowledges functioning and recognizes the importance of the broader learning environment. Such approaches do not depend on norm-referenced distributions, nor are they focused on sorting people out so that alternative forms of provision can be made. Perhaps some of the lessons learned from such approaches can be incorporated into the national systems of assessment. This is important because as Kirp (1982) reminds us: a way of knowing about a phenomenon can become the way of knowing about it. For example, in special education, systems of assessment and classification are deeply embedded at the heart of the enterprise and assessment decisions have particular consequences for where children are educated, what kind of curriculum they will receive, who they are educated alongside, which professionals they encounter, and what life courses are available for them. Traditional assessment practices were not only a way of knowing, they became the way of knowing; they had become deeply institutionalized. Therefore, shifting assessment practices from those based on norm-referenced assumptions and a focus on deficits in individuals, to one that focuses on functioning and achievement could bring benefits for all, not only for children with disabilities. It would also create the conditions for fairer and more relevant national systems of assessment that are capable of recognizing the achievements of all learners.

Impact of Assessment on Students' Test Anxiety

P Buchwald and C Schwarzer, Heinrich-Heine University Dusseldorf, Dusseldorf, Germany

Introduction

The assessment of student learning can be seen as an essential component of evaluating the effectiveness of learning in an organization. Identifying factors influencing student learning and performance is a major goal for teachers and educational researchers. Test anxiety is a major predictor of academic performance and various studies have demonstrated that it has a detrimental effect (Zeidner, 1998). Test anxiety can be defined as a student's reaction to testing or evaluating situations. However, testing and assessment does not only have an impact on test anxiety, but also influences motivation to learn and further performance. The potential impact seems to differ from how and by whom the assessment is done, in which way it affects the educational career, and also how it is perceived by the person assessed.

The effects of test anxiety on performance have first been explained by the Yerkes–Dodson law. Other explanations follow the interference and learning-deficit models. The interference model focuses on the mediating role of negative thoughts on the anxiety–performance linkage. According to the learning-deficit model, the student with high test anxiety tends to use inadequate learning skills while in the preparation stage of test taking. Due to their theoretical underpinnings, however, all these models look at anxiety in an individualistic manner. In order to get a more comprehensive understanding of the impact of assessment on student's test anxiety we introduce the conservation of resources (COR) theory (Hobfoll, 1998) which does not only stress individuals' perceptions but also takes environmental contingencies into account. COR theory makes it possible to look at both, teachers and students simultaneously and combines the aspects of psychosocial well-being of teachers and students with different categories of assessment.

Foremost, the effects of test anxiety on performance have been depicted as a curve (see **Figure 1**) by Yerkes and Dodson (1908). The Yerkes–Dodson curve shows that up to a threshold anxiety is related to increased performance. Conversely, performance efficiency decreases if anxiety is still at an ever-increasing rate. Up to the summit of the curve, anxiety can be adaptive because it motivates students, helps to prepare for a test, and improve their functioning. Beyond the optimal level, the peak, anxiety is considered maladaptive as it causes distress and impairs functioning. In general, high test anxiety is more closely associated with

lowered performance in low-ability students than in their high-ability counterparts (Hembree, 1988).

Two key components of test anxiety are cognition and emotion. Liebert and Morris (1967) suggested that test anxiety was composed of worry and emotionality. Worry was conceptually identified as cognitive expression of concern about one's own performance, while emotionality referred to autonomic reactions which tend to occur under examination stress as stated by Liebert and Morris. Negative effects of test anxiety on academic performance have been explained by two models: the interference model (Sarason, 1986) and the learning-deficit model (Naveh-Benjamin *et al.*, 1987). According to the interference model, anxious students are distracted due to worrying and task-irrelevant cognitions and the learning-deficit model proposes that it is students' ineffective study habits during preparation for a test that leads to anxiety and less performance on the test.

These stated aspects demand for answers and possible resultant actions. Assessment models and evaluative situations have to be modified allowing for successful learning, coping strategies, and better performance. In general, education has to rethink assessment procedures and integrate alternative assessment approaches such as portfolios, project assessment, or other classroom-assessment techniques which focus on students' resources rather than on their deficits in order to diminish feelings of test anxiety. Therefore, broader resource-oriented theories are required to get a more comprehensive understanding of the impact of assessment on student's test anxiety. First, we would like to introduce the COR theory as such an inclusive framework, and second, provide an overview about alternative assessment methods.

Stress, Anxiety, and Student Learning in the Framework of the Conservation of Resources Model

Students facing the challenge of coping with upcoming tests and assessment situations is a common phenomenon. Students seem to be more vulnerable at examination times, and adaptive coping with assessment is important for their achievement and psychological well-being (Zeidner, 1998). The role of stress, anxiety, and coping in an assessment situation has been investigated by a number of researchers. They mainly focused on the cognitively based

Figure 1 Effects of test anxiety on performance.

transactional stress concept of Folkman and Lazarus (1985) viewing emotions as arising from the individuals' perceptions of imbalance between individual resources and environmental demands. By highlighting perceptions when defining stress and coping capacity, primarily, the importance of individual difference factors are stressed and only secondary emphasis is placed on environmental contingencies. Hobfoll *et al.* (1998) developed the COR theory in response to the need to incorporate more fully both the objective and perceived environment into the process of coping with stress.

Theoretical Concepts of Conservation of Resources Theory

COR theory (Hobfoll, 1998) offers a comprehensive framework for understanding the impact of assessment on emotions and performance by focusing on the resources of individuals and groups (Buchwald, 2003). First, we outline the theoretical principles of COR theory and give more detailed examples of the application of COR theory to educational assessment settings on the individual and group level. Finally, we discuss future directions for integrating COR theory into best-practice models to enhance students' learning development.

According to COR theory, human beings' primary motivation is to build, protect, and foster their resource pools in order to protect the self and the social bonds that support the self. The theory provides a model for preventing resource loss, maintaining existing resources, and gaining resources necessary for engaging in appropriate behaviors. COR theory argues that resources are the key components

to determining individuals' appraisals of events as stressful and resources define how individuals are able to cope with stressful situations. As a result of the strong association to broader life conditions, COR theory (see Figure 2) can augment our understanding of stress and coping, particularly in complex learning situations in which students have differential access to resources.

Further, COR theory proposes that those already lacking in resources will be more vulnerable to the experience of loss spirals and those with plenty of resources will have more opportunity for resource gain. Loss spirals, as Hobfoll (1998) explains, occur when resources are expended, and are therefore not available to cope with future-loss threats, thus potentially leading to further loss. Initial loss leaves individuals, groups, and communities more vulnerable to the negative impact of ongoing resource challenges. Those endowed with greater resources will be more resilient, but ongoing resource loss will challenge even richly resource-endowed individuals or groups. Thus, loss spirals are a powerful force that is evident in individuals and communities already lacking resources.

As Figure 2 shows, the processes of resource conservation are a product of both broader life circumstances as well as resource-loss events. Conditions of resource loss tend to lead to further resource loss, sometimes engendering a cyclical process. When losses occur, individuals apply resource-conservation strategies, whereby they utilize resources available to them in order to adapt as successfully as possible. Successful adaptation generates new resources which, in turn, replenish people's resource pools and offset the conditions that produce acute and chronic resource loss. Those with less coping capabilities will have to employ riskier resource protection and gain strategies, which are less likely to yield the results hoped for (Hobfoll, 1998). Unsuccessful strategy employment results in both psychological distress as well as material loss, such as the diminishment of the resources invested. Such unsuccessful loss-prevention strategies further generates secondary resource loss, resulting in loss spirals.

Conservation of Resources Theory: Application to Learning, Assessment, and Test Anxiety

COR theory can be applied to education and assessment by conceptualizing test anxiety as a loss of resources (loss of self worth, motivation, and of productive cognitive processing) affecting students' learning and performance. Within the framework of COR theory, test anxiety can be understood as a severe stressor. Resources can be outlined commonly used to cope with resources loss in school and other learning settings. When individuals generally strive to obtain, retain, and protect what they value, testing situations increase the probability for test anxiety and a loss of the associated valued resources. Stress in testing situations can be so excessive that it hinders a person's

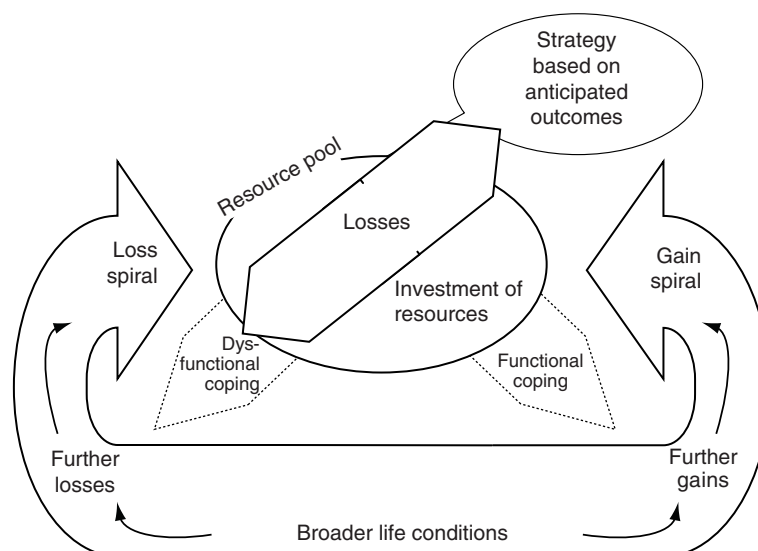

Figure 2 Processes of resource conservation.

ability to prepare properly and test effectively. Test anxiety is associated with poor performance, attacking self-worth and prospects for personal growth.

COR theory outlines four general categories of resources: objects, conditions, energies, and personal resources. Each of these resource categories aids coping efforts. For students facing testing situations we begin by considering object resources important to this group, such as a room of one's own, teaching books, and a computer. These resources provide the basis for coping: a computer provides access to knowledge and support; and a workroom provides a calm atmosphere for uninterrupted learning. In line with this is the finding that task interruption affects judgment and decision making. Condition resources facilitate acquisition or protection of valued resources. Critical conditions for students are: the kind of school, curriculum, stereotypes, assessment methods, and reference norm. For example, it is not uncommon for students to face social-referenced tests. The resulting phenomenon is also known as the big-fish-little-pond effect (BFLPE) and states that it is better for academic self-concept to be a big fish in a little pond (gifted student in regular reference group) than to be a small fish in a big pond (gifted student in gifted reference group). Empirical support for the BFLPE comes from numerous studies based on a variety of different experimental approaches. Zeidner and Schleyer (1999) examined this effect with respect to academic self-concept, test anxiety, and school grades in a sample of 1020 gifted Israeli children. The authors could confirm that academically talented students enrolled in special gifted classes, perceived their academic ability and chances for academic success less favorably compared to students in regular mixed-ability classes. These negative self-perceptions, in turn, served to deflate students' academic self-concept, elevated their levels of test anxiety,

and resulted in depressed school grades. Further, academic self-concept and test anxiety were observed to mediate the effects of reference group on school grades.

Other resources used to respond to stressful test situations are personal resources, including personal characteristics and skills. Individual characteristics most frequently studied in student samples include variables such as motivation, sense of control, and learning strategies. Anxiety has been shown to lower levels of motivation in highly evaluative learning settings and to impact learning strategies. It could be shown that anxiety was significantly negatively correlated with learning strategies involving rehearsal, active reflection, written help seeking, practical application, emotional control, motivational control, and comprehension monitoring. Self-efficacy, the individual's belief in their ability to execute behaviors necessary to achieve a certain goal, can be viewed as a potent resource that aids in coping with assessment and resultant stress. A series of recent studies has provided consistent evidence for the association between self-efficacy and test anxiety (see Zeidner, 1998 for a review). It can impact the goal of performing as well as enhance the internal motivation to manage the testing situation. Overall, results indicate that self-efficacy is a salient and powerful predictor of test anxiety and is negatively correlated with test anxiety.

Finally, energy is the fourth resource category in COR theory. Energy resources include money, time, and knowledge, and it allows access to other resources. With regard to test anxiety, examination-related knowledge is a significant energy resource. Empirical evidence was found for the fact that students with high test anxiety developed and maintained less complete conceptual representations of the course content. Their inadequate time management and procrastination of study tasks lead to various study problems. Thus, timely preparation and knowledge

gaining is a fundamental way to minimize test anxiety. A confident knowledge of course material is the first step in reducing test anxiety.

Resource Loss and Gain Spirals

COR theory states that those who lack resources are more vulnerable to resource loss, and initial loss leads to further loss. By contrast, those who possess resources are more capable of gain, and initial resources create further gain (Hobfoll, 1998). Many empirical findings in studies of learning, assessment, and test anxiety are consistent with such gain and loss cycles (see **Figure 3**). Young people with text anxiety are usually ambitious students who work hard and have high expectations of themselves. The situation may start with inadequate performance on a particular test, which then creates a general fear of the testing situation that hinders future performance, producing a vicious cycle of anxiety, learning, and poor performance associated with several losses in many ways and at many points in the learning process. Anxiety affects motivation during the learning process, the assessment of learning, and the learning strategies that are employed by students. The cumulative effect of anxiety can ultimately be detrimental to a student's overall learning. When considering the nature of the feedback process of emotion, cognition, learning, and assessment, test anxiety can continue to negatively impact a student's academic career in terms of an educational loss

spiral. Still, COR theory with its emphasis on conservation and protection of resources also has implications for understanding the potential positive impact of stressful events as described by Yerkes and Dodson (see **Figure 1**). Students experiencing stress and anxiety facing a testing situation seek both to repair the damage and to mobilize resources for further resource protection (Hobfoll, 1998). A little nervousness can actually help motivate students and provoke them to learn and seek for support. A limited amount of stress is natural and helps to keep learners mentally and physically alert. However, too much may cause physical distress, emotional upset, and concentration difficulties.

Different Assessment Approaches: A Comparison

Students' performance can be assessed in several ways in order to gain information that tells directly or indirectly about the learning process or results. Direct evidence of the process is gained if students show their mastery of learning goals through the demonstration of knowledge, skills, and other gained resources. Indicators for that mastery are resource-oriented ratings of students' competences in research projects, presentations, and performances. Indirect evidence is provided by grades of class tests or examinations that allow making inferences about learning, but does not demonstrate actual learning.

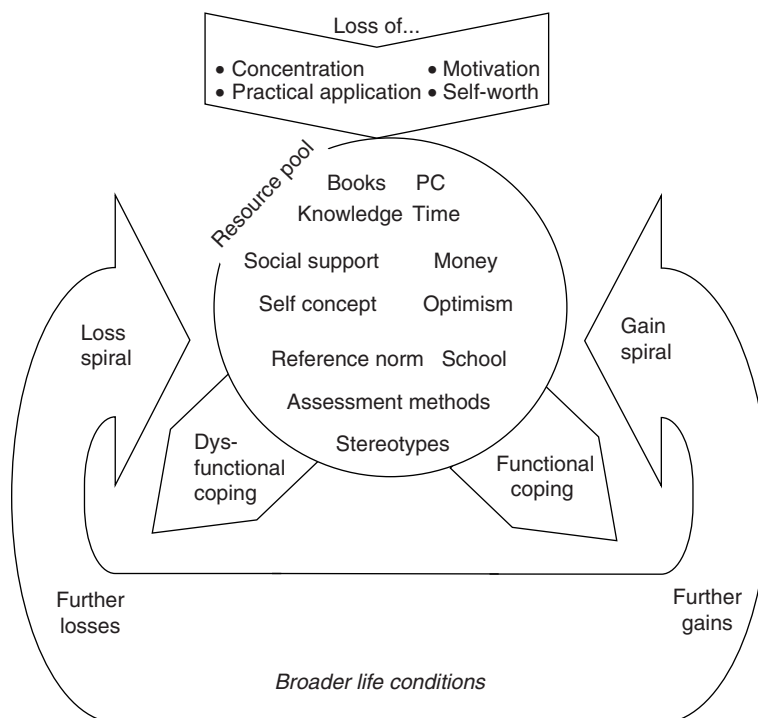

Figure 3 Processes of resource conservation of students facing an assessment. Note that words in upper case refer to object resources; words underlined refer to energy resources, words in lower case refer to condition resources ; and words in bold refer to personal resources.

(Standardized) Written Tests

A test or a written examination is a technique to assess students' knowledge, skills, or abilities. Tests are usually divided into several parts, each covering a different area of the field to be tested. It is generally recognized that these commonly used tests focus on deficits and can provide a teacher with only a limited view of students' achieved knowledge during a semester course or class (Slater, 1997). A standardized version of a test is one that measures ability of every individual subject against a norm or a standard that may be established independently, or by statistical analysis of a large number of subjects. Standardized tests, using multiple choices true–false or fill-in-the-blanks questions, also provide only a limited basis for understanding and evaluating student performance. They deal primarily with factual information. These deficiencies and others have been thoroughly described and documented. However, in the US and other countries, multiple-choice tests have come to be used for assessments of great importance (e.g., high-stakes tests). Testing becomes more and more omnipresent, and the consequences associated with test performances are ever increasing. Consequently, examination stress and test anxiety have become pervasive problems in modern society and the level of test anxiety in both students and teachers has increased as well.

Oral Examinations

An oral examination provides a meaningful procedure in terms of testing for extended problem-solving ability. It normally consists of 30–120-min sessions and is spent with an oral examiner or conducted by a panel. A typical oral exam involves one or two students interacting only with the instructors. Examinees have to demonstrate that they possess the knowledge, skills, and abilities required by giving complete answers to the questions. If the examinees do not know the answer to a question, anxiety can arise, hindering appropriate thinking. However, examiners may be assessing examinees' ability to deal with this difficult or complex situation. Besides exam-related knowledge, other skills are assessed, such as nonverbal language and communication skills. Considering the great variety of social tasks in an oral examination, it is evident that interpersonal resources are of potential relevance and are broadly recognized as important in this context. Buchwald (2003) focused on the examiner–examinee relationship with respect to test anxiety and communal coping during an oral examination. She explored how coping strategies of examiners were related to nonverbal stress behavior and performance of examinees. The study revealed that in examiner–examinee dyads, where male examiners utilize more dominant coping patterns (e.g., aggressive–antisocial action), female examinees were more likely to utilize passive–submissive patterns reflected by avoidance and showed poorer performance.

Online Assessment

Online and computer-based assessment, particularly for universities, are natural consequences of the rapid growth of using the Internet and computer technologies to enhance learning. As more students seek flexibility in their courses, there will be growing expectations for flexible assessment as well. The major educational question is whether online assessment, including multiple-choice questions, is having any influence on the learning benefits and on test anxiety. Although there is some evidence that online assessment can encourage students to focus on lower-level cognitive skills, there are possible positive effects as well on test anxiety. On the one hand online assessment concentrates primarily on true/false or multiple-choice responses, and can have direct negative effects on student approaches to learning by encouraging narrow reproduction rather than the development of higher-order cognition. On the other hand, students taking tests online reported lower levels of perceived test threat (Cassady and Gridley, 2005). This might be due to the fact that online tests enable students to schedule tests following their own workload and allow the students to reduce the level of contextual stress by strategically placing their testing times in convenient time slots.

Portfolios

Portfolios provide a forum for extended and complex learning activities and observations (Klenowski, 2002). Generally speaking, a portfolio is a systematic collection of a variety of teacher observations and student products, collected over time. It reflects a student's developmental status and progress made in a specific field. In such a procedure that focuses on learners' resources, much of the responsibility of both learning and assessment is transferred to the student. Slater (1997) explored the effectiveness of portfolio-assessment strategies and could show that students assessed by portfolios scored just as well on a traditional multiple-choice final examination as their traditionally assessed counterparts. In addition, the students reported reduced levels of test anxiety and enjoyed class discussion more because of the atmosphere promoted by the assessment strategies employed.

Observation of Cooperative Learning Activities

What are needed in addition to traditional assessment methods are those methods for understanding students' learning skills and learning styles (Panitz, 2001). Cooperative learning activity offers teachers an excellent opportunity to observe students interacting, explaining, arguing, helping their peers, and being helped. These observations can provide significant insights into a student's ability and performance level (Panitz, 2001). One important point is that it brings about informal conversations between

individual students, cooperating groups, and the teacher which help to create a more personal class environment. Students get to know the teacher and vice versa, which, in turn, might enhance sympathy and reduce uncertainty and test anxiety. Cooperative learning can also foster cooperation and connections with their peers, enhance team building and teamwork skills, and eliminate cheating. Further and most importantly, cooperating creates a more humane learning environment, is associated with higher levels of student satisfaction, and lowers test anxiety (Muir and Tracy, 1999). Observation of cooperative learning activities could also help identify students who are shy and anxious in order to encourage their participation in nonthreatening ways. Due to the permanent observation process, teachers know which students perform well and which need individual promotion. Teachers can help students understand when they have gained resources by mastering course material, which can reduce anxiety, raise students' self esteem, put them in control of their own destiny, and emphasize that they are responsible for their own learning. The results they obtain are based upon their efforts, not the teacher's. Only very few studies have examined the relationship between collaboration in an evaluative context and test anxiety and even fewer have attempted an empirical assessment of this association.

Product/Project Assessment

A project can be a task given to an individual student or a group and results in a product. The product as well as the processes used during the project can be assessed. Projects are primarily learning experiences, and secondly, an assessment task. There are several advantages of project assessment tasks; for example, they allow teachers to assign projects at different levels of difficulty to account

for individual learning styles and ability levels. They can be motivating and can provide an opportunity for positive interaction and collaboration among peers, and increase students' self-esteem as they would not feel tested as in tests or traditional writing assignments.

Overview of Alternative Assessment Approaches

We outlined the pros and cons of several assessments techniques and their relatedness to test anxiety. **Table 1** presents a wide range of assessment ideas classified into four categories: tests, project assessments, performance assessments, and process skills assessments.

Implications and Future Directions

We have introduced test anxiety as a major predictor of performance and have presented the basic framework of COR theory and offered it as a possible explanatory model for the study of assessment of student learning, stress, and anxiety. COR theory may be applicable to stress during testing situations as resources are often lost and challenged under such circumstances. Testing and assessment might produce a loss of resources and the consequences of such circumstances are often long term. For students, increasing pressure to perform well in tests, combined with cognitive interference, a lack of self-efficacy and motivation, as well as negative life conditions (e.g., inadequate opportunities to learn), can lead to test anxiety and feelings of hopelessness. This, in turn, can cause students to stop trying to improve their performance. Consistent evidence of poor performance repeatedly

Table 1 Alternative assessment approaches

<i>Tests</i>	<i>Products</i>	<i>Performances</i>	<i>Process skills</i>
Essay	Art exhibit	Activities	Checklist observations for processes
Fill in the blank	Audio cassettes	Character sketches	Experiences checklists

	Results of surveys		

reported to families, peers, and to the public can result in a long-lasting loss spiral.

Focusing on resources helps to appreciate that evaluative stress affects students, teachers, and schools, both on a personal level as well as on an environmental level. COR theory highlights that these different resource levels are interrelated and produce a web of interactions that must be understood if we are to explain stress reactions and test anxiety. That is, the potential impact of stress in evaluative settings seems to differ from how and by whom the assessment is done (object and condition resources), in which way it affects the educational career (condition resources), and also how it is perceived by the person assessed (personal and energy resources). Evaluative stress threatens and challenges resources and can result in the loss of the most precious resources. How well students respond depends, in part, on the degree of resources that are lost and the extent to which they can preserve resources in order to initiate the recovery and rebuilding of resources.

Using COR theory as a framework to understand the loss and resilience of students, we can work to make schools and other educational institutions more responsive to their unique needs. Despite large-scale assessment or written class tests, those assessments are needed that enable teachers gather information about student learning on a day-to-day basis and enable them to use it to benefit students. Individual classroom assessment might increase performance and decrease the loss of self-worth and self-efficacy. Black and William (1998) could confirm in their comprehensive meta-analysis, of more than 40 controlled studies, the impact of improved classroom assessment on subsequent student success. Underlying the various approaches to improving classroom assessment are assumptions about what is responsible for effective learning is in particular that students have to be actively involved in the assessment process. This includes a resource-oriented, student-involved feedback process. Moreover, student-involved record keeping brings students into the process of monitoring improvements in their performance through repeated self-assessments over time. One way to accomplish this is by having students build portfolios of evidence of their success over time and requiring periodic student self-reflections about the gains of resources.

COR theory also provides guidance for future research questions. Although much is known about stress, anxiety, and coping in evaluative settings on an individually perceived and deficit-focused level, a resource-oriented perspective leads to new questions. How can teachers help their students want to learn? How do they encourage them to feel self-efficacious and take responsibility for maximizing their own success? How can assessment be used not as a source of stress and anxiety but as a source of confidence? How can we provoke a gain spiral?

Using COR theory to better understand the impact of evaluating settings on the processes of resource loss and

gain might greatly expand our understanding of how students experience loss as well as how they become able to cope with these losses.

Summary

The topic of this article is in a way a tricky one because it stresses two facets of the role of teachers which are not really compatible: on the one hand stands the obligation to create a student-centered pedagogy, including, for example, problem solving in teams by using communal coping strategies, and on the other hand stands the requirement to evaluate these students. This dilemma which comes to its peak with respect to high-stakes testing can lead to negative feelings such as stress, anxiety, or bad mood in both, teachers as well as students. With respect to teachers, a wide range of literature refers to burnout as an outcome of this conflict, while the detrimental effects of assessment on students worldwide is documented roughly in this article. The research outcomes for both groups are depicted mostly in different bodies of literatures which might be due to the theoretical underpinnings of looking at the emotion of anxiety in an individualistic manner. The introduction of the COR theory focuses on the different aspects of resources and the possibility of experiencing loss and win spirals makes it possible to look at both, teachers and students simultaneously as persons who strive to build, protect, and foster their resource pools. This viewpoint gives way to new research combining the aspects of psychosocial well-being of teachers and students with different categories of assessment.

Impact of Assessments on Classroom Practice

J L Herman, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Since its inception, assessment has been advanced as a tool for improving educational practice. Initially, assessment was thought to exert such influence through the information it provided to educators and policymakers and thus presumably to improve decisions. Over time, however, recognition of assessment's sociocultural and broader influences on teaching and learning has grown, and recently researchers have differentiated the effects of assessments of learning – the historical focus of assessment policy, practice, and research – and those of assessments for learning – the use of assessment during the course of instruction to directly inform and improve the learning process. These two types of assessment, respectively, summative and formative, operate from distinct theoretical bases and have unique theories of action, which are explored below. The article starts by providing perspective on the purpose and uses of assessment of learning and how these may impact classroom practice before considering the research base on assessment's actual effects on practice and the factors that influence such impact. Finally, the article addresses theory and research on how assessment for learning, so-called formative assessment, influences classroom teaching and learning practice and draws implications for future research.

A note about use of terms: this article uses the terms test and assessment interchangeably as denoting measures of student learning, although the former tends to denote traditional, multiple-choice-dominated standardized tests and the latter a broader array of methods. Similarly, a number of terms have been used in the literature to capture the concept of the impact of assessment, including assessment effects, consequences, washback, and backwash. These terms too are considered interchangeable.

Historical Perspective: Assessments for Selection and Improvement Purposes

The imperial examinations of the Han Dynasty (220–206 BC) are credited as the first use of standardized testing and the idea that gathering standard information on individuals' capabilities could lead to better and more equitable advancement decisions, in this case, decisions about coveted civil-service appointments. One can imagine that faced with the exam, elite, would-be candidates would prepare for the test and engage tutors to do so, a first instance of the impact of assessment on educational practices. Used for purposes of

selection, the Han Dynasty assessments also are a first example of how an assessment result can influence the practices in which individuals are subsequently placed.

From this very early precedent, educational assessment's use in selection thrived in the last century and continues today worldwide. Following World War I in the United States, for example, many school districts used standardized, intelligence tests for placing students into homogenous classrooms, reinforcing tracking schemes that provided lower-track students with less-rigorous instruction than higher-track students. Similarly, Great Britain's tradition of using assessment to certify, select, and track students for subsequent education dates back to the nineteenth century. Although more essay based than those in the United States, these set the stage for tests that motivate performance and with it the substantial influence of testing on educational practice.

Side by side with traditions of testing for selection and placement developed that of using assessment to improve educational effectiveness. The father of modern educational measurement, Edward Thorndike, advocated the value of testing for guiding teaching, and Ralph Tyler's 8-year study (in the 1930s) created assessments designed to support progressive education goals. With a new objectives-based framework as the foundation for development, Tyler articulated the ways in which assessment could support teaching and learning, for example, monitoring student learning to inform instructional planning; affording school- and program-level accountability and improvement; and in loosening the confining influence of traditional scholarship tests. That is, predating current interest in assessment consequences, Tyler recognized that traditional tests constrained instructional practice, and that new forms of assessment were needed for permitting new, progressive approaches to education to take hold. Similarly, like hope-for-performance assessment in the United States nearly 50 years later, Tyler's assessments were intended to educate the public about important goals of schooling and help teachers' clarify their instructional goals and practices, serving also to sow the seeds for changes in practice.

Assessment Impact in the Context of Overlapping Purposes

These fundamental, formal functions or purposes of measurement – to sort and select students, to certify accomplishment, to provide data for purposes of improving the quality of education – have coexisted since the

beginning of educational testing. Further, while measurement experts advise that tests be designed to serve a specific purpose, the reality is that current educational policy tends to intertwine multiple purposes, and thus large-scale assessments of learning can impact instructional practice through multiple pathways. Whether the context be the test-based accountability systems in the United States, or the operation of A- and O-level-type examination systems in many countries across the world, testing serves not only to provide technical evidence that informs multiple categories of decisions and policy functions (e.g., accountability, admissions/selection, placement, diagnosis, progress monitoring, certification, accreditation, and evaluation), but also attention to and use of the technical data carrying important sociopolitical meanings that can translate into important consequences for educational practice.

Consider, for example, high school exit exams common in the United States that students need to pass for a high school diploma; Key Stage, General Certificate of Secondary Education (GCSE), or A-level-type examinations in the United Kingdom; and higher education admissions tests that operate in countries across the globe. The ostensible purpose of the assessment is to certify that students have the knowledge and skills that the state has determined are needed for subsequent success.

As doing well on the assessment is important to students' futures, the existence of the test is expected to motivate students to learn, to prepare for the test, and to acquire the knowledge and skills that are assessed, as well as to motivate parents to pay attention and support their children's education. Moreover, even in the absence of tangible rewards and sanctions, educators will be motivated to help their students to do well, both because they care about their students' futures and because they see public reports of their students' test performance as evidence of their own professional efficacy. Accordingly, schools are motivated to do what they can to assure that their students will succeed and to do so may modify the content of their classes, may develop or purchase special materials to prepare students for the test, identify and establish new programs to help students succeed, etc. Instructional materials providers may respond by adapting existing materials or creating new products to meet the needs created by the test. In the case of high school exit exams, educators also may use test results of students who do not pass the test to place them in special classes, provide extra tutoring options, and if the test provides subscale data on different aspects of performance, they may use the results to diagnose individual students' learning needs.

Those same results aggregated at the class, school, or district levels may be used to analyze and respond to curriculum strengths and weaknesses, to suggest specific topic areas on which new or supplementary materials may

be needed and in which teachers may benefit from professional development, or to infer priorities for budget allocations. Actors at the district, regional, state, and/or federal levels may similarly analyze and respond to the same data at different levels of aggregation, identifying schools and districts that are doing particularly well or that are in most need of help, including deriving implications for system priorities, needing changes, and/or new programs. Thus, data from a single test may fuel analysis and decisions at multiple levels, which in turn have cascading effects on instructional practice.

As another example, take a state-mandated teacher-competency assessment that teachers must pass to gain tenure. By mandating such an assessment, state policymakers communicate their commitment to educational quality, their recognition of the importance of students having access to good teachers, and their responsibility for assuring the quality of the teaching force. As the assessment is developed, it makes concrete and communicates valued knowledge and competencies for beginning teachers. Just as secondary schools may respond to the requirements of high school exit or college-readiness exams, so too can teacher preparation institutions be expected to adapt their curriculum and instructional pedagogy to the expectations of the teacher assessment and to use their students' results to strengthen their program's success in enabling students to pass. To the extent that sizable proportions are not passing, an institution may change its admission procedures, create special test-preparation courses or tutoring opportunities, and/or try to pressure pre-preparation institutions to prepare potential candidates better. To the extent that the assessment delves deeply into meaningful aspects of teachers' content and pedagogical knowledge and requires demonstration of quality practice, preparing for the test may well help new teachers become more effective, and responding to the assessment requirements may strengthen and deepen existing preparation programs. In any event, unless it is a trivial assessment, the assessment may function to homogenize or standardize preparation programs and the content and pedagogical knowledge that teachers gain from them. As they can influence the what and how teachers learn in teacher-preparation programs, and who is allowed to enter the profession, such teacher assessments may substantially influence subsequent instructional practice.

These examples are not meant to be exhaustive, but rather to illustrate the confounding of test purposes, the merging or accountability/summative and improvement/formative functions, and of the technical, sociopolitical, and symbolic roles that high-stakes or high-visibility assessments play in influencing practice. A single test can launch a whole network of interrelated motivations and cascading actions, only some of which directly involve the technical use of the test.

These same overlapping functions also may accrue in classroom assessments of learning, particularly those that are used for grading. They too function to motivate and focus students' effort, communicate what is important to learn and how to do it and, for learning-oriented teachers and students, to stimulate reflection on what has been learned, how to fill the gap between that and intended-learning goals, and how to improve the teaching and learning sequence. (See also the section on formative assessment.)

Research on the Effects on High-Visibility External Tests

What of the actual impact of high-visibility tests? Researchers around the globe have studied this question, drawing largely on interview and survey methods, sometimes supplemented with observations of practice.

Consistent Results on Potential Benefits

The rigor of design and methodology vary substantially from study to study, but results have been quite consistent regardless of locale, for example, studies of state accountability tests in more than a dozen states in the United States, of A- or GCSE, or Key Stage Exams in England, and language and higher education admissions-testing programs in countries such as Australia, Central and Eastern Europe, China, Hong Kong, Israel, Japan, New Zealand, and Sri Lanka:

- Testing signals priorities for curriculum and instruction: high visibility tests serve to focus the content of instruction. School administrators and teachers pay attention to what is tested, analyze test results, and adapt curriculum and teaching accordingly.
- Teachers tend to model the pedagogical approach reflected on high-visibility test. When a high-visibility assessment is composed of multiple-choice tests, teachers tend to rely heavily on multiple-choice worksheets in their classroom instruction. However, when the assessments use open-ended items and/or extended writing and rubrics to judge the quality of student work, teachers prepare students for the test by incorporating the same types of activities in their classroom practice.
- Curriculum developers, particularly commercial interests, respond to important tests by modifying existing textbooks and other instructional materials and/or developing and marketing new ones to address test content and format. These products in turn may become primary resources that influence practice and also influence teachers' understanding of test expectations.
- Test results can make visible and promote responsiveness to the needs of students who previously have been

underserved. In the United States, for example, where all students are held to the same standards and schools must reach test-based accountability targets for all subgroups, research shows schools and teachers paying more attention to traditionally low-performing students, including second-language learners and students with disabilities. Test results are used to identify and provide special help for faltering students, for example, through the creation of new courses, purchase of new materials, and provision of extra school opportunities (e.g., before or after school tutoring, summer school).

Consistent Results on Problematic Effects

While the above points demonstrate some ways that assessment, depending on the nature of the test, can leverage productive changes in instructional practice, research shows unintended, negative consequences:

- Schools and teachers may focus on the test rather than underlying standards or learning goals. With sanctions and incentives riding on test performance, educators give primary attention to what is tested and how it is tested, rather than to the standards or learning goals the test is intended to measure. For example, by how much teachers may shift classroom-instruction time, accorded to particular topics or curriculum subjects, will depend on the content emphasis of the test.
- What is not tested can become invisible. As a corollary to focusing on the test rather than the standards, that which is not tested tends to get less attention or may be ignored all together. Both the broader domain of the tested disciplines and important subjects that are not tested may get short shrift. In the United States, for example, many state tests tend to give relatively little attention to complex thinking and problem solving and tend to focus on lower levels of learning, which can lead to similar emphases in classroom practice.
- Focusing on the test, rather than underlying learning, may encourage performance orientation and transmission-type teaching. When passing the test, rather than learning, becomes the goal, schools may unwittingly promote a performance orientation in students, which can work against students' engagement and persistence in learning, metacognition, and self-regulation. Especially for high-visibility tests that are predominantly multiple choice, teachers may concentrate on direct instruction to help students acquire specific content, rather than use pedagogy that helps students build conceptual understanding and problem-solving capability.
- Instructional time is diverted to specific test-preparation activities. Schools provide students with practice on the specific types of tasks and formats that are expected on the test, through commercial test-preparation packages,

special classes, and homework. Such activities aim specifically to help students do well on the test, rather than promote students' learning, and depending on the school and the pressure to improve test scores, can divert weeks or more of instructional time.

- Assessment-driven instruction can spur more and more testing. In the United States, more and more districts are mandating interim assessments during the school year, largely mimicking the expected content and format of their annual state tests, to provide quarterly or so feedback on how students are doing, and to encourage teachers to keep their eye on student progress on the knowledge and skills that will be tested. Moreover, many districts have become more prescriptive about how and what teachers are supposed to teach and have created pacing guides detailing what is to be covered when.
- Rather than motivating teachers to improve teaching and learning, high-visibility testing can cause teachers to feel pressured and demoralized, particularly when they view testing targets as unrealistic.
- Testing schedules can distort teaching and learning plans. Teachers even may adjust the amount of time they devote to basic subjects (e.g., reading, math) depending on when each subject is assessed. For example, if math is tested after grade 4 and reading in grade 5, then math may receive relatively more attention in grade 4 and reading in grade 5. Similarly, the best teachers may be moved to the particular grades at which important assessments are given. The desire to boost test scores thus can trump goals for teaching and learning in curriculum and personnel decision making.

Factors That Influence Assessment Impact

While research shows various potential effects of assessment on instructional practice, it also makes clear that such effects are not automatic; neither do they tend to be uniformly positive or negative. A first issue in shaping potential impact is the nature of the test itself. In fact, worry in the 1990s that traditional, standardized multiple-choice testing in the United States was producing a narrow, drill-and-skill curriculum led advocates to advance large-scale performance assessments to be, in the words of Lauren Resnick, "tests worth teaching to." By requiring students to engage in more authentic tasks that required complex thinking and problem solving and extended responses, performance assessment was intended to drive instruction in a similar constructivist direction, an early case of testing policy being explicitly used to leverage change. Similarly, more than 20 years ago, J. Charles Alderson identified the potentially powerful washback of language testing and argued that changes in testing could support desired changes in language curriculum and

teaching. The 1993 Hong Kong Certificate of Education in English, as an example, was launched to encourage secondary teachers of English to adopt a more communicative and purposeful approach, rather than a structural approach, to language development. The new assessment included more authentic and interactive tasks that required students to integrate listening, writing, reading, and/or speaking and to apply their skills in context. Or more recently, Great Britain's key-stage tests ostensibly are designed to encourage teachers to address a broad curriculum within each assessed subject, to enable students to respond to and create a variety of forms of writing and to engage students in applying mathematical and scientific knowledge and skills.

Yet, the path from potential or intended impact to actual changes in practice is neither simple nor clear cut. The move from policy mandate to operational test involves a process of implementation, from public dialog and public discourse about the meaning of the policy, to how and by whom the test is specified and developed, and through a complex chain of visible and invisible decisions and actions that may redefine initial intentions. From operational test to impact on practice similarly involves a circuitous and unpredictable process, as the concept of impact necessarily involves some change in practice.

Succinctly summarizing the many factors that influence it, theorists have noted that change requires both the will and the capacity to change and have suggested that policymakers hoping to use assessment to leverage changes in practice must consider the resources and strategies needed to support such change. From a motivational perspective, for example, in response to any new testing mandate, stakeholders may choose to accept and use it, ignore it, or fight it. Only those in the first category have immediate potential for intended effects and if change is to occur, action must be taken to convert those in the other two categories.

Yet, even with willingness, intended changes in practice will occur only when educators understand what is expected and have the prerequisite knowledge, skills, and understandings, as well as relevant resources, to make the change. As a new test rolls out, for instance, educators may differ in their understandings of what the test actually assesses and thus in its implications for their practice. Teachers will vary as well in their capability to engage in new, expected practices, depending on how complex intended changes are and how far from existing practice. Thus what teaching to the test, a common response to high-visibility tests, actually means depends on the beliefs and capacities of the educators who are responding and the resources and support they have available to them. In response to the same test, some schools and/or teachers may make meaningful and productive changes in teaching and learning, while others may react more rote with test-preparation activities simply mimicking the test.

Research on the consequences of assessment world-wide, in fact, indicates that while teachers may easily modify the content of their teaching, pedagogy is more resistant to change. Teachers' initial pedagogical responses tend to be superficial, for example, simply incorporating samples of the new assessments as an add-on to existing curriculum. Over time and only with sufficient support do new practices become more integrated in ongoing instruction and new standards and quality criteria more deeply understood and acted upon. Effects on practice, in short, are not the product of a test, but the result of a process that is influenced by stakeholders' attitudes and efficacy, the meanings they make of what is expected, the school context, power, or other relationships in which the change is embedded, the stakes riding on test results, the nature of the intended change, and the resources and strategies used to help teachers incorporate new practices, to name just a few. Assessments may be mandated top-down with the intention of accomplishing various impacts, but even bolstered by policy incentives and sanctions, actual impact is neither easily controlled nor easily predicted.

The Effects of Assessment for Learning: Classroom Formative Assessment

In contrast to assessments of learning that are mandated top-down, assessments for learning, so-called formative assessments, occur bottom-up, within the actual context of classroom teaching and learning. Similar to standardized testing of learning, however, the roots of formative assessment also can be found in ancient history, that of Socrates in fifth century BC, Greece. Socrates educated his students through questioning and dialog, breaking down important ideas into a series of questions, whose answers, with probing, gradually helped students acquire new insights. Questions and answers were not judged right or wrong, but were the means to building knowledge and understanding. Similarly in formative assessment, assessment is used to elicit students' understanding in order to form subsequent teaching and learning.

The last decade has seen increasing, worldwide interest in formative assessment, fueled in large part by Black and William's landmark meta-analysis showing the strong effects of formative assessment on student learning, particularly for low-ability students. Policymakers and educators increasingly have recognized that while external tests of learning may help communicate priority goals, motivate improvement, and identify who has succeeded or not – summative functions – the results are too little and too late to directly improve practice. Rather, the most powerful use of assessment occurs hand-in-hand with classroom teaching and learning.

The use of data is key to the idea: to be considered formative, assessment evidence must be acted upon during

the course of classroom instruction. Rather than focusing backward on what has been learned, formative assessment help chart the learning road forward, by identifying and providing information to fill any gaps between the learners' current status and goals for learning. Moreover, more than solely a source of evidence that informs subsequent teaching and learning, formative assessment may enhance student learning directly. For example, in asking students to make public their thinking, formative probes can provide scaffolding that helps students confront their misconceptions, refine and deepen their understandings, and move to more sophisticated levels of expertise. By making learning goals explicit and involving students in self-assessment, formative assessment also can promote students as agents in their own learning, increasing student motivation, autonomy, metacognition, as well as learning.

Formative assessment itself involves a change in instructional practice. Rather than imparting knowledge in a transmission-oriented process, in formative assessment teachers guide students toward significant learning goals and actively engage students as assessors of themselves and their peers. Formative assessment occurs when teachers make their learning goals and success criteria explicit for students, gather evidence of how student learning is progressing, partner with students in a process of reciprocal feedback, and engage the classroom as a community to improve students' learning. The social context of learning is fundamental to the process as is the need for classroom culture and norms that support active learning communities – for example, shared language and understanding of expected performance; relationships of trust and respect; and shared responsibility for and power in the learning process. Theorists observe that enacting a meaningful process of formative assessment influences what students perceive as valued knowledge, who can learn and who controls, and is valued in the learning process. However, as with the effects of assessments of learning on practice, those of formative assessment do not happen automatically but involve a complex process of change. Moreover, at this point, the anticipated effects of formative assessment on instructional practice are based on theoretical argument and are yet to be fully confirmed through empirical or other research.

Conclusion

Available theory and research suggest the ways in which assessments of learning and those for learning may exert influence on instructional practice. In both cases, such effects are not automatic but rather dependent on a complex process of change that is influenced by many, difficult to control, factors. Marshalling the power of assessment to improve practice requires better understanding of how such change occurs and the nature of the assessments

and support processes that can best achieve positive effects while minimizing unintended negative ones. Continuing research needs to explore whether high stakes and formative assessments are effective in meeting their intended aims, how effective each is relative to other strategies for influencing instructional practice, and whether and how assessment may undermine or support other teaching and learning goals, including effects on educational equity. Most studies thus far have examined short-term effects. Additionally needed are longer-term studies that examine implementation and effects over time.

Social Practices in School Assessment and their Impact on Learner Identities

A Pollard, University of London, London, UK

A Filer, University of Cambridge, Cambridge, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In a review of sociocultural aspects of assessment, Gipps (1999) calls for more interpretive studies of the social world of the classroom. This contribution reviews work of this sort and offers a conceptualization of the factors in play. But why is this approach of consequence?

Accounts of the history of assessment practices show its roots in the selection and certification processes which were developed as national requirements for personnel standards emerged. Indeed, the first examinations are believed to date from the Han dynasty in China (206 BC to AD 220) and were used to select staff for government service. In seventeenth-century Europe, the Jesuits introduced competitive examinations within their schools and these became widely established in the late eighteenth and early nineteenth centuries as nation-states industrialized. The need for commonly understood and dependable standards of skill and knowledge in workplaces and the professions grew. Mass testing for service in the armed forces was thoroughly established by the two world wars of the first-half of the twentieth century, while the second-half saw school-outcome exams regulating entry with increasing precision to employment and more advanced study. In the twenty-first century, we now have many international standards and the market for specialized personnel is global.

Codified procedures and technologies for testing and assessment developed alongside these historic needs and applications. Fueled by early educational psychology, for instance, by studies of mental capacities and of intelligence quotient (IQ), these offered a scientific legitimation. Testing could be objective, valid, and reliable. People and their attributes and capabilities could be measured with accuracy. Examinations of various sorts thus provided an appropriate basis for decision making in the public interest. Such taken-for-granted confidence gave rise to a technical discourse of assessment in which required ends (e.g., practices of grading, comparing, and selecting individuals or schools on the basis of test scores) were not generally in dispute. Rather, the focus of concern became the means, whereby given ends could be achieved as fairly and objectively as possible. Within such a discourse, technicalities concerned with test validity and reliability, criterion and norm referencing, and so on tend to prevail. Such a discourse is thus about maintaining and improving

confidence in systems of assessment and results; thus, ultimately, legitimizing the uses to which they are put.

A contemporary educational critique of technicist assessment reflects concern with its consequences for learning itself. In particular, as this encyclopedia demonstrates, the significance of formative feedback as an integral part of teaching–learning processes can hardly be underestimated. Less constructively, the same is true of the capacity of high-stakes assessment to distort the curriculum and classroom practices. In any event, assessment as an integral part of teaching and learning processes, rather than simply as a source of input and output data, is now generating an important new discourse and body of knowledge. This directs attention to the social processes through which assessment is manifest.

Sociologists, such as Broadfoot (1996), have argued that assessment has a primary rationale in controlling access to positions in society. It is thus seen as a mechanism through which power and control is exercised and a means of social reproduction. In this analysis, testing and assessment are far from neutral or objective. Rather, they systematically enable and disable, enhance and retard. The sociological discourse of assessment also draws on social–psychological, anthropological, and some post-modern studies. It thus analyzes how, as well as having educational purposes, assessment fulfills a range of political and social functions within modern societies. These wider functions are concerned with social differentiation and reproduction, social control and the legitimizing of particular forms of knowledge and culture of socially powerful groups. In this, the discourse has a critical role in examining some of the myths and assumptions embedded in the activity of educational testing. It critiques the science of testing and offers insights into the fact that assessment, from the most formal to the most informal, takes place within social contexts. Assessment is conducted on, by, and for inherently social actors (William, 1997: 396) and so the social and cultural values, perceptions, interpretations, and power relations of assessors and assessed carry important implications for processes and outcomes. Sociological analysis is therefore particularly concerned with the social impact of assessment and the perpetuation of educational and social disparity, and its cumulative affects in shaping ways in which individuals and groups in society come to be seen, and to see themselves (Filer, 1995).

We have briefly reviewed assessment in terms of its historical evolution and its social consequence. We have also considered the technical, educational, and sociological discourses associated with it. However, in this contribution, our concern is mainly with the latter, sociological discourse, and with some of the ways in which it serves to illuminate aspects of those technical and educational discourses. In particular, we focus on a somewhat neglected dimension concerning the impact on individuals of assessment policies, procedures, and practices, and some of their hidden, as well as their taken-for-granted, roles in everyday schooling.

Assessment as a Social Process and Product

Assessment is not limited to the formal testing, grading, and classification of students. More expansively, the term also concerns ongoing, formative, and diagnostic judgments, day-to-day marking and recording, and numerous informal, often implicit, evaluations made of students' work, progress, and potential. It is also important to remember that many assessments explicitly or implicitly embody a number of social, emotional, and physical characteristics of students. Thus an assortment of behavioral, attitudinal, socioeconomic, cultural, and family characteristics often constitutes a social diagnosis in accounting for students' failure to make satisfactory progress or fulfill their potential.

But how does this occur? What social processes have this effect? Are assessment results really a social product? How can we make sense of these issues? Exploration of assessment as a lived experience is particularly important to this new strand of work. Thus, we are concerned with the sociocultural interpretations which pupils and teachers bring to their interaction, and to the differentiating consequences of classroom processes. There then follows the issue of how assessment outcomes are interpreted, contested, or otherwise mediated by learners and significant others and how the consequences of such outcomes are incorporated into future lives.

In recent years, we have begun to explore how a sociology of assessment could tackle such issues. A major source is Filer's (2000) edited collection, *Assessment: Social Practice and Social Product*, which identifies key themes within a sociological discourse of educational assessment and offers expert contributions to illuminate them. Another source is our collaborative theoretical development within *The Social World of Pupil Assessment* (Filer and Pollard, 2000) on which we draw below.

We will take each element of this model in turn:

- *When and where is the assessment taking place?* As we have seen, assessment policies, requirements, and prescriptions are culturally, structurally, and politically embedded in particular societies at particular times.

Comparative and historical studies have demonstrated significant variations over time and place, but it is also the case that modern, technologically and competitively driven societies are showing remarkable convergence in deploying the results of educational assessments as an evaluative and accountability device for the modern centralist state. We thus locate our analysis of social influences on assessment within specific sociocultural contexts of state policy, region, and community. That is to say, we ask the question, "Where and when is the assessment taking place?" In the case-study schools in which we carried out ethnographic empirical research over a 7-year period in the early 1990s, the contexts in question were those of two southern English primary schools serving what we would contrast as white, middle-class, and skilled working-class families. In these case studies, we were particularly concerned with the introduction of teacher assessment (TA) and standard assessment tasks and tests (SATs) into primary schools in England. Over the period, tests, administration, marking, and moderation procedures were introduced and standardized. Results were scrutinized from year to year to ensure that consistent standards were being maintained. Through such processes, assessment practices were legitimated and assumptions of impartial objectivity were established.

- *Who is being assessed?* This question focuses on the identity of the learner being assessed. We see self-perceptions held by individuals and judgments made about individuals as being inextricably linked to the social relationships through which they live their lives. Indeed, we argue that we can only make sense of individuals and their learning within the context of that dynamic relationship with the wider world. Of course, there are factors that are internal to the individual in terms of capacities and potentials. However, the realization of a pupil's capacity and potential is, to a very significant extent, a product of external social relationships and cultural circumstances, among which we can count the processes and outcomes of assessment, in all its various forms. In our case studies, we observed, year on year, formalized and informal representations of children as social beings, as learners, and as pupils. The succession of objective, highly personalized, and invariably confident accounts were, of course, very powerful in shaping pupils' emerging and ongoing classroom and learning identities, as well as their relationships with parents and peers. Equally inevitably, however, those assessments were partial and contingent, obscuring the ways in which individual behaviors, relationships, attitudes to work, and perceived intelligences were, in part, products of the social, emotional, and organizational aspects of classroom life that teachers themselves created. Despite the confidence that most primary teachers held regarding their

all-round knowledge of individual pupils, we found it is extremely problematic for a teacher to know the whole child for assessment purposes – as we illustrate later in this article through the story of a pupil, Elizabeth, and her primary-school career.

- *Who is assessing?* Having argued that pupil identity can only be understood in context, we clearly need to focus on teachers, since they are undoubtedly the most powerful classroom participants with whom pupils must interact. In particular, we need a sociological conception of pedagogy and its link to each teacher's own sense of personal identity. For this, we deployed the concept of coping strategy (Woods, 1977; Pollard, 1982) and traced how satisfying role expectations and the constant pressures of teaching must be balanced with maintaining a sense of personal integrity and fulfillment. In the immediacy of classroom dynamics, this can be seen as teachers juggle with the immediate pressures they face. At the level of the school, it is played out through negotiation between different interest groups and the formation of taken-for-granted institutional assumptions. We traced how teachers in the case-study schools coped with the national curriculum and assessment requirements which progressively challenged their autonomy and traditional practices through the 1990s. A case study of one teacher, Marie Tucker, and her classroom practice demonstrated the detailed application of this analysis. In particular, it shows how her coping strategies, classroom organization, and associated pedagogies produced particular contexts with which pupils, in turn, had to cope. In particular, Mrs Tucker prided herself on her reputation for maintaining classroom order and routine, and for being good with problem children. Indeed, she routinely perceived and assessed pupils in terms of their adaptation to her personal strategic criteria. Inevitably, requirement for new classroom and assessment practices constituted a very real threat to Mrs Tucker's ability to maintain her established order and routine. At the same time, she began to perceive her many problem children, less as a source of professional pride, and more in terms of their threat to her grip on classroom control, and to the reputation she was proud of – something rather different from assessment based on objective performance.
- *What is being assessed?* An official answer to such a question might point to the subject content of a test, or to listed criteria of judgment, and would draw conclusions in terms of the attainment of pupils. More colloquially, inferences about the particular abilities of children may be legitimated by faith in the objectivity and categoric techniques of standardized assessment. In our analysis, we argued that such confident conclusions are misplaced because pupil knowledge, skills, and understandings are embedded in particular, and often conflicting, sociocultural understandings and are further conditioned by factors such as gender, ethnicity, and social class. We particularly focused on the influence of peer-group relationships and the ways in which peer culture and the sociocultural identity of each pupil can condition performance. Thus, while pupils' subject knowledge, skill, or understanding may seem to be objectively revealed by the neutral, standardization technique of a test or by a classroom task or teacher questioning, tests and tasks also reveal the facilitation or constraint of sociocultural influences and forms of understanding. We illustrated this proposition through analysis of a year-3 news session at Albert Park Primary School. This showed how classroom meanings were created through interaction of circumstances, strategies, and identities. In particular, it showed how language was used to satisfy pupil agendas for entertainment, novelty value, and peer status in ways that were often in conflict with teacher-led instruction or approval. Assessment, the analysis suggests, can thus never tap pure knowledge or capability – any result will also always reflect the wider sociocultural circumstances of its production. Assessment is an interpretive process. For this reason, beyond academic subject matter, we must ask what else is being assessed?
- *How does assessment function in classrooms?* Our analysis foregrounds the links between assessment and other sociologically important influences on classroom life – ideology, language, and culture. As a whole, these factors are played out through particular power relations between teachers and pupils and have significant consequences for social differentiation. We explored these ideas by drawing on some of Bernstein's (2000) work. This highlights the ways in which classroom language is conditioned by patterns and forms of control, which are embedded in teachers' routine and everyday practices. The consequence is that it is not possible for teachers to be neutral either in their impact on pupil performance or in their assessment of pupil performance. We show how, irrespective of intentions, each teacher generates a particular set of circumstances in which interaction with each child takes place, and which will affect each child differentially. The scope for variability in the overall effect is enormous.
- *How are assessments interpreted and mediated?* Assessments are produced and delivered within networks of social relationships. We thus need to consider the audiences of assessment and, in school contexts, this requires particular reference to families and to peers. These are the major significant others in children's lives and we therefore traced their influence throughout the 7 years of schooling in the case-study primary schools. More specifically, we considered how families interpret, mediate, and give meaning to assessment outcomes, so that their impact on their child is shaped

and filtered. Once again, we found that the outcomes of assessment cannot be seen as categoric and direct in their consequence. Rather, their meaning is malleable and is likely to be drawn into existing frames of reference, relationships, and patterns of social interaction. For each learner, this is an extremely important process in the development of further phases of their personal narrative and in the construction of identity.

Overall, in relation to each of the major questions set out in the simple, cyclical model in **Figure 1**, we emphasize the influence of social factors on assessment. Learner, assessor, focus, process, and interpretation are all embedded in their sociocultural context and caught up in webs of social relationships. In such circumstances, we believe that the technical objectivity of assessment is a myth too far.

The Case of Elizabeth

We can illustrate the social processes and products of assessment through the case study of a young learner, Elizabeth – the only child of Eleanor and John Barnes, living in an immaculately kept, small, modern terraced house in the area of skilled, working-class families served by Albert Park Primary School. How did school assessment influence her life?

We described Elizabeth's school career at some length in *The Social World of Pupil Assessment* and recorded, year on year, her emerging identity and self-esteem as a pupil and as a girl. We saw her evolving classroom status and relationships among teachers, peers, and within the family, and her evolving approaches to academic tasks from

age 5 to age 11. Elizabeth was a lively child with a strong will. However, while her classroom playfulness and boldness allowed her to develop an attractive identity among her peers, her parents and many of teachers repeatedly expressed their disapproval of these aspects of her performance as a pupil and as a girl. These social and behavioral outcomes developed in a dynamic relationship with assessment outcomes concerning attainment and progress levels, etc. These in turn, of course, culminated in her SAT and teacher-assessment scores at age 11, and informed her progression to secondary education.

Social and academic outcomes were thus interrelated and, in addition to its ostensible role in supporting learning and monitoring outcomes, classroom assessment made a significant contribution to socializing Elizabeth into school life. As in the work of Torrance and Pryor (1998), we recorded this early socializing process in Elizabeth's career when, as well as being concerned with her academic progress, TAs (Teacher Assessments) and parental responses to assessment, focused on monitoring and supporting her adaptation to school expectations. While Elizabeth's intellectual and physical skills and progress across the curriculum were assessed as good, both formal and verbal reports to her parents were dominated by a range of negative assessments of her as noisy, quarrelsome, and disruptive with peers, especially boys. Such assessments led to friction, punishments, and warnings at home. As we have described above, in relation to Mrs Tucker, such socializing processes are linked to issues of control and the maintenance of a classroom environment in which effective teaching and learning can develop. Thus, the socializing and control functions of assessment in Elizabeth's case were related to her teachers' interests and

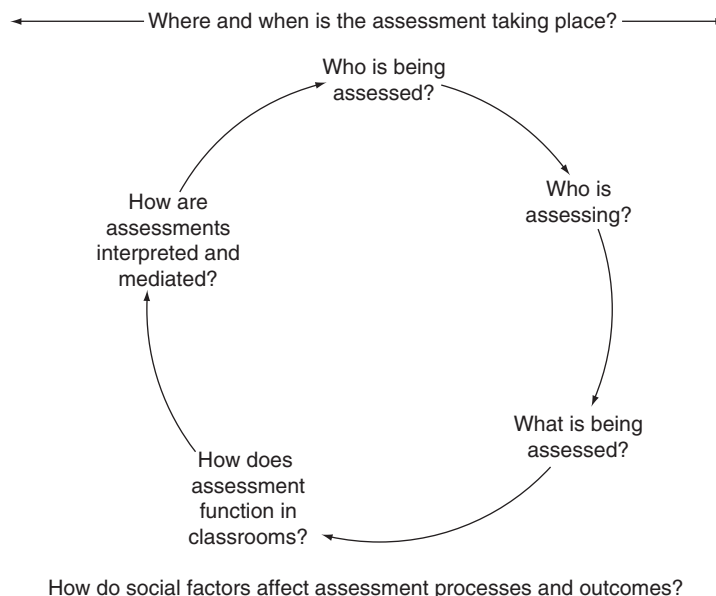

Figure 1 Social influences on assessment: A simple model. From Filer, A. and Pollard, A. (2000). *The Social World of Pupil Assessment*. London: Continuum.

to other children's learning as much as with Elizabeth's development as a pupil. However, assessment of Elizabeth's behavior and relationships went beyond straightforward conceptions of her as a pupil. The problem of her physical liveliness and association with boys, especially naughty boys, was a recurring theme in early TAs of Elizabeth, and a cause for further conflict and unhappiness at home. While accepting her daughter's identity as a girl – "that *is* Elizabeth, that's *her*" – her mother nevertheless strived to support teacher attempts to curb her daughter's boisterous association with boys, wishing, she admitted, that Elizabeth was more of a dainty child, and expressing the notion that her daughter, with all her enquiring energy was more like a boy. However, in the context of peer relationships, year-on-year sociometric questioning repeatedly revealed Elizabeth to be one of the most popular children in the class, for her playfulness, confidence, and boldness, for her artistic skills and willingness to help, academically. Further, she achieved this status on account of her appeal to boys, as well as girls. Thus, while continual attempts were made by her teachers, and on behalf of her teachers by her mother, to socialize Elizabeth into appropriate pupil behavior, and especially to socialize her as a female pupil, these efforts were in direct conflict with socializing process within the peer culture.

Thus, Elizabeth's case makes explicit some of the gendered norms and values that can remain implicit in assessments of pupils' behavior unless a pupil persistently contravenes them, as Elizabeth did. One of the functions of assessment in Elizabeth's life, therefore, was in providing a form of communication through which gender expectations were shared and communicated among her teachers, her parents, and her peers. While implicit norms relating to gender were made explicit here, other norms and values relating to culture and ethnicity of pupils similarly remain implicit until challenged. For example, Adams (1997), writing within the US context, presents the case study of a white adolescent girl, Sharon, who contravened gender and racial norms. Sharon's toughness and powerful identification with black gang culture gave rise to sustained criticism, in approaches to her mother and before her peers, as teachers tried to re-socialize her into an appropriate pupil identity.

Reviewing again the question of who is being assessed, we can note that Elizabeth's resources and potential with regard to her physical and healthy attractiveness and liveliness and her linguistic, physical, and artistic skills, were highly valued within the peer group. However, many of her teachers felt ambivalence regarding her social identity. For instance, her year-2 teacher made overt and strenuous attempt to curb Elizabeth's deviant pupil behavior, while recognizing that those same qualities made her attractive to her peers, exciting, and funny. Indeed, she recognized that Elizabeth's liveliness, lack of conformity, and well-developed sense of humor made for

an extremely vital and attractive social identity, among adults, as well as children. However, for many of her teachers and her mother, they also stood in the way of an acceptable pupil identity and, in some respects, in the way of an appropriate identity for a pupil who was also a girl.

Figure 2 is an elaboration of the simplified model previously introduced. Some elements of it have been referred to in Elizabeth's story, but others would repay further study within the original sources.

Conclusion

The conceptual model which has been introduced is an attempt to represent important, recursive cycles which underpin the social consequences of schooling. In particular, it highlights the ways in which identity, teacher practices, peer and family cultures, and the interpretations and mediations of teachers, family, and peers feed into, reinforce, and condition each other. Importantly too, of course, we have suggested that the microprocesses of pupil and teacher identities, practices, and interpretations are embedded in macro-sociohistorical and political contexts which shape the policies of schools and the perceptions and expectations of teachers and families.

This type of model was initially developed through two related studies, *The Social World of Children's Learning* (Pollard and Filer, 1997) and *The Social World of Pupil Career* (Pollard and Filer, 1999) and the recursive cycles represent the analytic insights generated through longitudinal tracking of pupils' identity, learning, and school careers.

The significance of this approach to assessment is that power, process, and consequence are foregrounded. Detailed study of assessment practices reveal patterns of social influence which question the aspiration to objectivity. Research on classroom interaction, identity, and relationships suggest that assessment outcomes are tainted and should be, at least in part, seen as social products as well as products reflecting purer forms of capability or achievement. Holistic enquiry into the social mediation of assessment outcomes by significant others shows the enormous variability of consequence for pupil identities and self-perceptions as learners.

A social analysis of assessment practices and products thus generates concerns in respect of the categoric, summative certification of performance. Indeed, we could go further and argue that established assessment practices often yield patterns and systematic effects which risk being fundamentally divisive. As policymakers configure education systems to meet the demands of international competition, they may also unwittingly reinforce social divisions and widen the life-chance gaps which some groups of children face.

Glossary

Functions of educational evaluation –

Educational evaluation in general can serve the function of describing what happens and how and why it happens, judging whether or not what happens meets the expectations, and then recommending what actions to take. However, evaluation practioners and evaluation researchers may view differently on the matter whether or not a particular evaluation should or can serve the three functions. Evaluation practioners tend to think an evaluation needs to fulfill these functions in order to meet the needs of the targeted evaluation users, whereas evaluation researchers tend to think that to provide an accurate description is most important for an evaluation. And judgment and recommendation will be constructive only when such descriptions are verified and collaborated with other and relevant replications.

Generalization of evaluation studies – The extent to which that a conclusion drawn from an evaluation study or a set of evaluation studies can be generalized to a different situation. There is disagreement with regarding whether or not evaluation study needs to concern about the generalization as the debate continues whether evaluation should be focused on particularization or on generalization. However, the author of this chapter thinks that choosing between the two is false.

Outcome-based accountability – Individuals (e.g., teachers) or institutions (e.g., schools) are asked to be accountable not only for what they do, but more importantly for whether or not what they do produce student learning outcomes, mainly achievement test scores. The outcome-based accountability is controversial especially when it is narrowly conceived as merely indicated by student test scores.

No child left behind act – The US legislation passed in 2001 requires the testing by the states of all children in third through eighth grades. Schools will be judged to be successful or in need of improvement based on student performance on the states' administered standardized assessments. This Act enacted the theories of standard-based education reform, which has raised prospects for public education, as well as problems and controversies.

Professional accountability – Regulations by a professional body to inform and to make the individual professionals to conduct the profession in a socially and ethically responsible way.

Program evaluation standards – The Program Evaluation Standards (1994, second edition) was published by the Joint Committee on Standards for Educational Evaluation of USA and Canada. The publication explicates four categories of standards concerning utility, feasibility, propriety, and accuracy of evaluation for evaluators and evaluation users to respect and to reflect in conducting educational evaluations and using evaluation results.

Regulatory accountability – Government regulations of schools, school personnel, and school practice to evaluate how well the schools and school personnel perform their institutional duties as specified by legislations and as expected by the society. School inspection by government-appointed assessors is an example.

Role-based accountability – Schools, school principals, and teachers are assigned institutional roles in the education of young people. Role-based evaluation establishes evaluation criteria based on job descriptions for a principal or for a teacher and uses the criteria to judge how well the principal or the teacher performs the institutionally expected roles.

The office for standards in education, children's services and skills (OFSTED) – OFSTED was

established in 2007 from a merger between the old Office for Standards in Education and the Adult Learning Inspectorate under the Education and Inspection Act 2006 of British. As a non-ministerial government department reporting directly to the Parliament, OFSTED is responsible for regulating and inspecting schools and other education and childcare services including adult learning and training, children's social care services, and initial teacher training in England.

Theory-driven evaluation – The evaluation approaches that emphasize program theory of why a program would produce expected changes and program implementation of how the program would achieve changes, planned or not.

An item of recent news from China caught the attention of the author while she was working on this article, that she was compelled by its significance to the present topic. On 30 June 2009, the Mainland Chinese government announced a delay in implementing a mandated installation of website-blocking software Green Dam Youth Escort into all computers sold in the country. This initiative – planned to commence from the first of July – was to block pornography as well as information on the Internet that was officially designated as undesirable. Implementation was delayed because of protest by hundreds and thousands of Internet users throughout the country. An incident such as this, forcing the government to stop what had been decided (also announced) under pressure from ordinary people – Internet users – was unprecedented in modern Chinese history. There are significant ramifications for this situation as it demonstrates the rise of civil society in Mainland China. It is also an indication of the extent to which information technology has helped to change modern China and the world. In relating this turn of events to the topic of the present article, a parallel could be drawn. As was the case with information technology, the development of educational evaluation practices and theories has been nurtured and has contributed to the rising and maturing of civil societies around the world.

Educational evaluation has become an integral part of civilized society because – as a social institution – its role is to judge the merit, worth, value, and impact of educational enterprise. Any educational evaluation engages consistent inquiry into what is good and the reason for its elevated status. The value feature distinguishes evaluation from other types of inquiry. Evaluation is also an empirical endeavor committed to finding evidence and the establishment of its credibility via a systematic procedure. The process must define and defend the judgment on the

merit of an educational enterprise. Educational evaluation has developed on these two fronts. In the last 15 years – as an indicator – the publication of the *Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994) demonstrates the maturity of the field of educational evaluation as a field and a profession. Under its guidance, there have been changes that are both significant and numerous. However, these have been achieved without compromising the ultimate purpose of educational evaluation – namely evaluation for accountability and for learning improvement. It could be said that educational evaluation is multifaceted, hence the need to determine, precisely, what is meant by effective accountability and effective learning improvement – which has driven value and methodological inquiries in the field and in the process – shaped its current landscape. The section 'Educational evaluation' is intended to reflect on the major developments in the evolving field of expertise that has taken place over the past one and half decades. This article aims to provide an overview of this section. Initially, the article presents an outline of the content and structure of the section. Subsequently, details are provided that illustrate the evolution. Finally, some sustained issues and challenges in the field are identified with suggestions for future development in educational evaluation.

Content and Organization of the Section

By utilizing Schwab's conceptualization of knowledge organization (Schwab, 1978), the section 'Educational Evaluation' is organized into five areas: purposes and models of educational evaluation, contexts of educational evaluation, evaluation methods, evaluation domains, and contemporary themes in evaluation. The first area consists of five articles that contribute to the objects and concepts of educational evaluation and theoretical approaches to educational evaluations. The second area – relating to contexts – includes seven articles and addresses influences of the circumstances, such as social, political, cultural, and ethnical aspects – factors that can affect educational evaluation. The third section – methods of evaluation – consists of four articles that describe various research tools with which to conduct educational evaluation. The fourth section deals with evaluation domains and contains 14 articles that discuss the theoretical constructs/models and the tools to attend to the major domains for educational evaluation. These include (but are not limited to), curriculum evaluation, program evaluation, school evaluation, educational personnel evaluation, educational policy evaluation, national evaluation programs, and international evaluation. The final area is one that deals with contemporary themes and includes seven articles on the emerging educational practices and their

evaluation, such as formative evaluation of teacher and teacher education, evaluation of educational technology and e-learning, and evaluation of integrated school health programs.

In terms of Schwab's conceptualization of knowledge organization, the first two parts correspond to the dimension of boundaries (the objects and the concepts) of the field; the third part addresses the dimension of methodology in relation to the objects and concepts of evaluation; and the last two parts relate to the domain or emerging applications of the objects, the concepts and the methodology in the field. The section contains a total of 46 entries, with 38 entries being full papers and eight using cross references of the articles from other sections of the International Encyclopedia of Education (IEE). The intention is for the content and its organization to provide the reader a relatively comprehensive perspective of the contemporary educational evaluation as a field.

Evolution of Educational Evaluation in the Last 10–15 Years

There is, undoubtedly, consensus among authors contributing to this body of research that educational evaluation has changed significantly over the last 10–15 years, but they may disagree with how to characterize these changes. Based on reading each of the contributions and others, descriptors have been identified and will be used in this article to capture the collective reflections of the contributions on these changes to educational evaluation. The descriptors are as follows: outcome-based accountability, stakeholder involvement, globalization of educational evaluation, diversity in value and method repertoires, and theory-driven evaluation. In the elaboration of each of the characterizations below, every effort was made to identify specific meanings and implications relevant to the field.

Outcome-Based Accountability

Educational evaluation is always about accountability since it obtained the legitimate status when the US congress passed the 1965 Elementary and Secondary Education Act (ESEA) – a document that includes an evaluation clause requiring the evaluation of federally funded programs. Evaluation for accountability is one key reason for evaluation to stay. That being said – in terms of concept and practice – educational evaluation has been transformed in a significant way as public education faces challenges from a number of political, social, and cultural developments. This impression has been reinforced by reading the articles of the section, particularly those such as 'School inspections' (Chapman and Earley), 'School-based evaluation' (MacBeath), 'Principal evaluation' (Glassman and Glasman), 'Evaluation of teacher

quality and practice' (Robinson and Campbell), 'Evaluation and accountability' (Sato and Rabinowitz), 'Evaluating education in three policy eras (Peters, Weber, and Britez)', and 'Purposes of educational evaluation' (Mathison). The transformation has taken place because evaluation for outcome-based accountability has become statutory and, in reality, had material consequences. This process began in the 1980s and was facilitated by increasing public dissatisfaction with public education. There was also a trend toward global neoliberalism that conceptualized education less as a process and more as a product or outcome. One of the key terms – outcome-based accountability – is in contrast to earlier education policy when accountability was more about what schools and teachers do than how student-learning outcomes are influenced by what they do. Another key concept is regulatory accountability – mandatory by governments for individual schools, classrooms, and teachers and in contrast to professional accountability which is regulated and highly regarded by the teaching profession – and, consequentially, in contrast to what was considered inconsequential. These changes have obtained prominence and become an integral part of educational systems in the last two decades. Two outstanding examples of this include the No Child Left Behind Act of 2001 in the US and the Education and Inspections Act in England which, in 2007, established the Office for Standards in Education, Children's Services and Skills (OFSTED). This important legislation was responsible for the systematic inspection of schools (and other providers of education and childcare) in the country.

Many articles found in this section provide lively and thoughtful accounts of this transformation in various aspects of education. Most of the authors see the potential benefits of this transformation while pointing to the critical issues brought about by the changes. Among the desirable effects brought about by the change, a school's operation and performance have become more explicit and transparent – not only to the parents and the public but also to schools, teachers, and students. Making school practice and performance explicit, discussable, and subject to a valid form of assessment and measurement has encouraged schools to recognize their own strengths and weaknesses. The emphasis on evidence of student-learning outcomes promotes and strengthens both internal and external accountability of the stakeholders in school education. For example, it has been suggested that the quality-assurance-evaluation system has greater validity for evaluating university teaching's impact on student learning and development than the common practice – one that relies on anonymous student evaluations. These have been found to reflect tutors' popularity, personality, and the ease of higher-grade achievement more than teaching quality. A teacher's promotion and career development can be equitably supported when it is based on evidence of the teacher's performance and its impact on student learning rather than on the

informal – or even nepotistic – arrangements for promoting teachers. The concern for evidence of student-learning outcomes also prompts the research and development designed to capture the connections between teaching and learning. (Under this section see articles by Kyriakides, Creemers, Teddlie, and Muijs; MacBeath.)

Along with the potential benefits, there are also questions and problems to consider that are associated with the outcome-based, regulative, and consequential accountability. First, it is necessary to identify what outcomes require accountability. Examples of typical educational outcomes are academic achievement, school attendance, school completion, graduates' employability, civic participation, social development, and so on. These outcomes require no justification. However, educational outcomes are unlike products of business organizations that are clearly defined and measured. Educational outcomes (or standards) vary considerably. They can be described as short or long term, intended or unintended, and singular, multiple, or hierarchical. For example, there is multiplicity of outcomes resulted from integrated school health programs, (see Franke; this section); complexity in identifying educational outcomes in cost analysis in evaluation (see Fletcher, this section). Consequently, it is, often, difficult to establish direct links between outcome and cause in educational settings (Scriven, 2005; Schwab, 1978). It remains very problematic in research to disaggregate the value added to student learning by individual teachers from that added by school factors (Reynolds *et al.*, 2003). With the difficulties in establishing direct links between student learning outcomes and actions of individual schools and individual teachers for rewards or punishments (e.g., performance-related pay arrangement for teachers, school closure because of insufficient student enrollment), connecting that with the outcome-based accountability is inevitably controversial. In addition, the regulative accountability has placed constraints on professional autonomy. This is a particular problem where working conditions in schools are more likely to be imposed from outside the profession, usually by government. This causes lower morale and learned incompetence in teaching professions, which, in turn, defeats the very purpose of outcome-based accountability intended to improve school effectiveness and student learning.

To address these concerns, three key relationships have been proposed by several contributors. These need to be addressed in practice so that evaluations for outcome-based accountability have a chance to succeed. The first of these is the relationship between professional and regulatory accountability, followed by between role-based and outcome-based accountability, and between bottom-up process and top-down formulas of accountability policy and implementation. With regard to the first relationship, Mathison (this section) discusses the necessity and limitations both of regulatory and professional accountability. Therefore,

the proposal is for pluralistic democratic accountability to balance the two. The pluralistic democratic approach to accountability requires educational stakeholders, including students, parents, government, schools, principals, teachers, to enter into a contract of mutual, collective responsibility for education and schooling. This places greater emphasis on local context and internal accountability – that is, mutual responsibility within contexts and communities.

The second key factor relates to a balance between role-based and outcome-based accountability. Schools, school principals, and teachers assume a significant institutional role in the education of young people – empowering them to become self-sufficient individuals and responsible citizens. Therefore, the focus of criteria should be whether or not teachers or principals fulfill their institutional roles for teacher or principal evaluation. In the article 'Principal evaluation', Glassman and Glasman explicate the complexity in role-based or outcome-based evaluation of school principals. They argue that role-based evaluation (assessing the qualities of the activities) needs to be the primary component of principal evaluation although outcome-based evaluation (assessing the results of the activities) presents an increasing pressure. Role-based evaluation establishes evaluation criteria as based on job descriptions for a principal or a teacher – that is, the roles of teachers or the roles of principals and how well they perform the institutionally expected roles (e.g., judging the principal's knowledge and skills with regard to managing the school's finances effectively and efficiently). Outcome-based evaluation sets evaluation criteria in terms of student-learning outcomes. Role-based and outcome-based evaluation should not be exclusive. Performing the institutional roles by principals or by teachers is believed to bring about expected educational outcomes in students. School principals and teachers may resign if they believe their efforts have nothing to do with student-learning outcomes. Role-based evaluation enhances the sense of agency among principals and teachers as professionals. Outcome-based criteria – for example, percentage of students that score at, or above, expected levels – when appropriately conceived by principals and teachers, or by a school as a whole, will provide a sense of purpose and encouragement for principals and teachers to perform their expected roles.

The third factor has as its focus the balance of the bottom-up and top-down process in formulating and implementing policies of evaluation for accountability (Chapman and Earley; MacBeath; Nevo, this section). School-based internal evaluation or teacher self-evaluation has been considered a good exemplar of pluralistic democratic accountability (Mathison, this section). This process should be initiated and governed by the school or by the teachers. However, schools and teachers are, often, perceived by society to be self-protective and conservative. Therefore, the internal or self-evaluations by schools and

teachers are under considerable influence of governments. MacBeath (this section) observes that the school-based internal evaluation in Britain is changing. It is seen as being very much influenced by top-down formulas from the government. Significant ways to make school-based evaluation or teacher self-evaluation, genuinely, professionally regulated and accountable by schools, principals, teachers, as well as governments, will be always a practical challenge for continual reflection and improvement.

The likelihood is high that the direction of evaluation for outcome-based accountability will not be reversed. The tensions inherent in the three sets of relationship, probably, are always present and no definitive course exists to achieve a resolution. Continuing dialog between the stakeholders is imperative in order to reach a consensus and provide new understanding to make the outcome-based accountability systems productive.

Stakeholder Involvement

Education has always been political because it is never without social and economic consequences for individuals (Bruner, 1996; Cronbach, 1982). Education is, therefore, too important for social constituencies to leave it to the educational profession. The same can be said of educational evaluation. Contemporary evidence indicates that nations have established outcome-based accountability systems. Consequently, the scope and depth of stakeholder involvement is ever increasing as there are greater demands being made for education and educational evaluation to be more responsive, transparent, and valid. Stakeholders (e.g., students, parents, principals, teachers, business community, and government agency) who have a vested interest in what is being evaluated are, at present, not merely a source of data but equally important as contributors, shaping the evaluation efforts, including formulating evaluation questions, identifying data sources, interpreting data, and assigning values to evaluation results. This has been documented in *The Program Evaluation Standards* (Joint Committee on Standards for Educational Evaluation, 1994). Many entries reflect this trend and discuss critical issues associated with it in educational evaluations, including 'Program evaluation' (Christie and Fierro), 'Curriculum evaluation' (Levin), 'Internal and external evaluation' (Nevo), 'Evaluation, governance and planning' (Picciotto), 'Evaluation reporting and communicating' (Torres), 'Evaluation and accountability' (Sato and Rabinowitz), and 'Moral and ethic issues in evaluation' (Morris). In particular, the article 'The roles of stakeholders in educational evaluation' (Taut and Alkin) provides a focused discussion on the constructs underpinning the notion of stakeholder involvement and factors affecting the stakeholder involvement and its results.

The evaluation literature indicates two theoretical orientations that underscore the notion of stakeholder

participation. One is the line of inquiry into evaluation utilization. It argues that stakeholder involvement increases and improves evaluation use. The other is from the democratic participation perspective – making evaluation more inclusive and interactive. It has been shown that social justice is not only concerned with distributing social benefits but also with distributing power and participation from different groups of people – especially by minority groups whose social participation is often marginalized. These two orientations are considered to result in deep involvement in contrast to broad involvement of stakeholders in its implementation (Taut and Alkin, this section). The utilization orientation focuses on securing the participation of a few key stakeholders – intended users of evaluation to enhance the extent to use evaluation results (e.g., Sato and Rabinowitz, this section). The emphasis of the democratic orientation is on securing the participation of a diverse range of stakeholders – especially those with least power in the context to achieve broader participation and social justice. Whether to implement a deep involvement or a broad involvement of stakeholders for an implementation, certainly, depends on difference in theoretical orientation. However, there is the factor of resource constraint to consider, such as time and money. Taut and Alkin's review of the recent literature concludes that the implementation of evaluations prioritizing deep over broad involvement seems less likely to fail. Furthermore, actively involving stakeholders to attain evaluation use seems to have been better documented in the literature. The conclusion indicates that a broad involvement implementation is under more constraints – such as time, money, and with more diverse stakeholders (also see, Levin, this section).

Stakeholder involvement is now a key principle in the implementation of educational evaluation. It is believed to make the evaluation in question more credible and more accessible to those who are involved in – and affected by – the educational evaluation. Evaluation and evaluative judgment that is anchored in a shared reality by participating stakeholders is expected to make evaluation, itself, a powerful learning system – allowing for organizational learning and improvement. Applying Bruner's analysis of education as aculturing, the learning can take place at two levels. At the macro level, participants will learn to see the culture (or a school) as a system of values, rights, exchanges, obligations, opportunities, and power. On the micro level, participants will learn to examine how the demands of a cultural system (or a school system) affect those who must operate within it. In that latter spirit, participants will learn how "individual human beings construct realities and meanings that adapt them to the system, at what personal cost and with what expected outcomes" (Bruner, 1996: 12).

As anticipated, stakeholder involvement brings challenges for educational evaluation. Many articles, such as 'The roles of stakeholders in educational evaluation' (Taut and Alkin), 'Evaluation and accountability'

(Sato and Rabinowitz), 'Program evaluation' (Christie and Fierro), 'Curriculum evaluation' (Levin), 'Informal education and evaluation' (Jeffs, this section) elaborate on the complications in various educational evaluations. For example, there is considerable stakeholder disagreement and apathy – given the fact that stakeholders differ in authority and power. The standard 'Political viability', therefore, warns against possible pressures from stakeholders and asks evaluators to prevent their involvement from biasing the evaluation and its findings. In addition, factors – such as inadequate individual expertise and experience, imbalanced representation of knowledge and perspectives, inadequate training and orientation, and lack of sufficient time – all pose threats to the validity and utility of evaluation and accountability efforts.

Stakeholder involvement is a necessity – as well as a challenge – for the contemporary educational evaluation. The ultimate goal is to improve evaluation use and to prompt democratic participation and organizational learning. There are constraints to the realization of the full potential with influence from many factors, such as those mentioned above. Affirming stakeholder involvement, dialog along with empirical and practical work are required to identify and create the conditions to maximize the positive effects and minimizing negative ones on educational evaluation.

Globalization in Educational Evaluation

The third feature of the contemporary educational evaluation appears to be a global trend toward outcome-driven or performance-driven educational evaluation. As a result international evaluations are obtaining prominence by providing an internationally comparative perspective to view school effectiveness across nations. Two of the more notable systems are the Organization of Economic Cooperation and Development (OECD)'s Programme for International Student Assessment (PISA) and the International Association for the Evaluation of Educational Achievement (IEA)'s international evaluations. This started, in the late 1950s, when the IEA was established. The scale and influence of the international evaluation has accelerated in the recent two decades. When the IEA conducted the first international mathematics study in 1964, 12 countries participated. Twenty countries took part in the second international mathematics study in 1980–81. The Third International Mathematics and Science Study (TIMSS) was completed in 1995, involving 20 countries. The subsequent TIMSS (now known as Trends in Mathematics and Science Study) took place in 1999, 2003, and 2007. More than 60 educational systems plan to participate in the fifth TIMSS evaluation to take place in 2011. In addition to mathematics, IEA conducts the cycle evaluation of student achievements in reading literacy (Progress in Reading Literacy Study (PIRLS)) and civic and citizenship education (International Civic and Citizenship Education Study

(ICCS)). The target student populations of the IEA evaluation are fourth-grade and/or eighth-grade students. PISA surveys every 3 years on the academic achievements of 15-year olds who complete the compulsory education in reading, mathematics, and science. PISA was conducted in 43 countries in the first assessment, in 2000; in 41 countries in the second assessment, in 2003; and in 57 countries in third assessment, in 2006. Sixty-two countries have signed up to participate in the fourth assessment, in 2009.

The original purpose of international evaluations by IEA was research motivated. More recently, however, the increasing prominence of PISA and TIMSS illustrates that the internationally comparative student-learning outcomes have become the benchmark for nations' public policy in education. One of the forces that determine this is the institutional and financial support of the international evaluations by the supranational bodies such as the OECD, United Nations Educational, Scientific, and Cultural Organization (UNESCO), the European Commission, and the World Bank. Another significant factor is the need for self-knowledge of student achievement by governments because of the accountability motive through which nations are compared – based on the performance of their students. These international evaluations help shape the current performance-driven educational systems around the world. The article 'International evaluations' by Andreas Schleicher (this section) provides an assessment of the developments and the impacts of the international evaluation.

The international evaluations contribute to the field of educational evaluation in several significant ways. The international evaluations inform nations, set national educational targets, and contribute to greater understanding of the relationship among input, processes, and educational outcomes. For example, the Netherlands is using the PISA performance levels to benchmark its school performance against the other OECD countries (Thijs *et al.*, 2009). The PISA assessment results allowed Germany to see the problem of educational equity in comparison to the OECD countries achieving better educational equity and influencing national policies to address the problem (Schleicher, this section). The TIMSS research indicates that the students obtained higher scores and displayed smaller achievement gap when taught by teachers who majored in mathematics or mathematics education compared to students whose teachers did not major in these fields. The findings influenced the Honk Kong Special Administrative Region (HKSAR) government to adopt the policy to require that primary school mathematics teachers have qualifications of either mathematics major or mathematics education major (the requirement exists already for secondary school teachers). In examining the history and development of the National Assessment of Educational Progress (NAEP) in the USA, Schneider (this section) observes that state governors of that country now want to compare their students to those in Korea or

Germany rather than Kansas or Georgia. PISA has certainly gained international attention. Indeed, many countries have considered administering PISA to a state-wide representative sample to benchmark their student performance against students from countries around the world. This also occurs in Shanghai – the only city in the Mainland China to take part in the PISA assessments. The impact of international evaluations on nation's public policy in education is unprecedented.

These international evaluations support the data-based decision making by building an infrastructure of data development, sharing, and access for educational research and development. The infrastructure makes it possible for investigators to work with the same set of variables, theoretical constructs, and to understand how variables and relationships between variables change over time (Committee on Scientific Principles for Education Research, 2002). The international evaluations also advance the techniques to implement cross-country/cross-culture international assessment programs. Andreas Schleicher (this section) provides an informative explanation of the challenges and the solutions in designing and implementing the international evaluations. Leonidas Kyriakides and his colleagues (this section) describe and explain the purpose of as well as the procedure for the development of the international system for teacher observation and feedback for teacher evaluation.

The strong presence of international evaluations is expected to continue given their authority in providing comparative evaluation of student-learning outcomes and, thus, inferring effectiveness of national educational systems. Moreover, the time may come for local evaluation systems to request the use of international data to evaluate program effectiveness or school effectiveness. For example, Hong Kong's PISA provides student-performance information for individual participating schools. Individual schools can use the information to infer how well their students perform compared to those of the other participating schools. The self-knowledge could be a useful tool for the school, students, and staff. However, any international evaluation is perspectival. Caution needs to be taken to prevent the international evaluations from becoming a dominating force – dictating local educational evaluations.

Diversity

The significance of diversity in modern society seems too obvious to be reiterated here. However, the introduction article would not be complete without reiterating the influence of diversity as a feature of this section. Diversity is a fact of life and, certainly, a fact of education. For example, stakeholder participation and the globalization of educational evaluation increase diversity in value, method, and practice for educational evaluation. Education

faces a range of diversity such as ethnic diversity, cultural diversity, language diversity, family diversity, gender diversity, ability diversity, and more. Diversity encompasses differences, conflicts, and vitality, and, consequently, there is a need for choice, equity, and inclusion in order to address these issues. All these facts, issues, and proposals are legitimate objects for educational evaluation. Diversity is also a DNA that is part of the birth and growth of the field of educational evaluation. From the very beginning, the theories and methods were heavily influenced by those of social sciences. Baker and Niemi (1996) attributed to four of such sources that have contributed to the field of educational evaluation. These include experimentation and measurement from psychology, system analysis from research on schooling and administration, and interpretive approaches from humanities critical of empiricism. The different orientations determine the types of evaluation questions asked, the evaluation goals to be realized, the type of interpretations considered valid or useful; the value system chosen and meaning ascribed to quality; the context of the evaluation process; and the evaluator identity and roles (Dahler-Larsen; Levin, this section).

The diversity in epistemological paradigms, methodological tools, and professional training continues to permeate today's evaluation field. The diversity brings viability as well as tension in the field and is clearly reflected in this section. The article 'Understanding approaches to evaluation' (Love, this section) takes on the daunting task in an attempt to delineate numerous evaluation approaches and their classifications from the instrumental chronological framework to many more value-rich frameworks. Each of the approaches has different assumptions, a different form, and different factors affecting it. In a similar vein, the article 'Evaluation methodology' (Chatterji, this section) – in describing various implementations of quantitative, qualitative, and mixed-method designs – addresses the complexity of interdependence of methods, uses, and values in making methodological decisions for doing educational evaluations. The article 'Curriculum evaluation' portrays a paradigm shift from instrumental evaluation to adaptive and situated evaluation and to emergent and emancipatory evaluation. In the article 'Cultural issues that can affect the validity of educational evaluations', Durán (this section) argues for the importance of understanding and taking into consideration the cultural ways of persons targeted by educational interventions in making educational evaluation more valid. In the *Zeitgeist*, the article 'Defining quality in evaluation' (Dahler-Larsen, this section) recounts the complication and controversy in defining quality in evaluation.

These articles reflect ways that the field of educational evaluation has developed more diverse perspectives and more varied methodological repertoire in response to the contemporary educational realities that are multiple, divergent, and interrelated. Diversity is an asset.

It reduces hierarchical and structural control from both inside and outside the field – providing the field with intellectual viability. Diversity also causes anxiety and incoherence (Mathison, this section). Incoherence is not necessarily a problem; rather, it can be the drive for pursuing new dialog, consensus, and understanding. However, this is only possible when diversity itself is prevented from becoming dogma and causing fissures between different thoughts and practices – that is, an evaluation approach, a practice, or even diversity itself can always be questioned and examined, similar to any other entity.

Theory-Driven Evaluation

In general, educational evaluation includes outcome evaluation and process evaluation. However, educational evaluation has focused on outcome evaluation in order to establish the merit of an educational intervention. It concerns outcomes – not the program itself – in program evaluation. This situation is changing. The author has learned this through personal experience when she submitted a manuscript last year to *American Education Research Journal* (AERJ). The paper reports a longitudinal study to compare learning outcomes of students receiving alternative mathematics curricular. The editor returned the submission to the author, explaining that the AERJ does not accept a manuscript on program evaluation if it does not provide evaluation details of the program implementation linked to the program outcomes. This was surely not an isolated incident. Rather, it indicated the field of evaluation research appeared to have developed – moving beyond a black box, input–output models focusing on outcomes to the approaches that emphasize program theory of why a program would produce expected changes and program implementation of how the program would achieve changes, planned or not – thus called theory-driven evaluation (Weiss, 1998).

In this section ‘Educational Evaluation,’ the move for theory-driven evaluation is evident in two aspects – one involves conceptual inquiry of critical concepts/issues, the other prompts systematic approaches to evaluate program theories, that is, the way in which produced educational outcomes are related to educational processes. The changing conceptualization of the construct evaluation use is an exemplar of the conceptual investigation. Thomas (Thomas, V., this section) traces this development of how the present multifaceted concept of evaluation use (e.g., process use, conceptual use) has been informed by practical needs and also informed practice. The enriched conceptualization of evaluation use not only helped clarify the theoretical question of what constitutes evaluation use but also stimulates new questions and new practices (Weiss, 1998). For example, the concept of process use inspired the innovative evaluation practices that has prompted organizational learning and capacity building – such as school-based evaluation (MacBeath, this section), self-assessment for

teacher professional development (Tillema, this section), self-assessment for adult education (Pauline, this section), and evaluating schools as learning communities (Thomas, S., this section).

The concept of process use refers to the evaluation process itself being utilized as a learning process to improve and to empower for participating individuals and organizations. Process evaluation is concerned with understanding reasons why an educational intervention works to bring about outcomes – expected or not. An emphasis on process evaluation that asks the questions of what happens, and how and why it happens, highlights the function of educational evaluation for knowledge development similar to any educational research. The article ‘Program evaluation’ (Christie and Fierro, this section) explains the importance of process evaluation for program understanding and program improvement. This is, clearly, echoed in the notion of multiple representations of curriculum – namely, intended, planned, implemented, and achieved curriculum, and their interrelationship for evaluation (Levin, this section). The thinking of multiple representations of curriculum or program and their evaluation have marked the present practice in educational evaluation. As an example, there is evaluation of mathematics-education programs (Cai, this section), evaluation of science-education programs (Berberoğlu, this section), and evaluation of social studies and civic education programs (Grant, this section).

Process evaluation prompts and is also consistent with a system-analysis approach to evaluate school effectiveness at four different – but interrelated – levels: societal or macro (system, nation, or state), institutional or meso (school), instructional (classroom) or micro (classroom), and individual or nano (Levin, this section). For example, PISA operates within the frameworks that require data from the different levels of the educational system. These include the educational system as a whole – that is, the educational institutions and providers of educational services; the classrooms or instructional setting; and the learners themselves. Each level is being investigated for education and learning outputs and outcomes, policy levers, and contexts shaping educational outcomes and antecedents or constraints that contextualize policy (Schleicher, this section). The NAEP High School Transcript Study (HSTS) gathers not only test scores but also information about school practices and how these practices might affect performance outcomes (Schneider, this section). The system-analysis approach integrating outcome evaluation and process evaluation has contributed greatly to interpret observed variation in learning outcomes between students, classrooms, schools, and educational systems. In educational evaluation – to understand what is happening at one level – it is, often, necessary to understand other levels. For example, student-learning outcomes in a given subject matter may be influenced by the teacher’s approach to instruction, the value a

principal places on the subject within the curriculum, the curriculum adopted by the school district, and different familial and community factors (Committee on Scientific Principles for Education Research, 2002; Ni, Chiu, and Cheng, in press).

Theory-driven evaluation that emphasizes process evaluation also makes it possible and more meaningful for meta-evaluation (Wingate, this section) and meta-analysis of educational evaluations (Weiss, 1998). Theory-driven evaluation is imperative for the field to contribute to understanding of the multiplicity of intervening factors operating in the educational systems that effect educational outcomes.

Sustaining Challenges for Future Directions

The five perspectives elaborated above are intended to provide a rough framework showing the new developments in educational evaluation in the last 10–15 years. These new developments – collectively reflected by their contributions – are taking place to meet the need for educational innovations that address social, cultural, and economical changes. Consequently, each of the new developments – such as outcome-based accountability, stakeholder participations, diverse approaches and practices, globalization of educational evaluation, and theory-driven evaluation – is raising a set of new questions and challenges. Some of the substantive issues associated with each of the developments have been identified in the previous parts of the article. In the present segment, the focus is on two basic issues that have serious ramifications for the field of educational evaluation. The first is the problem of generalization which is concerned with the extent to which a conclusion – drawn from specific evaluations – can be generalized to a different situation. The other issue relates to the specific functions of educational evaluation. It has been assumed that description, judgment, and recommendations provide legitimacy to educational evaluation. However, it can be argued that a concise account of relevant facts is the most important function of educational evaluation.

The problem of generalization is particularly acute for educational evaluation. The reason for this is that evaluation is deeply embedded in social and political activity (Cronbach, 1982). Evaluation and research are considered different in terms of the origin of study questions and the purpose for which study information is gathered. Evaluation questions are, often, elicited from program stakeholders whereas research questions are from researcher(s). Evaluation studies are, often, decision oriented, designed to generate information for program improvement and for informing the decisions based on the program under evaluation. Research is, often, not decision oriented but aims to understand the phenomena under investigation and contributes to knowledge development in an area

(see Christie and Fierro, this section). Therefore, some researchers argue that evaluation should be focused on particularization rather than generalization. Differentiating evaluation from research encourages evaluators to be more sensitive to local contexts that may be a constraint to an educational program under evaluation. It also encourages more orientation toward producing evaluation findings that are beneficial for the users. Acknowledging the distinction, however, evaluation or educational evaluation should not be exempt from the requirement of generalization. Conversely, it makes generalization more challenging and having a more critical role in educational evaluation. Overemphasizing the distinction may reduce evaluation or educational evaluation to merely a commodity to be contracted or purchased. Evaluation or educational evaluation has to be concerned with regard to generalization. Without this assurance of integrity, evaluation or educational evaluation will have no legitimacy. It is of the utmost important for knowledge development to inform policy and practice in a substantial and sustaining way. Raz (1999) uses an example of understanding Japanese humor to illustrate the relationship between social dependence of value and universality of value (see quote below):

How can the points about social dependence or creation of value be reconciled with the requirement of intelligibility which leads to the irresistible attraction of universality of value? Granted that we cannot have a thick understanding of the concept “Japanese humor” without familiarity with their society and with instances of their humor, still we cannot recognize their humor for what it is unless we can subsume it under a more general concept, and recognize theirs as an instance of humor. (p. 208)

The example provides a good illustration of the relationship between a general principle and its particulars. On one hand, a particular humor takes its meaning from the situations to which it refers; on the other hand, the particular humor is only illuminated with the general principles governing what makes a humor. The same point can be made with regard to the relationship between particularization and generalization in educational evaluation.

The need for improving generalization of evaluation and evaluation studies is being addressed within the field. For example, many contributors have raised this concern. Robinson and Campbell (this section) suggest that the present teacher-evaluation practice is derived from specific programs that have been *ad hoc*, lacking a robust evidence-based justification, and a robust knowledge basis. Glassman and Glasman (this section) observe that the practices of principal evaluation have been affected by stakeholder involvement. Unfortunately, there is no systematic research on how stakeholders have shaped the nature of principal evaluation and its results. The matter of whether and by what means school inspections contribute to school

improvement has been studied systematically in very few countries (Chapman and Earley, this section). Stufflebeam and Shinkfield (2007) have expressed dissatisfaction that the evaluation theories that prevail at present are mostly prescriptions for practice and have not been systematically examined in empirical studies. King (1998) made the same assessment, stating that the field of evaluation has been based more on theorists' ideas than on systematic research evidence.

The present literature has indicated that there are two groups of evaluation studies, among others, that provide exemplars for improving generalization of educational evaluations – making them more accountable for informing educational policy and practice. The first of these consists of a constellation of evaluation programs that assess effectiveness of similar and ongoing educational programs. There are concerted efforts that allow for the examination of robustness of similar education programs in different circumstances and with different methods. A good example of this is the evaluation of the federally funded early-childhood programs in the United States (Heckman *et al.*, 2009; Reynolds, 2000). On one hand, the implementations of the early-childhood education varied in different states and communities. This made evaluation-based generalizations with regard to its effectiveness difficult to obtain. On the other hand, the assemblage of evaluations on the programs that were carried out in diverse situations provided an excellent opportunity to examine whether or not a given finding about the effects of the programs could be observed over diverse circumstances. Converging evidence was obtained that indicated cognitive advantages for the children participating in the programs tend to disappear approximately 3 years after leaving the programs. However, those children who participated did benefit in terms of increased likelihood of retention in grade school, high school graduation, college education, and employment. The conclusions converging from numerous evaluations of the early-childhood programs have contributed to well-informed educational policy and practice for early-childhood education.

As the institutionalization of data systems is a reality (Baker and Niemi, 1996) at the multiple levels – such as state-assessment systems, national assessment systems (e.g., NEAP), and international assessment systems (e.g., PISA) – educational evaluations can be conducted in a less fragmented but more concerting way to achieve better generalization of evaluation studies. With the data systems as well as the advances in statistical tools (Chatterji; Ma, this section), multiple levels or systematic analysis using classroom and school as the relevant unit are starting to be prevail (Akiba *et al.*, 2007; Tarr *et al.*, 2008). With the powerful data systems and the advanced analysis methods there, whether one has some program theory becomes ever significant to identify new questions and to find

regular and meaningful patterns in social relations (e.g., school, classroom, teacher, family, and community) that produce educational outcomes.

The second group consists of experimental studies into effectiveness of educational programs. Generally, there is understanding that experimental studies present great challenges for conducting educational evaluations (Scriven, 2005). For example, the article 'Methods to evaluate technology' (Bewley, this section) discusses the difficulties with experimentally evaluating effects of technology use on student-learning processes and outcomes. The difficulties are apparent and so are the demands. Understandably, there is pressure for educational evaluations to provide an evidentiary base to inform educational programs or policies for their development, implementation, and refinement. Educational evaluations can be a *post hoc* process – understanding and evaluating an educational intervention afterward. It can also be a planned experiment – testing anticipated outcomes from educational activities. The fact that cooperative learning becomes a standard and widespread teaching procedure in classroom should be attributed to hundreds of experimental studies that verified and established the effectiveness of the educational procedure (Johnson and Johnson, 2009).

The issue of generalization is related to the second issue on the functions of educational evaluation. As the early-childhood education and the cooperative learning examples indicated, external validity is difficult to demonstrate with a single evaluation and has to be accumulated over many replications. Therefore, educational evaluation, in general, can serve the functions of describing what occurs as well as how and why it happens. Other important aspects are judging whether or not what happens meets the expectations and recommendations as to what action should be taken. However – for a single evaluation – it is neither productive nor feasible to include all three. In reality, the most important contribution of an educational evaluation is to provide a description that is as accurate as possible. These descriptions will have to be verified and collaborated with other similar and relevant replications. Then, it will be possible for judgment and for recommendations that are constructive.

Recently, the author and her colleagues were conducting an evaluation on the effects of a reformed mathematics curriculum on teaching and learning in Mainland China (Ni *et al.*, 2009). The results showed that – after accounting for the socioeconomic status (SES) variable – the reform group performed better than the nonreform group on open-ended tasks requiring mathematical explanation. However, the reform group did not perform as well as the nonreform group on measures of mathematical calculations and routine mathematics problem solving. Another finding showed that there was a decrease in the achievement gap in calculations and routine mathematics problem solving for both groups. However, the decrease

was more significant for the nonreform classrooms. The trend was not obvious for both groups on the complex problem-solving tasks. It was concluded that the differentiated patterns of mathematics achievement between the two groups appeared to reflect the relative emphases of the respective curricular. In this sense, the new curriculum was effective in achieving the intended outcome to improve students' competence to solve open-ended tasks. The researchers were then asked to judge whether or not the observed tradeoff was worthwhile, comparing the proficiency and the automaticity in computation skills and the competence in solving nonroutine mathematical problems. However, it was not possible to make a judgment about the matter according to these evaluation results. To understand the tradeoff in theory and to make the judgment about the merits of the tradeoff, among others, three kinds of empirical evidence need to be obtained. The first is concerned with relationship between the different dimensions of mathematics competence. The second requires longitudinal tracking of the development of the different mathematics competences in students receiving the new curriculum. The third kind of evidence needs to look into comparative results involving Chinese students using international assessments. The example suggests that it is feasible for an educational evaluation to make a specific judgment, such as whether or not a specific educational program produces expected results. However, it will be challenging for an evaluation to make a broader assessment – such as whether or not it is worthwhile for a program to gain in some areas at the expense of those in other areas. That would extend beyond the capacity of an educational evaluation to make recommendations for action. Scriven (1995) made an excellent analysis of this dilemma. According to these findings, educational evaluation needs to focus on expertise in the field to describe any given situation and factors that influence the outcome. Based on the careful descriptions of many evaluations, collective efforts can be exercised to compare different evaluation studies and dialogue to identify regular and meaningful patterns of relationships for the service of informing educational policy and practice in a substantial and sustaining way.

In sum, educational evaluation must be an integral part of civil society. The establishment of the importance of evaluation has seen consistent growth and is one that depends on dialog with practitioners in the field as well as between the field and other disciplines and the public. It is the purpose of this section 'Educational Evaluation' to facilitate wider access to the new developments, and also to provide greater understanding for educational professionals and the public – individuals who have a vested interest in education and educational evaluation and thus to help make the field more self-enhancing and socially empowering.

Glossary

Blog – A website on which the author keeps a record or log of whatever he/she wants.

Course-management system – An Internet-based system for organizing and operating a learning and teaching course.

Blended courses – The combinations of face-to-face and online or distributed instruction.

E-learning – Learning utilizing any form of electronic technology or media.

Evaluand – An object of evaluation.

Evaluation – Assessing the merit or worth of an evaluand.

Metaevaluation – Evaluation of evaluations.

Personal-learning environments – The combinations of digital learning resources learners assemble to bring information to them and through which they can communicate with others to improve their own learning.

Stakeholder – A person with interests in the evaluation of an object.

Web analytics – An analysis of how viewers are using a website.

Wiki – A website that allows multiple authors to jointly create the contents.

teaching people of all ages (Wesch, 2007). Multiple participants' innovations with technology-mediated learning require dynamic evaluative inquiry (Allen and Seaman, 2007; WestEd, 2008). Evaluators identify evolving evaluation objects (evaluands) in idiosyncratic combinations, involve stakeholders in prioritizing their values to select from thousands of possible evaluation questions, gather, analyze, and report answers to those questions, and make recommendations for action, while simultaneously meta-evaluating and improving their evaluation activities.

This article employs a flexible evaluation framework (Williams, 2006), exemplified in most articles of this volume and in evaluation literature, to illustrate a way to conduct e-learning evaluations (see **Figure 1**). Consideration of challenges and opportunities facing e-learning participants and evaluators, as educational uses of technologies proliferate, complete the article.

As **Figure 1** illustrates, evaluation involves several activities for reaching judgments by clarifying what should be. This usually entails understanding the evaluation context by consulting with stakeholders to identify evaluands to evaluate, clarify criteria that stakeholders value, and compose questions about the evaluands' nature and performance. Then, evaluators collaborate with stakeholders to determine what is by clarifying methods to effectively answer the questions, and collecting and analyzing associated data. Finally, evaluators and stakeholders juxtapose what should be with what is to judge how well what is meets what should be, make recommendations, and meta-evaluate the entire process and results.

Evaluating E-Learning

Hopeful visions for using new technologies are transforming the nature of learning and possibilities for

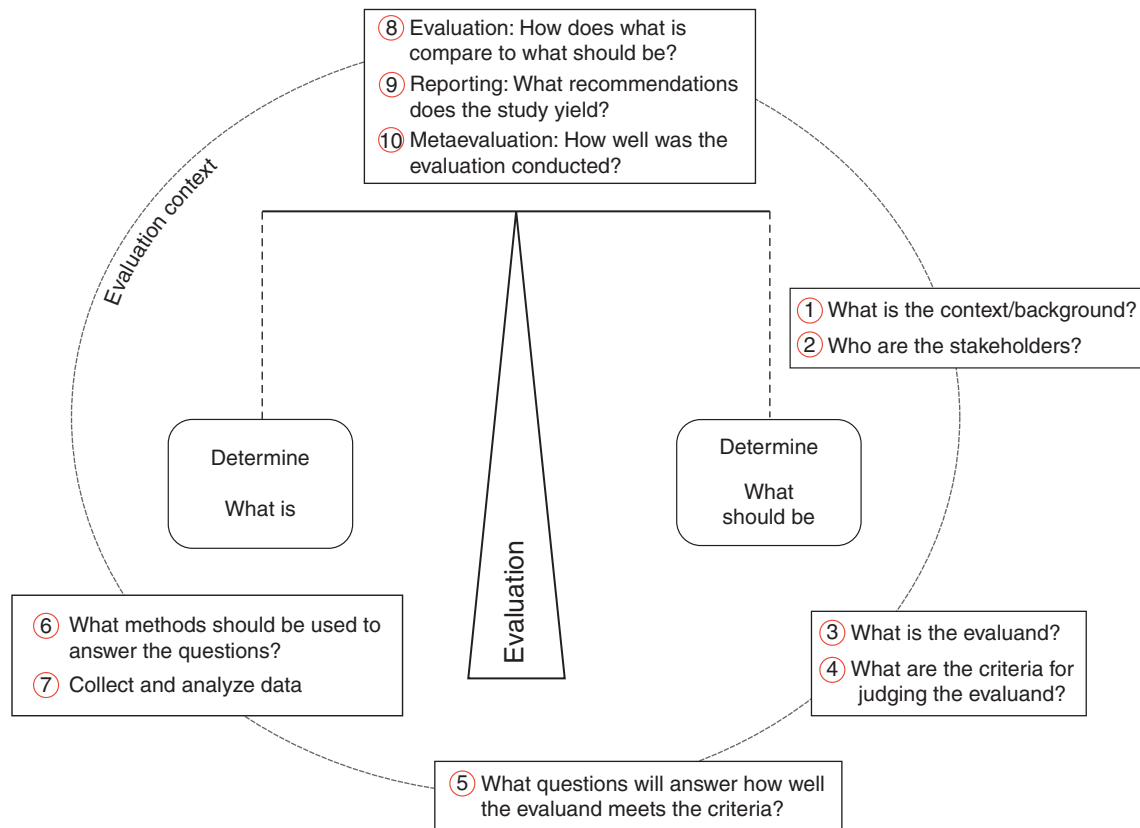

Figure 1 Key components in the evaluation process.

Table 1 Scope, stakeholders, and possible evaluands in an e-learning context

Scope of context	Primary stakeholders	Sample evaluands	Example criteria
Institutional level	Administrators	E-learning initiative Online course offerings E-learning policies	Cost effectiveness Enrolments Completion rates/satisfaction
Program level	Administrators	Distance-learning program	Enrolments Student satisfaction
Course level	Instructor/learners	Online course	Student satisfaction, learning, engagement Student access Resource/tech requirements
Activity level	Instructor/learners	Course activity	Student satisfaction, learning, engagement Participant time involvement

Elements of E-Learning Evaluation

After illustrating how activities summarized in **Figure 1** facilitate evaluation of e-learning experiences and results, an extended case is presented to demonstrate processes for clarifying what should be, describing what is, and comparing them.

Clarifying What Should Be

Clarifying what should be involves identifying context, stakeholders, evaluands, and criteria to generate evaluation questions.

Context

Beginning an e-learning evaluation involves understanding the context and setting the stage for deciding who the stakeholders will be, what evaluands will be studied, and what the criteria for judging the evaluands will be. For example, **Table 1** shows four scope levels that are often considered in e-learning contexts (Graham, 2006). At the institutional and program levels, administrators are often the primary stakeholders, while at the course and activity levels, faculty and learners are often the primary stakeholders.

Context also includes other variables summarized in **Table 2**: The setting for e-learning, the evaluation purpose,

Table 2 Context variables and examples associated with e-learning

Context variables	Examples
Setting	<ul style="list-style-type: none"> • Distance • Face to face • Blend of both
Purpose	<ul style="list-style-type: none"> • Formative (for improvement) • Summative (for judgment)
Who is evaluating?	<ul style="list-style-type: none"> • Learners (internal) • Teachers (internal) • Instructional designers (internal and external) • Administrators (internal and external) • Professional evaluators (internal and external)
Who is responsible for learning?	<ul style="list-style-type: none"> • Learners through personal-learning environments • Learners through institutional learning-management systems under instructor direction
Formality of evaluation	<ul style="list-style-type: none"> • Informal • Formal
Evaluand development stages during which evaluation is being conducted	<ul style="list-style-type: none"> • Before development and implementation • During implementation • After implementation
Evaluability of the evaluand	<ul style="list-style-type: none"> • Stability of the evaluand • Availability of evaluation resources • Availability of guidance from literature • Interest and attention of stakeholders

who is evaluating, who is learning, evaluation formality, the evaluand's stage of development, and evaluability of the evaluand. Diversity of contexts complicates the evaluation of e-learning; however, clarifying contexts involved as part of the evaluation process helps focus selection of stakeholders, possible evaluands or their characteristics, and criteria for judging the evaluands, and simplifies data gathering and interpretation.

The diversity of possible e-learning evaluation contexts is apparent in a review of article titles in the *International Journal on E-Learning*. The October 2008 issue includes articles on online communities, blended learning, students' perceptions of value of online learning, self-regulation by learners, designing and implementing courseware and systems, and many others.

Stakeholders

To clarify what should be, the contextual issues and others discussed below are clarified, usually through

negotiation among stakeholders (those internal to the learning process such as students, teachers, and instructional designers, as well as those who have a more external role, such as some administrators and independent evaluators), as led by both internal and external evaluators. Who are the stakeholders? Who should have a say regarding the quality of e-learning associated with various combinations of technologies, pedagogies, learners, and teachers?

Logically, the most important stakeholders for e-learning are e-learners, ranging from preschool children to university students, to people of all ages participating in social networks and/or learning on their own, to adults participating in corporate-training events. Learners are the ultimate evaluators of the knowledge and learning environments they receive; so e-learning evaluations should take their views, needs, and values into account along with the views of teachers, parents, administrators, educational company owners, government leaders, instructional designers, and others who care about the learners.

In recent years, evaluation theorists have promoted various participatory evaluation approaches (Cousins and Whitmore, 1998) to identify and include values of all people with interests in evaluands, particularly recipients of services, such as learners. Learner participation is especially important in e-learning evaluation because increasingly, there is no designated teacher in many e-learning situations. Learners' values and needs are becoming more essential in evaluations of their learning experiences and outcomes as growing uses of personal-learning environments and Web 2.0 tools suggest should happen. An Internet search on personal-learning environments provides videos and documents exploring how learners are using emerging tools to personalize e-learning.

A growing literature explores the nature of learners as key stakeholders in evaluating e-learning. For example, Clifford (2006) and Ito *et al.* (2008) conducted studies of learners' uses of social media and other technology tools to identify values, habits, learning styles, and characteristics of e-learning stakeholders. Evaluations of e-learning expand this growing literature and invite stakeholders to clarify their idiosyncratic values and evaluands.

Evaluands

What evaluands do stakeholders care most about and how do they define them and the issues associated with them? This is one of the more complicated questions to be answered in clarifying what should be in e-learning. Why? This is because stakeholders often struggle to agree about what the evaluand is in e-learning. **Table 3** lists a range of categories of evaluands often considered in e-learning contexts. The growing literature on the interface between technology, pedagogy, and content knowledge (TPCK) suggests most evaluands are complex combinations

Table 3 Examples of a few evaluands and criteria in diverse e-learning contexts

<i>Categories of evaluands</i>	<i>Example evaluands</i>	<i>Example criteria</i>
Content	Module Materials Course	Quality Accuracy Cost Access
Pedagogy	Pedagogical assumptions Course activities	Student engagement Student satisfaction Student learning
Technology	Course-management systems Production and delivery tools Labs/specialized equipment	Access to technology Student/instructor technology skills Cost of infrastructure Scalability
Instructor/learners	Online teaching/learning knowledge and skills Instructor/students dispositions toward e-learning	Instructor training Instructor/student comfort in online setting
Business model	Independent study model Teacher-led e-learning model Open-learning models Others	Cost effectiveness Enrolments Completion rates/satisfaction Scalability Balance between human and materials interaction

of these and other variables. To evaluate isolated effects of technological or pedagogical interventions does not make sense (Koehler and Mishra, 2008), as the literature on no significant differences due to technology indicates. Technology never operates alone in learners' personal-learning environments or in curriculum-supporting learners (Oblinger and Hawkins, 2006).

Criteria
