7. While a reform design team or other provider of external assistance presumably holds expert knowledge about both the intended changes and the processes of change, the experts on the realities of any given school are the professionals working within that school. Successful improvement efforts both recognize and build from both pools of expertise. The authors of the Rand Change Agent study noted that in schools there was either mutual adaptation between the design team and the in-school professionals or no meaningful change. Reflecting on recent multiyear studies of diverse reform efforts in large urban districts, scholars have referred to the same phenomenon in a more active voice as co-construction of reform. We are aware of no examples of sites in which a local school literally and uncritically adopted a reform *in toto*. Rather, in study after study, teachers and administrators obtained the greatest multiyear effects for their students by becoming active, engaged partners in the definition and conduct of improvement efforts in their schools.
8. LEAs have not received as much attention in research on educational change as have teachers or schools. However, emerging bodies of research suggest that LEAs can have substantial effects on schools' ability to implement any given reform. At the extreme, LEAs can mandate specific reforms, or the discontinuation of any given reform effort. More commonly, LEAs indirectly but clearly signal presence or absence of support for any given school-level reform efforts. Any of the above can be effective at enhancing or discontinuing a change effort.

Sustainability and Fidelity/Reliability

Two additional topics have received much less attention, and hence require a bit more speculation. The first relates to the issue of implementation fidelity/reliability. Since the 'eight-year study' of the 1930s, it has been clear that

those schools that engage in any given reform most fully and uniformly are the most likely to obtain desired changes in student outcomes. This has led to increasing calls from researchers and funders that local educators implement external reforms with high levels of fidelity. Several of the findings from large-scale research noted above probably are associated with success specifically because they improve the fidelity of an innovation. Whole-school efforts, specificity of desired changes, and ongoing professional development are examples of reform components likely to enhance implementation levels and, hence, fidelity.

Clearly without some sort of faculty fidelity to something beyond the *status quo*, school reform cannot happen. However, it is possible that calls for greater emphasis on fidelity to a specific, often abstract reform design are somewhat misdirected. Teachers and principals are not chemical reagents in a beaker. They are adults who have autonomy and agency. They tend to guard those characteristics as part of their perception of being members of a profession. Reforms are, in part, abstractions. By contrast, teachers deal with students in the concrete. No reform provides guidance for every situation students present and teachers face. Hence, teachers and administrators necessarily adapt the reforms they may be attempting to implement. Local professional educators co-construct the daily realities of reforms. These co-constructions will take somewhat different forms in classrooms beside one another and in schools thousands of miles apart.

It is possible that what is needed to achieve strong reform effects is to assist local educators in working with whole-school reform groups in reliably co-constructing reforms. Whereas high fidelity to specific components of a reform may not always be desirable, high reliability in implementing general principles may be.

There is 20 years of research on organizations that must work extremely reliably. Regardless of their place in the larger society, these very different organizations share characteristics that would be very useful in school-reform efforts. Highly reliable organizations (HROs) have a sharp focus on a small number of clear goals, have standard operating procedures, and, at the same time, they honor persons who find flaws in those procedures. They are vigilant to lapses of all sorts. HROs recruit and (re)train constantly, and they insist that efficiency drives do not reduce the reliability with which core tasks are performed. Interestingly, even within narrowly bounded types of organizations, such as air traffic control towers, no two HROs look exactly alike.

Although limited in quantity, extant research on efforts to help schools and districts become more like HROs has yielded promising, sometimes dramatic results. The implication is that school reformers may be well advised to acknowledge and honor local educators in their efforts to implement school-restructuring designs.

Finally, there is limited research on the sustainability of reforms and reform outcomes. If a reform is not going to produce lasting effects, it is probably not worth implementing. Studies of specific reforms tend to document a reform dropout rate, exceeding 50% over any given 5-year period.

Reforms go away for a variety of reasons. They may be viewed as expensive, and district administrators may conclude that they cannot afford them post-start-up funding. Alternately, a core group of teachers may retire or move to positions outside the school. A supportive principal or superintendent may receive a promotion. Often, the reform is replaced by the next great thing. Given such a history, teachers and administrators can and should be excused if they decline to tie their professional reputations and positions to any given reform effort.

On the more optimistic side of the sustainability issue is evidence that when reforms do last, their effects generally increase with time, particularly after the first 4 years. There are two plausible explanations for this. One is that the school or school system has finally, fully learned and integrated the reform, and its effects are most fully evident over the longer span of time. This is clearly true in some cases.

Equally true, the schools and districts most likely to drop a reform, or most likely to drop it first, are the schools and districts that either were unable to mount a credible change effort or, having mounted the effort, did not realize the hoped-for changes in student outcomes. If only the successful continue, then all who continue will appear successful, and the mean effect among the remaining participants will rise.

This later point should not be interpreted as taking anything away from the fact that some schools constitute existence proofs that positive, long-term change is possible.

Implications for Practice

Research on school reform has produced a range of implications for educational practitioners interested in achieving specific goals. The first several might be thought of as a gut check. Before beginning any reform effort, both the local authority and the school should ask themselves several questions: Can a consensus be achieved on a finite number of common goals? Do all concerned understand that the work of change will be much harder than they initially will hope? Do teachers, administrators, and funders possess the will and the resources to support change over several years? Are all willing to go at it hard? Are all willing to examine data on an ongoing basis to determine what fine-tuning is needed? Do they understand that change is resource intensive over time? Over the long haul, are all willing to stick to the change and resist the next new, shiny thing until they have mastered and grown

with the current reform? If the answer to any of the above is 'no' or 'maybe,' then the group should meet and discuss until all understand and agree to what change will require of all participants.

Assuming that the school and district are in agreement on goals and are prepared for the hard work of change, there are several additional implications of research on school change. A school and school district are more likely to succeed in producing overall student gains if they do the following:

1. use a research-proven whole-school reform;
2. work with experienced external-change facilitators;
3. support teachers and administrators in actively co-constructing the reform in their local context – passivity will not produce change;
4. monitor progress constantly – create data/information-rich environments, and use the data at multiple levels to help guide reform efforts; and
5. stick with the reform, and keep refining it over several years.

Implications for Research

Three of the most pressing implications of the above for future research are as follows:

1. *Build on what has come before.* One of the most striking and frustrating phenomena one encounters when reviewing school reform research is the regularity with which new research teams reinvent the wheel. There is a great deal of knowledge and wisdom that has come before, and new teams would be well advised to study it before gathering new data.
2. *Schools and districts are large, complex, multilayered organizations.* School reform researchers should choose methods that match the phenomena under investigation. This almost necessarily calls for mixed methods, multilevel research designs.
3. *In the area of educational reform, studies that only last 1 or two years are not worth doing, and may be misleading.* Given that previous research suggests that implementation takes years – and shifts over years, and given that reform effects seem to grow over time, studies of less than 3 years are likely to yield misleading conclusions, either positive or negative. Scholars would be well advised to plan 5-year (or longer) studies.

Summary

While progress in creating more effective educational reforms and progress in creating quality evaluations of school reform efforts have been equally slow, we know much more today about both the specific requirements

and the processes needed to create more effective-bearing reforms. As a profession, we educators can and should make much better use of the knowledge gained through decades of hard challenging research and practice. It is equally important that we do a better job of rigorously gathering data so that our future efforts can become yet more building blocks for the next generation of teachers, leaders, and educational reformers.

Glossary

Critical theory – A theoretical perspective that provides the descriptive and normative basis for approaches to social inquiry aimed at

decreasing domination, and increasing freedom in all their forms.

Dialogical – Dialogs in which two parties exchange arguments over a central claim.

Ideology – A system of political ideas.

Living theory – Explanations derived from an individual's lived experienced and embodied and expressed in practice and behavior.

Paradigm – An interpretive framework guided by a set of beliefs and feelings about the world, and about how it should be understood, studied and presented.

Participatory research – The perspective that suggests that those formally known as subjects of study should participate in every part of the research process – planning, data collection, analysis, and reporting.

Phenomenology – The study of structures of consciousness as experienced from the first person point of view.

Postmetaphysical – Often associated with Habermas, this philosophical perspective suggests theories of society and communication grounded in the inherent complexities of social interreaction – a plurality of language games, differing modes of power, and the structure of politics at play at any one time.

Pragmatism – A philosophical tradition focusing on the need to trace the practical consequences of a concept or hypothesis.

Primary stakeholders – Those most immediately affected by the issue investigated.

Stakeholder – A person or group having an interest in, or being affected by an issue.

Introduction: Situating Action Research

Action research has recently gained increasing credibility as an approach to research that challenges the prevailing orthodoxies of qualitative and quantitative research. Despite considerable resistance from an academic establishment that has built complex systems of administration and professional reward around the basic assumptions of the traditional paradigms, action research has rapidly created new spaces within the research community. It has moved the boundaries and goalposts of investigation, and provided windows into forms of inquiry and new ways of conceiving what counts as legitimate academic knowledge. As Guba (2007) noted "... there is indeed more in heaven and earth than has been dreamed of in the received philosophy."

Like qualitative research that emerged from relative obscurity in the period from the late 1960s onward to challenge experimentalism as the only acceptable form of research, action research is now increasingly acknowledged as a legitimate approach to investigation. Widely accepted in academic journals, and the subject of many university texts, increasing sales clearly indicate its

growing use in academic courses. Action research has achieved particular acceptance in education, where a wide variety of resources speak of its expanding popularity in teacher education and professional-development programs, and presentations and papers related to action research continue to proliferate in academic journals and conferences.

Action research is particularly attractive to educational practitioners. It enables them to break free from the complex systems and patterns of thought associated with more traditional approaches to inquiry, providing simple and coherent formats that are easily applied to problems and issues within classroom, school and other educational contexts. Whether these processes are sufficiently stable to have generalized use over a broad range of contexts, or whether it is an inherently localized production suited only to a limited context is still subject to debate. What is clear, however, is that the move to action research provides a clear indication of the need for processes of investigation that deliver effective solutions to many of the enduring problems confronting practitioners in educational contexts.

The History of Action Research in Education

The genesis of action research is often attributed to Kurt Lewin, a social scientist who sought constructive solutions to social conflict, particularly in situations when poverty and minority exploitation were predominant issues. His approach to action research (Lewin, 1946, 1948, 1952; Lewin and Lewin, 1942) drew on theories of progressive education from philosophers like Dewey (1938) who saw learning as emerging from processes of inquiry, questioning, and dialog. Lewin was interested in assisting people to learn how to solve their own problems through self-education that would enable them to improve their situation. Lewin presented action research as a cyclical or reiterative process that included fact finding, planning, action, reflection, evaluation, and refinement of the problem.

These types of investigation emerged in a variety of forms in a number of locations and were later applied to education by Stenhouse (1975, 1983) and Elliott (1987, 1990, 1991) in Britain, and Kemmis and McTaggart (1988) in Australia. The general thrust of their activity supported the notion of teacher as researcher, investigation being oriented to issues relevant to everyday classroom practices and problems. These types of development emerged more broadly from the profession's frustrations with research that failed to provide effective solutions to problems of professional practice and more obdurate problems within education systems – equity, class, race, gender, and so on.

Broad dissatisfaction with the inefficacy of the abstract and generalized experimental and quasi-experimental research that originally dominated university investigations of the period following World War II led to the emergence of qualitative research. This signaled a movement toward more localized research efforts typified by ongoing developments within qualitative research/naturalistic inquiry. The reason, suggested Guba (2007), lay in “the gap between general laws and specific applications; such laws can have, at best, only probabilistic implications for specific cases. The fact, for example, that 80% of patients presenting a given set of symptoms are likely to have lung cancer does not imply that a particular patient with those symptoms ought to immediately be rushed to surgery.” “It ought to be apparent by now,” he went on to say, “that generalized one-size-fits-all solutions do not work. . . . Without intimate knowledge of local context, one cannot hope to devise solutions to local problems. *All* problems are de facto local; inquiry must be decentralized to the local context” (p. xi).

While qualitative research initially showed promise of illuminating critical features and dynamics of the educational world, it ultimately failed to provide the means to develop effective solutions to educational issues that had dogged the educational establishment for many decades. The movement from qualitative to action research was at first slow, but is well chronicled in a number of texts and papers (e.g., Adelman, 1993; Foshay, 1994; King and Lonquist, 1992; McTaggart, 1991). Noffke’s (1997) review of this literature revealed a burgeoning field, and since that time a veritable explosion of activity has seen action research become an increasingly visible entity within educational research. Whether this movement signals the means to make headway against those issues and problems is yet to be realized, although there are signs that in localized contexts, rigorously applied action-research processes often produce effective outcomes that resolve the issues or problems on which investigation has focused.

Defining Action Research

Definitions of action research differ considerably, with writers responding variously to the diverse contexts, histories, and issues that provide the boundaries of their experiences and perspectives. Reason and Bradbury (2008) in the *Handbook of Action Research* define action research as:

... a participatory process concerned with developing practical knowing in the pursuit of worthwhile human purposes. It seeks to bring together action and reflection, theory and practice, in participation with others, in the pursuit of practical solutions to issues of pressing concern to people, and more generally the flourishing of

individual persons and their communities” (Reason and Bradbury, 2008: 4).

In education, action research has been defined as:

- ... a systematic approach to investigation that enables people to find effective solutions to problems they confront in their everyday lives (Stringer, 2007: 1).
- ... any systematic inquiry conducted by teacher researchers, principals, school counsellors, or other stakeholders in the teaching/learning environments to gather information about how their particular schools operate, how they teach, and how well their students learn (Mills, 2007: 5).
- ... a form of collective, self-reflective enquiry undertaken by participants in social situations in order to improve the rationality and justice of their own social or educational practices, as well as their understanding of these practices and the situations in which these practices are carried out (Kemmis and McTaggart, 1988: 6).

The diversity of definitions can clearly be attributed to the contexts in which its various practitioners worked, the diverse processes used, and the different types of outcomes they sought. As is evident below, differing theoretical and methodological orientations are often associated with the different distinctive purposes to be achieved. Although common threads permeate these definitions, the most evident being the pragmatic purposes to be attained through systematic investigation, there is even more variation in the enactment of these definitions. As becomes evident in the following section, philosophical and political orientations create wide disparities in the way action research is both conceptualized and practiced.

Orientations to Action Research

For some, action research is a purely pragmatic activity that focuses primarily on teacher practices, with classroom instruction and student performance outcomes being the major purpose of engaging action research (e.g., Mills, 2007; Koshy, 2005; Holly *et al.*, 2008; Baumfield *et al.*, 2008). The methods reflect an extension of commonly accepted classroom teaching practices, wherein teachers choose a promising practice that might enhance student learning. These are then implemented to see if they achieve the desired outcomes – often improved performance scores. This approach is particularly popular in preservice teacher education, since it requires little theoretical or methodological sophistication and links easily to readymade lessons for novice teachers.

This family of approaches tends to be modeled on first-person investigations (Reason and Bradbury, 2007), practitioners contending with no perspectives other than there

own, except for the voices inherent in the associated academic or professional literature. Clearly, this mode of operation reflects directive approaches to classroom instruction, or orientations to research that valorize the literature review. Models associated with this orientation range from the relatively simple plan–act–reflect–evaluate (an often simplistic application of a model suggested by Carr and Kemmis, 1986), to more sophisticated versions that include feedback loops (Mills, 2007). The bipolarity of this orientation to action research is evidenced in the vexed question of many researchers whether to attend the ‘Action Research’ special interest group or the ‘Teacher Researcher’ special interest group, which are usually scheduled at the same time at annual meetings of the American Educational Research Association.

These more pragmatic forms of action research differ considerably from the more ideologically driven approaches developed by Kemmis and his associates at Deakin University (Carr and Kemmis, 1986; Kemmis and McTaggart, 1988, 2005). Grounded in the critical theory of Jurgen Habermas, their work evolved to present a participatory, critical approach to action research that seeks to take into account many of the agendas emerging from recent scholarship in qualitative research. It incorporates elements of the work of Lewin (1952) that involves participants collectively in the process of investigation, Stenhouse’s (1975) notion of teacher as researcher, and Schon’s (1983, 1987, 1991) reflective practitioner (Kemmis, 2008).

Kemmis (2008) critiques much current educational action research as containing naive views that truth can be apprehended by knowing subjects, alluding to the common view that expertise derived from professional training can provide sufficient understanding to solve workplace problems. He applies a Habermasian post-metaphysical philosophy in which truth becomes manifest only through exploration in communicative action, where participants arrive at intersubjective agreement, mutual understanding, and consensus as the basis for practical action. This clearly postmodern view casts doubt on the ability of the master texts of government and other centralizing agencies to organize decisive unitary action because of the contested interactions that operate at all levels of these systems.

Kemmis therefore suggests the need for action research to work not just on self-reflections and realizations of individuals, or on the operation of organizations and institutions, “but in the interstices between people and organizations, and across boundaries between life-worlds and systems” (p. 123). His definition of action research includes “research undertaken collectively by participants in social practice to achieve historical self-consciousness . . .” (p. 135), a praxis that is, as morally informed, committed, action-oriented, and informed by tradition. The focus is therefore on collective deliberation aimed at shared self-understanding about particulars of a practical situation.

This approach to investigation research clearly has much in common with that presented by Stringer (2007, 2008) whose suggests a phenomenologically oriented participatory process grounded in a methodology that takes into account the sensitivities emerging from postmodern, critical, and feminist scholarship. Taking a more pragmatic stance, Stringer suggests that effective and sustainable action can only emerge from processes that incorporate the voices of all stakeholders, focusing particularly on primary stakeholders as the foundational text on which ongoing participatory processes of investigation are grounded. This orientation, suggests Stringer, provides the context by which democratic, empowering practices emerge as a natural consequence of the application of action research to the knowledge-production process, thus breaking down the ability of power elites to impose their definitions of the situation (Foucault, 1972). Like Kemmis, however, Stringer grounds his research in processes by which interacting individuals are able to construct mutual understanding and consensus as the basis for practical action, the pragmatism of Rorty (1981, 1989) therefore lying clearly in the background. Stringer suggests that social change emerges not from application of predetermined political agendas, but by the democratic operation of participatory processes that enable the voices of the less powerful to change the actions, procedures, and operational structures of organizations and institutions that act as stakeholding entities within the research process. Stringer is affected by his long experience working alongside Australia’s marginalized Aboriginal peoples in community and organizational contexts, a position from which he constantly challenges the master texts of the academic, political, and organizational world.

Although both Stringer and Kemmis relate their work to critical theory, they differ considerably in orientation from the social activist approaches to action research presented by adherents to participatory action research (PAR) who take a more conflictual, confrontative approach to action research. Based on a Marxian or neo-Marxian perspective, PAR advocates emerge from traditions of social activism grounded in historical political struggles common to the contexts class and union struggles or in the exploitation and disempowerment experienced by many people in developing nations. The work of Friere (1970, 1998a, 1998b) often provides an orientation to this perspective, but activist scholars (Fals Borda, 1979; Rahman, 2008; Fals Borda and Rahman, 1991) directly engage an approach to action research that consciously and openly challenges the structures and social processes sustaining the interests of power elites.

Within education, Kincheloe and McLaren (2005) provide examples of this theoretical orientation, although its application to action research also is exemplified in the work of Brydon-Miller *et al.* (2004) whose primary focus is on interrogation of systems of power and privilege within

social, organizational, and institutional environments. In a similar voice, Fine and Torre (2008) present an activist approach to action research that focuses on questions of audience, product, and provocation. Working with and from the perspectives of those with least power, they seek products that will most effectively provoke action leading to social change, or changes within a system. They seek to redress injustices through interrogating the operation of those systems, reflecting a confrontational and overtly political orientation that reflects much political life in the Americas. Typical of those who work within this genre, Fine and Torre therefore struggle for social justice in institutions with deeply entrenched operational systems that do nothing to change the social structures from which troubles and crises emanate. They quote Bordieu (1998) who speaks of "... a crisis of politics ... [in which we encounter] ... despair at the failure of the state as guardian of the public interest." The focus of PAR-oriented action research is therefore on an activist rather than dialogical critical theory, oriented to social organizing within unions and collectives, with the intent of interrogating, challenging, and disrupting the operation of institutional systems.

A more reflective approach to investigation is presented by Whitehead and McNiff (2006) who base action research on 'living theory' derived from people's lived experience. They distinguish the explanations of action researchers from the general explanations of propositional theory associated with the social and behavioral sciences. Living theory is that which individuals generate to explain educational influences in their own experience, and is grounded in a flow of life-affirming energy and relationally dynamic awareness that give meaning and purpose to the lives of individuals. The primary purpose of exploring living theory is to develop forms of understanding that illuminate features of educational life or generate ideas to improve teaching practices.

These differing approaches are encapsulated in the recent release of the *Handbook of Educational Action Research* (Noffke and Somekh, 2009). This presents a rich overview of the different traditions of action research, describing the diverse rationales and practices applied in educational settings, and broadly differentiating them according to professional, personal and political orientations inherent in the educational action research literature.

Applications of Action Research in Educational Settings

The dramatic increase in publications related to educational action research is evidenced by the wide range of texts now available. An incomplete list, covering a variety of approaches to action research includes authors from Britain, the United States, and Australia. Texts that focus

on the use of action research to improve teacher practices and/or student outcomes include those by Johnson (2002, 2007), Koshy (2005), Mertler (2005), Calhoun (1994), Brown and Dowling (1998), and Burnaford *et al.* (2001). In the same vein, Meyers and Rust (2003) and McNiff and Whitehead (2006) describe how teachers can use action research to engage classroom issues, formulate professional-development programs, and develop effective instructional practices.

Texts that focus on broader curriculum, ethical and legal issues in school settings include those by Holly *et al.* (2008), Armstrong (2004), Bray *et al.* (2000), Tomai (2003), Anderson, *et al.* (2007), and Somekh (2005). Phillips and Carr (2006) further extend the array of applications by describing how action research can increase the formation of professional identity for preservice teacher-education students, and Mclean *et al.* (2005) reveal the way teachers and administrators can employ it to find solutions to school problems.

Sagor (2004) uses action research for classroom improvement while Glanz (2003) and Hendricks (2008) suggest how it might be applied to school improvement. Some of this type of literature is clearly directed to educational and social change (O'Hanlon, 2003; Brown and Jones, 2002; Berge and Ve, 2000; Atweh *et al.*, 2005; and Christiansen *et al.*, 1997). Pedraza and Rivera (2005) likewise focus on school reform through educational research within Latino communities. A number of texts focus on specific areas of educational life – English-language teaching (Burns, 1999; Wallace, 1998), Teachers of English to Speakers of Other Languages (TESOL) (Edge, 2000) media within school libraries Sykes (2002), educational policy (Hollingsworth, 1997; McTaggart, 1997; Caro-Bruce *et al.*, 2007; Pedraza and Rivera, 2005; Ladson-Billings and Tate, 2006; Cammarota and Fine, 2008), Black Education (King, 2005), teacher education (Kitchen and Stevens, 2008), and educational leadership (James *et al.*, 2007).

These citations represent but a small proportion of the now voluminous literature featuring applications of action research to a whole range of educational contexts, endeavors, populations, and professional purposes. Most journals that focus on qualitative research in education incorporate action-research studies and, as becomes evident below, the dramatic increase in relevant websites further extends the range of this increasingly popular methodology.

Representation in Educational Action Research: Theater, the Arts, and Media

This diversity of literature reflects changes in all facets of educational research, requiring research facilitators and participants to take seriously the movements in qualitative research that evolve from questions of representation (Denzin, 1997, 2005). The participatory impetus common

to many action researchers has impelled them to find appropriate and effective ways of communicating both the processes and outcomes of action research projects to their diverse stakeholders and audiences. Academic journals and texts that have been the major vehicle for communicating research outcomes are now complemented by diverse formats that act for this purpose. Thus, we find theater (Guhathakurta, 2008), music, art, poetry, role play, video, and multimedia presentations providing powerful and effective means for transmitting the major messages emerging from action-research processes in educational settings (Stringer, 2008, Jack Whitehead's Web Page).

Whitehead (2009) focuses particularly on multimedia presentations and representations incorporating visual narratives that provide the means to communicate meanings not possible through printed texts. This approach to research is particularly significant as it opens up possibilities to incorporate and communicate voices that have traditionally been silenced by the text-based reports. The possibilities of including voices of parents, students, marginalized groups, and others are considerably enhanced by the ability to provide visual and aural narratives in a variety of creative forms. These movements away from purely textual modes of representation reflect an ideological position that challenges the right on an academic elite to control the processes of knowledge production. They also signal an ideological position that acknowledges the diverse ways of knowing required to give voice to, or represent the perspective of the disparate groups participating in an action research project (Heron and Reason, 2008; Kowlaski, *et al.*, 2008).

Website Resources

The desire to represent and communicate knowledge in diverse forms is facilitated by the burgeoning impact of electronic media, a continually expanding number of sites and resources providing access to information related to educational action research. A small sample of sites that have general relevance to action research in education includes sites for the Centre for Action Research in Professional Practice at the University of Bath, AR Expeditions, and the *Action Research Journal*. These types of sites provide a broad range of resources, comprising articles describing action-research projects and strategies for conducting action research. Other general sites include Action Research Resources that provides an online journal, access to an online course, useful papers, and other general resources, and Action Research at Queen's University that supplies links to programs, conferences, other action-research sites and resources, publications, and reports. Action Research on the Web Help (AROWHELP) provides a useful set of resources, including journals and links for teacher researchers. Similar resources can be accessed at the Action Research Page

from the University of Colorado at Denver School of Education, Jack Whitehead's Home Page that offers a wide range of offerings especially pertinent to schools and education, including examples of action-research theses, and Research for Action (RFA) the site of a non-profit organization engaged in educational research and reform to improve educational opportunities and outcomes for all students. These general resources are complemented by many others, including AROW (Action Research Open Web), and Links2Go: Action Research.

Sites relevant to teacher action research have recently proliferated and the following providing but a small sample of the type of resources available:

1. What is Teacher Action Research? Presents guidelines for teacher researchers.
2. Action Research Network provides resources and links for teacher researchers.
3. Action Research Rochester Teacher Centre Teacher Research Program provides a variety of useful resources for teacher researchers
4. Action Research Overview presents resources for teacher researchers that are oriented toward the development of a democratic, student-oriented learning community for improving teaching and learning for all.
5. Teacher Research (Action Research Resources) lists magazine and journal articles about action research, some of which are presented in full text form.

More specialized sites are also available:

1. Science Education Action Research provides information about instructional processes and teaching/learning materials for science education.
2. Early Childhood Education presents information about the use of action research in early-childhood education.
3. School Improvement describes how a district instructional leadership team used action research to conduct a 2-year study of three aspects of the district strategic plan.
4. School Renewal describes how a consortium of schools used action research processes as a framework for school renewal.
5. Action Research Listserv (AELACTION): Action Research in Schools and Classrooms describes five action research projects that show how participants select a focus, choose data collection methods, and reflect on findings.
6. An Action Research Module describes action research in primary and secondary schools.

While many of these sites are relatively stable, the general picture is one of a quantum foam of sites, some appearing and disappearing randomly, according to fluctuations in personnel, funding, and priorities at the institutions and organizations responsible for their maintenance.

Nevertheless, websites now provide what is rapidly becoming a major source of information about the trajectory and operation of action research in education.

Action Research in Higher Education

With the spectacular growth of action research as an approach to investigation that is superficially appealing to many researchers and professional practitioners, it is clear that it would suffer the pains of unsustainable growth. Many of the texts and projects that now emerge in the literature are not well grounded in any sense, but have been enacted within the common-sense worldviews of naive practitioners, or traditional researchers who merely impose their own frameworks of inquiry onto what is essentially quite a different approach to investigation. These become embedded in texts and related university programs and take on a life of their own.

Levin (2008) takes task with the superficiality of much of this research, and outlines the skills and knowledge needed by action researchers in order to ensure rigorous and effective implementation of this approach to inquiry. He suggests that practitioners need to develop the ability to support involvement in actions as well as the capability to critically reflect on process and outcomes of action research. He identifies the proficiency to work with social change to solve participants' problems, the skill to sustain collaborative learning processes, and the competencies required to effectively communicate the outcomes of a research process. These, he suggests, demand development of a broader spectrum of capacities than those required of more traditional un-involved approaches to research, with concurrent need to incorporate them into professional-development processes that are an integral part of higher education programs.

This theme is part of a wider call for reform of universities to provide them with the capacity to take advantage of developments in research methodologies and develop practical and enduring solutions to seemingly intractable social problems. (Levin and Greenwood, 2008; Sarason, 1990). Levin (2008: 211) suggest action research is one of the means to overcome the disconnection between the university and the public good, providing a "knowledge generation that is intrinsically capable of producing public goods through concrete and practical problem-solving..." (2008, p. 211) and that this may be achieved by using action research processes to restructure the teaching and research role of universities.

International Educational Action Research

Although this review speaks mainly to English-speaking countries, educational action research has spread widely

across the world and is practiced in countries as diverse as Scandinavia, Greece, Mexico, China, Korea, Japan, Thailand, Singapore, India, and others in Latin America. It is likely that activity in these countries will, because of social and cultural differences, challenge many of the orthodoxies of action research, and bring to question some of the underlying issues that sit comfortably beneath the surface of English-speaking countries. This has already been signaled in previous sectors of this article, where the revolutionary impulse embedded in the history of some South American countries has spawned a strongly critical approach to action research. It is likely that the Confucian traditions embedded in Chinese contexts (Sung-Chan *et al.*, 2008) and traditional structures of authority in tribal settings (Kirk, 2008) will likewise bring to question the egalitarian and collaborative perspectives common to many adherents to action research. The continued spread of action research across the globe is sure to both enrich and enhance the development of the genre.

Conclusion

Although there is dispute within the field about the nature of action research – whether it is essentially qualitative, can be quantitative, or both – its emergence has served to spawn rich and enlightening debate that pushes the academic world to clarify the nature, purposes, methods, and outcomes of forms of investigation that wish to be recognized as legitimate research. Action research enables academic and professional researchers to enhance their practice by engaging research processes that are constrained by the strictures and rigidities of experimental method, or perplexed by the complexity of multi-voiced narratives emanating from the postmodern turn in qualitative research. To use a cosmic metaphor, is it possible that the inflating and undifferentiated universe of perspectives of early big-bang postmodernism might be brought by action research to a more ordered accumulation of matter that forms more stable systems of thought? What is clear, however, is that action research continues to emerge as a significant research entity in education, providing the means to engage in rigorous and systematic inquiry that provides practical solutions to many educational problems.

Classroom Ethnography

F Erickson, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

It is necessary to put some boundaries around the notion of classroom ethnography. As qualitative, narratively descriptive studies of teaching and of everyday life in classrooms developed in the late 1960s and early 1970s, some researchers referred to any such studies as ethnography. That is too broad a characterization – it blurs some important distinctions between ethnography and other forms of qualitative inquiry. On the other hand, a rigidly canonical definition of classroom ethnography could be too narrow – it might rule as out-of-bounds studies that were ethnographic in spirit but not in form. That would be easy to do, since the term ethnography, as applied to classroom research, is a metaphoric characterization rather than a literal one. Classroom ethnography does not correspond exactly to the classical methods and content of general ethnography. Yet classroom research that is ethnographic in intent bears certain family resemblances to general ethnography. We hope to make clear here what makes classroom ethnography ethnographic, and to present and discuss some key examples of classroom studies that have been undertaken along ethnographic lines. Another way to say this is that ethnography, as employed in classroom research, is not so much a set of techniques or methods as it is a perspective, a particular intellectual stance (see the discussion of Wolcott (2008: 67–89) on ethnography as a way of seeing). Accordingly, we need to consider the intellectual history out of which the perspective and stance of ethnography has developed.

Origins of General Ethnography

The word ethnography was invented in the late nineteenth century as a new term based on the combination of two Greek words: *graphein*, the verb for to write, and *ethnoi*, a plural noun for the nations – the others. Liddell and Scott's *Greek Lexicon* defines the singular noun *ethnos* as "A number of people accustomed to live together, a company, a body of men." But this definition slides by a distinction that makes a difference. For the ancient Greeks, *ethnoi* were not just groupings of people – in whatever scale of grouping one might want to consider – they were the groupings of people who were not Greek. *Ethnoi* was the contrast term for *'ellenoi*. Hellenes were referred to as we and *ethnoi* were referred to as they – Thracians, Scythians, Phrygians, Persians, Etruscans, Egyptians, and Mesopotamians. The Greeks

were more than a little xenophobic, so that *ethnoi* carries pejorative implications. To see the force of this, we can consider that in the Greek translation of the Hebrew Scriptures the Hebrew term for them – *goyim* – was translated as *ethnoi*, and in modern as in ancient Hebrew the term *goy* is not a compliment. All this is to say that the most accurate definition of the term ethnography, given its etymology and its initial use in the nineteenth century to refer to descriptive accounts of the lifeways of non-Western people, is "writing about other people."

Another term that became current in the late nineteenth century was ethnology. This means the comparative study of the meanings of differing patterns of organization and custom across differing human groups. Ethnology looks across separate ethnographic case studies of particular human groups for similarities and differences across the groups. Descriptive data from ethnography thus becomes the grist for the analytic mills of ethnology. Ethnography is always conducted with a comparative frame around it – the assumption is that what is being seen is not simply natural but arbitrary – that local lifeways are constructed. Each separate society and its lifeways are considered against the backdrop of comparison with all other human societies, known from contemporary research and from archeology, history, and prehistory.

In the ancient world Herodotus, the Greek scholar writing in the fifth century BCE, had interests that were ethnographic and ethnological as well as historical. Writing in the second century CE, the Greek skeptical philosopher Sextus Empiricus conducted a cross-cultural survey of morality, showing that what was considered right in one society was considered wrong in others. He worked from the accounts of travelers, and these continued to provide the primary basis for comparative knowledge about human lifeways until the late nineteenth century.

Ethnography claimed to be more thorough and comprehensive in its description than had been the reports previously written by travelers, soldiers, and colonial officers. Perhaps the first monograph of the kind that would become modern ethnography comes from urban sociology. DuBois (1899) conducted a study of a particular census tract in Philadelphia which was then the primary neighborhood of residence for African-Americans in the city. His report, titled *The Negro in Philadelphia*, combined demographic data, area maps, recent community history, and surveys of local institutions and community groups, with some descriptive accounts of the conduct of daily life in the neighborhood. His purpose in writing what can be

considered the first ethnography was to make visible the lives – and the orderliness in those lives – of people who had been heretofore invisible. A similar purpose and descriptive approach, combining demography and health statistics with narrative accounts, was taken in the reports of working-class life in East London that were prepared in the 1890s by Charles Booth, together with Beatrice and Sidney Webb (see Booth, 1891). Even more emphasis on narrative description was found in *How the Other Half Lives*, an account of the everyday life of immigrants on the lower East Side of New York City, written by the journalist Jacob Riis and illustrated with photographs (Riis, 1890). All these authors were social reformers. They were not simply producing description for its own sake – they were describing in order to advocate and inform social change.

Although their descriptions were not value neutral, these early practitioners of what can be called ethnography did not claim to be describing everyday life from the points of view of those who lived it. Their descriptions, in other words, were conducted from an etic point of view – based on a descriptive language of facts that were presented as self-evidently accurate and objective, behaviorally. They did not claim to be identifying behavioral differences that made a difference for subjective meaning among the people whose lives they were describing, that is, they did not claim that their descriptions had emic epistemological status. The interpretive significance of certain behaviors for everyday meaning, as Geertz (1973: 6) says what distinguishes an eye blink from a wink, was not what they were aiming at.

To portray social action (as wink) rather than behavior (as eye blink) – that is, to describe the conduct of everyday life in ways that make contact with the subjective orientations and meaning perspectives of those whose conduct is being reported – is the fundamental shift in interpretive (hermeneutical) stance within ethnography that was claimed to have been accomplished by Malinowski (1922) in his monograph *Argonauts of the Western Pacific*. He said that ethnographic description should not only be factually accurate, but that it should represent “the native’s point of view, his relation to life, to realize his vision of his world” (Malinowski 1922: 25). Malinowski, who was Polish, began fieldwork in the Trobriand Islands in 1914 and was then interned by the British colonial authorities because they suspected he might be a spy. Forced to remain in the Trobriands for the next 4 years, Malinowski later made a virtue of necessity and claimed that his long-term fieldwork and knowledge of the local language enabled him to write a report that not only encompassed the system of everyday life in its entirety but which accurately represented nuances of local meaning in its daily conduct. As people would say later, his descriptive reporting had emic validity, or interpretive validity. After Malinowski, this became a hallmark of ethnography in anthropology – reporting whose descriptions made contact with the meaning perspectives of those whose daily actions were being described. (This aim is never

fully realizable. The ethnographer can never completely discover or communicate the vision of the world as it is held by the people he or she studies – nor is there necessarily a single vision shared identically among those that are studied. However, approximating the meaning perspectives of those studied is a defining intention in ethnographic work.)

To conclude this brief overview of general ethnography, here is a description of ethnography by the contemporary anthropologist Conklin (1968: 172): “[ethnographic data] derive ultimately from the direct observation of customary behavior in particular societies. Making, reporting, and evaluating such observations are the tasks of ethnography . . . [An ethnography] requires a long period of intimate study and residence in a small, well-defined community, knowledge of the spoken language, and the employment of a wide range of observational techniques including prolonged face-to-face contacts with members of the local group, direct participation in some of that group’s activities, and a greater emphasis on intensive work with informants than on the use of documentary or survey data.” More abstractly Conklin said in another place, “an adequate ethnography is here considered to include the culturally significant arrangement of productive statements about the relevant relationships obtaining among locally defined categories and contexts (of objects and events) within a given social matrix. These . . . should comprise, essentially, a cultural grammar.” (Conklin, 1964: 25). An even more modern definition of ethnography would be that it considers the setting that is studied as a local community of practice and identifies the full range of variation in practices that occur there, within the full range of culturally significant situations or activity types, considering the meaning perspectives that underlie the conduct of the cultural practices that take place (see also the discussion in Anderson-Levitt, 2006).

Classroom Ethnography

One of the chief differences between classroom ethnography and classic general ethnography is that classroom ethnography is usually done by researchers who have themselves spent time there as children. This is what can be called domestic ethnography in contrast to exotic ethnography. Classic general ethnography was done by researchers who went to places with which they were unfamiliar – either to village groupings or tribal groupings of so-called primitive people in the colonies ruled by Western empires or to slums inhabited by poor people in large European or American cities. The aim was to make visible the lifeways of people who were literally off the map and to communicate this portrayal to audiences in polite Western society generally and in academia more specifically.

The core task of exotic ethnography, then, is to make the strange and unknown familiar and intelligible. This is

very different from a study of a school classroom that is similar to those previously attended by the ethnographic researcher and also by the researcher's readers. In such domestic ethnography, the core task for the researcher as a fieldworker – and ultimately for the researcher's audience – is to make the familiar strange, and in so doing to make habitual actions visible. The reason to do ethnographic case studies of familiar places like classrooms is that they are too familiar for us to understand at first glance – habit makes daily practice partially and sometimes wholly invisible to its practitioners – thus we need to strangify the familiar in order to see it. Marx said that for scholarly inquiry “the problem is not to understand the world but to change it.” Yet we must be able to see daily practices before we can decide whether or not to change them. The critical inquiry that is inherent in domestic ethnography means that we study everyday practices with possible change in mind, yet we withhold judgment on changing things until we have made a detailed and comprehensive description of the everyday practices themselves. (this point is discussed in the Conclusion section).

It was said at the outset that the connections were not direct between classic general ethnography – portraying the whole way of life of a naturally occurring local grouping of people, with research typically being done by an outsider. Classroom ethnography portrays a topic-focused account of some aspects of a particular institutional setting in which none of the participants live their entire lives, with research typically being done by someone who, if not exactly an insider, still knows much about the setting, including knowledge that comes from prior life experience in similar settings. Having reviewed principal characteristics of general ethnography it is now appropriate to summarize key aspects of classroom research that might be ethnographic, bearing family resemblance to general ethnography if not one-to-one correspondence with it.

We want to present a deliberately generous definition – one that would include many studies although it would exclude some. A classroom study that was ethnographic in approach would have the following characteristics:

1. Long-term, close observation of and participation by the researcher in routinely recurring daily activities.
2. Consideration of the setting, both during fieldwork and in reporting, as a local ecosystem of relations of simultaneous and mutual influence among differing aspects or components.
3. Identification of the total cast of characters in the setting, the variation that obtains locally in ways of enacting their roles, and the structured relationships of power and authority in relation to one another (a portrayal of the overall social organization, formal and informal).
4. Identification of the full range of activities and social situations that take place in the setting (with special emphasis on the spatial and temporal location and

organization of each activity as well as on the culturally significant practices, verbal and nonverbal, of the various participants in those activities).

5. Identification of the meaning perspectives that are entailed in the conduct of the everyday practices that occur.

(Implicit and explicit beliefs, values, and identities, including local ontologies and epistemologies. These are systems of belief about what is real in the world that, in a classroom, take the place of a folk religious world-view – what truly exists, what is right and wrong, and how we can know that, what is knowledge, what are learners, what is learning, what is evidence of learning, and basic postulates such as “order must be established before learning can take place.”)

Unlike a general ethnography, a classroom ethnography would not include description of the practices by which subsistence is maintained and economic relations are conducted, just as there would be no literal description of a legal system or of folk medicine. Yet an ethnographic classroom study might document the exchange of goods in a symbolic economy (student effort as exchanged for classroom rewards such as grades and teacher regard), local notions of fairness and due process, and local notions of and standards for physical, emotional, and intellectual health and growth. (For an earlier discussion along these lines, see Erickson, 1973/1984.)

Given the emphasis on holism in general ethnography, an ethnographic classroom study might most appropriately be done in early grades classrooms, where teacher and students participate together across an entire day, in a variety of activity settings, confronting various subject matters – conditions that are more analogous to the intimacy of acquaintance and commonality of horizon in daily life that are found in a naturally occurring small community. In middle school, high school, and college classrooms, where only one subject is taught and the students meet as a class for a single instructional period and then move on to other classrooms, the analogy with daily life in a small community such as a village is more loose, and it may be less appropriate to consider such classrooms as settings for study that is ethnographic in spirit. Still there could be a family resemblance with ethnography in such settings.

In our judgment, approaches to classroom study that would not be ethnographic would include the following:

1. Studies of the formal subject matter being taught that do not include the hidden curriculum that accompanies subject matter instruction.

(When math or reading or any other particular subject matter is being taught, so are assumptions about the nature of knowledge and of knowers, gender, racial, ethnic, and language identity in relation to learning subject matter, power relationships with the teacher, relative privilege differences among students.)

2. Studies of relations between the teacher(s) and students that consider those social identity categories as unitary and fixed, rather than as multidimensional and in dynamic ecological relationship.

(Usually there is more than one kind of student in a class – various student characters – and more than one kind of way of enacting being the teacher. Moreover, power relations are reflexively related – teachers do not simply control students through classroom management – students push back, and upon occasion it is students who manage the teacher rather than vice versa.)

3. Studies conducted short-term – a 2-week – observational study, let alone a single class period's or a single school day's observation, would not be ethnographic.

(One might prepare a narrative descriptive account from such drive-by ethnography but genuinely ethnographic work presumes that local custom – local cultural practices – are nuanced and locally distinctive and that such subtleties in the organization of the conduct of everyday life in a local setting require repeated learning attempts by the fieldworker – repeated visits across substantial strips of time – in order to answer such questions as “What is the actual full range of different ways of being a student in this particular classroom?”

This is all the more necessary when the observer has surface familiarity with the classroom and thus needs time to make the familiar strange and visible.)

Let us consider a few illustrative examples of classroom ethnography, early and current. First, two case studies conducted in the early 1950s by George Spindler and published later. The first case study is of a fifth-grade classroom whose teacher was given the pseudonym Roger Harker (Spindler and Spindler, 1982). Spindler's description highlighted differences between formal and informal social organization in the classroom. He found that students who were doing well academically were all seated on one side of the room, while students who were not doing so well were all seated on the other side – and that was the side where the students of minority and/or of low family income sat. The second case study is of a girl from that classroom, called Beth Anne, who was chosen because of her reputation in the school as a well-adjusted child (see Spindler and Spindler, 1990). As Spindler observed Beth Anne across a wide range of activity settings in the classroom and on the playground, it became apparent that she was subtly anxious. She was a more complex, multiple-faceted person than she had been typecast as, on the basis of surface appearances and on the basis of seeing her in only a limited range of activity settings.

In a volume by Jules Henry titled *Culture against Man* containing chapters on elementary classrooms, the theme of student anxiety over achievement and over relationships among peers was continued and extended (Henry, 1963). Henry's portrayal of the classroom shows how competition among students and carping criticism of one

another's' performances were ubiquitous, as was the expression of affection by the teacher as a means of intensifying the students' anxiety over achievement. As in the Spindler's portrayals, the emphasis is on contrast between the official, formal social organization of the classroom and its unofficial informal organization, and the hidden curriculum of social relations and emotionality around learning is foregrounded, as well as consideration of the manifest curriculum of subject matter instruction. Another pioneering work was Philip Jackson's book length report *Life in Classrooms* (1968). In it he considered classroom practices and social organization from the perspective of ethology, the observational study of naturally occurring behavior among animals. Among the points Jackson emphasized was that as a child enters a school classroom, one of the things the child has to do (in contrast from family life at home) is learn how to be a member of a crowd. Also the child has to learn how to wait in the crowd. The development of boredom management techniques follows from this. Once again, informal social organization and hidden curriculum were being emphasized.

Perhaps the most comprehensive of the early attempts at ethnographic study of classrooms was the book length account of an entire year in an inner city seventh-grade self-contained classroom, co-authored by Louis M. Smith, the ethnographer, and William Geoffrey (pseudonym), the classroom teacher. Published in 1968 and titled *The Complexities of an Urban Classroom* (Smith and Geoffrey, 1968), this account emphasized the development of special roles by various children, in a distinctly local classroom social order that evolved over the first days and weeks of school – thus an emphasis on informal social organization. The book also described the teacher's approaches to personalizing instruction – relating differently to different students depending upon their distinct strengths and needs – while still working within the framework of traditional curriculum and use of standard textbooks.

Teacher-authored accounts of classroom life have often been done from a holistic ethnographic perspective. An early example of this is Kohl's (1968) *Thirty-Six Children*, and a more recent example is Cynthia Ballenger's account of literacy instruction in a bilingual classroom (Ballenger, 1999).

Frank (1999) has published a guide to teachers' research in their own classrooms titled *Ethnographic Eyes*. Hammersley (1990) is a good general resource on classroom ethnography, illustrating ethnographic studies of classrooms and discussing methods for accomplishing them. The discussion in Castanheira *et al.* (2001) is also useful.

Conclusion

In recent years, there has been a burgeoning of classroom studies, especially concerning instruction in literacy,

science, and mathematics, that describe themselves as ethnographic in orientation – far too many to review here. Some of these studies are ethnographic only in the sense that they are narratively descriptive, or in that they present a transcript of classroom discourse. Some of these incompletely ethnographic studies focus entirely on subject matter instruction – the manifest curriculum – and ignore the hidden curriculum. Many take a broader view that is indeed ethnographic; a holistic view of everyday scenes of classroom life as learning environments, socioculturally organized, with both official and unofficial aspects, with both manifest and hidden curriculum. These are studies that view the classroom as at once locally constructed and as connected with and influenced by wider spheres of social control and its contestation in society more generally. Routine classroom practices are portrayed as socially and culturally constructed, considering the particular local construction at hand as a specific variation within a world-wide range of possibilities. That ethnological backdrop for ethnographic case studies of classroom life continually suggests possibilities for change – it implies that what has been constructed locally in a particular way holds continuing possibility for reconstruction.

Yet the ethnographic emphasis on the specifics of local social and cultural ecology suggests that single-factor approaches to change – quick fixes – will not be successful. Rather, multiple components of the classroom ecosystem must be changed, in concert with one another. For example, let us consider a teacher who wanted to change mathematics instruction from an emphasis on procedures for finding the right answer to an emphasis on deep conceptual understanding of basic mathematical ideas. If students were to be able to discuss alternative ideas about mathematics, practices in the conduct of discussion would need to change, in order to alter the system of carping criticism, mockery, and overall competition among students as described by Jules Henry. As a student it is more face threatening to have to say what you think and defend it than it is to call out a right answer. The teacher, as manager of social relations in the classroom, would need somehow to make it safe for students to disagree with one another.

Teacher beliefs about learners would also need to change – students would need to be seen by the teacher as capable of understanding key concepts thoroughly and of articulating those understandings in talking and writing. Changes in other subject matter instructional practices might also follow. If right answers are no longer the primary focus in mathematics instruction, what about allowing invented spelling and punctuation in writing – emphasizing the primacy of the sense of what is being written over the canonical form of the writing? What about basic postulates? The teacher's assumption that order must be established

before learning can take place, as mentioned earlier, might well be replaced by an assumption that order usually follows student interest and understanding. Finally, what about assessment? If high stakes testing in an accountability system external to the classroom emphasizes student knowledge of facts and simple skills as evidence of learning, the teacher's attempt to teach mathematics for understanding might become difficult to implement – not impossible, but it would require the teacher to swim upstream against strong cultural currents.

Changes in the social organization of a classroom learning environment, the ethnographer would assume, would necessarily accompany changes in the subject matter content of instruction. In other words, the social-ecological perspective of classroom ethnography suggests that when change happens in one aspect of classroom practices, changes in a whole system of classroom practices would likely follow.

In sum, the ethnographic perspective on classrooms as learning environments assumes that what humans have made they can change, even though that may well involve changes in multiple aspects of practices. It further assumes that if enduring change is to happen in classrooms, local autonomy is necessary to be exercised on a daily basis by the teachers and students who live there. This is an inherently critical stance for classroom research, yet it is criticism with empathy for and understanding of members' points of view, and with respect for their capacities for sense-making even when the researcher may not fully agree with the sense that is being made. It is criticism presented by a researcher who was both stranger and friend to those among whom he or she became closely acquainted with their locally distinctive way of life.

Computer Assisted Qualitative Data Analysis

C Silver and A Lewins, University of Surrey, Guildford, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Autocode – To use software to search for words, strings, phrases, and code the results, possibly together with surrounding context.

CAQDAS – This stands for Computer-Assisted Qualitative Data Analysis Software.

Hyperlink – A direct link between two pieces of text, or out of the software to an external file or website.

Introduction

In recent years, the process of conducting qualitative research has become increasingly technologically driven. From the digitized collection and storage of data, through their transcription, analysis, and the presentation of results, technology is never far away. Computer-Assisted Qualitative Data Analysis Software (CAQDAS) packages are used across a wide range of academic and applied settings, in disciplines including education, psychology and sociology, business and management, government research, health studies, geography, and art history. Some packages and aspects of their functionality are referred to below, but only to illustrate potential differences or the individuality of some important tools within some packages. Details of functionality are transient because of the speed of technological advances, so the article deals with broad issues and does not attempt to be a comprehensive review of packages mentioned.

Technological developments generally occur more quickly than methodological ones, and in the field of CAQDAS, it is pertinent to ask to what extent technology is driving methodology. The computer does not analyze data for the researcher, and therefore the interpretation of results rests with the researcher. There are however certain tasks enabled by CAQDAS packages that would be difficult to replicate by more traditional craft methods and there are new types and combinations of data that can be incorporated because of technology.

The term CAQDAS was coined by Ray Lee and Nigel Fielding at the time of the first Surrey Research Methods conference in 1989, which brought together pioneers in the field. Their edited volume of papers by methodologists and software developers provides an historical context and is therefore a seminal work in the development of this technology and its adoption by researchers

(Fielding and Lee 1991/1993). An important typology was offered by Weitzman and Miles (1995), which categorized the then available software as text retrievers, code-and-retrieve packages, and theory-building software, but these categories lost relevance as each software offers new functions cutting across the typologies. Technological advances have also led to methodological innovations, many of which have been applied beyond traditional disciplinary boundaries. The applications of software tools have broadened. There are now many packages available which support various aspects of, and approaches to qualitative analysis. Alongside the market leaders of commercial software are a range of low-cost or freely available alternatives, and some bespoke tools providing a smaller range of tools for specific analytic tasks or data types. In particular, the analysis of visual data is becoming better supported, with some tools focusing specifically on multimedia analysis. Others which hitherto focused on textual analysis now incorporate more flexible ways of handling visual data.

It is increasingly difficult to apply a clear typology or to define what we mean by the CAQDAS label as some software that offer such qualitative functions also encompass tools that support a more quantitative approach to qualitative data, including basic content analysis methodology in which the statistics of word frequencies are given. Some CAQDAS packages, such as QDA Miner offer two quite different philosophical approaches to qualitative data with more sophisticated content (text-mining) analysis tools alongside good qualitative tools. We might then at least encourage a reconceptualization of the term CAQDAS to refer to any software tool, which includes specific support for the qualitative analysis of qualitative data. Such a tool would include first, thematic coding tools to organize and interpret concepts, processes, interactions, etc., in order to interrogate and identify meaningful patterns and relationships. Other necessary tools would be text-level tools with rich annotation, memo, and text-linking devices.

The aim here is to provide an up-to-date summary of the broad task-based areas of functionality in CAQDAS packages reflecting recent technological and methodological trends.

Qualitative Tasks Supported by CAQDAS Packages

In contextualizing software tools we refer to **Figure 1**. This points to the structure of the article and graphically

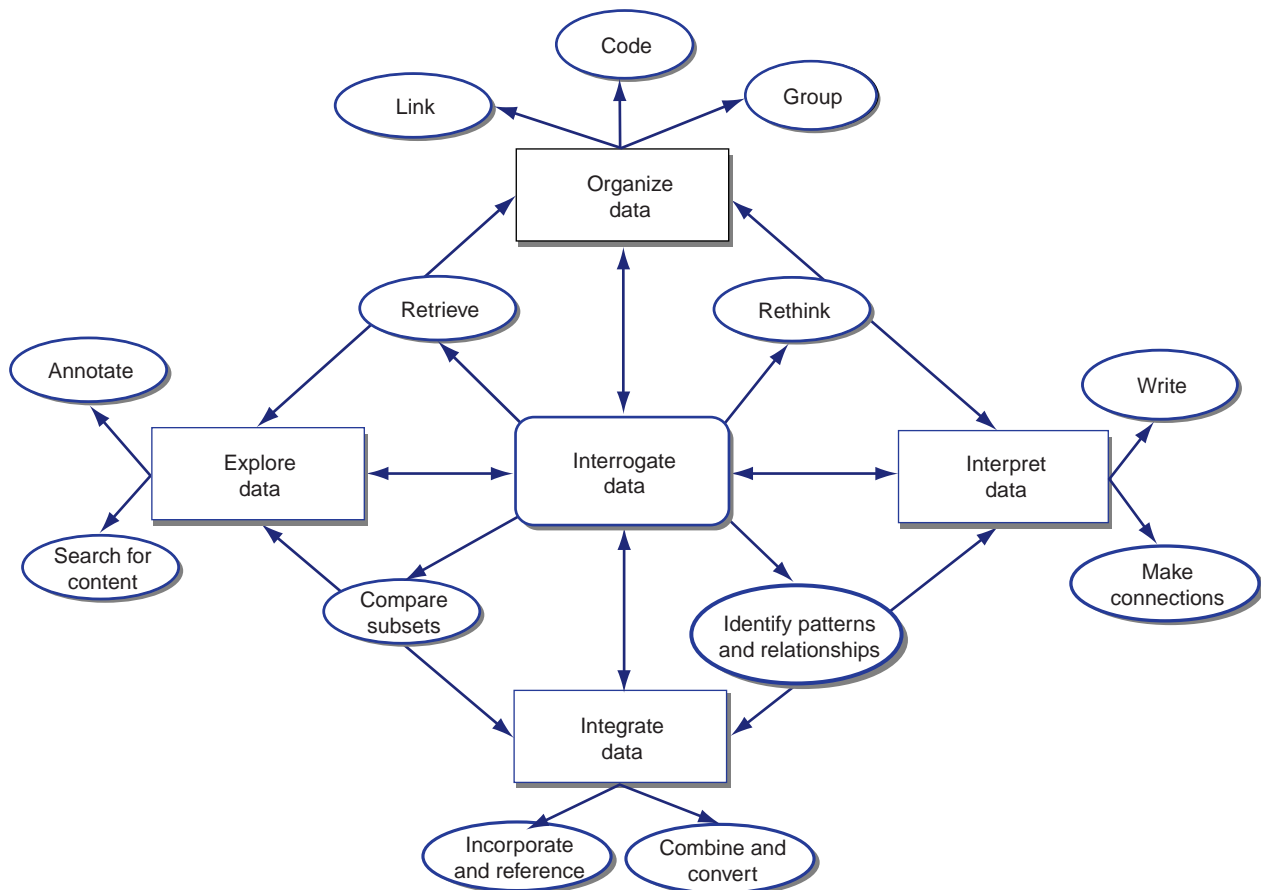

Figure 1 Qualitative tasks supported by CAQDAS packages. Adapted from Lewins, A. and Silver, C. (2007). *Using Software in Qualitative Research: A Step-by-Step Guide*. London: Sage.

illustrates linkages between the main qualitative tasks of integrating, organizing, exploring, interpreting, and interrogating data. Linked to the main tasks are indications of the generic tools in CAQDAS packages that support those main areas of work. **Table 1** summarizes some of these tools in more detail in the context of the practical aspects of project work as enabled by the software. The researcher can pick and choose which tools support a chosen analytic path in order to be creatively and efficiently in control of the software.

While these packages are generically referred to as qualitative data analysis tools, they are perhaps more accurately described as qualitative data management tools. Like most computer programs, the user remains in control of the executed tasks and it is important to stress that the tool is not undertaking the analysis, but simply storing the data and enabling the researcher to view, interrogate, and retrieve them in different ways.

Project Planning and Working in a Team

Planning which software to use and how and when to familiarize with it should be part of the wider research

project planning. This is especially true when a team of researchers are working together on a project.

Projects in software cannot usually be worked on concurrently by different users, and therefore, a strategy for dividing work needs to be developed (concurrent use in one software project, especially packages designed to handle textual data is not generally possible at the time of publication). Separate software projects can often be merged at various stages but the procedures for doing so can be quite involved. Only one or two software (and those only for multimedia such as video) now provide multiuser versions that do allow several researchers to work simultaneously on the same project. In these cases, users can see what each other is doing in real time and can communicate with one another using basic text messaging tools.

Another aspect of team working may be the negotiation and development of a shared coding schema, which can be a considerable task. Several CAQDAS packages now include integrated coder reliability tools that facilitate this process, providing a statistical measure of agreement between codings.

Table 1 Practical aspects of project work enabled by CAQDAS packages

<i>Practical aspects</i>	<i>Analytic rationale</i>
Planning and managing your project	Store and keep together the different aspects of your work in one place, that is, individual data files and your thinking about them. Aid continuity. Construct an audit trail as a natural part of the process of coding, and particularly by using memos.
Writing analytic memos	Manage your developing interpretations by keeping track of ideas as they occur, and building on them as you progress . . .
Writing memos about process	Reinforce record keeping about your thinking and improve continuity by logging tasks undertaken in a disciplined way and putting reminders about follow-up work for next work session. Log into this memo at the beginning and end of each session.
Read, mark, annotate, or comment on data	Discover and mark interesting aspects in the data as you see them. Tools variably enabled for different types of data and in different software.
Searching (for strings, words, phrases, etc.)	Explore data according to its content, observing how context may differ where words or phrases are found. Exploring prevalence and usage of jargon or respondents' particular ways of describing things.
Developing a coding scheme	Manage your ideas about your data, in themes, concepts, etc. Structure and function may depend on methodology and style of working. Create codes up front or as you see them emerge from what seems significant in the data, or in both ways.
Coding	Capture what is going on in your data in a consistent way. Bring together similar data according to themes, concepts, etc. Assign codes to chunks of data as required, include a little surrounding context in the data to enable better understanding when in retrieval mode.
Retrieval of coded segments	Revisit coded data chunks or segments to assess similarity and difference, influences, undercurrents, and context. Read and reread to consider how coding is helping your understanding and analysis, and whether it is helping you in where to go next in developing analysis.
Recoding	Recode into broader or narrower themes or categories if appropriate and necessary. Perhaps bring coded data back together in new groupings and think about them differently.
Organization of data	Organize data according to known facts and descriptive features to enquire into particular subsets of respondents, or compare across them. These aspects may be a central part of your sample and will contribute to your analysis.
Hyperlinking	Link data to other text segments and/or to other files to track process, contradiction, etc. Variable tools in this respect provided in software packages.
Searching/querying the database and the coding schema	Test ideas, proximity/co-occurrence of codes, interrogate subsets for similarity and difference, or generate another level of coding.
Mapping	Manage analytic processes by visualizing connections in a graphic way to display or remind of relationships, patterns, processes, ideas observed in the data. A way to step back from the data.
Generating output	Report on different aspects of your progress and the project at any stage. Save as files to capture status at an analytic stage or to work in other applications. Print off to get away from the computer and think and work in more traditional ways. Types of output reduce with multimedia.

Adapted from Lewins, A. and Silver, C. (2007). *Using Software in Qualitative Research: A Step-by-Step Guide*. London: Sage.

Integrating and Incorporating Data

A key benefit of using a customized software to manage qualitative research projects is the potential it provides to integrate data. Methodologically one can identify two ways in which data integration may take place when using qualitative software:

- (1) simple incorporation of diverse data types alongside one another within a software project to inform different aspects of the project, likely analyzed separately or sequentially; and
- (2) integrating the analysis of data types, either by combining qualitative and quantitative data within an

analysis or by converting qualitative data to quantitative variables for use in a statistical analysis.

Incorporating and Referencing Data

Many qualitative projects use several different forms of data which can be incorporated within or referenced from the chosen package in order to be handled together or separately as required. The software project either contains all the data you wish to work with, or links to the files which remain outside the software can be created (see Lewins and Silver (2007) for a discussion of the implications of each system).

Packages often allow a range of data formats to be directly handled often including a variety of multimedia, for example, graphic, audio and video formats, as well as textual formats, for example, .rtf, .doc (Check software developer websites for up-to-date lists of supported data formats.) Some packages also handle .pdf files, others now provide the ability to connect geographical references from Google Earth with (parts of) texts or codes.

Material relevant to the research project which either cannot be directly incorporated into the CAQDAS package because it is in the wrong format or which the researcher wishes to keep elsewhere, can be referenced from within the software project. These may include hard copy books or articles, handwritten diaries, television programs, films, etc. Material which remains external to the software project may be summarized in note form internally or incorporated in lists, and subsequently this information treated like any other data record. It can be annotated or cross-referenced by coding. Keeping records of routine reading of literature or writing a literature review can be a simple application of some of the tools in most CAQDAS packages.

Whatever data are incorporated or referenced in the qualitative software project, once work begins, access to them or the notes you have made about them become almost instantaneous, thereby enabling seamless flicking between relevant materials which may otherwise only be accessed through different programs. Such basic organizational tools facilitate continuity and keep the researcher in reliable and continuous contact with all manner of information.

Multimedia Data

Enhanced recording and storage facilities enable researchers to generate volumes of digitized data in audio, video, and graphic formats, allowing the capture of large quantities of high-quality images. The social world itself is both more technologically and visually driven, with multimedia data being an increasingly normal part of everyday life.

In response, software developers focus on effective and customized means of handling multimedia data for the purposes of qualitative analysis. Some of these are very low cost or even free. Transana (open source, low cost) was one of the first bespoke packages to provide specific tools for the analysis of audio-visual data, initially providing a sophisticated transcription tool, subsequently developing flexible annotation, coding, and play back tools. The Digital Replay System (DRS – open source and free) similarly provides transcription and coding support for multimedia, while also enabling other related or synchronous forms of digital data to be viewed, coded, and interacted with alongside. Teamwork is well supported by some of the low-cost multimedia packages Transana and MiMeg (open source and free) provide, a means by which teams can tap into a data set from different places at the same time.

Increasingly commercial packages such as ATLAS.ti, HyperRESEARCH, and now NVivo have sought to support work with multimedia alongside the textual data they were initially created for.

The utility of given software packages in multimedia analysis depends largely on two closely related factors; the status of that data within the research project and the methodological approach to its analysis. Audio visual data provides access to very different accounts than textual data, offering the researcher multifaceted perspectives of the realities of social phenomena. Projects in which such data is supplementary or provides background context to textual data have very different requirements than those in which the audio visual data is the primary source. For example, a key issue in analyzing audio visual data relates to the need for development and use of a written transcript or log. Most software now allow the audio or video file to be marked, annotated, and coded directly, without the need for a written log of any sort. This can be particularly useful when analyzing nonverbal interactions and body language, for example, between teachers and students, or doctors and patients. However, the development of a written log (which may vary from a fully verbatim transcription, to a summary overview, or an analytic memo), may be an important analytic task in its own right. It will certainly provide an additional dimension to the data. While audio visual data is incredibly rich, it can only be viewed and heard in real-time, and it is therefore difficult to consider as a whole without some written summary. Abstracting from the data by working with a written log as well as directly with the multimedia file can provide the researcher with an additional perspective and means of analytic consideration. Playback options and tools that allow shuffling through help to deal with this, but nevertheless, a written transcription of some sort usually acts as a valuable data source. Many software that handle multimedia data now enable full synchronization between a written transcript and the corresponding audio visual file.

Another recent development is the ability to integrate geo-referencing tools with CAQDAS software. The MAXqda and ATLAS.ti have been early pioneers in this integration. These packages allow geo-reference points accessed through Google Earth to be viewed and saved as data within the software. It is also possible to create hyperlinks from points in text files within the software, to geo-reference points in Google Earth for quick movement between applications. These developments provide new ways to handle the spatial elements of social research.

Integration of Qualitative and Quantitative Analyses

Mixed methods projects are commonly undertaken and can be increasingly facilitated by the use of CAQDAS packages. More sophisticated methodological integration

requires the transformation of qualitative data into variables. Where codes derived from qualitative data are recorded as the presence/absence of the code in each case or as a frequency of the code's occurrence, a case-by-variable matrix can be generated. While still within the CAQDAS software there might be interactivity between each cell in the matrix to the underlying qualitative data. On export of the quantified data to the quantitative package, contact with the qualitative data is lost but statistical techniques such as cluster analysis, correspondence analysis, and multidimensional scaling can be applied. A number of hybrid techniques to interrelate quantitative and qualitative methods have been demonstrated in single studies but are not widely used (Bazeley, 2006).

Many CAQDAS packages have long provided the facility to import quantitative information in the form of spreadsheets to link to qualitative records. An example would be to conduct a qualitative analysis of open-ended questions to survey data. The formatting of both the spreadsheets and the qualitative records needs to be considered for these processes to occur seamlessly and protocols vary according to the CAQDAS package being used. Depending on the nature of the qualitative records, it may be necessary to take the first step of autocoding repeated structures within or across data files in order to link up the quantitative information correctly. These repeated structures may represent speakers in a focus group or responses in open-ended survey data. Such facilities are available for instance in NVivo and MAXqda. But several leading CAQDAS packages allow the import of quantitative data to categorize whole files such as interviews.

Exploring Data

Searching the content of textual files for keywords, phrases, or character strings may be a simple explorative task, form part of a closer analytical reading, or be an essential component of a quantitative content analysis. Becoming aware of what is interesting and significant in the data is a process which begins during the first moments of data collection and while transcribing, as well as during the more formally analytic phases of annotating, coding, retrieving, etc. Exploring the content of data files and one's own notes in the form of memos or annotations can be iterative and consideration of the content as well as the meanings of texts can help reflect on them from different perspectives (see Lewins and Silver, 2007).

Word Frequency Tools

Many packages now include basic data mining tools such as word frequency counts which index textual strings in tabular format, providing counts by file and across (parts of) the data set. With roots in the quantitative

content analysis tradition, such tools may be criticized by qualitative researchers who view them as crude and irrelevant in uncovering meaning. Quantitative summaries of qualitative data should rightly be treated with caution, so as not to extrapolate beyond their relevance. For example, one limitation of these tools is their failure, in the tabular view, to discriminate between the origin of words (e.g., who used certain words in an interview file). Nevertheless, they offer alternative ways of viewing and accessing textual data which are extremely useful in many projects, in particular when analyzing documentary evidence or using software to facilitate a literature review.

Word frequency tools differ between packages. There is a difference between packages that provide word frequency tools which give interactive movement between the words and the text they are contained in (or Key Word in Context/KWIC) and those that do not. Again, the individual user should be aware of the varying levels of statistical information and how they are presented, in case it matters; see earlier section on Integration of Qualitative and Quantitative Data.

Text Search Tools

Building on word frequency tools, text search tools allow the reader to specify which strings, words, or phrases to search for, and be taken directly to those positions within the relevant textual files. Such tools not only provide access to keywords within the source file but usually allow for a user-specified context around each hit to be automatically coded (e.g., the sentence, paragraph, or other unit). Most CAQDAS packages enable the use of wildcards such as the asterisk character to find alternative endings or prefixes. Boolean operators and other functions refine instances for retrieval. Caution again needs to be applied as these tools will only locate when the searched-for words appear, and not where the text refers to the topic without using that word or phrase. Gaps in the data are often as analytically meaningful as those which contain certain words, yet projects with an extensive data corpus will find the ability to quickly and automatically code data according to the presence of key words a useful way of initial exploration.

Annotation Tools

Alternatively, close analytic reading of written texts may be the main focus of the analysis; as in, for example, forms of discourse, narrative, and conversational analysis phenomenology and the related interpretive phenomenological analysis (IPA). Historically, such analysts have been somewhat reluctant to use CAQDAS packages, often due to a perception of their reliance on coding tasks (see the following discussion in relation to linking tools). Recent technological developments however, mean that such methodological approaches are increasingly well-served

by CAQDAS packages (see Silver and Fielding (2008) for more discussion and illustration of this). Additionally, where audio visual data is directly analyzed, annotation tools can provide a key way of marking data and unpacking the meanings of identified processes or interactions.

Annotations are directly linked to the data segments which they are about. In textual documents, they act similarly to footnote functions in word processors and can usually be outputted in this way at the level of the whole data source, or when outputting data coded in certain respects. Depending on methodology, researchers may rely more or less heavily on these tools, some wishing to use them to the exclusion of coding tools. They add to the ways data can be effectively managed in general – ways implementing stable connections between data and the researcher's thoughts about them.

Organizing Data

Data organization is a key aspect of handling and analyzing qualitative data. The CAQDAS packages provide three main ways to organize data. Grouping data according to their known characteristics or structurally coding parts of files according to who is speaking are closely connected. More conceptually, coding is also key to organizing (and interpreting) data based on pertinent themes, etc. Related to conceptual work is the linking of data segments to track processes or interactions. The manner and extent of organizing data will largely depend on the methodological approach and forms of data involved.

Grouping and Filtering Data

Organizing data into groups enables the isolation of parts of the data corpus in order to focus on (combinations of) subsets of records or respondents. It is usually possible to group either whole files which represent a case or respondent such as interview files, published reports, or video files etc., or parts of files where, for example, several cases or respondents occur within a file, such as in focus group, survey, or field data. Whatever the situation, known characteristics, often conceptualized as sociodemographic attributes or variables, can be used to group whole data files or relevant parts of them. This enables the subsequent retrieval and interrogation of data based on an individual grouping, or combinations of them.

Characteristics which are known about the data at the outset, and perhaps sampled for, such as the sociodemographic attributes of respondents, for example, age, gender, and marital status, are common and powerful bases for grouping data. However, any analytically meaningful feature which is identified through the analysis can be handled at this level within CAQDAS packages, where it applies to the chosen organizational unit of analysis.

For example, in a project exploring the nonverbal interactions of university lecturers and their students in video-recorded tutorial sessions, analysis may reveal that some lecturers use certain hand gestures more often than others to reinforce particularly salient points. Where the individual is the organizational unit of analysis, an attribute which differentiates between lecturers according to their identified style of hand gestures, and another to reflect the frequency of their use, could be applied to all instances of individual lecturers' data. This would enable the subsequent grouping of lecturers who displayed similar hand gestures, in order to consider whether they also had other communicative techniques in common, and so on. In this way analysis can build incrementally as the results of a particular observation or interpretation are incorporated into the software and used to inform further enquiry.

Interpretive Coding

Many qualitative analyses involve organizing data by way of conceptually or thematically coding them. Coding is a main aspect of managing interpretation. There are many different approaches to qualitative coding which are not possible to discuss in detail here, but in general terms coding is the process by which segments of data are identified as relating to, or being an example of, a more general idea, instance, theme, or category.

Qualitative researchers may take an inductive, deductive, or combined approach to generating and applying code labels, each of which are usually well supported by software. From a technological point of view, all CAQDAS packages provide flexible means by which to code data. For example, codes can be generated from the data level, or independently from it. The same code can be applied to any number of data segments derived from any data source. In most of the packages designed originally for textual analysis, the same or overlapping or embedded data segment can be coded by any number of relevant codes. The amount of data coded can be increased or decreased. Codes can be merged or grouped; previously coded data can be recoded or uncoded. Codes can be defined, renamed, and lists printed or exported. Coded data can be easily retrieved and outputted (see the following text).

The coding functionality of most CAQDAS packages is similar, although there are some subtle variations which may be important to researchers from certain disciplinary backgrounds. One example is the way in which coding schema are visually presented within the chosen software. Researchers vary in their expectations of coding schema structures, some preferring visually hierarchical systems, others feeling constrained by perceived notions of hierarchy. What is more useful than any set structure is that you can often regroup, reorder, and visualize codes in alternative ways. This reflects the way that researchers, having broken data down by initial coding processes, often need

to combine codes and their data differently simply in order to output these new permutations of data for reexamination. Sometimes this can be part of a necessary stepping back from data having been immersed closely in them for too long.

Linking Data

Some approaches to qualitative data analysis view coding as limiting because it fragments and reduces the data to an extent which obscures the dialectic relationship between reading text (or viewing multimedia data) and writing. Associative trails through data are created rather than collecting similar segments at thematic or conceptual codes which abstracts away from the data. In these approaches, the analytic focus is the relationships between topics or objects rather than codes or concepts. Such work is best supported by hyperlinking and annotation tools.

Hyperlinking is a free association approach to building up an analytic chain of reasoning embedded in the data. It facilitates an unstructured, nonlinear approach to identifying, writing about, and linking ideas, whereby multidirectional associative trails can be created. Hyperlinking tools may be used to track processes as diverse as narrative, sequence, time, and interaction. To some extent the presence of these and other annotating tools in one or two CAQDAS packages counters arguments that the technology has cemented the dominance of code and retrieve as an overly dominant qualitative approach. A key debate concerning ethnographic approaches and the development of methodology alongside technology can be seen in *Sociology Online* (Coffey *et al.*, 1996; Lee and Fielding, 1996).

There are some customized software applications for handling data in this way and these developments have occurred separately from CAQDAS. These applications enable the creation of hypertexts; electronic multidimensional documents in which several writing spaces are viewable simultaneously, and multiple paths through the data are offered – see Silver and Fielding (2008) for more discussion on hyperlinking tools in CAQDAS packages.

Managing Interpretive Work

Interpretation is the core business of qualitative analysis. It takes different forms according to methodological approach, requirements of the research project, and the researcher's personal style of working. While it is important to reiterate that the software does not analyze or interpret data in itself, it does provide a range of tools which can facilitate these processes. As well as various ways of interrogating the data set discussed in the following interrogating data section, writing tools and visual ways to make connections offer powerful means of facilitating the interpretive process. Thematic coding and linking

between points in the data may already have contributed to the management of analysis itself (see the section on interpretive coding).

Writing

Taking notes, making annotations, and writing longer explanations about what is seen in the data are analytic processes which are undertaken throughout the process of qualitative research.

In addition to annotation tools already discussed, memo systems provide larger and more central writing spaces which can be used for a range of purposes. Recording the research progress, writing an analytic description, fleshing out a theoretical idea, summarizing what seems important about an interview, and referring back to research questions might all be managed in a well-designed memo system. The final written report can begin as separate memos within the software. The benefit of using integrated memo systems rather than keeping memos outside of the CAQDAS package relates to the systematic management and retrieval of writing, alongside the integration with data. This will be particularly so with methodologies relying on thick description. Familiarity with any software package which has a memo system enhances continuity, recall, and reflection.

Making Connections

Many CAQDAS packages include integrated mapping or networking tools enabling visual representations of aspects of work. The way these tools work vary considerably between packages and therefore offer quite different ways of working. Nevertheless, there are three key ways in which mapping tools can be particularly useful when undertaking qualitative analysis using CAQDAS packages. First, the user can graphically represent hypotheses, hunches, or theoretical models at the outset of a more deductive analytic project. Second, the user can represent the linkages which exist in the project, based on the tasks already undertaken. One may, for instance, use mapping tools to visually represent a developing theory or explanation having taken an inductive, bottom-up analytic direction. A less analytic use of mapping might be to illustrate the coding scheme in a graphic way to see at a glance the way it is structured. Where objects are illustrated, such as codes, documents, or memos, there is usually live interactivity back to the coded text, the document text, or the memo represented.

Interrogating Data

The CAQDAS packages offer various means to interrogate the data set based on earlier work, and these tools are the power house of moving beyond the basic tasks of code

and retrieve which characterize much qualitative work. Functionality ranges from simple to complex, not all of which can be included here.

Retrieving Data

Basic retrieval of coded or linked data provide means of reviewing progress across the whole database in order to reconsider a body of data, and perhaps to work on a more conceptual and abstract level. It is usually possible to retrieve data for these purposes without recourse to creating complex queries. Coded data can be viewed in context or lifted out of context to view in isolation, either within the software, or as output, for example, in a word processing application. This facilitates general consideration of all instances of a theme or concept, horizontally across all data files.

It is often also analytically useful to consider one file at a time, perhaps where a file represents an individual interview transcript or the field notes about a particular research setting. Viewing data vertically by all or selected codes provides a way of considering a case or situation as an independent entity. This can be achieved visually within the software, using a margin view illustrating where particular codes occur, or by generating an output report which lifts out all the segments within that file coded by each code.

Whatever the approach to coding qualitative data it will often be necessary to recode coded segments. If coding in a broad-brush or deductive way then this can be facilitated by most CAQDAS packages by first retrieving data coded at a general theme, and then recoding into more detailed codes. This process adds additional codes to the original data, thereby allowing the researcher to analyze the theme in more depth.

Most packages also provide a more quantitative overview of how data have been coded in various respects. Tables showing for example, frequency of code application by file, or number of words (or duration of an audio-video file) coded across the data set are usually either provided automatically, or can be generated very easily. Such tables are often fully interactive within the software; that is, each cell in the table provides direct link to the data regardless of the way it is counted in the table. Additionally, these tables can be exported to spreadsheet applications for more complex statistical analysis.

Identifying Patterns and Relationships

As discussed earlier, mapping tools can provide visual ways of making connections or viewing patterns and relationships in the data at an abstract level. Search or Query tools provide more sophisticated ways to interrogate the data set according to the presence and absence of codes as they have been applied to the data. The traditional CAQDAS packages initially developed for the analysis of textual data often provide the most sophisticated options.

Queries may be run at early stages of coding in order to test a hunch, or get a general overview of the current situation. Queries can usually be saved to be rerun at a later stage and doing so is a way of creating reminders of interesting aspects which deserve revisiting. They can contribute to the iterative and incremental coding process. It may be at the latter stages, however, when the researcher is confident the main coding process has been completed consistently, that the results of queries are used as the basis of analysis.

Boolean and proximity query operators are common to many CAQDAS packages, allowing the researcher to find where two or more codes occur together or separately in the data.

Comparing Subsets

Many qualitative projects include a comparative element, for example in cross-case analysis where it is necessary to compare how different cases or types of respondent discuss certain aspects, see section on Organizing data as discussed earlier.

The ease with which results, sometimes viewed as matrices, can be generated varies but many CAQDAS packages provide the facility to compare groups of codes by socio-demographic characteristics, such as gender, age, teacher, pupil, parent, etc. Alternatively, it may be useful to create a qualitative cross tabulation of codes by codes in order to see where particular codes occur together in the data.

Conclusion

This article has provided an overview of how CAQDAS packages can support the common tasks of qualitative data analysis. This is a rapidly changing area with new software developments occurring frequently. As basic CAQDAS tools have become well embedded, developers are able to stretch methodological and disciplinary boundaries by offering tools which provide means of handling and analyzing data in ways hitherto difficult or impossible. These developments provide the researcher with a range of options, some of which may be welcomed, others which may not be required by individual projects. The researcher determines the way the software is used, the sequencing of tasks, and the interpretation of the data. While software can certainly enable more transparency in process and offers means by which analytic rigor and the robustness of conclusions can be tracked, the quality of the output is not guaranteed or enhanced merely by use of the software. There is however great potential for parts of the analytic process to be more searching and ambitious and for the processes of analysis to be more flexible when using a CAQDAS package.

Conversational Analysis

H G Levine, University of California, Davis, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Conversational analysis (CA) is the study of interaction, both everyday, ordinary conversation, as well as the more formalized talk that occurs in institutional settings such as classrooms, courtrooms, and medical clinics. CA uncovers the underlying interactional rules and principles that guide the participants in a conversation to make intersubjective meaning possible. CA, as either a method of empirical inquiry or as theory of enacted social organization, has had an impact in a wide variety of social science disciplines and research arenas.

CA has its genesis in the late 1960s and early 1970s based, in large part, upon the earlier pioneering work of sociologists Harold Garfinkel and Erving Goffman. Their conceptual writings provided the intellectual justification for including everyday, commonplace activities carried out through mundane – but purposeful – interaction as core subjects for sociological inquiry. Garfinkel's further contribution was to argue that conversation represents an “institutional order *suigeneris*” (Heritage, 2005: 103) with a knowable set of interactional rules and practices of the participants as they construct meaning for each other in particular real-world contexts. For most writers in CA, conversations may reference or index sociological constructs/variables, such as social class, race, and gender; but do not depend upon, or necessarily derive their ordering from, them.

Harvey Sacks, Emanuel Schegloff, and Gail Jefferson are credited with founding CA as an approach to the study of talk-in-interaction as an inherently human practice that is constitutive of the lived social order. Sacks argued that the study of interaction was preferred over the then-standard preoccupation among academic sociologists with abstract conceptual structures that, by definition, were at a distance from – and, Sacks argued, could only be vaguely tied to – the specific events and actions in a group's life that the field of sociology was designed to understand.

For Sacks and others, there are three important assumptions that underlie CA (Heritage, 1984):

1. Interaction is structurally organized and this structure can be discerned through careful analysis – primarily with the aid of audiotaped recordings of natural interaction and a robust transcription system (which was developed to meet this need) that would allow the researcher to pinpoint not only what was said, but

how (e.g., with simultaneous or overlapping utterances, pauses, and intonation particularities).

2. Conversation is always contextual. Individuals bring context with them; that is, their utterances can only be understood (by them, as well as by researchers) in terms of what came before. An individual in an interaction then reaffirms this context for what comes next, thereby building a “turn-by-turn sequential organization of interaction,” one of the early discoveries of conversational analysts (Psathas, 1995: 13). These paired orderings are known in the field as adjacency pairs, and they have been identified and studied in a large variety of settings, including cross-culturally (e.g., Moerman, 1988).
3. Because of (1) and (2) above, no detail of interaction can be dismissed, on *a priori* grounds, as irrelevant. A further contribution of CA researchers has been to demonstrate how seemingly deviant or irregular instances of adjacency pairs recorded in real conversations can further demonstrate the underlying normative structure by which they operate.

One of the earliest, and still frequently cited, applications of CA to education is the work of Mehan (1974). Mehan studied classroom discourse and was able to demonstrate the ordering principles of student–teacher interaction. Mehan argued that, to understand how schooling impacts students and their learning, it is essential to start with “descriptions of the actual processes of education” (p. 5). Both the sociological facts of race, status, gender, and so on and so forth, as well as educational constructs, such as teacher quality or opportunity-to-learn, must be instantiated in the actualities of interaction.

Critical Ethnography

D Foley, The University of Texas at Austin, Austin, TX, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Action anthropology – Sol Tax's 1950s style of engaged, politically active ethnography.

Collaborative ethnography – The twenty-first-century experimental ethnographic practices that empower the research subjects to produce accessible texts.

Cultural broker – An ethnographer who seeks to mediate between powerful institutions and powerless subjects.

Cultural critiques – A late twentieth century style of policy-relevant ethnography that critiques public institutions.

Decolonizing ethnography – Australian Aborigine model of ethnography that seeks to protect tribal interests.

Feminist perspective of science – A philosophy of science that deemphasizes a grandiose notion of absolute truth and scientific method.

Investigative ethnography – A sociological style of ethnography that uses covert field methods to critique societal institutions.

Participatory action research – An activist type of educational ethnography based on the philosophy of Paulo Friere and Fals Borda.

Positivism – A philosophical doctrine of social science that tries to emulate physical science methodologies.

Self-critical reflexivity – An alternative approach to positivist methods that emphasizes the interrogation of the ethnographer's subjectivity and field relationships.

Introduction

The purpose of this article is to highlight the post-1960s shift in educational ethnography toward more critical, policy-oriented studies of American society and its public schools. Initially, critical ethnography was often based on classic Marxism or neo-Marxist critical theory (Carspecken, 1996). Several recent literature reviews of educational ethnography (Levinson and Holland, 1996; Foley *et al.*, 2001; Villenas and Foley, 2002) note that the philosophical base of critical ethnography has expanded to include race,

gender, sexual identity, and postcolonial perspectives. These developments underscore the widespread disenchantment with the positivist notion of the social science as objective and value-free.

This academic and methodological revolt against positivism is political in two senses: first, it generally seeks to transform the knowledge production of the academy, and second, it seeks to use the knowledge produced to make society more egalitarian. This transformation of knowledge production is rooted in new ways of understanding social scientific and educational research. Educational philosopher Schwantz (2000) argues that the post-1960s methodological revolt has interpretive, hermeneutic, and constructivist alternatives. Elsewhere, we have chronicled the following self-critical reflexive practices in post-positivist critical ethnography: confessional, theoretical, intertextual, and deconstructive (Foley, 2002).

These new reflexive ethnographic practices are often grounded in a feminist perspective of science. Donna Haraway (1988) and Sandra Harding's (1998) concept of science allows politically progressive critical ethnographers to make strong, yet more focused knowledge claims. Harding's discussion of standpoint theory and Haraway's notion of situated knowledge are so well known that there is little need to elaborate here. Suffice to say that many critical ethnographers have replaced the grand positivist vision of speaking from a universalistic, objective standpoint with a more modest notion of speaking from a historically and culturally situated standpoint. Interpreting from a historically specific standpoint acknowledges the impossibility of what Haraway aptly calls the god trick of an omnipotent standpoint. If an investigator subscribes to this philosophy of science perspective, they see themselves as mere culture-bound mortals speaking from very particular race, class, gender, and sexual identity locations. Since all standpoints represent particular interests and positions in a hierarchical society, they are partial, thus ideological in the sense of transparent positionality.

Once an ethnographer abandons the positivist fallacy that specific research techniques and methodologies can produce a detached, objective, or omnipotent standpoint, it also opens the door to use more intuitive or subjective ways of knowing. Hence, contemporary critical ethnographers of various philosophical stripes are beginning to practice introspection, memory work, autobiography, and even dreams as important ways of knowing. In the current experimental moment, the road to more defensible accounts goes through the ethnographer's reflections on

her subjectivity and intersubjective relationships (Denzin, 1997). The new, more reflexive critical ethnographer explores the intense self–other interaction of fieldwork and the constructed nature of ethnographic narratives.

Consequently, many twenty-first-century critical ethnographers have lost faith in the belief that knowledge production is innocent or neutral in a society marked by class, racial, and sexual conflict. Anthropologists in post-1960s era began calling for reinventing the field (Hymes, 1999), studying up (Nader, 1996), and studying people without history (Wolfe, 1982). They began advocating cultural critiques of modern society and its institutions (Marcus and Fischer, 1986). Such cultural critiques often studied ruling groups and ruling ideologies and/or the struggles of various oppressed groups (Foley and Moss, 2001). Investigators subscribing to this perspective are generally committed to value-oriented research that promotes an egalitarian society.

One pre-1960s engaged anthropologist, who helped initiate anthropology's historical transformation, was Sol Tax (Foley, 1999). His action anthropologists operated without the sponsorship of government bureaucracies or private nongovernment organizations (NGOs). They found independent funding and worked more directly with and for the people they were studying. Tax argued that because action anthropologists became accepted insiders, they were positioned to collect better data on social change and acculturation than detached scientific ethnographers. Consequently, action anthropologists would help the community while they wrote trustworthy ethnographies. In effect, Tax envisioned a social science that created knowledge that was as practical and useful as it was theoretical and universal. For him, academic social scientists had produced a false notion of science and knowledge that privileged the theoretical over applied, practical knowledge.

In effect, anthropologists subscribing to action anthropology and the subsequent anthropology-of-cultural-critique approach began to occupy the methodological and ideological terrain that the earlier sociologists occupied. Vidich and Lyman (2000) note that in the 1930s and 1940s community sociologists such as Lynd (1956) and the Chicago School of Sociology were writing critiques of social class inequality and positive portraits of marginalized, stigmatized groups. One of the most powerful critical sociologists who emerged from this era was C.W. Mills (1959). He urged positivistic sociologists to abandon arid grand theories and to historicize and situate their studies in the everyday realities of power structures and social movements. Mills wanted to produce useful knowledge that addressed societal problems. An excellent contemporary illustration of this approach in education is Hugh Mehan's (2008) career as a design sociologist. After writing numerous critiques of American public education, Mehan helped create a California public school that detracks and

promotes the academic achievement of racially and culturally different populations.

In a complimentary fashion, existentialist sociologist Jack Douglas (1976) preferred an investigative posture to study societal problems. Tapping into muckraking new journalism (Wolfe, 1974), Douglas advocated operating covertly to expose corrupt bureaucrats or hate group leaders. He argued that in a politically corrupt, conflict-filled society, any means used to get the story was justifiable, if it exposed harmful public practices. Marxist educator Michael Apple's (2006) recent philosophical and empirical reflection on the religious right's attempt to privatize American public education illustrates nicely the investigative impulse in much critical educational ethnography.

After reviewing many contemporary studies of American culture, Foley and Moss (2001) concluded that late twentieth-century critical ethnography had developed a complex philosophical basis in the continental philosophies of post-Marxism, postmodernism, and feminism. The current crop of critical ethnographers seems to be focusing more on dramatic public issues, and they are finding ways to reach wider audiences. The work of Peggy Sanday (1990, 1996) on campus date rape and her involvement and coverage of rape trials is a case in point. Nancy Scheper-Hughes (1992) and Scheper-Hughes and Sargent (1998) study of child welfare issues and Third-World organ harvesting is also exemplary.

In the field of educational anthropology, we tried to document the gradual shift toward more critical qualitative and ethnographic approaches from the mid-1980s on (Foley *et al.*, 2001). Kemmis and McTaggart (2005) provide an excellent introduction to activist educational research using more collaborative methodologies called participatory action research (PAR). PAR researchers often base their approach on the philosophy of Latin American social activists Paulo Friere and Fals Borda. These researchers have affinities with the more activist-oriented applied anthropologists (Eddy and Partridge, 1987). They often play the role of democratic facilitator and consciousness-raiser, or cultural broker between powerful institutions and the disenfranchised citizens. The exemplary educational studies of Linda McNeil (2000) and Angela Valenzuela (2005) have forcefully critiqued the present federal policy called No Child Left Behind. These scholars have worked tirelessly with local teachers, community educational leaders, and state legislators for Texas school reform, and they have publicized their critique on national TV shows such as *Sixty Minutes*.

Increasingly, anthropologists who seek to serve the public interest are advocating a more politicized type of policy studies (Levinson and Sutton, 2001; Okongwu and Mencher, 2000; Kane and Mason, 2001). These surveys of the field, and a recent school of American research conference on critical ethnography (Marcus, 1999), describe a

host of new politically relevant sites of cultural critiques: corporate agriculture, environmental pollution, pharmaceutical dumping, transnational labor migration, the publishing industry, cyberspace hackers, the AIDS crises, and media and legal system demonization and criminalization of urban street life and informal economies based on drugs, sex, and cultural rebellion. These new critical ethnographers are beginning to write more accessible, less jargon-filled accounts. They are also finding additional ways to step outside the narrow publication circles of academia to influence public opinion. This may mean appearing as experts on talk and news shows. It may also mean providing reporters with expert testimony for their journalistic exposes, and working as policy advisors with state legislators, thus influencing educational legislation (Foley and Valenzuela, 2004).

A recent Wenner-Gren conference reaffirmed this explosion of politically and policy relevant critical ethnographies (Fox and Fields, 2008). The Wenner-Gren Foundation is the anthropological equivalent of the Spencer Foundation. It is the most prestigious foundation that sponsors research and conferences. During a recent theme conference on where anthropology as a field is headed, participants Charles Hale and Joan Rappaport advocated a much more politically engaged type of ethnographic practice. In their version of critical ethnography, activist ethnographers become deeply involved in progressive social movements and community-based reforms. These ethnographers reported using much more collaborative field methods, which invite the research subjects to co-theorize and co-author the ethnographies. Luke Lassiter (2005) has written an excellent historical review of how collaborative ethnographic methodologies developed in anthropology. Although still not the dominant mode of ethnographic research, collaborative and activist approaches are definitely gaining ground in the field. A recent special issue of the *Anthropology and Education Quarterly* (2008) on activist educational ethnography reports on a variety of projects in which ethnographers empowered youth and immigrant populations through ethnographic research, oral history, film production, drama, and writer's workshops. Many of these ethnographic projects used highly collaborative methodologies to produce written and multimedia accounts of their communities.

Conclusion

Overall, it would seem that progressive social scientists and educational researchers are creating a more publicly activist role for themselves. The cultural diversification of the academy and the social sciences is part of this change process. People of color, women, gays, and working-class academics are slowly replacing the upper-middle-class

white male gentleman scholars of early twentieth-century anthropology. Further, the emergence of the interdisciplinary field of critical cultural studies has created many new journals and special series in university presses. A market for more critical, investigative ethnographies that expose relations of power and exploitation has clearly evolved. However, these developments have their limits.

All young scholars are aware that Division I research institutions operate under a publish-or-perish logic. One either publishes articles in the refereed journals of his/her field – and books if his/her department is a book department – or he/she is not awarded tenure. The rub for many critical ethnographers is that their scholarship must be political in an academically acceptable manner. Consequently, many progressive academics tend to produce knowledge that other academics recognize as having universal or theoretical virtue. This may lead them away from producing local knowledge for activist groups that helps win lawsuits or rent strikes or that decolonizes the power of outside researchers that Maori scholar Linda Tuhiwai Smith (1999) advocates. Somehow, activist critical ethnographers have to find a way to satisfy the demands of the academy and local groups.

As many participants in the aforementioned Wenner-Gren conference noted, this has proven to be no simple task (Fox and Fields, 2008). A number of the conference participants pointed out interesting career shifts. These conversations left the participants wondering if critical ethnographers, who become deeply involved in local political struggles, have stopped writing academic books and articles. Contrary to concerns that radicals are taking over academia, the conference participants felt that activist colleagues often failed to get tenure, or they left the academy before such decisions were made. Unfortunately, we know precious little about where pushed-out activists go. Are they teaching in community colleges? Are they writing articles for local newspapers? Or have they succumbed to political disillusionment? Most critical ethnographers rarely chronicle the psychological and monetary price they pay for their political activism. There are few good intellectual histories of how the twenty-first-century academy is changing.

Overall, we have tried to raise some issues and make some distinctions that will move self-proclaimed critical ethnographers to interrogate their current ethnographic practices. Moreover, we have suggested many ways to question our notions of purpose, positionality, collaboration, and writing styles. We see many promising new varieties of critical ethnography emerging from the post-1960s revolt against positivism and a social scientific/educational establishment that was content with producing arid, a-historical studies that serve academic interests rather than the public interest. Transforming the academic knowledge production industry obviously requires much more than challenging the ideology of positivism

and scientism. We also need to change the way academic publishing is organized and controlled, and the way the academy awards promotion and tenure for publication and public service. In addition, we must continue to open up the academy to underrepresented groups.

Critical Race Theory

D Gillborn, Institute of Education, London, UK

Glossary

Color-blindness – An approach that claims to treat everyone the same regardless of their race. Although this view asserts a liberal and equitable intent, by refusing to acknowledge the significance of historic and contemporary race inequity, color-blind policies act to protect the status quo.

Contradiction-closing case – A perspective, developed by Derrick Bell and Richard Delgado, highlighting the limited and uncertain long term effects of landmark civil rights breakthroughs. Although such cases appear to close the contradiction between the rhetoric of equal opportunities and the reality of racial injustice, radical changes are typically thwarted by obstruction and delay.

Critical race theory – A multi-disciplinary approach that combines social activism with a critique of the fundamental role played by White racism in shaping contemporary societies.

Differential racialization – Refers to the constantly changing and malleable nature of racist stereotypes. Mainstream society constructs different stereotypes of different ethnic groups, but also, those stereotypes can change over time.

Interest convergence principle – An analysis, first proposed by Derrick Bell, noting that advances in race equality have historically come about only when White elites see the changes as in *their* own interests; especially as a means of limiting civil unrest and protecting against fundamental change.

Intersectionality – An approach that is especially sensitive to the ways in which multiple axes of oppression interact. For example, analyzing how racism operates within and across factors such as social class and gender.

Praxis – A combination of critical theoretical analysis and applied practical strategies of resistance.

Racial realism – A perspective that insists on the need to interrogate the workings of race and racism in their historical context in the real world rather than as hypotheticals in an abstract analytic form.

Social constructivism – A perspective that views phenomena such as race, class, and gender as socially constructed categories. Although ‘race’

masquerades as fixed and natural, it is a constantly changing, malleable and contested category.

White supremacy – Commonly refers to individuals and groups who engage in the crudest, most obvious acts of race hatred (such as extreme nationalists and neo-Nazis). In critical race theory (CRT) the term refers to a regime of assumptions and practices that constantly privilege the interests of White people but are so deeply rooted that they appear normal to most persons in the culture.

Critical race theory (CRT) is the name taken by a radical perspective on the nature and significance of race inequality in society. The approach assumes a social constructivist view of race and races as products of social thought and relations. Not objective, inherent, or fixed, they correspond to no biological or genetic reality; rather, races are categories that society invents, manipulates, or retires when convenient (Delgado and Stefancic, 2001: 7). The name critical race theory was coined in the 1980s to describe a movement of legal scholars, mostly people of color, who were dissatisfied with existing approaches to the field. Subsequently, the approach grew in popularity and transcended its disciplinary boundaries, moving into educational studies in the mid-1990s. The approach is now established as an important part of educational studies and, although it was originally focused entirely on the US, CRT is being taken up by critical scholars internationally.

The article examines the origins of CRT and identifies the key defining elements that characterize the approach. Some common myths and misunderstandings are also addressed.

The Origins and Development of Critical Race Theory

CRT has its roots in the centuries-old diasporic experiences and struggles of people of color, especially enslaved Africans and their descendants in the US. The perspective builds on this tradition in numerous ways, including the central role it devotes to political struggle, its concern for storytelling (and other narrative approaches), and the significant position accorded to key Black intellectual figures

of the nineteenth and twentieth centuries such as Frederick Douglass and W. E. B. Du Bois (Baszile, 2008; Mills, 2003).

As a self-consciously new and oppositional form of anti-oppressive theory, CRT began in the 1970s and 1980s in the work of legal scholars. It began as an alternative to dominant perspectives, not only the conservative mainstream but also the ostensibly radical tradition of critical legal studies (CLS) which, in the words of West (1995: xi) deconstructed liberalism, yet seldom addressed the role of deep-seated racism in American life. Frustration with the silence on racism prompted CRT scholars to foreground race and to challenge not only the foci of existing analyses, but also the methods and forms of argumentation that were considered legitimate. The foundational critical race theorists in law include Derrick Bell, Kimberlé Crenshaw, Richard Delgado, Alan Freeman, Angela Harris, Charles Lawrence, Mari Matsuda, and Patricia Williams. These writers represent a range of racial/ethnic heritages (including people of African American, Latina/o, Asian American, and White backgrounds) but share a commitment to analyze and oppose the workings of race inequality in legal culture and, more generally, in US society as a whole.

There is no single canonical statement of CRT; the perspective is built upon a series of key insights which are constantly refined through their application analytically and practically. In this sense, critical race theorists view social theory as a work in progress. But this does not mean that CRT is any less serious about the importance of theory – quite the contrary. From its first iteration as a new approach, critical race scholars have staked a claim to the conceptual importance of their work. Kimberlé Crenshaw, for example, describes how she and colleagues sought to find a form of words that could be used to describe (and provide a rallying point for) the new ideas they were developing as they began to organize what was to become the first ever CRT workshop (held at the University of Wisconsin, Madison, in July 1989):

Turning this question over, I began to scribble down words associated with our objectives, identities, and perspectives, drawing arrows and boxes around them to capture various aspects of who ‘we’ were and what we were doing (...) we settled on what seemed to be the most telling marker for this peculiar subject. We would signify the specific political and intellectual location of the project through ‘critical’, the substantive focus through ‘race’, and the desire to develop a coherent account of race and law through the term ‘theory’ (Crenshaw, 2002: 1360–1361).

This practical and strategic orientation reflects a perspective that Bell (1992) terms racial realism, that is, a determination to continually interrogate the workings of race and racism in the real world rather than as hypotheticals in an abstract analytic context. The real-world focus of CRT

should not be seen as in any way lessening its claim to be taken seriously as a major innovation in social theory. From its inception, CRT has encountered patronizing and dismissive responses from academics who found its focus on racism distasteful and/or threatening (Crenshaw, 2002: 1357).

CRT quickly began to move beyond law schools and was introduced into educational studies in the mid-1990s by Ladson-Billings and Tate (1995). Subsequently, the approach has been adopted by numerous scholars, especially people of color working with qualitative methods, most notably Thandeka Chapman, Adrienne Dixon, Marvin Lynn, Laurence Parker, Celia Rousseau, Daniel Solórzano, David Stovall, Edward Taylor, and Tara Yosso. CRT is also building an international presence, including work in the UK (Gillborn, 2005, 2008; Hylton, 2008) and Australia (McDonald, 2003; Moreton-Robinson, 2004).

Tenets of CRT

From its earliest formulations, CRT has generally been united by a dual concern to understand and oppose race inequality. In an influential statement of the approach, Kimberlé Crenshaw and colleagues state:

Although Critical Race scholarship differs in object, argument, accent, and emphasis, it is nevertheless unified by two common interests. The first is to understand how a regime of white supremacy and its subordination of people of color have been created and maintained ... The second is a desire not merely to understand the vexed bond between law and racial power but to change it (Crenshaw *et al.*, 1995: xiii).

Within CRT, the term white supremacy is used in a particular way that differs from its usual understanding in mainstream writing: whereas the term commonly refers to individuals and groups who engage in the crudest, most obvious acts of race hatred (such as extreme nationalists and Neo-Nazis), in CRT the more important, hidden, and pervasive form of White supremacy lies in the operation of forces that saturate the everyday mundane actions and policies which shape the world in the interests of White people:

[By] ‘white supremacy’ I do not mean to allude only to the self-conscious racism of white supremacist hate groups. I refer instead to a political, economic, and cultural system in which whites overwhelmingly control power and material resources, conscious and unconscious ideas of white superiority and entitlement are widespread, and relations of white dominance and non-white subordination are daily reenacted across a broad array of institutions and social settings (Ansley, 1997: 592).

Many critical race scholars view White supremacy, understood in this way, as central to CRT in the same way that the notion of capitalism is to Marxist theory and

patriarchy to feminism (Stovall, 2006). This perspective on the nature and extent of contemporary racism is one of the key defining elements of CRT.

The Centrality of Racism

CRT begins with a number of basic insights. One is that racism is normal, not aberrant, in American society. As racism is an ingrained feature of our landscape, it looks ordinary and natural to persons in the culture (Delgado and Stefancic, 2000: xvi).

CRT views racism as more than just the most obvious and crude acts of race hatred; it focuses on the subtle and hidden processes that have the effect of discriminating regardless of their stated intent. In the political mainstream racism tends to be associated with acts of conscious and deliberate race hatred; discrimination is assumed to be an abnormal and relatively unusual facet of the education system. In contrast, CRT suggests that racism operates much more widely; often through the routine, mundane activities and assumptions that are unquestioned by most practitioners and policymakers, for example, through the design of the curriculum, the operation of certain forms of assessment, and the selection and training of teachers who overwhelmingly replicate dominant cultural norms and assumptions about race and racial inequality (Ladson-Billings, 2004).

Critical race theorists do not view racism as a simple or unchanging aspect of society. CRT challenges ahistoricism by stressing the need to understand racism within its social, economic, and historical context (Matsuda *et al.*, 1993: 6). The notion of differential racialization refers to the constantly changing and malleable nature of racist stereotypes. For example, a group once seen as conservative and conformist might be redefined as competitive and threatening at another time, for example, Japanese workers in the US and Asian groups in the UK during the twentieth century.

The focus on racism in CRT does not operate to the exclusion of other forms of social inequality. Indeed, a key aspect of CRT is a concern with intersectionality, that is, an attempt to analyze how racism operates within and across other axes of differentiation such as social class and gender (Crenshaw, 1995; Tate, 1997).

A Critique of Liberalism

Another distinctive theme is CRT's critique of liberalism. CRT portrays dominant legal claims of neutrality, objectivity, color-blindness, and meritocracy as camouflages for the self-interest of powerful entities of society (Tate, 1997: 235). In the education system, for example, racism is figured in the distribution of material and educational resources and even in teachers' notions of ability and motivation (Gillborn, 2008). In this situation, the adoption

of color-blind approaches (which refuse to acknowledge racial reality) and an emphasis on supposed merit (as measured by dominant assessments) may appear open and equitable, but the playing field is not level. Minoritized students are more likely to attend poorly funded schools, with less-highly qualified teachers and, because of socio-economic inequalities, they are less likely to enjoy additional educational resources at home, such as Internet access (Ladson-Billings, 2006). Under such unequal conditions, a color-blind insistence on a simple merit standard will not only ensure that race inequalities continue but also present them as fair and just.

The Call to Context (Experiential Knowledge and Storytelling)

CRT places a special importance on the experiential knowledge of people of color. There is no assumption that minoritized groups have a singular or true reading of reality; rather, there is recognition that by experiencing racial domination, such groups perceive the system differently and are often uniquely placed to understand its workings. Delgado (1989) is one of the leading advocates of the need to name one's own reality. Inspired by the scholarship of Derrick Bell, and the centuries-old traditions of storytelling in minoritized communities, Delgado argues forcefully for the use of narrative and counter-storytelling as a means of presenting a different reading of the world, one that questions taken-for-granted assumptions and destabilizes the framework that currently sustains, and masks, racial injustice.

A Revisionist Critique of Civil Rights Progress (the Interest Convergence Principle)

Detractors have sought to present CRT as disrespectful of civil-rights campaigns and their victories but this misreads the approach. CRT is not critical of the campaigns or the people who sacrificed so much to advance race equality (Crenshaw *et al.*, 1995). Rather, CRT examines the limits to reform via law and policymaking, and shows how even apparently radical changes are reclaimed and often turned back over time. A key element here is the concept of interest convergence. Put simply, this view argues that advances in race equality come about only when White elites see the changes as in their own interests. Bell (2004: 59), who coined the interest-convergence principle, summarizes the idea like this:

Justice for blacks vs. racism = racism.

Racism vs. obvious perceptions of white self-interest = justice for blacks.

It is important to note that interest convergence does not envisage a rational negotiation between minoritized

groups and White power holders, where change is achieved through the mere force of reason and logic. Rather, history suggests that advances in racial justice must be won through protest and mobilization, so that taking action against racism becomes the lesser of two evils for White interests. For example, the moves to outlaw segregation in the 1960s are usually thought of as signs of enlightenment and a landmark civil-rights victory. But they must be understood within the context of the Cold War and the need for the US to recruit friendly African states (Dudziak, 1988):

No such decision would have been possible without the world pressure of communism which made it 'simply impossible for the United States to continue to lead a "Free World" with race segregation kept legal over a third of its territory W. E. B. Du Bois (1968 quoted in Bell, 2004: 67).

The obvious signs of segregation – such as separate toilets and lunch counters – may have gone but the reality of ingrained racism continues in economic, residential, and educational terms. It has been argued that more African Americans now attend segregated schools than they did in 1954 at the time of the Supreme Court decision in the *Brown versus Board of Education* case (Delgado and Stefancic, 2001: 33). Delgado and Stefancic (2001: 24) describe the process like this:

... after the celebration dies down, the great victory is quietly cut back by narrow interpretation, administrative obstruction, or delay. In the end, the minority group is left little better than it was before, if not worse. Its friends, the liberals, believing the problem has been solved, go on to something else ... while its adversaries, the conservatives, furious that the Supreme Court has given way once again to undeserving minorities, step up their resistance.

Landmark victories may actually come to operate in ways that protect the racist *status quo*: these are sometimes known as contradiction-closing cases, which operate like a safety valve to provide a solution when the gap grows too large between, on one hand, the liberal rhetoric of equal opportunities and, on the other hand, the reality of racism.

[contradiction-closing cases] are a little like the thermostat in your home or office. They assure that there is just the right amount of racism. Too much would be destabilizing – the victims would rebel. Too little would forfeit important pecuniary and psychic advantages for those in power (Delgado, 1995: 80).

Landmark cases – such as the *Brown* desegregation case in the US, and the Stephen Lawrence Inquiry in the UK (Macpherson, 1999) – appear to have addressed blatant race inequalities but, in reality, little or nothing changes. Indeed, such cases are sometimes used as yet another weapon against further reform because they:

... allow business as usual to go on even more smoothly than before, because now we can point to the exceptional case and say, 'See, our system is really fair and just. See what we just did for minorities or the poor' (Delgado, 1999: 445).

CRT is a wide-ranging perspective that can be applied to numerous different issues within the field of education. For example, Ladson-Billings (1998) has noted CRT's relevance to the curriculum (where the selection of material typically promotes a sanitized version of historical and contemporary race relations), instruction, and pedagogy (where teachers' assumptions often disadvantage particular minoritized groups who are seen as a likely source of conflict rather than academic achievement), assessment (where the instruments used to grade and select students frequently encode unrecognized race bias), and in school funding (where, for example, African American students are more likely to attend schools with the lowest per-pupil funding and where teachers have less secure prospects).

Myths and Misunderstandings

Like any new perspective, CRT has been subject to a range of responses and critiques. Some of the engagement has been positive and constructive, pushing critical race scholars to clarify their arguments and develop further analyses. Other responses, however, have sought to reassert traditional assumptions (in the guise of scientific rigor) or dismiss CRT as misguided or simplistic (see Stovall (2006) for a review and response). As we have noted above, CRT offers a view of the world that is fundamentally at odds with mainstream assumptions and so it is no surprise that the approach is sometimes misunderstood. Three myths seem particularly common: first, that CRT views race as the source of all major inequalities; second, that CRT views white people as uniformly racist and privileged; and finally, that CRT promotes a sense of hopelessness and pessimism.

Despite its central focus on racism, CRT does not insist that race is always the single most important factor in every situation. CRT argues that race/racism is always relevant to an understanding of wider social inequalities but it is not the only element. Indeed, race inequity often cannot be fully understood in isolation from other axes of differentiation such as class and gender. As Stovall (2006: 252) notes:

Vital to this misinterpretation is the semantics of referencing CRT as a critique solely of 'race'. In no CRT literature is there a claim to the unanimity of race. The critique has and continues to be one of the functions of White supremacy and the complexities of race.

Similarly, it is sometimes argued that by identifying the underlying forces that legitimate and support white supremacy CRT imagines all white people to be the same: in fact the criticism betrays a one-dimensional reading of CRT. Critical race theorists do not imagine that White people are uniformly privileged and racist, nor do they feel that all Whites benefit equally from White supremacy. Such a position is patently ludicrous, especially in view of the fact that foundational CRT writers have repeatedly noted how interest convergence usually operates to defend White elites at the expense of lower-class Whites (Bell, 2004). However, CRT does show how even working-class Whites draw advantage from their Whiteness (Harris, 1993). Whites do not benefit equally, but they do all benefit from Whiteness to some degree (McIntosh, 1992). For example, when the attainment of the most economically disadvantaged White students in the UK dipped marginally below that of their Black peers, the media responded with stories blaming “the race-relations industry” and claiming that neo-Nazi groups would gain advantage. The stories failed to mention that White students outperformed virtually every minoritized group among the 86% of the school population not counted as living in poverty (Gillborn, 2008). Hence, even for the White students living in greatest poverty, their race meant that the media perceived a national scandal if their achievement was not greater than similarly disadvantaged minoritized peers.

A third myth about CRT is that, by viewing racism as such a deep-rooted aspect of contemporary society, the perspective promotes hopelessness. Bell (1992: ix) recalls an incident when he was challenged at a public reading of his work:

Professor Bell, you have achieved much despite racial discrimination. How dare you now deny our children the hope that they may enjoy a success like yours?

The author responded that “it was the society and not me” that closes down opportunities for African Americans; he did not create the situation, he simply chronicled what society had done and was likely to do. In fact, far from promoting a sense of hopelessness, CRT insists on the vital importance of active resistance against racism.

Bell argues that a total victory over racism may prove elusive but sees a duty to combat injustice (against all oppressed groups) as a central component of what he calls a life fulfilled (Bell, 1992: xi). The history of racism and education in the UK, for example, clearly demonstrates that all meaningful advances in race equality have come about as a result of community action (Tomlinson, 2008). Antiracist action may never entirely remove racism but in the absence of resistance, it is certain that racist inequity would worsen. As Frederick Douglass observed more than 150 years ago: “If there is no struggle, there is no progress ... Power

concedes nothing without a demand. It never did, and it never will” (quoted in Crenshaw, 2002: 1372).

Delgado and Stefancic respond to the accusation that CRT is a theory of despair by asking “Is medicine pessimistic because it focuses on diseases and traumas?” (2001: 13). Indeed, Delgado turns the accusation on its head and identifies the lie at the heart of liberal perspectives which appear optimistic but disguise the true scale and nature of contemporary racism:

Suppose I am sent to an inner city school to talk to the kids and serve as role model of the month. I am *expected* to tell the kids that if they study hard and stay out of trouble, they can become a law professor like me. That, however, is a very big lie: a whopper. When I started teaching law sixteen years ago, there were about thirty-five Hispanic law professors, approximately twenty-five of which were Chicano. Today, the numbers are only slightly improved (...). Despite this, I am expected to tell forty kids in a crowded, inner city classroom that if they work hard, they can each be among the chosen twenty-five (Delgado, 1991: 1228 original emphasis).

Continuing Debates and Unresolved Issues

CRT is gaining increasing attention but it is by no means a finished and settled set of approaches. CRT is a living and changing perspective, not a monolithic structure. There are, for example, many spin-off movements from traditional CRT, including critical race feminism and LatCrit – a version of CRT that focuses on the particular experiences and struggles of Latina/o communities (see Delgado and Stefancic, 1998; Dixson and Rousseau, 2006; Solórzano and Yosso, 2001; Wing, 1997). Although CRT in the US began with work that often focused on the position of African American communities, it is not the case that CRT adopts (or has ever supported) a simple racial binary perspective that views the world as divided between Whites and a unitary racial Other.

There are many important debates within CRT about the best way of conceiving its work and, in particular, the most effective means of moving things forward through a critical praxis, that is, a combination of theoretical analysis and applied practical strategies of resistance (Lynn and Parker, 2006). Many of these debates raise issues that are relevant to a number of different perspectives and are by no means unique to CRT. For example, there is discussion about the level of group-identification/abstraction that is appropriate for different analytic and political purposes: sometimes it may be best to organize around a collective signifier that includes numerous minoritized groups, while at other times a more specific identity may be preferred (national, linguistic, or religious).

There is a continuing concern within CRT to understand the numerous, complex, and changing ways in which race/racism intersects with other axes of oppression, such as class, gender, disability, and sexuality. This concern with intersectionality is especially strong in critical race feminism (Wing, 1997; Youdell, 2006). Indeed, building on Crenshaw's work, UK scholars Brah and Phoenix (2004) argue that intersectionality itself can provide a useful focus that offers numerous advances on current single-issue thinking. As Crenshaw (1995) argues, rather than viewing intersectionality as a kind of problem to be solved, the best way ahead may be to use intersectionality as a key means of understanding how White supremacy operates and how to mount effective resistance.

Summary

CRT began as an oppositional movement, mostly involving scholars of color, in US law schools in the 1970s and 1980s. The approach has developed rapidly and is now an interdisciplinary perspective with a growing presence in educational studies internationally.

There is no single canonical statement of CRT but certain elements have emerged as central themes that characterize the movement. The first of these is the central role accorded to racism, which is seen as a subtle and pervasive force in society that is so deep rooted as to appear normal to the majority. CRT is also characterized by a critique of liberalism, which points to the failure of notions such as merit, neutrality, and color-blindness which masquerade as fair and just but, because of the uneven playing field of contemporary racist society, they actually function to ensure the continuation of race inequality.

Building on a long tradition of oral histories and subversive storytelling, CRT writers sometimes adopt a narrative approach and, distinctively, they give particular prominence to the experiential knowledge of people of color. This has been a point of controversy with the academic mainstream but reflects CRT's constructivist view of knowledge and its determination to challenge the common-sense assumptions that often encode majoritarian interests.

This deep commitment to promoting real change in the position of minoritized groups is a central tenet of CRT and fuels its disenchantment with traditional notions of civil-rights progress. Critical race scholars draw inspiration from their activist predecessors but they are far from content with the scale of changes that have been won to date. Indeed, a central concept is the interest-convergence principle which notes the benefits to White people at the heart of even the most celebrated civil-rights cases.

This perspective on the enduring nature of racism has led to CRT being condemned by some detractors as a council of despair. Such a reading, however, oversimplifies the approach and fails to appreciate the activist theme that lies at the core of critical race analyses. Similarly, CRT is sometimes caricatured as being concerned with race inequity alone and viewing all white people as uniformly racist and privileged: both these myths reflect a failure to grasp the complexities of CRT which continues to grow and develop in new ways. In particular, the notion of intersectionality is increasingly important, providing a basis for critical race scholars to examine the changing and complex intersections between racism and other axes of oppression, such as class, gender, and disability. As CRT spreads internationally, and generates off-shoot movements such as critical race feminism, it is likely that the approach will generate further interest and controversy.

Glossary

Critical pedagogy – A teaching approach that brings together critical theory and educational practice in order to help students question and challenge dominant beliefs and practices for higher social, critical consciousness.

Dialectic – Initially conceptualized as a Socratic technique of employing discussion, reasoning, and, therefore, dialog to expose false beliefs, Hegel applied the dialectic to mean a critical investigation of the process of change resulting in the theoretical application of such a process to the social sciences.

Domination – The exercise of ruling power with supremacy or preeminence over another.

Exploitation – The act of making use of another in an unfair or mean manner for one's own advantage.

Inquiry – A systematic investigation and examination of facts or principles.

Praxis – A union of action and reflection and of theory and practice; critical praxis in education refers to a threefold process of self-reflection, reflective action, and collective reflective action for social change.

Critical Theory: An Overview

Critical theory has a long history of informing and shaping diverse qualitative research practices. Such a theoretical lens – both for educational researchers and otherwise – has proven particularly valuable in – first, challenging qualitative researchers to question more positivist approaches that can inaccurately assume scientific neutrality among objective observers while, second, engaging researchers in more reflexive research practices that question the biases from which they view the world. Through using critical theory, qualitative researchers can push educational reform for the better of all humanity.

Although it is difficult to point to one, universally accepted critical theory that has been unproblematically embraced by all critical philosophers, one could still recognize a shared notion of critical theory as referring to both the legacy of Western theoretical traditions following the Frankfurt School, as well as an evolving school of thought and process of critique.

As a philosophy within the social sciences, critical theory refers to the prolific work of several generations of German thinkers belonging to Western European and Marxist traditions who can be broadly categorized as members of the Frankfurt School. Philosophers of the Frankfurt School moved away from traditional theory by seeking to radically reconstruct the meaning of human emancipation through what Max Horkheimer has described as “liberate[ing] human beings from the circumstances that enslave them” (Horkheimer, 1972: 244). Critical theory is rooted in historicizing, critiquing, and exposing the relationships of domination and subordination as well as the contradictions in which humankind is entrenched and thus, in essence, is a liberatory philosophy. Such critique focuses on deconstructing how knowledge is produced, whose knowledge is valued, and how control of such knowledge equates to power in society, with the purpose of preventing people from becoming slaves to the ideas and activities that societal institutions push upon them. As a result of this search for a theory that – through critique of social constructs – could articulate freedom for all, while arguing against the suppression of human consciousness, multiple and diverse critical theories have developed since the birth of the Frankfurt School, including (but not limited to): critical race theory, critical pedagogy, critical literacy, critical feminist theory, etc. (see the section titled Global Critical Philosophies).

Viewed as a process of critique or methodology, critical theory may also be defined as a type of self-conscious means of addressing the need for dialog and a dialectic approach around transformative, emancipatory practice. Such a process of critique pushes theorists to continuously question how they look at – and depict – the world in comparison to how the world actually exists, and, as a result, challenges theorists to question the very theories they form through such a process. According to critical theory, when a philosophy is embraced without question and fails to problematize wider society, it has become an ideology in need of critique. The Frankfurt School valued the use of such inquiry or critique as a tool articulating praxis – therefore, engaging a relationship between theory and society.

A Brief History of Critical Theory and the Frankfurt School

The best way to understand critical theory is to first locate it within Western philosophy's historical trajectory.

In doing so, one will find that critical explorations of the nature of knowledge production that form the framework of critical theory today can be traced back as far as 2500 years before the first critical scholars.

Classical Philosophers

A critical approach to understanding the relationship between knowledge and power in society can be found in the work of the Greek philosophers Socrates (469–399 BCE), Plato (428/427–348/347 BCE), and Aristotle (384–322 BCE). Through Plato's dialogues – most notably *Gorgias* and *The Apology* – one can see how Socrates (Plato's mentor) questioned the way the Sophists (classical Greek philosophers who exercised great power in Athens) used rhetoric to persuade people to manufacture and believe in false truths, rather than use rhetoric to search for ultimate truth for the better of humankind. Similarly, Plato's determination to record Socrates' stories through the written word – despite Socrates' skepticism about the technology of writing – reflects the ways in which Plato recognized the importance of language as a meaning-making tool for the development of critical thought. Following Plato, Aristotle theorized and deconstructed the power of knowledge creation in language manipulation through *The Art of Rhetoric* and *Poetics*. Aristotle outlines the process of writing persuasive speeches that appeal to *logos* (reason), *pathos* (emotion), and *ethos* (confidence in the orator's personal character). Although thousands of years would pass between the lives of these Greek philosophers and the foundations of critical theory which grew out of the Enlightenment, the examination of linguistic tools in knowledge production that explored in Socrates, Plato, and Aristotle's work proved invaluable to Western philosophy traditions.

Kant, Hegel, Marx, and Modern Foundations of Critical Philosophy

Following the Middle Ages – that marked the hegemony of the Catholic Church – and the Renaissance, that marked the break from this Church's control, came the birth of the Enlightenment in Europe and America. During this era, Immanuel Kant (1721–1804) highlighted the value of critique as the only way to find true knowledge and combat illusory ideologies by separating the self from the dogmas surrounding us and by questioning those concepts that are presented to us as facts. Georg Wilhelm Friedrich Hegel (1770–1831) also theorized about knowledge production but wished to push beyond Kant's separation of mind and self when deconstructing ideologies. Hegel, instead, sought to historicize the process of arriving at truth. Hegel's approach suggested that history could be viewed as progress toward a greater humanity – and Utopia – through a higher consciousness of self in and

with the world. Hegel's great contribution to the foundations of critical theory exists in his use of dialectic reasoning to reach perfection, which involves engaging in dialog to overcome the contradictions between thesis and antithesis toward a synthesis that would, in turn, be challenged repeatedly until perfect synthesis (Utopia) could be reached.

Following Hegel, Karl Marx's (1818–83) work with Friedrich Engels with regard to the historical and material conditions of capitalism, is recognized as the most influential to shaping critical theory. Although seen, primarily, as an economic philosopher, Marx's elucidation of how the proletariat (working class) has been alienated and exploited by the bourgeoisie (ruling class) – who benefit through the accumulation of wealth – helped develop an understanding of how ideologies reinforce false consciousness that can be used to maintain power in the hands of those in control. Thus, Marx provided the basic idea on which critical theory is constructed: those who have economic power in society also control the cultural superstructure of that society. Marx recognized how production and consumption of media (through language) controlled class consciousness and how, simultaneously, such a tool could also be used against oppressive capitalist ideologies for a better humanity.

The Frankfurt School

The original home of the Frankfurt School was in the Institute for Social Research (Das Institut für Sozialforschung) that was originally founded in Frankfurt, Germany, in February 1923, but was forced to move under Nazi threat, in 1933. In 1930, the Institute came under the directorship of Max Horkheimer and grew to include critical theorists such as Erich Fromm, Herbert Marcuse, Theodor Adorno, and Walter Benjamin who shifted its theoretical focus from an analysis of bourgeois society's socioeconomic substructures to bourgeois cultural superstructures. Although primarily influenced by Marxism, the Frankfurt School rejected an orthodox reading of Marx and represented a different form of Marxism than their Bolshevik contemporaries, as they did not envision an inevitable proletariat revolution nor focus solely on economic production. Instead, the Frankfurt School sought to understand the relationship between theory and society through a dialectical framework that also examined the realm of culture “including not only the so-called spiritual contents of science, art, and religion, but also law, ethics, fashion, public opinion, sport, amusement, life style, etc.” (Horkheimer, 1972). Thus, the Frankfurt School became both a representation of Western Marxism and a critique of it.

Central to the Frankfurt School's articulation of critical theory was its critique of the Enlightenment's conceptualization of instrumental reason, rationality, and positivism (as explored by diverse thinkers including

Saint-Simon, Comte, the Vienna Circle, and others). The Frankfurt School believed there was a breakdown in reason due to a “crisis of science” that reduced the concept of knowledge to a limited scientific methodology of “description, classification, and generalization of phenomena, with no care to distinguish the unimportant from the essential” that could only be resolved through the creation of “a correct theory of the present social situation” (Horkheimer, 1972). Echoing Nietzsche’s belief that it was not science but the scientific method that proved triumphant during the nineteenth century, the Frankfurt School sought to rescue the world from the basic assumptions of logical positivism – that valued objective observation as the only way to produce truth – by envisioning critical theory as an improved approach to human reasoning, supporting a more self-conscious critique of human action for transformation. The Frankfurt School believed that positivist rationality and its narrow view of science endangered human ability to think critically and subjectively with regard to the world – freezing human history behind selected, organized, and fetishized facts in false-value neutrality, rather than recognizing how natural reality and science relate both to human consciousness and lack of consciousness as well as subjectivity and objectivity positions. Furthermore, the Frankfurt School articulated how those engaged in using positivist rationality were not necessarily conscious of the ways in which such an approach could maintain an oppressive power imbalance or the *status quo* in work labeled as scientific, and thus urged philosophers to consider their positionality as producers of knowledge.

In order to address these problems with logical positivity and Enlightenment rationality, the Frankfurt School formulated a critical theory that first recognized the relationship between individuals and society as a whole. In this way, critical theory develops a capacity for meta-theory by acknowledging the cultural–historical positionality of interested, non-neutral parties whose political or social interests affect how they navigate and present knowledge or information. With such a self-critical and self-conscious lens, critical theory engages in dialectical thought that lives within the tension between critique and theoretical reconstruction. As noted by Marcuse (1960), “Dialectical thought starts with the experience that the world is unfree; that is to say, man and nature exist in conditions of alienation, exist as ‘other than they are.’ . . . Thought ‘corresponds’ to reality only as it transforms reality by comprehending its contradictory structure.” Dialectical methodologies synthesize philosophy, the social sciences, and radical politics to help illustrate how society, state, economy, culture, and the individual are all related to one another. Thus, critical theory should work towards an improved society devoid of injustice and oppression and “emancipation from slavery” (Horkheimer, 1972) through equal engagement of theory and practice in critical praxis.

The Frankfurt School also used critical theory to reject essentializing and hierarchical perspectives of culture that were supported by sociologists and orthodox Marxists of the time. The Frankfurt School rejected definitions of culture as a stagnant, objectified ideology, and, instead, embraced culture’s processual and politically and economically situated role in the development of human relationships over time. Such was visible in the work of Horkheimer and Adorno.

More specifically, Theodor Adorno (1903–69) powerfully shaped the future of cultural theory through his work in the Frankfurt School by recognizing how major culture industries used popular culture – such as film and radio – to advance the oppressive ideologies of the dominant, capitalist society. Through Adorno’s work, critical theory grew to question the dehumanizing relationship between media culture and its consumers, while simultaneously recognizing the power of using new media literacies against such control. In *One Dimensional Man* (Marcuse, 1964), Herbert Marcuse (1898–1979) critiques industrialism’s oppression of individuals for the maintenance of systems of production. Through this work, Marcuse pushed critical theory to demonstrate how individuals are completely controlled by a system of production and consumption. In other work, Marcuse also helps to elucidate the purpose of dialectical thought as a connection between thought and action in *Reason and Revolution* (Marcuse, 1960), where he writes how “Thought ‘corresponds’ to reality only as it transforms reality by comprehending its contradictory structure . . . to break down the self-assurance and self-contentment of common sense, to undermine the sinister confidence in the power and language of facts.” Max Horkheimer’s (1895–1973) work focused primarily on the function of reason within philosophy and the creation of oppressive ideologies in larger society which proved particularly significant during a period in which the Nazis were using evil and dehumanizing methods to manipulate society to engage in the mass murder and torture of Jewish people. Horkheimer used critical theory as a tool to fight such destructive mass ideologies in a rapidly changing world. Habermas’ contributed to critical theory in his development of the theory of communicative reason or communicative rationality couched in discourse ethics and idea exchange. Walter Benjamin (1892–1940) engaged in critiques of literary and artistic work – building on aesthetic theory while pushing critical theory to discuss the realm of culture and its historical context. Thus, critical theory was created to give people the agency to challenge taken-for-granted assumptions through tools such as dialectical reasoning and praxis that promote free-thinking and self-determination for all individuals in society. As elucidated by Horkheimer, a truly critical theory “has as its object human beings as producers of their own historical form of life” (Horkheimer, 1993: 21).

Global Critical Philosophies

Although critical theory itself was born of a Western and European philosophical history, other great philosophies have also developed worldwide that should be recognized as part of the critical theory canon in its current, living form. Some such traditions have borrowed from Western philosophies while others have developed more independently and, while not all such work has been unearthed due to language barriers and imbalanced power relationships between Western imperialists and scholars of other nations, an attempt will be made here to bring some of these global critical philosophies to the mainstream of Eurocentric critical thought.

Within the African American tradition, one can see important developments in critical theory through the work of W.E.B. DuBois (1868–1963) in his famous work – *The Souls of Black Folk* (originally published in 1903, DuBois, 1903). Through his deep exploration of race in America, DuBois theorizes about “double consciousness” experienced in the African American who sees herself/himself through the gaze of those who hate people of color, and describes the torment this places on the spirits of all people in a racist society. DuBois recognizes how ideologies of race are formed through dominant languages, but how a critical approach to education could help transcend such oppressive ideologies for social change. Following the Harlem Renaissance and the growth of amazing art and literary works that helped engage humanity in a critique of America’s social structures and institutions, Carter G. Woodson (1875–1950) published *The Miseducation of the Negro* (Woodson, 1933) which challenged the ways classical education incorporated forms of scientific racism by revising world histories to enforce ideas about the racial inferiority of people of color. By removing African Americans and African peoples from school knowledge with regard to history and science, classical education dehumanized African Americans and continued to oppress and mold them to the racist, hierarchical American fabric. Woodson calls for a critical education in which people of color could question the schooling they receive for individual and community liberation. Such works not only influenced innumerable educators, scholars, artists, and activists toward a critique of society for the purpose of social change as is visible in the work of Frederick Douglass, Langston Hughes, Marcus Garvey, Malcolm X, and the Black Panther Movement – all of who engaged in challenging how knowledge is produced and used to manipulate truth in a racially hierarchical society.

During the 1980s, other great scholars – such as Edward Said and Homi Bhabha – pushed critical theorists to think in new ways by developing studies in colonialism and postcolonialism. Recognizing how Western colonialism maintained its hegemony through the control of knowledge and knowledge production, postcolonial

theorists engage critical theory in ways most applicable to the current reality of globalization. Although often associated with postmodern theory in its methodology under the influence of Jacques Derrida’s concepts of deconstruction, Jacques Lacan’s psychoanalysis, and Michel Foucault’s discourse analysis, postcolonial theory still relates to critical theory in the ways that colonized, indigenous peoples have found agency in critiquing the oppressive societies in which they live. In *Orientalism* (Said, 1978), Said critiques the ways in which the West continues to romanticize Asian and Middle Eastern nations as the archaic and unchanging ‘other’, while using such false ideologies to justify continued imperialism throughout the Orient. Similarly, in *Nation and Narration* (Bhabha, 1990), Bhabha problematizes how postcolonial countries continue to be treated as one, homogeneous group by their ex-colonizers, with concepts of nationhood narrativized through power imbalances between ex-colonizing nations and their ex-colonial states.

Frantz Fanon (1925–61) made immeasurable contribution to the furthering of critical theories through his own work in Africa focusing on Algerian resistance to French rule. Believed to be influenced by the 1930s Négritude movement – that rejected French colonial racism and was led by Martinican poet Aimé Césaire, Guianan Léon Damas, and future Senegalese President Léopold Sédar Senghor – Fanon explored how the psychology of oppression and the impact of colonialism affected the mental health of colonized people in works like *A Dying Colonialism* (Fanon, 1959) or *Black Skin, White Masks* (Fanon, 1967). By critiquing the way colonial powers control colonial ideology production and dissemination and how media is used to manipulate colonized people into believing in Western racial hierarchies of language, custom, or skin color, Fanon illustrates how indigenous peoples can deconstruct dominant language and texts toward ideology change for liberation. Fanon’s work highly influenced the revolutionaries of other nations – most notably Fidel Castro in Cuba, Paulo Freire in Brazil, and the Black Panthers in the United States.

Of course, Latin American and Central American development of new critical theories can be traced through the work of Liberation Theology that united indigenous people with Catholic clergy against the oppressive, racist structures of the European Catholic church, or in the work of Ernesto Ché Guevara – Minister of Education in post-revolution Cuba and organizer of the guerrilla mountain schools – but the most notable development of critical theory can be found in the work of Paulo Freire (1921–97), in Brazil. Freire’s most famous work – *The Pedagogy of the Oppressed* – explores the ways the educational system proves central to the dehumanizing processes of capitalist and neocolonial societies through banking education that treats students as empty vessels that passively collect the oppressive norms and knowledge of teachers. Freire focused on literacy and literacy education while teaching illiterate adults how to

interrogate and deconstruct dominant texts within a racist, classist Brazil. Freire believed in the power of praxis and dialog to push critical thought against oppressive forces that control schooling structures.

While critical theory has surely influenced revolutionaries, scholars, and activists throughout East Asia, the continued imbalance of power relationships that maintain hierarchies with regard to race, class, color, and language in the Western world continues to negate and oppress East Asian critical scholarship. Little of East Asian critical theory has been translated and shared with Western academia and this issue should be immediately addressed.

Critical Theory in Education

The critical theory of the Frankfurt School and other global critical theories prove crucial to educational reform and can be used to revolutionize today's schools toward a more just, humanizing, and democratic system. First of all, the ways in which critical theory challenges positivist rationality that assumes political neutrality in educational spaces is invaluable to opening a space for educators to recognize the hidden curricula of current standardized schooling. Second, critical theory values historical consciousness as fundamental to engaging in critical thought and critical literacy. Recognizing the sociohistorical framework in which knowledge is produced and the pedagogical tools used by teachers in today's schools proves essential not only to deconstructing what students are learning, but also how students are learning. Third, engaging in historical consciousness through critical theory in education simultaneously forces us to re-mediate the ways in which educators and administrators of schools view race, class, gender, language, sexuality, and culture. Critical theory perspectives allow for people to engage in an informed critique toward reforming education so that it treats each student with respect toward the funds of knowledge and perspectives from which she/he comes without essentializing or reifying her/his experiences. Fourth, critical theory can be usefully applied to education through the use of dialectical thought and praxis which pushes teachers and students alike to actively use social inquiry to question oppressive, dominant structures in society while moving toward a more liberatory practice. Fifth, critical theory in education believes in the power of schooling as a tool for social justice by engaging in the needs of students' home communities. Thus, using critical theory not only as a means of meaning-making, but also as a means of connecting diverse students and teachers to each other in shared practices through education can build a new community of learners who can change the world. As recognized by Freire and Macedo (1987), critical theory can be engaged in education through critical praxis that involves "reading

the world . . . through reading the word" (p. 35) as students gain new critical literacies by being taught to engage in questioning social relations existent in society.

Following this critical theory tradition, developers of critical pedagogy – including, but not limited to, Paulo Freire, Peter McLaren, Ernest Morrell, Henry Giroux, Ira Shor, Antonia Darder, bell hooks, Joe Kincheloe, Paula Allman, Donald Macedo, and Maxine Greene – encourage educators to apply the ideas of critical theory to schooling structures in ways that revolutionize the ways we think about both the purpose and practices of education. Although diverse in its applications to schooling, critical pedagogy challenges the conservative policies and practices of banking education that – in the current era – are tied to standardized testing and curricula in a classist, racist, sexist, and heterosexist world. By embracing the power of student, educator, and researcher agency within an oppressive American school system, critical pedagogy grounds social justice education using tools of critique that question how knowledge is produced, controlled, and disseminated. Critical pedagogy proves a valuable example of how critical theory can be applied to education. Critical revolutionary pedagogy (see the work of Peter McLaren, Paula Allman, Glenn Rikowski, Mike Cole, and Dave Hill) has also been developed in opposition to more domesticated and sanitized versions of critical pedagogy and critical theory found in educational reform efforts that do not contest neoliberal capitalism, and attempts to unite critical pedagogy and classical Marxist theory.

Critical theory pushes educators and educational researchers to rethink the power dynamics that both influence and work within schooling systems and, as explored by Antonio Gramsci (1891–1937) – who believed that all humans were capable of intellectual and rational faculties – critical theory can help us recognize the ways in which education, similar to media, is an ideological apparatus of the state that reproduces the hegemony of those in control. Thus, educational researchers can find agency through critical theory to engage in social inquiry that transforms the space of schools, the practice of teachers, the treatment of students, the sharing of diverse knowledge, and the improvement of society at large.

Glossary

Critical media literacy – A branch of media education designed to foster a critical approach to popular texts, with an emphasis on how media images connect to broader cultural understandings. In addition to developing techniques of interpretation, critical media literacy approaches cultural production as a valuable site of learning.

Ethnography – Methodology through which anthropologists and some sociologists study cultural phenomena. It involves prolonged periods of observation and participation within a particular cultural context.

Frankfurt School – Originally an institute of social research founded in 1923, led by prominent Marxist scholars Theodor Adorno, Walter Benjamin, Max Horkheimer, and Herbert Marcuse. Their work inspired the evolution of ‘critical theory,’ and is best known for critiques of ideology and industries of mass culture.

Hegemony – Concept developed by Italian scholar Antonio Gramsci to explain how unequal relations of power are maintained through popular consent and taken-for-granted assumptions. Hegemony refers to the process whereby members of a society participate in reproduction of dominations through the assumptions of ‘common sense’ values that benefit those who have power.

Hybridity – In cultural theory, hybridity refers to the process through which two or more cultural forms come together to create a new form of cultural practice. It is often associated with cultural practices that emerge from the encounter of multiple groups through processes of migration, globalization, and dissemination of cultural forms through media.

Postcolonial theory – A theoretical approach that seeks to counter the racism that underlies the systems of knowledge and cultural production that support colonial or imperial conquest. It calls into attention the ways in which both scientific knowledge as well as cultural production are employed as tools of conquest and oppression, as well as the ways in which colonized communities respond to conquest through complicated cultural practices.

Queer theory – Building on the notion that both gender and sexuality are social constructs that require the daily practices – or ‘performances’ – of

individuals to come into being, it draws on feminist and psychoanalytic theories to explore questions of embodiment, desire, and the ways in which sexual subjectivities are shaped by, while also resisting, power dynamics.

Tyler rationale – First articulated by Ralph Tyler in 1949, the Tyler rationale refers to the dominant approach of curriculum development based on a technical view of learning and teaching. It is based on four key steps: defining learning goals, identifying experiences that will yield those goals, organizing those experiences, and assessing how well the goals were met.

Cultural studies developed as a scholarly field over the second-half of the twentieth century. There are multiple ways of defining cultural studies, in part because it has developed into different streams of scholarship influenced by an array of academic disciplines and theoretical frameworks. Cultural studies scholars engage a varied range of cultural phenomena within many fields of practice – including education, mass media, science, literature, film, consumer culture, architecture, leisure, corporate culture, and the academy, to name a few. These fields are characterized by a range of cultural practices involving different institutional arrangements, discourses, and material as well as symbolic resources that to some extent or another shape the experiences of those who participate in these fields. In turn, individuals and groups engage these cultural practices in ways that often support, sometimes resist, and others redefine these arrangements. In general terms, cultural studies scholars are concerned with understanding these cultural practices in contemporary societies and the ways individuals engage and make meaning of their relationships with others and with the institutions that mediate those relationships.

Cultural studies is interdisciplinary in scope, bridging sociology, anthropology, literature, philosophy, linguistics, and political science. Cultural studies scholars draw on theoretical frameworks from critical theory, postmodernism, feminism, psychoanalysis, and, more recently, from queer and postcolonial theory. Each of these frameworks provides a different lens through which to understand the relationship between individual experience and the various structures and institutions around which cultural activity is organized.

During the early part of the twentieth century, academics as well as community-based and political organizers around the world turned their attention to culture as the locus of social and political change (Wright, 2004). For community and political organizations, this meant engaging their communities through cultural practices in an attempt to challenge oppressive social and political institutions by revealing their otherwise hidden cultural logics. For academics, this meant turning to the analysis of the cultural lives of various groups in cotemporary society. As Wright (2004) has argued, cultural studies as a field emerged out of the confluence of these social and academic movements in their efforts to recenter cultural politics.

Despite these worldwide movements, most accounts of the emergence of cultural studies credit the work of British scholars, such as Richard Hoggart, Raymond Williams, and E.P. Thompson, who were primarily interested in the cultural lives of the British working class. Their work led to the establishment of the Birmingham Centre for Cultural Studies (BCCS) in 1964, thus naming a field that had been evolving for over 50 years in other parts of the world. BCCS scholars rejected the two opposing views of culture that predominated academic work; the first drawn from anthropology, which looked for culture in the ways of living of non-European societies, and the second drawn from fine arts and literary criticism, which looked for culture in what were deemed the great accomplishments of European civilization. Instead, these scholars turned to the Marxist insight that there is a relationship between social structures and cultural practice, while rejecting the Marxist tenet that social structures overdetermine or predefine cultural experience.

Drawing on the intellectual legacy of Italian Marxist Antonio Gramsci, these early cultural studies scholars viewed culture as the dynamic interplay between social structures and the everyday practices of individuals. For Thompson (1963), for example, the working class was not an ahistorical structural formation, but rather, it came alive through the cultural practices of individuals. It is in and through these cultural practices that the possibility for social transformation resides. For cultural studies scholars, then, cultural analysis is not simply about understanding culture, but about fomenting social change through the transformation of cultural practice.

Against the essentialist view of culture as an inherent characteristic of different groups, cultural studies views culture as a practice that is always contextual – always negotiated within specific relationships and under specific circumstances – and not always predictable. Schools are one of those institutional contexts in which cultural experience evolves and where various actors engage each other through cultural negotiation. Indeed, cultural studies raises crucial questions about the relationship between schooling and society. Cultural studies scholars have made important contributions to our understandings of cultural processes in

school settings as well as in nonformal educational contexts. In particular, youth and youth cultural practice has been one of the central foci of cultural studies. Cultural studies has held an important place in certain areas of educational scholarship, particularly within curriculum studies, critical pedagogy, critical multicultural education, language and culture, and media education.

However, the fields of cultural and educational studies remain in tension with each other (Gaztambide-Fernández *et al.*, 2004). While a few education scholars have embraced cultural studies as a foundation of their work, cultural studies remains largely marginal to contemporary thinking about education in general and schools in particular. One reason for this marginality is that insights from cultural studies challenge some of the fundamental assumptions made about education. Here, we introduce the field of cultural studies through an exploration of three ways in which it has challenged dominant views of education. These challenges revolve around different (1) approaches to institutions, (2) conceptions of youth, and (3) relationships to social and political change. For each of these, we first discuss what cultural studies has contributed to this particular dimension. Second, we discuss how these contributions exist in tension with how education has traditionally framed the issue. Third, we argue that rather than obstacles, these tensions present opportunities for deepening our understanding of the relationship between culture and education. Our discussion of the opportunities that a cultural studies lens opens for educational thinking are premised on the marginality of cultural studies within educational discourse while also drawing on the work of education scholars that explore these opportunities.

Framing Schools

Until the 1960s, most sociologists framed schools as black boxes and studied them only on the basis of the relationship between inputs, such as school resources and family background, and outputs, mainly academic achievement. Challenging this model, scholars, informed by Marxist cultural theory, argued that structures and practices within schools played a crucial role in the reproduction of economic and social inequality. As they explored these internal mechanisms, they paid little attention to how students themselves participated and made sense of their experience within schools.

In 1977, building on the work of the BCCS on youth culture, Paul Willis turned his attention to the lives of youth at a British working-class school (Willis, 1977). Drawing on a long tradition of ethnographic fieldwork, Willis was interested in how young people's daily cultural practices were related to social class reproduction. In his book *Learning to Labour*, Willis reveals that it is not only (or mainly) school structures and practices that lead working-class kids to

working-class jobs. Rather, he describes the complicated ways in which working-class youth resist schooling and how this resistance is implicated in the apparently inevitable outcome of class reproduction. It is not through compliance, but through resistance that working-class youth develop and cultivate the cultural dispositions necessary for factory work.

The scholarship inspired by Willis' work demonstrates that schools are not simply sites of social reproduction; rather, cultural processes yield certain unpredictable outcomes that challenge the black-box model of schooling. This framing of schools, as the settings in which cultural production yields specific economic arrangements, has predominated within cultural studies scholarship. At the same time, Willis' work has been criticized for the way it positioned young women and its lack of attention to sexism in the lives of working-class youth. McRobbie (1991), whose early work focused on how young women engaged with magazines, brought a feminist lens to the analysis of youth culture. Other scholars, such as Kobena Mercer and Paul Gilroy, brought a focus on racism and racial politics to cultural analysis. It is in this context of analytic expansion into matters of race and gender that cultural studies traveled to the United States, where scholars such as Wendy Luttrell, Cameron McCarthy, and Kevin Kumashiro, have built on these initial insights to explore how dynamics of race, gender, and sexuality also play out and intersect in the context of schools.

The focus on cultural practice is in tension with the notion that schools are the great equalizer, a place where the playing field is leveled and where only hard work and aptitude matter in determining outcomes and achievement. Education scholars have largely framed schools as, at least, benign institutions that socialize students into their proper place and, at most, sites for the potential transformation of society and social change. Cultural studies scholars, on the other hand, have explored schools as sites where power dynamics operate to produce and sustain particular inequalities. Underlying these different approaches to schooling are distinct conceptions of the notion of culture. Educational studies tend to presume that culture preexists schools and that through curriculum and pedagogy established social patterns can be transformed into more equitable ones. In contrast, cultural studies suggests that culture happens in schools and that the institutional arrangements of schools are implicated in the reproduction of inequality.

One way in which this tension plays out is around the question of multicultural education. Conventional educational approaches to multiculturalism are often framed simplistically as a celebration of diversity. From this perspective, multicultural education involves learning about the food, dress, and customs of various ethnic groups, with the goal of fostering openness to differences among students. A cultural studies approach shares this interest in

difference, but rather than taking cultural identifications for granted, it asks how understandings of difference are produced. This approach engages culture not as a predetermined attribute, but rather as a set of practices through which individuals make sense of themselves in relation to those around them. Critical of educational approaches that view culture as a discrete identity, cultural studies scholars have drawn on postcolonial theory and the notion of hybridity in order to explore the multiple and complex identifications that students perform in schools. Even as these scholars embrace possibilities for fluidity and agency in students' identity constructions, they continue to foreground relations of power. As a result, a cultural studies approach to multicultural education explores how racism, sexism, and other forms of oppression shape students' schooling experiences (Carlson and Dimitriadis, 2003).

Cultural studies does not deny the possibility that schools can serve as a site of social transformation, but it does challenge scholars of education to examine the power relations that structure this practice and to examine the complex relations of power and resistance. Thus, the tension that emerges from these two conceptions of schooling provides an opportunity for exploring schools as complex spaces, where inequalities are produced alongside possibilities for social justice. Cultural studies foregrounds the work of cultural processes, as scholars attend to the ways in which notions of identity and difference are relationally constructed, rather than the product of some predefined attribute. Cultural studies brings to studies of education a more fluid notion of what culture means, and views schools as places where boundaries are negotiated and redefined, and where the possibility of social transformation is opened, but not guaranteed. Schools have the potential of being the site of cultural transformation, even as they are also primarily the site of social reproduction. Reflecting the generative nature of this tension, this complex conception of schooling has prompted scholars to reconsider conventional approaches to youth, shifting from the notion of behavior to that of practice in order to capture the fluidity of cultural processes.

Framing Youth

Educational scholars have historically framed youth as a developmental stage. Early educational psychologists examined adolescence as a period of personal growth on the path to adulthood. This developmental conception of youth has led to students being framed as the objects of pedagogy. By contrast, cultural studies attends to youth not as a period of psychological development, but rather as active producers of meaning. Scholars in this field have foregrounded the question of agency within youth studies and have sought to explore the extent to which young

people's actions can be understood as responses to certain social circumstances rather than a manifestation of psychological development.

Early cultural studies research at the BCCS focused on the notion of resistance, by examining how groups of young people engage with and contest relations of cultural hegemony and the demands of economic capital (Hall and Jefferson, 1976). Situating youth's struggles within historical and structural relations of power, cultural studies scholars demonstrate how young people forge personal identifications through collective experiences of resistance. In 1979, Dick Hebdige brought the lens of cultural resistance to the study of self-presentation. His book *Subcultures* explores how young people use style as a way to symbolically subvert dominant systems of meaning. Similar to Willis and Hebdige, early work on youth subcultures tended to focus narrowly on the experiences of heterosexual white men living in urban centers. More recent work on youth cultural practice has turned its attention to notions of desire, and has examined the relationship between sexuality and consumption, as well as racial discourses and identity politics.

While education studies tends to privilege the concerns of formal curriculum and pedagogy, cultural studies suggests that in the context of schools, what teachers teach and how they teach is just a fraction of what youth actually learn. In fact, youth cultural practices are a substantial part of the curriculum and of students' school experiences. This view of learning has prompted cultural studies scholars to critique conventional models of curriculum and pedagogy whereby, as Freire (1970) famously observed, students are viewed as empty vessels into which information is deposited. In contrast, cultural studies provides a lens for understanding how youth make contributions to their own learning.

One tension produced by these two contrasting conceptions of youth is in the different ways that education and cultural studies view the pedagogical possibilities of popular culture. Recently, education scholars have acknowledged popular texts as a source for engaging students by connecting the formal curriculum to young people's interests and experiences. Yet, for the most part, these scholars continue to conceive of popular culture as a lesser form of cultural expression, viewing the role of schooling as one of inoculating students against potentially corrupting influences. In contrast, cultural studies takes seriously young people's investments in popular culture. As a pivotal field in which young people interpret, contest, and rearticulate meanings, popular culture can be a generative site, in which youth are not simply consumers, but are also active cultural producers of their own representations.

Recent work has explored transnational processes through a cultural studies lens, and emphasized the impact of global media flows on youth's understandings

of themselves and of their own social and geographical locations. At the heart of these processes is the issue of representation, a key concept in cultural studies. The work of Hall (1997) has been central to how dynamics of representation are understood within cultural studies and education. For Hall, representations are never simply free-floating signs that have inherent or predetermined meaning. Rather, how cultural products come to have meaning and to stand for ideas and people is a constantly contested process through which signifying practices evolve and are negotiated. Representations are never settled and their meanings are always in flux. As different people engage images and ideas in different contexts and under different circumstances, they reconfigure the meanings attached. This is most evident in the constant flux of images associated with popular media.

Critical media literacy provides an example of how these competing understandings of youth and popular culture create a tension that is productive for educational research. Buckingham (2003) argues for engaging popular culture as a pedagogical site where educators can move beyond the conventional objective of cultivating savvy consumers and toward a more dynamic practice of cultural production. Based on empirical research in media education classrooms in the United Kingdom, he demonstrates the pedagogical possibilities that arise from young people's playful approach to media production, as students rework popular texts in order to produce new forms of meaning. In doing so, Buckingham highlights the importance of popular culture as a resource that youth draw upon to construct and perform shifting identities. Even as he promotes youth media production as a promising site of learning, Buckingham dispels the myth that such projects are inherently transformative. His research reveals that students produce cultural texts that both challenge and uphold stereotypical representations of gender and race. Thus, critical media education must be grounded in an analysis of power that attends to the ways in which individuals reproduce as well as challenge dominant structures through their own meaning-making practices. This work also has implications for how youth become active participants in a democratic civic sphere, as they define new and alternative modes of engagement in public discourse.

Cultural studies emerged as an attempt to challenge both the notion that youth behavior stemmed from psychological processes of development and also the perception that young people were unaware actors in the social world. An approach to education that views youth practice as a form of active meaning-making suggests a rethinking of curriculum and pedagogy that parallels long-standing debates in curriculum studies, particularly in relation to the critique of the Tyler rational and traditional forms of curriculum design. Highlighting the value of popular culture as a site of learning, cultural studies

scholars demonstrate that engaging with students in their preferred forms of cultural expression can cultivate opportunities for youth to contribute to the public sphere. This expanded conception of education views cultural production as a form of democratic participation, and reflects cultural studies' enduring insistence that teaching and learning are intimately connected to political practice.

Relationship to Social and Political Change

From its inception, cultural studies sought to problematize the notion of the political and the relationship between culture and social change in at least two ways. First, as articulated above, the work of community-based organizations around the world in the early part of the twentieth century was grounded on the idea that cultural practice could undermine political and economic domination. Likewise, cultural studies scholars drew insight from the work of the Frankfurt School of critical theory and the ways in which Gramsci turned the Marxist frame on its side to suggest that cultural practice is not just the outcome of economic arrangements, but rather plays a role in those arrangements. These scholars were also convinced that academic work also had a fundamental role to play in social transformation. This belief is at the heart of the notion of public intellectuals that cultural studies scholars, such as Said (1994), have vehemently promoted, and continues to be central to the discourse of cultural studies. To the extent that academic work is itself a form of cultural practice, scholars play a role in reproducing, redefining, and/or resisting the social order and are therefore directly or indirectly implied in the oppression of others.

Dominant educational discourse generally fails to recognize teaching and learning as political. This is in part because of a narrow definition of politics that is limited to political parties, elections, and government policies. More fundamentally, however, this failure to understand how teaching and learning are fundamentally political has to do with a view of teaching as a neutral task that is purely technical and prescribed. By contrast, education scholars who draw on cultural studies have persisted in their commitment to thinking about teaching as a political act. As a form of change-directed engagement with individuals and groups, teaching is fundamentally political, whether it is as a form of reproduction or as a form of transformation. In her 1994 book, *Teaching to Transgress*, Bell Hooks elaborates the role that teachers can play in the transformation of consciousness and in the process of engaging social change toward justice and equity (Hooks, 1994). Drawing on Freire's (1970) understanding of teachers as cultural workers and teaching as a political project,

Hooks invites educators to realize that their daily engagement with students is a constant opportunity to imagine things otherwise.

The idea that teaching is political is not new, and education scholars have argued as much throughout the twentieth century, albeit in different ways. Yet, dominant education discourse has remained impervious to this insight and has insisted in framing teaching in terms of accountability, scientifically based evidence, and curriculum mandates. The tension between viewing teaching as a purely technical task, which still predominates in schools of education, and the view of teachers as intellectuals and political agents persists. The traditional educational approach suggests that teachers implement programs that are assumed to be a redress for social inequality, yet teachers are simply technicians. By contrast, cultural studies recognizes that teaching and schooling are inherently implied in the idea of inequality, while empowering teachers to engage in political practices in which teachers are not just implementers of programs but rather are directly engaged in political struggle.

Over the last 20 years, as cultural studies has become institutionalized within the academy, critics have suggested that it has lost its commitment to social justice. This presents an interesting irony – on the one hand, cultural studies provides theoretical lenses through which to understand teaching and learning as cultural practice and illuminate the ways in which they are inherently political; on the other hand, cultural studies scholars, in having to deal with the institutional structures that shape their work, have tended to lose sight of their political implications as they engage in these processes. Critical education scholars have sought to revitalize the political project of cultural studies (e.g., Giroux, 2000; Dimitriadis and Carlson, 2004; McCarthy, 1998), even as others have challenged some of the dynamics underlying how cultural studies has evolved (e.g., Weiler, 2001; Wright, 2004). In this sense, educators have a lot to offer cultural studies because their direct engagement and experience in education contexts provides ample evidence of the challenge of maintaining commitments to social justice and anti-oppressive education while working within institutional constraints. This tension is productive because it demands that cultural studies recognize the realities and challenges of institutional contexts and the immediate issues facing students and teachers, rather than escape to the intellectual realm of academia. In addition, it yields a view of teaching and educational practice that is collaborative, generative, and recursive, and that takes culture seriously as a site of social transformation.

Conclusion

The most important contribution that cultural studies makes to education is a view of culture as always in the

making – as a practice. This opens the door for seeing teachers as participants in the production of culture, and for an understanding of that process as essential for social transformation. Cultural studies provides a set of lenses through which to make sense of the experiences of students and teachers in school contexts as well as their educational experiences outside of school walls. It allows us to understand what students and teachers do as cultural practice and to consider how these practices have the potential to reproduce, resist, and redefine – sometimes at the same time – the structures that organize educational experience. In this way, cultural studies has been intimately related to recent developments in curriculum studies. Indeed, curriculum itself is now understood as a practice. Curriculum is an experience that emerges through encounters between learners (and, sometimes, teachers), in various educative contexts, whether formal or informal (even, sometimes, in schools).

Many education scholars have not missed the key insights of cultural studies, and many already engage in educational practices that view schools, youth, and teaching and learning in complex ways. Dominant educational discourse, in its attempt to universalize, essentialize, standardize, and measure all educational practice, has successfully ignored the challenges of cultural studies. Yet, many educators, in their search to humanize, contextualize, politicize, and bring more complexity to their teaching, have come to understand that schools are not neutral institutions, that youth are active participants in the world that surrounds them, and that teaching is a powerful form of political activism. The success of their work is evidence that cultural studies has much to offer to education.

Cultural–Historical Activity Theory

Laboratory for Comparative Human Cognition, University of California, San Diego, San Diego, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

A long-standing challenge in educational research is to describe and explain the complex dynamics of learning and development that occur in educational settings. This article summarizes ways in which qualitative methods are essential to this enterprise from the perspective of scholars who approach the issues using the theoretical lens of cultural–historical activity theory (CHAT). After summarizing basic principles of this theoretical approach we provide four examples involving different levels of analysis and methodologies. (Methodology is used to refer to the ensemble of methods that mediate between theoretical statements and data used to evaluate them.)

To some researchers who employ qualitative methods, the very fact that we enter into this topic guided by a theoretical framework disqualifies our claim to be qualitative researchers. Smith argues that “qualitative approaches in psychology are generally engaged with exploring, describing and interpreting the personal and social experiences of participants. An attempt is usually made to understand a small number of participants’ own frames of reference or view of the world rather than trying to test a preconceived hypothesis on a large sample” (Smith, 2003: 2).

Our approach involves small samples, and we are interested in participants’ own understandings; however, we do operate from a preconceived theoretical base and in that sense we have preconceived hypotheses. Moreover, the approach we espouse does not preclude quantification. However, such quantification is more likely to be used for purposes of comparative analysis of qualitatively different activities (Cole *et al.*, 1978) or summary evaluations of products than for a deep analysis of the process of change (cf., Hayes, 1997).

The Theoretical Framework

CHAT refers to an interdisciplinary approach to studying human learning and development associated with the names of the Soviet Russian psychologists, L. S. Vygotsky, A. R. Luria, and A. N. Leontiev. (There has been a lively debate in recent years about the extent to which these three thinkers represent a single theoretical perspective. According to one line of interpretation, those who follow Vygotsky have focused attention on processes of mediation, adopting mediated action in context as a basic unit of analysis (Wertsch *et al.*, 1995). This line of work is often referred to as sociocultural research. By contrast, followers

of Leontiev are said to choose activity as a basic unit of analysis (Kaptelinin, 1996). For our present purposes, these distinctions are not central and we will treat the differing formulations as expressions of a single family of theoretical commitments.) The following are some theoretical principles of this approach:

1. *Mediation of experience through artifacts.* The initial premise of the cultural–historical school was that human psychological processes are bound up with a form of behavior in which material objects (e.g., hammers, pictures, gestures, and vocal sounds) and corresponding ideal objects (e.g., meanings and values) are incorporated into human actions and modified over generations as a means of regulating humans’ interactions with the world and each other. Artifacts incorporated into human action do not both change a person’s conditions of existence, and react back to that person’s psychological processes. Consequently, such artifacts are both symbolic and material mediators. Vygotsky referred to this kind of mediated action as the cultural habit of behavior which enables human beings to begin to regulate themselves from the outside.
2. *Activity as the essential unit of analysis.* The analysis of human psychological functions must be situated in relation to historically accumulated forms of human activity which are the proximal loci of human experience. The early Russian CHAT theorists demonstrated that at least in some institutional settings (among which schools and classroom activities were a major focus of attention) it is possible to make mediated-actions-in-activity/context a genuine object of study. Contemporary research has enormously broadened the range of activities and institutions to which scholars have been able to turn their attention (Engeström *et al.*, 1999).
3. *The cultural organization of human life.* Implied by the dual emphasis on mediation and activity is the centrality of culture in human life. Culture is present in the form of the tools, signs, cultural practices, architectural arrangements, social institutions, etc., that mediate human activity. It consists of all the material/ideal artifacts accumulated over the social group’s history, whether that history is of long or short duration.
4. *The primacy of the social.* From a CHAT perspective, children’s relationship to the world is, from the beginning, a social relation. However, especially in the beginning, children are maximally dependent upon adults not only

because of their physical immaturity but because they have no knowledge whatsoever of the cultural tool kit of the social group into which they are born. Thus, social others have a primary role in the development of psychological processes because it is only by already-enculturated adults arranging for the child to appropriate the cultural heritage of the social group that specifically human, culturally mediated, forms of psychological life become possible.

5. *Genetic analysis.* Vygotsky (1978) used the notion of genetic in the sense of seeking the origins of current phenomena by studying their history. Individual human development (ontogeny), he held, is the emergent outcome of processes of phylogenetic, cultural–historical, and microgenetic history.

CHAT Approaches to Learning and Development

A critical issue in CHAT approaches to education is the relationship between learning and development.

Learning

Vygotsky (1978) discusses learning in terms of the ideas of E. L. Thorndike, whose theory represented the original framework of behaviorism. According to Thorndike, learning is the result of trial and error during which associations form between stimuli and responses. Such associations or habits become relatively stronger or weaker when certain responses come to dominate others because they lead to rewards. According to Vygotsky, Thorndike proposed that:

[...] learning is the acquisition of many specialized abilities for thinking about a variety of things ... which does not alter our overall ability to focus attention but rather develops various abilities to focus attention on a variety of things. According to this view, special training affects overall development only when its elements, material, and processes are similar across specific domains. (p. 83)

Development

Vygotsky (1978) strongly differentiated learning from development. In his words:

Our concept of development implies a rejection of the frequently held view that cognitive development results from the gradual accumulation of separate changes. We believe that child development is a complex, dialectical process characterized by periodicity, unevenness of the development of different functions, metamorphosis or qualitative transformations of one form into another,

intertwining of external and internal factors, and adaptive processes which overcome impediments that the child encounters. (p. 73)

Vygotsky and his colleagues emphasized that not only are there changes in specific psychological functions (e.g., word meaning or memory) but that “the entire history of the development of higher psychological functions is nothing else than the alteration of primary interfunctional relations and ties, and the appearance and development of new psychological functional systems” (Vygotsky and Luria, 1930/1994: 167).

The Relationship of Learning to Development

Vygotsky (1934/1987) famously argued that school instruction should be organized in such a manner that “instruction moves ahead of development. When it does, it awakens a whole series of functions that are in a maturation” (p. 212). The kinds of functions Vygotsky had in mind included logical memory, abstraction, comparison, and differentiation. “These complex mental process,” he argued, cannot simply be learned in completed form, “like a mental habit” (p. 170).

But how is such arranging to be done? The problem does not arise for those who believe that learning equals development. For them the answer is clear: by direct instruction in which teachers provide appropriate stimuli and students are rewarded when they provide appropriate responses, that is, drill and practice with clear-cut consequences. However, as many critics of this form of instruction have noted, this method is inadequate:

The teacher who attempts to use this approach achieves nothing but a mindless learning of words, an empty verbalism that simulates or imitates the presence of the concepts in the child. Under these conditions, the child learns not the concept but the word, and this word is taken over by the child through memory rather than thought. Such knowledge turns out to be inadequate in any meaningful application. (Vygotsky, 1934/1987: 170)

It is to solve this problem that Vygotsky introduces the idea of a zone of proximal development (ZPD). The task confronting the teacher is to create a system of culturally mediated social interactions, organized in such a way that the student can, drawing upon prior and ongoing learning, achieve a qualitatively distinct new understanding, a conceptual re-organization that enables conscious control over the newly acquired knowledge. Creating such instructional circumstances is easier said than done. Although Vygotsky offered various suggestions about how to implement a ZPD, he never offered a systematic methodological system. (As Kozulin and Gindis (2007) comment, “Consequently, One can ... be true to the word and meaning of Vygotsky’s theory of the ZPD, but

one cannot follow or deviate from Vygotsky's ZPD assessment methodology for the simple reason that he never spelled it out" (p. 353).

Examples of CHAT Research

Recognition that the development side of the learning/development dance that constitutes successful academic education is a complex, dialectical process orients us to study the qualitative changes over time (longitudinally), at an appropriate genetic time scale. These dynamics involve the kinds of complex interactions between individuals in groups that routinely occur in instructional settings. CHAT-inspired research captures this complexity by focusing simultaneously on the activities or practices that contextualize these interactions. It also focuses on micro-genetic changes, ontogenetic changes, and cultural historical changes in relation to one another. Appropriate methods of data collection include digital voice and video recording, interviewing, structured and informal observation, participant observation, and quasi-experiments. Each example below represents the study of qualitative changes that occur in interaction under different levels of constraint in different social settings (dyadic teaching, a classroom lesson, weaving instruction in a Mexican village, and a small-group reading intervention).

Example 1: Puzzles

An early American study illustrating the centrality of structured observational method to CHAT research was carried out by James Wertsch and his colleagues (Wertsch *et al.*, 1980). In this work with middle-class families whose children attended preschool, mothers were asked to assist their infants (1–4 years of age) to copy a jigsaw puzzle depicting a cargo truck created from different regular shapes and colors. The researchers' particular interest was in the dynamics of adult and child discourse in relation to the child's puzzle-constructing actions. They hypothesized that these dynamics would change in conjunction with various adult communicative behaviors aimed at helping the child copy the puzzle.

Numeric registers alone, such as the number of times that a child glanced at the model when seeking to put a piece into the copy would yield a puzzling finding: The children all gazed at the model for roughly an equal amount of time. Careful analysis of the pattern of interactions indicated that the children had all learned names for the colors and shapes of the pieces of the puzzle, and the mother's often used the terms shape and color when seeking to assist them. However, it turned out that there was a regular change with age in who regulated the gaze at the model – sometimes the child gazed spontaneously, and sometimes the gaze seemed to require some sort of communicative gesture from the mother. In this respect, the children differed greatly: the youngest children were

least likely to attend spontaneously to the model. In Vygotskian terms, these data reveal a change in the interfunctional relations between attention and problem solving that had to be understood in terms of the developing child in relation to the enculturating mother. The mother's prior cultural knowledge, embodied in child-directed speech in conjunction with the children's prior learning (which in turn was mobilized by the mothers' when the children experienced difficulties), served to constitute the ZPD.

Example 2: Gazzinta and the process of long division

Petitto (1986) observed the process of teaching long division to fourth graders who were encountering it for the first time. Classroom interactions were videotaped. The data permitted the researchers to explore students' ZPDs as well as qualitative transformations in the interactions.

The children were expected to have learned their multiplication facts ($6 \times 7 = 42$) and simple division as reverse multiplication ($? \times 7 = 42$), as a preamble to the development of a qualitatively new form of arithmetic understanding – division that leaves a remainder. The teacher told the children that the seven *gazzinta* (goes into) 46 problem is solved in the same way as simple division, by finding a number which, when multiplied by seven produces a number close to 46 except it does not go over and then subtracting to find the remainder. The fourth graders seemed to have a difficult time grasping the *gazzinta* relation; however, with repeated examples using multiplication tables, over time the children began to catch on to what was being requested of them.

During a conference attended by several researchers from Japan, Petitto described the children's difficulty understanding the goes-into operation. Her description made perfect sense to members of the research team who had been discussing the work for some time, but the Japanese researchers were baffled. Eventually, one of them raised his hand to ask for an explanation of this new concept, *gazzinta*. Andrea was nonplussed. "Goes into" she said, slowly and with exaggerated intonation, and then demonstrated the entire procedure for determining how often seven *gazzinta* 46.

A fourth grader encountering long division for the first time faces a far more difficult task than the Japanese colleagues who knew the concepts involved in division. The child hears the word, *gazzinta*, and seeks, like the Japanese visitors, to figure out its meaning. But teachers do not say what *gazzinta* means. In fact, it probably is not possible to give an unambiguous explanation of *gazzinta*. *Gazzinta*, for long division with remainders, involves an iterative estimation procedure that is a combination of multiplication and subtraction carried out in no specifiable sequence on the number line. Faced with the difficulty of explaining the concept of *gazzinta*, teachers create a procedure to assist

the child, often putting the requisite times tables nearby. This offloads the work of retrieving the fact that $6 \times 7 = 42$, which is too little, and $7 \times 7 = 49$, which is too much, allowing the child to realize that seven *gazzinta* 46 six times, and that after subtraction, four will be remaining. The child must form the concept of *gazzinta* under the constraints provided by the adult and the cultural conventions for representing long division.

Researchers also noticed a strange phenomenon that further demonstrated the problematic relation between direct instruction and conceptual development. There were times when the teacher and a child were unknowingly talking about different parts of the same problem (e.g., the teacher said something about the quotient, the child understood it to be about the dividend) but there was no noticeable disruption in the conversation and the child arrived at a correct answer. It was as if the teacher and child were in close enough coordination, despite local discrepancies in the precise part of the problem they were referring to, to permit the action to unfold.

Petitto's work shows how instruction operates within a medium created by graphic symbols and classroom routines that provide constraints for, but cannot provide direct instruction for, mastery of a new concept.

Example 3: Remediating reading difficulties

Despite significant differences among them, modern approaches to reading have distinguished two, presumably distinct, major components of the reading process: decoding (the process by which letters of the alphabet are associated with corresponding acoustic patterns) and comprehension (the process by which meaning is assigned to particular visual/acoustic representations). Within this seemingly obvious dichotomy, theorists differ on the question of how to sequence instruction (code emphasis first vs. meaning emphasis first), how best to help children break the code (by teaching phonetic analysis or by teaching whole words), and how to motivate children to engage in reading (Burns *et al.*, 1999).

The following example seeks to solve these problems by creating a scripted, small group activity in which all of the theoretically important aspects of reading are brought together in a routine, coordinated, manner. The core of the procedure (described in more detail in Cole, 1996) was to create a set of roles or division of labor, each of which specified a different role in the overall process of reading. The roles were printed on index cards and every participant was responsible for fulfilling at least one role. The roles were:

- the person who asks about words that are hard to say;
- the person who asks about words that are hard to say what they mean;
- the person who asks a question about the main idea of the passage being read;

- the person who picks the person who has to answer the question at hand; and
- the person who asks about what is going to happen next in the text.

All the participants were given pencil and paper to jot down words, phrases, or notes (in order to answer questions about the text) and their card to remind them about their role. There was also a kitchen alarm to signal the start of reading time, and when it was over, the scripted activity of going through the roles in order to come up with a question about the main idea of the passage began. After a few sessions, the children and adults were able to engage in question–asking–reading, including children who still were unable to read for comprehension. The whole act of reading was not the responsibility of any one participant, but rather, was constructed for all in the act of working through the roles collectively and coming up with a question about the main idea.

Evidence for the way in which this procedure worked is derived from several sources to reveal qualitative differences in the children's ability to read and changes in those abilities over time: videotaped recordings of the instructional sessions, children's written work on the quizzes that completed each session, and various test results. Although data were gathered from the beginning of the first session, the crucial data for analysis of the process of reading development came after several sessions when the children had learned the overall script so that the group was working as a coordinated structure of interaction. Under such circumstances, different children became disoriented in different ways. Some children had difficulty saying how a written word sounded; others had difficulty understanding the meaning of the word; all had difficulty, at first, figuring out what the main idea was or using the information in the text to anticipate what would follow.

Data were also analyzed for instances in which misunderstandings moved up from decoding the comprehension of individual words to emerging comprehension of the text as a whole. Both forms of data helped the researchers to identify children's ZPDs and how the persons involved, the scripted procedures, and the cultural tools used contributed to change over time in both the participants and the activity.

Example 4: Developmental changes in learning to weave

In the 1960s, Patricia Greenfield and colleagues began to study the social organization and cognitive consequences of learning to weave among the Zinacantan Maya of Chiapas, Mexico (Greenfield and Childs, 1977). The researchers carefully described the way that mothers introduced young girls into weaving, analyzed mother–child interactions, and of the kinds of woven products produced. In the 1990s, they returned to the same village and conducted

parallel observations of parents (former child subjects) inducing their children into weaving. Greenfield emphasized the interconnectedness of historical change in economic activity, including exposure to new products and practices from contact with the modern sector of Mexican society, socialization practices (in particular, modes of socializing girls into weaving), and cognitive processes involving the mental representation of the patterns in woven cloth (Greenfield, 2004).

The instructional mode characterizing the mother-child weaving sessions in 1970 emphasized a long process of gradual apprenticeship involving many roles preparatory to weaving itself. When children first began to weave, mothers hovered close by and guided children with their own hands and bodies, using little verbal instruction. The entire system appeared to focus on maintenance of tradition and was characterized as interdependent cultural learning. In the 1990s, mothers who were more involved in the modern economy (e.g., weaving products for sale) instructed their children verbally from across the room. The mothers sometimes asked older children to take over instruction and only kept an eye on the processes, which were characterized by a good deal of explicit verbal instruction. Over time, the types of interactions changed as well as the number of artifacts used as a part of instruction. The gradually transformed participation in production of the 1970s gave way to increased verbal instruction and work with simplified weaving tools in the late 1990s.

In conjunction with changing verbal and nonverbal instructional practices, young girls were provided with simplified weaving tools of two levels of complexity. The simpler of the two was a tool for winding thread that maintains the orientation of the threads that would later be used in weaving the cloth; the more complex tool involved doubling the long (warp) threads around a dowel. This more complex approach required the weaver to visualize the extended warp (undoubled) rather than simply see it. Greenfield and her colleagues argue that the complex warping frame required the ability to engage in mental transformations while the simplified winding frame did not.

The changes in instructional practices came with an increased respect paid to individual innovation, seen in changes in the variety of products. In the late 1960s, the variety of products was limited, reflecting a very small set of right ways to weave. By the 1990s, there was no longer a small set of simple, correct patterns, but an efflorescence of patterns of great variety and complexity. This change was also shown in the way children represented weaving patterns in an experimental task, with children who attended school being more likely to create novel patterns. Overall, these results nicely illustrate several general theoretical claims derived from a CHAT perspective: the interconnections between cultural-historical change and ontogenetic experience, the ways in which microgenetic, minute-by-minute forms of interaction provide the

proximal locus for ontogenetic change, the primacy of the social in organizing specific cultural practices, and the changing nature of the artifacts that are employed to mediate these developmental processes at different scales of time.

Discussion

We have now presented four examples of research in the CHAT framework. They are characterized by two common elements. First, there is a shared focus on change over time in individuals, groups, and the activities in which they interact, even as the temporal and spatial dimensions of the activities under study vary greatly. Second, all four studies are explicitly theoretically informed. In **Table 1**, we summarize how each of the studies exemplifies different levels of analysis, different time and spatial scales, and different methods appropriate to each study.

These research examples highlight how qualitative methods are used to test the theoretical constructs we described as central to a CHAT approach. In our examples, the unit of analysis is not the individual learner, the teacher, or the learning environment. In all four examples, the unit of analysis is joint-mediated activity, which includes two or more individuals in interactions mediated by cultural artifacts (e.g., puzzles and terms for shapes and colors, a blackboard, math notation, times tables, texts, and a scripted process for reading and asking questions, and weaving tools and procedures).

All four examples, involved data collection that permitted analysis on at least two levels. In example 1, the role of social interaction in the development of problem solving involved analysis of primary social relations which are the source of the cultural resources the child will be expected to obtain and deploy as an adult. This example also illustrates the need to take into account, modes of discourse as they relate to qualitative changes in individual ontogenetic development associated with the acquisition of higher (e.g., culturally mediated) psychological functions. Methodologically, the brief temporal extent of example 1 indicates that it is focused on relatively short-term (microgenetic) interactions provoked by a puzzle task in a laboratory setting. It might also be considered a quasi-experiment.

In example 2, learning/instruction in a classroom, in particular, long division and the ineffable process labeled *gazzinta*, is the complex phenomenon being studied. The methods used included a series of observations and videotapes of math lessons on long division and subsequent analysis of discourse. In addition to the location of the study in a math classroom, the interaction data collected focused on microgenetic processes embedded within routine lessons.

Originally, analysis focused on the process of instruction, changes in the children's understanding, and the group processes and tool use that mediated those changes.

Table 1

<i>Example</i>	<i>Level 1: Sociocultural phenomenon</i>	<i>Level 2: Areas of specific focus</i>	<i>Temporal/spatial scale</i>	<i>Methods used</i>
1. Puzzles	Development of primary social relations	Mother–child interactions, discourse	Microanalysis: Short-term interactions in lab	Structured observation
2. Long division (<i>gazzinta</i>)	School-based math instruction	Classroom instruction, teacher–students	Microanalysis: Sequence of class periods, <i>in situ</i> in math classes	Natural observation
3. Question – asking–reading	Practice of reading school-based reading	Scripted activity as medium for experience of mature reading	Microanalysis of artifact-mediated social interactions over time, mesoanalysis of the scripted learning activity, ontogenetic changes in reading ability.	Design intervention
4. Weaving	Practice of weaving	Mother–child interaction, practice of instruction, practice, and artifacts of weaving	Microanalysis: Sequence of instructional interactions over time, <i>in situ</i> in homes Cultural–historical: Changes to the practices of weaving and instruction of weaving	Ethnography, and structured observation

Questions from Japanese visitors prompted analysis of the assumptions underlying the assumption that *gazzinta* was transparent as a term and a concept. A focused analysis of the complex cognitive routines involved in *gazzinta* – the meaning of *gazzinta* – remains to be conducted.

In example 3, rather than a quasi-experimental study in a laboratory or an observational study *in situ*, the research involved design of a learning environment in which a set of scripted procedures was used by adults and children to mediate the development of reading comprehension. The learning environment and the scripted procedures comprised an intervention, which the researchers hypothesized would permit participating children to experience qualitative change in their reading comprehension. In this study, group interactions were tracked over time in order to gain understanding of the microgenetic social and mediational processes related to individuals' changes in reading comprehension. At the same time, the development of the learning environment itself over time, a mesogenetic process that is longer than microgenetic interactions, but of a much shorter time scale than the cultural history of the practice of school-based reading, was tracked and analyzed. This allowed for a process of iterative design and ongoing refinement of the learning environment itself, even as the social interactions and individual changes in reading behaviors and comprehension provided particularly acute insight into the distinct strengths and weaknesses of each participating child, providing an ideal medium for remediation of their difficulties.

The timescales in example 4 are both microgenetic (instructional interactions) and cultural historical (change in the practices of weaving and weaving instruction over 30 years). The methods used included observation and

video recording *in situ* as well as ethnography that included both households and the political economy of the national context in which the activities of those households took place. This example illustrates the value of a historical lens in making sense of human interactions and practices such as instruction, which change in relation to societal changes, that is often not considered directly in educational research.

In all four example studies, the processes by which artifacts and social interaction with adults or more experienced peers helped to regulate children's behavior was of interest. In each case, the studies focused on the ways in which actions and the arrangements of artifacts were organized in order to promote or restrain learning.

In each case, there is a dual-mediational process at play. On the one hand, learning was mediated by more capable partners – mothers' communicative gestures, a teacher building on prior knowledge of multiplication tables and simple division, adult guides using a game-like script for reading instruction, and mothers and siblings using the traditional practice, verbal instruction, and modified tools for weaving. In all four examples, the children internalized or appropriated the use of symbolic tools (e.g., terms for color and shape, math language, the procedural rules in a script, written text, and visual and verbal instructions) in order to coordinate their roles in the different activities with the adults and other children. In all four examples, there were qualitative changes in observed behaviors, that is, the children's participation in the activities that indicated development. Observation of these changes and the social and mediational processes related to them required systematic collection of multiple forms of data over time and rigorous analysis of those data.

Conclusion

CHAT is a genetic and generative approach to understanding the living processes of learning and development. Research in the CHAT tradition is complex, but the rewards are many. As CHAT methods are deliberate models of cultural practices, there is an immediate reciprocal relationship between theory and practice. The ultimate criteria for success are not the discoveries and explanations that the research generates, but the uptake and the deployment of this knowledge by the educational communities crowding our country where education is woefully inadequate to the challenges of modern economic life.

Design Experiments

A Collins, Northwestern University, Evanston, IL, USA

Glossary

Design experiment – A formative experiment carried out to evaluate a particular design for a learning environment. It usually involves multiple iterations in order to identify problems with the design and to make refinements to improve the design.

Randomized-control design – The design of a comparative intervention experiment, where different groups of learners are assigned randomly to different conditions.

The evolving methodology of design experiments began as a reaction to traditional psychological experimentation (Brown, 1992; Collins, 1992) which had dominated educational research in teaching and learning. The methodology of psychological experimentation was based upon notions of controlling variables in order to be able to precisely determine what causes different effects. This led to conducting experiments under laboratory conditions according to carefully defined procedures. Design experiments, in contrast, attempt to carry experimentation into real-life settings, in order to refine the design so that it works in practice. This means giving up the notion of controlling variables, and therefore necessitates developing a new methodology for carrying out research.

While the initial work on this topic was carried out under the rubric of design experiments or design studies, more recently the terms design research and design-based research have come into common usage. Most of the research carried out in this vein concerns the design of computer-based learning environments. Designers of computer-based systems often go through multiple versions of a system until all the bugs are worked out, and in applying this approach to the design of learning environments, they bring a product-design mindset to the enterprise.

The novelty of the design-experiment methodology is seen most strikingly by comparing it to the experimental methodology used to study human learning in psychological literature. Learning research started before the turn of the century with the German psychologist Hermann Ebbinghaus, who invented the nonsense syllable in order to be able to study learning in its purest form. He identified many of the most important variables that affect learning, such as the similarity of stimuli to each other and the nature of the activity between learning and recall.

This tradition of research on learning continues to this day and has evolved to address questions about how humans learn to solve problems and carry out complex tasks. It has produced many important findings about the conditions that affect both learning and transfer.

Seven major differences can characterize how design-experiment methodology that is currently evolving differs from the kind of psychological methodology that has dominated education research heretofore:

1. *Laboratory settings versus messy situations.* Experiments conducted in laboratories avoid contaminating effects. Learners concentrate on the task without any distractions or interruptions. The materials to be learned are well defined and are presented in a standardized manner, rather than the manner a particular teacher may choose at any given moment. In fact, the presentation is usually one directional, rather than relying on interactions between teachers and learners. In short, learning in a laboratory does not look anything like what goes on in a typical classroom, workplace, or home, where most learning occurs in life. Design experiments are set in the messy situations that characterize real-life learning, in order to avoid the distortions of laboratory experiments.
2. *A single dependent variable versus multiple dependent variables.* In most psychological experiments, there is one dependent variable, such as the number of items recalled or the percent correct on a test of some kind. In design experiments, there are many dependent variables that matter, though the experimenter may not pay attention to them all. They fall into three types of variables: (a) climate variables, such as engagement of the learners, cooperation among learners, and risk taking by learners, (b) outcome variables, including the learning of content, skills, strategies, and dispositions, and (c) system variables, such as spread of use, sustainability, and ease of adoption.
3. *Controlling variables versus characterizing the situation.* Psychological experiments use a methodology of controlling variables borrowed from early physics. The goal is to identify a few independent and dependent variables, and hold all the other variables in the situation constant. Therefore, for example, if the experimenter regards amount of learning as the dependent variable, the goal will be to hold motivation constant. But the goal of teachers in classrooms is to find ways to motivate students, so that they learn something. Thus, holding

motivation constant fundamentally undermines the usefulness of the results. In design experiments, there is no attempt to hold variables constant, but instead the goal is to identify all the variables, or characteristics of the situation, that affect any dependent variables of interest. The goal is not only to characterize what affects any dependent variable, but also to identify the nature and extent of the effect.

4. *Fixed procedures versus flexible design revision.* Psychological experiments follow a fixed procedure that is carefully documented, so that it can be replicated by other experimenters. Design experiments, in contrast, start with planned procedures and materials, which are not completely defined, and which are revised depending on their success in practice. For example, Brown (1992) developed a design called Fostering a Community of Learners, where elementary school children worked in groups to learn about ecology. In design experiments, the experimenter should characterize what happens as completely as possible, and document any changes made in the plans, together with the reasons for the changes. The goal is to start with teaching methods that are most likely to succeed, but to monitor how they are working and to modify them when appropriate. This progressive refinement is standard practice in the product-design community, as can be seen in the many refinements that are made in products over time. However, until recently, progressive refinement was not the approach taken with education innovations, because of the strictures for replicability on the experimental methods, inherited from psychology.
5. *Social isolation versus social interaction.* In most psychological experiments, the subjects are learning in isolation. There is no interaction with other learners and usually no interaction with a teacher or expert; the material to be learned is simply presented by text or video. By contrast, design experiments are set in complex social situations, such as a classroom where students may be working in groups (Brown, 1992). In consequence, students are sharing ideas, distracting and making fun of each other, being interrupted in their work, trying to make life difficult for the teacher, etc. Design experiments have to cope with all the noisy data that arise from such situations.
6. *Testing hypotheses versus developing a profile.* In psychological experiments, the experimenter has one or more hypotheses, which are being tested by systematically varying the conditions of learning. In design experiments, the goal is to see what conditions lead to different effects. Design experiments ideally are much more like what consumer reports do when they evaluate the quality of different automobiles. The goal is to look at many different aspects of the design and develop a qualitative and quantitative profile that characterizes the design in practice. There are a large number of

contextual variables that determine the success of an innovation, such as the setting and professional development needed. It is best if evaluation is done with respect to a number of dimensions in a comparative fashion, as when consumer reports evaluate different products.

7. *Experimenter versus co-participant design and analysis.* In psychological experiments, the experimenter makes all decisions about the design and analysis of the data in order to maintain control of what happens and how it is analyzed. In design experiments, there is an effort to involve the different participants in the design, in order to bring their different expertise into producing and analyzing the design. Thus, teachers, curriculum designers, technology experts, cognitive psychologists, and anthropologists may all be involved in developing the design and evaluating its effects. Design experiments require many resources to be staged and hence it makes sense to bring to bear wide expertise in their design and evaluation.

Methodology of Design Research

The design-research community is developing criteria for carrying out and reporting on design experiments. Not every design experiment embodies these criteria, but they characterize the elements the design-research community is responsible for. In an ideal world, design research will move in the direction of embodying many of the practices we outline here. But it will take teams of researchers and accessible archives documenting design experiments to make these practices possible.

Implementing a Design

Each implementation of an education design is different. Therefore it is important to identify the theory behind the design, the critical elements of the theory for the design, and how the elements fit together. In order to evaluate any implementation, one needs to analyze each particular case in terms of these key elements and their interactions. Some elements will be implemented more or less as the designers intended, some will be changed to fit the circumstances, and some will not be implemented at all. What is needed is a profile for each implementation as to how each of the critical elements were implemented and how well the elements in the implementation worked together toward the designers' goals.

Modifying Designs

A goal of design research is to improve the way a design operates in practice. The teacher or researchers may see that an element of the design is not working in the course of the experiment. It is important to analyze why it is not

working, and take steps to fix whatever problems appear to be the reasons for failure. In this way we collect information about failures, plus information gathered from the attempted repairs to the design, and whether they succeed or fail. It is critical to document the failures and revisions, as well as the overall results of the experiment.

The experimental methods inherited from psychology that assume a fixed procedure are used throughout the experiment. Design research assumes continuous refinement. This difference has deep ramifications and requires changes in the way researchers analyze and report what is done. They should document their designs in detail, recording all major changes in design. These design changes mark the borders between phases. The goal then is to characterize the design elements that are in place in each phase and the reasons for the transitions from each phase to the next. Data relevant to research questions should be collected in each phase. For example, if there were four phases in a particular implementation, then it would be good if there were an intermediate assessment of learning outcomes between phases 2 and 3, as well as pretests and posttests. A detailed design history of this kind allows research audiences to evaluate the credibility of design decisions and the quality of lessons learned from the research.

Multiple Ways of Looking

Rogoff (1995) calls for analysts of learning environments to attend to three critical aspects: the personal layer (the experience of the individual), the interpersonal layer (one-on-one interactions), and the community layer. In the context of design experiments, researchers must additionally attend to interactions of learners with elements of the environment. There are many different aspects of what makes for an effective design, and so both designers and evaluators need to wear many hats in order to design and assess educational interventions. Consider some of the different aspects that are relevant to educational designs:

- *Cognitive level.* What do learners understand before they enter a particular learning environment, and how does that understanding change over time? Some of the tools for analysis at this level include observations of thinking through learners' representations and explanations. Through visual and verbal descriptions of ideas, researchers ask learners to expose their thinking. Are the explanations clear? Do representations capture important relationships?
- *Interpersonal level.* This viewpoint addresses how well teachers and students interact personally. Is there sharing of knowledge? Have the students bonded with each other so that they respect and help each other?

Researchers use ethnographic techniques to observe these kinds of interactions.

- *Group or classroom level.* This viewpoint addresses issues of participant structure, group identity, and authority relationships. Is everyone participating? Is there a sense of the goals and identity of the group? Again, ethnography is an effective approach to analysis.
- *Resource level.* This level deals with what resources are available to learners and if they are easy to understand and use. How accessible are the resources? How well are they integrated into the activities?
- *Institutional or school level.* At this level, issues arise as to communication with outside parties and support from the entire institution. Are parents happy with the design? Do administrators support it strongly? What are the micro-political issues that impact the design?

These levels are very much intertwined. To design and assess these different issues require many different kinds of expertise: teachers, administrators, psychologists, anthropologists, media designers, etc. Conceivably one person can address all these different perspectives, but it helps to have them all represented explicitly.

Characterizing Dependent Variables

Success or failure of an innovation cannot simply be evaluated in terms of how much students learn on some criterion measure. Different kinds of evaluation are necessary for addressing questions such as how sustainable the design is after the researchers leave, how much the design emphasizes reasoning as opposed to rote learning, how the design affects the attitudes of students, etc. To evaluate different variables, it is necessary to use a variety of evaluation techniques, including standardized pretests and posttests, survey and interview techniques, and systematic scoring of observations of the classrooms. Both qualitative and quantitative evaluations are essential parts of design-research methodology.

At least three types of dependent variables are important to assess: (1) climate variables, such as engagement, cooperation, risk taking, and student control; (2) outcome variables, such as content knowledge, skills, dispositions, metacognitive strategies, and learning strategies; and (3) systemic variables, such as sustainability, spread, scalability, ease of adoption, and costs.

Evaluating climate variables requires observational techniques, either by producing field notes while observing the intervention in practice, or collecting video records of the intervention and scoring those records subsequently. For example, these techniques might be used to evaluate three kinds of climate variables: the degree of engagement of students in learning in the classroom, the degree of cooperation among students in the classroom, and the degree of effort students are making to

understand the curriculum topic. To evaluate these variables, one might collect videos of different classes spread out over the time the teacher is carrying out the designed intervention. These videos can be scored systematically by multiple raters using a five-point scale for each specified interval in the lesson. Raters would be trained using benchmark lessons for which scores have been calibrated with experts.

Outcome variables are best assessed by collecting pretest and posttest measures. For example, pretests and posttests can be used to evaluate three kinds of learning variables: content, reasoning, and dispositions. To evaluate learning of content and reasoning, it is possible to use short-answer or essay questions, oral interviews, or multiple-choice items. By using items from standardized tests, it is possible to compare performance to national norms for the items. To evaluate learning of dispositions, one might apply instruments developed by Dweck (1986) to assess whether there are changes in students' beliefs reflecting a move from performance goals to learning goals. There have been such changes reported in a design experiment carried out by Scardamalia *et al.* (1994).

Systemic variables are best evaluated by interviews and surveys. For example, one might evaluate systemic variables, such as the ease of adoption of a design into the curriculum, the degree to which it is sustained in subsequent years, and the spread of use to other teachers and students. These can be measured by surveys and structured interviews with teachers and students. It is possible to develop a questionnaire that addresses the advantages and difficulties teachers encountered in adopting a design in their classroom. The other variables can be evaluated by surveys administered to both teachers and students at regular intervals. The surveys will ask about what aspects of the design are being sustained and are spreading, and which aspects are not.

Characterizing Independent Variables

In evaluating any design, there are a large number of independent variables that may affect the success of the design in practice. It is important to determine what general aspects of the situation researchers need to consider in order to decide what is affecting the success of the design. The contextual variables that can determine the success of an innovation include the following:

- *Setting.* The setting of the learning environment is a critical variable in how any design fares. The setting might vary over homes, workplaces, museums, schools, or colleges; elementary, middle or high schools; public or private schools; urban, suburban, or rural schools; elite or community colleges; etc. How broadly applicable an innovation is can be determined only by trying it out in many different settings.

- *Nature of the learners.* Critical variables about the learners include things such as their age, socioeconomic status, turnover rate, attendance rate, etc. For example, some innovations may work with weaker students and some with gifted students. So it is important to determine for which type of learners the design is effective, and in what ways.
- *Required resources and support for implementation.* In order to carry out any design, there will be a need for resources and supports of various kinds, including materials, technical support, administrative support, and parent support. If a design requires teachers to gather materials, spend time in preparation or other activities, enlist administrators or parents to make the design succeed, then these requirements need to be identified.
- *Professional development.* Often in order for a design to be successful, teachers (and perhaps others) need to be provided with professional development of various kinds. These can encompass workshops, design meetings, courses, videos of exemplary practice of the design, guided practice with expert practitioners, reflective meetings with colleagues, etc. Identifying what teachers need to implement the design successfully is an important aspect of designing an innovation.
- *Financial requirements.* Any intervention adds costs that need to be tracked, including equipment costs, service costs, professional support and development costs, replacement costs, etc. Very often substantial costs, such as technical support and replacement costs, are ignored when calculating the cost of a technological innovation.
- *Implementation path.* This term covers the variables involved in implementing a design, such as how the innovation is introduced, the time devoted to it, the difficulties teachers may face in introducing the design, etc. There is a structure to the introduction and evolution of a design that needs to be characterized in analyzing any implementation.

Reporting on Design Research

The experimental literature developed a conventional structure for reporting on experiments that evolved over time. The structure consists of four parts: background to the problem, experimental method, results, and discussion. As design research reconceptualizes the experimental process, there needs to evolve a different structure for reporting, perhaps including five sections in reporting on design experiments:

- *Goals and elements of the design.* An important aspect of reporting on design experiments is to identify the theory behind the design, the critical elements of the theory, and how they fit together to accomplish the goals of the design. The critical elements of a design may be materials, activities, a set of principles, or some

combination of all these. It is equally important to describe the goals of the design and how all the elements are meant to work together to attain those goals. Goals, critical elements, and their interactions need to be described in enough detail, so that it is possible to evaluate how well the design was implemented in different settings.

- *Settings where implemented.* The description of the settings needs to include all the information relevant to the success of the design outlined in the section titled 'Characterizing independent variables' above. Differences between how the design was implemented in each setting should be detailed, so that readers can evaluate how faithfully the design was carried out in each setting.
- *Description of each phase.* The design is likely to go through a different evolution in each setting, so it is necessary to describe each phase in each setting. When changes are made in a setting, the reasons for the changes should be specified along with the effects of making the changes. It also makes sense to describe how the critical elements of the redesign accomplish the goals of the original design or how the goals have changed.
- *Outcomes found.* The outcomes should be reported in terms of a profile of values on the dependent variables in the different settings, just as qualitative and quantitative data are reported about different products in consumer reports. These should be included to the extent that intermediate data describing the different phases were collected.
- *Lessons learned.* Considering what happened in the different implementations, the report should attempt to pull together all the findings into a coherent picture of how the design evolved in the different settings. It is important to describe the limitations and failings of the design, as well as the successes, both in implementation and outcomes.

Implications for Summative Evaluation

While design experiments were conceived as a formative evaluation strategy, the principles involved do have implications for summative evaluation. Any such assessment of educational innovations must carry out both quantitative and qualitative assessments, using a randomized-control design as Cook (2002) advocates, and comparative analysis, which consumer reports use. For example, to compare how effective two reading programs are, one would need to carry out comparative analyses in a variety of different settings, such as urban, suburban, and rural schools, and perhaps even homes, workplaces, and military settings. In such studies there must be a fixed experimental procedure, unlike the flexible design revision necessary for formative evaluation. The assessment should produce a

profile that shows the strengths and weaknesses of the designs being compared. Hence, different designs might be found to be more effective in some settings or with regard to some outcomes.

In order to have a sound assessment process, educational researchers as a community should develop a consensus process to determine what variables to look at and how to assess them. The assessment should address the multiple concerns of different stakeholders, including developers, and so they should be included in the consensus process. The design-research methodology argues that we need to look at multiple contextual and dependent variables, as described earlier.

To carry out such evaluations effectively, the country would need to invest in an independent agency, in the style of Consumer's Union, with the expertise to carry out comparative evaluation. Such an agency could develop the expertise and methods for looking in a cost-effective manner at innovations in use, in a way that best informs the many different stakeholders.

Conclusion

Brown (1992) felt that laboratory experiments, ethnographies, and large-scale studies are all valuable methodologies to study learning, but that design experiments fill a niche these methodologies do not address. Specifically, they allow researchers to evaluate and refine learning environments that are designed on particular principles and then revise the environment and the principles. Tharp and Gallimore (1982, 1988) have elegantly described how different methodologies can most effectively work together.

It is clear from the spread of these kinds of research methods (Barab and Kirshner, 2001; Barab, 2004, 2006; Edelson, 2001; Design-based Research Collective, 2003; Kelly, 2003; Sandoval and Bell, 2004) that design research is becoming an established practice. But design experiments often lead to the collection of large amounts of data that go unanalyzed. Hence, it makes sense for the design-research community to establish an infrastructure that would allow researchers at other institutions to analyze the data collected in design studies, in order to address their own questions about learning and teaching. This would require the community to honor such reanalysis of data with the same status as original research and it would require research journals and tenure committees to take such work seriously. Other fields, such as child language, have developed widely available archives of data, enabling researchers to discuss and analyze the same data from many different perspectives. The design-research community should strive to set up an infrastructure that can support researchers at different sites in analyzing the large data sets that design experiments are now producing.

Discourse Analysis

P Nikander, University of Jyväskylä, Jyväskylä, Finland

S Vehviläinen, University of Helsinki, Helsinki, Finland

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Conversation analysis – The systematic study of talk in interaction in everyday and institutional settings. Teases out the moment-to-moment, turn-by-turn sequential unfolding of discourse as a generic order in interaction.

Critical-discourse analysis – A specific tradition within discourse studies that (often following the Foucauldian notion) approaches language and discourse practices not as an innocent, transparent, or neutral means of description, but rather, as a means of regulating, controlling, and governing discourse subjects.

Discourse analysis – A broad umbrella term for a variety of research traditions across disciplines that take talk, texts, and interactions as the analytic foci.

Discursive pattern – A recurrent feature or sequence in text or talk that structures certain discourse environments. For example, the initiation, response, and evaluation sequence in the classroom that furbishes speakers with certain positions.

Discourse and discourse analysis have become central catchwords in social and education sciences in recent decades. Closely linked to the constructionist or linguistic turn across disciplines, research in the field of education increasingly resorts to a range of discursive analyses that take language in context – texts, talk, and social interaction – as the starting point for their qualitative inquiry. In this article, we lay out for view the range of analytic foci under the broad umbrella term discourse analysis. Center stage is given to the variety of theoretical approaches and analytic emphases, and to the differences, dialog, and points in common between different traditions and schools of thought.

First, discourse analysis is best understood as an interdisciplinary collection of methodologies with varying theoretical standpoints within and across disciplines. Educational researchers have for decades drawn on a mix of theoretical and methodological developments, concepts, and analytic styles developed in linguistics, linguistic anthropology, post-structuralism, sociology, discursive psychology, and sociolinguistics when turning toward the study of discourse. Following a discursive epistemology (Nikander, 2008), researchers in education have covered an impressive

range of research topics, ventured outside the confines of teacher–student classroom interaction, branched out to questions of nonverbal, multimodal interaction, and tackled crucial and critical questions of how identities, knowledge, power, and ideology are constructed in face-to-face encounters and in-and-through historically unfolding educational and institutional texts and practices.

One decisive difference between the theoretical starting points and methodological brands and flavors of discourse analysis is based on whether the researcher foregrounds the microsituation in which an interaction takes place, or the wider political underpinnings of educational encounters, texts, and practices, and the more wide-reaching ideological effects of discourse. Based on these criteria, **Table 1** presents one way of breaking down the general rubric of discourse analysis into three traditions, and aims to pinpoint some key differences between them. **Table 1** should be taken as a broad-brush depiction of major developments and analytic foci. Out of necessity, some nuances within this area of research are silenced and some of the complexities lost.

Combining an interest both in the close analysis of language and communication acts with culture and context that surround them, ethnography of education has produced early insight into how race, class, and other cultural orders in communities outside the classroom have consequences on the dynamics and interactional processes in and across educational contexts. Large ethnographic, anthropological research projects based on close analysis of discourse, participant observation, and other means of data collection, have provided a nuanced picture of how notions of academic success, situated identity performance, and competence among others, are related to race, class, and cultural backgrounds.

Drawing on critical linguistics and post-structuralist discourse theory, critical-discourse analysis (CDA), seeks to identify the constitutive and disciplining force of educational discourses. Following the Foucauldian notion, language and discourse practices, in this tradition, are seen not as an innocent, transparent, or neutral means of description, but rather, a means of regulating, controlling, and governing discourse subjects. According to Luke (1996), the emergence of multicultural, multilingual, and global Western communities, and their rapidly changing demographic, ethnic, gender, and class profiles call for critical analysis of power in pedagogic surroundings, and genealogical studies of the ideological functions of curriculum and educational policies.

Table 1 Discourse analytic traditions, analytic foci, and typical data sets

<i>Tradition</i>	<i>Analytic focus</i>	<i>Approach and data sets</i>
Ethnography of communication	Speech events, practices, and repertoires	Analysis of linguistic data and participant observation in and outside the classroom
Critical discourse analysis (CDA)	Analysis of how discourses of/ within education are infused with ideology and power	Analysis of official texts and documents Deconstruction of power relations and the constitutive forces of discourse
Micro-level analyses, for example, conversation analysis, linguistic analyses of discourse	The turn-by-turn unfolding of interaction and situated action	Videotapes of institutional interaction within and outside the classroom and in other education-related settings

The third approach in **Table 1**, micro-level analysis of interaction *in situ*, is by far the most detailed approach to discourse. Research within this tradition focuses on mapping the architecture and the multimodal nature of our everyday and institutional interaction.

Based on videotaped materials from microsettings, and the detailed transcriptions produced thereafter, analyses seek to tease out the moment-to-moment sequential unfolding of discourse as a generic order in interaction.

Discourse Analysis and Education

From the above, one can deduce that the broad field of discourse analysis in education can be delineated by the division into (1) micro-level analyses of social interaction and verbal communication in various social settings and the social construction of activities, knowledge, competence, and identities thereof; and (2) macro-level genealogical analyses of institutional regimes and knowledge structures, the analysis of the production of realities and facticities. Third and more recently, feminist and postcolonial analyses have focused on situated accounts on individual learning experiences and the development of identities and positions in the society (e.g., Luke, 1996). In what follows, we further flesh out the picture of discursive research in education and discuss some empirical examples and future challenges. More specifically, we take a closer look at some of the topics and themes relevant in one of these basic fields, namely the micro-level interactional analyses. We start from the most descriptive, basic linguistic analyses and move toward more applied studies that aim to improve educational practices.

Micro-level analysis of interaction and speech stand at the intersection of several disciplines (anthropology, linguistics, sociology, social psychology, communication studies, and gender studies). Many scholars of classroom discourse have chosen to focus on this setting for reasons other than the interest of improving educational practice or even learning as such. For instance, for linguists Sinclair and Coulthard (1975), the classroom provided a setting for constructing an analytic framework for the systematic linguistic analysis of verbal discourse in general. For some

researchers, on the other hand, discourse analysis is a means of examining learners' interaction so as to identify the most successful practices for enhancing collaborative learning at school and to challenge the participatory patterns and epistemic division of labor in the traditional classroom (Mercer, 2004).

The Linguistic and Ethnographic Analyses of Verbal Communication

The roots of the study of classroom interaction and discourse reach to the 1970s and the multidisciplinary linguistic turn. The main historical influences have been the interactional sociology of Erving Goffman, ethnomethodological sociology as the analysis of mundane meaning making and of social activity as participants' practical accomplishment (Mehan, 1979), and conversation analysis as the systematic study of social interaction as a turn-by-turn, sequential accomplishment. This approach, sharing many core assumptions with discourse analysis, has a tradition for analyzing institutional discourse (for conversation analyses on classroom settings, see McHoul, 1978; Seedhouse, 2005). A prominent influence has been provided by the ethnography of communication, with the notion of speech communities and related communicative competence, as well as the development linguistics and the analysis of discourse as a linguistic phenomenon (Sinclair and Coulthard, 1975). In the 1970s, the so-called new sociology of education in Britain had also begun to produce micro-level analyses of the reproduction of social inequalities through language use in the classroom. (For overviews of these historical developments see Cazden, 1986; Luke, 1996; Warriner, 2008).

This branch of study has brought about a line of inquiry, combining linguistic and ethnographic orientations and methods to what is mostly a qualitative, data-driven analysis of naturally occurring social interaction, verbal communication, and activities in the classroom as well as in other pedagogical or education-relevant settings. In these studies, audio- or video recordings of naturally occurring social situations are generally used, as well as ethnographic data like observations, interviews, and various

textual materials consisting of assignments, tests, and student essays. The discursive practices are treated as contextual situational accomplishments, while the context itself – the shared frame for interpreting a given utterance or action – is viewed as a dynamic accomplishment of the participants. Context is invoked in various ways by participants and therefore should not be treated as a prefigured frame for analysis. Furthermore, it is assumed that classroom discourse is organized in terms of particular participation structures, with specific rights and obligations for the participants' communication and contributions, as well as particular access to knowledge. Participation in classroom activities – and thereby demonstrations of learning – take place through this, often implicitly acquired, set of assumptions. These studies, thereby, demonstrate and examine the socially achieved and dynamic nature of the classroom (or other educational activities and settings) as well as the identities, competencies, and subjectivities that are invoked and performed through these constellations of participation (Cazden, 1986).

Linguistically oriented microethnographic analyses of classroom interaction have evolved into a vast field of literature on various aspects of talk and interaction. Most prominently, this field has produced analyses of various events, actions, or patterns in interaction, of how these events act as constituents of the classroom activity, shape the participation and contributions of the participants, create possibilities or obstacles for communication and participation, and shape identities, memberships, and competencies of participants (Baker, 1997; Mehan, 1979; McHoul, 1978; Cazden, 1986; Stubbs, 1983; Lemke, 1990; Mercer, 2004). Some studies place more emphasis on detailed qualitative analyses of particular actions, discursive techniques, or activity types, while others include quantitative evidence of their distribution, thereby presenting evidence of general tendencies of their use during lessons and the entire school day.

Perhaps the most studied discursive phenomenon in the classroom is the three-partite sequence that typically organizes most of the dialog between the teacher and the class, namely the teaching cycle. This cycle, or the initiation, response, and feedback (IRF) or initiation, response, and evaluation (IRE) sequence represents the typical recurring unit, organizing the formal classroom interaction (Sinclair and Coulthard, 1975; Mehan, 1979; McHoul, 1978). It consists of the teacher's question, student's response, and the teacher's reaction (evaluation or feedback) to that response. Through this pattern, the teacher is able to control the topic of the talk and thereby the joint focus of the attention of pupils. This pattern is also a vehicle for controlling and allocating the pupils' participation, for monitoring their competence and providing feedback to individual pupils as well as to the entire class.

The dynamics of the teaching cycle sequence provide the teacher with the position of questioner: the controller

of the topic, as well as the evaluator of the content of the response and the competence of the responding speaker. The teacher's position as the epistemic authority is incarnate in this pattern, while the pupil is positioned as the speaker who demonstrates knowledge and competence, and offers it for the teacher's checking, control, and authorization. This pattern has been viewed as the basic element and constituent of the lesson and its components. The participation structure it provides for the counterparts has also been heavily criticized. Responding to questions can be seen as a fairly limited way of participating in learning activities. It can be stated, for instance, that instead of demonstrating their competence or understanding of the content or issue at hand, students end up demonstrating their ability to recognize the teacher's cues for the correct answer or an acceptable performance.

All three elements or turn types of this sequence have merited numerous studies of their own. For instance, in the studies on the questioning activities of the teacher, various ways of modifying the question have been identified. When pupils have problems in producing an answer, teachers are found to modify and reformulate their questions, using various ways of eliciting the appropriate answer thereby discursively scaffolding the pupil's performance. Teachers are shown to orient to the importance of having pupils themselves make some attempt at the question. Thus, this three-partite sequence is also an important way of involving the students and eliciting participation from them.

The IRE sequence is, of course, but one of the discursive patterns used in the classroom (cf. Lemke, 1990), and not all situations are organized as exchanges between the teacher and the class as a collective. A formal situation where a group is meant to learn by means of listening to an individual's monolog and reacting to it or responding to questions about it is nevertheless a common one, not only in schools but also in various adult settings. For instance, Tracy (1997) analyzed the academic departmental colloquium as a communicative situation, focusing on types of discursive actions in relation to the participants' discourse positions. Discourse positions refer to the various interests, entitlements, and constraints related to participants' institutional (academic) identities and their task of appearing both knowledgeable in academic-subject learning from each other and gaining new knowledge. When a novice (doctoral student) has given a departmental presentation, a senior staff member (such as a professor) may present a question signaling a problem of understanding without risking her or his epistemic authority or competence: the problem is likely to be treated as the presenter's problem. The situation is quite different with the roles turned around: if a student indicates problems of understanding, it is likely to be treated as her or his own. Thus, competence and expertise, as identities, are social accomplishments managed and negotiated in the discourse of institutional encounters.

An early focus was to analyze the interactional patterns in the classroom and the formal discourse between the teacher and the class. In recent years, the scope of the analysis has evolved from the teacher–pupil/teacher–class formal interaction toward various types of peer interaction and collaborative work in groups of pupils, as well as in their informal moments during breaks or meals (Goodwin, 2006). In addition, analytic dimensions have evolved: not only verbal and nonverbal communication is focused on, but the analysis extends to gestural and postural action, movement in space, the use of visual resources and material artifacts. Furthermore, the focus has moved from the examination of solely cooperative and coherently organized formal situations toward the analysis of conflict, negotiation, and improvisation – in other words, the interplay between organization and disorganization in the life of a classroom.

The Discursive Production of Memberships, Identities, and Differences

A key focus in the linguistically oriented discourse analysis has been the discursive production of the subjects of the pedagogical relationship: the pupil, the teacher, and the parent. These analyses focus on the categorizations and assigned obligations, responsibilities, moral expectations, and category-bound attributes invoked in face-to-face situations, in talk about absent parties, or in texts (e.g., Baker, 1997).

Variation of practices in discourse has been central within linguistically oriented ethnography of discourse. Speaking connects the speaker to a community, but may also disconnect her or him from others. In this vein, a key focus within micro-level analyses of classroom discourse has been to identify the construction and management of differences in speech and communication. At issue is how differences are recognized and interpreted in classrooms and other educational settings, and how they can be used to support the learning of different students. Similarly important is the question of how these interpretations work to maintain unequal treatment of pupils or students from different backgrounds (Cazden, 1986).

A seminal example of a discourse analysis of both construction of identities and linguistic variation in an educational setting is Erickson's and Schultz's (1982) microethnography of American college counseling. Erickson and Schultz point out that the counselor's work is essentially about defining, through the counseling interview, who the student is, in other words, categorizing the student for institutional purposes. Using videotapes of encounters and participants' commentaries on the tapes, the authors studied various phenomena such as verbal and nonverbal contextualizing cues or the rhythm of speech, identifying several interactional features that are likely to affect the way individuals experience each other and their encounter,

and the ways in which these experiences are related to the social (especially ethnic or speech community) identities of the participants. One of their main arguments was that communication styles, and situationally defined co-membership in a social category (speech community or other) have consequences on the friendliness of the encounter and the amount of personal attention and help the student receives. These studies provided evidence that college counseling, in fact, functions as a gate-keeping activity, and that the local management of social identities – ethnicity and various locally invoked co-memberships – influence the counselors' gate-keeping, and thereby also the potential outcome of counseling.

Discourse Analysis and Pedagogical Applications

Some approaches to discourse analysis not only describe the construction of meaning, participation, and knowledge in interaction, but also connect discourse analytic understanding of the interaction to the learning outcome. Studies within these approaches are usually informed by activity theory, Vygotskian psychology, and sociocultural or situational theories of learning. Social interaction is viewed as a constituent of learning itself. Many researchers have come to agree that learning should be viewed as an intrinsic dimension of participation in social activities, practices, and communities (Lave and Wenger, 1991). The sociocultural approach views learning, not as a function of individual cognition, but as a function of constant change in the constellation of participations in communities of practice. Along with the focus on the social nature of learning activity, there is a demand for a firmer empirical grasp on social interaction as the constituent of learning activity (Mondada and Pekarek Doehler, 2004; Martin, 2004).

One application of empirical work in this area is found in Mercer (2004) and his colleagues' work. The usefulness of discourse analysis is both in the possibilities for describing learning-relevant discourse as it unfolds, by the use of data-driven categories, and, based on these analyses, in creating typologies of discourse that enable teachers to improve their practice. Within this approach, language is viewed as a cultural and psychological tool for joint activity – a means and media for thinking and solving problems together. The overall interest in Mercer's and his colleagues' studies (for overview, see Mercer, 2004) has been the way in which different, relatively distinguishable discursive practices provide for learning, participation, and epistemic agency for children in classrooms. The focus is both on the teacher–student interaction and on the peer-group collaboration, and both qualitative and quantitative approaches are utilized. At issue is how participants of a learning situation use language to create meaning together.

Mercer's analyses distinguish discursive techniques used by teachers – types of elicitations (such as questions),

responses (such as evaluations or confirmations following responses to questions), and various kinds of recaps (statements describing aspects of shared experience). Importantly, Mercer and colleagues have also differentiated between three kinds of discourse in children's group situations and task-oriented work: disputational, cumulative, and exploratory discourse. In disputational talk, speakers mainly focus on maintaining their own position and resisting that of others. Speakers tend to disagree, using a lot of assertions and challenges. In Mercer's example below, pupils try to decide how to get about their group task and who should do what:

Example (from Mercer, 2004: 148, Transcript 1):

Carol: Just write in the next letter. "Did you have a nice English lesson".

Jo: You've got to get it on there. Yes that's you. Let's just have a look at that. "Hi Alan did you have a nice English lesson. Yes thank you, Yeah, yes thank you it was fine".

Carol: You've got to let me get some in sometimes.

Jo: You're typing.

Carol: Well you can do some, go on.

Jo: "yes thank you"

Carol: [unintelligible]

Jo: You're typing. "yes thank you" "I did, yeah, yes thank you I did"

Carol: You can spell that

Jo: Why don't *you* do it?

Carol: No, because *you* should.

In cumulative talk, on the other hand, participants build on each other's contributions without criticism or argument. Common knowledge is created by accumulation, using agreement, repetition, confirmation, and elaboration. The following excerpt is found from a Finnish classroom group work session (eighth to ninth graders), where pupils plan and coordinate their work.

Example (Turkia, 2007, 218 Example 2, translated from Finnish by SV; conversation analytic transcript simplified by SV, () = a pause, [] = overlap):

Toni: which part shall we present then () on the presentation day

Tuomas: I don't know (looks at a book)

Toni. well we should () have [something]

Tuomas: [lets see () a movie]

(Tuomas looks at Toni)

Tuomas: because those Niskavuori's have been done seven times or

Toni: let's take a piece of that [movie and show it]

Tuomas: [five]

()

Tuomas: yeah,

()

Toni: [that's a good idea]

Tuomas: [(yes) and besides we won't need to read anything.]

The third type can be both accumulative and confrontational; ideas are argumentatively examined and knowledge is made publicly accountable. This type of talk makes reasoning available to the participants. Many researchers have been interested in how to enhance such explanation, argumentation, and joint testing of ideas among groups. The following example comes from a Finnish teacher education setting, where second-year teacher students are learning about the concept of solubility through an experiment carried out in groups. The authors analyze the following episode as a case of joint construction of meaning of the concept of dissolving. The episode unfolds after a series of attempts to understand the experiment as well as what solubility means.

Example (from Kaartinen and Kumpulainen (2002), 201, Table 4, Episode 6, data translated from Finnish by the authors):

Juho: I do not know what dissolving is... whether one substance gives something to another

Paula: You can never read about it

Jarmo: Many times in high school, but I have forgotten

Elina: On the other hand, in dissolving it seems to me that the crystal structure gets smaller in salt so that the sodium

Juho: Sodium chloride breaks down

Elina: Sodium and chloride those ions go there

Jarmo: Yes the idea is like that those crystals in a way break down

Elina: Yes

Jarmo: And when water is being evaporated those ions join together again

Elina: that is how it seems to be

Jarmo: I think it is also a chemical explanation on the basis of formulae.

Sociocultural discourse analysis identifies these types of discourse, but also facilitates analyses on related applied issues. It is possible to examine, for instance, to what extent children of different ages engage in explorative discourse, and how their discourse helps them to accomplish their task. Another focus, directly relevant to teaching, is how children's discourse changes over time and whether teacher's facilitation enables such change.

Future Challenges of Discursive Research in Education

The diffuse nature of discursive analysis as a set of varied methodological and theoretical approaches to the systematic study of language in interaction presents a challenge to anyone new to the field. Scholars interested in utilizing discourse analysis need to distinguish between the multiple intellectual and theoretical histories, conceptual demarcations and emphases associated with discourse as a term, and to take care when situating their own (under)standing

and approach in this field of traditions. Discourse analysis as an approach may bring to the foreground the minute-to-minute construction of talk, identity, and meaning in the flux of microsituations, as well as historical, structural, and ideological power policies and their links to the construction of texts and interactions in and out of school settings. The researcher's gaze focusing on both the foreground and background – the zooming between the micro and macrostructures of educational encounters, discourses, and texts – thus needs to be based on an educated judgment of the field at large, the research question, notions of context, and the relevant unit of analysis (Warriner, 2008).

Numerous methodological and topical challenges to the field arise from shifting population demographics, multiculturalism, and new information technologies. Global social relations, new sources of information and learning expand the confines of the curriculum and provide new alternatives for the content, direction, and control of learning and teaching. As new technologies push the boundaries of teaching and learning beyond the classroom walls, discursive analysis also needs to continue moving beyond this comfort zone toward the analysis of multimodal aspects of learning, toward human-machine-based learning and the adoption, use, and interactional dynamics of new technologies in education. Simultaneously, qualitative and discursive analyses move ahead from the already-known basic dynamics of teaching and learning in interaction and increasingly focus on some of the more nuanced aspects of topics like resistance, embodiment, and emotions across educational situations. These developments mean that previous understandings of what discourse data consist of also continuously expand. In addition, our understanding of student positioning in and through discourse needs to be enriched by analyses of how class, race, and gender are re-negotiated and mixed into new intersectional youth identities and what the potential consequences of this are for educational institutions and for teacher identities and qualifications.

Basic discursive research on the phenomenon of teaching and learning are also essential for the future. The cultural and physical surroundings and modes through which these take place, however, are expanding in ways that need constant tackling and research effort. Simultaneously, practice-oriented discursive research, that not only seeks to understand and depict educational discourse processes, but also aims at direct practical impact or intervention, is imperative. Ongoing and future developments, evolving new structures, interaction processes, and forms of textual existence of educational institutions call for equally alert and informed development of discourse analytic tools. The future development of discursive research in the field of education thus depends on how scholars new to the field adopt and understand existing methods and traditions, how they further add to, refine, and extend the existing empirical and theoretical knowledge pool, and how new insightful

means of analyzing discourse in educational contexts are introduced and implemented. Theoretical and methodological advances in the field of discursive research in education will, also in the future, result from the continuous, unprejudiced, and well-informed cross-fertilization and dialog between analytic traditions.

Document Analysis

T Rapley and K N Jenkins, Newcastle University, Newcastle upon Tyne, UK

Introduction

Documents are a seen-but-unnoticed part of our everyday lives. Whether held in one's hand or viewed on a screen, they are staple elements of all areas of our lives. They shape our thoughts, actions, talk, and writing. We not only consume them in vast quantities, routinely refer to them in conversations, but also produce them. However one conceives of them, they are essential to the formation of our contemporary societies and institutions.

Document-based research in qualitative educational research, as in all areas of the social sciences, is a relatively small-scale enterprise. The notable exception is historically orientated research – where given the lack of living sources of evidence – the document is the only potential source of evidence. In addition, the practice of reviewing the literature relies on collecting, analyzing, and speaking about a range of documents. Commonly, this is often relegated to the front sections of articles and reports, prior to a primary focus on interview-based talk or observations of others' interactions.

In this article, we begin to explore some of the variety of ways that qualitative researchers have actively sought to engage with documents as a central part of their research practice. We explore some more general issues about conducting research on and around documents. We then focus on two main areas. First, we look at research that focuses on the substantive content of documents – the relatively new area of systematically reviewing qualitative research articles – and the more discursive work that looks at how documents, be they newspaper articles or policy documents, create specific versions of the world. Second, we look at research that focuses on the situated use and creation of documents – how interview-based and ethnographic studies have also looked at the place of documents in the lives and routines of those they study and on the more ethnomethodological work, that seeks to describe in detail the practical ways that documents are used and created in specific instances of interaction.

Approaches to Analyzing Documents

In this article, we are using the term documents to refer to both paper-based and computer-mediated texts. This includes both the written elements of texts alongside the extra-textual elements – images, photos, graphs, and diagrams – that are routinely embedded in documents.

The post-structural and postmodern turn in academia has led to an expansion of the meaning of the term text, to include buildings, bodies, clothing, alongside artifacts, devices, and other aspects of material and technical culture. Simultaneously, interview transcripts, field notes, and video recordings are referred to and analyzed as texts, but we will not focus on either of these genres of work here. Instead, we are concentrating on four relatively distinct areas of work around documents (see **Table 1**). The table proves an at-a-glance comparison of the four analytic methods in terms of their general focus; a more descriptive account of their analytic focus; examples of their typical research questions; the data collected to answer these questions; the key methods involved in data collection; the methodologies often related to these approaches; and the type of results each produces. These four analytic approaches are described individually in greater detail below.

Analytic work on documents can be loosely divided into two areas (see **Table 1**, focus):

1. work that focuses on the actual textual and extra-textual content of documents (meta-synthesis and discourse analysis) and
2. work that focuses on the use, role, and function of documents in interactional and organizational settings (ethnography and ethnomethodological ethnography).

The first focuses on the document as an object in its own right, as an orphaned or docile text, as a container of knowledge. Such work forgoes empirical observation of how people actually read, refer to, or use the documents in question. Whereas the second area is primarily observational, seeking to understand how documents are active agents in organizational and/or interactional life. Obviously, the same topic can be approached in multiple ways and within the same project. Therefore, with a research project on, say, student evaluations of lecturers, one might focus on: the written comments students give (via discourse analysis); how results of these evaluations are fed back on websites, internal memoranda or official reports (via discourse analysis); how lecturers introduce, distribute, collect, and read such forms (via observation); what students, lecturers, and managerial staff think is the value of such documents (via observation and interview); the role of such evaluations in creating institutional change (via observation and interview); and so on.

Whatever approach people take, and irrespective of the methodological traditions they follow, the practical work of analyzing data related to documents closely echoes that

Table 1 Approaches to analyzing documents

	<i>Meta-synthesis</i>	<i>Discourse analysis</i>	<i>Ethnography</i>	<i>Ethnomethodological ethnography</i>
Focus	Content of documents		Documents-in-action	
Analytic focus	Intertextuality	Language and intertextuality	Social interaction and organizations	Language and social interaction
Typical research questions	What is the evidence for a specific intervention?	What versions of the world do documents create?	What part do documents play in the organization of a social institution?	How do documents shape (and are reflexively shaped by) ongoing social interaction?
Data	Academic outputs	Any	Any	Any
Method	Collect documents	Collect documents	Collect documents, field notes, and interviews	Collect documents, field notes, interviews, and audio-visual data
Methodologies	Meta-ethnography, meta-synthesis, and thematic synthesis	Discourse analysis, critical discourse analysis, Foucauldian discourse analysis, and semiotics	Interactional ethnography, grounded theory, phenomenology, and symbolic interactionism	Conversation analysis and ethnomethodology
Results	Synthesis of findings of a collection of documents	How documents construct and reflect a specific version of an argument, truth, social identities, or institutions	Use, role, and function of documents in specific organizational contexts	Use, role, and function of documents in specific interactional contexts

of all forms of qualitative research. Therefore, the data – whether they are documents, interview, field notes, or audio–video recordings (see **Table 1**, method) – will be subject to some form of sampling, as it is collected it will be coded, and some version of the constant comparison method and deviant case analysis undertaken, as well as some level of reflection on the role of the analysts in the process.

The analysis of documents is also related to the research tradition of content analysis (Weber, 1990). In this, researchers gather specific documents, then establish a coding frame and apply that coding frame to the documents to count the number of times particular words, phrases, or themes are used. This enables descriptive and statistical findings to be established. However, this is often seen by qualitative researchers as a relatively limited, albeit systematic approach, in that it predefines the key aspects of analysis alongside removing words and phrases from their context. Some researchers use content analysis alongside other more discursive methodologies, in part to gain a general overview of their data, although this is not discussed here.

Meta-Synthesis: Documents and Creating Evidence

The social, medical, and political sciences have seen the rise of evidence-based policy and practice. Education research has been central in this trajectory, and this shift

has not been without its critics. The growth in systematic reviewing and meta-analysis has also been significant in prescribing a new format for the textual analysis of research (see **Table 1**, first column). In relation to reviews of nonexperimental research, Noblit and Hare's (1988) work on meta-ethnography has been influential. They sought to combine the findings of six ethnographies on the impact of desegregation on urban schools in the US in the late 1970s. They translated the relatively diverse findings of the case studies into a general theory about the impact of desegregation. Following this intertextual work, a range of approaches to synthesizing the findings of qualitative research have emerged. They have been referred to under various terms including: meta-synthesis (Sandelowski and Barroso, 2007), critical interpretative synthesis (Dixon-Woods *et al.*, 2006), and thematic synthesis (Thomas and Harden, 2007). They all rely on insights from Noblit and Hare's (1988) original work, and all seek to move beyond simply aggregating and summarizing findings from qualitative research papers to actively create new conceptual models or theories and to provide evidence for future interventions.

As with quantitative systematic reviewing, this qualitative synthesis work involves searching, evaluation, data extraction, and presentation. However, given the non-numerical nature of the findings, they have adapted each stage in the process. Importantly, the process echoes and draws on key ideas from how one conducts empirical, primary, qualitative research. For example, when searching the literature one seeks a broad range of heterogeneous

studies, purposively sampling studies that cover a range of approaches and findings to the substantive topic of the review. One may engage in further rounds of sampling to find further documents that challenge or extend one's initial findings. The evaluation of the quality of studies is also complex, in that there is no hierarchy of evidence available for qualitative research. In this way, inclusion and exclusion criteria and judgments about quality are more flexible with an initial focus on how relevant the article is to the topic and to the development of the synthesis, and only papers deemed to have major flaws are rejected at the outset. Currently, we have a range of approaches for judging quality that draw on and combine the key aspects of various quality guidelines that exist.

With data extraction, the focus is on collecting data that enables the researcher to outline the key ideas, concepts, and themes within the article. This also includes extracting verbatim quotes from interviews, field notes, and other sources alongside summarizing key aspects. The final stage of synthesizing the data shifts the focus beyond just summarizing the extracted data, to producing explicit interpretations. Again, this process is similar to that undertaken in analysis of primary data in qualitative research. The extracted data is coded in some detail, coded sections are compared and contrasted, and one generates a coding frame which outlines the main themes and issues and relationship between them. These recurring lines of argument (Noblit and Hare, 1988) are drawn from both the new conceptualization of the original data alongside some of original concepts used in the articles.

This style of working with documents is still very much in its infancy, much of the work has been undertaken in relation to health-related topics, and currently we have a range of complimentary methods and methodologies. What they do share is a concern to compare, combine, and critically interpret the findings of different qualitative articles. In this way, they attempt to generate new micro- and meso-level conceptual models of the topic of the review.

Discourse Analysis: Documents Create Realities

Rather than see the documents as neutral sources of information to be searched, evaluated against some external quality criteria, and then the data abstracted from the context, another way that researchers analyze documents is to undertake a relatively close and detailed analysis of the language and meaning within the document (see **Table 1**, second column). This style of research, known as discourse analysis, focuses on how documents produce specific versions of reality. Within this approach, language (written or spoken) is never treated as a neutral, transparent, means of communication. Instead, language is understood as

performative and functional. So, for example, describing something as systematic review instead of as, say, a review of the literature or a child as gifted and talented over, say, bright for their age does specific work, and directs thoughts and actions. Researchers are interested in the specific versions of the world that documents produce, the effects they have both on the potential reader and on the wider culture, society, and institutions.

Within this style of research, the focus is on how words are used. Methodologically, there are two main research trajectories – discourse analysis (Potter and Wetherell, 1987) and critical discourse analysis (Rogers, 2004) – although in practice they often somewhat overlap. Whatever approach is taken, when studying documents in this way one is interested in the rhetorical work of the text, how the specific issues it raises are structured and organized, and how it constructs a specific version of the world.

One might try to understand how the document seeks to persuade someone about the authority of its understanding on an issue. So, for example, one might focus on the range of sources of knowledge and evidence a document draws on – so within a newspaper article one may have verbatim quotes from leading practitioners or academics, references to policy documents or academic articles, and report on conflicting sides of the argument. Such intertextual work helps build the factual status of the account. Moreover, one might focus on the forms and modes of language, knowledge and evidence that are employed. So, for example, systematic reviews and meta-analysis rely on statistics, graphs, and tables – especially forest plots – alongside a detailed account of the methods employed. We have no way of knowing whether in practice any of these methods was actually followed in just this way, but trust and authority are built in and through presenting the case in just this way. Centrally, one is trying to make sense of how the document produces a specific argument, the positions it takes in relation to a topic alongside the other alternate or contradictory positions that are excluded or silenced.

Another central question asked of documents from work in this tradition is how are specific ideas, practices, or identities produced, sustained or negotiated within texts? Some researchers seek to understand and describe the historical trajectory of the contemporary ideas we all currently take for granted. People often work quite closely with some of the writings of the French philosopher Foucault (1977). One of Foucault's interests was in how specific discourses, specific formations of what he called power/knowledge (e.g., medical, psychological, or pedagogical discourses) produce, shape, and enable specific subjects (e.g., attention-deficit/hyperactivity disorder (ADHD)-diagnosed children) and specific actions (e.g., prescribing medications like Ritalin). For example, Rafalovich (2004) has focused on the the conceptual antecedents of the contemporary diagnosis of ADHD. Drawing on articles and books from 1877 to 1929, Rafalovich looked at the

trajectory of three concepts – idiocy; imbecility; and encephalitis lethargica – and shows the initial attempts by medicine to establish an organic basis for children's immoral, or unconventional behavior.

Such histories of the present remind us that what we take for granted often has complicated and esoteric beginnings. This style of work may lead us to the question why exactly we act in just this way or why certain groups of people have the knowledge and power to understand and act on others. Importantly, it seeks to map the trajectories of these discourses, to outline the specific strategies that led to our present as well as those that were rejected or seen to fail. Obviously, given its historical nature, this style of work often uses documents to explore specific topics or questions, although saying that such histories may focus on something that has emerged in the recent past and may also rely on other forms of data – a multi-method approach. Therefore, in Rafalovich's (2004) study of ADHD, he also undertook interviews with parents, children, teachers, and clinicians. In addition, rather than focus in great detail on a small sample of texts these studies can focus on a broad range of texts as they try to show the styles of thought as they emerge, consolidate, and compete across and between texts often over a large timescale. Importantly, such work asks "What are the assumptions in specific documents?"

Ethnography: Documents, Interactions, and Organizations

The ethnographic approach to documents (see **Table 1**, third column) can cover a broad spectrum of activities and sites, although it routinely focuses on the use, role, and function of document in the context of schools. In general terms, such work seeks to combine a more micro-focus on moments of social interaction with and around documents in a range of classroom settings, a meso-focus on the organizational ecology of schools and a macro-focus on broader community and political factors. One of the most obvious roles documents play in education is reading, especially reading in class. Ethnographers are not really concerned with reading in terms of the cognitive processes involved and do not understand it as a monadic activity – that is, that reading can only be understood as something people undertake in isolation. Rather, they focus on reading as a practice situated within and related to the broader contexts of classroom activities and organizational cultures.

For example, the video-based ethnography of literacy by Castanheira *et al.* (2001) demonstrates the situated roles and relationships that people can establish around documents. They show how one teacher positions a specific workbook as the authoritative source of knowledge and how the student orientated to this text and their partner as

potential resources for defining and completing the task. Whereas in a different lesson, a teacher directly engages with the student, asking questions, encouraging them, draws a graph on the student's paper, etc. In this context, the student and teacher collaborate on the problem at hand, thus the student is positioned as central in producing knowledge with the workbook supporting him. Such ethnographic work also seeks to make sense of such situated reading work within the organizational ecology of education. Therefore, one may compare the use, role, and function of workbooks over time, over single classes, over different students, or over multiple subject areas; one may research the background of the teachers or how the workbooks get selected as well as the schools or regional policies around such workbooks. In this way, such research focuses on the embeddedness of reading documents in relation to both student's classroom interactions and their broader educational and social worlds (Green and Meyer, 1991).

As education is bureaucratically organized – and routinely involves coordinating a diverse array of professionals, administrators, and technicians alongside learners over a range of activities, times, and spaces – documents become central, a glue that binds these people and their work together. Mehan's (1993) ethnographic study of the identification, classification, and labeling of educationally disabled children shows us the central role that documents can play in the coordination of educational interactions, decision making, and organizational work. His study draws on a range of methods; these include observing, interviewing, video-recording meetings, and lessons alongside asking teachers to reflect on the videos of these lessons. He uses the sequential paper trail that is created by a student (in class work, examinations, and educational testing sessions with the school psychologist) and created about a student (in their personal school records, school appraisal team committee, and eligibility and placement committee meetings) to focus the fieldwork on the range of sites where bureaucratic assessment and classification work occurs in the special-education referral process.

Documents, in the form of student records, are continually created and discussed by a range of professionals in multiple sites and spaces. Centrally, these records come to represent and stand-on-behalf of the student. In meetings about students, discussions routinely draw on and highlight aspects of the paper trail created by and about the student. The decisions that emerge from these meetings are central in classifying the child and, therefore, are central in creating their specific educational trajectory. In his study, Mehan (1993) does not present us with the documents themselves, rather he focuses on the distributed talk and actions of those people who create and use them. He shows us how the documents created by and about students become objectified and how the technical talk and decisions they facilitate are given much higher status than other forms of evidence such as a parental voice.

Ethnomethodological Ethnography: Documents-in-Interactions

Research on documents within the tradition of ethnomethodological ethnography – and we include conversation analysis within this area – focuses on describing in great detail the moment-by-moment social organization of interactions with, around, and about documents (see **Table 1**, fourth column). Like ethnographic work outlined in the last section, it is not so much interested in the content of documents, but in the organization of interactions where documents take some role. However, in general terms, there are two central differences. First, for ethnomethodological work, the immediate, here-and-now, to-and-fro of the participants interactions is the central object of interest, description, and analysis. Broader contextual factors, like participants' backgrounds or organizational policies, are generally not drawn on as a resource to explain why an interaction happens in a specific way. Instead, the focus is on what the participants in the interaction show themselves to actually do, the resources they draw on in just that moment of interaction. Second, ethnomethodological work increasingly relies on audio or video recordings of naturally occurring interactions. These form the centerpiece of analysis, are subjected to repeated viewings, and sequences of interaction – including verbal and nonverbal features – are transcribed in very fine detail, analyzed, and revised in conjunction with the original recordings.

An example of this method in practice is Heap's various analyses of audiotapes of young children reading in classrooms (e.g., Heap, 1985, 1991). Rather than assuming we already know what reading looks like, or when it occurs in classrooms – through some *a priori* theory or criteria – he focuses on the broad range of interactional activities that produce the ongoing activity as reading. For him, children learn what counts as reading criterially, by learning what counts as reading procedurally, in and through taking part in interactions where good reading is shown to be taking place. For example, Freebody and Freiberg (2001) show how in a moment of a parent-child interaction, where a child is reading a book aloud, the parent works to praise, instruct the child to sound the letters, correct a sounding, etc. In this moment of reading a document, the central interactional task is reading out loud a written text, and good reading is orientated to and produced as correct word-saying. In other contexts, say a university seminar on a specific article, in and through debating and discussing, students learn what good academic reading involves – finding fault, contrasting with other documents, quoting and referencing from this and other documents, reading footnotes, following up references, etc.

Such work focuses researchers' attention on unpacking, in detail, how specific tasks are undertaken.

Documents are not only paper-based, single-user, objects and ethnomethodological ethnographic research

has focused on how mundane and digital technologies shape the world of educational activities. Such research has focused on how people interact, work with, and draw on such document-related technologies as white- and blackboards, overheads, computer-based presentations, and videos. Rendle-Short's (2006) study of computer-science seminar presentations focuses on the academic monolog. She shows us how presenters work to interact with the audience not only through their talk, but also through their gestures, gaze, and bodily movements. Using a collection of videotapes of seminars and transcribing in great detail the moment-by-moment verbal and nonverbal behavior, she focuses on how presenters coordinate a range of documents and technologies as they seek to engage with the audience. As presenters talk, they time their slides to focus, support, and supplement the issues they are raising. The text-based and visual images on the slides work to illustrate some aspects of their ongoing talk, and presenters through their hand gestures work to direct the audiences' attention to a specific aspect or issue. In this way, we begin to see how, what appears as a relatively simple task – giving a seminar – is saturated with a complex range of interactional work. The documents the presenters work with, be it notes available to them, or slides available to all, are brought to life and shaped through the concerted, moment-by-moment, organization of talk, gesture, and technology.

Such ethnomethodological ethnographic research findings can seem focused on the quite obvious, in that it can show us what we take for granted. However, researchers in this tradition argue that it is only through an understanding the details of what we actually do (the details of which can largely escape our notice), over what people tells us they do, or what we think they do, that we can then develop theories or interventions that are actually relevant to current practice.

Conclusion

Given the ubiquity of paper and computer-based documents in contemporary social and organizational life, the range of potential types of documents open to qualitative analysis is immense. However, the primary sources for educational research are policy documents (be they national, regional, or local), textbooks, and internal organizational documents; the secondary sources are from the academic canon. Documents in any broader sense – be they blogs, diaries, magazines, newspapers, or websites – are underused and underanalyzed. As noted above, the lack of focus on documents is not restricted to qualitative educational research, but is endemic to the social sciences. On the one hand, this is quite surprising, given the centrality of documents to everyday experiences, the readiness-to-hand of document-based raw data, and that it does not have to

require large amounts of time in the field collecting data. However, ideas around hearing peoples' voices, witnessing things with your own eyes, have been increasingly positioned as a central requisite of authentic and high-quality qualitative research and increasingly involve documents.

Nevertheless, in relation to critical discourse analysis style studies of education, Rogers *et al.* (2005) see the turn away from a focus solely on written documents toward a focus on talk as a positive direction, in which new theoretical, methodological, and analytic possibilities emerge. Notwithstanding these potentials for development alongside the existing tradition of ethnographic work focusing on the use, role, and function of documents-in-action, we are still left with a relatively limited corpus of work that focuses on the social and educational lives of documents. Documents shape, and are reflexively shaped by, our perceptions, interactions, institutions, policies, and society. They are central in the production, reproduction, and transformation of our educational landscapes. As such, they deserve a more sustained and systematic analytic focus.

Ethnography

M Hammersley, The Open University, Milton Keynes, UK

© 2010 Elsevier Ltd. All rights reserved.

The terms 'ethnography' and 'ethnographic' have been in common use within research on education since at least the 1950s (Spindler, 2000). Initially, they had a relatively specific meaning, referring to anthropological research that focused on the process of cultural transmission within schools, studied against the background of local communities, and usually with a particular interest in the experience of minority or subordinated groups. However, from the 1960s onward, within education and beyond, the word 'ethnography' began to be used in other disciplines and in a wider range of ways, with some other methodological labels treated as near-synonyms – including 'case study', 'field research', 'interpretive inquiry', and 'qualitative method'. Moreover, where previously the label had referred to studies employing participant observation over relatively long time periods, now the data collection tended to be of shorter duration and some studies relied primarily if not exclusively upon in-depth interviews. Diversity in orientation also increased: some of this more recent ethnographic work formed part of evaluation projects, some drew on sociological theory and on sociolinguistics, and some of it was influenced by Marxism, feminism, and other critical and activist approaches – though critical and activist strands can be traced within US anthropology of education from quite early in its development (Yon, 2003). There was also dispersion in geographical terms: prior to 1960 almost all ethnographic work in education was carried out by US scholars, but from that decade onward there was considerable growth in this kind of research elsewhere, most notably in the UK, but also in Australia and on the European continent (for the case of Sweden, see Larsson, 2006). The result is that there is now a huge amount of work that labels itself as ethnography.

Over the second half of the twentieth century, there was also diversification within anthropological research in education, for example with some of it developing an international comparative dimension, while another flourishing genre focused on language-use, stimulated by the ethnography of communication and other work in sociolinguistics. A further influential strand developed within the Chicago tradition of US sociology, with studies of schoolteachers (for instance, Lortie, 1975; and the work of Becker, see Burgess, 1995), and of students (e.g., Geer *et al.*, 1961). From the 1960s onwards, outside of anthropology and sociology, there were many investigations of life in classrooms (Jackson, 1968), some of which could be described as ethnographic. In the UK, some early ethnographic work focused on the effects of streaming or tracking in secondary

schools (e.g., Lacey, 1970). Subsequently, in the 1970s and 1980s, developments around the new sociology of education led to a considerable range of studies concerned with both teacher and student perspectives in the context of classroom interaction (see Hammersley, 1999). Under the influence of feminism and anti-racism, this work spread out into a range of investigations concerned with inequitable treatment within the education system. More recently, in the UK and elsewhere, much ethnographic work has been concerned with investigating the character and consequences of managerialist forms of educational policymaking (for instance, Woods *et al.*, 1997; Troman *et al.*, 2006). There has also been a small amount of work that has extended the focus beyond teachers and students in state-funded mainstream schools, for example, looking at religious schools (Peshkin, 1988), at vocational training (Atkinson *et al.*, 1981), and at educational processes in non-institutional settings (Delamont, 2006).

The Meaning of Ethnography

In etymological terms, 'ethnography' means writing about a people, and came to refer to producing an account of the way of life of a particular community or society. In early twentieth-century anthropology, what was aimed at was a descriptive account that captured a distinctive form of social organization or culture. Initially, ethnography was contrasted with ethnology, an influential form of nineteenth-century anthropological work which focused on the historical and comparative analysis of societies, and was usually based on accounts produced by travelers and missionaries. Over time, the term 'ethnology' fell out of favor, and 'ethnography' came to refer to theoretical interpretation of cultures on the basis of firsthand investigation carried out by anthropologists and other social scientists themselves. Moreover, the word has a double meaning, referring both to a form of research and to the product of that research: in other words, ethnography as a practice produces ethnographies as published accounts. A contrast has also sometimes been drawn between doing ethnography and using ethnographic methods. This distinction has been employed by some anthropologists in an attempt to mark off their own practice from what passes for ethnographic work within sociology and evaluation studies (Wolcott, 1999). However, the distinction raises a more general issue: that the various methodological ideas and strategies associated at any particular time with

ethnography have been by no means universal or fixed. So, if we look back from the twenty-first century a hundred years or more, across different disciplines and different countries, we find considerable variation in the nature of ethnographic principle, practice, and products. Even anthropological research has changed considerably over this period, and become more diverse in methodological terms. For many anthropologists in the past, ethnography required living with a group of people for an extended period – for a year or even several years – in order to document and explain their distinctive way of life, the beliefs and values integral to it, the social institutions (including those relating to education) characteristic of it, and so on. However, today, ethnography has come to be defined in more specific methodological terms as the use of participant observation and/or in-depth interviewing; though even this meaning has been breached by the notion of virtual or internet ethnography, where the primary form of data is online rather than face-to-face (Silva, 2002).

Despite variation in meanings given to the word, in practical terms of method ethnography usually involves many of the following features:

1. People's actions and accounts are studied primarily in everyday contexts, rather than under conditions created by the researcher – such as in experiments or in highly structured interview situations. In other words, research takes place in the field or is naturalistic in character.
2. Data are gathered from a range of sources. While participant observation and/or relatively informal conversations are usually the main ones, documents, artifacts, and even statistical data may also be employed.
3. Data collection is usually relatively unstructured, in the sense that it does not involve following through a fixed and detailed research design setup at the beginning. Nor are the categories that will be used for interpreting what people say or do generally built into the data collection process itself – via prestructuring of observation, interviews, or documentary analysis. Instead, they are to be discovered or constructed during the course of inquiry.
4. The focus is usually on a small number of cases, perhaps a single setting or group of people, occasionally just one person, as with some forms of life history and auto-ethnography (Reed-Danahay, 2001). Sometimes a larger number of cases are studied, notably where these are small-scale, for example, school lessons.
5. The analysis of the data involves interpretation of the meanings and functions of human actions, and usually also how these are implicated in local, and wider, contexts. What are produced by ethnographic analyses, for the most part, are verbal descriptions, explanations, and theories; quantification and statistical analysis play a subordinate role at most.

There have been continuing disputes about whether any of these features is essential, and about the relationship with other work of various kinds that is placed today under the broader heading of 'Qualitative method'. There is no definitive answer to these questions, they are a matter of dispute.

Ethnography as a Distinctive Methodological Orientation

As a practical approach, ethnography is not far removed from the means that we all use in everyday life to make sense of our surroundings. However, it involves a more deliberate and systematic attitude, as with any form of research, and also a distinctive mentality. This can perhaps best be summarized as starting from an attempt to make the strange familiar – in the sense of finding intelligibility and rationality in what is initially inexplicable – and, at the same time, making the familiar strange – by suspending those background assumptions that immediately give apparent sense to much of what we experience, at least in contexts with which we are well-acquainted (Hammersley and Atkinson, 2007).

Over the course of its development, ethnography has been influenced by a range of methodological and theoretical movements. Early on, within anthropology, it was shaped by German historicist ideas about the difference between the human and the natural sciences, by folk psychology, but also by nineteenth-century positivism. Subsequently, in the form of the case study approach of the Chicago School, it was informed by philosophical pragmatism, while in more recent times phenomenology, hermeneutics, structuralism, and post-structuralism have all played an important role. As noted earlier, it has also been influenced by various critical orientations: Marxism, feminism, anti-racism, disability activism, and queer theory. The forms that ethnographic work has taken, and the particular influences operating on it, have varied across different fields and different countries, as well as over time.

Despite these diverse influences, at an abstract level ethnography tends to be characterized by a few distinctive methodological ideas about the nature of the social world and how it can be understood. These have influenced how ethnographers have studied educational structures and processes. They can be summarized as follows:

1. Human behavior is not an automatic product of either internal or external forces or stimuli. People's responses to the world are constructed and reconstructed over time and, across spaces, in ways that reflect the biographies and socio-cultural locations of the actors, how they interpret the situations they face, and how these situations develop over time.

2. There are diverse cultures that can inform human behavior, and these vary not just between societies or local communities but also within them.
3. Human social life is not structured by fixed, law-like patterns, but displays emergent processes of various kinds that involve a high degree of contingency.

While these generic ideas have informed much ethnographic work, they have been interpreted in a variety of ways, and have generated some tensions.

Tensions Within Ethnography

In recent times, there has been some dispute over the character of the phenomena that ethnographers study and how they should study them. There are a number of dimensions to this.

One is a tension between naturalism and constructionism. For the first, the task of ethnography is to document stable cultures, patterns of social interaction, institutions, and so on, as they exist in the world independently of the researcher. By contrast, constructionism is concerned with the interactional or discursive processes whereby cultures and institutions are ongoingly, and contingently, produced and sustained. Indeed, in its more radical forms, constructionism treats the phenomena studied by ethnographers as effectively constituted in and through the research process itself, and especially through the process of writing (see Clifford and Marcus, 1986).

These disputed assumptions about the nature of the social world are closely linked with ideas about how we can understand it. And here too significant differences in approach come to the surface. One of these concerns the nature of context. On the one hand, some ethnographers focus on the details of what happens in specific, small-scale contexts on particular occasions, and perhaps on how participants themselves define these contexts. On the other hand, there are ethnographers who insist on the need to locate what has been studied within a theoretical understanding of some larger social whole. Over the past few decades there has been a trend towards more micro-focused ethnographies (Erickson, 1992), but there has long been, and remains, a counter-tradition which stresses the need to locate what is studied in a wider context, whether a national society or the global pattern of social relations (Burawoy *et al.*, 2000).

Parallel to this have been criticisms of much ethnography for being ahistorical. It is sometimes portrayed as preoccupied with describing and explaining what happens at some particular place and time, thereby neglecting longer-term trends. One response to this has been to advocate longitudinal ethnographies, for example following the development of students' lives over several years as they traverse the education system, investigating the

changes experienced, the adaptations made, and the outcomes (see Pollard, 2007). Also relevant here are restudies (e.g., see Smith, 1983; Burgess, 1987), and life history investigations that trace, for instance, the patterns of teachers' careers and the factors shaping these (Goodson and Sikes, 2001).

A third tension within ethnographic thinking is between a focus on the unique and the use of comparative analysis: between seeking to study the distinctive aspects of particular cases and being concerned with producing generalisations or building theories. Ethnographers vary considerably in their position on this dimension, but most seek to satisfy both demands simultaneously in one way or another, to at least some degree. The concept of thick description (Geertz, 1973) represents one sort of trade-off, where theories are primarily means for understanding what is going on in particular cases; but are developed in the course of this. Toward the other end of the spectrum are grounded theorizing and analytic induction, where the intended product of ethnographic work is some kind of general theory, albeit evidenced through data from particular cases (see Hammersley, 1989, 2008).

Another issue concerns whether the emphasis is on description or explanation. For some, the primary ethnographic task is explicating the perspectives, or cultural orientations, of the people being studied in their own terms. For others, the goal is to explain why people see the world and act in the ways that they do, and perhaps also to account for the consequences of this. The first approach emphasizes the role of careful description, of understanding the meanings people give to the situations they face and to their own identities, perhaps even seeking to amplify their voices. By contrast, the second often produces accounts that raise questions about the validity of people's beliefs about themselves and their world. This may involve explaining their attitudes and actions in terms of causal factors whose existence or significance they do not acknowledge, or even explicitly deny. Sometimes these two approaches have been applied selectively within the same study, with the perspectives of some actors being presented as at least partly representing genuine understanding of the world while other aspects of their perspectives, or the perspectives of other people, are treated as ideological (see Hammersley, 1998).

A related variation concerns attitudes toward the distinction between appearance and reality. Some ethnographers see their work as challenging official or public appearances, the fronts people display, in order to find out what people really believe or what is really going on. A somewhat different orientation involves viewing social life as a matter of socio-cultural performance, with the task being to study the processes or strategies by which people bring off particular performances on particular occasions (Bloome *et al.*, 1989; Atkinson and Coffey, 2002). From this second point of view, there is no true

or fundamental reality behind appearances, only constitutive, interactional processes that generate one set of phenomena rather than another.

Even for those ethnographers who place emphasis on documenting people's perspectives, there are questions about the nature of understanding. How far it is ever possible or necessary for ethnographers to understand participants' perspectives 'from the inside?' It has been suggested that this involves reducing the Other to the Same, forcing what is different into terms that are familiar. At the same time, ethnography has also sometimes been accused of Othering, of rendering non-Western societies or marginalized groups within Western societies exotic and alien, a criticism that parallels Said's discussion of orientalism (Said, 1978). Closely related are criticisms of the totalizing orientation of much older ethnography, where cultures are described as if they were objects in the world that are internally homogeneous, and as if membership of a culture determined everything of importance about any individual person.

A further dimension of difference in orientation concerns whether an appreciative or a critical stance is judged to be most appropriate. In some influential forms, ethnography has involved a concern to capture the beliefs and actions of the people being studied in such a way as to minimize the effects of the research process and of the attitudes of the researcher. Here, ethnography was usually distanced from any concern with practical improvement or social intervention, and therefore adopted a nonjudgmental or appreciative orientation (Matza, 1969). However, in the mid-twentieth century there developed forms of applied anthropology that treated ethnography as a basis for interventions designed to improve the lives of the people being studied. Later, some ethnographers adopted Marxist or other critical perspectives in which the phenomena studied were to be located within a political perspective that generated evaluations and recommendations for social change. At the same time, the impact of post-structuralism and postmodernism has challenged reliance upon political positions involving meta-narratives, notably but not exclusively Marxism, in favor of subordinating ethnographic work to local struggles, with one of the tasks being to liberate those repressed forms of knowledge that have been banished to the margins of conventional society. These developments have also raised doubts about, but in practice also sometimes reinforced, the idea that at least part of the ethnographic task is to give voice to those treated as low status or marginalized within particular societies and communities: for example, students or parents from minority ethnic groups.

Closely associated with some of these developments have been pressures to do ethnographic work *with* people rather than *on* them, along the lines of various participatory forms of inquiry or action research (Reason and Bradbury, 2006). In some cases this has built on a commitment to

advocacy by anthropologists, and on the notion of indigenous ethnography; while, elsewhere, it also derived from feminist and other approaches to research ethics which have challenged what is seen as the hierarchical relationship between researcher and researched in conventional forms of ethnography and other kinds of social research. However, there is a tension here not only with the commitment of older forms of ethnography to appreciation and understanding but also between subordinating research to participants' orientations and using it as a means of raising their consciousness in order to generate desirable social change. Within the field of education, there has been considerable work drawing on ethnographic methods that has been aimed at working with practitioners, or enabling the latter to do research themselves, notably under the banner of educational action research, but some of it also involving a critical orientation (e.g., see Gitlin *et al.*, 1989).

A final, related, trend worth mentioning is increasing pressure to recognize the extent to which, and ways in which, all research, including ethnography, plays a political role in the world. To some degree this began long ago with criticism of how anthropology was implicated in Western imperialism. In more recent times, the concern with the politics of ethnography has become much broader, reflecting the influence of new social movements of various kinds, and wider socio-political circumstances. For some commentators, the whole enterprise of research is political through and through, in the sense that it cannot but involve reliance on value assumptions, and these cannot but reflect the identity, commitments, and social location of the researcher as a person. This runs against earlier forms of ethnography where research was treated as concerned simply with producing objective scientific knowledge about diverse communities and cultures, an orientation that is now regarded by many, though not all, ethnographers as simply an ideological disguise for political interests that serve the status quo.

Some Further Developments

As noted earlier, ethnography refers not just to a process of inquiry but also to a particular type of product: to the sort of account generated by ethnographic research. Prior to the early 1980s, the task of writing up ethnographies was given relatively little attention in the methodological literature. Most of the focus was on problems surrounding data collection and analysis. However, in the past three decades there has been considerable interest in this topic, not just from a practical point of view but also in terms of analyzing how ethnographic accounts represent or effectively constitute the social contexts and people investigated. Epistemological, political, and ethical concerns are intermingled in what has come to be seen as a crisis of representation (see Hammersley, 2008).

Developments in technology have also had an important impact on ethnographic work. In the second half of the twentieth century, the availability of increasingly portable audio- and video-recorders meant that fieldnotes came to play a subordinate role in much ethnography. Furthermore, the use of video-recording has built on earlier developments in visual ethnography that employed photographs and film. These technologies may have encouraged the spread of an increasingly micro-focused concern with the details of what is said and done on particular occasions.

Advances in computer technology, and in software for processing qualitative data, are another important area of development, one where there is disagreement about whether the technology serves or distorts ethnographic practice. What seems clear, though, is that digitization of data, and the increased capacity of computers to handle multimedia material, will open up considerable opportunities for ethnographers, as well as no doubt also raising new problems, or old problems in new forms. Closely related here is the development of the internet, and the opportunities that this provides not just as a source of information but also for the investigation of virtual communities.

Finally, it is worth mentioning a significant feature of the changing environments in which ethnographers seek to carry out their work. Both anthropologists and sociologists have encountered increasing barriers in gaining access to settings in many societies, and this includes those relevant to education. These stem from a variety of factors, among which are managerialist forms of regulation within both privately owned and publicly funded organizations, and increasing commercialization. A related external factor is increasing ethical regulation, the ethical codes on which this is based often assuming a model of research that is at odds with both the theory and the practice of ethnography (Lincoln and Tierney, 2004).

The rise of the notion of evidence-based policymaking and practice, and associated demands that educational research be reformed to provide more effective evidence about what works, has become a significant feature of the environment in which ethnographic inquiry is now carried out, in many countries. What is involved here is not just a push toward more applied kinds of work but also the imposition of distinctive research criteria. Even where randomized controlled trials are not treated as the gold standard, the methodological orientation associated with the evidence-based practice movement in education is at odds with ethnography in some key respects, for example, in demanding closely specified initial research designs. Of related significance here is increasing strategic management of research and modes of research training within universities, which are also sometimes informed by a similar methodological model.

In conclusion, then, term 'ethnography' now refers to a range of flourishing approaches within educational

research and social science. Much is shared among these approaches, but there are also some significant differences and tensions, as well as important challenges.

Ethnomethodology in Education Research

Glossary

Formal analysis – A gloss for the expert practices of social science analysis that aim to reproduce either or both the measurement program of the natural sciences, or its discoveries of formal causative structures. But unlike those achievements in the natural sciences, formal analysis in social science – whether statistical or theoretic – must specifically ignore the endogenous organizations of the affairs it aims to formally render. The hearable (indexical) contingency of an interview, for example, is lost to every scheme of codes.

Indexical expressions – Expressions whose definite sense and meaning are tied to the occasions of their use. Natural language is shot through with indexical expressions. This means that common understanding is achieved, and has an analytic foundation. Speaking and listening are analytic exercises. In our unrelieved use of these expressions, we achieve the “rational properties of indexical expressions,” and worlds in common.

Reflexivity – Ethnomethodological reflexivity refers to relations of co-constitution. Questions, for example, are reflexive to answers: We know what was said was a question because we hear an answer next. Its canonical formulation is the “essential reflexivity of accounts,” or how our accounts of the world are constitutive of the affairs they render accountable. Among other interests, a constitutive reflexivity spells the end of representational models of language. Talk does not represent; it acts.

Situated action – Action that is not situated, that is, it is not formulated in local settings that give it cause and sense, is difficult to imagine. For EM, situated action is a unifying formulation. It is part of an argument for the local study of cases-in-context.

Introduction

This article takes up a certain intellectual history in matters of educational study. It is certainly not the only one, or even, perhaps, a central one, for understanding the central tendencies of the research literature. However, it is

an important one for making sense of where we have come in understanding the relationship of social science to professional education, and what claims, promises, and offers of assistance can usefully, sensibly be made from the one to the other. There are two tasks it hopes to accomplish: To bring into view a period of great conceptual innovation in our thinking about the ordered character of social worlds for a current generation of young scholars who may know it less well. Those innovations struck to the core of the promise of a social science, and became the curriculum for the generation of education scholars who wrote the qualitative turn in education in the 1970s. The second is to clarify what is persistently relevant about those conceptual innovations in the particulars of ethnomethodology (hereafter, EM). EM is not well understood in the textbook literature, although it has been a central participant to an invisible college of commentaries, criticisms, and alternative proposals that have rewritten social science and educational study over the last 40 years.

There are several instructive accounts of EM in the sociological literature (see especially Heritage, 1984; Lynch, 1993) and in education (see Baker, 1997; Watson, 1992). But the motivated reader should also turn to its founder, Garfinkel (1967, *passim*) and his 50-year corpus of work. Garfinkel has been articulate and detailed about the program he intends, although by many accounts his articulations do not make for easy reading. Included is the story of his coinage of the term ethnomethodology, having to do with the intellectual currents of the early 1950s and the developing fields of the ethnosciences, as in ethnobotany, ethno-astronomy, and ethno-pharmacology. Garfinkel found their demonstrations kindred to his interests in how ordinary worlds owned practices of disciplined inquiry long before the first graduate student was ever minted.

The ethnosciences were organized by the rubrics of modern science (astronomy, and the like). But Garfinkel was taking interest in methodic practices far more quotidian, and foundational. Ethnomethodology is a covering statement for the endlessly diverse member-methods that give form and recurrence to the most ordinary social-organizational things in the world (e.g., the order of a queue at the supermarket, or a classroom lesson), and how those things are jointly produced, and thus contingent, and therefore achieved. The members here are cultural members, and at every turn, social life and order show our methodic actions in concert. In the measure, EM articulates a

program of studies that is quite different from the culture and conceptualizations of social science and educational research as we know them.

By many accounts, EM is a puzzle, a source of confusion for some, even consternation for others. A reputational penumbra remains from its early reviews having to do with vexing texts, odd experiments, and relentless though perhaps penetrating discontents with normative social science. All could be true. However, in addition, the most troublesome readings seem to follow from the very term ethnomethodology itself.

EM tends to be read as yet another professional methodology, and thus another proposal for technical methods that might bring distinction to the field. Such a reading takes EM as something to apply, on the promise that this application will serve our purposes better than another. The reading thus relies on our familiar expectations for scientific methodology, and the place of science in society as a site of high technical expertise. It is a reading that preserves the promise of science and its appointments, and thereby misses entirely EM's commentary on those self-same ambitions.

EM refers not to scientific or social scientific methods. It proposes a very different understanding of a world that already owns methods of inquiry and analysis. In full, EM is the topic for EM studies. EM is EM's object, interest, and task to describe. EM sights a world of diverse methods of inquiry, action, and instruction, from laboratory science to bird watching to learning a second language. These are the first methods on the scene, and thus it is their practitioners – cultural members – who are our first methodologists. Yet, to say that EM is the topic of EM inquiries begs the question of how those inquiries might be organized. The question returns us to the presumptive authority of formal methodology, as though an inquiry could not be credible unless its methods were regular, repeatable, and vetted in advance. It is this very culture of methodism that EM sets aside. One might agree or not, but if we understand how EM is talking about methods, we understand how it is saying that we proceed with the life of the quarry in mind. Our professional-study methods, whether interviews, audio tapes, or document collections, are measured to our occasions of inquiry.

In this light, the lunchroom at noon takes on a methodic orderliness. So also, for teaching quadratic equations and poetic forms. EM writes a comprehensive view of social order as a methodic, praxeological assemblage, and a proposal to study its diverse tasks and occasions for what is methodic and disciplined about them (Garfinkel, 1967). On the face of it, its relevance for educational studies is quite substantial. For a world of disciplined practices, pedagogy is a central exercise. Competent worlds – worlds competent to storytelling and computer games – must already own methods for teaching

and learning the orderly affairs they display. How they do is perhaps the great ignored topic of the educational research literature.

The Mid-Century

EM was a development of mid-century sociology. Harold Garfinkel was party to an extraordinary generation of conceptual innovation in matters of social science, including critical commentaries on its very possibility. The registers ranged from sociology to anthropology to philosophy, and how they were all unavoidably joined at the hip of natural language study. Lists will not do those developments justice, and space will not permit a fair accounting, but between the mid-1950s and early 1970s, Anglo-American social science experienced a profusion of excavations, proposals, and demonstrations from Herbert Blumer to Erving Goffman to Clifford Geertz, and from Thomas Kuhn to Charles Taylor to Peter Winch and Wittgenstein.

From these various directions, the formal structures and distinctions that underwrite the natural-science model for social science became the objects of critical inquiry that yielded sociology's qualitative turn of the 1950s and 1960s. Central to the rethinking was the question of what purchase the model could have for understanding meaningful social worlds (or science, for that matter) in any actual case. One need not insist on understanding actual cases to see how the familiar empiricism of social science and educational research can say little, if anything, about them. As a familiar example, for all kinds of practical administrative purposes, it can be very useful to know that the average American family produces 2.2 children. For program-planning purposes, for the professional administrative offices of modern life, this can be very useful stuff to know; and it is entirely descriptive, although in a peculiar way: It tells us – and can tell us – nothing of any actual family. It tells us nothing of the formative histories that yield its aggregate finding. It can be of no use for understanding the very affairs it reports (though the report can be of interest to other affairs). For these reasons, should we take interest in the affairs that produce such data in the aggregate, we will have to look to them, and do our looking in a very different fashion.

Within social science, Garfinkel's EM was perhaps the most analytically radical proposal among the commentaries, radical in that it recast the exercise of sociological analysis and its relationship to the worlds we study. The formulation of member methods broke the conceptual monopoly on where and how we might find methods of inquiry, and who a methodologist or analyst could be. His work drew on an eclectic yet thematic collection of prior work, in Husserlian and Heideggerian phenomenology, conversations and readings with Alfred Schutz and Aaron Gurwitsch,

readings in philosophical pragmatism, the liminal works of Merleau Ponty, the formal architectures of Talcott Parsons, his advisor at Harvard, alongside the sociological canon. He set out to topicalize, and then write an alternate to sociology's consensus project of formal, synthesizing analyses whose aim and achievement would be expressed in synoptic theory. Parsons' theory of social action became an exemplar for the explication of what Garfinkel refers to as "formal analysis" and its identifying exercise of "generic representational theorizing" (Garfinkel, 1996).

As for the promise of formal analysis and its synoptic field of view – the macro-end of the familiar macro–micro divide, and the confident panoptics it delivers – it was observed in return that every observation of a distant landscape is a local reckoning. To see a learning disability, best practice, or hegemonic complicity is to collect local reckonings by the basketful, to rely on them, arrange them, submit them to certification procedures, and render them as practical evidences of a structure that was there all along. When we see this work, the comforts of distinctions such as form and content, structure and function, and macro and micro, collapse into fields of reflexive relations of co-constitution. Content becomes constitutive of form. Structure lives in function's local occasions. Rather than genealogies, we find constitutive relations. Rather than causal chains, we find demonstrable sense. (Notions of reflexivity are now familiar in the literature. We have the reflexive practitioner and the reflexive ethnography. These formulations trade on the wisdoms of the early-moderns, who counseled know thyself. The counsel is beyond reproach. We should. But the reflexivity of constitutive relations is quite different, as a topic and task of analysis (Garfinkel, 1967).)

This is analytically radical fare, in that to take it seriously is to re-think our received analytic appointments and ambitions. Central to this account is the place of constitutive detail for the analysis and understanding of social action, or what Garfinkel refers to as the concreteness of the plenum (Garfinkel, 1996). Husserl and Schutz spoke of the *lebenswelt*. Each refers to the life world, the profusion of sense, meaning, action, and others that fills our lives in the natural attitude of everyday life. Neither idiosyncratic nor subjective, the plenum refers to the meaningful character of evident – and thus objective – worlds. EM proposes to describe and understand the production of this public, witnessable order. Yet it is a central premise of our familiar research methods that the social world as we find it naturalistically, in its mundane presenting forms as, for example, the chatter of a classroom during third period, is without useful analytic possibilities. If we are to make good on the promise of a social science, we cannot work with it that way, in its actual, temporal durations and material productions. The contextual coherence of students engaged in chit chat defeats the promise of science.

For that reason, we rely on formal methods to craft stable representations of those ordinary worlds, by the familiar devices of code and variable constructions, set in play within fields of mathematical – or theoretical – relations, that might then yield models or logics that can, in turn, reveal unseen order or structure. This is the family of practices Garfinkel refers to as formal analysis, and by the expression he means to topicalize the unspoken premise that there is no order in the concreteness of actual occasions. Order, on the formal account, lies elsewhere. But one need not doubt that there are indeed structures unnoticed or out of view – as in the vector of a flu transmission or the collapse of a housing market – in order to take interest in the local enactments that yield such things as vectors or collapses, or the work of finding them.

Conversation Analysis

The subsequent and closely aligned development of conversation analysis (CA) (Sacks, 1992; Sacks *et al.*, 1974) gave these arguments a vivid field of demonstrations, vivid in the profusion of circumstantial detail recorded in tapes and on transcript. Conversation shows itself as a primordial members' method. In the organization of natural conversation, turn by turn, we can see what such vernacular analyses could be. (The formative history and conceptual relations between EM and CA is a regular topic in the EM/CA literature, for example, Heritage, 1984.)

Sequential analysis gave detail to the proposition that meaning owns a practical–analytic fabric, as in how every next turn to a conversation – without exception – displays an understanding of the turn that has gone before, and shapes the sequential horizon, or context, of next turns (Sacks *et al.*, 1974). Indeed, to speak next, whether at the dinner table or in the classroom, is to evidence an understanding of the speaking just done, what action it produces, what horizon of relevant next actions it projects, and, of all things, where the ongoing turn might end, so that we might begin our own. To speak next is to analyze all these things, whose analyses are revealed in the production of an apt next turn, on time (Moerman and Sacks, 1971/1988). The very formulation of turn taking in classroom discourse studies owes a very large debt to these first studies.

EM studies thus aim to show that there is indeed order in the plenum, an ignored, constitutive orderliness. To understand and describe it is to have use for the circumstantiality of meaning's productions. The point is not that somehow one should have use for this worldliness, because it has been ignored. It is rather and only that the order and structure of ordinary worlds turns upon it. In our everyday lives, we do not remotely ignore this circumstantiality. We live by it.

Invisible Colleges and the College of Education

There developed around these initiatives, a cohort of students and colleagues taking interest in this very different vision of what social-science inquiry might be. EM argued the primacy of meaning for the production of order, structure, and recurrence. Besides, if meaning were the solar furnace of orderly worlds – if order follows meaning – it was not a great leap to see that order and its complements took root not in distal formal structures, but in local, situated ones, as meaning does. Such a reading is neither a critique nor a dismissal of history, as though the history of childhood, for example, does not show us great innovations in matters of what the cultural category of child means. It is rather that history writing is itself an exercise in Garfinkel's treatment of Mannheim's documentary method of interpretation, wherein fragments and shards are seen for larger forms, and larger forms organize our seeing of fragments and shards. There is no relief from this constitutive reflexivity. We take interest not to be skeptical or to pose as arbiters, but to see how it is done. (Historians take the measure of their own work.)

For the college of education, these developments began at a great distance, and their relevance was a generation away. The tracks lead in several directions, and the notion of invisible colleges is a useful one for framing them. Invisible colleges are those identifiable, yet indefinite, communities of thought and interest that underwrite disciplinary history. The phrase traces to the early-modern science scholars of the seventeenth century who produced, among other things, the British Royal Society. Invisible colleges are the social histories of disciplinary formations. The field of sociolinguistics was once one. So too were child language-acquisition studies and post-Kuhnian studies of science. The formative period of the qualitative turn in educational studies was also one. In 1986, Fred Erickson wrote the first chapter on qualitative research to appear in the *Handbook of Research on Teaching*. The (invisible) conversation was of course much older (as seen in an early EM study of education by Cicourel and Kituse, 1963).

For its first 50 years, education's conceptual-analytic orbit had everything to do with psychology. Its first borrowings were there, mediated by the aims and promises of Thorndike and his students. (See McDermott and Hood (1982), on the analytic dispositions that followed.) However, in the 1970s, the disciplines beyond psychology began to matter a great deal for a cohort of young scholars who would write the qualitative turn for educational studies. As it happened, their degrees were, in the main, elsewhere: in anthropology, linguistics, developmental psychology, and sociology. But their interests were intently educational. They were bringing their readings of what were then exotic literatures for the college of education, and insisting that there was

news to be found that had direct bearing on matters of classroom life and instruction. Their studies were empirical, rather than empiricist, and had everything to do with the study of cases. Not all were reading EM or conversation analytic studies, but many were. Some were reading them very closely while others were reading them into the mix of their graduate and postdoctoral curricula.

The list of this transformational cohort includes Courtney Cazden, Michael Cole, Fred Erickson, James Heap, Ray McDermott, Hugh Mehan, Marilyn Merritt, Elliot Mishler, and many of their students and colleagues. The list is hardly exhaustive, and there were contemporary developments in the British educational literatures, for example, the works of Wes Sharrock, Rod Watson, George Payne, David Hustler, David Francis, Stephen Hester, and others, all of whom were studying EM/CA with great energy, and bringing its program to classroom studies. (See Hester and Francis (2000) for a diverse collection of EM educational studies.) These lists only suggest the serious trading that was going on between the disciplines and the college of education. Intellectual history is made of such tradings, and EM was party to the mix (see Erickson, 1992).

Its influence in educational studies began to show itself in formulations of situated action (Cicourel *et al.*, 1974), sense making and ethnographic adequacy (McDermott, 1976), constitutive ethnography (Mehan, 1979), situated instruction (Cook-Gumperz, 1977), in a growing interest in the sequential analysis of classroom discourse (McHoul, 1978) and, more generally, in the most unremarkable and unremarked upon order of the room. The everyday life of classroom education came into view as an un-examined plenum. Studies of the early grades flourished, with close attention to the jointly constructed order of, for example, circle time and kindred organizational curricula. Journals took interest and dissemination venues developed, for example, the series *Working Papers in Sociolinguistics* published by the Southwest Educational Development Laboratory in Austin, Texas, and the journals *Anthropology and Education Quarterly*, the *British Journal for the Sociology of Education*, and *Discourse Processes*, among others.

It is not being suggested that EM solely wrote these developments. It did not. There were kindred developments in sociolinguistics, the ethnography of communication, and child language and developmental studies. But EM was party to a turn in the analytic culture of educational study that now had use for the most ordinary things in the world of classroom life and instruction. It was a major resource for rewriting the kinds of questions we might ask, where we might pursue them, and how we might take interest in what we find there.

Central to EM's contribution was the understanding that the hinges of classroom order, and therefore instruction, were to be found in filaments of meaning, and that meaning owned a local, temporal, and public organization.

The insight was not simply a celebration of context. Context turned out to be more than an oblique invocation of what everyone knows. It was more than a normative repository, or the frame to a picture. The insight was effectively captured in the title of Mishler's benchmark publication, "Meaning in context: Is there any other kind?" (Mishler, 1979), and if the answer is no, then we are condemned both to the study of meaning and its contextually reflexive relations. Context becomes a generative field, prospectively and retrospectively. Each next turn of talk trades upon and (re)writes it. In the bargain, our maps of the life of the room – and of interaction – are rewritten. The study of cases in their constitutive detail displaces the promise of formal, causative analysis.

It is difficult to overstate the implications of the difference, both conceptually, programmatically, and for the very terms of relationship between the professional and research communities. In such fashion, a 90-year program for developing a generalizing theory of learning or instruction or curriculum discovered a pedagogical landscape of diverse locales. The promise of a unified instructional method that would be normative and prescriptive (Bruner, 1966), would then go the way of a unified scientific one. EM was a formative influence in shaping these currents; it wrote an early and articulate critique of a world ordered for the convenience of academic genealogies, and sighted an alternative.

The Local Study of Situated Action

We sometimes cannot tell the history of our ways of speaking, although they surely have one, and seldom only one. The programmatic initiatives collected in this section are those of local study, on the one hand, and EM's interest in the coherence of situated action, on the other.

Local study was of course the mark of the qualitative turn. It was the ethnographic impulse, the turn to cases in context, to Malinowski's "imponderabilia of actual life". In its more familiar expressions, local study yields stories we did not know existed. At its most penetrating, it rewrites a very large conceptual map: The consensual macro-micro divide is inverted, and then dissolved. The local is not derivative of the distal; it is constitutive. Formal structure owes to ordinary, practical enactments and ordinary organizational things (Garfinkel and Sacks, 1970), and in studies of situated action, we can see something of the dissolution, or how reflexive relations do not own firsts. Every meaningful expression already has a world attached, and re-writes it.

Garfinkel often uses the example of freeway traffic, for how the order of the flow is reflexive to the competence of the drivers who produce it. Their competence is visible in the orderly traffic they assemble, and formal accounts of traffic flow are a gloss for the situated analyses of competent drivers engaged in driving. Drivers thus produce the

order that others then search for evidence of autonomous rules and structure. EM sights instead an order of practice.

Questions of order, as in classroom order, quickly yield to questions of meaning. For EM, the organizations of meaning *in situ* – the achievements of common understanding via grammars of natural language – are the central problematic. These are not a grammarian's grammar. They are rather a grammars of social action, played out on fields of relentlessly indexical expressions, expressions whose definite sense and meaning are tied to the occasions of their production and use. As it turns out, there is very little that we say – or can say – whose sense is not occasioned. Every expression is indexical in that way, even $2 + 2$, for whether it is a problem to be solved, a joke, or remonstrance, or a phrase in the argot of design. Classroom instruction is unimaginable absent the exercise of disciplining indefinite expressions, as when a teacher asks, "Do you remember what we were doing last week?" and the students reply in unison, "Yes." Propositionally, of course, the question is simply impossible; too many things were done last week, and none of them definitely so. But the question is understood for what it is doing, namely, introducing what we are about to do now. The production and recognition of the question's sense are contextually embedded products of situated action and analysis. Thus, Garfinkel proposes to analyze the "demonstrably rational properties of indexical expressions," or how indefinite talk yields definite sense and meaning, and thus worlds in common. "The appropriate image of a common understanding is therefore an operation rather than a common intersection of overlapping sets" (Garfinkel, 1967: 30).

If so, meaning has an actionable basis. It is therefore produced and achieved, and action's temporal parameters are included in the production. The meaning of a pause following a teacher's question to a student is a useful example. It begins as an unremarkable duration, a time to formulate a considered reply. But as it continues, it becomes a puzzle of interpretation – did the student hear the question or not? And should it continue further, the duration gives palpable evidence of trouble, or a failure to acquit the task, and thus becomes a remark on the student's capacities, identity, or standing. As a student in my corpus excitedly observed of another's ongoing pause in response to a question about a homework problem, "He can't do it." The conclusion is an analytic one, a remark on the meaningful shape of a developing temporal field.

By these understandings, meaning is neither private nor subjective. It is rather public, methodic, and communitarian. Meaning underwrites the separation of action from behavior, the difference between Gilbert Ryle's winks and blinks. In this light, we can see how a praxeology of social action underwrites every normative glossary. This is not an account of contingency run wild. It is rather an account of the production of normative order as the work of situated action.

Situatedness is now a familiar formulation in educational studies. We find it in the literatures of situated cognition and learning, and activity theory, as arguments on behalf of social action as the foundational field for our inquiries. There is very good sense to them, and taken together they constitute a profound challenge to the psychological metaphors that have anchored and organized educational research. The braiding of these several intellectual histories, however, is less clear.

Among its most familiar discussions in the educational literature is the publication *Situated Cognition* by Brown et al. (1989). It is widely cited and has been enormously influential. Yet, there is some irony in the observation that situatedness was in its earlier formulations, part of a critique of the cognitive metaphor. It was a sociological formulation, and the conceptual arguments found in EM and CA point to public spaces, rather than cognitive ones.

We also tend to find readings of situated action wherein some actions or occasions are situated, and some not. In short order, we can be led to understand that occasions can be *authentically* situated, or not. We have now fashioned a kind of moral metric from a concept that was, at the outset, analytic rather than invidious. A formulation that comes to us as a unifying concept, wherein drill and practice is understood as no less a situated production than whole-language instruction, is rendered a device for parsing and evaluation. This is understandable, given education's professional charge to continually assess, improve, and decide what's best. Every new conceptual resource is examined for what it may give to that effort, and overwhelmingly, interest in situated action has been taken up for how it might leverage change in the efficiencies of the institution and/or the performances of the students it serves. It may be an instructive case in how a conceptual innovation can be hitched to a deeply familiar task, and then, perhaps, lost.

Classroom Studies

EM classroom studies tend to proceed with a different purpose. James Heap, for example, has written a penetrating alternative to the analytic habits of research on reading instruction (Heap, 1982, *passim*). He takes up how classroom reading instruction is organized, *in situ*, and points out the profound consequences of misdescription in classroom research. When we fail to faithfully describe what the parties are doing – the order and grammar of their affairs for them – the consequences for our analyses and understandings of those affairs are devastating. Description is a conceptual matter, and his texts are not simply critiques, but conceptual reformulations of the tasks of reading research, and instruction. Rather than leveraging efficiencies, they attempt to uncover the conceptual knots that yield failed descriptions, and write new ones to replace them. As a way of casting

the difference, EM classroom studies are written for the instruction of the adults in the room.

Similarly, EM studies of science education take interest in the practical classroom enactments that carry it off. Here, especially, we see what may be misplaced about the measure of authenticity. Calls for real science in the classroom date to the nineteenth century. Yet, authentic science is what scientists do (and postdoctoral students struggle to do). The tasks and judgments of science students are not identical with those of a discovering science (although the relationship is more interesting still: there is ample measuring, mixing, watching, and giving of accounts going on in each). To insist on or promise authentic science in the classroom authorizes a daunting gap-closing exercise. It begs the question of what these sciences might be, and elides the work of instruction we actually find there.

Instead, by EM's reading, a curriculum for novices routinely shows itself as a kind of mock-up or version of the affairs it speaks of (as in the difference between driving and driver's education). In a startlingly brief and clarifying discussion, Garfinkel and Sacks (1970) develop the pedagogy of the mock up, and how it makes "deliberately false provision" for certain features of the affairs it represents. But these false provisions are not, then, candidates for correctives. On the contrary, the instructional effectiveness of the mock-up turns on them, as in their example of a plastic engine showing pistons, crankshafts, and connecting rods. It teaches us the internal movements of an engine by not being one. There will be ample time for real engines later. So also, it is for textbook formulations of the causes of the American Civil War, or the well-formed paragraph. Each is a mock-up of topics and competencies that own a lifetime of professional complexity, but must be rendered as a curriculum that novices can do.

Note especially that the difficulty for the authenticity program is not that fifth graders, or undergraduates, are not engaged in inquiry; surely they are, whether in math instruction, language arts, or geography. Instruction is a practical analytic task for students and teachers alike. However, it is precisely these practical forms of inquiry that are missed when we are in hot pursuit of professionally authorized ones. EM classroom studies are bringing these endogenous forms of inquiry into view, and among the forms missing from the literature are the disciplined inquiries that turn our instructions into courses of action we can do. This is the work of following instructions (Amerine and Bilmes, 1988), and when we cannot go on with them, whether in our homework or in assembling a piece of IKEA furniture, instruction founders. Instruction turns on diverse forms of inquiry, if only because the achievements of common understanding that underwrite it are themselves practical tasks of inquiry.

EM has a strong presence in the general mix of classroom discourse analysis through the 30-year corpus of

studies of natural conversation developed by Sacks *et al.* (1974). The linguistic turn announced for philosophy in the 1950s seems to have arrived in education, though surely not the same one. Various iterations of discourse analysis, some affiliated to Gumperz or Hymes, some to Halliday or Sinclair and Coulthard, have taken root in education. But perhaps the most familiar forms derive not from natural language study at all, but from theoretical and continental treatments of Discourse. The most familiar register of classroom discourse studies is found in various expressions of “critical discourse analysis” (and Bakhtin’s theory of dialog). Yet, notwithstanding the attractions of theory-driven analyses, there persists an interest in the sequential analyses of students and teachers engaged in talking their way through their lessons, as we see in a robust literature in foreign and second-language studies. (Firth and Wagner, 1997).

Lee (2006), for example, reexamines the notion of communicative competence. Competence becomes not only the outcome of instruction – the thing we are supposed to learn – but instruction’s very grounds. Students may not know their curriculum, but they must be competent to the interactional co-production of their lessons, and the fixing of misunderstanding, for their learning to proceed. Their competence to those tasks reminds us of an ignored orderliness in instruction’s every enactment, and EM studies of classroom lessons tend to look there, to what is taken for granted about instruction’s work.

The corpus is not limited to primary and secondary classrooms. It includes studies of medical school instruction, law-school pedagogy, and MBA classrooms, alongside studies of undergraduate science and second-language education. In every case, one will find that instruction premises common understanding, and it may be that instruction’s tasks and problematics never stray too far from the achievements of common understanding. In the measure, the order of instruction never strays far from the order of natural language.

Conclusion

This article sketches an account of how a very different vision of disciplined inquiry found its way into a college that has pursued an applied science with great energy for a very long time. EM offers a comprehensive view of the order of everyday worlds. It treats phrases such as situated action or the social construction as real work in the world, and sets out to describe them in the material detail of actual occasions. It has produced a corpus of studies that shows us what such things look like, and has written descriptions that revise many taken-for-granted confidences about things like science, technical reason, and the formal administration of order. These last phrases are among the desiderata that have organized the history

of educational study, and EM writes a very different account of them. At the same time, however, and no matter how keen the critique, the conceptual commitments it criticizes seem no less firmly held.

The attachment to science in matters of education is clearly still with us. Although it has continually escaped our grasp, it apparently feels not quite so distant as the last time we reached for it. Thus, the moral re-authorizations of testing, measurement, and clinical trial models, the dusting off of familiar phrases about what works, and perhaps less noticed – because it is now most pervasive within the qualitative research literature – the return to grand theory, the muse of formal analysis and autonomous structures. In these ways, the strength of our cultural commitments to the technical administration of education seems undiminished.

In sociology, EM has produced departmental communities of scholarship over the last 40 years at University of California, Los Angeles (UCLA), the University of California at Santa Barbara, Boston University and elsewhere in the US, and at Manchester University, Lancaster University, and elsewhere in the UK and Commonwealth countries. Contemporary scholarship has developed in France, Scandinavia, and throughout Europe, and in Japan and Korea, and includes the latest mark of invisible colleges, the LISTSERV. EM/CA is a section of the American Sociological Association, and has a strong presence in science, technology and work place studies. (See, e.g., Button, 1993; Livingston, 2008; and Lynch, 1993.) Yet, EM has never, as a practical matter, challenged the prevailing analytic forms of sociological or educational study.

This is not surprising. EM offers no vision of corporate solutions, no promises of what the research has shown, or complaints about how schools have failed to make good on those promises. Instead, it recommends studies of how students and teachers encounter and acquit their daily tasks of producing the order and instruction of their affairs, and how they show us what is irreducibly social and local about teaching and learning. The question, of course, persists of what on earth would we ever do with such accounts, in the presence of our seemingly perpetual climate of crisis and blame. It should be no surprise that Dewey took interest in the same question. Rather than an administered order grounded in technical expertise, he had in mind a professional cohort of classroom teachers in full possession of “independent judgment” (Dewey, 1965/1904). But if that were so, the familiar pyramid of technical expertise would yield to something quite different; pyramids would become continua. To the researcher, theorist, or consultant, the practical analyst would be no less analytic. There would be a leveling of the epistemic field.

For such a world, EM descriptions and analyses of educational settings and occasions might be a very fine curriculum. For EM, social science is not an arbiter of

things like best practices, only a keenly interested party. Its task is not to trump the professional or moral narratives that are already in place, but to understand them, on the hunch that such understandings might be instructive. But to be clear, the instruction it offers is not for the children in the room. In matters of educational study, it is our instruction that may be the most neglected.

Others hold confidence that this is not so, that there are best practices, and none too many of them. If we could find, reproduce, and install them, we might finally reap the efficiencies promised by the other wing of the progressive movement. This has been the modernist vision – and conundrum – for educational research. Although his topics were different, thematically they were kindred when Wittgenstein summed his discussion of forms of expression and how we use them in the following image:

In the actual use of expressions we make detours, we go by side-roads. We see the straight highway before us, but of course we cannot use it, because it is permanently closed (Wittgenstein, 1958: 426).

EM has been writing this road sign for 50 years, as signage for a world of local meaning, action, order, and competence. EM sights a world we might study to see how it works, and thus find instruction in how indeed it does. Garfinkel speaks of EM studies as tutorials. As with all instruction, however, there are no warranties attached. What we take from them is always a pending discovery. This, of course, is widely known by professional teachers, even university faculty. Yet, it is these very terms of instruction – of every kind and venue – that education's program of formal analysis cannot quite allow. It aims at reproducible certainty, and in these several ways, we are likely to continue to find what is both penetratingly relevant, but improbable, about EM's program for educational study.

Focus Groups

D L Morgan and K Hoffman

© 2010 Elsevier Ltd. All rights reserved.

Researchers use focus groups to generate qualitative data on their topic of interest by creating a conversation about that topic among a set of participants. While the interaction between participants provides focus groups with their unique identity as a method, it is important to recognize that these are not naturally occurring conversations. Instead, the researcher explicitly creates these groups as a means for collecting research data. A related issue is whether there is a difference between group interviews and focus groups. Although there are various examples of group interviewing throughout the history of the social sciences, the most common practice over the past two decades has been to refer to all forms of group interviewing as focus groups.

Although the current popularity of focus groups in the social sciences is a relatively recent phenomenon, they were originally developed in the 1940s by two sociologists, Robert Merton and Paul Lazarsfeld (Merton *et al.*, 1990). After World War II, while focus groups almost disappeared from the social sciences, they also became the most common qualitative method in marketing research. Starting in the 1980s, contacts with marketing researchers led to the reintroduction of focus groups in the social sciences. This renewed interest in focus groups corresponded to the growing importance of qualitative research in education and many other fields. As a result, focus groups are now used so widely that they appear in over 1000 articles per year (according to searches that combine databases such as ERIC, PsychInfo, PubMed, etc.).

One of the main reasons for the increased popularity of focus groups is the variety of not only different forms they can take but also different purposes they can serve (Barbour and Kitzinger, 1999; Krueger and Casey, 2009; Morgan, 1997; Morgan and Krueger, 1998). In a typical focus group, six to eight participants are led by an interviewer – known as the moderator – in a discussion that lasts between 1 and 2 h. The researcher chooses the topics for the conversation, and the participants typically share a similar background with regard to those topics. In addition, focus groups can be conducted in either a relatively unstructured fashion that is oriented toward exploration and discovery, or in a more structured style that is built around the research team's predetermined agenda. This flexibility means that there is no one right way to do focus groups. Instead, there are a number of different factors influencing the design of any research project using focus groups, depending on the goals that the focus groups must meet within that project.

Within qualitative research as a whole, participant observation and individual interviewing are the two most likely alternatives to focus groups as a method for collecting data. For participant observation, the fundamental strength of this method is the ability to provide data about behavior that occurs in a more natural context. Hence, whenever researchers need to know how people actually behave in specific situations, there is an obvious advantage to observing such behavior, rather than listening to discussions about it. In particular, although focus groups rely on the observation of interaction among the participants, it is important to recognize that they fundamentally are interviews. As such, they produce talk data rather than indicators of actual behavior in real contexts.

Shifting to the comparison between individual interviews and focus groups, the first one to be considered is the logistics of bringing together an appropriate group of people. In some situations, it is difficult to locate participants who share an interest in the research topic. In other situations, it may be possible to locate potential participants but difficult to bring them together in the same time at the same place. Whenever those problems are severe, individual interviews have an obvious advantage over focus groups.

At a more substantive level, focus groups and individual interviews differ in the amount of information that they provide about each participant. As focus groups consist of several participants and typically last between 1 and 2 h, a corresponding set of individual interviews would provide a much deeper and more detailed understanding about each participant. There is thus a trade-off between the strengths of focus groups and individual interviews. On the one hand, focus groups offer the opportunity to hear several participants discuss their similarities and differences, but they yield correspondingly less information about each participant. On the other hand, individual interviews offer richer data about the lives of specific participants, but it is up to the researcher – rather than the participants themselves – to make comparisons across participants' responses to the research topic.

Even though focus groups and individual interviews each have their own distinctive set of strengths, it is important not to overstate the differences between the two. In particular, there are many situations where either method could pursue the same goals, so the choice between them often depends on practical considerations. In addition, researchers can often combine focus groups and individual interviews in the same project, instead of facing a forced

choice to use only one method or the other (Morgan, 1997). For example, individual interviews with key informants can provide vital information for designing a focus group research project. Alternatively, focus groups that follow-up on the analysis of individual interviews can serve as a useful form of member checking. This ability to combine focus groups and individual interviews is yet another illustration of the flexible range of uses that have led to the rapid increase in the popularity of focus groups.

Uses for Focus Groups

There are two main reasons why focus groups have found such a wide range of uses. First, focus groups are especially useful for applied research, although these practically oriented uses have been less common in education than in other fields, such as healthcare and social services. Hence, this section includes a number of hypothetical examples of potential uses for applied focus groups within education. The second reason for the popularity of focus groups is their value across a wide range of research goals and research designs. In particular, focus groups work well as either a self-contained method or as part of a project that combines both qualitative and quantitative methods.

In combinations with quantitative methods, focus groups can serve as either inputs or follow-ups to the quantitative portion of the project. In fact, contributing inputs for the content of survey questionnaires was one of the earliest and still best-known uses for focus groups. In this role, focus groups allow the survey researchers to hear the perspective and language of their respondents, prior to developing the actual survey instrument. Focus groups can also serve a similar function as input to experimental program interventions. In that case, the qualitative inputs help the research team learn more about their clients' perspectives prior to designing a program for those clients. In both cases, this input is especially useful for projects working with unfamiliar research populations or new research areas. For example, a preliminary set of focus groups with students could shed light on the relatively new phenomenon of online bullying. Both the issues and the language captured in the focus groups could be especially useful in writing a survey for the larger student body.

Using focus groups as a follow-up to surveys or program interventions typically emphasizes learning more about the results from the quantitative portion of the overall project. When the quantitative results match the researchers' expectations, the follow-up focus groups can put a human face on the data by illustrating the actual experiences associated with the quantitative results. Alternatively, when the goal is to learn more about the quantitative results, exploratory focus groups can provide more depth and detail about the actual processes involved. In both cases, the broad goal of the follow-up focus groups

is to say more about the quantitative results, including how and why those results occur.

For example, consider a school district that wants to pilot test a free breakfast program, based on teachers' reports that students who regularly eat breakfast are more alert and have longer attention spans, leading to better test scores and attendance rates than children who often skip breakfast. One way to enhance the effectiveness of the pilot program would be to conduct focus groups with teachers and parents after the first month, and then use this early feedback to improve portions of project. Later, in the final month of the project, a further set of interviews with both teachers and parents could investigate their responses to the program. In these later groups, the primary topic for both sets of participants would be their feelings about the program. For the teachers, these later groups could also ask about their perceptions of the program's effects on the students' learning and behavior, while additional questions for the parents could ask about any effects on their children's health or behavior. Overall, these two sets of follow-up focus groups could both improve the program's chance of success as well as provide insights into the sources of the program's ultimate outcomes.

As the examples in this section demonstrate, focus groups can be used on their own or in conjunction with other research methods, as well as before or after a larger data-collection effort. Of course, successful focus group projects require careful decisions about research design, regardless of the specific uses for the data from those groups.

Research Design for Focus Groups

One fundamental principle that applies to all aspects of research designs for focus groups is the importance of balancing both the researchers' and the participants' needs. At the most fundamental level, the researchers' needs do come first because they determine the topic for the group discussion. Even so, this starting point is most likely to produce useful data when researchers explicitly consider the needs of the participants. This balancing process occurs in each of the basic aspects of focus group research design:

- selecting the research participants;
- writing the interview questions; and
- moderating the focus groups.

The following sections pay equal attention to each of these three aspects of design. This approach differs from many discussions of focus groups, which devote most of the coverage to moderating as the key to success. Although the role of the moderator is a distinctive aspect of focus groups, this does not mean that skillful moderating is

any more important than selecting appropriate sets of participants and choosing effective questions to guide the discussion. Thus, even the best moderators will struggle if they have to ask poorly written questions to inappropriate participants.

Selecting Research Participants

From a research design point of view, decisions about who to choose as participants is a matter of determining the group composition. The principle of balancing both researchers' and participants' needs is central in making choices about group composition, because of its impact on the interaction that is so essential to focus groups. At a minimum, the participants must feel comfortable discussing the research topic with each other. This is, however, only a minimal requirement; high-quality discussions are most likely to emerge from a group composition that brings together people who are truly interested in the research topic. One common standard for group composition is to find the kind of participants who are just as interested in the topic as the researchers are. Even more effective discussions happen when the participants are not just individually interested in the topic, but also interested in what the others have to say about that topic. Although it is obvious that group composition which meets this standard will increase the quality of the data, another point that is often overlooked is how much easier it is to moderate groups where the participants are highly motivated to share and compare their points of view. Thus, one of the first steps to successful moderating is careful attention to selecting the group composition.

The most common way of facilitating the kind of conversation described above is through recruiting participants to emphasize homogeneity. The value of homogeneity in the group composition comes from the ease of interacting when participants share relatively similar perspectives on the research topic. Thus, the kind of homogeneity emphasized here involves things that the participants have in common with regard to the topic, rather than matching demographic characteristics (such as age or gender). Of course, background characteristics can also be quite relevant to the topic in question. For example, issues related to racial advantage and disadvantage would be a good candidate for using racially homogeneous groups. Focus groups do not, however, have to be limited to homogeneous groups. In particular, groups composed of participants who represent different stances on an issue can provide information about both the sources and implications of those differences – as long as the participants meet the fundamental requirement of feeling comfortable about discussing this topic within the group.

When the design for the research project as a whole is explicitly built around comparing predetermined differences in group composition, this is known as segmentation.

In a project that relies on segmentation, the research team will carefully select the composition of each group in ways that create useful comparisons across the full set of groups. Once again, there is an element of balancing needs by separating the groups in sets that are both homogeneous. From the participants' point of view, the similarity in group composition facilitates their interactions; from the researcher's perspective, the differences between groups create analytic comparisons.

For example, consider a situation where administrators in a school district were interested in implementing Spanish/English dual-language immersion (sometimes known as two-way immersion) in kindergarten classrooms. In particular, if another district in the state had recently proposed this model but met with opposition from stakeholders such as school principals, teachers, and parents, then the administrators in the current district could run into opposition. First, they would want to better understand the dynamics of the previous attempt in the district where the dual-immersion proposition had failed. A method of generating this information would be to do a pair of focus groups with key informants who were either proponents or opponents of that earlier attempt. Within the proponents group, questions could focus on: Why participants felt inclined to support dual-immersion? Where and how they encountered opposition? Also, what they might have done differently to gain the acceptance of stakeholders? Within the opponents group, questions would focus on: Why they did not support the proposal? What they objected to? Also, were there different approaches that might have increased their buy-in? The researchers could use this information to create a revised plan for introducing this language-immersion program, and then conduct a set of focus groups in their own district to hear whether their own stakeholder groups would have a more favorable response.

As a final topic on selecting participants for focus groups, no presentation on this issue would be complete without considering recruitment. Although recruiting may seem like a relatively routine task, it is far and away the most common cause of problems in focus group research. These problems arise when recruitment is treated as merely clerical work, in comparison to the supposedly more important work of designing the project and moderating the groups. Yet, even the best research design and most accomplished moderators are of no use if not enough participants show up or if they arrive with misguided expectations. Fortunately, recognizing the potential magnitude of this problem is the most important step in solving it, and there are several useful descriptions of how to do effective recruitment (e.g., Krueger and Casey, 2009; Morgan, 1998).

Writing Interview Questions

The full set of questions for a focus group is referred to as the interview guide. These guides typically vary along

one basic dimension: from less structured to more structured. Less-structured interview guides are especially well suited to projects where the goals are broad and exploratory, because the participants are encouraged to discuss a relatively small number of questions from their own point of view. In contrast, more-structured guides are most appropriate when the goal is to generate depth and detail on a predetermined agenda, because the discussion consists of a larger number of well-defined questions that match the researcher's own agenda. Focus groups work equally well with either less-structured, exploratory questions or more-structured, agenda-driven questions; the decision between these two approaches is a function of the goals for the research project, rather than the strengths and weaknesses of focus groups as a method.

Many research projects call for both more exploratory and more agenda-driven questions, and the most common approach for this combination is a funnel format. The funnel metaphor represents the idea that the interview begins with a set of broad, exploratory questions before shifting to a more tightly focused set of questions. The less-structured questions at the top of the funnel are thus devoted to hearing the participants' perspectives in their own terms, while the more-structured questions in the later section are devoted to learning about the researcher's pre-selected topics. One of the principal advantages of the funnel format for interview guides is that the early section shows the extent to which the participants are interested in the same issues as the researchers, while the later sections ensure that the research team hears about the topics that are most central to their own interests.

Regardless of the degree of structure in the guide, it is once again important to consider both the participants' and the researcher's needs. The core issue is how appropriate the questions are for these participants as a basis for discussing this topic. Thus, the kind of conversation that will be most useful for the researcher's interests also has to consider what will interest the participants. Finding an approach that will make it easier for the participants to talk about the research topic is especially important for the first question, that is, the one that starts the actual group discussion.

As an example of questioning strategies, consider a case where the administrators at a state college are interested in female students' low levels of enrolment and high rates of attrition in science and math and engineering (SME) classes. The goal for these focus groups would be to learn more about the barriers and strategies for engaging and retaining women in SME programs. A research design for this project could compare newly admitted female students with equivalent Scholastic Aptitude Test (SAT) scores and high school grade point average (GPA), where one segment had enrolled in SME classes and the other had

not. In this case, it would be appropriate to use a funnel approach, beginning with general curriculum interest questions, such as "What were some things you considered when you chose which courses to take?" From the participants' point of view, this would be a relatively easy and interesting question to talk about, thus starting a free-flowing discussion. For the researchers, this would allow them to hear what students had to say about SME courses, before any of the later questions in the funnel explicitly introduced this topic. Finally, narrower, follow-up questions could ask about more specific issues related to both SME classes and the appeal of an SME-career-associated lifestyle.

Moderating Focus Groups

Like interview guides, approaches to moderating typically vary from less structured to more structured. With a less-structured moderating style, the moderator provides rather little active direction during the discussion, to create a conversation that concentrates on the participants' thoughts and feelings about the topic. To accomplish this less-structured approach, moderators will typically use the introduction at the start of the session to explain that their primary role will be to listen to and learn from the participants, so the participants themselves will be generating and carrying on the conversation. In contrast, a more-structured moderating style requires an active role in directing the discussion, so that participants concentrate on topics that match predetermined research goals. For this approach, moderators would typically introduce their role as ensuring that each question gets covered as thoroughly as possible, even if that means the moderator must occasionally either remind the participants to stay on topic or move them on to the next question. Once again, focus groups work equally well with both less-structured and more-structured approaches to moderating, so the choice depends on the purposes for the research. For example, a less-structured moderating style would be more appropriate for an exploratory study aimed at hearing how parents of special needs children want classrooms to be improved to meet their children's challenges, while a more-structured style would be more appropriate for investigating how those same parents evaluated a program that had already redesigned classroom participation for their special needs children.

As a final comment on moderating, it is useful to return to the point that was made at the beginning of this section on research design: moderating is only one component of successful focus groups; the selection of participants and the writing of interview questions are just as important. In particular, as any experienced moderator will tell you, it is much easier to conduct a focus group that consists of participants who are genuinely interested in the questions being asked.

Analysis

In addition to data collection, another important issue is how the data will be captured during the sessions. Audio recording is by far the most common technique for generating the actual data from focus groups. In contrast, video recording is relatively rare due to the difficulty of creating camera setups that provide sufficient detail on all the participants. Relying strictly on written notes is another option, especially when ethical issues make audio recording inappropriate. Written notes are also the preferred method for relatively small preliminary projects, such as using focus groups to help design specific questions for a survey questionnaire. In that case, the note taker is usually an assistant who sits in and then debriefs with the moderator after the group. This debriefing process usually consists of writing up a summary of the discussion that can be distributed to the rest of the team the next day. In addition, another valuable role for note-taking assistants can be to keep a log of who said what during the focus group. This kind of log is crucial for analyses that examine the contributions from individual participants, because that information requires a knowledge of who said what.

The actual methods for analyzing focus group data require relatively little discussion, because they are quite similar to individual qualitative interviews in this regard. Specifically, the most common approach is to transcribe the audio recordings and then apply coding and other interpretative processes to the text data. For example, one common approach is to use content analysis as a basis for attaching codes to sections of the conversation that meet prespecified criteria. Alternatively, there are more inductive approaches, such as grounded theory, where the analyst begins with open coding to create initial codes which are then grouped into interpretative categories, and so on.

The main element that requires unique attention in analyzing focus groups is the obvious fact that the data do come from groups of individuals. In particular, the data from the various participants are not independent due to the influence that participants have on each other's contributions to the discussion. The key issue in considering data from a set of focus groups is determining the topics that mattered most to the full set of participants across all the groups. The first tactic for addressing this situation is what is known as group-to-group consistency, where the topics that are important in one group are also important in other groups. Beyond that, the importance of a topic is reinforced by the number of participants who join in the relevant discussion, where widespread interest clearly counts for more. The third criterion is the level of energy that participants devote to the discussion of that topic,

because it is entirely possible for most of the participants in most of the groups to acknowledge a topic without becoming engaged in the discussion of that topic. Thus, the easiest way to make the case that a particular topic was important to the participants consists of three elements: the topic should be discussed with enthusiasm by nearly all the participants in nearly all of the groups. Note, however, that this process is designed to locate topics that were important to the participants, which is not the same as saying that they will be central to the researcher's analysis. In particular, if you are conducting an inductive analysis that is oriented toward locating themes and building theory, then information about what the participants considered important may be only one aspect of your broader interpretive goals.

Conclusions

The final point that we would like to emphasize about focus groups is the widespread acceptance they have received as a general-purpose method throughout the social sciences. They are thus useful for both classic qualitative goals such as generating theory and for more applied purposes such as program design and evaluation. In addition, they are equally appropriate for less-structured, exploratory research and more-structured, in-depth examinations of researcher-determined topics. Finally, they work equally well as a stand-alone method for generating purely qualitative data and as a contribution to projects that combine qualitative and quantitative methods.

One of our goals throughout this article has been to encourage the increased use of focus groups within the field of education. In particular, if we have successfully demonstrated the value of focus groups by combining a design-oriented presentation with a series of practical examples, then that will help accomplish this goal.

Glossary

Constructivist grounded theory – A twenty-first-century revision of Barney G. Glaser and Anselm L. Strauss's classic statement of grounded theory. This theory adopts grounded theory strategies without the positivist epistemological underpinnings of the original statement. Instead, constructivist grounded theory (1) is founded on a relativist epistemology, (2) views the method as interactive as well as comparative and inductive, (3) takes into account the multiple and shifting standpoints of the researcher and the researched, (4) builds on the method's pragmatist heritage, and (5) emphasizes reflexivity.

Theoretical sampling – A grounded theory strategy that involves sampling for the development of the researcher's emergent theory. Grounded theorists engage in theoretical sampling to fill out the properties of their theoretical categories, to refine relationships between categories, and to identify variation and difference in their emerging theories. Theoretical sampling is only used to develop or test categories late in the analytic process; it is not an initial sampling procedure for beginning data collection.

Grounded theory has two related meanings: (1) a set of systematic methodological strategies that constitute a distinct method for conducting research and analyzing inductive data and (2) the product of this process, the completed theoretical analysis of these data. Here, we focus on the method and the construction of the product, typically a grounded theory that illuminates a substantive area of research interest. Grounded theory strategies consist of systematic, but flexible, guidelines for data gathering, coding, synthesizing, categorizing, and integrating concepts for the explicit purpose of generating middle-range theory. Most fundamentally, grounded theory strategies invoke comparative methods for analyzing data and entail an iterative process of simultaneous data collection and analysis. Grounded theorists engage in emergent analysis to direct their subsequent data collection, which, in turn, they use to develop and check their emerging ideas.

This paper discusses the history and development of grounded theory; compares the contemporary version of

the method, constructivist grounded theory, with positivist versions; outlines its main methodological strategies; and suggests its future directions. The originators of grounded theory, sociologists Glaser and Strauss (1967), explicitly developed analytic strategies for constructing theory from qualitative data; hence, they proposed grounding emergent theories in the data. Thus, the resulting grounded theories explain the data that give rise to them, rather than being separate from the collected data or imposed on them.

History and Development of Grounded Theory

The development of grounded theory reflects its historical location in the 1960s and the intellectual standpoints of its founders. Glaser and Strauss (1967) defended qualitative research at a time when quantitative methods had gained dominance in sociology and throughout most of the academy. Many of Glaser and Strauss's quantitative contemporaries saw qualitative research as useful only for exploratory research or for constructing more precise quantitative instruments, if they saw any value in it at all. Vibrant University of Chicago qualitative traditions of life-history research and field studies had significantly informed the discipline throughout earlier decades in the twentieth century but had become imperiled by the 1960s.

At that time, qualitative researchers attempted to defend their practice through the framework of quantitative inquiry with its emphases on reliability and validity. Qualitative sociologists focused on making their studies objective through the accuracy and thoroughness of their data collection. Novices had few methodological texts available to guide their work. Instead, they learned about conducting qualitative inquiry primarily through mentoring and immersion in fieldwork.

Glaser and Strauss (1967) took up the methodological debates of their day and answered criticisms of qualitative inquiry in their initial statement of grounded theory, *The Discovery of Grounded Theory: Strategies for Qualitative Research*. They realized that other researchers could use the methods they had developed in their studies of the social organization of dying. In this book, Glaser and Strauss explicitly confronted their discipline and also implicitly revealed the traditions that each brought to the research process. Strauss

brought his University of Chicago background to grounded theory with its Chicago School traditions of naturalistic inquiry, pragmatist assumptions, and symbolic interactionist perspective. Thus, Strauss emphasized field research, viewed individuals as active agents, saw interaction as open ended, took into account language and meaning, and focused on action, all of which informed grounded theory.

Simultaneously, Glaser brought systematic methods, an explicit logic, and a concept-indicator model to grounded theory. Glaser's training at Columbia University in rigorous quantitative methods influenced his goal to create an analogous codification of qualitative methods like his mentor, Paul Lazarsfeld, had established in quantitative inquiry. Glaser supplied much of the logic and language of grounded theory and built the method on assumptions of externality, neutrality, and parsimony.

The two originators converged on five main points. Both of them:

1. emphasized constructing emergent theories with new ideas;
2. contended that qualitative research could generate theory;
3. viewed grounded theory as a method for conducting rigorous, processual analyses;
4. advocated using comparative methods throughout the analytic process; and
5. intended to provide specific tools for theory construction.

Glaser and Strauss (1967) challenged the nature and purpose of sociological theory and attempted to demystify what theorizing entailed. By the 1960s, theorizing in sociology had become the purview of a few elite scholars who seldom based their theoretical notions on empirical research. The division of labor separating empiricists and theorists had widened into a chasm. Most theorists aimed to create grand theories that would explain social structure and change at societal levels. Those quantitative researchers who attended to theory invoked a logico-deductive model to derive hypotheses from the narrow range of concepts that these grand macro-sociological theories offered. Many empirical researchers, whether quantitative or qualitative, worked on concrete research problems such as consumer surveys or ethnographic description. Glaser and Strauss called for qualitative researchers to move their work from description to theoretical analyses, and in so doing they sought to extend the reach and significance of qualitative inquiry.

Grounded theory played a significant role in creating and advancing the qualitative revolution that began in the late 1960s, grew in the decades thereafter, and broadened research in education. The arguments in the *Discovery* book repositioned and revitalized qualitative research. Glaser and Strauss attacked the dominant methodological views that relegated qualitative research to a marginalized position in sociology. They contended that

1. qualitative analysis could be rigorous and systematic, rather than impressionistic and idiosyncratic;
2. theory and method could be joined;
3. the sharp division of labor between theorists and methodologists was arbitrary;
4. systematic qualitative analysis of data could produce fresh, useful theories;
5. sociologists should aim for empirically grounded substantive and formal theories of the middle range rather than airy macro-level theories unrelated to social life; and
6. theorizing would be democratized because grounded theory methods gave ordinary researchers tools of theory construction.

From the beginning, Glaser and Strauss intended to create systematic theories that fit the studied realities were modifiable as further data became manifest and were useful to policymakers, practitioners, and research participants as well as to disciplinary colleagues. They argued for constructing analyses that would give research participants a theoretical explication of a fundamental social process that affected them. Glaser and Strauss were convinced that researchers could make their most significant contributions by offering abstract ideas about data that were thoroughly grounded in these data.

Glaser and Strauss made a powerful case for legitimizing qualitative research in sociology that appealed to researchers in sociology and other disciplines alike. Glaser and Strauss's work inspired generations of graduate students in the social sciences and professions to pursue qualitative research and to claim grounded theory as their method of choice. Most of these students treated grounded theory as a justification for conducting inductive qualitative research. Even if they adopted several grounded theory strategies, they seldom used them as Strauss and, particularly, Glaser had envisioned. Glaser and Strauss's (1967) book made rallying claims and proposed explicit methodological strategies, although the latter remained opaque to most readers. Glaser's (1978) book, *Theoretical Sensitivity*, made the methodological strategies more explicit but his dense writing, dearth of clear definitions, and lack of an index reduced the book's effectiveness as a research resource for most readers who had not studied with him.

Strauss's (1987) publication of *Qualitative Analysis for Social Scientists* and the 1990 book, *Basics of Qualitative Research*, co-authored with Juliet Corbin, provided grounded theory instructions for thousands of teachers and graduate students. Strauss saw grounded theory as a method of verification, and he and Corbin introduced several techniques to apply to the data analysis. Glaser's (1992) acrimonious rebuttal, *Basics of Grounded Theory Analysis: Emergence vs. Forcing*, countered Strauss and Corbin's claims and objected to their new techniques. Glaser argued that Strauss and Corbin had abandoned the emergent analytic

process of theory construction inherent in grounded theory in favor of conceptual description and preconceived techniques. When stripped of their acrimony, several of Glaser's main charges were correct. The first two editions of *Basics of Qualitative Research* seemed procedural and prescriptive and lacked the emphases on flexible guidelines and emergent inquiry in the earlier works. Most researchers, however, remained untroubled by the apparent discontinuities between the *Discovery* book and Strauss and Corbin's texts (Bryant and Charmaz, 2007).

Charmaz's (2000) and Bryant's (2002) critiques took grounded theory in new directions. They each viewed both Glaser's (1978, 1992) and Strauss and Corbin's (1990, 1998) versions of grounded theory as tied to positivist epistemologies. Unlike earlier critics of grounded theory, Charmaz and Bryant each argued that researchers could adopt the methodological guidelines of grounded theory without importing positivist assumptions with these guidelines. The guidelines could be used from a variety of epistemological starting points and initial theoretical standpoints, as is evident in educational studies. Thus, Charmaz and Bryant aimed to retain key grounded theory strategies but to reposition them in twenty-first-century epistemologies and ontologies. Publication of Charmaz's (2006) book, *Constructing Grounded Theory: A Practical Guide through Qualitative Analysis*, offered an accessible explication of how to conduct a grounded theory study founded on a different set of epistemological principles. The subsequent *Handbook of Grounded Theory* (Bryant and Charmaz, 2007) covered the range of versions of grounded theory from positivist to constructivist and showed the varied ways in which grounded theory informs the contributors' thinking and research practice.

Comparing Constructivist and Positivist Grounded Theory

Constructivist grounded theory builds on the original statements and strategies that Glaser and Strauss (1967) first articulated. The contrasts in epistemology between constructivist and positivist versions of grounded theory, which we outline here, are greater than those between constructivist grounded theory and Strauss and Corbin's (1990, 1998) postpositivist versions (Corbin and Strauss, 2007). Grounded theory is an evolving method, not simply because of different methodologists' visions but because Glaser (e.g., 1998, 2003) and Corbin (Corbin and Strauss, 2007) have revised their earlier versions of the method. Nonetheless, Glaser has maintained a highly consistent logic and epistemology over four decades.

In brief, constructivist grounded theory arises from a relativist epistemology, challenges positivist assumptions in earlier versions of grounded theory, and aligns the method with interpretive inquiry. It treats grounded theory

strategies as flexible guidelines that serve as heuristic devices. Constructivist grounded theory has roots in social constructionism, takes action as a central concern, builds on the pragmatist legacy of Anselm Strauss, and assumes that the researcher is part of the research process. Subsequently, constructivist grounded theorists engage in reflexivity throughout the research process, which fosters attending to the varied standpoints of both the researcher and the researched. Constructivists argue that all knowledge flows from standpoints, both those preceding inquiry and occurring within it.

The relativism inherent in constructivist grounded theory assumes multiple, layered realities that shift and change under different conditions. Realities may then be elusive and the researcher's actions become part of them. Fact and value merge. Constructivist grounded theorists define facts through the values that allow them to see. For example, a nuanced understanding of poverty may alert an educational researcher as to how its invisible consequences affect the relative effectiveness of program initiatives in the schools. A middle-class researcher without this sensitivity may not see the same facts as the first researcher.

The relativity of constructivism contrasts with the objectivism inherent in positivism. Grounded theorists, who adhere to positivism, treat reality as unitary and, for the most part, self-evident. Fact and value are separate in this view. Positivist grounded theorists attempt to find objective facts in an external reality and question the subjectivism that may enter constructivist grounded theory through the researcher's choice of topics and methods, such as intensive interviews. Constructivists attempt to recognize the subjective origins of method – and knowledge – rather than to erase their existence. Thus, constructivists try to place subjectivity in its social locations and examine it reflexively.

Constructivist and positivist grounded theorists take divergent positions on data collection. Constructivist grounded theorists advocate gaining an insider's view of the research problem, setting, and participants, which means gathering extensive rich data about research participants' lives and worlds through sustained interaction rather than limited interviews or isolated visits. The depth and extent of data facilitate the researcher's efforts to go beneath the surface and enter the liminal world of research participants' implicit actions and meanings. Constructivists follow the pragmatist prescription of paying attention to language as a way to learn participants' implicit meanings and to understand their actions. For constructivists, the detailed work involved in gaining an insider's view allows discovering variation in the studied process and identifying difference in the analyses. Gathering extensive rich data is also the first step toward making the subsequent research product credible.

In contrast with constructivists, positivist grounded theorists do not attend closely to data collection. They

believe that detailed data distract researchers from discovering and pursuing the analytic focus. Hence, several proponents argue against transcribing interviews, a step most qualitative researchers see as a given. Positivist grounded theorists emphasize gathering only enough data to explicate their emergent category or categories. These researchers tend to take language and meanings for granted without examining their implicit meanings and relationship to action.

The objectives of constructivist and positivist grounded theory differ, particularly those in Glaser's (1978, 1998; Glaser and Strauss, 1967) version of grounded theory. He aims to identify variables, make parsimonious generalizations, and offer useful explanations, all of which transcend the particularities of historical and social locations. Constructivist grounded theory, in contrast, aims for interpretive understanding and situated knowledge. This approach locates the research process and product in its historical, social, and situational contexts. Hence, situated knowledge takes into account positionality and particularities (Clarke, 2005) and informs the researcher's interpretations of the data.

Given the relativity and reflexivity that constitute constructivist grounded theory, it follows that constructivists view data as co-constructed with research participants, whether these data consist of interviews or documents or anything else. The co-construction of an interview may be readily discernible as interviewer–respondent interactions proceed. Nevertheless, co-construction occurs with other forms of data as well. We may not construct documents, but how we read them depends on our view of their purposes and, moreover, the questions and frames we bring to them.

As Bryant and Charmaz (2007) point out, grounded theory has become a general method albeit with several versions. It reaches multiple disciplines and fields and stretches across the globe. Several grounded theory strategies, particularly qualitative coding and simultaneous involvement in data collection and analysis, have become generalized as routine practices in qualitative inquiry. Other qualitative researchers may not use specific grounded theory methodological strategies as grounded theorists do, but nonetheless adopt aspects of them. Many educational researchers adopt grounded theory coding strategies for synthesizing data and defining themes but not for theoretical analyses of processes.

Despite its differences from other versions of grounded theory, constructivist grounded theory practice shares much in common with them. All versions of grounded theory:

1. begin with an inductive logic;
2. emphasize the analytic process;
3. endorse explicit analytic guidelines, although we differ on which guidelines we adopt;
4. aim for abstract conceptualization to advance theory construction;

5. engage in an iterative process to advance the analysis; and
6. intend to encourage innovation.

Perhaps ironically, the recent explication of constructivist grounded theory has advanced all variants of the method because it concretely showed how to employ grounded theory logic and strategies.

Grounded Theory Strategies and Educational Research

The grounded theory method consists of flexible, yet distinct, strategies that distinguish it from other qualitative approaches. Educational researchers have adopted and adapted certain strategies, particularly grounded theory coding, to fit their research problems and practice. A major contribution of educational researchers is to integrate grounded theory strategies with ethnography, case studies, and often multisite case studies that use several types of data collection.

The relationship between extant theory and grounded theory construction and the place of the literature review remain contested by both grounded theory critics and its proponents. Classic grounded theorists eschew relying on extant theory and enjoin researchers to delay the literature review until they develop their own analyses. Both strategies are intended to help researchers avoid preconceiving their ideas by forcing data into extant concepts.

The constructivist response to these strategies is consistent with grounded theory practices in educational research that draw upon earlier ideas but subject them to empirical inquiry, such as Coburn and Talbert's (2006) use of sense-making and institutional theory while starting with descriptive codes with little interpretation. Constructivist grounded theorists argue that researchers:

1. already possess a fund of knowledge and experience before they begin;
2. may draw on broad ideas from their experience or discipline as starting points for data collection but not as ending points analysis;
3. should remain open to the empirical world; and
4. must subject all ideas about it to rigorous scrutiny, including their own emerging theoretical notions.

Constructivists position their research in relevant literatures and explain how it advances knowledge. This approach fits theoretically driven studies in education, which begin inquiry from theoretical positions, such as Thornberg's (2008) inclusion of domain theory in moral education, Qin and Lykes (2006) starting with feminist theory, and Valadez's (2008) use of structuration.

The specific methodological strategies of grounded theory support analyzing processes. Three main strategies

comprise the grounded theory method: coding, memo-writing, and theoretical sampling. Coding means applying a short-hand label to sort, synthesize, and conceptualize data. It involves two stages: initial coding, which emphasizes gaining an analytic handle on the data by defining them, and focused or selective coding, which entails using the most frequent and/or significant initial codes to sort and synthesize data. Memo-writing consists of writing about tentative ideas and emergent categories and includes the crucial intermediate stage of writing between coding data and writing the first draft of a paper. Theoretical sampling is the strategy that grounded theorists use after developing some tentative conceptual categories to fill out these categories, although most do not take their studies into explicit theory construction.

During initial coding, grounded theorists look for processes in the data and attempt to show processes through choosing words as codes that describe what people are doing and what is happening in the settings. Educational researchers often pursue practical problems, which their codes reflect. Eich (2008) aimed to discover the elements of effective student leadership development programs and began by coding for program attributes, actions, and outcomes.

Glaser (1978) described grounded theory as sociology of gerunds because these words depict actions. Using gerunds helps researchers to see what people are doing and what is occurring. Furthermore, coding with gerunds helps researchers to identify a significant process that conceptualizes and integrates the studied phenomena.

Qin and Lykes (2006) not only capture the grounded theory emphasis on a significant process in their study, 'Reweaving a fragmented self', but they also show how specific subprocesses, such as "integrating traditional values" (p. 185) and "breaking the web" (p. 187), and "rethinking 'the homeland'" (p. 191) become analytic categories that contribute to this overall process. Qin and Lykes delineate the conditions under which Chinese women students' understanding of themselves (1) had become fragmented before leaving China, (2) became fragmented after coming to the United States, and (3) became woven into a transformed self. Qin and Lykes's use of grounded theory reflects constructivist principles of using a theoretical perspective as an initial lens to look at data, acknowledging standpoints and starting points, maintaining reflexivity throughout the research process, and subjecting their theoretical notions to rigorous scrutiny. They end their analysis by challenging grand meta-narratives of feminist theory.

Initial line-by-line coding is a heuristic device that leads the researcher to study each line of data to discern the action it indicates. When researchers code in gerunds and keep their codes short, precise, and analytic, as Qin and Lykes's categories indicate, they can discern relationships between codes and begin to see larger processes unfold.

This type of coding differs from most qualitative coding because the latter typically defines general topics and themes, rather than actions and processes. Furthermore, grounded theorists compare data with data, as Eich compared the attributes and actions of programs with each other. The next stage of coding, focused coding, takes the comparative process a step further. Here, researchers use the most frequent and/or significant codes to sort and synthesize data. Hence, focused coding prompts researchers to scrutinize data through the lens of selected initial codes and thus puts these codes to test.

Memo-writing proceeds from the start and becomes more analytic and directed as inquiry ensues. Initially, a researcher's memos might consist of hunches, questions, and areas to explore during subsequent data collection. Gradually, researchers write more analytic, abstract memos on their emerging theoretical categories. A major purpose of memo-writing is to explore the potential of selected focused codes as tentative categories. Subsequently, researchers define these codes by the properties they see in the data. These definitional aspects are crucial. The defined properties do not inhere in the data. Rather, researchers define them through interacting with the data during the analytic process as well as during actual data collection. Through memo-writing, a researcher can break a tentative category open as well as articulate the conditions under which it develops or changes, its relationship to other categories, and its consequences. Memo-writing allows constructivist grounded theorists to explore research participants' tacit as well as overt meanings and actions.

Writing memos keeps the researcher active in the analytic process as well as alert to unanswered questions about the data. These memos demonstrate the links between the researcher's emerging theoretical analysis and the data. Not only does a memo capture the researcher's ideas about a tentative category, but it also contains and weighs evidence for this category. Memo-writing encourages the researcher to make systematic comparisons between data as Thornberg (2008) compared children's responses to moral questions for their similarities and differences.

As an intermediate but imminently correctable stage of writing, memo-writing shortens the distance between coding and writing first drafts. Advanced memos provide the substance for framing papers and chapters and, when taken collectively, may indicate a logical ordering. If grounded theorists define a major process in the data, their explication of the process can order the memos.

By engaging in memo-writing, researchers often find that they need more data to illuminate their categories or to find variation in the studied process. Hence, they return to their research participants and gather more data or build further questions into subsequent data collection. In short, they engage in theoretical sampling to fill out the properties of their categories. Perhaps because the term

theoretical sampling borrows language from quantitative research, it is the most misunderstood of the grounded theory strategies. Theoretical sampling is a sampling that develops the researcher's emergent theoretical analysis; it is not representational or initial sampling. Having developed a set of categories is prerequisite for conducting theoretical sampling. In short, theoretical sampling provides a means for researchers to check, elaborate, and assess their emerging categories and to obtain the data to help them demonstrate how their analytic categories fit together. Thus, conducting theoretical sampling buttresses researchers' claims to making their studies grounded.

Future Directions

Grounded theory offers educational researchers a method that complements varied forms of qualitative data collection and that will expedite their work. Adopting more grounded theory strategies will enable educational researchers to further the theoretical reach of their studies and to make tacit meanings and processes explicit. Constructivists have not only re-envisioned grounded theory, but also revised it in ways that make the method more flexible and widely adoptable than its earlier versions.

In the past, grounded theory has often been viewed as separate from other methods. Now, the constructivist version makes the usefulness of combining grounded theory with other approaches more apparent, as is evident in grounded theory studies in education. Grounded theory can make ethnography more analytic, interview research more in-depth, and content analysis more focused. Several computer-assisted qualitative data analysis programs are built on grounded theory, and this method can add innovation to mixed methods research. Grounded theory emphasizes focusing data collection and checking and developing analytic ideas. Hence, grounded theory offers the tools for building strong evidence within the analysis and for explicating processes. Consequently, grounded theorists in education have a bright future for making powerful arguments in areas such as curricular studies, educational leadership, and educational policy.

Hermeneutics

J Dyer, Memorial University of Newfoundland, St. John's, NL, Canada

The ancient messenger god Hermes transforms that which is beyond human understanding into intelligible form and invents language and writing, the tools of intelligibility.

The field of hermeneutics refers to a manifold of methodologies of interpretation, understanding, and the related issues of translation, communication, and information exchange. It includes practices of interpretation and theories of understanding, where both involve intellectually comprehending the meaning of things and justifying that meaning to others. For this reason, hermeneutics is fundamental to contemporary theories of education because they are guided by the same concerns.

Ancient and Medieval Background to Hermeneutical Inquiry

The ancient Greek terms *hermeneuein* and *hermeneia* mean to assert, to express, and to translate and they are a topic of discussion in texts by Euripides, Xenophon, Plutarch, Epicurus, Longinus, and Plato. Plato (428–328 BC) uses *hermeneuein* to refer to the stated meaning of poetry or rhetoric, distinguishing it from the conscious reflection of *sophia*. Aristotle pushes the relation of hermeneutic enquiry toward truth in his text on language and logic, the *Peri hermeneias*, by placing *hermeneia* with the intellect, where it refers to the mind's operation of perceiving truth value in statements. Philo of Alexandria (20 BC–50 AD) takes up *hermeneia* as a practice of systematic interpretation that can reveal allegorical meanings. In Augustine (AD 354–430), hermeneutics is a practice of systematically revealing layers of meaning in the Bible. The practice of understanding and communicating divine truth involves a basic threefold of will or love, mind, and knowledge. Understanding begins with an intuition of divine truth that imprints on but is hidden in the mind. In order to rediscover this truth, the self requires a way to identify it. For Augustine, this way is love. Love brings together self and divine other and only when love binds the two together can mind realize knowledge of divine truth in an ongoing process of continual self-realization with the other. Augustine's scriptural hermeneutic of understanding brings together language, interpretation, and self-understanding in a triadic model that foreshadows the later theories of Friedrich Schleiermacher and of Hans-Georg Gadamer.

Medieval interpretations of Scripture develop Philo and Augustine by calling attention to the allegorical levels

of sacred texts. For the Church Fathers, understanding as interpretation is both an individual and an inter-subjective experience guided by tradition. Tradition operates as a set of accepted rules used to clarify scriptural interpretation. While tradition is open to misunderstandings, it reduces misunderstandings because it accounts for the possibility of historical change that can break with accepted doctrine. The problem of history gives rise to the hermeneutics of medieval theology and law, where a normative, authoritative tradition of interpretive practices establishes a canon of rules or methods of right practice rather than a theory of understanding.

There are obvious connections between the ancient and medieval practices of understanding and the modern theories of understanding. The former establishes as a part of hermeneutics the practice of consciously reflecting on meaning, the notion of layers of meanings, the problems of authorial intention, historical transmission and the role of tradition, and the concept of a mediating principle which relates self and other, or interpreter and text. Before the modern move into a theory of understanding, however, Reformation and Humanist thinkers problematized the roles of tradition and history, a development fundamental to the transformation of hermeneutics from a practice into a theory.

Humanism and The Introduction of History into Hermeneutics

Hermeneutics as a theory of understanding takes on its modern meaning after the Reformation. Martin Luther stressed that faith and the Bible are the only sources of religious authority and cannot be mediated by tradition. This led to the Reformation insistence on literal exegesis of what the text directly states and on the study of Greek and Hebrew, bringing a historical dimension into scriptural study. The emphasis on literal interpretation opens the possibility of individual interpretation of scripture, where meaning is produced by and for the individual reader of the Bible. The Protestant principle of Scripture explaining itself replaces tradition with an historical understanding of scripture buttressed by faith. Eighteenth-century theologians extend this rejection of tradition and develop the historical dimension of texts, considering scripture a historical document to be understood in its historical context, thereby making interpretation increasingly critical and historically defined. The upshot of this account is that the object of

hermeneutics, rather than the practice, becomes problematized and history becomes central.

The centralization of history is re-enforced by Humanist thinkers, such as Giambattista Vico (1668–1744) and Benedict de Spinoza (1632–77). Neither outlines a system of interpretation, but both emphasize the importance of history for all understanding, thereby laying the ground for the Romantic hermeneuticians. Vico argues that the true is the constructed, such that we can only have certain knowledge about things we create, such as cultural, political, linguistic, economic, and intellectual structures. The natural sciences offer approximate truths because they imitate natural processes, but the social sciences provide exact knowledge because their objects are created. Vico makes history primary and, in doing so, he strengthens the fundamental position of the interpretive subject, for if we are historical beings, then to understand is to understand oneself. The world is not mind independent but identified with the historical subject. Historical, interpretive analysis becomes the apex of scientific knowledge.

Similarly, Spinoza locates the structure of understanding in a historical context when he claims that understanding must place its objects in their historical framework. His *Tractatus Theologico-Politicus* treats the Bible as a historical document that reflects the intellectual practices of its culture; further, God and nature are held to be one substance. Spinoza thereby proposes an analogical relation between the natural and human sciences in which the method of scientific inquiry is made into a historical, proto-dialectical process of relating parts to their contextual wholes, such as Scripture to its context, or natural processes to God, where each can only be understood in relation to the other.

The Romantic Tradition: The Precursor to Modern Hermeneutics

A number of influential figures develop theories of interpretation out of humanism. For example, the eighteenth-century theologian J.S. Semler (1725–91) enforces the distinction in interpretative practice between personal contingent interests and universal permanent meanings while the philologist J.A. Ernesti (1707–81) brings the grammatical to the historical and logical readings of texts. The crux of their analyses is that the linguistic is as explanatory as the historical in objectively interpreting historical documents. It is Johan Martin Chladenius (1710–59), however, who provides a truly systematic treatment of interpretation theory. His hermeneutics is a theory of understanding that offers an account of interpretive procedure. First, texts address readers and are intended to induce complete understanding. Second, understanding requires the use of reason, located resolutely in the human mind, in conjunction with common sense. Third, the reader must be suspicious of

everything that is not self-evidently true. Chladenius takes up the notion of perspectivism (articulated in G.H. Leibniz' monadism) and emphasizes the hermeneutic significance of point of view. Misunderstanding is due to historical, subjective changes in perspective, so Chladenius outlines a typology of points of view intended to clarify opaque meanings. Reading, he argues, requires skeptical interpretation, achieved through trial and error and the continual negotiation of points of view to determine the true meaning of a text. Reading is a fundamental science that results in objectively correct interpretations which can be justified. For Chladenius, hermeneutics is necessary because texts are opaque; his theory predicts the twentieth-century hermeneutics of suspicion.

G.F. Meier's (1718–77) theory of signs holds that signs are meaningful only in relation to other signs. The meaning of a word is not dependent on the object it represents, but on the entire differential structure of words. Hermeneutic theory takes up Meier's focus on interpretation in terms of the differential linguistic structure of texts without appeal to extra-linguistic aspects such as authorial intention, Divine mind, or the object-referent of the sign. Meier's account initiates the practice of relating sign and structure, or parts and wholes in ongoing interpretative activity.

Still more influential are the pre-Romantic classical philologists Friedrich Ast (1778–1841) and Friedrich August Wolf (1759–1824), both of whom extend the domain of understanding from the interpretation of historical texts (Chladenius) and the relational interplay of signs in a system (Meier) to knowledge and understanding as a whole. Ast argues that the history of understanding must be put into the context of the entire history of reason and that the meaning of individual texts can be understood only when interpreted in the context of world history. Wolf's classical philology is developed as a science of interpretation in which historical, cultural, and linguistic elements are critically understood only in the context of the whole of world history. Influenced by Idealism and the emerging Romanticism, both thinkers push the bounds of the hermeneutic framework to include not just the author's point of view and historical situation but the entire historical horizon of human reason.

The Romantic Emergence of Modern Hermeneutics

The theologian G.W.F. Schleiermacher (1768–1834) is a key figure in the development of hermeneutics. In *Hermeneutics and Criticism*, he argues that hermeneutics is the universal condition of all understanding and his general hermeneutic theory is meant to overcome misunderstanding by combining a scientific, methodical practice of interpretation with empathy. Hermeneutic practice

unites the objective, linguistic-historical, and the subjective theological dimensions of interpretation because, he claims, in order to understand a text we must understand it even better than its author did. Schleiermacher thus advocates re-experiencing the text from the perspective of the author, but with the benefit of knowing the author's historical context. Interpretation interrelates the text's grammatical sense with the author's intentional or technical meanings. Grammatically, language is the shared medium of understanding, so to grasp the text's meaning, the interpreter must understand its syntax and grammar. In his technical re-experiencing of a text, interpretation requires an intuitive leap or act of divination to relive the consciousness of the author and grasp her style or treatment of language. There is no directing tradition for this divination; Schleiermacher's subjective idealism grants the interpreting subject the intuitive capacity to move from universal to particular. In this way, Schleiermacher's contribution is in defining interpretation as an interrelational process of continually moving from the universal to the individual, grammatical to technical in a circular process of development. The goal of correct interpretation may not be fully realizable, but it nevertheless requires a sustained and focused comprehension of the author's historical context and unique subjectivity. Only when interpreters can put aside the obstacle of their own presuppositions and relive the author's historical experiences can the meaning fully be comprehended. Schleiermacher's process of interrelating comparative and intuitional, syntactical, and intentional aspects of interpretation develops what will become the hermeneutic circle of understanding and interpretation, or speculation and reflection, developed later by Martin Heidegger, Gadamer, and Paul Ricoeur.

Schleiermacher's systematic general hermeneutics was taken up by thinkers such as Alexander von Humboldt, Friedrich Carl von Savigny, Leopold von Ranke, and Johann Gustav Droysen and applied to their various disciplines. Ranke's (1795–1886) historiographic appropriation of hermeneutics explains historical understanding through the continual interrelation of particulars and universals with the aim of achieving consciousness of historical life. Droysen (1808–84) contends hermeneutics allows for objective understanding of the telos of history by manifesting the mediation of historical being through traditions of understanding. However, it is Wilhelm Dilthey (1833–1911), Schleiermacher's biographer, who clarifies his general hermeneutics by continuing Schleiermacher's emphasis on revealing the conscious knowledge of the subject within its surrounding living totality. Dilthey's *Formation of the Historical World in the Human Sciences* broadens the scope of these insights, reasoning that history and the conscious, intentional subject share a reliance on symbolic expression or mediation. Meaningful expression is a form of symbolic mediation; therefore, understanding the world requires understanding its

mediation through symbolic expressions, a point which is developed with reference to two key concepts: *Erlebnis* (self-understanding) and *Verstehen* (understanding others). There is no understanding of self without an understanding of the self as mediated through the world shared by others. *Erlebnis* and *Verstehen* mediate each other, indicating a universal human nature. Moreover, Dilthey rejects Schleiermacher's psychological intentionalism by claiming that all experience is mediated by pre-reflective symbolic expressions. This means symbolic mediation reveals universal history. Dilthey maintains an inextricable, ongoing relationship of self and other in his theory of understanding, opening up the human sciences to a study of the objective conditions of life experience, pointing toward the twentieth-century ontological turn in hermeneutic theory.

The Twentieth-Century Ontological Turn in Hermeneutics

The philosopher Martin Heidegger (1889–1976) is influenced by Dilthey's attempt to re-live the experiences of past human expressions, but he rejects Dilthey's subjectivism, claiming that the entirety of historical experience cannot be represented in historical self-understanding. Heidegger's hermeneutics of facticity, presented in his work *Being and Time*, recognizes that understanding is primarily about practical experience, not conceptual meaning. Heidegger argues that there is no getting outside historical situatedness. The world is made intelligible through our everyday, practical and pre-reflective projections onto the world of our presumptions, expectations, and categories, the horizon of experience that informs understanding. Understanding is neither a methodology nor a realm of experience but the human mode of being, or *Dasein*, a means of orienting ourselves in the world that is limited by the facticity of historical existence. Reflective interpretation is therefore always already shaped by this horizon of understanding. While understanding discloses the world as a totality in which being is at home, we cannot access anything beyond. Interpretation brings understanding to reflective consciousness by revealing both the facticity of the world and its limits, for there is no understanding of otherness without interpretively appropriating it into our horizon. This is the crux of Heidegger's hermeneutical situation of existence: understanding and interpretation mediate each other and there is no escaping that mediation. The understanding of our mode of being is mediated by the world, and understanding the world is mediated by our mode of being, how the world is disclosed to us. *Dasein* has a circular hermeneutical structure whereby interpretations alter our understanding, which is modified by continually re-interpreting the totality of world. Heidegger's hermeneutics is ontological because it is structured by *Dasein*.

The meaning of things is tied neither to linguistic, propositional truth values nor to the alien historical horizon of past experiences but to the ongoing relational process of the world's disclosure to us. His hermeneutic circle of understanding and interpretation is existential and productive. However, it fails to address the problem of the unappropriable, unintelligible other.

Heidegger's difficulty is addressed by his student Gadamer (1900–2002), who asks in his fundamental work *Truth and Method* what we can do with things that cannot be intelligibly appropriated into our world. Gadamer holds that our understanding is formed by the prejudices of our horizon of understanding, but that these prejudices are the basis of intelligibility, or understanding and misunderstanding. Prior to any reflective identification of meaning there is the world-disclosing interaction of understanding and interpretation revealed through language. That is, we are linguistic beings who recognize, interpret, and change in relation to the world's self-disclosure to us through language, a process of understanding with four components.

First, Gadamer includes others in his hermeneutic circle of understanding and interpretation. Understanding a thing is a matter of projecting it onto our horizon of experience; prejudice or, better, tradition mediates rather than obscures understanding. To be is to be practically immersed in a tradition of meanings, values, and expectations that shape understanding. Inevitably, however, tradition cannot fully interpret the thing, throwing understanding back to reflectively modify its grounds of intelligibility. Hitting an interpretive impasse reveals that tradition is limited, but flexible. The hermeneutic circle of understanding and interpretation is a process that constantly discloses and changes the limits of intelligibility. That is, the traditions historically handed down as our horizon of understanding bear the potential to be modified, crucial to the possibility of further understanding, and in modifying our traditions we open their potential toward understanding the alien object.

Second, this does not imply Heidegger's appropriation of the object into our world because interpretation expands tradition by critically reconsidering its limits. Engagement with retractable objects begins a dialog with the other that requires our openness to the unrealized potential effects of history. History has an authority as both part of and more than, preceding and informing tradition such that tradition is a never completely realized basis of intelligibility that is open to change. Gadamer calls it effective history, the continual expansion of tradition that enriches self-understanding; in understanding the other, we change.

Thus, thirdly, Gadamer describes the mode by which we engage with the other as play. Without appropriating the unintelligible, understanding plays with it by submitting to or fully immersing itself in its structure as we would in, say, a game or conversation. Play is an open relation to the other which begins interpretation, suggesting that the

process of interpretation and understanding is dialogic and open-ended.

Fourth, this means that playing with the unintelligible productively opens our horizon of understanding or prejudices to another's. It enables a fusion of horizons. The hermeneutic circle is now an interplay of effective history and responsible interpretation that neither absorbs the other into one tradition nor denies the possibility of new understanding. In this respect, Gadamer's hermeneutics is an indefinitely ongoing process of dialogical transformation of both object and subject, or text and reader. Like Heidegger, Gadamer's account can be considered idealist because it deals only with the human world. But Gadamer's is also a practical philosophy of enriching our world.

Gadamer's hermeneutical ontology was rejected entirely by Emilio Betti (1890–1968) who charges Gadamer with destroying the classical hermeneutical ideal of objective understanding by denying the independent objectivity of the object. Texts, for instance, are objective representations of an author's intentions with only one true meaning that is not connected to the interpreter's subjective horizon. Returning to Schleiermacher, Betti insists that interpretation must recreate the author's intended meaning. Similarly, E.D. Hirsch (b.1928) argues that Gadamer ignores the possibility of right and wrong interpretations. Gadamer, however, is not engaged in distinguishing interpretation rules but in analyzing the structure of understanding. His hermeneutics is ontological, outlining the structure of being itself.

Jurgen Habermas (b.1929) critically considers Gadamer's hermeneutics with reference to the problem of validity. Habermas' famous debate with Gadamer concerns Gadamer's emphasis on the authority of tradition at the expense of critical judgment. Habermas holds that hermeneutics requires a distinction between distorted and true communication found only in the standards of validity of communicative reason. Gadamer responds that hermeneutics is universal because situatedness in a tradition is the possibility condition of any intellectual inquiry and the revision of tradition is thereby critical. Still, Habermas insists that because inquiry is also always directed by sets of interests (practical, technical, or emancipatory), no theoretical inquiry is universal. Intellectual inquiry which aims for self-knowledge must engage in a critical hermeneutics to account for ideological distortions of tradition. This is the critique of ideology found only in the critical social sciences because they have the goal of emancipation. The critique of ideology questions the traditions it takes up, exposing and amending distortions. Karl-Otto Apel (b.1922) shares Habermas' concern with the emancipatory character of the critical social sciences; Apel calls for an ideal communicative community similar to Habermas' complete communicative competence, namely a regulative ideal of freedom underlying the critique of ideology that questions history's

authority. Without a critical hermeneutics, Gadamer's fusions of horizon can be an unrecognized fusion of misunderstandings.

Phenomenological Hermeneutics and the Semiotic Turn

Paul Ricoeur's (1913–2005) phenomenological hermeneutics mediates between Gadamer's hermeneutics of tradition and Habermas' critique of ideology by installing critique within the hermeneutic process. When the unintelligibly other admits to no fusion of horizons, neither thinker explains how we can responsibly come to understand the other. Ricoeur answers by expanding the hermeneutic circle to include explanation, understanding, and appropriation. Explanation determines the object's structure, since the formal structure of, say, a text is mind independent, open to certain interpretations and impervious to others. Understanding discerns the meaning of the subject matter, such as the author's chosen words. Interpretation compares our understanding of the text's meaning with the explanation of its form to approach an increasingly determinate interpretation out of its possible meanings. Interpretation is open and never fully determinate, for interpreters engage different traditions and subjective associations with the text. Ricoeur's hermeneutic circle sustains the objective independence of the other in relation to the subject, while maintaining their dialogical openness to change.

In *Time and Narrative*, Ricoeur develops the hermeneutical role of tradition, admitting that there is no stepping outside of tradition and that even Habermasian critique is an authoritative form of tradition. However, Ricoeur calls for a hermeneutics of historical consciousness which reveals the implicit distinctions within tradition by proposing another threefold of traditionality, traditions, and tradition. First, all thinking is situated in traditionality because it is embedded in a communicated history of prejudices. Traditionality is similar to explanation, for both concern formal structure. It is transcendental, for it is the purely formal, universal structure of situatedness in some tradition. Second, traditions are the particular symbolic heritages of meaning that cultures inherit differently from history. Third, tradition is specifically one's own heritage that is accepted as the legitimate tradition above all others. Whatever tradition we find ourselves in is *de facto* the normative tradition or Heideggerian world with which our interpretation engages, even when dialogical engagement changes it. Alternately, tradition is what Ricoeur calls narrative, that which engages with the symbolic capacity of others.

The relation of narrative and symbol is crucial to Ricoeur's hermeneutic theory and the basis of his hermeneutics of suspicion, the discernment of what a text hides.

On the one hand, symbols are objects of interpretation, inciting interpretation because they suggest more than their self-evident facticity and they can only be understood when dialogically engaged. Initially, speculation interprets the symbol pre-reflectively in terms of our own tradition, but upon reflection we realize the potential for further meanings not encompassed by tradition. Like explanation, speculation is directed by the symbol's materiality while, like interpretation, reflection opens those traditional meanings and associations to further possible understandings. Symbols show there is more to know than tradition suggests. On the other hand, narrative concerns the possibilities of one's own being. In a return to hermeneutic's ontological thrust, Ricoeur argues that narrative is the specificity of the interpreter's tradition. Our lives are narratives which evince unified structures not entirely explicable by our subjective intentions because they are structurally open to affect and be affected by others. For Ricoeur, hermeneutics concerns continually realizing new ways to exist in the world.

Despite Ricoeur's attempt to incorporate objective determination into the hermeneutic circle, his approach remains firmly with the idealism of his predecessors, for Ricoeur's determination of meaning is still grounded in the interpreting subject's willing, dialogical engagement with others. In his *Of Grammatology*, Jacques Derrida (1930–2004) takes issue with the dialogic approach, arguing that the appropriation of Heidegger's ontology misunderstands its power. With echoes of Meier, Derrida contends that meaning is not dependent on the fusions made in open-ended dialog but on their lack. What drives interpretation is precisely the misunderstandings upon which Gadamer bases his hermeneutics, the absence of meaning that impels us to make connections within language's interminably differential system of signs. Derrida questions the possibility of responsibly understanding the other because interpretation never allows full understanding.

The enduring influence of hermeneutics can be found in a variety of thinkers in the latter half of the twentieth century, such as Richard Rorty, Richard Shusterman, John McDowell, Donald Davidson, and Mary Hesse. Recently, hermeneutics has been challenged as both an interpretive practice and a theory of understanding by the semiotics of C.S. Peirce (1839–1914) and followers like Umberto Eco (b.1932). They understand interpretation as having a threefold structure of sign, object, and interpretant. Against the idealist orientation of hermeneutics, this structure is held to constitute the real nature of all things: the universe is a triadic system of information exchange or communication, of which human activities are but an instance. Ultimately, however, from Plato through to Ricoeur, hermeneutics offers a deeper understanding of the educational process, as Shaun Gallagher argues in his *Hermeneutics and Education*. In relation to educational

theory, hermeneutics is employed as a dialogical mode of learning, for it shares with education theory the basic tenets of analyzing and developing notions of understanding and interpretation, authority and tradition, communication and distortion, and self-realization and objectivity.

Glossary

Chronotope – The manner in which literature represents time and space.

Constructivism – An approach to inquiry that positions knowledge as constructed rather than received. Knowledge is culturally and historically situated and replete with values.

Critical theory – A theory that emphasizes the importance of integrating knowledge across disciplines in order to illuminate the many ways in which power functions in societies.

Empiricism – A view that gives primacy to sensory experience as a source of knowledge.

Epistemology – A theory of knowledge. Positivism and constructivism are examples.

Modernist – A point of view that embraces Enlightenment ideals such as empiricism and progress through science.

Positivism – A philosophy that posits that objective truth is the essence of knowledge.

Postmodernist – Related to the theory that involves a radical reappraisal of modern assumptions about classification, culture, identity, history, and language.

Post-positivism – An approach to inquiry that positions human knowledge as a series of conjectural theories, which may be recursively revised with the discovery of new information.

Transformationist – Related to the theory that ideas, beings, identities, histories, languages, and cultures have originated by the modification of some other previously existing forms.

Introduction

Over the past few decades, scholars throughout the field of education have increasingly engaged in what is generically termed interpretive research. While interpretive research has amassed considerable currency in social research writ large, divergent perspectives have emerged as researchers have variously parsed what it means to conduct interpretive research and how such research ought to be distinguished from other forms of inquiry. This article provides an introduction to central concepts and tensions that characterize the genre of interpretive research in contemporary

education inquiry. Specifically, drawing upon the work of key theorists from the social and human sciences within and beyond the field of education, this article identifies three archetypal approaches to interpretive research as represented by three groups of thinkers and doers who share ideas while staking distinct turf in the research landscape: the signpost group, the big tent group, and the hybrid identities group. Before addressing each group in turn and concluding with a discussion of the viability of the interpretive research genre, this article begins with an overview of the subject of interpretation.

The Matter of Interpretation

The term interpretive research invites a conspicuous question: What do interpretive researchers set out to interpret? Although answers to this question abound throughout disciplines concerned with social and cultural theory, most education research textbooks find firm footing in anthropology when tracing the antecedents of contemporary interpretive inquiry. Specifically, the words of Clifford Geertz, an American cultural anthropologist, are commonly cited:

Interpretive explanation ... trains its attention on what institutions, actions, images, utterances, events, customs, all the usual objects of social science interest, mean to those whose institutions, actions, customs, and so on they are. ... Inquiry is directed toward cases or sets of cases, and toward the particular features that mark them off; but its aims are as far-reaching as those of mechanics or physiology: to distinguish the materials of human experience. (Geertz, 1983: 22)

The overarching intent of Geertz' project was to describe (and thereby interpret) the constitutive components of human experience in such a way that aspects of a group's culture could be understood by people outside that culture. One classic example of his work consisted of describing a Balinese cockfight and arguing how it can be used as a window for understanding gender roles in Balinese culture (1973). The significance of this particular work was two-fold. First, by describing in evocative detail the practice of cockfighting engaged by the Balinese people, Geertz invited readers to experience it vicariously. Second and, moreover, through this experience, readers are compelled to understand how the cultural text of the cockfight is not merely a game but a rulebook for masculinity and power.

In education, many researchers take a similar approach. They describe human experience as it relates to their fields and subfields. They immerse themselves in the culture of a classroom, school, or other relevant organization and provide their audiences with a rich, multilayered account of what occurs in that particular context. The model for this descriptive work is derived from the British philosopher Gilbert Ryle's notion of thick description (introduced to many US audiences by Geertz in 1973). A thick description is a detailed narrative account produced through prolonged fieldwork engaging multiple sources of data and multiple participants. However, like Geertz, interpretive researchers in education do not solely provide highly descriptive accounts of lived experience. They also attempt to make sense of how norms, actions, customs, gestures, dispositions, etc., work together in that (school, classroom, or institutional) culture, thereby generating meaning through their interpretations.

The connection between thick description and meaning generation can be seen by considering the following classic example. Two boys are rapidly contracting their right eyelids. What does this rapid eyelid contraction mean? Through focused investigation the researcher learns that one of the boys has a twitchy eye (i.e., his movements are involuntary) and the other boy is winking at a friend. Although their actions are physically similar, it is only because the researcher is fully embedded in his/her culture that he/she can distinguish between the two actions. A third boy enters the scene and is also contracting his right eyelid. This boy is parodying a wink for comedic purposes. Thin or simple description would not and could not distinguish among these three actions, while the goal of thick description is to do just that. This is because what distinguishes interpretive research from other forms of description is its interpretive intent, namely, its commitment to understanding that focuses on the meanings of actors in local settings.

In summary, interpretive researchers set out to interpret the meaning inherent in concrete, observable phenomena – a position that is exemplified and continuously advanced by the signpost group and divergently extended by the big tent and hybrid identities groups.

The Signpost Group

The signpost group of interpretive researchers in the field of education is made up of individuals who link their identities to what many call the interpretive turn in social research – a concept about which Rabinow and Sullivan (1987) offer several key points:

The *interpretive turn* refocuses attention on the concrete varieties of *cultural meaning*, in their particularity and complex texture, but without falling into the traps of historicism or cultural relativism in their classic forms.

For in the human sciences both the *object of investigation* – the web of language, symbol, and institutions that constitutes signification – and *the tools* by which investigation is carried out share inescapably the same pervasive context that is the human world. Interpretation begins from the postulate that the web of meaning constitutes human existence to such an extent that it cannot ever be meaningfully reduced to constitutively prior speech acts, dyadic relations, or any predefined elements. Intentionality and empathy are rather seen as dependent on the prior existence of the shared world of meaning within which the subjects of human discourse constitute themselves. (Rabinow and Sullivan, 1987: 6, emphasis added)

First, they note that interpretive research focuses on local lived experience and that its description is produced through a multilayered interpretive process – participants and researchers are mutually interpreting their interactions, in dialog with their histories and social networks. This means that all interpretive research is located in specific times and specific places. As a result, interpretation at every level is referenced – meanings are in relation to particular things. Charles Taylor specified three elements of meaning:

- (a) Meaning is for a subject: it is not the meaning of a situation *in vacuo*, but its meaning for a subject, a specific subject, a group of subjects, or perhaps what its meaning is for the human subject as such . . . (b) Meaning is of something; that is, we can distinguish between a given element – situation, action, or whatever – and its meaning. . . (c) Things only have meaning in a field, that is, in relation to the meanings of other things. (Taylor, 1979: 41)

This focus on situated interpretation shifts the researcher from a passive role describing a separate, given reality, to an engaged actor who uses personal and cultural understandings in interpreting experience. This is the essence of the interpretive turn.

Within the interpretive turn is the introduction of a particular mode of authority for the interpretive researcher. Enacting Taylor's elements of meaning, the value of an interpretive account comes out of a sense of being there, an ability to convince the reader that the analysis comes out of the researcher's lived experience in the research context:

In fact, what gives the ethnographer authority and a text a pervasive sense of concrete reality is the writer's claim to represent the world as only one who has known it firsthand can, which thus forges and intimate link between ethnographic writing and fieldwork. (Rabinow, 1986: 23)

By using the rhetorical power of a text depicting field experience, interpretive research locates meaning in a context and persuades through descriptive portrayal. However, this approach has a notable drawback:

Which brings us, finally, to theory. The besetting sin of interpretive approaches to anything – literature, symptoms, culture – is that they tend to resist, or to be permitted to resist, conceptual articulation and thus to escape systematic modes of assessment. You either grasp an interpretation or you do not, see the point of it or you do not, accept it or you do not. Imprisoned in the immediacy of its own detail, it is presented as self-validating or, worse, as validated by the supposedly developed sensitivities of the person who presents it; any attempt to cast what it says in terms other than its own is regarded as a travesty – as, the anthropologists severest term of moral abuse, ethnocentrism. (Geertz, 1973: 24)

The Big Tent Group

Written in the late 1980s as qualitative approaches to educational issues were finding their way into the mainstream, Frederick Erickson's chapter on qualitative methods provides an historical bridge between the psychologically oriented perspectives on teaching to the interpretively oriented viewpoints coming out of anthropology, sociology, and other disciplines using qualitative methods:

I will use the term *interpretive* to refer to the whole family of approaches to participant observational research. I adopt this term for three reasons: (a) It is more inclusive than many of the others. . . . (b) it avoids the connotation of defining these approaches as essentially nonquantitative; . . . and (c) it points to the key feature of the family resemblance among the various approaches – central research interest in human meaning in social life and in its elucidation and exposition by the researcher. (Erickson, 1986/1990: 77–78)

At the time, interpretive research was an up-and-coming alternative to the statistical inference and causally motivated approaches that predominated research on teaching. Erickson provided an articulate case for the contributions of interpretive research, positioning his argument in relation to quantitatively oriented approaches and from within an interpretive framework.

For Erickson, interpretive research is differentiated from other forms of inquiry in its intentions and substance. Method does not serve to distinguish interpretive research; instead, its critical attribute is that its purpose is to examine meaning. Erickson's discussion of interpreting the patterned nature of lived experience highlights the social theorization so important in interpretive research:

Humans, the interpretive perspective asserts, create meaningful interpretations of the physical and behavioral objects that surround them in the environment. We take action towards the objects that surround us in the light of our interpretations of meaningfulness. Those interpretations, once made, we take as real – actual qualities of the objects

we observe. . . . We see the ordinary world as if it were real, according to the meanings we impute to it. (Erickson, 1986: 97)

This approach operates such that the focus is on concrete particulars rather than on abstract universals. Returning to the example of the boys who were rapidly contracting their right eyelids, the particular details of each boy's situation must be learned in order to fully understand why he is performing the action. If the second boy is unable to speak with his friend due to the situation they are in (e.g., school during an examination), the boy could be communicating a number of things by winking. Perhaps in the school, it is a custom for groups of students to produce practice tests in preparation for an exam. If they attempt to accurately guess the questions on the examination, the wink could indicate one of them guessed correctly and they will plan to work together again. To understand the situation, both the concrete particulars (the boy winked, to a friend, during an examination) and the abstract universals (people wink to get each other's attention in a friendly way) would have to be known. Importantly, the researcher could not claim this to be the case in all schools. His/her findings are not generalizable. Interpretive researchers work a tension among universals, limited generalizations, and local uniqueness, noting, "The paradox is that to achieve valid discovery of universals one must stay very close to concrete cases" (p. 109). Building from the interpretive turn, Erickson introduces interpretive research to a cultural group socialized to value a post-positivist approach to research, linking key concepts to research across paradigms.

Another example of a broadly inclusive framing of interpretive research is Howe's (1998) philosophical exploration of education's engagement in the interpretive turn (and its aftermath). Under an epistemological umbrella of constructivism, Howe places interpretivism in relation to empiricism (which he links to positivism). His definition of this approach to inquiry is derived from the interpretive turn and represented by Taylor's rejection of value-free science communicated with impersonal language: "We have to think of man as a *self-interpreting* animal. . . . [T]here is no such thing as the structure of meanings for him independently of his interpretation of them" (Howe, 1998: 13). This provides a context for his view of interpretivism as a "broad epistemological turn" focused on the culturally embedded identities and interests (p. 13). While this perspective might seem quite similar to those suggested by those in the interpretive signpost group, what distinguishes it is the way it frames the rest of the world.

Placing interpretivist research in opposition to positivist research, Howe's definition sets multiple posts for a big tent encompassing all research endeavors. This is clear in his inclusion of two distinct approaches to interpretivism, what he calls postmodernist and transformationist. The former he links to a rejection of the modernist core of

Enlightenment philosophies and the latter he sees as holding true to the commitment to modernist notions of progress. This big tent philosophy toward interpretive research takes the notion of interpretive practice so far that it makes ascertaining what is not interpretive rather difficult. Arguably, the recognition that researchers do not have direct access to lived experience and that they interpret it as participants and investigators stands to benefit more from fine-tuning than from judgment regarding its placement inside or outside that tent. For this reason, the next group – the hybrid identities group – can be understood as being characterized by more permeability.

The Hybrid Identities Group

Critiques of interpretive research have highlighted the conceptual differences in assumptions among theoretical groups. Garrick (1999) examined the foundations of interpretive research, identifying three sets of theoretically situated concerns. From the positivist perspective, interpretive research is limited because interpretation implies subjectivity, which short-circuits the mechanisms of generalization. For critical theorists, interpretive research does not have the tools to interrogate historical, social, economic, structural, and environmental forces on the individual that can be used to investigate issues of power. Finally, postmodernists find interpretivism's focus on individual experience problematic because of its contention that individuals are largely autonomous and agentive subject: "Human beings do not live in worlds entirely of their own devising" (p. 152).

Together, these critiques illustrate the limited contribution of framing interpretive research as all things that interpret. Researchers whose affinity lies with the hybrid identities group assert that the interpretive landscape is much more nuanced than the big tent metaphor would imply and that researchers lose the generative power of the contributions that each theoretical perspective provides.

A variety of philosophers and qualitative researchers have parsed the terrain of inquiry, with attention to the ways that epistemology shapes the practice and criteria for judging research. Bredo and Feinberg (1982) contrasted positivist, interpretivist, and critical theory in terms of the relation between the researcher and the researched, which range from absolute separation to mutually constituting each other. Their portrayal of interpretivism as a theoretical perspective that creates meaning through interaction makes it subject to the same critiques as those suggested by Garrick.

Crotty (1998) framed social inquiry in terms of methods, methodology, theoretical perspective, and epistemology and argued that good scholarship has these elements coherently related to one another. He depicted the world epistemologically in terms of objectivism, constructionism, and subjectivism, and then described an array of theoretical perspectives. Interpretivism is one of those theoretical

perspectives, "conceived in reaction to the effort to develop a natural science of the social. Its foil was largely logical empiricist methodology and the bid to apply that framework to human inquiry" (Schwandt, 1994: 125). For Crotty, interpretivist research "looks for culturally derived and historically situated interpretations of the social life-world" (p. 67). While this definition may sound very similar to earlier views, what distinguishes his framework is its approach to mapping that loosely links elements into groups. He reminds researchers to maintain awareness of how tools (like methods) have deeply embedded meanings related to ways of seeing the world. By extending this mapping beyond the quantitative-or-not distinction, Crotty not only complicates but also enriches researchers' understandings of interpretive research. Interpretivism is more fully linked with specific theoretical frameworks – in Crotty's typology it is paired with hermeneutics or symbolic interactionism in relation to post-positivism, critical theory, feminism, and postmodernism.

Kamberelis and Dimitriadis (2005) developed a map through an historical analysis of theories foundational to qualitative inquiry that recognize relations in explicit and contradictory ways. Specifically, they posit four overlapping categories or chronotopes – snapshots of time with permeable boundaries and related histories – that "index historical realities that constitute what is common, natural, and expected by collectives of social scientists who conduct particular kinds of qualitative research" (p. 25):

1. objectivism and representation;
2. reading and interpretation;
3. skepticism, conscientization, and praxis; and
4. power/knowledge and defamiliarization.

In essence, these chronotopes are eras or stages of qualitative inquiry. A reading of Kamberelis and Dimitriadis' distinctions between the second chronotope (reading and interpretation) and the other three recognizes a reality that is socially constructed through experience and language while maintaining a core that can be identified through consensus. In particular, in contrast to the two subsequent chronotopes (skepticism, conscientization, and praxis and power/knowledge and defamiliarization), the reading and interpretation chronotope poses language as a natural mediator, one that constitutes our worlds but that is not particularly interested in power and its play in the world. Interpretivists are committed to describing lived experience in ways that enable the illumination of what is uniquely human but that have limited attention to forces that privilege some and marginalize others. Reflecting its roots in an empiricist past (the prior chronotope, objectivism and representation) with colonialist practices, interpretive research can be seen as relativist and realist, socially oriented yet individually focused in many cases.

Adherents of the hybrid identities group would argue that this kind of portrayal of the research landscape allows

researchers to appreciate the complexity at play in qualitative research today. By distinguishing inquiry in this historically reflective way, what could be seen as promoting Balkanization is instead suggesting hybrid descriptions that are more nuanced and interested in diverse dimensions of inquiry reflective of the practice of research. Their permeable boundaries are illustrative of Geertz' notions of blurred and blurry genres, originally written to describe the border crossing between anthropology and literary theory but now layered to include multiple ways to theorize and practice research. Interpretive research, rather than being all things that are qualitative, represents a particular set of theoretical and therefore methodological tools interested in examining the social construction of meaning in particular settings and with specific participants. Its focus on concrete particulars and a consensus model of truth make it a transitional model of inquiry, a theoretical bridge between the modernism of post-positivist approaches and postmodern multiplicity. Its unique blend of realism and relativism gives the researcher a particular power as an author who recounts his/her field experience to create a sense of meaning. Jennifer Greene's description is particularly apt:

Interpretivist social inquiry is an opportunity to give voice to one's self, to offer a view of human experience that promotes one's own values and ideals. Interpretivism retains its essential relativism on this issue, such that it can be used as a platform for many different, even competing, advocacy stances and beliefs. (Greene, 1992: 39)

Conclusion

With the myriad affinity groups circulating various perspectives on interpretive research, is interpretive research a viable term today? In other words, does the existence of multiple meanings ascribed to the term interpretive research mute or amplify its importance to the field of education inquiry? An answer to this question lies in the reader's interpretation of this article, for it is very much an object lesson in interpretive theory and practice. Rather than generating a single definition of interpretive research, this article provides a set of interpretations made through its authors' experiences with the literary discourse espousing a multiplicity of perspectives concerning interpretive research. To be sure, the ideas shared in these pages may do more to

frustrate than to clarify, an experience analogous to an allegory famously presented by Geertz:

There is an Indian story – at least I heard it as an Indian story – about an Englishman who, having been told that the world rested on a platform which rested on the back of an elephant which rested in turn, on the back of a turtle, asked (perhaps he was an ethnographer; it is the way they behave), what did the turtle rest on? Another turtle. And that turtle? “Ah, Sahib, after that it is turtles all the way down.” (Geertz, 1973: 28–29)

The adventure through the interpretive literature would say that the interpretive research term is indeed viable because it is, like turtles, all the way down. However, as this article makes clear, its viability rests on the capacity of the inquirer to identify the perspective used to make the interpretation.

Interviews and Interviewing*

A Marvasti, Penn State Altoona, Altoona, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Active interview – A type of unstructured approach to data collection and analysis that treats the interview as a social occasion for reality production.

Constructionism – A philosophical orientation that focuses on how human practices create social reality.

Ethnographic interview – A variant of unstructured interviews that is particularly sensitive to the social context of the respondents' lives.

Focus group – Interviewing a group of respondents at the same time with the goal of stimulating discussion.

In-depth interview – A variant of unstructured interviews with special emphasis on revealing the respondents' inner feelings and attitudes.

Interview – A technique of collecting information by asking questions and receiving answers through face-to-face, phone, or Internet interaction.

Positivism – A theoretical model for conducting social research modeled after the natural sciences and based on a search for universal laws and strictly empirical evidence.

Postmodernism – An interdisciplinary movement that is based on the relentless critique of established social conventions.

Structured interview – An interviewing technique that relies on closed-ended questions and strict procedures for collecting data.

Unstructured interview – An interviewing technique based on open-ended questions that encourage respondents to elaborate on their statements.

Interviewing is a basic form of data collection based on a question-answer format. However, one does not need to be a social scientist to have participated in this mode of communication. Teachers, for example, conduct informal interviews with students who have missed assignments, asking them why they missed the assignment before deciding whether to allow the student to complete the work. Similarly, in a physician's office, patients participate in intake interviews where they answer specific questions about their medical history. Job applicants typically undergo a face-to-face interview before they are selected

for a position. Television and popular magazines entertain their audiences with celebrity interviews.

The setting and the purpose of the interview aside, the format is fairly consistent: questions are posed to individuals and they are expected to provide meaningful responses. Arguably, information gathering through interviewing is so ubiquitous that it typically goes unrecognized. Given the prevalence of interviews as a mode of communication in all facets of social life, we may refer to our social world as an interview society (Atkinson and Silverman, 1997). Yet, from a historical standpoint, this seemingly natural mode of inquiry is a relative newcomer in the world of collecting data about human behavior (Gubrium and Holstein, 2002). That is to say, the interview is based on certain assumptions and role expectations, which in turn inform how the interview is conducted and for what purpose. Let us briefly consider these taken-for-granted assumptions and how they relate to methodologies of qualitative and quantitative research.

Conceptualizing the Interview

Let us begin by noting that the so-called quantitative and qualitative research methodologies are two extremes on a continuum of research with much variation in between. To the extent that there are real differences between these two research methods, the distinctions have more to do with theories of the social world and reality than research techniques *per se*. Specifically, qualitative researchers tend to be interested in: (1) the fluidity of social life, (2) individual and situational variations of human experience, and (3) the deliberate or subjective work of conveying human experience. These points of emphasis collectively may be referred to as constructionism (an orientation aimed at understanding variable constructions of knowledge). By comparison, quantitative researchers emphasize a static cause-effect model of social reality and accordingly seek: (1) explanations of human behavior that are universally constant and (2) representations of human experience that are objective, true, or free from subjective distortions or biases. The philosophical paradigm informing quantitative research may be termed positivism (an orientation inspired by the natural sciences and committed to discovering positive, conclusive knowledge about the social world). Each standpoint then requires certain techniques of discovery that complement its theoretical view. For example, the twin sciences of survey

* Adapted from Marvasti, A. (2003). *Qualitative Research in Sociology*. Thousand Oaks, CA: Sage.

research and statistics allow quantitative investigators to summarize opinions and social trends for large aggregates. Such findings are then shared with readers in the form of numerical tables, or static representation of social reality. By comparison, qualitative researchers use techniques that show the depth and fluidity of experience as their variations across social settings. Qualitative data often are represented in the form of narratives, interviews, or field notes.

The interview method is used by both qualitative and quantitative researchers. While it is possible to distinguish the usage in purely technical terms (structured interviews for quantitative and unstructured for qualitative), the differences imply deeper understandings of research participants and their relationship to the investigators. Before delving into a discussion of research techniques, in the next section, we consider how the two camps might conceptualize the interview as a process of communication between the researcher and research participants.

Structured Interview: Extraction

From a quantitative standpoint, the research interview is primarily about extracting information from a subject. What matters first and foremost is that the information remains pure, or free from potential distortions or diversions. The data-collection process and its techniques are therefore designed to reduce biases that could originate from the data collection instrument, the investigator, or the participants. This type of objectivity is achieved through a structured research design (e.g., random samples and closed-ended questions) that provides consistency, uniformity, and structure to researcher–subject interactions while the information is being extracted.

Gubrium and Holstein (2002) argue that this particular view of the research interview is founded on three premises. First, this interview format assumes that human beings share a common experience, which can be articulated by any random member of society. The authors refer to this assumption as “the democratization of opinions” (p. 4), which implies every person’s opinion of the world is valid and that the statistical summary of these views paints a reasonably complete picture of social reality. According to Gubrium and Holstein, the second assumption of conventional interviews is the division between the formalized roles of the researcher and the respondent. In a positivistically-oriented interview, these roles and expectations resemble a leader–follower relationship. The interviewer is the leader; he or she asks questions and in doing so decides the topic, the pace, and the relevance of what will be discussed. The respondent’s primary responsibility in turn is to provide coherent, presumably truthful, answers when prompted to do so. The third premise of a positivistic interview format is that respondents are essentially vessel of answers (Gubrium and Holstein, 2002), or

proverbial fountains of information that could be turned on by the right questions. In this positivistic framework, the subjects’ involvement in the interview is limited to only answering questions and that researcher’s primary job is to extract answers. Positivistic researchers treat the context and the nature of the researcher–respondent interaction as a sort of background noise that interferes with true findings. Such interferences are controlled or manipulated to improve the objectivity of the data. As David Silverman points out,

For positivists, an observation that interview responses might be an outcome of the interview setting would be heard as a charge against the reliability of the technique. To the extent that this possibility arises, checks and remedies are built into the research design. Similarly, for positivists, the language of the interviewee serves primarily as an instrument for the communication of social or psychological facts. (Silverman, 2001: 88)

As a whole, these assumptions regarding democratization of opinions, formalized roles, and respondents as vessels of answers help shape the structured interview and its related data-collection techniques. Let us now consider a qualitative orientation, and theory informs the interviews and interviewing.

Unstructured Interview: Interaction

For most qualitative researchers, the traditional model of structured interviewing lacks the analytical tools for understanding how the social context and the interactional dynamics of the interview shape the research findings. From a qualitative standpoint (particularly derived from a constructionist view), research participants cannot and should not be treated as mere conduits or vessels of information to be used and disposed of at the interviewers’ whim. This emerging sensitivity to social context and the interactional nature of interviewing is best captured by the following edict: “Do not assume that the subject behind the respondent is merely there for the asking” (Dunbar *et al.*, 2002: 295). Thus, for a growing number of sociologists and other social scientists, the interview process is no longer limited to the simple give and take of asking and answering questions. While gathering information about people remains a central purpose of interviewing, exceedingly, qualitative researchers try to couple technical and procedural matters with matters of meaning making, social interaction, and social context.

The most notable attempt to incorporate these concerns into a unified approach can be found in Holstein and Gubrium’s (1995, 1997) active interviewing. According to this perspective, the interview is a social occasion, or an event, in its own right whereby researchers and respondents jointly create social reality through interaction. As Holstein and Gubrium (1997) put it, “From this

perspective, interview participants are practitioners of everyday life, constantly working to discern and communicate the recognizable and the orderly features of experience" (p. 121).

Viewed from an active-interview orientation, the elaborate procedural guidelines of survey interviews take on a different meaning. Instead of producing less-biased, more-objective data, the structured interview and its rigid rules can be seen as creating simply another version of truth, one that reflects the interviewer's assumptions (e.g., what topics are relevant, what is bias, and what is a proper answer), as much as it tells us about real experiences or attitudes. A positivistic perspective on the interview suggests that the subjects' knowledge is a thing that can be extracted from them, but from an interactional or constructionist view, interviews and interviewing are relative to time and place. Instead of seeing the interview as a social vacuum where the general principles of human interaction are suspended in favor of truth finding, qualitative researchers approach the interview as a social encounter with its own set of constructive practices and interactional dynamics.

Having said that, it should be noted that the open-ended, unstructured format of qualitative interviewing does not mean anything goes. On the contrary, this alternative format requires greater attention and analysis of a wide range of issues that tend to be ignored by the more standardized interview format. Among other things, unstructured interviewing demands that researchers be more reflective and deliberate about the reality they are jointly constructing with their participants. As Gubrium and Holstein (1997) put it, seeing the interview as an active interaction means: "All participants in an interview are inevitably implicated in making meaning" (p. 126).

Given these broad theoretical distinctions, let us now consider some interviewing models often associated with qualitative research.

Range of Qualitative Interviews

As the name implies, unstructured interviews are less stringent about the assumptions of interviewing. Also referred to as open-ended interviews, they allow more fluid interaction between the researcher and the respondent. In most qualitative interviews, respondents are not required to choose from a predesigned range of answers; instead, they can elaborate on their statements and connect them with other matters of relevance. In fact, in some published manuscripts, this data-collection procedure is simply referred to as talking, signifying its informal and conversational style. The following is an example of an open-ended interview with a nursing home resident.

Jay: Everybody has a life story. Why don't you tell me a little about your life?

Rita: Well there's not much. I worked in a telephone

company as a telephone operator before I was married. After I got married I moved to New Jersey and had two boys . . . (Gubrium, 1993: 20)

As seen in this example, unstructured interviewers are procedural minimalists: they simply provide a general sense of direction and allow respondents to tell their stories.

Two variants of the unstructured format are in-depth and ethnographic interviews. It is important to note, however, that the terms unstructured, in-depth, and ethnographic interviewing are sometimes used interchangeably in social science literature. Both in theory and in practice these orientations overlap. Furthermore, every study could and often does either create its own version of these techniques or uses them in combination. With these qualifications in mind, the following section offers an overview of these two interviewing techniques.

In-Depth Interviews: Manifesting the Inner Self

In-depth interviewing, as the name suggests, is founded on the notion that delving into the subject's deeper self produces more authentic data. John M. Johnson (2002) suggests that in-depth interviews are based on a number of assumptions. First, understanding the deeper self in this context means seeing the world from the respondent's point of view, or gaining an empathic appreciation of his or her world. In-depth interviewers aim to gain access to the hidden perceptions of their subjects, or as Johnson puts it,

[In-depth interviewing] begins with commonsense perceptions, explanations, and understandings of some lived cultural experience . . . and aims to explore the contextual boundaries of that experience or perception, to uncover what is usually hidden from ordinary view or reflection or to penetrate to more reflective understandings about the nature of that experience. (p. 106)

Another common assumption of in-depth interviewing is that it can and should be mutually beneficial to the subject and the researcher. That is, in addition to helping the subject uncover suppressed feelings through the interview process, the researcher also gains knowledge of his or her own hidden or conflicting emotions (p. 106). Lastly, according to Johnson (2002), in-depth interviewing provides a multi-perspective understanding of the topic. In other words, by not limiting respondents to a fixed set of answers, in-depth interviewing has the potential to reveal multiple, and sometimes conflicting, attitudes about a given topic.

In sum, the procedural guidelines of in-depth interviewing encourage mutual self-disclosure in the context of an emotionally charged atmosphere where the interviewer and interviewee freely express their views about an issue (Douglas, 1985). The questions are designed to go beyond the presumed surface level of respondents' feelings and into the deeper levels of their consciousness. That is to say, the

inquiries are directed at the unseen or the hidden dimensions of the self. Not surprisingly, all this gives this particular brand of in-depth interviewing the quality of talk therapy. Its procedures are reminiscent of Freudian psychoanalytic techniques aimed at uncovering the subconscious through free association, or random expressions of thoughts.

Ethnographic Interviews: Recording Life in Context

Ethnographic research has its roots in the discipline of anthropology where interviews tend to be conducted in everyday settings and greater attention is given to the context of social life. Indeed, early ethnographies were essentially anthropological travelogs that provided accounts of exotic people and their cultures (Tedlock, 2000). Its ethnocentric flaws notwithstanding, anthropology's emphasis on culture has greatly contributed to the development of ethnographic research, which is regarded as uniquely suited for connecting empirical observations with the contingencies of the setting.

In particular, ethnographic interviewing differs from other approaches in that it takes place in, or is related to a particular physical setting, sometimes referred to as the field. The ethnographic field is the social context that guides the interview in terms of what questions are asked, which people are interviewed, and how their answers are interpreted. Ethnographic researchers typically rely on informants for assistance in navigating the field. In addition, ethnographic interviewers use observations from the field to assess the meaning and relevance of their interview data.

In the course of conducting ethnographic interviews, greater attention is given to where, when, and with whom the interviews are conducted. The ethnographic research enterprise, which begins with selecting a research site and gaining access and rapport, uses interviewing to supplement field observations and other sources of data (e.g., official documents). Therefore, the interview questions, its timing and place, and the choice of respondents depend on what the ethnographer needs to know at a given stage of the research. For example, an ethnography of illicit drug culture in an urban high school might begin by asking students about illicit drug use but could gradually shift to their parents' and teachers' attitudes about the topic. As the field work progresses, the researcher may have to develop new questions and recruit a wider range of participants than originally planned.

In essence, the ethnographic interview is typically unstructured like most other qualitative interviews. The main difference is that the researcher, or ethnographer, typically has greater rapport and understanding of the social context of the respondents' lives. Furthermore, the interview itself is more likely to be conducted in the field, or places where the respondents actually live or work.

Focus Group Interviews: Encouraging Group Interaction

In focus groups, the researcher asks questions from a number of respondents at the same time to "stimulate discussion and thereby understand (through further analysis) the meanings and norms which underlie those group answers" (Bloor, *et al.*, 2001: 43). According to Fontana and Frey (2002: 651), historically, focus groups owe much of their popularity to marketing researchers and political candidates who wanted to gauge the opinions of their consumers or constituents about a particular product or issue (see also Bloor *et al.*, 2001: 1–3). From there, focus groups gradually made headway into the social sciences and now occupy a well-respected position among the various data-collection methods.

The format ranges from very structured with respondents taking turns answering each and every question to a more flexible brainstorming session where participants voice their opinions at will. The interactional nature of focus groups can stimulate respondents' memory of specific events and facts (Fontana and Frey, 2002: 651). As a whole, as Rubin and Rubin state,

In focus groups, the goal is to let people spark off one another, suggesting dimensions and nuances of the original problem that any one individual might not have thought of. Sometimes a totally different understanding of a problem emerges from the group discussion. (Rubin and Rubin (1995: 140), quoted in Berg (2001: 115))

Other advantages are that focus groups can be very stimulating to the respondents (they will not become bored), and provide participants with the opportunity to elaborate on each other's answers (Fontana and Frey, 2002: 252). However, the approach is not without its problems. Some of the challenges of focus group interviewing include:

1. one person could dominate the group;
2. respondents may be reluctant to discuss sensitive topics in the presence of others, or they could distort their answers in an effort to appear socially desirable;
3. some individuals may be shy and thus require more encouragement to participate; and
4. the interviewer has to be skilled at managing the group dynamics and asking questions simultaneously (Merton *et al.* (1956), cited in Fontana and Frey (2002: 652)).

Respondent Characteristics

Interviewers are becoming more sensitive to how the respondents' characteristics influence their data-collection procedures and outcomes. An important consideration for researchers in the area of education is how to deal with

obvious inequality of power and status between researchers and their underage respondents. As Eder and Fingerson (2002) note, interviewers who work with children and adolescents have to take special care to minimize the risk of exploitation. The recommended solution is to make certain that the young respondents' participation in the research is of some value to them and their communities. As Eder and Fingerson state,

The researcher's desire to gain information from child participants without giving something in return reflects an underlying sense of the adult researcher's privilege. However, by giving something in return for receiving information, researchers can reduce the potential for power inequality. (p. 185)

According to the authors, this can be done in two ways. First, the interview questions and procedures can be designed to help children and adolescents learn something about themselves or become empowered. For example, in a study of young adolescent girls, respondents reported higher levels of self-awareness and enhanced communication skills as a direct result of participating in interviews. As one subject reported,

But since the question came up, it let me know how I felt. I think that's good. I can do this forever you know . . . keep on going . I'll bring a lot up with just easy questions that you would ask anybody, you know. It lets you know about yourself. (Taylor *et al.* (1995: 129), quoted in Eder and Fingerson (2002: 186))

Another way in which social scientists can give something back, or reciprocate, is through action-oriented research, or research that produces concrete positive changes in the respondents' lives and their community. For example, Eder and Fingerson note how Valenzuela's (1999) work with Mexican-American adolescents in their classrooms helped reduce tension and misunderstanding between them and their teacher.

Other Considerations

This article began with a comparison of the traditional understanding of an interview as a research tool based on questions and answers. We gradually moved to the more analytically complex idea that an interview is a social occasion that creates a particular version of social reality. Interviewing, a once simple and seemingly innocuous data-gathering method, is being critiqued and expanded into new territories. According to some commentators, this is due to the influence of postmodernism (Fontana, 2002), which for our purposes can be defined as an interdisciplinary movement that is relentlessly critical of established social conventions. Among the various questions raised by postmodernism are: How could the traditional

interview model be transformed into something more liberating and empowering for the respondents? Who owns the text and the stories that emerge from an interview? Is it the researcher's story to write as he or she wishes or is it the respondents' version? (Gubrium and Holstein, 2002: 16–17). These are just a few of the many concerns that postmodernists have brought to the realm of social science research.

As is the case with many interests in sociology, these debates will likely continue well into the next century. On a more practical level, it is important to keep in mind that one's choice of interview technique should be in sync with the topic of one's interest and the questions one wishes to answer. If one is interested in the relationship between income and grade point average among college students, a survey interview will do the job efficiently and inexpensively. If, on the other hand, one wants to study how the privileges of social class shape a person's identity and worldview, he or she might proceed differently. For example, one might ask low- and high-income people an open-ended question such as, "What is the most important thing you want people to know about you?" and compare their answers; or one could supplement structured interviews from a large sample with unstructured in-depth interviews from a smaller group of respondents. The important point is not to impose arbitrary limitations on one's curiosity about the social world because of methodological orthodoxies.

Glossary

Life history – A mode of qualitative research that seeks to apprehend, understand, and render individual life stories within their personal, social, economic, political, and historical contexts.

Life history is a mode of qualitative research that seeks to apprehend, understand, and render individual life stories within their personal, social, economic, political, and historical contexts. Its emphasis on theorizing individual biographies in relation to the pervasive influences of the contexts that surround them is the hallmark of this kind of social research. Life historians use interviews, observations, artifacts, and other qualitative data to generate life stories from individual participants; but they go beyond narrative accounts of individual lives and undertake in-depth analyses of the collective contextual influences in which those lives are situated. Life history has been called “sociologically read biography” (Bertaux, 1981), “life story located within its historical context” (Goodson, 1992), “genealogies of context,” and “stories of action within theories of context” (Goodson, 1995). Each of these expressions emphasizes the place of both story and context. If both are not theorized in relation to the other, the product is something other than a life history.

This article describes the unique contributions of life-history research; provides a brief history of life history, tracing its roots to a variety of disciplines; compares life history to other qualitative approaches, narrative research in particular; describes data collection and analysis possibilities for life-history work; and discusses issues related to doing life-history research.

Unique Contributions

Life-history research is positioned to make unique contributions to the knowledge base in education and the social sciences because of its focus on relationships between individual subjective experience and the complex contexts in which that experience is embedded. Life-history research illuminates both the logic of individual decision making and the impact of societal-level conditions within which decisions are made. It provides ways to

study connections among individual lives, culture, and social structure that are not possible using other research methodologies – quantitative or qualitative. Life-history researchers are committed to examining perspectives on culture and social structure that are not available to those applying a wider methodological lens. By making individual lives the centerpiece of the research enterprise, life-history researchers generate findings that reveal the lived experiences of social actors. These findings make possible a dialog between abstract theoretical and empirical descriptions of cultural and social phenomena and the subjective encounters of real people with the real-world expressions of those phenomena.

By taking the perspectives of individual participants as a point of departure, life-history studies disrupt the assumptions of traditional social science research. Life-history researchers’ concern with the perceptions of individual social actors elevates subjectivity to the status of a methodological necessity, rather than a flaw to be controlled at all costs (Cole and Knowles, 2001). Further, the emphasis on collecting rich data with a few informants runs counter to newly revived positivist contentions that such strategies are not scientifically based. Life-history projects are valuable because they emphasize detailed contextualized analyses of the subjective experiences of selected individuals. It is assumed that the perspectives of these individuals can supply different, perhaps better, knowledge of prevailing social conditions than the detached observations of traditional social scientists (Casey, 1992).

Life-history research is unique because it allows for systematic inquiry into the human condition through a close examination of living in the world as experienced by individuals. The logic of this kind of research is based on the maxim that the general can best be understood through analyses of the particular. For life-history researchers, to understand the intricacies of one life is to gain insights into the collective. That is not to say that to understand one is to understand all; but understanding one life helps to shed light on the complexities of lives in communities (Cole and Knowles, 2001). Life-history researchers capture stories of lives set within social, political, socioeconomic, and historical contexts. These stories contribute special kinds of knowledge that enriches understandings of individual and collective experience.

Life-history research provides a forum that allows authentic voices to speak for themselves. In this kind of research, the voices of participants are of central importance to the stories being told – the more authentic the

voices, the more powerful the stories. Life-history research typically asks questions not from the point of view of powerful actors, but from the perspective of those being acted upon (Becker, 1970). The goal is to elicit expressions of what people living in particular social worlds already know about those worlds. They are the experts at understanding the meaning structures and discourses that define their experiences, and life-history research seeks to utilize their expert voices to help educate the rest of us. Individuals from all groups have the right to speak for themselves and have their voices accepted as legitimate (Gilligan, 1982/1993). Life-history work depends on the authentic voices of individuals to make research findings meaningful.

History of Life-History Research

The foundations of life-history research can be traced within the histories of a number of scholarly disciplines, including anthropology, sociology, psychology, and education. The popularity and acceptance of life-history approaches in these and other social science fields of inquiry have waxed and waned since the early twentieth century. The period between 1920 and World War II is recognized as a period of early substantial interest in the study of life histories (Runyan, 1982). Anthropologists who collected the life stories of Native Americans were among the first to produce life-history research. Sociologists from the University of Chicago, who viewed individuals and their stories as living illustrations of the social conditions of the times, powerfully influenced the academic landscape of the 1920s and 1930s. Thomas and Znaniecki's (1920) *The Polish Peasant in Europe and America* is widely acknowledged by anthropologists and sociologists as the most influential early publication of life-history work. Psychologists of the same period used idiographic methods to study individuals and their stories in order to understand personality development and psychological maladjustments.

From World War II through the mid-1960s, a significant decline in life-history research was seen (Runyan, 1982). This decline was evident across the social sciences, and scholars of the day attributed it to the ascendancy of abstract theory, experimental research designs, and quantitative data analyses across the disciplines (Bertaux, 1981). While the study of life histories did not completely stop during this period, such work was less highly valued, less widely recognized, and less well funded than research based on testing hypothetical relationships among measurable variables.

A resurgence in interest in studying life histories occurred in the late 1960s, leading social scientists to explore areas such as psychopathology, personality development, life-span development, aging, social mobility, and socialization (Runyan, 1982). Life-history work of this

period emphasized exploring how the life course is influenced by social, demographic, and historical conditions. During the 1980s and 1990s, many feminist researchers and those who research aspects of sexuality began to use life-history methods in their studies, in large part because of the ways life histories are able to give expression to hidden or silenced lives. In the 1980s, educational researchers, many of them from the United Kingdom and Canada, began to apply life-history methods to the study of teachers' lives. Throughout the 1980s and 1990s, a small but influential cohort of scholars in the field of education continued to produce life-history accounts of administrators, teachers, and pupils, along with generating important theoretical and methodological texts (Goodson, 2001).

From the late 1980s onward, the influence of postmodern thought had an impact on life-history research across the academic disciplines. On the one hand, the postmodern challenge to the master narrative of objective science made the inherently subjective nature of life history an attractive alternative. On the other, the postmodern notion of plural, fragmented, nonlinear selves created for life historians a crisis of representation – how could researchers ever capture the complexities of the lives they were studying? (Hatch and Wisniewski, 1995). Early in the twenty-first century, a return to modernist definitions of what constitutes science has occurred in the United States and other nations. Based on positivist models used in medical studies, the federal government in the United States has stipulated what is considered to be scientifically based research. As life-history research is not based on experimental methods with large numbers of subjects, double-blind treatment designs, and control groups, its future is under challenge.

Relationships with Other Qualitative Approaches

Life-history research is one of several qualitative research approaches that fit under the larger category of narrative research. Along with life history, narrative research includes such approaches as life-story research, oral history, biography, personal experience methods, and narrative inquiry. As a narrative approach, life history shares the following characteristics that distinguish narrative from other forms of qualitative inquiry:

- Focus on individual stories – understanding individual lives through individual stories is central to the processes and products of life history and narrative research.
- Personal nature of research processes – researchers and participants must work closely together to come to a shared understanding of the participants' stories.

- Practical orientation – because of their goal of capturing real lives as lived, research outcomes make it possible to connect understandings to the everyday world.
- Emphasis on subjectivity – more than other qualitative methodologies, life history and narrative go beyond scientific and empiricist standards, relying on the authentic voices of participants to generate confidence in research findings (Hatch and Wisniewski, 1995).

These characteristics mean that life history and narrative approaches fit within some qualitative research paradigms and not others. Because of their emphasis on subjectivity and co-constructed understandings, life history and narrative do not align with characteristics of the postpositivist research paradigm, which assumes that approximations of reality can be discovered through rigorous data collection and analysis procedures. There is a better fit for life history and narrative within constructivist, critical/feminist, or post-structuralist paradigms, which assume different relationships between researchers and participants, different connections between sociopolitical positionings and research, and different possibilities for representing the complexities of postmodern life. Excellent life-history and narrative research has been done within the assumptions of each of the constructivist, critical/feminist, and post-structuralist paradigms (Hatch, 2002).

Life history is a kind of narrative research, but it is distinct from other narrative approaches. All life histories are narratives; but not all narratives are life histories. All narrative research is focused on collecting individual stories, but what distinguishes life-history work is its broad purpose. Life-history research goes beyond personal accounts and individual interpretations and examines those accounts and interpretations within an array of social, historical, and cultural contexts. While other narrative approaches seek to make meaning of individual experiences, life-history work draws on individual experiences to make sense of broader social phenomena (Cole and Knowles, 2001).

Data Collection and Analysis

Data collection in life-history studies utilizes many of the techniques of anthropological research, including informant interviewing, participant observation, and document and artifact collection. As data need to be collected that allow for individual life stories to be told in social–historical context, data gathering methods that get at both personal biographies and contextual influences need to be employed. Overlap exists between the data-collection techniques that are used to capture the personal and those used to describe the contextual. In the following sections, data for life-history projects are organized into three general types: researcher-generated materials, participant-generated

materials, and other-generated materials (Cole and Knowles, 2001). Data of each type can be used to generate life stories and understand contextual influences.

Researcher-generated materials include data such as interview transcripts, observation field notes, and videotapes or photographs taken by the researcher. Life-history interviews are characterized by reciprocal relations between interviewers and interviewees. Interviewers ask their respondents to tell the stories of their lives and interpret the historical, social, and political contexts in which the stories are embedded. Often, data are collected through a series of open-ended, informal interviews that resemble conversations between friends more than structured interviews between researcher and subject. Later interviews build on previous conversations and other data collection to build contextualized life-history accounts. Interviews are almost always audiotaped and transcribed, and life historians sometimes interview people who are acquainted with or know the contexts surrounding the individuals they are studying as a way to enrich the data of their studies.

Life-history researchers often study lives in context by acting as participant observers in the settings experienced by their informants. By directly experiencing the life circumstances of those being studied, life-history researchers are better able to understand and relate the influence of setting on individual experience. Some researchers shadow their informants in order to make a record of events that make up their daily experience. Participant observers typically take copious notes during the time they are in the settings being observed, then they fill in their notes with details soon after leaving the research scene. Researchers sometimes make video or photographic records as part of their data collection.

Participant-generated materials are a second general type of life-history data. These data include materials such as reflective journals and diaries; time lines; photographs and family albums; and letters, e-mails, and other work-related or personal documents. Journals and diaries can be those that study participants have been keeping on their own, or it might be part of the research design to ask informants to keep reflective records of their experiences. Some researchers (e.g., Goodson, 2001) have participants construct time lines of key events in their lives and use the time lines as a device for facilitating life-history interviews. Photographs that participants have collected or which they have taken as part of the research process can be important data in life-history studies. In addition, participant-generated letters, memos, e-mails, and other documents can be valuable sources of information when trying to construct a contextualized story of a life.

Other-generated materials include documents and artifacts that have a bearing on the individuals or contexts of the study, but are not produced by the researchers or their participants. These data include institutional

records (e.g., memos, reports, agendas, minutes, and press releases), artifacts (e.g., physical objects such as tools or toys that represent something important in the life or context under examination), and historical records (e.g., archives or newspaper records that shed light on individual experience or social contexts). Collecting such data can help fill in spaces in time, trigger memories in participants, and bring coherence to the creation of a life-history report.

Data analysis in life-history research parallels data analysis done in other qualitative research approaches. While it is understood that there is an artistic, intuitive dimension to making sense of the large amounts of data that are typically collected, life historians are careful to insure that their interpretations are grounded in empirical evidence. Like many other qualitative researchers, life-history workers are reluctant to assign formulaic methods to their data analyses. They are more likely to note that each project and data set will lead to different data analysis processes, applying different analytic frameworks. However, no matter what the framework, life-history analysis is focused on making sense of the information the researcher has decided to count as data, including information about the life stories of individuals and the contexts in which the life stories are contained. While many life historians are against rigid analytic schemes, most would agree that data analysis must be based on “systematic and disciplined attention” (Cole and Knowles, 2001: 101).

Wolcott’s (1994) well-known classification of data transformation into description, analysis, and interpretation has been used to distinguish different dimensions in life-history data analysis (Cole and Knowles, 2001). For example, at the descriptive level, researchers may search for data excerpts that allow participants’ direct accounts to tell their own stories. At the analysis level, researchers might look for potential patterns, categories, themes, models, or typologies, then systematically return to the data to confirm or disconfirm their existence. At the interpretive level, researchers construct artfully written life histories, using their data to bring together the stories of individual lives in relation to relevant socio-historical contexts and discipline-based theories. As Wolcott explained, all qualitative research has some elements of each dimension – it’s the proportion of each that changes within individual studies. So it is for life-history data analyses: some emphasize description, some analysis, and some interpretation.

Life-history scholars agree that researchers must be reflective and reflexive throughout the data collection and analysis process, self-consciously keeping track of their own place in generating and making sense of life-history data. Since a life history is always contextual and researchers are part of the context, it is the researchers’ obligation to keep track of their own place in what

happened and to share that information with their readers. Data analysis in life-history research requires researchers to monitor their place in the study’s descriptive, analytic, and interpretive processes. Life-history reports are enriched when researchers are explicit about their data collection and analysis practices and their reasons for using them, including a reflexive exposition of their positioning throughout the research.

Issues in Life-History Research

As with any methodology, scholars from inside and outside the community of scholars doing and writing about it have identified several issues related to life-history research. Some of the most prominent of these issues are discussed next. The nature of the issues chosen for discussion range from modernist concerns for the reliability, validity, and generalizability of life-history reports to postmodernist critiques of life historians’ epistemological and ontological positionings. Here, the effort is not to resolve the issues raised but to identify salient tensions in the field.

As life history is a qualitative research approach that relies on subjective interpretations of individual life stories, critics who operate within the assumptions of the positivist research paradigm argue that life-history reports lack sufficient rigor to be counted as scientifically based research. Such reports are thought to be based on less-than-valid data. These data take form in retrospective and introspective accounts that are perceived to be seriously limited by participants’ abilities to remember and their willingness to provide objective descriptions. The usefulness of life histories is automatically suspect if one assumes that it is unwise to generalize from single subjects to larger populations. Further, as in other qualitative approaches, life-history researchers are the principal data-collection instruments in the research process, and their perceived lack of objectivity is judged by some to be a significant limitation.

Life historians assume the primacy of subjectivity in their studies, but they also have concerns about the place of the author in the production of life-history texts. It is the researcher/author who finally puts the life history into text, and that person’s power in shaping how data are collected and interpreted and how stories are reported is an issue in life-history work. Some argue that the feigned invisibility of authors in telling life stories is a thin facade that distorts the reality of the research process (Fine, 1994). Others call for an open exposition of authorial positionings so that readers can decide for themselves the impact researchers may be having on the life stories being told (Tierney, 1998). Still others have challenged life historians’ ability to translate lives as lived into lives as text. They see the complexities involved in attempting to

represent others as coherent unitary selves as very difficult to overcome (Munro, 1998). Based on the thinking of Derrida (1972), Denzin (1989) explains, "there is no clear window into the inner life of a person, for any window is always filtered through the glaze of language, signs, and the processes of signification" (p. 29). The attending crisis of representation continues to be an issue in life-history research.

Another issue is tied to the risks involved for participants because of close relationships developed between themselves and researchers as life-history research is undertaken. Because of the necessity of close proximity and the advantages of sharing sensitive information, life-history work has been called "licensed voyeurism" (Mearor and Sykes, 1992: 209). Researchers ask their participants to share the intimate details of their lives, and the more intimate the information, the more risk is assumed by the sharer of that information. The obvious concern is that life-history takers will exploit their participants to serve the researchers' own ends.

Another layer of exploitation is identified by postmodern theorists as an additional issue in life-history research. Some scholars have argued that life-history work has the potential to disempower those who have been silenced historically and who appear to be given voice through participation in life-history projects. Tierney (1998) has characterized life-history work that objectifies participants as examples of particular groups as neocolonialist, essentially serving to reinscribe traditional notions of power. Denzin (1992) goes even farther, arguing that some researchers are agents of the modernist surveillance state, collecting life histories as information that keeps the myth of autonomous individualism alive.

Finally, some postmodern thinkers have challenged the metaphysical assumptions on which life-history work has been grounded. Cary (1999) points out that life history's reliance on contextualized and collaboratively constructed stories represents a turn toward a realist ontology that seeks truth through reliance on method. She argues that the need for rigor through contextualization and collaboration reaffirms realist assumptions and thereby contradicts postmodern understandings about what is knowable and ways to do research. Along with Lather (1996), Cary chides life historians for their failure to problematize the desire for totality that continues to frame their research.

Summary

Life history has a long history as an important research method in the social sciences. Its focus on contextualized life stories places life-history research in a unique position to provide important insights into the experience of

social phenomena through the eyes of individual social actors. Utilizing data collection and analysis methods adapted from other qualitative approaches, high-quality life-history work generates artistic portrayals of real-life experience that are grounded in carefully collected empirical evidence. Like other qualitative research methodologies early in the twenty-first century, life history faces challenges from both sides of the modernist/postmodernist divide, and its future is difficult to predict.

Emergence of Narrative Inquiry on the Research Landscape

Narrative inquiry is a ubiquitous practice in that,

Human beings have lived out and told stories about that living for as long as we could talk. And then we have talked about the stories we tell for almost as long. These lived and told stories and the talk about the stories are one of the ways that we fill our world with meaning and enlist one another's assistance in building lives and communities. What feels new is the emergence of narrative methodologies in the field of social science research

(Clandinin and Rosiek, 2007: 35).

Given this newness, it is important to define terms and how they are lived out in data collection and analysis within the emerging field of narrative inquiry. This is the focus of this article.

Terms and Definitions

Even though Reissman and Speedy (2007) point out that "narrative inquiry in the human sciences is a 20th century development; the field has 'realist', 'postmodern', and constructionist strands, and scholars and practitioners disagree on origin and precise definition" (p. 429), there is some agreement on the following definition:

People shape their daily lives by stories of who they and others are and as they interpret their past in terms of these stories. Story, in the current idiom, is a portal through which a person enters the world and by which their experience of the world is interpreted and made personally meaningful. Narrative inquiry, the study of experience as story, then, is first and foremost a way of thinking about experience. Narrative inquiry as a methodology entails a view of the phenomenon. To use narrative inquiry methodology is to adopt a particular view of experience as phenomenon under study

(Connelly and Clandinin, 2006: 375).

Commonplaces of Narrative Inquiry

Narrative inquiry is a way of understanding and inquiring into experience through "collaboration between researcher and participants, over time, in a place or series of places,

and in social interaction with milieus" (Clandinin and Connelly, 2000: 20). Three commonplaces of narrative inquiry – temporality, sociality, and place – specify dimensions of an inquiry and serve as a conceptual framework. Commonplaces are dimensions which need to be simultaneously explored in undertaking a narrative inquiry. Attending to experience through inquiry into all three commonplaces is, in part, what distinguishes narrative inquiry from other methodologies. Through attending to the commonplaces, narrative inquirers are able to study the complexity of the relational composition of people's lived experiences both inside and outside of an inquiry and, as well, imagine the future possibilities of these lives.

Temporality

"Events under study are in temporal transition" (Connelly and Clandinin, 2006: 479). Directing attention temporally points inquirers toward the past, present, and future of people, places, things, and events under study. The importance of temporality in narrative inquiry comes from philosophical views of experience where the "formal quality of experience through time is [seen as] inherently narrative" (Crites, 1971: 291). Drawing on philosophers such as Carr (1986) who shows that "we are composing and constantly revising our autobiographies as we go along" (p. 76), narrative inquirers need to attend to the temporality of their own and participants' lives, as well as to the temporality of places, things, and events.

Sociality

Narrative inquirers attend to both personal conditions and, simultaneously, to social conditions. By personal conditions, "we mean the feelings, hopes, desires, aesthetic reactions and moral dispositions" (Connelly and Clandinin, 2006: 480) of the inquirer and participants. Social conditions refer to the milieu, the conditions under which people's experiences and events are unfolding. These social conditions are understood, in part, in terms of cultural, social, institutional, and linguistic narratives. A second dimension of the sociality commonplace directs attention to the inquiry relationship between researchers' and participants' lives. Narrative inquirers cannot subtract themselves from the inquiry relationship.

Place

Connelly and Clandinin (2006) define place as "the specific concrete, physical and topological boundaries of

place or sequences of places where the inquiry and events take place” (p. 480). The key to this commonplace is recognizing that “all events take place some place” (p. 481). Indeed, for narrative inquirers such as Marmon Silko (1996), our identities are inextricably linked with our experiences in a particular place or in places and with the stories we tell of these experiences.

Possible Starting Places for Narrative Inquiries

While most narrative inquiries begin with telling stories, that is, with a researcher interviewing or having conversations with participants who tell stories of their experiences, “a more difficult, time-consuming, intensive, and yet, more profound method is to begin with participants’ living because in the end, narrative inquiry is about life and living” (Connelly and Clandinin, 2006: 478). Furthermore, from either starting point, narrative inquirers situate themselves in more or less relational ways with their participants. Some narrative inquirers see themselves and their participants as co-composing each aspect of the inquiry as well as their lives as they live out the inquiry. Other narrative inquirers see themselves and their participants at more of a distance, and acknowledge the relational aspects as less important. We discuss a special form of narrative inquiry, autobiographical narrative inquiry, in a separate section.

Within each section, we outline ways of analyzing field texts. These ways of analyzing are framed by thinking narratively, that is, by inquiring within the three commonplaces: temporality, sociality, and place.

Beginning with telling stories

Most narrative inquiries begin with asking participants to tell their stories, either in one-to-one situations or in groups. In one-to-one situations, participants are asked to tell their stories in a variety of ways: by responding to more or less structured interview questions; by engaging in conversation or dialog; by telling stories triggered by various artifacts such as photographs or memory-box items. In group situations, two or more participants meet together with the inquirer to tell stories of their experience when they have lived through similar situations. Texts are created from the told stories and these texts are analyzed using different analytic frames. Chase (2005) identified five diverse approaches for analyzing told stories: a psychosocial developmental approach; an identity approach with a focus on how people construct themselves within institutional, cultural, and discursive contexts; a sociological approach with a focus on specific aspects of people’s lives; a narrative ethnographic approach; and an autoethnographic approach. While Chase’s approaches do not have clear borders distinguishing one approach from

another, they give a sense of the diversity of approaches used in analyzing texts when the starting point is telling stories.

Beginning with living stories

As noted above, some narrative inquiries also begin with participants’ living stories although telling or told stories also take their place within such studies. Craig and Huber (2007) summarize the tensions within narrative inquiries undertaken from this starting point. Others such as Bach (2007) using participants’ photographs of their unfolding lives and Nelson (2008) highlighting change in participants’ lives through engaging in narrative inquiry also begin with living stories. Analysis and interpretation of living stories use some of the same approaches as narrative inquiry beginning with telling stories although tensions, bumping places, and temporal threads are more commonly used as analytic tools.

Autobiographical Narrative Inquiry

Autobiographical narrative inquiry is a special form of narrative inquiry and is closely linked to autoethnography. Understanding life as narrative led Bruner (2004) to posit that “the stories we tell about our lives ... [are] our ‘autobiographies’” (p. 691). Yet, narrative inquirers understand that telling stories is not an untethered process. How people tell their stories and what their stories tell is shaped by “cultural conventions and language usage ... [and] reflect the prevailing theories about ‘possible lives’ that are part of one’s culture” (p. 694). Audience also shapes autobiographical narrative inquiry. Who the characters are in people’s stories, the plotlines people choose to tell, and the audiences to whom they tell, all influence autobiographical narrative inquiry. As Freeman (2007) writes about autobiographical narrative inquiry, “the interpretation and writing of the personal past ... is ... a product of the present and the interests, needs, and wishes that attend it. This present, however – along with the self whose present it is – is itself transformed in and through the process” (pp. 137 and 138). These ideas, highlighted in autobiographical narrative inquiry, are also present in narrative inquiries undertaken with others but are often less visible.

Research Design Considerations

Whether a narrative inquiry begins with telling or living stories and is more or less relational, there are generally agreed-upon considerations in designing narrative inquiries. A more detailed description of these considerations is found in Connelly and Clandinin (2006) and Clandinin *et al.* (2007). We outline the most salient design considerations in what follows.

Justification

In narrative inquiry it is important to think about justifying the research in three different ways.

Personal justification

Narrative inquirers begin with personal justification, that is, by justifying the inquiry in the context of their own life experiences, tensions, and personal-inquiry puzzles. Personal justification is commonly only thinly described in published narrative inquiries. Narrative theses and dissertations include more detailed personal justification for the inquiry.

Practical justification

In order to justify narrative inquiry practically, researchers attend to the importance of considering the possibility of shifting or changing practice. For example, practical justifications are sometimes made in narrative inquiries around teacher-education puzzles concerning the kinds of situations in which preservice students might undertake practicum, deepening their understandings of who they are in relation with children and families or in medical education around puzzles concerning the conditions under which medical residents engage in reflecting on their clinical practice.

Social justification

Narrative inquiries are socially justified in terms of addressing the so-what and who-cares questions important in all research undertakings. We can think of social justification in two ways: theoretical justification as well as social action and policy justifications. Theoretical justification comes from justifying the work in terms of new methodological and disciplinary knowledge. Social action or policy justification comes in terms of social action such as making visible the intergenerational impact of residential schools on Aboriginal youth.

Naming the Phenomenon

Thinking narratively about the phenomenon throughout the inquiry

Thinking narratively about a phenomenon, key to undertaking narrative inquiries, entails thinking within the three commonplaces of narrative inquiry – temporality, sociality, and place. Thinking narratively about the phenomenon is necessary throughout the inquiry from framing the research puzzle, to being in the field, to composing field texts, and finally, to composing research texts. For example, as Paley (1997) thinks narratively about children's experiences in preschool settings she attends to social, cultural, and institutional narratives in which particular children's lives unfold. Thinking in this way, Paley

attends to the particularities of the places in which each child lives and goes to school, to each child's particular interactions and relationships and how each child responds in particular esthetic, emotional, and moral ways. Thinking in this way highlights the shifting, changing, personal, and social nature of the phenomenon under study. Thinking narratively about a phenomenon challenges the dominant story of phenomenon as fixed and unchanging throughout an inquiry. Thinking narratively also influences the living of a narrative inquiry. Many narrative inquirers draw on ideas such as self-facing, liminality, relational knowing, world-traveling, truth as communal, and unknown and not-knowing to describe their own and their participants' living throughout an inquiry.

Framing a research puzzle

Framing a research puzzle is part of the process of thinking narratively. Each narrative inquiry is composed around a particular wonder and, rather than thinking about framing a research question with a precise definition or expectation of an answer, narrative inquirers frame a research puzzle that carries with it "a sense of a search, a 're-search', a searching again", "a sense of continual reformulation" (Clandinin and Connelly, 2000: 124).

Living the Narrative Inquiry

Narrative inquiry is a process of entering into lives in the midst of each participant's and each inquirer's life. What this draws attention to is the importance of acknowledging the ongoing temporality of experience when it is understood narratively. Narrative inquiry always begins in the midst of ongoing experiences. In this process, inquirers continue to live their stories, even as they tell stories of their experiences over time. Inquiries conclude still in the midst of living and telling, reliving and retelling, the stories of the experiences that make up narrative inquirers' and participants' lives, both individual and social. The process of narrative inquiry is described as a recursive process of being in the field, composing field texts, drafting and sharing interim research texts, and composing research texts.

From field to field texts

Living in the midst of stories in the field is not an easy undertaking. The field can be the ongoing conversations with participants where they tell their stories or the living alongside participants in a particular place or places. Being in the field, then, involves settling into the temporal unfolding of lives. Sarris (1993) notes that stories are often not shared in "chronological sequence" (p. 1) and hooks (1997) explains that people's lived and told stories are not linear – they do not necessarily "move from point A to

point B". These narrative qualities of lived and told stories arise from the temporal nature of experience in which people are simultaneously participants in and tellers of their life stories (Carr, 1986).

There are multiple ways to gather, compose, and create field texts (data) from studying the experiences of participants and inquirers in a narrative inquiry. Field texts can include transcripts of conversations, field notes, family stories, memory-box artifacts, photographs, and other texts that are composed by narrative inquirers and participants to represent aspects of lived experience. Whether narrative inquirers are listening to participants' told stories or living alongside participants as their lives unfold in particular contexts, interpretation of the stories lived and told is an essential, ongoing aspect. Being attentive to the relational aspects of working with participants within the conceptual frame of the commonplaces requires that narrative inquirers and participants acknowledge that they are always interpreting their pasts from their present vantage points. In this way, narrative inquirers actively attend to and listen to participants' stories knowing that they "give shape to what . . . [they] hear, mak[ing] over . . . [participants'] stories into something of . . . [their] own" (Coles, 1989: 19).

From field texts to interim research texts

"Dissection is an essential part of scientific method, and it is particularly tempting to disassemble" (Bateson, 1989: 10) people's experience when narrative inquirers leave the field and begin analysis and interpretation at a distance from participants. Narrative inquirers work to resist this temptation. The movement from composing field texts to composing interim research texts is a time marked by tension and uncertainty for narrative inquirers. While some interpretations are always underway as the inquiry continues to be lived out with participants in the field, at some point there is a move away from the close intensive contact with participants. Given the quantity of field texts from interview and conversation transcripts and possibly artifacts, documents, photographs, and field notes, all composed with attention to temporality, sociality, and place, beginning the analysis and interpretation by drafting interim research texts allows narrative inquirers to continue to engage in relational ways with participants. In composing interim research texts, narrative inquirers continue to think narratively, that is, positioning field texts within the commonplaces. Interim research texts are often partial texts that are not closed to allowing participants and researchers to further co-compose storied interpretations open to negotiation of a multiplicity of possible meanings. Bringing back interim research texts to further engage in negotiation with participants around unfolding threads of experience is central in composing research texts. The dialog with participants around interim research texts can lead the inquirer back for more intensive work with the participant if further field texts are

needed in order to compose a more complex account of the participants' experiences.

From interim research texts to research texts

Mishler, in conversation with Clandinin and Murphy (2007) and reflecting on the enormous quantity of field texts that narrative inquirers compose with participants, notes that what becomes shared in research texts is usually only a small portion of the overall data. Mishler encourages narrative inquirers to make visible in their research texts the process by which they chose to foreground particular stories. As earlier described, there are multiple approaches to analyzing field texts. However, as Gergen (2003) cautions, an "analytical method of deconstructing stories into coded piles" could undermine "the aims of the research" (p. 272) by directing attention away from thinking narratively about experience.

Working with metaphors, creating visual and textual collages, found poetry, word images, and photographs, narrative inquirers create research texts that show the complex and multilayered storied nature of experience. In this way, they create research texts that represent the complexity of people's lives and experiences.

Ongoing negotiation with participants allows narrative inquirers to create research texts that both critically and deeply represent narrative inquirers' and participants' experiences while also maintaining each person's integrity and their relationship into the future. When, for example, a narrative inquiry shows the bumping up of participants' lives (and narrative inquirers' lives) with dominant cultural and institutional narratives, various ways of working with fictionalization in research texts can enable these stories to be told without harming participants' lives or the relationships composed by narrative inquirers and participants. Signature and voice both shape research texts. It is important that the voice of the inquirer does not write over the voices of participants in the final research texts by using an overly dominant researcher signature.

Positioning

In relation to other research

Some forms of qualitative research focus on a search for common themes across participants' stories or use participants' stories to develop or confirm existing taxonomies or conceptual systems. As narrative inquirers attend to individual's lives as they are composed over time in relation with people and situations in a particular place or places, the focus remains on lives as lived and told throughout the inquiry. The knowledge developed from narrative inquiries is textured by particularity and incompleteness – knowledge that leads less to generalizations and certainties

(Clandinin and Murphy, 2007) and more toward wondering about and imagining alternative possibilities.

In relation to research undertaken from differing epistemological and ontological assumptions

Working from a metaphor of borderlands between narrative inquiry and research undertaken from other epistemological and ontological assumptions, such as those underlying postpositivism, poststructuralism, and Marxism, Clandinin and Rosiek (2007) delineated ways in which narrative inquirers work from different assumptions. Beginning with ways experience is often viewed differently by narrative inquirers and researchers of other methodologies, Clandinin and Rosiek trace how a Deweyian view, in which experience “is understood as the continuous interaction of human thought with our personal, social, and material environment” (p. 39), shapes “the kinds of questions asked and methods employed” (p. 43) across methodologies. This understanding of experience also shapes ways in which the inquiry is both lived through and subsequently shared with a broader audience. Differences in views of reality, knowledge developed from an inquiry, the relationship between experience and context, and the relationship between researchers and participants all shape borders. Clandinin and Rosiek encourage narrative inquirers to understand and to learn from differing epistemological and ontological assumptions so as to strengthen the future of narrative research.

Ethical Considerations

Narrative inquirers comply with the legal and procedural aspects of ethics held by institutional research boards. However, because of the relational aspects of narrative inquiries, ethical considerations are of prime importance throughout the inquiry. Lieblich urges narrative inquirers to move beyond the institutional narrative of do no harm by learning an attitude of empathic listening, by not being judgmental and by suspending their disbelief (Clandinin and Murphy, 2007: 647) as they attend to participants’ stories.

Often woven deeply by “fidelity to relationships” (Noddings, 1986), the ethical considerations in narrative inquiries are commonly thought about as responsibilities negotiated by participants and narrative inquirers at all phases of the inquiry (Clandinin and Connelly, 2000). These relational responsibilities are increasingly understood as long term, that is, as attentive to participants’ and narrative inquirers’ lives both as the inquiry is undertaken and research texts are written and, also as their lives continue to unfold into the future (Huber *et al.*, 2006).

The relational aspects of narrative inquiries compel narrative inquirers to pay attention to particular ethical matters as research texts are written. Narrative inquirers understand that a person’s lived and told stories are who

they are and who they are becoming and that these stories sustain them. This understanding shapes the necessity of negotiating research texts that respectfully represent participants’ lived and told stories.

Negotiating research texts creates a space where participants’ narrative authority is honored. Issues of anonymity and confidentiality take on added importance as the complexity of lives are made visible in research texts. Strategies such as fictionalizing and blurring identities and places are often used. Narrative-inquiry research texts often call forward increased attentiveness to ethical matters.

Issues in Representation

As noted earlier, voice and signature are key considerations in composing research texts. There are a range of possible narrative forms. However, it is important to attend to forms that fit the lives of the participants and narrative inquirers being represented. Sometimes, particular metaphors or genres become apparent in the field texts and are used in representational forms in final research texts. However, these cannot be imposed on the field texts *a priori*. It is often helpful for narrative inquirers to participate in response communities where, alongside narrative inquirers as well as researchers from differing methodological backgrounds, they share and respond to one another’s thinking or writing in progress in ways that are attentive to the lives being represented.

Issues of audience are also important. Narrative inquirers need to be attentive to the features of the discourse communities where research texts are shared so that the lives represented are respected. Given that narrative inquiry is a new methodology, some audiences are unfamiliar with criteria to judge and respond to narrative-inquiry research texts. Criteria for judging narrative inquiries follow from the definition of narrative inquiry and the conceptual frame for thinking narratively.

Change Dimension in Narrative Research Living, Telling, Retelling, and Reliving Stories

Narrative inquirers see change as part of the process of narrative inquiry. Linking back to personal, practical, and social justification, change is seen as possibly occurring in multiple dimensions. Through engaging with participants, narrative inquirers see themselves and participants as each retelling their own stories, and as coming to changed identities and practices through this inquiry process. Change also occurs as phenomena under study are understood in new ways and, in this way, new theoretical understandings emerge. In this midst, much possibility exists for social change, that is, for the creation of shifted social, cultural, institutional, and linguistic narratives.

Glossary

Action research – A research methodology increasingly popular with professionals, in all walks of life, who engage in researching their own practice in the workplace in order to improve the quality of professional understanding, judgment, decision making, and action. More broadly, it can be employed by anyone in any context as a strategy to stimulate change and a sense of empowerment and emancipation from the limitations imposed by current conditions on action.

Intentionality – In phenomenology, this term refers to the directedness of acts of consciousness. Whether thinking, dreaming, desiring, touching, or, otherwise, sensing something, there are states of mind that seem to point toward – or focus on – an object, qualities of things, states of affairs, or events. This feature of intentionality is useful in developing analyses of people's talk concerning their life-worlds and how they relate to people, objects, states of affairs, locations, and the production of events. It is particularly useful in analyzing the typical relationships that obtain between actors in terms of intentional networks.

Intertextuality – Texts do not exist in isolation from other texts. The meaning of a given text takes on further meanings as it is placed into relation with other texts. In this way, meanings are loosened from the author's or speaker's intentions as a particular text takes on meanings derived from other texts. For example, a teacher may talk about the need to discipline a child for his/her own good. In the context of other texts that discourse on the essential sinfulness, or dangerous instincts of human beings, or indeed the sexual connotations of discipline, the original context of talking about disciplining a child in school may take on darker meanings in relation to the broad range of texts in which the term discipline is used. Every text exists in relation to every other text and, in that sense, is intertextual. Text – in its broadest sense – does not just refer to the written word but to any sign, symbol, gesture, or mark that, in some way, can be made to mean something to people. In this way, everyday life is fundamentally intertextual where each meaningful sign relates to and takes on different meanings and a range of possible

interpretable across a range of different contexts. Kristeva coined this term.

Phenomenology – Broadly, in philosophy, this refers to the appearance of phenomena to consciousness. The phenomenological philosophy that influenced Schutz's sociological phenomenology derived from Husserl. Husserl made a distinction between the "natural attitude" of everyday life and the philosophical attitude that is employed to suspend any position for or against the truth or falsity of what is said to be known and real. It is this distinction that Schutz employed in developing his view of the sociological implications of Husserl's phenomenology. Where Husserl developed the philosophical methodology focusing upon the domain that arose following the suspension of belief – or epoché, as Husserl called it – Schutz developed the sociological domain where belief is not systematically suspended but rather is taken for granted as being true for all practical purposes. This focus on the practicality or pragmatism of peoples' typical attitude toward states of affairs in everyday life also drew upon the pragmatism, in particular, of William James and George Herbert Mead and, thus, has much in common with the later developments of symbolic interactionism. In the study of psychological, social, cultural, and political developments in phenomenology has drawn from a multitude of influences – Marxism, psychoanalysis, existentialism, and Hegelian phenomenology among many others.

Triangulation – On a map, a position can be defined by correlating – or triangulating – its latitude and longitude or its position in a grid. Metaphorically, the validity, objectivity, and, indeed, reliability of an observation, and object, a category, a meaning, a state of affairs, or an event is increasingly established through correlating – or cross-checking – a multiplicity of viewpoints directed toward it over time and across contexts. What looks like a street of houses at first sight, might – on further inspection – turn out to be simply a facade constructed for a film set. By walking up to the facade, trying the doors, walking around the back of it, talking with people working at the site, and so on, its nature can be assessed. To come to an appropriate judgment with regard to the validity of the street, more than one

method and more than one perspective had to be employed. In social settings, participant observers can talk with – or, more formally, interview – a range of people, in order to see whether they share understandings about given phenomena. These understandings can then be compared with what is seen during observations where the phenomena described in the interviews are supposed to occur. The more agreements there are between different methods and viewpoints on social phenomena, the stronger the triangulation.

Participant observation claims a special access to insights and understandings concerning the lives of individuals, groups, communities, and peoples. Evolving from the writings of adventurers and missionaries and, later, the early anthropologists, it was adopted by sociologists who wanted to explore the meanings and experiences of people rather than measuring and counting (deWalt and deWalt, 2002). At present, participant observation is employed in any research, methodological perspective, or discipline in order to gain insight into the lives of others. In many ways, it is more than a method for the production of knowledge, understanding, and theory. It is a way of life which – for some – may last a lifetime.

According to Spradley (1980: 58–62), there are different degrees of participation – complete, active, moderate, passive, and nonparticipation. As a passive participant, the observer is present but not engaged – more a bystander looking at a scene of action rather than being part of it. Rather than merely hanging around, loitering, or being a bystander, one can then try to act like the members by moving on from the stage of recording what went on to actually joining in – but not enough to be acceptable as a member. Going further than this involves entering the world of the other as an accepted member – like Whyte (1943) when he joined Doc's gang in Cornerville. However, to be a complete participant observer, Doc would already have had to be a gang member who decided to undertake research while participating. The parallel would be, say, a teacher who decides to research the classroom – perhaps, focusing on their own practice in order to improve it as in Action Research.

In each case, participant observation involves being with others – whether living with people far from home whose language, customs, or behaviors are not known, as did Malinowski in his study of the Trobriand Islanders, or, perhaps, like Whyte (1943), where the participant observer goes to live a slum area, or join a criminal gang or study power elites. In these cases, there is a clear demarcation line between my home and their home, my way of life and their way of life, and where I go to visit strangers with the object of becoming familiar with their way of life, their

view of the world. The demarcation becomes less obvious when what is observed is already a part of the researcher's everyday life as, for example, in observing what happens in one's life, one's own community – say in a school or in one's own place of work (as in action research) and the virtual worlds of globalized communications technologies. Whenever, wherever, and however people interact, share experiences, and, in some way, organize their lives in relation to each other, it becomes a possible focus for the participant observer. Understanding the nature and process of being a participant observer begins only at the moment of joining.

Joining

To know the world of others – to understand a particular group – involves joining them in some way, being with people in their everyday locations and activities, and learning how to do what they do in the ways that they do it in the locations where they do it. Joining with, witnessing what happens, and acting alongside others makes participant observation more than just a method or technique for data collection. The participant observer is part of the data itself – that is, responsible for how this data is to be represented, analyzed, interpreted, and used, as in this example from a narrative account of fieldwork by Schostak (1980):

Entering the tutor room, a chemistry laboratory, under the gaze of Jacko's mates, I feel inverted – watched, examined. Where shall I sit?

Carol, a girl I know, smiles, invites me to Jacko's group.

The tutor, a teacher I know well enters. He ignores me.

"Jacko. All of you, come and sit at the front."

No one moves. I feel uneasy.

"Come on now!"

"But there's gas taps at that table."

"I don't care, I've told you to sit down here. Now do it."

Carol moves, the rest follow and I am last.

After the formalities of the tutor period – registration, reading a pupil news letter – the teacher approaches smiling. "So you're following Crawley around today?"

"Yes," I turn away as best I can.

"Good luck," the teacher retreats to the doorway where for the remaining time he blocks the escape of three girls who push against him.

Being there and living it, the researcher is a direct participant. It is an approach owing much to the sociologists who, during the first-half of the twentieth century, became known as the Chicago School. Their attention was on the city as a natural laboratory of human behavior (Park and Burgess, 1925). For example, Thomas studied the communities of Polish immigrants (1918) – and, Whyte, the Italian community (1943) – as the natural

areas produced by human habitation and use. In any city, there are many such areas, such as the business district, the Red Light area, or the territories of particular gangs, as well as the secluded areas of the wealthy. In each case, the initial concern is to gain entrance. This, typically, involves finding a gatekeeper— that is, someone whose knowledge and authority can ease the passage into the world of others by hanging around sufficient times in a place where the target group tends to meet until someone begins a conversation. Such gatekeepers are easier to identify and contact in formal organizations – for example, the headteacher or principal of a school, the leader of a youth group or sports team, the head of a committee or director of a business. In other circumstances, greater secrecy may be vital as in the study of a criminal gang. To openly identify oneself might cost one's life, or, at least, physical health. Whether open or covert, participant observation requires developing strategies for meeting, joining, and engaging with others in their everyday scenes of action.

Ethics, *Dramatis Personae*, Locations, and Scenes of Action

Joining with others means getting to know the members of scenes of action – the *dramatis personae* – getting to know their values, their reasons for action, and their ways of acting. For example, being with Jacko meant going where he went, meeting other people along the way – pupils and teachers – and, when engaging with these others, reflecting ethically on the decisions concerning what to say, how to act, and what and how to record. Observing Jacko's (A) actions toward his mates (C, D, and E) and say a teacher (B) as they approach or keep their distance, patterns can be observed and noted (Figure 1).

Each individual acts in some way toward another – whether in friendship, hostility, or authority. In phenomenology, this directedness toward another is called an

intentional relation. The diagram, thus, describes an intentional network (Schostak, 2002) of people as they repeatedly engage with each other. In Figure 1, Jacko's (A) attention is directed, in various ways, toward B, C, D, and E. B also has a particular relationship of mediation with G (say, a senior teacher, a parent, or a police officer, or a rival gang leader). This mediation may play out in events such as B telling G about A or misleading G about A's real intentions. Or, instead of people, the focus could be upon valued object B that A and G both desire hence leading to a conflict of interest and thus contributing to a study of the ways in which such conflicts are handled. The participant observer becomes a part of this structure, say G, as participants recognize and trust the researcher and as a valid part of the scene able to apply the ethics of the participants – that is, what is right, good, fair in their eyes.

Following Jacko throughout a particular day was part of a larger study of a school and its community (Schostak, 1983). The ethical principles for the conduct of the project had to be agreed. To do this, the participants needed to have an idea of the purposes of the project, what it involved and how data was going to be used. They needed to be assured that they could not be identified and that what they said and did would be treated confidentially so that others could not use the information to harm them. Such principles can be seen more formally in the guidelines provided by discipline-based organizations such as the American Educational Research Association or the British Sociological Association. Indeed, particular organizations – such as hospitals and universities – typically, have their own ethics committees that oversee research involving their institutions. In practice – for each organization – ethical protocols need to be tailored for the specific circumstances of projects. With a formal organization such as a school, general principles may be agreed in writing with its governing committee. Letters describing the research and assuring confidentiality and the anonymity of names in the use of data will be sent to parents as a basis for agreement to be involved in the research. Participants may be asked to sign letters that confirm their understanding of and agreement to the conditions of participation. However, ethical practice is not simply reducible to – nor does it stop with – satisfying the formal ethical procedures of committees.

The different circumstances of each meeting continually pose ethical issues. Not all of the people – the *dramatis personae* – involved in a given scene of action in the various locations of the project may be aware of the status of the participant observer as researcher rather than as an ordinary member of the scene. Indeed, Hilbert (1980) argues that there is always a degree of covertness in research, as aspects of the researcher's biography and later uses of the data remain obscure in the eyes of participants – whether through lack of understanding, familiarity with academic discourse, or disinterest. In the extreme circumstance of

Figure 1 Intentional networks.

joining a gang, or being a football hooligan, it may be argued that not only may acts be seen that are criminal, but also, to gain trust as a *bona fide* member, illegal acts may have to be committed requiring a rethinking of what it means to act ethically (Ferdinand *et al.*, 2007). Without trust, no access to the world of the members would be granted, thus no research into their life-world is possible.

The researcher needs to demonstrate a commitment to the reality of those being observed, however they define this reality as being true, natural, or right – it is what Quine (1948/1949) would call an ontological commitment. Commitment to what there is in the world is revealed through people's vocabulary, ways of talking, ways of justifying beliefs and actions, as well as in carrying out the kinds of acts expected of members. In this way, a shared sense of reality is constructed that acts as the natural, taken-for-granted, familiar basis for undertaking social action. Typically, when this familiar world of shared ontological commitments is disturbed, its constructed features are revealed.

The Familiar and the Strange

Schutz (1964) described how being a stranger sensitizes the researcher to practices, knowledge, beliefs, and values that participants take for granted as being true, real, or right. In learning how to belong – to be a part of a scene of action – a distinction between two worlds is posed: that of the stranger and that of the members of a given group or society that the stranger attempts to enter. Participant observers, similar to strangers, can take nothing for granted – a standpoint paralleling the phenomenological attitude of suspending any position for or against the truth and reality of the world. Presupposed by this phenomenological attitude is a domain of taken-for-grantedness – or paramount reality that is placed in suspension and becomes the focus for the sociological phenomenology of Schutz. As with the symbolic interactionism (Mead, 1934; Blumer, 1969) of the Chicago School, to understand the everyday worlds of people and learn the meanings that actors gave to actions, objects, and the scenes of action in their everyday lives, participant observation was a natural strategy. For symbolic interactionists, it is not enough simply to observe behavior. Behavior has a symbolic dimension. Its meaning to an actor and its relevance to a social situation cannot be known without asking the actor(s) involved. The focus of the symbolic interactionist, then, is upon the symbolic nature of the actions and interactions of people who engage with each other in social settings. Mead (1934) is considered the father of symbolic interactionism, although the name was coined by Blumer (1969).

Being a participant observer, however covertly, heightens awareness of the artificiality or socially constructed nature of the ways in which people behave in everyday life.

Whether standing in bus queues, waiting at hotel reception desks, or relaxing at home – what are the regular behaviors that occur? Why do they occur in that way? Could they be changed as in changing the rules of chess? Garfinkel (1967) demonstrated the fragile nature of social rules in his experiments where, for example, a student might go home and act like a stranger, thus transgressing the tacit rules of normal behavior – often, leading to angry reactions by family members. Less dramatically, when participating in Jacko's activities during the school day, the researcher – as a 32-year old – could not pass as a 14-year-old pupil. What becomes noticeable then, are the moves of inclusion as well as those of exclusion made by different members of the *dramatis personae* in the classroom, in the corridors, and out in the playground. Although Jacko had given permission to be followed, he always placed a distance between himself, his friends, and the researcher, although others invited the researcher to join them. Through such a process of seeking permissions, invitations to join, or distancing and excluding, social space becomes dynamically organized as boundaries between who is in, who is out, who is close, and who is distant. This negotiation of boundaries also took place between the researcher and the teachers and the placing of boundaries varied according to circumstances. Thus, the physical reality of streets, houses, and parks are continually mapped and remapped by the ways in which individuals project and negotiate boundaries around them over time. To see it requires distinguishing between “the scene of action, the human picture of that scene, and the human response to that picture working itself out upon the scene of action. It is like a play suggested to the actors by their own experience, in which the plot is transacted in the real lives of the actors, and not merely in their stage parts” (Lippmann, 1922). In this early statement can be seen the seeds of studying social action like a performance on a stage where the analysis of performance, talk and narrative structure, and a focus on biography becomes important rather than static descriptions of states of affairs (Schostak, 2006).

The projection of a world and its boundaries is most obvious when there is a sense of disjunction or clash between alternative perceptions. This can be seen in the following transcript extract from an action research project involving creative practitioners (artists of various kinds), teachers, and pupils (funded by CapeUK Creative Partnerships for Education (CAPE) 2004–05; see also Schostak and Schostak, (2008: 48–50)). The focus was on making representations of local communities – both real and imagined. The pupils – aged about 10 years – had just watched a video that had been made of their area:

Boy: . . . if you looked at the surroundings they were like, you know ‘oh I wouldn’t like to live there’. Cos if you looked at all the houses they were all boarded up and, all

the graffiti and smashed bottles (. . .)

JFS: So would you have done a different story, you know for (place name)?

Boy: yeah.

JFS: What would you have shown?

Boy: Well I'd have shown the good bits, like the park and . . . (laugh) hmmm, there's a point.

Girl: The good parks, the local parks are all trashed up so we don't get anywhere to play.

Immediately there is a clash between the picture in the head and the picture on the video. There are also the explicit and implicit viewpoints of the *dramatis personae*: the boy, the girl, the creative practitioners, the teachers, and the unnamed people who trashed the parks. The participant observer can elaborate the multiple pictures in the head by meeting, observing, and talking to representatives of the different viewpoints. How these viewpoints relate to each other can be represented as intentional networks in **Figure 2** where the children are represented by group C who are able – through their reflection on their community – to imagine alternative visions of community that are, perhaps, seen to be enjoyed by group B. The depressing reality experienced by group B is represented by the trashed parks. However, group B never enter the children's location. For them, it is – for all practical purposes – invisible.

The central bar symbolizes a boundary dividing the two groups – B and C – and thus two ways of projecting a picture of the world. By participating in each group, the

researcher A is able to build up pictures (a_1 , a_2) of how each constructs their ways of seeing the world with their different ontological commitments: whether the hard-and-fast realities of the social organization of gang territories or the views and fears of locals residents who want to freely walk the streets, or the police and other figures of social and political authority who have quite different conception of how the world should be organized. If group B represents the dominant voice in the social, political, and economic organization of society, it will see itself as exemplars of good order. The boundary that delimits their picture of the world acts like a mirror reflecting back their own values (represented by the double arrow in the diagram). For B, C is rendered marginal at best – perhaps an underclass – invisible at worst.

Rendering the invisible visible means transgressing the bar between the dominant and the powerless. The role of the participant observer is already transgressive. Between these multiple camps, the participant observers are always, to a degree, out of place because they are always between worlds. The danger is in slipping into a position of authority granted by some superior insight into what are the right ways of seeing.

Fieldwork as a Basis for Validity, Generalization, Reliability, and Objectivity

Fieldwork involves making records of what is seen, heard, and done in particular locations under particular conditions: making extensive notes, maps, and drawings; committing to memory what happened; recording sounds and images; collecting artifacts and documents, etc. It involves decisions regarding how obvious the process of recording will be. Note taking when being a member of a gang is unlikely to be perceived as natural but, as a student in a classroom (Hilbert, 1980), it is perfectly natural. Thus, depending upon circumstances, making notes may take place either during or following the scenes of action.

Even as a bystander, or recipient of stories, the participant observer becomes a member of the *dramatis personae* of a scene of action and thus as a member of the different *dramatis personae* that engage with each other in scenes of action across a range of locations and becomes a carrier of the local stories similar to the other members – each with their views. The multiplicity of views constructing stories of what happened, with whom, how, where, and why are retold for particular purposes and become vital elements in the sense of reality and drama of everyday life.

Each story retold connects to other stories, weaving each actor, the scenes of action, and the objects involved in the action into a reality, a sense of my place, my people, and my world where what happens becomes familiar, expected, routine, and ritualized and where the unusual

Figure 2 Mirror groups. From Schostak, J. F. and Schostak, J. R. (2008). *Radical Research. Designing, Developing and Writing Research to Make a Difference*, p 172. London: Routledge.

stands out. Aspects of one story may recall other stories – stories that elaborate on the character of one of the actors, or add to a sense of pride, frustration, or tragedy whether it is “teachers always pick on you like that” or “that’s what always happens to people like us.” This connectedness – or intertextuality – composed of shared and sharable anecdotes, local histories, and biographies becomes the vital data of the participant observer (Schostak, 2006) who also contributes to the stories through various degrees of participation. This intertextuality, with its multiplicity of viewpoints scanning shared or disputed locations, territories, scenes of action, and events, contributes an intersubjective sense of generalizability, validity, reliability, and objectivity of observations and accounts described during fieldwork. More specifically – in phenomenological terms – across all the variations of viewpoint some relatively invariant or typical relations, actions, objects, and meanings attributed to them can be identified, thus leading to judgments as to the generalization of the observations and analyses made. The process is, typically, referred to as triangulation. Features seen with one group and in one scene of action can be compared and contrasted with other groups, scenes of action, and locations. With the aim of identifying the range and limits of variation across individuals, forms of social organization, and locations, the participant observer can seek out comparative and contrastive situations, people, and locations in order to test out emergent understandings, analyses, and theories in a process called theoretical sampling.

The participant observer, then, is continually learning, making analyses, and searching for opportunities to test out emergent understandings and theories concerning the social world being studied. As well as making field-notes to describe observations of people, events, and places, analytic memos can be written in order to formulate potential categories by which insiders describe the circumstances of a situation and provide motives for their action (cf. Mills, 1940) and theoretical memos on emergent theory that can be tested out through further observations (Schostak, 2002). The participant observer is interested not just in a single subject’s point of view but in how the sense of a common world, shared reality, and orchestrated behavior is brought about as an intersubjective reality in the lives of people.

When the researcher is able to represent the intersubjectively constructed world(s) of actors in ways that they recognize as their world, their definitions, and their way of doing things – whether through performance as a member or in spoken and written accounts – this achieves a degree of validation and reliability. More critically, participant observation by seeking out the multiple voices and perspectives and learning from their viewpoints provides a critical resource for researchers in their debates with regard to what counts as knowledge. Whether it is the view that there is the inevitability of a distortion – a

violence even – in the interpretations of the researcher as shown by the critiques of feminists or by critical race theory or poststructuralism, the debate is continually renewed, shifted, and challenged by a return to the field.

The Significance of Participant Observation

In summary, as Thomas (in Thomas and Thomas, 1929: 571–572) put it: “If men define situations as real they are real in their consequences.” The task is to learn how situations are defined as a member, how reality is constructed as a member, what it means to be a member, or even to pass as a member of a particular group. This is not to say that the social realities of members are homogeneous. Indeed, where there are disputes or disagreements, these are managed or resolved according to the rules, rituals, habits, beliefs, values, and social positions of the members. For that reason – from an ethical and democratic standpoint – the participant observer records the range of disagreements as well as agreements in order to produce a record that the French political philosopher Jacques Rancière calls being faithful to the disagreements (cf., Schostak and Schostak, 2008). This includes not only a representation of the world of those being studied but also extends to the public debates concerning what counts as knowledge and whose knowledge and perspectives are to be included in public debates that affect people’s lives. In this way, participant observation contributes to the creation of public debate about what counts as knowledge, justice, and the good society.

The only way of learning participant observation is to do it, be there, and live it.

Phenomenology

M van Manen and C A Adams, University of Alberta, Edmonton, AB, Canada

© 2010 Elsevier Ltd. All rights reserved.

Phenomenological research in education is a project of careful and systematic reflection on the lived experience of educational (pedagogical, psychological, teaching, learning, and parenting) phenomena. Careful, in the sense that reflecting on experience must be as much as possible free from theoretical, prejudicial, and suppositional intoxications. Systematic, in the sense that phenomenology in education is an approach to inquiry that is guided by philosophical phenomenological methodology and assisted by human science procedures and techniques. However, phenomenology is not just a method that one can employ; it is also an attitude that relies on the perceptiveness, creative insight, interpretive sensitivity, scholarship, and writing competence of the researcher.

The phenomenological attitude comprises a fascination with the uniqueness, the particularity of an experience or phenomenon. When I am in love and I reflect on the meaning and significance of this love, then I am compelled not by abstractions but by the concreteness of my experiences: the sweet taste of that last kiss this morning, the tenderness I feel when I look in my love's face, the longing I experience when reading the love letter, the desire I feel to be the object of my lover's desire, the arousal of voluptuousness. Thus, a phenomenology of love is not primarily pursued through a theoretical discourse or a conceptual analysis of the notion of love. It is pursued through attempts to awaken the experience as we live it, and make contact – through concrete examples and reflection – with the living sensibility of its uniqueness.

Phenomenological research is oriented to the lifeworld as we immediately experience it – prereflectively, rather than as we conceptualize, theorize, categorize, or reflect on it. It is the study of lived or experiential meaning and attempts to describe and interpret these meanings in the ways that they emerge and are shaped by consciousness, language, our cognitive and noncognitive sensibilities, the ontics of meaning, and our personal, social, and cultural preunderstandings. Phenomenology can be adopted to explore the unique meanings of any educational experience or phenomenon. For example, it may study what it is like to have a classroom conversation, how students experience difficulty in learning certain concepts, what it is like to read and write poetry, how tests and examinations are experienced, how digital media technologies such as PowerPoint shape the teaching-learning relation and the knowledge that students learn, how young people encounter success and failure, how students experience

recognition and respect (or the lack of it) in schools, and so forth. Phenomenological inquiry also addresses larger questions of educational significance such as the technological presumptions of curriculum, the increasing instrumentalities of teaching and learning, the scientization of everyday life in schools and classrooms, or the rationalistic–technocratic ontotheology that progressively dominates our thinking. Besides, phenomenology may concern itself with shifts in pedagogy due to new technologies, such as reading and writing online, and the changing quality of privacy, intimacy, and contact in virtual learning environments. In a broad sense, any human experience may become the focus of phenomenological research.

Maurice Merleau-Ponty explained that a proper understanding of phenomenology is only accomplished through doing it. Phenomenological understanding needs to be practiced as method, and identified as a style of thinking – a manner of orienting to experience as we live through it. Within the domain of phenomenological philosophy there exist a variety of traditions and orientations. These traditions have spawned different expressions in the manner that phenomenology is pursued in education and other professional disciplines. In addition, in education certain liberties are taken with the nomenclature of phenomenology. Some research texts classify ethnography, biography, narrative inquiry, and arts-based and action research approaches as falling under the purview of phenomenology, in part because all these social and human sciences have an interest in studying experience and have adopted some of the vocabulary of phenomenology. However, from a stricter phenomenological perspective as reflected in the thoughts and writings of scholars such as Edmund Husserl, Martin Heidegger, and Merleau-Ponty, phenomenology differs from other qualitative approaches in that it remains primarily concerned with the prereflective, preconceptual, prepredicative, and pretheoretic dimensions of existence.

Phenomenological research aims for a certain effect, one that can lead us to suddenly see or grasp a human phenomenon in a way that enriches our understanding of everyday life experience. Such seeing may transform our being and thus our practices. The production of insight is not merely a cognitive affair but must proceed through the creation of a research text that appeals to our cognitive and noncognitive sensibilities. Thus, phenomenological understanding is distinctly existential, emotive, enactive, embodied, situational, and nontheoretic. A powerful

phenomenological text thrives on an irrevocable tension between what is unique and what is shared, between particular and transcendent spheres of the lifeworld. Without this tension, the qualitative research text tends to turn flat, shallow, boring, because it loses the power to break through the taken-for-granted dimensions of everyday life.

Phenomenology may be described as the study of lived experience. The term lived experience is presently rather widely used among the disciplines, but it possesses special methodological significance for phenomenology. The term lived experience derives from the German *Erlebnis* – experience as we live through it and recognize it as a particular type of experience. It could be argued that human experience is the main epistemological basis for many other qualitative research traditions, but the notion of lived experience, as used in the works of Husserl, Merleau-Ponty, and like-minded phenomenologists, announces the intent to explore directly the originary or prereflective dimensions of human existence. So, phenomenology prioritizes and investigates how the human being experiences the world; for example, how the teacher experiences the pedagogical encounter, how the student experiences a moment of failure, how a child experiences distress, and so forth.

From a phenomenological perspective, we always exist (act, think, feel, etc.) in the present of the now. Even when we dwell in memories or in anticipations, or when we dream or hallucinate, we do so in the experiential immediacy of the present moment or the living now. Yet when we try to capture and reflect on the now of our experience, we are always too late. The strange fact is that we always live in the present of the temporal now and yet we can never capture this present. Or perhaps it is better to say that the present as we constantly recall and reconstruct it has never really existed. Phenomenology does not just research human experiences and phenomena, it also continually questions the assumptions and presuppositions that prevent us from adequately understanding and expressing in words the living moments of experience – no matter how conceptually powerful or poetically evocative our words may be.

So, phenomenological research or inquiry is interested in recovering somehow the living moment of the now – even before we put language to it or describe it in words. At the same time, phenomenology tries to show how our words, concepts, and theories always shape (distort) and give structure to our experiences as we live them. For example, it is one thing to get lost in a novel but it is another to retrospectively capture what happened to us, just now, as we slipped into this textual space and began to dwell in the story. Similarly, we may identify and rate with empirical descriptors the nature and intensity of various forms of pain, but the actual experience of pain somehow seems to be beyond words.

Phenomenological Traditions

From a historical and philosophical perspective, phenomenology consists of a complex and diversified web of traditions starting well before Hegel in Germany, spreading all over Europe and eventually branching out to North America, Asia, and other continents and countries. Often these traditions are strongly associated with renowned phenomenological scholars. Here we mention a few of these traditions and briefly focus on selected terminology and the implications for research methods.

Transcendental phenomenology is the name of the tradition that begins with Husserl. Transcendence refers to the realization that we can never see a thing from all sides or perspectives at once, so the full essence of a thing can only be appropriated in transcendental or pure consciousness – in some sense abstracted from the perception of the experiential world. According to Husserl, consciousness has a transcendental structure. So phenomenology orients to the way that consciousness structures or constitutes the phenomena of the world. Early Husserlian phenomenology is understood as eidetic description: determining the essential nature and acts of consciousness. Phenomenological research proceeds through transcendental reflection as practiced through the eidetic reduction (bracketing) or epoché. In the transcendental reduction the researcher withdraws from the natural attitude of the taken-for-grantedness of the everyday world and of objective science and turns toward the intersubjective level of the transcendental ego. Husserl stresses that the phenomena (persons, things, objects, events, ideas, etc.) of which we are conscious are not simply in consciousness (as in a box), rather they are constituted as being what they are for us and as what they mean for us. Therefore, transcendental phenomenology could also be called constitutive phenomenology. It should be added that for Husserl, phenomenological intuition (the imaginative variation of the eidetic reduction) grasps the essence of things with all the vagueness that belongs (essentially) to them, and these are necessarily inexact essences. Only mathematical essences are exact.

Ontological phenomenology inquires into the nature of human existence or modes-of-being in the world. Heidegger distanced himself from the Husserlian preoccupation with *eidetics*, consciousness and intentionality, in favor of an ontological and hermeneutic perspective. In *Being and Time*, Heidegger argues that human existence (*Dasein*) is always already embedded in a world of meanings. Things are not first of all phenomena that are constituted in consciousness; rather we encounter them immediately in the world where we use them. In his early work Heidegger shows through a variety of concrete topics how phenomenology captures in language how things such as a jug, a bridge, a tool, show themselves. In his later writing Heidegger uses an increasingly evocative and poetic

discourse. Phenomenology is the study of what shows itself in the unique manner that it shows itself to us. Every mode of being (such as the mode of being a student, a teacher, a reader, a scientist, a parent) is always simultaneously a way of understanding the world. These modes of being in the world need to be interpreted. So, ontological phenomenology becomes hermeneutical when its method is taken to be interpretive, rather than purely descriptive as in transcendental phenomenology. But the contrast between descriptive and interpretive phenomenology is sometimes over-simplified by researchers in the professional disciplines. Heidegger says that all description is always already interpretation. Every form of human awareness is interpretive. Hans-Georg Gadamer, Heidegger's student, continues the development of a hermeneutic phenomenology, especially in his famous text, *Truth and Method*. Although Heidegger and Gadamer do not offer a method for conducting phenomenological inquiry, their works are examples both in their form and content. In *Truth and Method*, Gadamer (1975) carefully explores the role of language, the nature of questioning, the phenomenology of human conversation, and the significance of prejudice, historicity, and tradition in the project of human understanding. All these topics have relevance for educational researchers.

The works of Jean-Paul Sartre, Maurice Blanchot, Simone de Beauvoir, and Merleau-Ponty are known also as different forms of existential phenomenology. The relevance of existential phenomenology for education lies in its focus on the embodied, linguistic, gendered, and intersubjective dimensions of human existence. In his preface to the *Phenomenology of Perception*, Merleau-Ponty (1962) asks, "What is phenomenology?" and suggests that phenomenology begins in awakening and describing the basic experience of the world. Merleau-Ponty's clarification of the notions of intentionality, the reduction, wonder, and phenomenological reflection should be mandatory reading for those interested in developing more pragmatic approaches to phenomenological research.

In the post-structuralist writings of Jacques Derrida and his French colleagues such as Julia Kristeva and Hélène Cixous, we can address a radical linguistic phenomenology. Derrida aims to show that meaning is always primarily linguistic. Meaning resides in language and the text rather than in the subject. His famous claim that there is "nothing outside of the text" illustrates this well. For Derrida intersubjectivity is intertextuality. In contrast to Husserl's search for an indubitable ground of human understanding in the cogito, Derrida points out the essentially unstable and undecidable character of the nature of signs and meaning. Through the method of deconstruction Derrida aims to demonstrate, not the invariance (essence) of human phenomena but the essential variance, the *différance* that destabilizes all meaningful distinctions and discernable identities.

Ethical phenomenology originates with Max Scheler, a contemporary of Husserl. It also finds its origin in Jean-Paul Sartre's concern with ethical themes of freedom, responsibility, and choice. However, ethical phenomenology is especially associated with the original and influential work of Emmanuel Levinas intending to radicalize the thinking of Husserl and Heidegger into a phenomenology of otherness. For Levinas, the Husserlian focus on the essence of things and Heidegger's preoccupation with the modalities of being in the world all are manifestations of the primacy of the self or mine-ness in traditional philosophical phenomenology. For a truly profound understanding of the human reality, one must not ask for the meaning of being, self, or presence but for the meaning of what is otherwise than being, alterity, or difference. Levinas finds the phenomenological power of this question in the encounter with the face of the other who makes an appeal on us. In the vulnerability of the face of the other we experience an appeal: we are being called, addressed. Our response to the vulnerability of the other is experienced as a responsibility. This is an ethical experience, an ethical phenomenology.

Phenomenology as a Human Science

Next to these philosophic traditions, phenomenology became popular as a qualitative research approach in the social sciences. Although ethnography and ethnomethodology are characterized by their own distinct methodologies and epistemological assumptions, these disciplines prepared the way for a reception of phenomenological inquiry in North America. Ethnography offered ways of examining how subjects construct their own meanings and cultural reality; ethnomethodology enabled the social sciences to study the practices of everyday life and the meanings associated with those practices. At first, the rise of these qualitative approaches encountered considerable opposition. The root of the commotion was the challenge to traditional social science regarding their taken-for-granted assumptions about everyday life.

It is especially through disciplines such as education, pedagogy, and psychology that phenomenology was introduced in the practical, applied, or professional fields. For example, in psychology there was the influence of the Duquesne University scholars such as psychologist Adrian van Kaam and social psychologist Rolf von Eckartsberg. The Duquesne School became especially known for publishing qualitative methodological explications of phenomenological research that lent itself for application to the more practical fields of counseling and clinical psychology.

Before there was any significant interest in phenomenology in North America, a unique experiment had taken place in the Netherlands, Belgium, and Germany. For

example, the University of Utrecht School – a loosely associated group of phenomenologically oriented psychologists, educators, pedagogs, pediatricians, sociologists, criminologists, jurists, psychiatrists, and other medical doctors – can be considered a genuinely original contribution to the international discussion about phenomenology as a research perspective in the professions. Among these, scholars such as J. H. van den Berg wrote about the changing nature of childhood; the pedagogue-philosopher O. F. F. Bollnow wrote on the pedagogical atmosphere; the educator M. J. Langeveld established the field of phenomenological pedagogy.

In recent years, further developments in phenomenological methodology, inspired by continental scholars, are found in all the major professional disciplines. Practically oriented explications of phenomenological research methods are found in psychology through the efforts of Amadeo Georgi and Clark E. Moustakas, and in education through the writings of Max van Manen. Early phenomenological authors in education carved their own unique paths through the complexity of strands and traditions. Maxine Greene focuses especially on the writing of Hannah Arendt. Donald Vandenberg orients to the Husserlian philosopher Stephen Strasser and the educational thoughts of O.F. Bollnow. Madeleine Grumet and William Pinar experiment with gender based and post-structuralist phenomenologies. More recently, there is a growing interest in the pedagogical import of the phenomenology of technology and media, such as in Catherine Adams' study of PowerPoint and the pedagogy of digital media technology, and Iain Thomson's critique of the culture of technology and modern university education in light of Heidegger.

The Method of the Reduction

The idea of the reduction occupies a special place in phenomenological method. Reduction is the technical term that describes the phenomenological device which permits us to discover the experiential surge of the lifeworld. The aim of the reduction is to reach a direct and primal contact with the world as we experience it rather than as we conceptualize it. But the discovery of the prereflective lifeworld through the technique of the reduction always transcends the lifeworld: when we bracket lived experience we experience meaning. The method of reduction is meant to bring the aspects of meaning that belong to the phenomena of our lifeworld into nearness. In particular, it aims to bring into focus the uniqueness of the particular phenomenon to which we are oriented.

There exist many philosophical investigations and explications of the reduction that can make this topic complex and confusing. This is not surprising in view of

the fact that the project of phenomenology can be understood in a variety of ways. Below several levels or dimensions of the reduction are distinguished for their eclectic value and methodological usefulness: wonder or heuristic reduction, openness or hermeneutic reduction, concreteness or experiential reduction, and universality in contingency or eidetic reduction. Each of these dimensions of the reduction needs to be practiced as if in concert. Yet it may be helpful to deal with them separately while keeping the integrity of the larger phenomenological project in view.

At the most basic level, the heuristic reduction consists of the attitude or mood of wonder in the face of the world. What does this mean? It implies an approach that can shatter the taken-for-grantedness of our everyday reality. Wonder is the unwilling willingness to meet what is utterly strange in what is most familiar. To wonder is to step back and let things speak to us, a radical passive receptivity to let the things of the world present themselves in their own terms. When we are struck with wonder we seem to have evaporated momentarily our present preoccupations. We are suddenly struck by the strangeness of this thing, this phenomenon. Perhaps it is strange to speak of wonder as a method. But if we understand method as *methodos*, as path or way, then we may indeed consider wonder an important motive in human science inquiry. The way to knowledge and understanding begins in wonder. So methodologically the heuristic reduction requires discovering the miraculous moment of wonder; and in this moment a question may emerge that addresses us. The heuristic reduction involves the awakening of a profound sense of amazement at the mysteriousness of the belief in the world. This fundamental amazement may animate one's questioning of the meaning of the lived experience of the world. In terms of the particular research project in which one is engaged the heuristic reduction challenges the researcher to be receptive and awakened to a profound sense of wonder. But it also challenges the researcher to write in such a way that the reader of the phenomenological text is similarly stirred to the same sense of wondering attentiveness to the topic under investigation. Phenomenological inquiry continually edifies a wondering attitude of attentiveness.

At the level of the hermeneutic reduction, the phenomenologist needs to reflect on his or her own preunderstandings, frameworks, and biases regarding the psychological, political, and ideological motivation and the nature of the question. This is a search for genuine openness to engage in a conversational relation with the phenomenon. On the one hand, this means that one needs to practice a critical self-awareness with respect to the assumptions that prevent one from being as open as possible to the sense and significance of the phenomenon. The researcher needs to forget as it were vested interests and preunderstandings. On the other hand, it means that one needs to realize that forgetting

one's preunderstandings is not really possible and, therefore, these various assumptions and interests may need to be explicated so as to exorcise them in an attempt to let speak that what wishes to speak. Practically, the hermeneutic reduction consists of reflectively examining and turning over in one's textual labor the various preunderstandings that seem to impinge on the reflective gaze. This does not mean that one must hope to arrive at some pure vantage point, as if such a pure gaze were possible. But it requires that the various dimensions of lived meaning of the selected human experience are investigated for their different sources and layers of meaning, rather than being overlaid with a particular frame of meaning. Phenomenological inquiry is continually open to questioning assumptions and preunderstanding.

The experiential reduction requires that one avoids abstraction, theorizing, and generalization. Indeed, for any research project one must examine the available theories and discuss the body of knowledge about the topic. Theories need to be reviewed for how they inform (but fail) concreteness. Many theories contain some phenomenological material, or they are built on certain intuitions that presume phenomenological understandings. In the phenomenological reduction one needs to strip away the theoretical or scientific conceptions and thematizations that overlay the phenomenon one wishes to study, and that prevent one from seeing the phenomenon in a non-abstracting manner. The way in which to bracket theoretical meaning is not to ignore it but to examine it for possibilities of extracting phenomenological sensibilities. It is helpful to examine how the theories of conceptualizations gloss or hide the experiential reality upon which they ultimately must be based. Theories tend to explain phenomena that are not really understood in a lived or concrete sense. So one must ask: how is this topic actually experienced? What are examples of possible incidents or events? Phenomenological inquiry is continually oriented to the beginning, to the concrete, to experience as lived.

The eidetic reduction is the most central to the phenomenological method, especially for those traditions that borrow from Husserl. The researcher asks: What makes this experience uniquely different from other related experiences? In the eidetic reduction one needs to see past or through the particularity of lived experience toward the essence or *eidōs* that lies on the other side of the concreteness of lived meaning. The idea of phenomenological essence or *eidōs* does not refer to some immutable universal or generalization about human nature of human life. This would be committing the fallacy of essentialism. Phenomenological inquiry is only concerned with possible human experiences – not with experiences that are presumed to be universal or shared by all humans irrespective of time, culture, gender, or other circumstance. In addition, phenomenological determination of meaning is allusively and ultimately always indeterminate, always tentative, always

incomplete, always inclined to question assumptions by returning again and again to lived experience itself, the beginnings of phenomenological inquiry. The eidetic reduction is partially accomplished by comparing the phenomenon with other related but different phenomena. For example, in exploring the phenomenology of secrecy one would practice the eidetic technique of variation in imagination. How is the experience of secrecy different from the experience of privacy or the experience of reserve? What makes keeping a secret different from lying? Are there different kinds of secrecy? How is keeping a secret different from lying? What are concrete examples of this experience? and so forth.

In the eidetic reduction, patterns of meaning or themes seem to emerge. These are not themes in the sense of theoretical or conceptual abstractions; they do not belong to existing theories, taxonomies, genres, paradigms, philosophies, or conceptual frameworks. Phenomenological themes are the working material for phenomenological writing. The eidetic reduction differs from concept analysis in that the reduction does not claim to clarify linguistically the boundaries of a phenomenon or how a concept is being used in different contexts. Rather, the reduction attempts to offer intimations of meaningfulness. The eidetic reduction asks: Does this piece of text bring the experience into view? Does this phrase resonate with our prereflective sensibilities? Are these portrayals of lived meaning recognizable? Do they evoke something unique about this human experience? The eidetic reduction is not a simplification, fixation, or contraction of the world into a system of eidetic concepts – rather it is the exact opposite: the eidetic reduction makes the world appear as it precedes every cognitive construction: in its full ambiguity, irreducibility, contingency, mystery, and ultimate indeterminacy.

Human Science: Empirical and Reflective Methods and Procedures

The reduction is the method that is central to the phenomenological study of the lifeworld. But as phenomenology is adopted by other disciplines, empirical and reflective methods are imported that are derived from the humanities and the social sciences. Empirical methods such as interviewing, observation, eliciting written descriptions, and borrowing from literary and artistic sources are now used to gather experiential material. Reflective methods of thematization, etymological analysis, and meaning analysis are used to facilitate the challenges involved in the various forms of the reduction.

Our personal life experiences are immediately accessible to us in a way that no one else's are. However, the phenomenologist does not want to trouble the reader with purely private, autobiographical facticities of one's life.

In drawing on personal descriptions of lived experiences, the phenomenologist knows that the patterns of meaning of one's own experiences are also the possible experiences of others, and therefore may be recognizable by others. To conduct a personal description of a lived experience, the researcher aims to describe a phenomenon (lived experience) as much as possible in experiential terms. The focus is on direct description of a particular situation or event as it is lived through, without offering causal explanations or interpretive generalizations. It is to the extent that a personal experience can be recognized by others that the phenomenologist wants to be reflectively aware of certain experiential meanings.

To gain access to the experience of young children, it may be important to play with them, talk with them, puppeteer, paint, draw, follow them into their play spaces and into the things they do while the researcher remains attentively aware of the way it is for children. Participatory activities and close observation may generate different forms of experiential material than is obtained through the written or the interview approach. Observational method may require that one be a participant and an observer at the same time, that one maintains an orientation of reflectivity while guarding against the more manipulative and artificial attitude that a reflective attitude tends to insert in a social situation and relation. Literature, such as novels and short stories, are sometimes excellent sources for experiential material. The phenomenological value of a novel, for example, is determined by what may be called the perceptiveness and the intuitive sensitivity of the author. Through a powerful novel one is given the chance of living through an experience that provides the opportunity of gaining insight into certain aspects of the human condition.

Whereas empirical methods aim to explore the range and varieties of prereflective experiential material that is appropriate for the phenomenon under study, reflective methods aim to interpret the aspects of meaning or meaningfulness that are associated with the phenomenon and that assist with the reduction. Researchers commonly use the device of thematization to explore the qualitative dimensions of a phenomenon. For example, when we are interested in the phenomenology of reading a novel, we may soon notice some possible themes: (1) When we open a book we experience this wondrous sensation that this thing-like object, the book, can draw us into the other-worldly space of the text. (2) When we begin to read a book, we enter it, as it were. (3) Reading a novel means that we begin to care for the people who make up the novel. (4) While we read a story we experience action without having to act ourselves. (5) When we interrupt a book, we exit the world created by the word, etc. These kinds of themes are only fasteners or foci around which a web of phenomenological descriptions of the experience of reading a novel can be constructed.

Ultimately the concept of theme is itself primarily of heuristic importance. It may be considered simply as a means to get at the phenomenon that the researcher is addressing. Thematic reflection can provide a measure of control and a sense of order in our research and writing. Our lived experiences and the structures of meanings (themes) in terms of which these lived experiences can be described and interpreted constitute the immense complexity of the lifeworld. We can even speak of the multiple and different lifeworlds that belong to different human existences and realities. For example, the lifeworld of the child has different experiential qualities from the lifeworld of the adult. There are the lifeworlds of the elderly, the sick, the man, the woman, the researcher, and so forth. Each of us may be seen to inhabit different lifeworlds at different times of the day, such as the lived world of school and the lived world of the home.

One can also speak of existential themes that pervade the lifeworlds of all human beings, regardless of their historical, cultural, or social situatedness. Existential themes that may prove especially helpful as guides for reflection in the research process are lived space (spatiality), lived body (corporeality), lived time (temporality), and lived human relation (relationality). They are productive categories for the process of phenomenological questioning, reflecting, and writing.

Qualitative Case Studies

S B Merriam, University of Georgia, Athens, GA, USA

Case studies can be found in all subfields of education and most of us have encountered them in our professional training and in our practice. However, despite the prevalence of case studies in our literature, there is still some confusion as to exactly what a case study is. The fact that a lawyer, a social worker, an economist, a medical doctor, and even a detective can be involved in research on a case further confounds the issue as to what constitutes case study research. Until the late 1970s, the only time textbooks on research design included a chapter on case study was as a catchall for any study not statistical or experimental (such as historical, ethnographic, and biographic). Even today, as Stake (2006: 8) observes, “here and there, researchers will call anything they please a case study.” This article is intended to clearly define what a case study is and, in particular, what a qualitative case is. To that end, this article is organized into the following sections: definition and characteristics of a qualitative case study, design and implementation of a qualitative case study, and writing up a qualitative case study.

Definition and Characteristics

What makes a case study a case study is the unit of analysis; that is, a case study is an in-depth description and analysis of a bounded system. While some authors define a case study as the process of conducting a case study (Yin, 2003) and/or the end product of an investigation (Wolcott, 1992), we have concluded that it is the unit of analysis that makes something a case study. By unit of analysis we mean a bounded system (Smith, 1978), a single entity, a unit that is selected for study around which there are boundaries. We can fence in what we are going to study. The case then, could be a single person, a program, a group, an institution, a community, or a specific policy (see, e.g., Bennett’s (2002) case study of Indiana University’s project to increase ethnic diversity in their teacher education program or Koosimile’s (2002) study of a new science curriculum in Botswana). Miles and Huberman (1994) think of the case as “a phenomenon of some sort occurring in a bounded context” (p. 25). They graphically present it as a circle with a heart in the center. The heart is the focus of the study, while the circle “defines the edge of the case: what will not be studied” (p. 25).

The unit of analysis, not the topic of investigation, defines a case study. For example, a study of how teens negotiate online social relationships would likely be a qualitative study but not a case study; the unit of analysis would

be the teens’ experiences, and there could be an indefinite number of teenagers and their experiences negotiating online relationships selected for the study. In other words, the sample is without boundaries. If there is no end, actually or theoretically, to the number of people who could be interviewed or to observations that could be conducted, then the phenomenon is not bounded enough to qualify as a case. For it to be a case study, one particular Internet social site or one particular teenager selected on the basis of typicality, uniqueness, success, etc., would be the unit of analysis. Stake (2006: 1) explains:

A case is a noun, a thing, an entity; it is seldom a verb, a participle, a functioning. Schools may be our cases – real things that are easy to visualize. . . . Training modules may be our cases – amorphous and abstract, but still things, whereas “training” is not. Nurses may be our cases; we usually do not define “nursing activity” as the case. “Managing,” “becoming effective,” “giving birth,” and “voting” are examples of functioning, not entities we are likely to identify as cases. For our cases, we may select “mangers,” “production sites,” “labor and delivery rooms,” or “training sessions for voters.” With these cases we find opportunities to examine functioning, but the functioning is not the case.

The bounded system is of course embedded in the larger sociohistorical context in which it exists. As Geertz (1996: 262) points out, “No one lives in the world in general. Everybody, even the exiled, the drifting, the diasporic, or the perpetually moving, lives in some confined and limited stretch of it – ‘the world around here.’” Accounting for this context is one of the strengths of case study research.

The Qualitative Case Study

Certainly an in-depth study of a bounded system can employ a variety of quantitative and/or qualitative data. For example, a case study of a community could be based solely on demographic and economic data and thus be considered quantitative. Case studies might also include a mix of quantitative and qualitative data as is often the situation in evaluation case studies. An evaluation of a hospital’s disaster readiness and response, for example, might include timed responses, mapping of personnel deployment, interviews with supervisors, and on-the-ground observations. In keeping with the focus of this section on qualitative research methods, this article is devoted to case studies that are qualitative.

The question then becomes what makes a case study qualitative? Qualitative case studies share several characteristics with other forms of qualitative research. Qualitative researchers are interested in understanding how people interpret their experiences, how they construct their worlds, and what meaning they attribute to their experiences. Drawing from interpretive and constructivist notions of reality, it is assumed that reality is socially constructed, that is, there is no single, observable reality. Rather, there are multiple realities, or interpretations, of a single event. Researchers do not find knowledge; rather, they construct it. Constructivism is a term often used interchangeably with interpretivism. Cresswell (2007) explains:

In this worldview, individuals seek understanding of the world in which they live and work. They develop subjective meanings of their experiences. . . . These meanings are varied and multiple, leading the researcher to look for the complexity of views. . . . Often these subjective meanings. . . are formed through interaction with others (hence social constructivism) and through historical and cultural norms that operate in individuals' lives. (pp. 20, 21)

For example, rather than finding out what types of jobs college graduates get and if there is any correlation with their major, one could investigate the transition from full-time study to full-time work – what was the process, how were obstacles negotiated, what are the changes in daily activities, how have the historical and economic contexts shaped the process, and so on. These questions are about understanding their experiences and would call for a qualitative design. The overall purposes of qualitative research are to achieve an understanding of how people make sense out of their lives, to delineate the process (rather than the outcome or product) of meaning-making, and to describe how people interpret what they experience. These constructions or interpretations are context dependent with context broadly defined to include social, historical, economic, and cultural dimensions, all of which intersect at any particular point in time.

A second characteristic of all forms of qualitative research is that the researcher is the primary instrument for data collection and analysis. Since understanding is the goal of this research, the human instrument, which is able to be immediately responsive and adaptive, would seem to be the ideal means of collecting and analyzing data. Other advantages are that the researcher can expand his or her understanding through nonverbal as well as verbal communication, process information (data) immediately, clarify and summarize material, check with respondents for accuracy of interpretation, and explore unusual or unanticipated responses.

Often qualitative researchers undertake a qualitative study because there is a lack of theory or an existing theory fails to adequately explain a phenomenon. Therefore,

another important characteristic of qualitative research is that the process is inductive; that is, researchers gather data to build concepts, hypotheses, or theories rather than deductively testing hypotheses as in positivist research. Qualitative researchers build toward theory from observations and intuitive understandings gleaned from being in the field. Bits and pieces of information from interviews, observations, and/or documents are combined and ordered into larger themes as the researcher works from the particular to the general. Typically, findings inductively derived from the data in a qualitative study are in the form of themes, categories, typologies, concepts, tentative hypotheses, and even theory about a particular aspect of practice.

Finally, the product of a qualitative inquiry is richly descriptive. Words and pictures, rather than numbers, are used to convey what the researcher has learned about a phenomenon. There are likely to be descriptions of the context, the participants involved, and the activities of interest. In addition, data in the form of quotes from documents, field notes, and participant interviews, excerpts from videotapes, electronic communication, photos, or a combination of these are always included in support of the findings of the study. These quotes and excerpts contribute to the descriptive nature of qualitative research.

A qualitative case study then, is an in-depth study of a bounded system in which meaning and understanding of the phenomenon of interest are sought. The case study researcher is the primary instrument of data collection and analysis, findings are inductively derived from the data, and the end product is richly descriptive.

Types of Case Studies

Bogdan and Biklen (2007) differentiate among historical organizational case studies, observational case studies, and life histories. The first type, the historical organizational case study, is exactly what the name implies – it is a study of the development of a particular organization over time. The key to historical case studies, organizational or otherwise, is the notion of investigating the phenomenon over a period of time. The researcher still presents a holistic description and analysis of a specific phenomenon (the case) but presents it from a historical perspective.

Historical research is essentially descriptive, and elements of historical research and case study often merge. Yin (2003) discusses the two approaches:

The case study is preferred in examining contemporary events, but when the relevant behaviors cannot be manipulated. The case study relies on many of the same techniques as a history, but it adds two sources of evidence not usually included in the historian's repertoire: direct observation of the events being studied and interviews of the persons

involved in the events. Again, although case studies and histories can overlap, the case study's unique strength is its ability to deal with a full variety of evidence – documents, artifacts, interviews, and observations – beyond what might be available in the conventional historical study. (pp. 7, 8)

An observational case study is one in which “the major data-gathering technique is participant observation (supplemented with formal and informal interviews and review of documents) and the focus of the study is on a particular organization (school, rehabilitation center) or some aspect of the organization” (Bogdan and Biklen, 2007: 60). Using the workplace as an example, an observational case study could focus on a particular place in an organization (e.g., the director's office, or the staff break room), a specific group of people (e.g., the evening shift, or mid-level managers), or a particular activity (e.g., implementing a new computer system, or team meetings). An observational case study can be exploratory, descriptive or explanatory (Yin, 2003). The third type of case study described by Bogdan and Biklen is the life history. Here “the researcher conducts extensive interviews with one person for the purpose of collecting a first-person narrative” (p. 63). This type of case study goes by several names, such as life story, biographical case study, and portraiture (Patton, 2002).

Yet another typology of types of case studies is the one by Stake (2005). He identifies three types of case studies, differentiated by the researcher's interest – intrinsic, instrumental, and collective. The intrinsic case study is undertaken when the researcher is interested in the particular case itself – it is intrinsically interesting. “The purpose is not to come to understand some abstract construct or generic phenomenon;” nor is the purpose “theory building.” Rather, the “study is undertaken because of an intrinsic interest in, for example, this particular child, clinic, conference, or curriculum” (p. 445). An instrumental case study, on the other hand, “is examined mainly to provide insight into an issue or to redraw a generalization. The case is of secondary interest, it plays a supportive role, and it facilitates our understanding of something else” (p. 437). Finally, in a collective or multiple case study, a number of cases are studied “to investigate a phenomenon, population, or general condition” (p. 445).

Finally, several writers point to case study's usefulness in evaluation research (LeCompte *et al.*, 1993; Patton, 1996, 2002). Evaluative case studies involve description, explanation, and judgment. Yin (2003) has identified several different applications of case studies in evaluation research with the most important being “to *explain* the presumed causal links in real-life interventions that are too complex for the survey or experimental strategies” (p. 15, emphasis in original).

Design and Implementation of a Qualitative Case Study

As stated above, a case study is an in-depth analysis of a bounded system. For a case study to be qualitative, the focus is on understanding a phenomenon from the perspectives of those in the case. How do they make meaning of what is going on? How do they interpret their experiences? How is the context an important component in this understanding? In designing a qualitative case study, one must first identify a problem. A research problem is actually a gap in our knowledge and understanding of some phenomenon. The research problem is always lodged in the literature on the topic and forms the theoretical framework for one's study (Merriam, 2006). From previous scholarship in an area, we can identify models, theories, frameworks, and we can find out what we do know. When we identify something we do not know, there's a gap in our knowledge. It is this gap that one's study is designed to address. For example, there is a voluminous literature on math anxiety, including hundreds of studies. Parker (1997) however, could find no research on how adults who were math anxious were able to overcome their handicap and become comfortable with math tasks in their daily lives. Parker's qualitative study was on the transition these adults went through from being math anxious to comfortable with math. An example of a qualitative case study is Corvey's (2003) study based on Wenger's (1998) theory of communities of practice. His theory posits that learning is a social activity in which we collectively make meaning as we mutually engage in some activity. Further, that learning not only impacts our practice, but also changes who we are, our identity. To see if this theory held up in practice, Corvey (2003) studied an online community of practice of clinical nurses. The overall purpose of her study was to determine how Listserv membership in a community of practice of advanced practice nurses fostered both their practice and their professional identity.

Case Selection

Once the problem to be investigated is identified, the next step is to select the case. This selection is purposive or purposeful, not random. The logic of purposeful sampling is that one has to select the case that will yield information that can best address the study's purpose. Two levels of sampling are usually necessary in qualitative case studies. First, one must select the case to be studied. Then, unless he/she plans to interview, observe, or analyze all the people, activities, or documents within the case, there will be a need to do some sampling within the case.

A case is a single unit, a bounded system. As Stake (1995) points out, sometimes selecting a case turns out “to be no ‘choice’ at all . . . It happens when a teacher decides

to study a student having difficulty, when we get curious about a particular agency, or when we take the responsibility of evaluating a program. The case is given” (p. 3). Other times, we have a general question, an issue, or a problem that we are interested in, and we feel that an in-depth study of a particular instance or case will illuminate that interest.

To find the best case to study, one would first establish the criteria that will guide case selection and then select a case that meets those criteria. For example, if one’s interest is in schools that appear to be successful in integrating a multilingual, multicultural student body, he/she would establish criteria for what constitutes a successful program; then one would select a school that meets those criteria. This particular school would be the case. For multicase or comparative case studies one would select several cases based on relevant criteria. One of the criteria might be that one would want as much variation as possible; hence, one would be employing a maximum-variation sampling strategy in the selection of cases. Using the above-mentioned example, one might seek out successful schools representing a range of socioeconomic neighborhoods or that address a wide range of linguistic or cultural diversity.

Thus, the researcher first identifies the case – the bounded system, the unit of analysis – to be investigated. The case can be as varied as a second-grade classroom, the training department of a company, a system-wide model science program, or a patient education clinic at a local hospital. Within every case, there exist numerous sites that could be visited (as in the model science program), events or activities that could be observed, people who could be interviewed, and documents that could be read. A sample within the case needs to be selected either before the data collection begins or while the data are being gathered (ongoing or theoretical sampling). Random sampling of a particular unit, for example, teachers in a school can be used within the case. More commonly, however, purposeful sampling as outlined earlier is used to select the sample within the case, just as it is used to select the case itself. However, a second set of criteria is usually needed to purposefully select whom to interview, what to observe, and which documents to analyze.

Data Collection and Analysis

Since a case study is an in-depth description and analysis of a bounded system, rich and detailed data are crucial to being able to describe the case and answer the research questions. For most qualitative case studies, data are collected through interviewing, observations, and document analysis. Case-study researchers are encouraged to use all three methods of data collection where possible, as multiple sources of data enhance the validity of the findings. That is, if we as researchers hear people tell us about the

phenomenon, if we also observe it, and if we read about it in supporting documents, we can feel some confidence that we are capturing their understandings/interpretations of the phenomenon as closely as possible.

Interviews range from highly structured, where specific questions and the order in which they are asked are determined ahead of time, to unstructured, where one has topic areas to explore but neither the questions nor the order are predetermined. Most interviews fall somewhere in between. The semi-structured interview contains a mix of more and less structured questions. Usually, specific information is desired from all the participants; this forms the highly structured section of the interview. The largest part of the interview is guided by a list of questions or issues to be explored, and neither the exact wording nor the order of the questions is determined ahead of time. The quality of the data obtained through interviews is dependent upon the questions asked. Fewer, more open-ended questions, such as “Tell me about a time when. . .” or “How would you describe that. . .” or “How did you feel about that. . .” will generate the best data.

Data collected through observations represent a first-hand encounter with the case rather than a secondhand account obtained in an interview. Observation is the best technique when an activity, event, or situation can be observed firsthand, when a fresh perspective is desired, or when participants are not able or willing to discuss the phenomenon under study. Like interviewing, there is a range here also from being a complete observer to being an active participant. A complete observer is unknown to those being observed and a very active participant observer might be someone who is a member of the group or organization and is thus participating while observing. In most case studies, the observer is known to the participants and is minimally, if at all, involved in the activity being observed. In some case studies, somewhat informal interviews are conducted in conjunction with observations. This joint data collection strategy is labeled fieldwork or field study.

Since case studies are of a single bounded unit, such as an individual, an event, or an organization, what is loosely called documents are invaluable sources of information and insight about the case. These documents can be written, oral, visual (such as photographs), or cultural artifacts. Public records, personal documents, and physical material are other types of documents. The strength of documents as a data source lies with the fact that they already exist in the situation; they do not intrude upon or alter the setting in ways that the presence of the investigator might. Nor are they dependent upon whims of human beings whose cooperation is essential for collecting data through interviews and observations.

Interviews, observations, and documents are standard sources of data in qualitative case study research. Data can

also be collected online. Web pages, papers available online, etc. can be considered documents; artifacts in the form of illustrations and games can be downloaded; interviews can be conducted by e-mail; and researchers can observe online chat rooms. Correll's (1995) ethnographic case study of an online lesbian community is a good example of data collection through this medium. She observed the online postings and discussion of the community and conducted interviews via e-mail.

In qualitative case studies, as with all qualitative research, data analysis is best done simultaneously with data collection. Analysis should begin with the first interview, the first observation, or the first document accessed for the study. Simultaneous data collection and analysis allow the researcher to make adjustments to collect the best data. For example, once an interview transcript or field notes from an observation have been at least cursorily analyzed, it might be determined that people representing other interests need to be included or different activities should be observed. At the very least, an analysis of a transcript or set of field notes is likely to suggest other, better questions to ask, or adjustments in what is being observed. Most importantly, tentative findings or answers to one's research questions can be weighed against subsequent data. This iterative process of qualitative data analysis leads to solid and well-supported findings.

Data analysis is not only iterative but inductive. One begins with a unit of data (any word, phrase, or narrative that possibly seems to address/answer the research questions guiding the study). These data are compared to another unit of data, and so on, all the while looking for common patterns across the data. These patterns are given labels and are refined and adjusted as the analysis proceeds. In multiple case studies, one should first analyze the data within each case, then conduct an analysis across the cases. Bogdan and Biklen (2007) recommend doing fieldwork one site at a time, rather than simultaneously collecting data from several sites. "The reason for this is mainly that doing more than one site at a time can get confusing. There are too many names to remember, too much diverse data to manage. After you finish your first case, you will find that in multicase studies subsequent cases are easier. . . . the first case study will have provided a focus to define the parameters of the others" (p. 70).

Writing Up the Case

Since a case study is an in-depth description and analysis of a bounded system, the write up of a case study includes a detailed description of the case as well as the analysis of the data collected in the case. Many case-study write-ups have two parts; first, a description and, second, the findings in some form of an organizing scheme of categories, themes, concepts, or typology. Some writers present

a descriptive narrative first, followed by analysis and interpretation. This is what Lightfoot (1983) did in her well-known study of what makes a good high school. She studied six different high schools and her findings are presented first as six individual case studies (or portraits as she calls them); she then offers a cross-case analysis leading to generalizations about what constitutes a good high school. Another common organization is to integrate descriptions and vignettes with commentary. This is how Abramson (1992) wrote the case study of his Russian immigrant grandfather.

The descriptive component affords the reader the vicarious experience of having been there. "The case study," Patton (2002) writes, "should take the reader into the case situation and experience – a person's life, a group's life, or a program's life" (p. 450). Of course, in order for a reader to vicariously experience a phenomenon, the writer must transport the reader to the setting. This is done through writing a vividly descriptive narrative of the setting and the situation. These descriptions can be of any length, depending on whether they are describing the context generally, or illustrating a specific point. Detailed description of particulars is needed so that the reader can vicariously experience the setting of the study; detailed description is also necessary for the reader to assess the evidence upon which the researcher's analysis is based.

Donmoyer (1990) offers three compelling rationales for conveying the vicarious experience of a case study to the reader. First is the advantage of accessibility. "Case studies can take us to places where most of us would not have an opportunity to go" (p. 193). This does not have to refer to exotic places. Case studies allow us to experience situations and individuals in our own settings that we would not normally have access to. A second advantage to case studies is seeing through the researcher's eyes. By this, Donmoyer means that case studies may allow us to see something familiar but in new and interesting ways. The third advantage he identifies is decreased defensiveness. "Vicarious experience is less likely to produce defensiveness and resistance to learning" (p. 196). People can learn from a case study, perhaps more willingly than from actual experience. "Resistance to accommodating novelty" in a case study, for example, "will not be as great as when a threat is experienced in real life" (p. 197).

Stake (1995) points out that the case report usually falls somewhere between storytelling and the traditional research report. According to Stake, the development of most case-study reports follows one of several paths: "a chronological or biographical development of the case; a researcher's view of coming to know the case"; or "description one by one of several major components of the case" (p. 127). He also offers an outline tailored to case studies, including an entry vignette, the purpose and method of the study, narrative description of the context,

key issues for understanding the case, data in support of the issues and assertions about the case, and a closing vignette. In summary, writing up a qualitative case-study report is not a lot different from writing up any report of qualitative research. In both situations, it is crucial to consider the audience, which in turn, helps determine the style and voice of the report, as well as how much attention should be devoted to each of the necessary component parts. Case studies, which have as their goal to convey understanding, must contain enough description to provide a vicarious experience for the reader.

Generalizing from Qualitative Case Studies

The worth of qualitative case studies for contributing to the knowledge base of a field and to improving practice has been challenged over the years. Most recently, the federal government's preference for evidence-based research, that is, research that is experimental or quasi-experimental, has led to some questioning of all forms of qualitative research. However, those who conduct research in education for the most part fully appreciate what can be learned from qualitative research and qualitative case studies. In a recent presentation critiquing the new gold standard of randomized controlled trials in educational research, Shields (2007) argues for qualitative case studies: "The strength of qualitative approaches is that they account for and include difference – ideologically, epistemologically, methodologically – and most importantly, humanly. They do not attempt to eliminate what cannot be discounted. They do not attempt to simplify what cannot be simplified. Thus, it is precisely because case study includes paradoxes and acknowledges that there are no simple answers, that it can and should qualify as the gold standard" (p. 13).

Education is a social science that involves real people in real time and an in-depth snapshot of some aspect of educational practice can be enormously instructive to others in the field. Such studies can also lead to models or theories that inspire even more research. For example, Piaget's theory of cognitive development, which has inspired literally thousands of studies over the years, was derived from case studies of his two children. Moreover, in citing single cases, experiments, and the experiences of Galileo, Newton, Einstein, Bohr, Darwin, Marx, and Freud, Flyvbjerg (2004) makes the point that both human and natural sciences can be advanced by a single case. He also argues that formal generalizations based on large samples are overrated in their contribution to scientific progress.

The problem of generalizing from a qualitative case study is a problem only if one thinks from a positivist understanding of knowledge construction and relies on

the statistical notion of generalizing from a random sample to a population. There are other ways to think about generalizability more congruent with the constructivist philosophy underlying qualitative research. Perhaps because a case study focuses on a single unit, a single instance, the issue of generalizability looms larger here than with other types of qualitative research. However, much can be learned from a particular case. Readers can learn vicariously from an encounter with the case through the researcher's narrative description (Stake, 2005). The colorful description in a case study can create an image – "a vivid portrait of excellent teaching, for example – can become a prototype that can be used in the education of teachers or for the appraisal of teaching" (Eisner, 1991: 199). Further, Erickson (1986) argues that since the general lies in the particular, what we learn in a particular case can be transferred to similar situations. It is the reader, not the researcher, who determines what can apply to his or her context. Stake (2005: 455) explains how this knowledge transfer works: case researchers "will, like others, pass along to readers some of their personal meanings of events and relationships – and fail to pass along others. They know that the reader, too, will add and subtract, invent and shape – reconstructing the knowledge in ways that leave it...more likely to be personally useful."

Summary

The term case study is not used precisely in the literature and is still used by some as a catchall category for studies that are clearly not experimental, survey, or historical. Further, case study is sometimes used interchangeably to refer to qualitative research. In this article, we have delineated the nature of qualitative case studies. We begin with the definition of a case study as an in-depth description and analysis of a bounded system. Case studies are case studies because the unit of analysis is a single bounded system. When the question asked of this single bounded system or the case, is about meaning and understanding of a phenomenon from the perspectives of those within the case, we have a qualitative case study. All of the assumptions underlying qualitative research apply then to this case study. Sample selection, data collection, and data analysis are all congruent with qualitative research. Also discussed is the write up of a case-study report. The article concludes with a discussion of the issue of generalizability of qualitative case studies.

Glossary

Monoepestemological – A single aspect utilized to generate knowledge.

Polyepistemological – Many aspects utilized to create knowledge.

Philosophical Issues

Good organization of data in qualitative research is essential if researchers are not to end up swamped by a room full of files about which they may well have forgotten important details. Management needs to start early when the first interview/observation/document is collected. Aspects which will impact on how best to manage qualitative data during data collection lie in the following:

- differences among research designs relating to the traditions from which particular approaches emerge;
- the impact of frames which the researcher brings to data collection and analysis;
- the positions the researcher takes in the process of data collection along the subjective–objective dimension; and
- where the form of data analysis and the style of presentation places the audience – the future readers of the documents that will be produced from this research.

All these will influence decisions as to how data will be managed.

Research Styles

Taking each of these aspects in turn, researcher approaches to qualitative research slide along a continuum from subjective to iterative to investigative to enumerative and each has a different focus. Subjective approaches would favor more intact data in the autoethnographic, post-modern, phenomenological, oral, historical, and narrative traditions where intact stories, with a beginning, a middle, and an end, are of importance; iterative will overlap with subjective in terms of the process of constant feedback enriching the holistic view sought, but will often fragment data in order to reassemble them in another form, for example, as in grounded theory, action and evaluative approaches; investigative is even more selective in terms of aspects to be analyzed and has a focus on language,

particularly that of discourse, deconstruction, content, conversation, and sociolinguistic narratives; while enumerative utilizes quasi-statistical and matrix-type approaches, counting incidences and applying predesigned coding formula.

Researcher Characteristic and Beliefs

Frames are the principles of organization which govern social events and the actors' subjective involvement in them (Goffman, 1974: 10). Researchers' views of the world come from their socialization in a particular culture and these experiences influence their interpretation of data collected. Life experiences which may impact on interpretation include class location, age, gender, ethnicity, personality, and religious or political affiliations. Other influences lie in the disciplines researchers have been trained within, be it philosophy or psychology or sociology together with the literature relevant to their research question which researchers have examined prior to data collection. Understanding which particular aspects of life and educational experiences influence one's perceptions is important and exposing these in a diary in the process of self-reflexivity, is necessary when data collection and analysis are undertaken.

Researcher Position

Where the researcher stands is also important. This may well develop as a result of the research question, the approach decided upon, frames accumulated, and anticipation of the potential audience. For example, a phenomenological approach requires the researcher to achieve an in-depth understanding of the experiences of interviewees of the phenomenon under investigation – here a passive empathetic position is essential and the researcher simply collects and displays data with minimal analysis. An autoethnography would require one to go deep into one's own experiences and emotions in order to achieve the complete insider view and then have the capacity to move to a more distant position in order to interrogate oneself about these experiences. At the other extreme, analysis of existing documentation such as television programs or policy documents would require a distant pseudo-objective stance where researcher feelings and emotions would be of lesser importance and data fragmentation and relinking of greater importance.

The Reader

The audience to whom the final outcome of data analysis will be displayed also influences decisions about the form analysis may take and the degree to which data segmentation/intactness occurs. The role the reader can assume is created both by the tone of the report or article that is produced from the research and also by the form of presentation of data. If the researcher takes a strong authoritative voice along the lines of “I, as an expert in this field have undertaken this piece of research and here are my findings for you to digest,” then the reader is placed in a passive take it or leave it position. In this situation, support data for researcher findings will be displayed but this display may be fairly minimal and the reader would have to trust that the researcher has displayed the most relevant data rather than that which best supports her/his particular view. On the other hand, the reader may be encouraged to come close to the raw data in order to see more of what the author has experienced and to judge the interpretation of this through hyperlinks or the display of extensive quotes, case studies, vignettes, and the exposure of many participant voices.

The issues of validity (demonstrating that the author has gained truths regarding the research question) and reliability (demonstrating sound design to gain these truths) are also of importance and are clarified via the notion of transparency. Detailed explanations need to be provided so that the reader can judge what has been done, and how particular conclusions have been arrived at.

Managing Data during Collection

There are four different types of data that can be collected: individual interviews, focus group, observation data, and the collation of existing documentation, be it written, visual, or material. Although the actual organization of transcription approaches for individual pieces of data is idiosyncratic to suit each researcher, there are various mechanical processes which tend to be used widely.

Managing Interview Data

For interviews, it is desirable that transcription occurs as soon as possible after the interview has been undertaken so that the nonverbals can be recalled and inserted appropriately. Transcription is usually undertaken double-spaced for ease of reading and with a column of about one third the width of the page being left blank on one side for preliminary data analysis to be written in. Within the text of the transcript various indicators are used that is, . . . indicates silences or pauses for thinking where each dot represents a period of time defined by the researcher – usually one second per dot. Nonverbals are usually indicated in brackets and with italics (e.g., *(smiles)*

or *(coughs)*). Emphasis is added in bold (i.e., . . . he said that but **it is not a view I share**). Clean copies (without any form of analysis can be sent back to the interviewee for verification of the transcript).

Managing Focus Group Data

Focus group data are not usually transcribed – partly not only because it is not necessary to send transcriptions back to participants but also because the immediate cross-referencing that occurs in the group makes further verification unnecessary. Another factor is that transcription is difficult to do and many transcribers refuse to attempt this because of the difficulty of unscrambling individual voices. With the introduction of videoed focus groups, the need for written transcription has disappeared.

Managing Observational Data

Observations are usually either taped or written up without discussion and preferably within 24 h after the observation has been undertaken. Discussion is thought to start the process of interpretation often bringing in the perceptions of others. Each observation may be accompanied by a brief overview map which indicates movement within the setting of both the researcher and those under observation. This provides a useful aid for prompting memory and a visual diagram for the reader.

Managing Textual Data

Textual/verbal documentation once collected will either be left as it is, apart from chronological compilation or sorting into broad groupings, or it may be scanned or transferred onto a disk for greater ease of management and analysis.

Preliminary Data Analysis

This process is undertaken in some form or another regardless of the design approach which has been chosen. The purpose of preliminary data analysis is twofold; first, to track data as it is being collected so that any gaps that may be emerging can be dealt with early and second, to start the process of identifying major trends in the data as they emerge. It is an ongoing process of engagement with the text in order to gain a greater understanding of the meanings, values, and actions which are being portrayed.

There are various idiosyncratic ways of undertaking preliminary data analysis but most approaches include some aspects of the following six points as the researcher reads through each interview, observation, and document as they are collected:

- Questioning one's own assumptions and those which appear in the data – this can be done by asking why? or

what about...? or what if... or well if this, then how does that fit...? From these critiques, a list of further questions to pursue can be developed.

- Comparing the data with one's own experiences, with findings which appeared in the literature review and with any theoretical/conceptual explanations which look as though they may shed light on what is emerging to date. Brainstorming the ideas these comparisons bring up is helpful here.
- Reading the data in a different order or even haphazardly in order to gain different perspectives.
- Chunking data – starting to group together segments of data, for example, experiences in the classroom, and creating broad labels and sub-labels for these groupings, that is, as negative experiences or positive experiences.
- Writing analytic memos about each segment incorporating ideas, questions, and additional information recalled from the actual collection of these data (setting, context, other events, processes, interactions, etc.).
- Taking some of the groupings as they become more established and turning them into forms of presentation, for example, poems, vignettes, or narratives in order to identify orientations and information missing, and to trial approaches of data presentation.

Examples of preliminary data analysis

Figures 1–4 provide examples of preliminary data analysis.

Face Sheets

Following completion of the above processes of preliminary data analysis for each piece of data collected, it is

useful to collate the major points in some easily accessible form such as a face sheet which can be attached to the transcript or document. This face sheet should identify who/what the data comprise, for example,

Interview No 1 with 'John' School Principal. Date Location. and Time in the setting. Or, if it is an observation; Observation number ... of ... undertaken (date), (time in setting). Any special circumstances which may have an impact on the data collection should also be noted: the day was very hot/cold/I was late/X was late. Interruptions occurred here... and here.... If the data is an existing document; Document name... Source location ... Date accessed ... Verification of the authenticity of this document made by...

Then a summary usually in dot-point format should clarify what the researcher has found of interest in the data with regard to:

- the major issues emerging; and
- aspects which need to be followed up.

Assuming the above example from an interview (Figure 1) was a complete interview, the face sheet could look like this (see Figure 5):

Focus group data tend to be analyzed soon after the exercise using a replay of the video/audio recording so that developing themes can be visually/manually identified. But aspects of preliminary data analysis will also be built into this process and questions developed for exploration in the next focus group. These will be pursued in depth in face-to-face interviews with individuals identified from the group who have indicated they would be happy to provide further information.

Interview transcript segment from an interview with the director of an adult training center for young people with intellectual disability	Preliminary data analysis
<p>Question: What better ways might there be of integrating people with intellectual disabilities into community activities?</p> <p>Answer: Well regarding physical activity, everyone functions better and are more mentally alert if they are physically fit. I think for the severely disabled it is essential they get more from this part of the program than any other. For years, most of them have just had a ball thrown at them. we've got a basketball team that used to stand on the court and wait for a ball to be thrown - its all a matter of education, with community access, you just add a grade to the local district association so they play at their skill level and the system is open to them to move on up if they are capable.</p>	<p>How do you get these people to shift from passive to active activity? What forms of education/processes were used here?</p> <p>Re-grading, is this really integration? Aren't we just creating another segregated layer for these people who are already marginalized to the fringes of society and who will continue to be separated on the basis of their limited capacity?</p>

Figure 1 Interview data. From Grbich, C. and Sykes, S. (1989). *What about Us! A Study of Access to School and Work of Young Women with Severe Intellectual Disabilities*. Melbourne: Monash University, Krongold Centre for Exceptional Children.

Observation transcript segment from a case study of drug education in colleges.	Preliminary data analysis
Set on the windswept plains of one of the outer limits of X suburban sprawl, this new school is being developed to meet the needs of a housing estate. The estate is a fenceless collection of architect-designed display houses and standard homes with a mixture of bald turf and newly turned clay gardens. It is an isolated development with a long walk to the shops and a bus to connect with the major public transport systems. Most of the houses seemed empty in the mid-morning with closed curtains and no one in a yard or on the streets. The school is still being built. The buildings are spaced apart with brick-paved courtyards and the occasional well-protected shrub. It is lunchtime, students huddle together in small groups in a yard in the lee of buildings and movement between groups appears to be hindered by a fierce wind. There are no games being played. Not even the usual handball game is evident. The unpaved areas of the school are deep in wet clay.	<p>What are the demographics of this estate?</p> <p>How do students entertain themselves during school breaks and after school in this community?</p>

Figure 2 Observational data. Adapted from Garrard, J. and Northfield, J. (1987). *Drug Education in Victorian Post-Primary Schools*. Melbourne, VIC: Monash University, Victoria.

Textual document segment from policy documents identifying aims, values, and beliefs in junior school education	Preliminary data analysis
<p>Values are internalized sets of beliefs or principles of behavior held by individuals or groups. They are expressed in the ways in which people think and act. No schooling is value free. Values are mostly learned through students' experience of the total environment, rather than through direct instruction. The content of a school's curriculum reflects what is valued by a society and a school community.</p> <p>A belief in education, at home and at school, is a route to the spiritual, moral, social, cultural, physical, and mental development, and thus the well-being, of the individual. Education is also a route to equality of opportunity for all, a healthy and just democracy, a productive economy, and sustainable development. Education should reflect the enduring values that contribute to these ends. These include valuing ourselves, our families, and other relationships, the wider groups to which we belong, the diversity in our society, and the environment in which we live. Education should also reaffirm our commitment to the virtues of truth, justice, honesty, trust, and a sense of duty.</p>	<p>The purpose of education in New Zealand appears to consolidate the student into the values of her/his community. Does this mean that achievement beyond this group or criticism of these values is not encouraged?</p> <p>In the United Kingdom, education is seen as a way of providing equality of opportunity as individual well-being and to foster the greater good of the wider community. How many of those in the lowest socioeconomic class would move up through education? Or does education fail to equalize opportunity?</p>

Wellington: Learning Media; and Qualifications and Curriculum Authority (QCA) (1999). *The National Curriculum: Handbook for Primary Teachers in England Key Stages 1 and 2*. London: DTEE and QCA.

Data Summaries and Early Theory Generation

These are seen as useful ways to start consolidating data as they are collected. Every three to six data sets, a summary is produced which starts teasing out related issues which

are starting to appear as recurring themes. The twin advantages of undertaking this process are to further identify any holes in individual themes which may require further data collection and to start the process of writing

Visual document segment	Preliminary data analysis
 <p>Nursery children from a crèche at a cylinder factory dancing in a forest with their teachers in Russia 1935.</p>	<p>Young children dancing in the forest probably during summer in the early depression era. Why are they wearing knitted caps but no shirts? They look well fed despite the depression era. What was happening in Russia at this time?</p> <p>Do the knee-length white clothes and bobbed hair of the teachers reflect women's fashion in 1935? Or are they unique to this country?</p>

<p>Identifiers: Interview number 1 with director of an adult training center for young people with intellectual disability</p> <p>Location of interview: the director's office</p> <p>Date: 02/03/89. Time: 3.00 – 4pm. Initial coffee and unrecorded introduction. Recorded interview lasted 45 min. Debrief and chat.</p> <p>Special circumstances: None</p> <p>Major issues emerging:</p> <ul style="list-style-type: none"> ▪ People with intellectual disability may benefit from specific educational programs to change attitudes and maximize their potential ▪ Integration may simply mean isolation and segregation under a different label. <p>Aspects to be followed up</p> <ul style="list-style-type: none"> ▪ Information required regarding the content of education programs to convert passive games response of people with intellectual disability to an active response. Success rate? ▪ Interview needed with state/national basketball organizers to explore the feasibility of integration through an additional grade of players ▪ Has genuine integration occurred in any sport?

Figure 5 Face-sheet example.

up and interpreting results. Early re-presentation of data may also be trialed here (poems, etc.).

The following example (**Figure 6**) consolidates six sets of interview and observation data in a study which sought to explore the integration of young people with severe intellectual disabilities into school and community settings. Early themes from parents' and teacher's views are interpreted through various theoretical concepts such as normalization and integration.

Following the processes of both preliminary data analysis and data summaries, the researcher should be able to provide some answers to their research question and should be on top of her/his database, avoiding ending up in the unenviable situation of being surrounded by a pile of data with no clear idea of how to make sense of it.

Some researchers, particularly those working within the subjective tradition, may well decide not to pursue processes of data analysis beyond this point as their

Perceptions of integration in schools: Researcher's observations, parents' and teachers' views

One of the central issues emerging so far is how different people view the integration of special school students into regular schools (maximum of one half to 2 days per week). Parents (of X, Y, and Z) all favor this, seeing it as a glimmer of hope, an indication of improvement and a move across the great divide from special to regular schools with accompanying connotations of normality. All are very anxious their son/daughter should remain in the integration program despite fitting (epileptic fits) experienced on regular school days by X (none on special school days), isolation and aloneness of Y when his mate was withdrawn from the program (teacher's perception). X seems to be settling down over time. He likes the pop music in practical classes and although he can't speak, he can sing along to the radio/cassette/CD player and the girls think he is cute and encourage him to sing. Y is ignored (nonverbal and almost blind) and Z has full aide support and a home room to retreat to (which he shares with all the special students being integrated in this setting). Regular students are encouraged to come in and play cards with Z and other students with disabilities in their home room. This is very popular on wet days as it beats standing around in the windswept covered ways which is the only other option. Z seems calm and settled but the presence of an aide may be preventing interaction with regular students in the classroom setting. The school environment and forms of/lack of support do appear to impact on the integrated students' experiences.

Teachers in special settings fear integration, seeing it as leading to a loss of students with the potential of job loss for them – they feel that if the students are starting to move to regular settings they should go too, as they could provide expertise to support regular teachers. The latter view integration as ideologically sound but pointless in practice unless there is full aide support so they don't have to worry about the presence of X, Y, and Z or adjust their curricula (and none have so far). X and Y's teachers in the regular classrooms express concerns about what X and Y are gaining from the integrated experience, viewing it as negative and stressful for both them and the student. It seems clear that schools that are more academically oriented (like the ones X and Y attend) are more resistant to any disturbance caused by integrating low-performing students whereas less academically oriented schools, such as the one where Z is located, express less hostility and are more oriented to giving it a go.

Figure 6 Example of a data summary. From Grbich, C. and Sykes, S. (1989). *What about Us! A Study of Access to School and Work of Young Women with Severe Intellectual Disabilities*. Melbourne: Monash University, Krongold Centre for Exceptional Children; and Grbich, C. (2007). *Qualitative Data Analysis: An Introduction*. London: Sage.

preference will be to keep the data as intact as possible. Careful preliminary data analysis together with data summaries which consolidate information emerging will have provided all the analytical processes necessary to manage their data.

Other researchers, particularly those with large databases or data that they feel require a more rigorous process of analysis will move to thematic analysis. Rather than a vertical building up of the database as in preliminary data analysis, thematic analysis is more a process of horizontal segmentation and regrouping.

Managing Data after Collection

Thematic Analysis

Once all the data have been collected and the processes of preliminary data analysis have ensured that any major gaps have been plugged, the researcher/s should take a break in order to achieve a more distant perspective.

It is also useful at this point to pass a clean copy (without preliminary data analysis) of the transcribed or collated data to a friend, colleague, partner, or another member of the research team and encourage them to go through and identify the issues which they see as being present. This will help locate aspects which the researcher may have overlooked or deliberately discarded as not fitting into their view of what is important.

The researcher then starts the active process of moving across the data and selectively grouping particular aspects. These groups may comprise a set of answers to a particular question? For example, "How do you try to meet the different intellectual levels of students in your class?" Or grouped stories associated with "When did you first understand that your child had a disability?" Or, the researcher may consolidate emerging themes from the database. These themes and responses may be collated either using the block-and-file approach in which the researcher can choose to either keep data intact or to fragment them, or, they may prefer to use a conceptual mapping approach.

The Block-and-File Approach (Intact Data)

The first stage involves identifying the relevant responses to a question such as, “What was your experience of gaining a diagnosis and support for your child?” and placing them in a file.

The second stage involves underlining or shading the different themes within these responses and placing them in separate columns and attaching general headings.

The responses have been kept intact and overlapping is not an issue (Figure 7). The headings given may stay in this form but may well change as new data are added. Consolidation and the development of new columns are desirable. For example, the column containing responses of health professionals to parents may need to be broken

down into responses of doctors and responses of other health professionals’ or even further into male and female health professionals’ responses as more data are added.

Block- and File-Approach (Data Fragmentation)

A slightly different approach to thematic analysis involving further fragmentation and some de-contextualization might focus in on a more refined aspect of the data such as doctor’s interactions with parents. The process involves identifying relevant key words and listing these, regrouping and labeling them, and developing a working proposition about what has been found. See Figure 8.

Length of time to gain diagnosis	Responses of health professionals to parents	Responses of parents to the situation
1. For the first 10 months no one helped. I went to several doctors and a pediatrician.	1. He (pediatrician) told me “He’s retarded. I haven’t time to answer your questions; I’m on the phone to the Physiotherapist. I hope I haven’t ruined your weekend. Try an intervention program. Some kids it helps, some it doesn’t. The second pediatrician we saw at X hospital was nice but hasn’t given us advice on where to go. I have to go and find everything myself. He didn’t even tell me there was a developmental disability nurse at the hospital.	1. Its not a very caring hospital. Information is not given freely. They don’t bother to remember a child’s name – don’t give any extra attention. I wouldn’t leave my child overnight there. I did once, he was in a very bad way when I came back in the morning. They told me he was very spoilt.
2. We finally were referred to a pediatrician at 6 months.		
3. I knew there was something wrong at 6 weeks but they didn’t test her until she was two and a half.	2. He was absolutely atrocious – he treated the situation as though it was a damaged brain independent of the child. He didn’t refer to the services in the hospital, let alone outside. There was a total lack of information as to what cerebral palsy was.	2. There is a lack of co ordination of services when disability is diagnosed. It should be function of the hospital to provide a support base from which to move out into the community to whichever services are most appropriate.
4. Two days after her birth the doctor came and told me my child had Downs Syndrome	3. I was told she had curvature of the spine and that’s all I was told. When she was 4 years old I became dissatisfied and went to a private physiotherapist. She got my daughter’s medical history and on my next visit she told me my daughter had cerebral palsy.	3. When she was 4 years old I became dissatisfied and went to a private physiotherapist.
	4. Two days after her birth, the doctor came and told me my child had Down’s Syndrome and we were strongly advised to put her in a home and forget her because she wouldn’t live past 15 and would just be a vegetable	4. I was so upset – she was my own flesh and blood - so I took her and left the hospital and vowed to ignore this doctor. Now look at her – she can walk, talk, and see with glasses; she is now 16 and in good health.

Figure 7 Block- and file-approach (four intact interview responses).

List relevant data:

Rude and abrupt, I haven't time to answer your questions, 'He's retarded'...try an intervention program some it helps others it doesn't, the pediatrician was nice but gave no advice on where to go, he didn't even tell me there was a disability nurse at the hospital, information isn't given freely, absolutely atrocious, referred to damaged brain separate to the child, he didn't refer to the services at the hospital let alone outside, total lack of information, there is a lack of coordination of services when a disability is diagnosed, it should be a function of the hospital to provide a support base and link to community services, I was told she had curvature of the spine and that is all I was told, we were strongly advised to put her in a home as she would only ever be a vegetable.

Group under particular labels:

Uncaring attitude: rude and abrupt, I haven't time to answer your questions, 'He's retarded'...try an intervention program some it helps others it doesn't; absolutely atrocious - referred to damaged brain separate to the child, we were strongly advised to put her in a home as she would only ever be a vegetable

Unhelpful attitude: the pediatrician was nice but gave no advice on where to go, he didn't even tell me there was a disability nurse at the hospital, I was told she had curvature of the spine and that is all I was told

Connection to services: information isn't given freely, he didn't refer to the services at the hospital let alone outside, total lack of information, he didn't even tell me here was a disability nurse at the hospital, there is a lack of coordination of services when a disability is diagnosed, it should be a function of the hospital to provide a support base and link to community services.

Develop a summary proposition to which case examples can be attached in the writing-up process:

Proposition: Doctors' attitudes to this group of parents of a young child with a disability have been uncaring and unhelpful providing poor information and failing to connect parents either with existing hospital or with community services.

Figure 8 Block-and-file approach (focused and fragmented data).

Conceptual Mapping

This is another way of tracking the outcomes of thematic analysis. This approach is useful when a broad overview or a specific aspect is required. More than one map will need to be developed in order to represent different parts of the database.

From the above examples, parents' experiences with doctors could be displayed in a conceptual map (**Figure 9**):

Coding

If the researcher has a large database or plans to utilize computer management of data he/she will need to undertake a process of coding involving the attachment of numbers to the groupings identified in the database. This process may be undertaken prior to thematic analysis especially when preliminary data analysis has clearly identified the major groupings. However, it is suggested that it is better undertaken following thematic analysis when the researcher has finalized all the groupings in

the data. The application of codes prior to thematic analysis can lead to information being randomly assigned to particular coding groups and the researcher then has to spend considerable time sorting through these groups to weed out irrelevant data and develop new codes and subcodes. In addition, the development of a coding framework too early in the piece may lead to the researcher becoming so attached to it that all subsequent data are forced into this framework regardless of fit. In this manner, new directions in the database are often overlooked completely.

Codes should include all the themes identified as well as the concepts linking to theoretical perspectives which may be useful in the interpretative process. These may have been generated by the researcher or are grounded in the data and used by participants. Other aspects which may be useful to code include: methods used, important events, aspects of the setting, for example, school organization or structures which may impact on the data collected, the political situation which may influence funding or values, relationships developed between researcher and researched, etc. The number of codes will

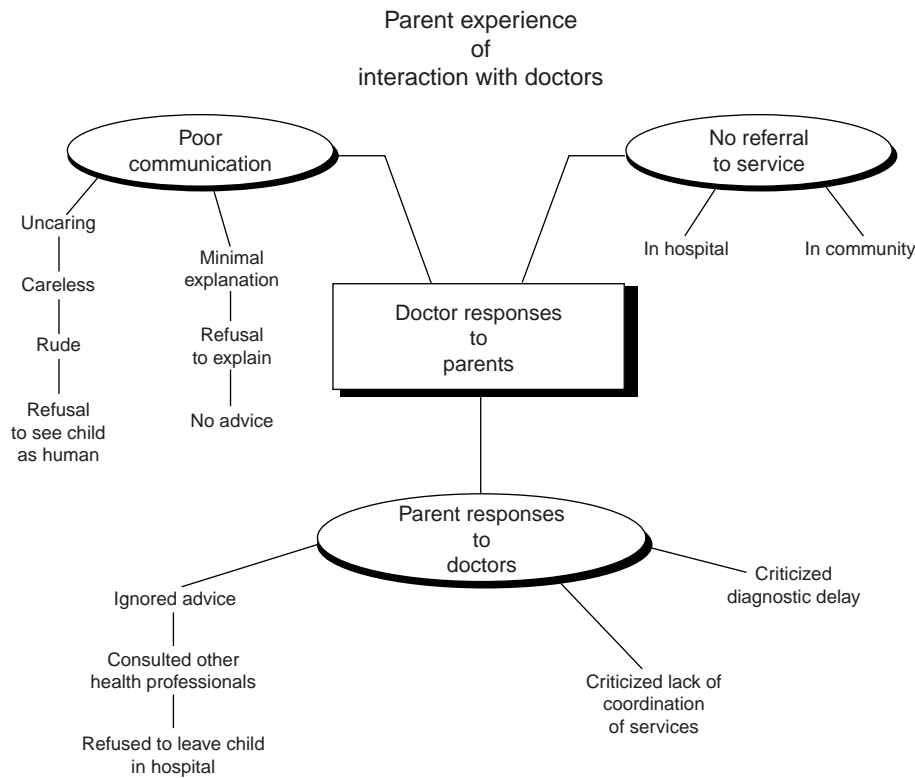

Figure 9 Parents' experiences with doctors, in a conceptual mapping.

depend on the database but more than 50 codes and subcodes in a moderate-sized database would be regarded as unwieldy.

Example

In the study examining integration of young people with intellectual disability which involved 80 randomly chosen multiple-member case studies (the individual, his/her parents, regular school teachers and special school teachers, and principals/sheltered workplace organizers, and halfway house carers) the following broad codes were developed: demographic details (age, sex, living situation, and attendance at school/work), diagnosis, communication regarding diagnosis, developmental issues, level of independent living skills, social networks, social activity, disability funding, family income, services accessed, family composition, effect on family, schooling/work history and capacities, family expectations, sexual activity (actual and expected), home activities, school/workplace tasks, transport, and community integration. These formed the broad frameworks the data became grouped into but within each were a series of subgroups. For example, independent living skills included the subcodes, cooking skills, telephone use, toileting, self-washing, feeding, washing clothes, and communication level: verbal/nonverbal/communication/board, as well as dressing, showering,

coping with menstruation, sexuality issues, budgeting and other, in order to identify the range of living skills and the issues therein evident in this group.

Data Management Using Computer Programs

Brief History

Although computer packages cannot analyze qualitative data, only manage it, there has been a proliferation of these programs in recent years. The main clearing house for these programs is Computer Assisted Qualitative Data Analysis (CAQDAS) (see the section titled 'Relevant web-sites' section for the link to this where a number of programs are listed and links and demo programs provided).

The development of these packages has undergone three distinct developmental eras since their emergence 30 years ago.

- Systematization: code and retrieve,
- Theory generation, and
- Content analysis.

Systematization

The notion of systematic data emerged in the 1970s following an earlier push to make qualitative research

look more like quantitative and to be more transparent regarding methodological approaches. This resulted in pressure for more rigorous exposure by researchers in order to justify their findings. The programs developed in this tradition focused on the storage and retrieval of data and the provision of subviews of the data through the assigning of codes and categories. These early programs were termed code and retrieve.

Code-and-retrieve programs are generally single-file systems and require the segmenting of the text and the attaching of codes to these segments. These coded segments are then filed with some form of identification, for example: "Interview No 1 with xy, Date..." and some programs also have the capacity to attach memos to individual segments and to undertake Boolean searches of and, or, or not. The capacity to define variables and links to statistical software such as Statistical Product and Service Solutions (SPSS) is often provided to allow frequency counts. Files can then be printed out for further examination and consolidation. Coding can occur either on or off screen. On-screen coding has always attracted debate because of the limited screen views and also because of the error rate of reading on screen.

Ethnograph 5 (PC) is an example of this type of program being the most well developed of the cheaper code-and-retrieve programs. It can create and import data files, format the file, and automatically save it as an ETH file and import an unlimited number of data files. It can also rename, move, merge, duplicate, delete, or back up projects as desired, apply several codes at once, create a master code list, organize words into code families and code family trees, attach memos of up to 32 pages long to specific lines in the data file, search by Boolean codes, search by author-created code, and cross reference segments. Code frequencies can also be identified via export to SPSS.

Theory Generation

During the mid-1980s, researchers at qualitative computing conferences recognized the benefits of the first generation of code-and-retrieve programs but pointed out their limitations, particularly their inability to facilitate theoretical interpretations. Another perceived limitation was the incapacity to support the combining of qualitative and quantitative data. These debates resulted in the development of a second generation of computer-management programs. These theory-generation programs comprise a two-file system (data and literature) and are often underpinned by the structural framework of grounded theory, in particular the constant comparative process which the researcher can operate between the two files using Boolean logic. This process facilitates the pitting of propositions against previous literature and existing theoretical interpretations in the generation of new explanations.

Atlas/ti v 5.2.15 (PC) has been a popular program within this tradition. It has an object-oriented graphical user interface for processing of textual, graphical, audio, and video data, on-screen coding (drag and drop), no fixed definition of data segments, simultaneous display of data segments in context, codes, and memos, virtually unlimited number of documents and segments, integration of all relevant material – primary texts, annotations, theories – into separate files, mind mapping and graphical network editing, semi-automatic coding with multi-string text search and pattern matching, theory building, hypertext links, Boolean logic, hypotheses, end-on SPSS, presentation templates, and networking.

The development of these more sophisticated theory-generation programs prompted further discussion regarding the methodological and theoretical implications of the use of computers to manage qualitative data. Initial concerns included the possible impact on the craft of qualitative research and the moves toward control rather than diagnosis and toward explanation and method direction rather than method evolution and interpretation.

Content Analysis

These packages are useful tools for breaking into documents. Most have the capacity to undertake the following: word frequencies to display how often each word occurs in a document; category frequencies which group synonyms into categories and indicate how many times each category occurs in the document; key word in context (KWIC) which displays, in alphabetical order, each word together with a number of words on either side to provide information on its context in the document; cluster analysis where groups of words can be identified as being utilized in similar contexts; and co-occurrence of pairs of words. Dictionaries and cultural grammars are often included and the more sophisticated of these programs are developing the capacity for more complex semiotic analyses.

Textpack 7 (PC) is a basic content-analysis package originally developed to cope with open-ended questions in surveys. It undertakes word frequencies, KWIC and keyword-out-of-context, cross-references, and concordances, and can undertake word comparison of two texts.

Management by Computing Packages: Some Concerns

Despite their usefulness in the management of large databases, the concerns which emerged in the 1980s regarding these packages have persisted. The following is a summary of the major issues which center round the construction of knowledge.

Processes of interpretation

The interpretive processes of data management and analysis which occur without computer management are fluid, involving an *ad hoc* process of building up and fitting together groups of information while regularly standing aside to allow the light of previous literature and the lens of various theoretical perspectives to provide insight. The structure of computer-management programs limits the chaotic nature of this process. In order to facilitate computer management, the database often has to be carved up into lines or paragraphs and this segmentation process completely changes the way the researcher interacts with data. The more sophisticated programs allow for researcher-defined text segments but even with this facility, the framing devices of structured coding, categorizing, relinking, and reinterpreting required by most computer programs cannot fail to have an effect.

Theoretical underpinnings

In addition, most programs are underpinned by their own particular theoretical structures. The impact of the inverted tree-framing structure of NUD* 1ST parallels the development of cognitive frames for knowledge where networks of nodes and relations hang off a defined aspect or category. Adaptation of nodes and replacement frames through matching and accommodation are part of the continuing development of new knowledge. The consolidation of this knowledge is drawn from branches to the singular trunk, leading to a definitive and fairly linear conclusion. In contrast, ATLAS/ti uses a nonhierarchical horizontal rhizomatic frame which stretches to infinity and is constantly evolving. This latter approach fits more closely with the expectations of qualitative research that transformation and change are intrinsic. Whatever form they take, these program underpinnings must inevitably shape the outcomes and perceptions of data collected.

Program structures

Tools constructed for a particular program must also structure thought processes and texture the data in particular ways. Each tool creates artifacts and metaphors which are not neutral in effect and which change our ways of thinking and seeing. The procedural aspects of coding, categorizing, and relinking are fundamentally reductionist and affect our views of the data as they move from a complex, multifaceted reality of intersecting aspects embedded in rich contexts, to a simplified version viewed as discrete groups of representation and subrepresentation.

Once the researcher starts to think in a reductionist manner and to use high-frequency logic, the speed of data atomization will far exceed the speed at which data would be contemplated in the reflexive process off screen. Although speed and a capacity for logic may be advantageous in coping with computer technology, these may well foster superficial and decontextualized interpretations of qualitative data.

De-contextualization

The de-contextualization of data is clearly an issue. The production of narrowly coded segments confines the data separating them from both the researcher and the context. Discovery then tends to be linear rather than chaotic and complex. It seems inevitable that these procedures must simplify what we see, limiting the potential for change and transformation of both researcher and data in the research process.

The introduction of the third-to-fifth-generation languages incorporating Boolean logic and true-false dichotomies foster an emphasis on objectivity, minimization, variable analysis, and enumeration. These approaches have links with positivism. Views of reality tend to become algorithmic and sequential favoring deterministic logic. The representations of reality that are produced are based primarily on discrete objects, although fuzzy logic (where variables are less precise and can overlap) has been used in a couple of programs. The current emphasis in qualitative research has been away from stage-based coding programs such as traditional Straussian grounded theory and toward postmodern versions of all methods particularly ethnography and feminist approaches where the emphasis is on data which are intact and contextualized rather than atomized.

Apart from texturing, fragmenting, and de-contextualizing reality, the emphasis in computer programs on mathematical logic tends to distance the multi-perspective, creative approaches which form the backbone of qualitative research. The thin segmented data which eventuate from computer programs are more likely to be forced into a particular outcome to fit a particular purpose rather than allowing them to challenge current knowledge.

Database size

The increasing capacities of many programs encourage the collection of larger and larger databases and there is a tendency to emphasize the common and shared properties of a large number and to make the framing device more real than its content. In this manner, meaning is lost, people are de-personalized, events neutralized, and the variations in the minutiae of detail of small numbers of participants lost. Another result may be the application of the principle of garbage in and gospel out (GIGO). The reification of computer technology often incorrectly convinces researchers that qualitative research cannot be undertaken without a program and that the codes they develop within these programs can rise to the state of variables capable of quantitative analysis.

Data quantification

Quantitative analysis through the introduction of end-on SPSS and other statistical packages fails to take into account the differing paradigms between quantitative and qualitative data. Where the same data set is involved, the different sampling techniques between the two styles

and lack of variable definition and control in qualitative approaches are relevant. The qualitative emphasis on diversity, nonrepresentativeness, small numbers, self-selection, and thick ethnographic description, suggests that drawing quantitative outcomes from qualitative data is contraindicated and that such a transformation produces unrealistic versions of the original. Where the quantitative data come from a separate data set with the designs kept separate, this is not an issue.

Theory Generation Using Qualitative Data

Regardless of whether computer management is, or not, used, the process of theory generation involves taking the consolidated data groupings derived from preliminary data analysis, thematic analysis, and coding, and subjecting them to two processes. The first involves contrasting the findings with existing literature in order to question, challenge, and add knowledge to the field. The second is to interpret the results found from a more abstract position utilizing whatever theories, models, or concepts are relevant to the discipline where the author is situated, or to the anticipated readership. For example, the study on intellectual disability cited earlier in this article was initially published as a government-funded report; so interpretation was placed within practice-based models of integration within the concepts of integration and normalization. When parts of the study were published in academic journals, both these frameworks and Max Weber's ideal democracy and his concept of economic rationalism were also utilized.

Conclusion

Managing data adequately is crucial not only for preventing the researcher from drowning in his/her data but also for demonstrating researcher trustworthiness and dependability. The subjectivity of the researcher and the complexity of the analytical and interpretive processes require considerable transparency if the reader is to be convinced that the project has been managed properly. The construction of knowledge and how the information researchers collect within a particular research design transfers into results and then is interpreted into conclusions and recommendations is a process we need to be fully aware of. Data-management benefits from starting at the beginning of data collection through the vertical processes of preliminary data analysis, face-sheet development, and regular data summaries. Post data collection, further data segmentation of a horizontal nature can be

undertaken through thematic analysis. In large databases or those to be managed through computer programs, coding should occur but in order to prevent oversimplification and de-contextualization, this should preferably follow thematic analysis rather than precede it.

Computer programs provide a useful management tool for larger databases, but the use of these continues to be contentious. When data become segmented and ordered in monoepistemological computer programs rather than in polyepistemological mind processes away from computers, then we need to consider very carefully the frames, processes, and structures we are imposing. We must always be wary of systems which have the capacity to direct and simplify the views of researchers and ultimately those of readers.

Glossary

Connotation – The extended or acquired meanings of a sign.

Denotation – The referential or intentional meaning of a sign.

Markedness theory – The theory which posits that one of the two elements in an opposition is the default (unmarked) form and the other the marked form (the one that stands out).

Opposition – A binary relation that keeps signs distinct from each other through opposition (night versus day).

Paradigmatic structure – Any aspect of signs that keeps them distinct.

Semiosis – The process of producing and understanding signs.

Signification – The process of using signs for various psychological and social-cultural reasons.

Signified – The conceptual part of the sign; what the sign encodes and refers to.

Signifier – The physical part of a sign; also known as form.

Syntagmatic structure – The combinatory structure of signs (how they have been constructed).

and the like; the latter include not only words, but also gestures and the various symbols that humans invent to serve their psychological, social, and communicative needs (Deely, 2001: 24–56). It was the British philosopher John Locke (1632–1704) who first put forward the proposal of incorporating the study of conventional signs into philosophy in his *Essay Concerning Human Understanding* (Locke, 1690). However, the idea of fashioning an autonomous discipline of sign study did not emerge until the late nineteenth century, when the Swiss philologist Ferdinand de Saussure proposed such an idea in his *Cours de linguistique générale* (de Saussure, 1916). Saussure suggested that the main goal of a science of signs was to understand how signs stand conventionally for things in specific social environments and how they permit people to interact meaningfully.

The first sophisticated classification of signs is due to the American pragmatist philosopher Charles S. Peirce (1839–1914), who identified 66 species of signs in total. Some of these are simply terminological strategies that provide detail as to how signs function cognitively. For example, as its name implies, a qualisign is a form that draws attention to some quality of its referent (the object it represents). In language, an adjective is a qualisign since it draws attention to the qualities (color, shape, size, etc.) of nouns. In other sign systems, qualisigns include colors (painting), harmonies and tones (music), etc. A sinsign is a form used to single out a particular object – a pointing finger and the words here and there are examples of sinsigns. A legisign is a form that designates something by convention (literally by law). Legisigns include symbols, emblems, such as those used on flags, and various other forms that are used according to specific social rules or conventions. However, there are three signs identified by Pierce that are now part and parcel of every semiotician's methodological toolkit – icons, indexes, and symbols. Signs originating in the perception of some property in a referent are icons. Iconic signs stand for their referents by resemblance, imitation, simulation, or emulation. Portraits are icons of human faces (and what they mean); onomatopoeic words are icons of sounds made by certain objects or actions (drip, bang, etc.); and so on. The meanings of icons can generally be figured out even by those who are not a part of the culture that use them. Signs that relate referents, sign users, and even other sign forms in some way are known as indexes. The pointing finger is a perfect example of an index. When we point to something, we are in fact relating it to our location as pointers. If it is close by, we refer to it as

Classifying Signs

The first fundamental task of any science is the classification of its objects of investigation. This is also the case with semiotics. The first classification system of signs goes right back to the ancient world, starting with the definition of sign by Hippocrates (c. 460–370 BCE), the founder of Western medicine, as a symptom. Hippocrates argued that the particular physical form that a symptom takes – a *semeion* (mark) – constitutes a vital clue for finding its etiological source. Shortly thereafter, philosophers started referring to signs as being either natural (produced by the body or nature) or conventional. Among the first to tackle this basic typology was St. Augustine (354–430 CE) in his *De Doctrina Christiana*, in which he describes natural signs (*signa naturalia*) as forms lacking intentionality and conventional ones (*signa data*) as forms produced by human intentions. The former include not only symptoms, but also such phenomena as plant coloration, animal signals,

near or here. If not, we refer to it as far or there. Finally, signs that stand for referents in historically based or conventional ways are symbols. The V-figure standing for peace has symbolic valence, that is, it is interpreted conventionally for peace as a result of some historically or culturally based event.

Signs and Meaning

Semiotic inquiry is guided by two fundamental models of the sign – Saussurean and Peircean. Saussure saw the sign as a binary form with two components – a physical part, such as the sounds that make up the word cat, which he called the signifier, and the mental concept that the sign elicits, which he called the signified (de Saussure, 1916: 101). He claimed, moreover, that a sign is created purely by convention and its connection to a referent is arbitrary. As discussed above, Peirce saw some signs as originating instead in perceptual modeling tendencies (icons). In contrast to Saussure, he claimed that iconicity is a basic tendency in sign-creation (known as semiosis) and that conventional and arbitrary semiosis are a later development, phylogenetically and ontogenetically. Peirce also put forward a triadic model of the sign – a structure consisting of the actual physical sign form, called the representamen, the thing to which it refers, termed the object, and the meanings that it elicits in real-world situations, called the interpretant (Peirce, 1931–1958: vol. 2, 247–248, 307). The interpretant is itself a derived mental sign, because it entails the further production of meanings (senses) arising from the context in which the sign is used. In our culture, a cat is considered to be a domestic companion, among other things; in others, it is viewed primarily as a sacred animal; and in some others, it is considered to be a source of food. Thus, while the sign refers to virtually the same mammal in different cultural contexts (no matter what name is used), its interpretant varies considerably.

A major problem for semiotics is to determine what meaning is and how it manifests itself through signs. To avoid ambiguity, the terms semiosis and signification are used by semioticians. The former refers to the psychological process itself of producing and recognizing specific forms as signs (Fisch, 1978: 32, 41); the latter refers to the mental images that crop up in the brain when a sign is used. Signification involves two main meaning-making processes – reference and sense. Reference is the process itself of identifying what the sign form captures; sense is what that form elicits psychologically, historically, and socially. Signs (such as words) may refer to the same (or similar) things, known as referents, but they have different senses. For example, the ‘long-eared, short-tailed, burrowing mammal of the family Leporidae’ can be called rabbit or hare in English. Both words refer essentially to the same kind of mammal. However, there is a difference

of sense between the two words – hare is the more appropriate term for describing the mammal if it is larger, has longer ears and legs, and does not burrow. Another difference is that a rabbit is often perceived to be a pet, while a hare is unlikely to be perceived as such (Danesi, 2007: 34).

The terms denotation and connotation are preferred to reference and sense. Consider, again, the word cat. The word elicits an image of a ‘creature with four legs, whiskers, retractile claws’, etc. This is its denotative meaning. As this shows, the function of denotation is referential – that is, it allows users of the sign to determine if something real or imaginary under consideration is a cat or not. Denotative meaning thus divides the world of reference into yes–no domains – something is either a cat or it is not. All other meanings of the word cat are connotative – “He’s a real cool cat,” “She let the cat out of the bag,” and so on. These meanings are products of the historical associations forged between cats and socially significant concepts or processes. Connotation thus connects the world of reference to larger historical processes. Connotation is not an option, as some traditional philosophical and linguistic theories of meaning continue to sustain to this day; it is something we are inclined to extract from a sign. The numbers 7 and 13 have specific denotative meanings – each digit stands for a specific quantity of things. However, in our culture, both invariably reverberate at the same time with connotative meanings such as fortune, destiny, bad luck, and so on. In 1957, the psychologists Osgood, Suci, and Tannenbaum showed how connotative meaning is built into everyday concepts by using a technique that they called the semantic differential. This consists in asking a series of evaluative questions to subjects about a particular concept – Is X good or bad? Should Y be weak or strong? etc. – which they are then told to rate on seven-point scales. The ratings are collected and analyzed statistically in order to sift out any general pattern that they might bear. Suppose that subjects are asked to rate the concept “ideal American president” in terms of the following scales: Should the president be: (1) Young or old? (2) Practical or idealistic? (3) Modern or traditional? (4) Male or female? and so on. A subject who feels that the president should be more youngish than oldish would place a mark toward the young end of the top scale; one who feels that a president should be bland, would place a mark toward the bland end of the attractive–bland scale; and so on. Research using the semantic differential has shown that connotation is invariably culture specific.

Structure

In order to extract meaning from a sign, sign system, or sign assemblage (text), one must be able to recognize it as such in the first place. This means that it must have

structure. Specifically, a sign (or sign assemblage such as a text) is recognizable as such if: (1) it is physically distinctive and (2) it is organized in a patterned way. The former implies paradigmatic and the latter syntagmatic structure. The phonic difference between cat and rat, for example, is a paradigmatic feature, allowing the native speaker to perceive the difference as a cue to meaning differentiation. Paradigmatic structure, as this simple example shows, involves some form of meaning-bearing differentiation in the physical makeup of a sign. In music, major and minor chords of the same key are perceivable as significantly different on account of a half-tone difference in the middle note of the chord; raising the index and middle fingers in a vertical orientation can mean victory, or peace (among other meanings), but aiming the same two fingers in a horizontal way at someone would be interpreted instead as a threat; and so on. Now, the way in which the sounds of the word cat are put together is a further cue as to its signifying value. Simply stated, the sounds of the word have been put together in line with English syllable structure. This is an example of syntagmatic structure. In music, for instance, a melody is recognizable as such only if the notes follow each other in a certain way (e.g., according to the rules of harmony); writing words in English involves putting the letters in a left-to-right form; and so on. In essence, a sign is perceivable as a meaning-bearing form if it has paradigmatic (differential) and syntagmatic (combinatorial) structure.

Another main tenet of semiotics is signs can vary in size, that is, in actual physical form. A sign can thus be something small, such as two fingers raised in a V-form; or it can be something much larger, such as a mathematical equation or a narrative. The interpretation of the sign is in all cases holistic, not discrete (decoded in terms of its constituent parts). If asked what $c^2 = a^2 + b^2$ means, a mathematician would say that it stands for the Pythagorean theorem, not for specific digits captured by the letters used (even if this is also true). If we ask someone who has just read a novel what it was all about, we would receive an answer that reveals a perception of the novel as a form containing a singular (holistic) message or purpose. The larger signs constructed by combining smaller ones (such as words in the novel) are called texts and the meanings we extract from them are called messages, rather than just signifieds. The term text embraces such things as conversations, letters, speeches, poems, myths, novels, television programs, paintings, fashion styles, scientific theories, mathematical equations, musical compositions, and so on. Texts are composite structures (signs made up of smaller signs) that are not interpreted in terms of their constituent parts, but holistically as single meaning-bearing structures.

Texts function primarily as representation devices, intended to relate, depict, portray, or reproduce something perceived, sensed, imagined, or felt as requiring signification by means of a complex (combinatorial) form.

This implies knowledge of how signs cohere into systems or codes. To enter into a conversation, for example, one would need to know the language code involved – the system of sounds, words, syntactic rules, etc. that allows for conversation to occur. Language, dress, music, and gesture, among many other things, are examples of codes. These can be defined, more formally, as systems of signs that can be used over and over to encode and decode texts. There are many kinds of codes. For example, intellectual codes contain signs in them (numbers, words, symbols, etc.) that allow for representational activities of a logical, mathematical, scientific, or philosophical nature. Social codes (dress, gender, food, space, etc.) contain sign structures for making messages about oneself in socially appropriate ways and for regulating interpersonal activities. Food codes, for example, underlie how people interpret certain foods as signifiers of various rituals, meanings, etc. It is important to note that once a text is constructed, it takes on its own paradigmatic and syntagmatic properties – that is, it is differentiable from other texts in terms of the kinds of signs that constitute it (verbal, pictorial, etc.), and it is the result of specific syntagmatic properties associated with the code or codes utilized to construct it (language, narrative, and so on).

To identify forms as meaning-bearing structures, Saussure introduced the notion of *différence*. This was expanded by the so-called Prague Circle of linguists in the 1920s and 1930s into the technique known as opposition, which has been used across disciplines, from psychology to linguistics. For the sake of historical accuracy, it should be mentioned that this notion is, implicitly, an ancient one, being characteristic of myths (good vs. evil, youth vs. old age, etc.). The Prague Circle linguist Trubetzkoy (1936, 1968), however, was the first to apply it formally to the study of the structure of language. According to psychologist Ogden (1932: 18), an early promoter of opposition theory, opposition had general applicability because it offered “a new method of approach not only in the case of all those words which can best be defined in terms of their opposites, or of the oppositional scale on which they appear, but also to *any* word.” In the 1930s and 1940s, semioticians started noticing that oppositional structure was not confined to language. It cropped up in the analysis of nonverbal systems and codes as well – in mathematics, for example, fundamental oppositions include positive versus negative, odd versus even, and prime versus composite; in music, they include major versus minor and consonant versus dissonant; and so on.

The Prague Circle linguists also argued that there were orders of oppositions that went beyond the purely binary. In mathematics, for example, the addition-versus-subtraction opposition is a basic or first-order one, while the multiplication-versus-division opposition is a derived or second-order one – since multiplication is repeated addition and division repeated subtraction. French semiotician

Algirdas J. Greimas later introduced the notion of the semiotic square to connect sets of oppositions (Greimas, 1987). Given a word such as *rich*, Greimas suggested that we determine its overall meaning by opposing it to its contradictory, not *rich*, its contrary, *poor*, and its contradictory, not *poor*, in tandem. Moreover, as work with the semantic differential showed in the 1950s (mentioned above), there seem to be gradations within the binary oppositions themselves, which are due to culture-specific connotative processes. Anthropologist Lévi-Strauss (1958) further expanded opposition theory by showing that pairs of oppositions often cohere into sets forming recognizable units. In analyzing kinship systems, he found that the elementary unit of kinship was made up of a set of four oppositions: brother versus sister, husband versus wife, father versus son, and mother's brother versus sister's son. Lévi-Strauss suspected that similar sets, or orders, characterized oppositions in other cultural systems.

Although the idea goes right back to Aristotle, the cognitive importance of opposition was noticed by the psychologists Wilhelm Wundt (1832–1920) and Edward B. Titchener (1867–1927), who were the ones to term it opposition. Its use in semiotics and linguistics is due, as mentioned, to the Prague Circle linguists (Hjelmslev, 1939; Benveniste, 1946; Jakobson, 1939). The theory was criticized from the start as being useful but highly artificial and not really consistent with human psychology. However, already in the 1940s, Jakobson (1942) empirically showed that the theory of opposition predicts the sequence of phone acquisition in children, since he found that the sound oppositions that occur frequently are among the first ones learned by children, while those that are relatively rare are among the last ones to be acquired by children.

Another early criticism of opposition theory was the fact that it seemed to neglect the importance of another structural relation that is vital to understanding semiosis – associative structure. The study of such structure came, actually, to the forefront in the latter part of the 1970s, becoming a major trend within linguistics itself (Pollio, *et al.*, 1977; Lakoff and Johnson, 1980, 1999; Fauconnier and Turner, 2002). American linguist George Lakoff and philosopher Mark Johnson set the ball rolling by claiming that a simple linguistic metaphor such as “My friend is a gorilla” is really not an idiomatic exception to basic literal meaning, but a systematically formed utterance; it is a token of a cognitive associative structure that they called a conceptual metaphor (Lakoff and Johnson, 1980). This is why we can also say that John or Mary or whoever we want is a gorilla, snake, pig, puppy, and so on. Each specific linguistic metaphor (“John is a gorilla,” “Mary is a snake,” etc.) is an instantiation of a more general associative cognitive structure – people are animals. The question becomes: How are such concepts formed? They are formed through

image schemata, as the two scholars argued (Lakoff, 1987; Johnson, 1987). The source for the people are animals conceptual metaphor seems to be an unconscious perception that human personalities and animal behaviors are linked in some way. In other words, it is the consequence of an ontological opposition: humans as animals. This is a perfect example of how opposition manifests itself as an associative mechanism, not just a binary or multi-order one (as discussed above). In this case, the two poles in the opposition are not contrasted (as in night versus day), but equated: humans as animals. This suggests that oppositional structure operates in a noncontrastive way at the level of figurative meaning.

Post-Structuralism

The most severe critiques of opposition theory have revolved around the relative notion of markedness (Tiersma, 1982; Eckman *et al.*, 1983; Andrews, 1990; Battistella, 1990). In oppositions such as night versus day, the question becomes: Which of the two poles is the more basic one (culturally or psychologically)? This is called the unmarked pole (the default one) and the other pole, the marked one (the one that stands out). It is easy to identify day as the unmarked form and night as its marked counterpart, since generally speaking we sleep at night and carry out conscious activities in the day. For example, we ask, “How many days are left before your birthday?” not “How many nights are left before your birthday?” Now, the problem is deciding which pole is marked and unmarked in a problematic opposition such as the male-versus-female one. The answer seems to vary according to the social context to which the opposition is applied. In patrilineal societies the unmarked form is male; but in matrilineal ones, such as the Iroquois one (Alpher, 1987), it appears to be female. Markedness, thus, seems to have social consequences. The late French semiotician-philosophers Michel Foucault (1926–84) and Jacques Derrida (1930–2004) claimed that this whole approach to sign study is flawed, which in itself is the unwitting source of social inequalities (Foucault, 1972; Derrida, 1976). Their refutations led to the movement known as post-structuralism, starting in the late 1950s and gaining prominence in the 1970s. In this movement, the oppositions identified by linguists and semioticians are seen as the result of an endemic logocentrism on the part of the analyst, not the result of some tendency present in the human brain. Saussure claimed that every sign was understandable in terms of its difference from other signs. In contrast to Saussure's idea of *différence*, Derrida coined the word *différance* (spelled with an ‘a,’ but pronounced in the same way), to intentionally satirize Saussurean theory. With this term, Derrida aimed to show that Saussure's

so-called discoveries were unwitting, biased ones, because a science of language cannot succeed since it must unfold through language and thus partake of the slippage (as he called it) it discovers.

Derrida argued further that all sign systems are self-referential – signs refer to other signs, which refer to still other signs, and so on *ad infinitum*. Thus, what appears to be descriptive or objective to the structuralist turns out to be illogical and paradoxical. Post-structuralism has had a profound impact on many fields of knowledge, not just semiotics and linguistics. As written language is the fundamental condition of knowledge-producing enterprises, such as science and philosophy, post-structuralists claim that these end up reflecting nothing more than the writing practices used to articulate them. However, in hindsight, there was (and is) nothing particularly radical in post-structuralism. Already in the 1920s, Jakobson and Trubetzkoy started probing the relativity of language oppositions in the light of their social and psychological functions. Basing their ideas in part on the work of German psychologist Karl Bühler (1879–1963), the Prague Circle linguists posited that language categories mirrored social ones. The goal of a true semiotic science, they claimed, was to investigate the isomorphism that manifested itself between sign and social systems. In other words, opposition theory was the very technique that identified social inequalities, not masked them.

Concluding Remarks

Semiotics is ultimately a form of inquiry into how humans shape raw sensory information into knowledge-based categories through sign creation, that is, by using forms that stand for the categories. Signs are selections from the flux of information that is taken in by our senses allowing us to encode what we perceive as meaningful in it and, thus, to remember it. We are born into a system of sign use, called the semiosphere by the late Estonian semiotician Juri Lotman (1922–1993) – that will largely determine how we come to view the world around us (Lotman, 1991). The semiosphere, like the biosphere, regulates human behavior and shapes social evolution. However, although they can do little about the biosphere, humans have the ability to reshape the semiosphere any time they want. This ability to create new signs and sign systems is what distinguishes human semiosis from all other kinds of sign and signal systems in other species. Our textual resources, for instance, stimulate us to seek new meanings and new ways of seeing the world. These open up the mind, encourage creativity, and engender freedom of thought. As Charles Peirce often wrote in his correspondence, it would seem that as a species we are inclined to “think only in signs.”

Symbolic Interactionism, Naturalistic Inquiry, and Education

J A Forte, Salisbury University, Salisbury, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Contextualism – Theoretical assumption that each moment is a unique and complex event but one situated in a historical timeline and a distinctive spatial context.

Culture – The interrelated set of perspectives that persons who interact together intensively and extensively develop to meet role and institutional challenges.

Life history – The documentation of the interplay of identity, commitments, situational demands, and strategies across a career by the use of various qualitative research tools especially interviewing to make sense of critical events and the life course.

Naturalistic inquiry – An approach to the study of self, relationship, and community processes as they occur requiring minimal interference but maximal immersion by the investigator.

Perspective – The coordinated set of images, ideas, and actions a student uses in dealing with some problematic situation.

Teaching strategy – A creative package of intentions and actions used to achieve goals and respond to the constraints experienced while enacting the teacher role.

Verstehen – Interpretive understanding.

Symbolic Interactionism

Symbolic interactionism (SI) is a theoretical perspective and school of thought created between 1890 and 1910 by philosophers, sociologists, and social workers aligned with the University of Chicago in the United States. The naming of the tradition is credited to Herbert Blumer (Forte, 2006). The perspective focuses attention on the symbolic and the interactive together as they are organized and experienced in everyday life. It looks at how the meanings attached to symbols emerge during social interaction, how agreements about meanings are negotiated, how people use these shared and conventional meanings to do things together, and how meanings are transformed over time. Interactionist theorists and researchers give attention to symbol creation, use, and change as conditioned by interaction, cultural memberships, and social order. Applied

interactionists are interested in how members of groups and organizations redefine objects and events, create new meanings, alter their plans of action, and change the direction and quality of their lives (Forte, 2003).

History

As a school, SI is a network of scholars appreciative of the legacy of the founders (George Herbert Mead, John Dewey, and Jane Addams), committed to a particular paradigm of empirical reality and a set of assumptions about scientific inquiry, and dedicated to transmitting the interactionist vision, theories, and methods across generations (Forte, 2001). Notable members of the school include W. I. Thomas, Herbert Blumer, Ernest Burgess, Robert Park, Everett Hughes, Manfred Kuhn, Carl Couch, Anselm Strauss, Norman Denzin, Helene Lopata, and Erving Goffman.

Several sub-schools have been identified (Forte, 2001). A major dividing line is the conception of the social self and science. The Chicago School affirms the theoretical dispositions of Blumer, emphasizes the human capacity for creative and novel action, and uses a set of core empirical studies, ethnographies and life histories, especially those conducted or sponsored by Burgess and Park between 1917 and 1942, as models (Deegan, 2001). The Iowa School developed under the tutelage of Kuhn theorizes about the solid, persistent aspects of self and the shaping influence of social roles and social organizations, and prefers survey and experimental methods. In the last decade, the identification of interactionists with particular sub-schools has become rare. This article characterizes the Chicago School and its contribution to qualitative research.

Assumptions

Interactionists assume that human beings have species-specific capacities, distinctive strengths (Forte, 2003). Human learners are different from and more complex than members of other species in their capacities for self-awareness and reflection, emotionality, intelligent problem-solving behavior, symbolic interaction, and tool use. Humans are capable, unlike animals, of reflective participation in membership processes and free, responsive choices. The interactionist embrace of bio-evolutionary tenets regarding human differences demands suitable methods for inquiry. Consequently, interactionists developed approaches, such

as personal document analysis, life history, and participation observation sensitive to human characteristics (Denzin, 1992). Interactionist educators also endorse this humanistic assumption. For example, Quicke (2003) asserted: "We should study the learning process from the perspective of the persons at the center of the web of interaction (pupils and teachers) and appreciate that these persons are 'reflective agents'" (p. 52).

Interactionists assume that humans live in a symbolic environment (Forte, 2003). Effective action requires the interpretation of the particular objects (persons, things, events, and other social constructions) constituting one's field of operations. Effective interaction emerges when participants in an encounter interpret each other's conduct (appearance, gestures, expressive and discursive symbols, accounts, and narratives) in a roughly consensual way allowing for the coordination of lines of action. Scientific inquiry, consequently, is a process of *verstehen* or interpretive understanding. Prus (1996), for example, advises ethnographers to use Mead's method of "taking the role of the other" to gain the intimate familiarity with subjects necessary to interpret their situated meanings. Becker summarized educational field work as interpretation: "we try to establish the meanings of various activities, objects, or words by looking at them as they occurred, as they were used, or as they were engaged in a great variety of settings" (Debro, 1986: 43). Woods (1983) research agenda includes topics such as "how teachers and pupils interpret school processes, personnel, and organization such as lessons, the curriculum, their peers, and each other?" and "What factors bear on these interpretations?" (p. 17).

Interactionists take a pragmatic position regarding knowledge production (Forte, 2003). Theory and practice cannot be separated. Knowledge is valuable to the extent that, for example, it can be used practically in social reform and advocacy campaigns. Science is conceptualized in accord with the vision of Charles Sanders Peirce, a founder of American pragmatism, as free and unrestricted communication among a community of inquirers sharing standards for investigation, committed to the revision of understandings following real-world tests, and determined to solve problems of collective concern. Consequently, scientific inquiry is judged by the pragmatic triad of critical scrutiny, experimental consequences, and moral valuation. Does a pedagogical theory satisfy a critical teacher's concerns about its reasonableness and usefulness? Will a pedagogical theory contribute to the achievement of preferred and predicted learning consequences in field experiments? Can the pedagogical theory be used in ways concordant with ethical ideals of the school and community?

Interactionists assume that theorists and researchers should be engaged and critical contributors to bettering personal, social, political, and economic processes

(Forte, 2003). Many interactionists, for example, affirm the progressivism of Dewey, Mead, and Addams. Many have indicated an affinity with the critical theory of Jurgen Habermas (Forte, 2001). Consequently, scientific inquiry takes sides. Becker (Debro, 1986), for example, rejected a definition of the educational researcher role as impartial agents of their employers indifferent to power inequities. Ethnographers should study, he suggested, "everyone connected with the school" (Becker, 1995: 118), even if this is disturbing to some teachers and administrators, and ethnographers should investigate the discrepancies between an educational establishment's goals and actual performances. Good ethnographers report the facts about the causes of school system troubles, "the existence of which no one there would admit" (Becker, 1995: 113), in ways not restricted to students' shortcomings and even when the causes incriminate conditions or processes that administrators do not want to do something about. Science should also be a process generating ideas and images that reconstruct problematic situations and make possible new solutions. Becker characterized scientific inquiry as a search for radical results, "a radical result is one that rises above current orthodoxies, whether they are political, moral, institutional, scientific" (p. 38). Such inquiry is an important prelude to creative policy advocacy.

Finally, interactionism has been built on the root metaphor or assumption of contextualism (Forte, 2006). Each moment is a unique and complex event but one situated in a historical timeline and a distinctive spatial context. Personal processes (human development, learning, and individual action) can best be understood when connected to social processes, practices, and forces as these are related to relevant cultural, ecological, and historical constraints and opportunities. Learning, for example, is considered an event that emerges out of dynamic social interaction between person, setting, and temporal contingencies. Consequently, scientific inquiry must maintain sight of foreground, the acting person, and background, the ecology. The interactionist researcher immerses himself/herself in the teachers' or students' context; appraises the interconnectedness of subjectivity, intersubjectivity, temporal factors, and situational factors; and translates the context-specific meanings for users of the research. Applied interactionists have a preference for case studies: individualized, detailed, and problem-driven accounts of what worked in particular educational contexts.

Concepts

The interactionist perspective includes a set of concepts that can sensitize theorists and researchers to the tradition's central concerns, and also guide observation and data collection in specific educational settings (Forte, 2001).

Identity-related concepts include self, I, me, meanings, identity, identity salience, identity commitments, self-esteem, significant other, reference group, and generalized other. Role-related concepts include roles, counter-roles, formal and informal roles, careers, role-taking, role-making, and socialization. Interaction-related concepts include self-presentation, impression management, significant others, definition of the situation, negotiation, working consensus, aligning actions, strategies, and vocabulary of motives. Context-related concepts include negotiated order, meso-structure, interaction order, symbolic order, and social worlds.

Scholarly Association

The traditions of SI are now celebrated and refined by members of the Society for the Study of Symbolic Interaction (SSSI). This association is an international organization of scholars and practitioners interested in the study of a wide range of issues from the interactionist perspective. The society holds an annual meeting that includes paper presentations, distinguished lectures, business gatherings, and an awards ceremony. The journal, *Symbolic Interaction*, and the research annual, *Studies in Symbolic Interaction*, are the major vehicles for the dissemination of reports on research, theory, and practice.

Exemplary Models

Three interactionists have special value as exemplars to educators and educational researchers. These exemplars represent three different generations.

George Herbert Mead

Recent historical scholarship has documented that Mead, the originator of the tradition, contributed significantly to educational practice, theory, and research (Biesta and Trohler, 2008; Deegan, 1999). Mead played a leadership role in many civic organizations and committees devoted to educational reform. He was a member of City Club of Chicago for almost 20 years and chairman of the Club's Committee for Public Education. He served as president of the Parent's Association for the University of Chicago's School of Education (1902–03), and worked as editor and editorial note writer for the *School Review* and *The Elementary School Teacher*. Mead taught a philosophy of education course regularly between 1905 and 1911, translating his social psychological ideas about self, meaning, and reflective consciousness into language useful to educators. George Herbert Mead was a colleague of John Dewey; and Dewey asserted that he derived many of his seminal ideas about education from exchanges with Mead.

Mead's scholarship addressed topics, such as science education, vocational training, and the role of play. For

example, Mead theorized that play was an essential ingredient in the education of children. Effective education, he argued, blends work, activity to achieve a predesignated end, and play, free and spontaneous activity leading to exploration. Mead recommended objective setting and kindergarten design organized around the use of children's imagination and capacities for spontaneous activity. Teachers should relate learning tasks to children's interests and motivations in ways that channel students' physical energies while supporting experimentation. Such an approach fosters the natural unfolding of students' potentials.

Mead developed an innovative and substantial theoretical framework. He suggested that education is a process of symbolic communication between occupants of teacher and student roles, a process dedicated to the creative formation and transformation of meaning in a way linking learner and society. Teachers should promote a method of thought, that is, scientific reflection, which prepares novice members for effective, competent, responsible, satisfying participation in groups, organizations, and institutions. The medium for teaching is communication by symbols (language, images, gestures, and objects), and this is characterized as a social, intersubjective, and cooperative partnership between teacher and student. The materials of education are more than the lesson plans and learning activities brought to the classroom by the teacher; the meanings jointly constructed during the symbolic interaction in relation to the plans and activities are the critical materials. Mead related teaching to phases of human action. The affective phase requires the activation of the learner's emotion of interest. During the esthetic phase, the teacher helps the learner to attend to and grapple with the presented image or idea and its esthetic or sensuous qualities. In the intellectual phase, the teacher promotes the analyzing and appraising of the image or idea with special reference to its specific and planned uses. Mead's pragmatic theory of consciousness informs the teaching process also. Consciousness is intermittent according to pragmatists, and consciousness is activated when inner or environmental obstacles impede forward action. A curriculum that presents intellectual problems that confound students' action inclinations will compel reflection. As a correlate, Mead adds that learning problems identified and accepted as a problem by the learner rather than imposed by an outside authority increase the reflective qualities of concentration and focus essential to the problem-solving effort.

Mead and his associates also investigated and reported on the public library system, vocational education in public schools, and on the funding and administration of local education. His sponsorship and guidance of two Chicago stockyard district studies, for example, resulted in findings about the employment opportunities of teenage dropouts, the reasons that children and parents gave

for early withdrawal from school, and parental attitudes toward school. These studies, like later interactionist research, used interview methods to solicit the perspective of their participants. Also like later pragmatic and interactionist studies, the research of Mead and his associates included suggestions for improved policies and programs such as increasing the age of compulsory education and increasing opportunities for industrial education.

Howard Becker

Becker, a second-generation interactionist, began his study of education in the doctoral program at University of Chicago and became a diligent interactionist. In his lifetime, he produced “a series of articles on schools and schooling that influenced generations of researchers in Britain and the USA” (Burgess, 1995: 1). The pioneering *Boys in White* (Becker *et al.*, 1961) study investigated the student culture of medical school and the transition of interns from novice to competent status. *Making the Grade* (Becker *et al.*, 1968) examined and detailed the perspectives used by college students to deal with academic work in the context of college.

Becker’s conceptualization of perspectives, culture, and situational adjustment are significant contributions to educational theory (Burgess, 1995). Becker characterized a perspective as the coordinated set of images, ideas, and actions a student uses in dealing with some problematic situation (Becker *et al.*, 1961). For example, medical students have more schoolwork than available time. Many develop a clinical experience perspective. The medical student perceives that clinical experience is the essential prerequisite for a career as a doctor. School activities that provide clinical experience are judged desirable and prioritized. Progress depends on attention to and the accumulation of clinical lessons; and other educational obligations merit minimal effort. Culture, Becker theorized, is one way to understand the relationship of person and organization. Culture is defined as the interrelated set of perspectives that persons who interact together intensively and extensively develop to meet role and institutional challenges (Becker *et al.*, 1968). It helps students coordinate their actions with administrators, teachers, and staff. Once developed, the culture provides situational definitions, understandings of problems and possible solutions, and guidelines regarding preferred ways of prevailing against obstacles. Those who are socialized into a culture relate to the larger organization in a somewhat predictable way. Becker discovered, for example, that culture directs and regulates the degree of student effort. Culture provides a framework for action, permitting creative adjustment to organizational constraints but allowing deviance from rules that does not result in academic failure. Becker’s labeling approach to deviance also has utility for educators and education research (Burgess, 1995). Becker explained that no particular act (e.g., classroom conduct or performance) is inherently deviant. An act becomes deviant

when persons with socially powerful statuses or positions in a hierarchy of credibility label it as deviant. If the label sticks, the actor’s self-concept, interaction, and career are changed as others adjust their behavior to the new and damaging definitions.

Asked about his career, Becker (Ben-Yehuda *et al.*, 1989) asserted “most of my work has been done in education, studying educational institutions, and also in . . . qualitative methodology” (Ben-Yehuda *et al.*, 1989: 485). About design, Becker suggested that theory and method should inform but not dictate a researcher’s approach. His team (Becker *et al.*, 1961), for example, started the medical school study embracing SI theoretical assumptions. Rather than developing detailed research agendas or hypotheses, the team agreed to examine the matters of importance to the people studied. Becker contrasted the fixed design of quantitative methodologies to the flexibility of field research, and argued that the “main advantage of so-called qualitative methods is that you get to change your mind . . . if I learn something useful from my field research, my observation, I can go out tomorrow and use it. You lose the advantages of standardization and you gain the advantage of flexibility” (Mullan, 1996: 133). Becker also valued the hard-earned knowledge obtained through participation observation. He said that “the hardest, most tedious work” often results in the amalgamation of all the materials gathered into compelling empirical arguments and valuable insights into group cultures (Mullan, 1996: 142). Becker is credited with teaching researchers how to make the familiar strange when studying schools. He also inspired extensive inquiry into how teachers observe, classify, react to, and label pupil behavior (Burgess, 1995).

Peter Woods

Woods is a contemporary interactionist with a long record of scholarship relevant to education. From a base of interactionist theory and ethnography, he has written research reports, treatises on the methodological dilemmas faced by qualitative researchers, practical guides for educators, policy analyses, and comprehensive overviews of the SI approach to education and educational research (Woods, 1983, 1996).

Woods’ (1980) major theoretical work develops the interactionist approach to strategies. Teaching strategy, he suggests, is a creative package of intentions and actions used to achieve goals and respond to the constraints experienced while enacting the teacher role. The effective use of strategies enhances a teacher’s adjustment to and survival in the organization. The construction of a teaching strategy is individually motivated and influenced by teacher self-awareness, identity, and commitment to the profession. Each teacher selects and uses teaching strategies, however, in ways influenced by the pool of available cultural symbols, the stability of daily educational situations, support from others, and characteristics of the school and larger social

structure. Woods has conducted much research and supported the research of others on teaching strategies. For example, Woods summarized his findings as a typology of teaching strategies, including domination, negotiation, fraternization, absence, removal, ritual, routine, and moral boosting. Careful observation also revealed the patterned, coherent, and relatively permanent nature of many teachers' choice of preferred strategies.

Woods has also been an active editor and interactionist researcher. With Hammersley, he provided a collection of ethnographic studies of students' interpretations of teachers, pedagogy, and school organization (Hammersley and Woods, 1984). He has pioneered the use of interactionist life histories for purposes of teacher development (Woods, 1993). A life history uses various research tools, especially interviewing to make sense of critical events and the life course. For teachers, a life history can document the interplay of identity, commitments, situational demands, and strategies across a career. Life histories have restorative functions. A life history can help a teacher better understand the distinctive and common aspects of his or her disciplinary knowledge, the transformative processes leading to the contemporary self, the meaning of critical career events and turning points, and the influence of organizational conditions (e.g., a school's gender- and race-based structure) on personal and professional development.

Naturalistic Inquiry and Educational Research

The Blumer (1969) and Denzin (1970, 1971) methodological stance and set of methodological directives undergird the preferred interactionist approach to science, naturalistic inquiry. Qualitative research, ethnography, and interpretative research are terms associated with this approach. Blumer (1969) conceived of social science as a process yielding "verifiable knowledge of human group life and human conduct" (p. 21). Due to the distinctive symbol-creating and-using capacities of humans, Blumer argued, the scientific study of human life requires a methodology radically different from that used by positivist social science. To "respect the nature of the empirical world" (Blumer, 1969: 60), naturalistic inquiry calls for the collection of naturally occurring data in naturally occurring situations for natural time spans by a naturalistic researcher.

Naturalistic inquiry studies self, relationship, and community processes as they occur when there is minimal interference but maximal immersion by the investigator (Denzin, 1970). Mechanical and intrusive investigative methods used by an authoritative social scientist will not capture the emergent and continually constructed nature of social reality. Instead, the researcher attempts to become an insider or group member. George Herbert Mead, John Dewey, W. I. Thomas, and other educators at the University

of Chicago Department of Sociology worked closely and frequently with Jane Addams and Hull House social workers. The settlement house worker, therefore, is a role familiar to the first symbolic interactionists. The role provided a template for their conception of the research process. By living among community members, learning their customs and language, sharing meals with them, participating in cultural traditions, and honoring their significant symbols and practices, these social workers became privy to and participants in diverse social worlds. They shared their knowledge with the larger public to gain sympathy and support. Immersion of this kind increases the likelihood that the naturalistic researcher will witness and understand central interaction processes, such as stage setting, self-presentation, perspective taking, meaning negotiation, novice socialization, culture creation, policymaking, and problem solving. Role boundaries and distinctions dissolve, and the researcher intentionally becomes a native.

Naturalistic inquiry prefers research sites in the community, places where group members act, interact, and develop cultures rather than in scientific laboratories. Blumer (1969) contended that actors could not be understood independently of their social context, "the world of objects, the sets of meanings, and the schemes of interpretation that they already possess" (p. 20). For interactionists, actors act according to the meanings assigned to objects composing their particular fields of interaction. Group patterns are made intelligible and the veil covering the subjects' interpretations can best be lifted *in situ* (Blumer, 1969; Denzin, 1970). Naturalistic inquiry can be compared to the acquisition of a new language and the translation of this language to nonspeakers. Language mastery occurs fastest when the researcher obtains an invitation to the language user's home, workplace, neighborhood, and other locales. Through careful and tactful observation of language use, flexible and conversational interviewing, and participation in daily routines, the researcher learns the language: the system of significant symbols, for example, related to self-conceptions, grades, teachers, school lunch, classrooms, or educational policies. The research report is a translation from the natural language of the members studied to the language of the science-speaking audience.

Naturalistic inquiry requires a time commitment because insight into meaningful symbols and interaction patterns develop slowly. The point-in-time approach of surveys or short-term engagement in most experimental studies is rejected. As each educational setting is a somewhat unique configuration of selves, temporality, and place, the researcher can only make minimal use of prior knowledge and needs time to grasp the distinctive features of the setting. Taking the other's role and then, viewing the world from the other's point of view enable the educational researcher to achieve a depth of understanding. However, achieving the degree of closeness and trust necessary for perceptive and accurate role does not occur

quickly. Symbolic interactionists often produce natural histories. Ethnographies that extend months or years make possible discoveries about meaning-making across time as related to biological aging, developmental progression, learning achievements, student and teacher careers, educational sequences, problem formulation and resolution steps, and mental health trajectories (Denzin, 1971).

Naturalistic inquiry requires a particular stance toward the research role and approach to data collection and analysis, the grounded theory method (Glaser and Strauss, 1967). The naturalistic researcher is the research instrument rather than a survey or standardized measure, and the researcher reflects continuously on the fit of his or her lines of action with the study subjects, and adjusts his or her self, self-presentation, and action accordingly. The researcher maintains a state of responsiveness to the values and influences emerging naturally in symbolic interaction at the research site. Theorizing does not precede the data gathering and possibly render artificial findings. Data collection and data analysis are not separated as in positivist methods. The naturalistic researcher generates theory from the qualitative data with the theorizing and analysis grounded at every stage of the research process in real-world observations (Lincoln and Guba, 1985).

SI, Naturalistic Inquiry, and Qualitative Methods: Conclusion

The charge of this article has been to demonstrate the relevance of SI as a paradigm for educators and educational researchers. Space limits preclude discussion of theoretical and research advances into the micro-aspects of conduct (cognition and emotion) or the macro-processes and structures conditioning meaning-making (power, class, and culture). Interactionist's alignments with other traditions, including semiotics, critical theory, Vygotsky's sociocultural approach, and feminism as well as the recent interactionist responses to criticisms of the naturalist approach (e.g., issues of generalizability, utility for policy advocacy and practice, and the rhetoric of science writing), cannot be reviewed.

SI represents a distinctive tradition of scientific inquiry and applied science offering educators an assumptive base supportive of interpretive, engaged, and practical theorizing about human subjectivity and situated conduct; an opus of work rich with grounded theories, methodological innovations, and naturalistic studies; a set of exemplary theorists and researchers; a framework for the amelioration of educational problems and betterment of educational institutions; and an approach to inquiry that can make sense of the qualities (immediacy, complexity, uniqueness, and symbolic mediation) related to the perspectives, actions, and interaction of members of diverse learning communities.

The Quality of Evidence in Qualitative Research

S K Biklen, Syracuse University, Syracuse, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Assessing the quality of evidence in qualitative research is not straightforward. While scholars do say, “This is what good evidence looks like” and “This is what it is not like” – suggesting that data that are descriptive, detailed, and complex are preferable to field notes that are thin, summarizing, and superficial – these statements are limited. There is a complicated and tension-filled relationship between data and evidence, the context for claiming data as evidence of a particular finding or analytic is always significant, and evidence looks different and may take different forms in the many kinds of scholarship that are included under the umbrella term qualitative research including ethnography, life history, narrative inquiry, and visual methods.

Since qualitative approaches study well the complexity of everyday life, any discussion of evidence must address the complications involved in representing complexity. Funders of major qualitative-research projects may typically want more definitive findings from qualitative researchers than they are sometimes prepared to give, and they want it in the form of useful nuggets that definitively point to specific truths. While published qualitative studies often do make straightforward claims about their focus, equal numbers of studies articulate processes that occurred in complicated ways over time in a setting, capturing the complications rather than highlighting specific claims. Both sorts of projects involve evidence, but the evidence is represented in contrasting ways. In addition, qualitative researchers often must account for conditions where many more people in a setting will assert a particular truth while fewer people who articulate views quite contrary to the first position are closer to what is going on and know more about it. In other words, sometimes the most insightful informants are not the most numerous. Researchers must continually make judgments about how to understand and evaluate what people say.

Discussions of the quality of evidence in qualitative studies, then, in relation to fieldwork, involve wide-ranging concerns such as whether or not the fieldworker trusts the research participants, how to account for what participants assume and know but do not talk about, how what informants do not know about their subjectivities may be a dominant issue, what the particular investments are that research participants have in their perspectives, and what discourses are prominent and available for them as resources – and these are only a sample of concerns. These caveats do not suggest that researchers should retreat from discussions of what constitutes evidence, because assuming the transparency of research participants’

meanings and leaping too quickly to assume understanding of what informants say is dangerous. But we must find ways of grappling with these concerns without developing too narrowly conceived criteria that mimic a positivist view of the world. Evidence is political as well as epistemological and politics must always be taken into account.

Evidence is political on several different levels. First, evidence is political in the sense that it is related to the state. There are particular kinds of evidence that the state supports when it promotes certain forms of research. The state’s interest over the first 10 years of the twenty-first century in randomized clinical trials, for example, that has been so central to defining the evidence-based research movement, has meant that it has little interest in funding qualitative projects, seeing them as too messy for its interests. In this sense, politics references the power of the government to determine what counts as evidence because it limits what methods can be used to collect it. Politics shapes what vested groups want studied, and hence what evidence will even be considered.

Second, evidence is also political because it relates to power relations. From this perspective, the politics of evidence refers to concerns such as whose perspectives qualitative researchers study, who is considered an expert, how language is understood, and the investments people have in particular readings of evidence. Evidence, in other words, is not value neutral. As Denzin (2009) has written, “standards for assessing quality are forms of interpretive practice that enact a politics of evidence and truth” (p. 139).

The question of evidence in qualitative research, in other words, is complex. Its consideration in the postpositivist moment, where criteria for standards for proof in qualitative research are questioned, demands the negotiation of many tensions: what it means to be in the field when the field might refer to someone’s office where an interview takes place; what different groups want qualitative methods to do for them; how audiences understand the question of voice in relation to representation; the dangers and attractions of particular forms in relation to evidence; and the question of theory. This article examines the question of evidence in qualitative methods from an historical perspective, illustrating shifting ideas of evidence and the vocabularies in use; discusses the investments that different groups have in how the social reality of qualitative research in education is constructed (these are not separate tasks, even if they appear so here); and engages some criteria for evaluating evidence as part of the empirical research process.

What Is Evidence?

Evidence for a claim, an argument, or even a portrait involves and relies on data, but data and evidence are not the same. Data are necessary for evidence, but they only become evidence when they relate to a specific question or concern: “Evidence... is data brought to bear on specific questions, theories or experiences. Evidence is data with a purpose. The purpose may be historical, theoretical, evaluative or descriptive, but it is arrayed to some larger end, and it is arrayed in a specific kind of order. Evidence represents data to which have been added a layer – or multiple layers – of interpretation...” (Lincoln, 2002: 5). Data become evidence not only in relation to the question investigated but also in relation to the paradigm or theoretical orientation (articulated or not) that animates the research project. Evidence is structured data. Evidence is always related to interpretation but evidence is of varying quality, and the variation and the interpretive aspects must always be addressed.

To articulate that evidence is data interpreted – or even that observations or interview transcripts must be interpreted to be named as data – does not indicate clearly how the process of interpretation occurs. It might sound as if the frameworks that qualitative researchers use for interpretation determine what the researcher will notice and hence doing that fieldwork comes to equate filling in the empty spaces of a view of the world that is already known to the researcher. Interpretation covers basic processes such as recognizing and considering, where recognizing refers to the researcher’s decision that something seen was worth recording as data, and considering includes the work of figuring out what something recorded as data might mean. At the same time, researchers who spend significant time in the field frequently come to see what they did not expect, or learn a way of making sense of the world that was not previously on their radar. In fieldwork, researchers may hear what is new to them. But they are positioned for this to occur. Finding evidence involves a process of negotiation, a kind of encounter between researchers with specific social locations that orient them to the world in certain and specific ways and those whose ways of seeing the world they try to account for and reflect on. This process of reflection includes imagining alternative ways that readers will interpret an analysis and working to account for them or respond to them.

Contexts

What is it that we seek evidence about? The topics that qualitative researchers study in relation to education travel an extremely broad range, from educational reforms, to student or teacher identity, literacy curricula, punishment, to classroom innovation, to white privilege and color-blind

ideology, and to questions of identity, discomfort, and voice. But whatever is studied, as Mischler (1979) so cogently put it, for the qualitative researcher, meaning must always be made, ascertained, analyzed, and viewed in context. People do not make meaning outside of particular contexts, but contexts are not always local. Social discourses about what is right, how the world is organized, what matters, and who is an authority, for example, are broader than particular locations even as they interact with them. So the researcher articulates and frames the context(s), within which sense making is brought to the data. Contextualizing the data helps transform it into evidence.

When Willard Waller published *The Sociology of Teaching* in 1932, he relied on qualitative data from in-depth interviews, life histories, participant observation, diaries, letters, personal documents, and case records to capture the social worlds of schools. Waller believed that “children and teachers are not disembodied intelligences, not instructing machines and learning machines, but whole human beings tied together in a complex maze of social interconnections. The school is a social world because human beings live in it” (Waller, 1932: 1). His influential work was undertaken at a time when the field of educational sociology, like the current moment in government-sponsored research, was highly quantified. Researchers tended to dismiss the use of approaches such as the life history, describing it as more suitable for social-service work in fields such as social work, rather than for sociology of education. But his approach to focus on the complicated contextualized person and situation, certainly what Mills (1959) defined as the intersection of biography and social structure, demanded an approach where evidence could build a picture.

Characteristics of Qualitative Research

Qualitative research is empirical, a method for studying social life; and what is central to it, shifts over time. When students and faculty did qualitative research during the time of the Chicago School approach, they customarily stayed in the field studying communities for 2 or 3 years (see Becker, 1970a: 53, note 20). Today, graduate students and scholars conducting funded research might interview 10 or 20 people on several occasions for their data collection and consider that a qualitative study. Some students and scholars still undertake the kind of longitudinal work that qualitative research was originally known for, but there is a much wider variation in what counts as adequate time in the field than before. What counts as adequate evidence is one criterion that is not self-evident and that shifts over time. While the life history, the study of a single person that almost takes the form of biography but is a kind of qualitative research, has been around for over 50 years, the standard for numbers of informants that qualify as adequate for studies other than the life history has dropped. When Howard Becker

did his doctoral research, using qualitative interviews with urban schoolteachers, his sample was 50. Many scholars in education used that sample size 20 or 30 years ago as a marker for what was possible. In many circles today, that number would be seen as high. As the approaches for doing qualitative research have expanded in interpretive methods, agreement about what a sample size should be depends on what the local context accepts as adequate. At the same time, ideas about how to evaluate adequacy are also changing. The power of the conservative federal government's politically conservative emphasis on scientific evidence that has marked research in education also affects how qualitative researchers design their studies, what kind of work gets funded, and what research is seen as significant. That is, while funding agencies are willing to fund more traditional qualitative studies, scholars on the margins try to push the limits of what counts as research so that research becomes more inclusive of varying cultural modes.

A range of methods is encompassed under the qualitative label. Traditionally, qualitative researchers in the field gather where research participants normally spend their time; they collect data that are descriptive in narrative form; their focus is on process rather than outcomes; their interest centers on the meaning-making process, that is, on how things, actions, interactions, and situations come to have the meanings that research participants assign to them; and the analysis of the data tends toward the inductive (Bogdan and Biklen, 2007). Newer forms of work emphasize or de-emphasize particular aspects of these characteristics. Institutional ethnography, for example, explores the social relations that structure people's everyday lives, emphasizing how the relations of ruling, that is, hierarchical power relations, can be traced through official texts and discourses into the lives of individuals (Smith, 2005). Auto-ethnography centers the narrator's story and may dispense with the idea of the field. Qualitative methods based on critical race theory assume a world where racism is understood as a central rather than peripheral feature of American life. Qualitative methods using critical race theory start from the assumption that racism exists. Research may look at different forms it takes, the varied vocabularies that represent it, or the kinds of communities that support it, but the researcher does not explore whether racism exists in American culture. Silverman (2004) argues that qualitative researchers need to "broaden our conception of qualitative research beyond issues of subjective 'meaning' and towards issues of language, representation and social organization" (p. 1). This view insists that it is not adequate to study the perspectives of research participants as the participant understands them, but to examine larger social discourses that shape how informants speak. Participatory action research dispenses to some degree with research subjects, informants, or participants (at least as they are traditionally understood), and works toward collaborative interventionist approaches for social change.

Qualitative researchers gather evidence in multiple ways. Strategies of interviewing and participant observation have predominated over the years, although how people have listened and to whom they have listened have changed. These traditional methods of gathering evidence, that is, have not remained static. Harding (1987), for example, has suggested that in interviews, feminist qualitative researchers have listened "critically to how traditional social scientists conceptualize women's and men's lives" (p. 2). Additionally, they have paid attention to behaviors that might earlier have been thought unworthy of observing. Even though qualitative methods have always been oriented to everyday life, what is included within that frame should not be taken for granted.

One sort of qualitative study that has witnessed growth is problematic in several ways. The sort of qualitative study that has expanded is the attraction to work that employs qualitative technique rather than the interpretive approach. This expansion may have occurred because of the desire to combine qualitative and quantitative approaches in the same study or because the federal emphasis on a more positivist approach has had these effects. The use of qualitative technique occurs when researchers collect narrative data to questions they have already predetermined. Their questions are already set before they begin their project. In this form, qualitative is simply a synonym for research where the evidence takes narrative form. The data which researchers using qualitative techniques amass are in response to their questions. The participants in this research approach serve as a kind of answer-providers, giving responses and information – even interpretations – but are shut out from helping to make certain that the focus and emphasis of the study connect to their daily lives. Here, the narrative form of the data is really the reason that it is called qualitative (i.e., not statistical or experimental).

That is, it does not take advantage of the strengths of interpretive approaches. Qualitative research is capable of representing social processes. One of its most significant strengths is that it can elicit what people take for granted and frame perspectives within this context. It studies well the logic of people's views. It beautifully addresses the complexity of lives, situations, and institutions, and therefore, unlike approaches that work to simplify environments, it is useful for actual policy development.

Interpretive qualitative evidence emerges from work that has postponed defining the questions' parameters. In this mode, researchers have a general question when they enter the field, but refine it through the process of being in the field or by talking with participants. This is why a broad question is the strongest one with which to enter the field. Evidence based on qualitative techniques results in more conventional and superficial findings because the researchers sidestep the process of negotiating with informants about what the study is. In the interpretive approach, researchers must learn from the people they

encounter in the field about a range of issues – what the organization, community, or setting is like; what is on people's minds; what kinds of vocabularies people employ to talk about concerns; what seems common sense to them; and what kinds of knowledge are valued. This sort of qualitative research does not privilege professional knowledge over the knowledge of ordinary people because it rejects the hierarchy of credibility. The researcher must take questions of power into account: "In any system of ranked groups, participants take it as a given that members of the highest group have the right to define the way things really are" (Becker, 1967). This means that qualitative researchers always study something from a particular vantage point and must communicate what that vantage point is. It is important for qualitative researchers not to reproduce what is taken for granted in these hierarchies, that those who are more educated or more trained are more insightful. At the same time, researchers should not romanticize those without power, assuming that their standpoint is both innocent and a window to truth. In disability-studies research using a qualitative approach, therefore, the perspectives of people with disabilities cannot be missing from the research. At the same time, their perspectives should not be conceptualized as either transparent or uncomplicated.

Previously, when the collection of evidence was accomplished primarily through participant observation, researchers negotiated with informants over the direction of the research because the length of time researchers spent in the field and the scope of the projects meant that researchers could not know the story to tell in advance. Today, with the press away from longitudinal studies on the one hand, and the insistence in many schools of education on the other that the literature has to drive the shape of questions that doctoral students pose for their dissertation research, students end up doing more limited, narrow, and in some ways weaker, less-robust studies. The increased conventionality means a weaker study because the opportunities are diminished for collecting evidence on the assumptions that informants have about their lives.

Evidence is gathered, mulled over, sorted, analyzed, and used to illustrate arguments. In these different aspects of the research process, thinking about evidence as strong or weak, thick, or thin, involves particular concerns. They involve different standards of judgment. When gathering evidence, for example, questions about the relationship of researchers to their informants must be addressed. Traditionally, researchers used the category of rapport to describe the formation and nurturing of this relationship. Did the researcher create a trusting relationship with the informant? When conducting interviews, we worry and write about whether the interviewer asked leading questions. Evidence is less trustworthy, that is, if interviewers use versions of "Don't you think that. . ." to start a question. It is also less trustworthy if they ask questions that

force interviewees to choose between two competing ways of approaching an issue rather than allowing the interviewee to decide how a response will be framed. Attention to the process of fieldwork is still significant even if evidence is understood in the interpretive frame.

Another question about evidence during fieldwork concerns how the researcher understands the norm, or the social construction of the norm. When, for example, fieldworkers talk about research participants on the one hand and black interviewees on the other, this vocabulary illustrates that the researchers assume that whiteness is a norm for a research participant and black people are constructed as other, or a deviation from this norm. This point is significant as a contradiction for the old argument that qualitative researchers once made, that just being in the field for a long period of time was a good criterion for establishing the worth of the data. Researchers' class, race, gender, sexual orientation, and age, to name a few significant identity markers follow them into the field and contribute to the construction of how they see and how they label what they see.

In the analysis stage, questions about the trustworthiness of evidence are visible in considerations of the context. Did researchers investigate how the particular context in which the researcher observed or interviewed and the specific time period in which the research was conducted come into play? If the data were analyzed as if they were context free, the study becomes less believable because the evidence is not grounded in time or place. Contexts can be defined geographically, socially, and linguistically. Any qualitative study that examines what participants take for granted, and particularly research that emphasizes discourse analysis negotiates multiple contexts, the local and the nationally regulating.

From the Traditional to the Postpositivist

Historically, qualitative researchers were not themselves satisfied with the idea that just being in the field was enough. Scholars discussed how it was that people came to say what they said. In their study of medical students, for example, Becker and his colleagues found that the students talked differently depending on the context and to whom they were speaking. In public groups, for example, the students tended to express their more cynical side, speaking little about the idealistic motivations they may have had or still continued to have about being doctors. In interviews or conversations with the researchers, though, they spoke more about it. Becker (1958) discussed how in fact people express different parts of themselves in different settings and that researchers can account for these contradictions rather than work to figure out which mode of speaking is true. This kind of discussion about the multiple allegiances of people being studied presages

more poststructural ideas about identity and subjectivity as both unstable and multiplicative.

Traditionally, qualitative researchers, to use the anthropologist James Spradley's metaphor, saw ethnographers as attempting to hold a mirror to the world. The idea was that ethnography should reflect the world that the ethnographer studied. This work was not simple as one captured informants' views through the lens of culture, and much cultural knowledge was either hidden from view or not even recognized as knowledge. Yet, tensions existed in this mirror view as qualitative anthropologists asserted that we represent one culture in terms of another, referring to how central the anthropologist's own culture was in the analysis. However, another anthropologist, James Clifford, firmly planted in the postpositivist world, argued that the metaphor of the mirror was false because one could only learn partial truths (Clifford, 1986). By partial truth, Clifford meant that there is no location that the researcher can occupy that affords a vantage point from which 'the truth,' and by this he meant a single truth, could be determined. Additionally, because the product of research is a written text, results become representations. Research efforts, then, lead only to partial truths.

In addition to the mirror metaphor, researchers relied on several ways of framing what was studied that emphasized the social construction of reality. The social construction of reality refers to how knowledge comes to be socially established as reality (Berger and Luckmann, 1967, 3). What people assume and take for granted is always central to the qualitative project. In articulating this view, Berger and Luckmann argued that ordinary people live in worlds that they understand as coherent. Further, the reality of everyday life appears already objectified (p. 21), that is, sense-making schemes seem embedded or integral. Engaging with the world includes figuring out what the coherence depends on, who benefits from the arrangements, and whose views are silenced. Of course, since humans participate in multiple worlds, this is not a single place. The definition of the situation is one aspect of the social construction of reality that is central to the ideas of symbolic interactionism, one of the threads of the history of qualitative methods. The definition of the situation refers to the idea that people act in situations they find themselves in on the basis of how they interpret the situation because there are no inherent meanings in the situations themselves. These interpretations come from people's interactions with others and with institutions and written texts, and they represent how they have learned what the situation means in the particular setting.

In the postpositivist era, the researchers' views and values, and their social location must also be examined. Of particular concern is the issue of power relations. Harding (1987) argued that the "inquirer . . . be placed in the same critical plane as the overt subject matter, thereby recovering the entire research process for scrutiny in the

results of research" (p. 9). This means that the researcher's identity markers of race, class, gender, disability, and age need to be considered as partly defining the researcher's investment and influence on the research. Evidence, in other words, is political, epistemological, socially constructed, and invested in certain frames.

When Donna Haraway addressed the idea of the inevitability of situated knowledge in 1991, she wrote that engaging the term objectivity was inescapable. While she was speaking specifically about tasks for feminists engaged in research, the term is something that qualitative researchers must address when they explain qualitative methods to quantitative-research audiences because of the different assumptions the groups make about research. Discussions of objectivity are also inescapable at this current moment because of the government's insistence on funding only research that employs randomized experimental designs (see Cho and Trent, 2006). These designs rest on a particular view of objectivity, one that emphasizes the positivist scientific tradition. The traditional definition, Haraway explained, seems to suggest that those who conduct objective research are not embodied, while those whose research is often accused of bias are not allowed not to have a body, and so are inevitably disqualified because they are seen to have a finite point of view (183). Objectivity, she argued, "turns out to be about particular and specific embodiment" (190). This alternative view of objectivity, she wrote, is the only kind of responsible knowledge claim because views that assert that they see the world from a neutral position are in fact irresponsible. They pretend that an unmediated account of the world is possible.

The significance of the question that Haraway proposed has been addressed by others. Harding (1987) argued that researchers need to represent themselves in their texts as actual "historical individuals[s] with concrete, specific desires and interests" (p. 9). These actions – engaging in greater reflexivity and representing these reflections in the text – open up the text for greater scrutiny by the audience and hence increase the narrator's trustworthiness and lessen possible distortion. Harding, who distinguishes between objectivity and objectivism, a "stance that attempts to make the researcher's cultural beliefs and practices invisible while simultaneously skewering the research objects' beliefs and practices to the display board" (p. 9), insists that the researcher's views and beliefs become part of the evidence that readers can evaluate. Since the judgments of different readers are central to evaluations of the quality of qualitative research, this movement has significant weight. Introducing subjectivity into the analysis increases the objectivity of the research (Harding, 1987). Therefore, evaluating the quality of evidence is partially related to the visibility of the social location of the researcher, where the social location refers to the researcher's race, class, gender, and other identity markers and how these markers are

invested in the design, understanding, and production of a qualitative project. These are by no means the only significant aspects of a project, but they count. Historically, qualitative researchers in the Chicago tradition suggested in their methodological discussions that simply having respect for the world and studying it closely to try and figure out how people in their particular contexts see it and act can enable any researcher to understand any research participant. Researchers never discussed in their methodological commentaries the possibility that their access to understanding could be limited by their social locations.

For qualitative researchers who are somewhat alienated from the idea of objectivity, framing this problem that Haraway and Harding discuss relates to a researcher's reflexivity and its representation in published accounts. Posed this way, we could say that reflexivity increases not the objectivity of the research but its trustworthiness. Since the worth of a qualitative study depends so heavily on the audience's response to it, trustworthiness takes on heightened importance. If we pay attention to the subject position of the researcher through reflexivity, this attention works to make it visible and addresses the subjectivity question rather than leave it unaddressed. In *Trouble on Memory Lane*, for example, this researcher addressed what happens when narrators of qualitative studies are not reflexive about their age in relation to their research participants when they study adolescents (Biklen, 2004). Many researchers in studies of adolescents draw unproblematically upon their own experiences as youth to illustrate to readers that they understand youth because they were once youth themselves, ignoring the different time periods where they lived through adolescence, and the social changes that have created a world that contrasts significantly from their own time as teenagers. They also describe their own experiences of youth, often in an unreflective way, to bolster their narrative authority.

Readers seeking to evaluate the quality of evidence in a study must be able to assess how authors construct their narrative authority in written texts. Narrative authority means that narrators of written texts have authority with readers because of how they represent themselves in the text. There are a variety of strategies that narrators use to gain this authority, including sharing vulnerability, articulating theoretical sophistication, using various rhetorical strategies, sharing details about significant time spent in the field; so having narrative authority does not rely on being forceful or authoritarian. One can gain narrative authority as Lareau (1989) does by sharing all of the mistakes she made in fieldwork. As readers we trust her because we see her as willing to lay her cards on the table. She is not protecting an image of herself as the sophisticated and naturally capable researcher. Another important strategy for establishing narrative authority with some audiences is to discuss how one's identities (gendered, raced, and classed) shaped the interactions with informants, the problems that

arose in the field, and the shape of the project. This kind of discussion builds on the notion of the embodied researcher that Harding portrays and emphasizes the notion of partial truths (see, e.g., De Andrade, 2000; Pascoe, 2007).

Before the postpositivist moment, qualitative methodologists assumed to some extent that doing empirical work meant that they could, to use James Spradley's metaphor, portray the world they studied as if it were almost a mirror reflection. The social location, the investments – the positionality of the researcher – did not engender much interest partly because of the points that Haraway (1991) so forcefully made, that researchers did not particularly think of themselves as embodied. Becker (1970c), for example, described participant observation in the following way:

The participant observer gathers data by participating in the daily life of the group or organization he studies. He watches the people he is studying to see what situations they ordinarily meet and how they behave in them. He enters into conversation with some or all of the participants in those situations and discovers their interpretations of the events he has observed. (p. 25)

Becker suggests here that doing participant observation is a fairly straightforward task.

Several aspects of these sentences stand out. First, they seem to assume that the researcher is male. Becker had long experience working with Blanche Geer, his co-author on studies (e.g., Becker *et al.*, 1961; Becker *et al.*, 1968), and respect for Helen Hughes and other academic women who were sociologists; so speaking in this way did not come from his research experience. But it may have come from the standards of writing at the time which subsumed women under the category of men. The assumptions Becker made to produce this sentence contradicted some of his experiences and reflected others.

Second, Becker describes the nature of this work in extremely simple language, seeming to challenge the idea that doing research requires jargon, specialized ways of knowing, and a professional demeanor. This style of presentation attracted many students to this method because it seemed to emphasize the significance of the world rather than a science to study it. The method relies on ordinary skills of looking, listening, and talking, as this way of writing suggests. A significant part of doing research, it suggests, involves hanging out.

Third, the observer conducts research, and in the process 'discovers' the perspectives of informants, perspectives that are already there. The research effort and experience are not seen as a process of production – the researcher and the informant do not together produce accounts – but, rather the researcher's time in the field and the careful recording of what is said and done enable the researcher to learn what informants think and why they develop the accounts of their world that they do.

Fourth, the researcher is involved in an enterprise that is inductive. The researcher enters the field with some idea of what will be studied, but must spend time in the setting in order to understand enough to understand what must be understood. Becker's view downplays the ways of making sense of the world, the ideologies and values that make particular aspects of a setting visible and other aspects invisible. Elsewhere, he and many other researchers have argued that the amount of data that rigorous qualitative researchers collect means that the researcher's values and perspectives will not dominate the research because of the weight of qualitative evidence. These researchers spend significant time in the field and so collect enormous amounts of data.

Finally, the researcher who has observed what really happened in the field works to understand what the interpretations of the people who acted in their worlds are on the events that have been observed. Becker does not argue that the researcher stops with the perspectives of informants, but gaining these perspectives is an important task for the qualitative researcher. In a later publication, Becker did say that he almost always studied issues that were immediately relevant to his life (Becker, 1996) suggesting that he did not only report the research participants' perspectives because he already had an investment in the topic.

Becker's comments on participant observation came near the beginning of an essay on 'Problems of inference and proof in participant observation,' first published in 1958 (Becker, 1958). His comments reflect what ways of thinking about qualitative methods have changed significantly since he wrote those words on method so many years ago and what assumptions no longer carry credibility. Just as qualitative methodologists argue that the good researcher studies meaning making in context, qualitative researchers themselves write in context. At the time he wrote, Becker argued that one of the problems in presenting evidence in qualitative studies is that there are no agreed-upon guidelines for presenting evidence: how much, what makes it convincing, and what the rules are for its display. In the end, one of the most important questions to ask in relation to evidence is whether or not the interpretation is credible. The next section of this article examines some of the foundational issues about evidence in empirical qualitative studies. It addresses questions about the amount of data considered necessary, the importance of the relationship between researchers and their research participants, and the discourses that shape the research effort.

Evidence and the Field

Qualitative methods are, taken together, a form of empirical investigation. This means that they are related to data. They are different from other interpretive works, say in

the humanities, where the rules for inquiry have different foundations. Data and interpretation are interrelated and connected. What kinds of empirical issues are important in evaluating evidence?

How much data? As discussed above, how much is a time-sensitive question that has changed over the years. One of the significant characteristics of this approach that does affect evidence is that qualitative approaches get at complications rather than work to simplify them. Therefore, researchers have to have a way to spend enough time or talk to enough people in a setting not only to get a feel for the place and situation, but also to be able to say in some way, "this is how things work around here for the people I am studying." One can use member checks to make sure that the researcher understands what people think and feel, but it always takes time. So-called *blitzkrieg* ethnography (Rist, 1980) produces only superficial readings of situations, people's perspectives, and settings. Imagine moving to a country where the temperature is expressed in terms of Celsius rather than Fahrenheit. Figuring out the temperature when it is expressed in terms that the traveler does not have an intrinsic feel for demands some conscious work that will make the translation known. Brought up in a Fahrenheit society, the citizen knows what 72° feels like, but has to work to make the connections, in a Celsius society, to what 22° feels like. Qualitative researchers work to find out what it feels like to know what 72° or 22° feels like.

Whatever changes have shaped how we consider data and their analysis, spending time in a setting or with participants in interview research is a minimum requirement for strong evidence. It does not guarantee a thoughtful, elegant piece of research, but without time in the field and a significant quantity of field notes, the evidence cannot be strong. Detail does not in itself yield thick description (Geertz, 1973). Field notes are not rich just because their data are detailed. Thick description refers to a particular understanding of social life that the ethnographer works to capture: "social life is densely coded and performed through multiple frames of reference. There are multiple forms through which the social is enacted and accounted for. It is rendered through actions, narratives, texts, visual representations, and material artifacts. These do not cumulate to convey one simple set of cultural 'messages,' but they constitute multiple semantic domains, multiple arenas of action, and multiple sources of significance" (Atkinson *et al.*, 2003: 114). Thick description is the result of engaging people's complicated and layered lives in order to communicate something significant about them without losing the complexity.

Evidence and Social Location

How does the relationship between the researcher and the informant matter? The kind of evidence that results from

qualitative in-depth interviews depends on the sorts of questions that get asked. Asking leading questions pushes informants to respond to the interviewer's ideas and assumptions about what is significant and how the world is ordered. Asking questions in a way that presses the informant to choose the frame from which to respond offers greater access to the informant's sense-making frames. Just asking open-ended questions, in itself, does not secure this access as sometimes a reliance on particular vocabularies and assumptions within, say, a 'how' question can lead informants out of a frame that might have been attractive to them. There is also the issue that many informants want to please the researcher and so they work to tell a story that the researcher wants to hear. That is why the one-time or one-shot interview is a weaker form of data collection that results in evidence that is less trustworthy.

Interviewers not only ask questions, but they also listen. How researchers hear or understand what is being talked about, even what is enacted in the interview process, is shaped by the frameworks within which they listen. One way that scholars who write about methodology refer to these frameworks is with the vocabulary of theory. When interviewers listen, that is, they listen to what informants say through a lens or filter that orders the interviewee's words; for example, positioning some words as important and some words as unimportant, according to ideas about how the world works and what matters. Theory – that is theories about human life – is this lens. How does the researcher understand power relations? How does the researcher understand the relationship between an individual's biography and the larger events of history? How does a researcher see or take into account the identity of the person being interviewed. This is a question not only of how the researcher listens to the informant but of how the researcher understands the identity of the research participant being interviewed. Theory refers to the most basic aspects of identity. Does the researcher see the different markers of an informant's identity as separate or as inter-connecting? How researchers theorize this question shapes what they ask, what they hear, what they even consider to be data. In a study of gender and elementary school teachers, for example, I understood the racial and gendered identities of the research participants to be separate rather than intersecting. I assumed that I could study women teachers, whether black, white, or Latina teachers as women. This affected how I listened to the informants.

One example about questioning and listening is instructive. An instructional specialist, one of very few Black teachers I interviewed multiple times, had children who were about my children's age. Like my children, they were in day care. Whenever I entered the building to do participant observation and encountered her, or had an interview arranged with her, she always spent significant time asking about my children, how they were doing, and talking about

her children and how they were doing. I read this conversation as chatting, and categorized this kind of talk as rapport building. From my perspective, I wanted to get down to work. I experienced talking about our children as an effort to place me in a domestic realm. I felt resistant to this pressure because I saw myself as working on a funded research project where I needed to collect meaningful data. I already had a good relationship with her, I thought, so why did we need to continually develop rapport?

What I did know about my informant was that she was one of the few teachers who spoke clearly about her ambitions to be a principal. She assumed that adult women had continuous employment, and she connected her ambitions with strategies about how to advance in the workforce. These were the issues that I saw as central to my study, and that I wanted to explore. At the same time, she was one of the only teachers who had children in day care. Had I interpreted her talk about children and childcare as connected to her work, as in fact it was, I would have taken these interchanges as serious engagement about the topic of my research rather than as rapport building or chatting. I could also have asked her in greater detail about her mother traveling from the south to help with childcare so that she would not have to miss too much work when her children were born. How much time was enough? Did her mother help her with both children? How did she understand her mother's views about her daughter's ambitions for the principalship? All of these significant aspects of her perspective were missing because I listened to her talk through theory that separated work and family. I might have been one of the only people she could have spoken with about her children as she and I both held shared beliefs in the value of public child care (see Biklen (1995); and Biklen *et al.* (2008) for a longer discussion of these concerns).

The Question of Distance

In the modernist frame, representing reality truthfully meant that one had to have distance from the object of study (Potter, 1996). Closeness to the informants could mean that the researcher was too invested to get it right. In qualitative methods, however, closeness is a significant requirement for knowing. Lofland (1971) evaluated this by four criteria: physical proximity to the people studied, staying connected to informants or to the community studied over time, closeness in terms of 'social intimacy' and a sense of 'confidentiality' in the relationship, and finally, closeness in terms of recording the 'minutiae' and details of everyday life (p. 3) so that they appear in field notes. This last point about recording the details in field notes suggests that the articles written from the study directly quote from what people in the field say. If the texts resulting from qualitative fieldwork do not

contain these direct quotations, their believability is lessened. This perspective emphasizes both the significance of the reader's or audience's role in relation to deciding the credibility of an interpretation and the strategies that researchers use to gain the reader's trust in their insights. Qualitative studies depend on field notes the researcher writes up from fieldwork and from samples of interview transcripts to illustrate and reconfirm analysis. This evidence can be woven throughout the text as in Diamond's (1992) study of nursing homes, or separated out in individual chunks to show how the author's view rests on the data as Lacy (2007) does in her study of Black middle-class communities.

Conclusion

The vocabulary frequently used to refer to the credibility of interpretations is validity, which researchers understand as the trustworthiness of inferences drawn from data (Eisenhart and Howe (1992), 644 cited in Freeman *et al.* (2007)). Validity as most scholars use this shorthand refers to the part of the equation that insists that there is a 'there there,' and frames how the research represents it. It is not as useful in adequately addressing assertions about theoretically framing a project or in addressing what counts as evidence and why. But it lurks adjacent to all published accounts, particularly during times when the federal government has moved discussions about research value toward a particularly constructed scientific model, or model of scientism. Readers bring questions about the trustworthiness of an account to each text, so researchers need to communicate not only what counts as evidence in the project and why, but how they represent themselves and the evidence in the text as they do. Evidence is not only related to research design, fieldwork, and data analysis but to writing, rhetorical strategies, and textual representation as well.

The quality of evidence in a published text reporting qualitative research is important for multiple reasons. One reason is that in order for an account to be understood as the author of the account intends, the writer must be able to convince the reader that the account is believable and that the narrator's authority is trustworthy. The quality of the evidence is constructed by the author and the reader together as the reader makes judgments about its quality. When readers consider the quality of the evidence, they continually consider its believability. If audience members do not share understandings with the research participants, they need to have enough examples of what informants say to believe the narrator. They also have to believe the narrator's interpretations of what those who were studied say.

This article opened with the complications of evaluating evidence after the interpretive turn. This does not

suggest that because qualitative researchers tend to operate on the basis of the social construction of reality, the implications of social constructions are not real. As Potter (1996) suggests, there is a "there there." In addition to basic demands that researchers spend time in the field, know their informants well, understand that people's lives are complicated and layered, and that the goal of these methods is to capture those complications, there are additional concerns about how the worlds that researchers and informants live in are structured. Questions about evidence are embedded in issues of power relations, identity markers, investments, and enormous inequalities. In order to make judgments about whether or not a qualitative study is believable, readers must take all of these factors into account.

Glossary

Brown versus Board of Education, or Brown decision

– The decision by the U S Supreme Court in Brown versus Board of Education to overturn the legal precedent of separate but equal in favor of abolishing racially segregated schooling.

Conscientization – A term proposed by Paolo Freire to describe the empowerment of indigent populations through political education and consciousness development.

Emic (and etic) perspective – Accounts of natural phenomena in terms that are meaningful to insiders, participants, or subjects of a study – contrasts with etic.

Etic (and emic) perspective – Accounts of natural phenomena in terms that are meaningful to outsiders, observers, or researchers – contrasts with emic.

Image-based research – Research that considers visual images and imagery as a key dimension of culture and social life.

Microethnography – The application of ethnographic perspectives and methods to investigate social interaction in relatively small-scale settings and exchanges – that is, conversation, performance, teacher–student questioning, game playing, etc.

Photo elicitation – Using photographs as interview prompts.

Projective interview – An interview designed to reveal something about the person being interviewed (in contrast to interviews that focus on the interviewee as a source of information about external matters).

Visual anthropology – A perspective within anthropology that emphasizes the analysis of visual dimensions of culture and social life and/or uses visual imagery to develop or explicate anthropological knowledge.

Visual data – Data that take the form of visual images, including visible artifacts, photographs, and videotape recordings, maps, drawings, etc.

Visual sociology – A perspective within sociology that emphasizes the analysis of visual dimensions of culture and social life and/or uses visual imagery to develop or explicate sociological knowledge.

Education researchers have used visual data to investigate diverse phenomena and to communicate about their research to colleagues, policymakers, practitioners, and the public. The forms of visual data most common to these purposes include videotape recordings, photographs, drawings, material artifact collections, and graphic figures, logs, and tracings.

In application to education research, visual data of this sort support two different modes of research. In the first mode, researchers examine phenomena independent of the human agency and experience that might bring them into being. In the second, visual data are used to explore the knowledge, values, and perspectives of individuals and groups.

Research cast in the first mode involves investigators as external observers who record and analyze what they see in terms that make sense to other researchers. Photographs, videotapes, drawings, and visual artifacts can provide useful data for studies of this sort and contribute to what anthropologists refer to as the etic perspective, or outsider's point of view. In the second mode, research questions focus on how phenomena are experienced, shaped, and perceived by individual and groups. Visual materials can also provide valuable data for studies aimed in this direction and that reflect what anthropologists call the emic perspective, or insider's point of view.

Of special interest to educators, visual data can play a role in research-based interventions – either locally or farther afield. A videotape recording of classroom interaction, for example, could be analyzed solely for its methodological significance to other researchers who make videotape recordings, but it could also be used to stimulate reflection among the students and teachers recognizable in the recording – or among others who identify with them – or to document the work of an individual teacher for a certification review. Visual studies of textbooks or classrooms could be framed by historical questions that have few contemporary implications, but they could also play a role in multi-million dollar law suits and challenges to state or district school policies.

These general observations about visual data apply in part to numerical and text data as well. All three forms of evidence can support research directed toward etic or emic accounts, and all three can inform interventions and social action. For many social scientists, however, visual imagery is linked more closely with an emic or semiotic perspective, numbers with a natural science or etic approach, and texts

more or less with both. In anthropology and sociology, these associations have led researchers working with visual data to establish separate professional organizations, journals and conferences. Visual studies in education have been shaped somewhat by these developments in allied fields, but they also reflect the distinctive ethos of a profession that values both interdisciplinary and applied inquiries.

The Visual Heritage of Education Research

The work of Lewis Hine during the early part of the twentieth century provides a useful starting point for considering these matters further. Hine is best known today as a documentary photographer of child laborers, immigrants, and the Empire State Building, but his camera work began as an assistant teacher of nature study and geography at the Ethical-Cultural School in New York City. Hine came to this position in 1904 after completing undergraduate work in sociology and anthropology at the University of Chicago and while working toward a master's degree in education at New York University. Shortly after he arrived at the school, he was asked by Principal Frank Manny to serve as the official school photographer.

The Ethical-Cultural School supported, and was supported by, a remarkable group of educators, social researchers, and social reformers, including John Dewey (two of his children attended the school) and the anthropologist Ruth Benedict. Consistent with the progressive ethos of the school, Hine expanded his school-photographer role to make images of culture and social life outside the school that he hoped could enrich instruction within it. This ideal led him to begin photographing – and encouraging his students to photograph with him – immigrant families as they arrived at Ellis Island. The visual data he used to teach students about immigration and cultural diversity stimulated Hine's interest in using photography to teach the public about similar issues. With that in mind, in 1909 he left teaching for photography and generated an oeuvre of visual data that served both researchers and reformers.

Somewhat similar connections between fieldwork, visual documentation, pedagogy, and social reform characterized Charles Hamilton Houston's work for the *National Association for the Advancement of Colored People* (NAACP). The Association was founded in 1909 with strong support from the Ethical-Cultural Society, the parent organization of the school where Hine had been teaching. Some 25 years later, after a term as dean of the Howard University Law School, Houston was appointed special counsel to the association. His signal contribution was to craft a legal strategy for undermining the separate but equal principles used to legalize racial segregation since the US Supreme Court's landmark 1896 decision in *Plessy versus Ferguson*. Houston's proposal to the NAACP

membership was not to challenge this principle directly, but to illustrate the social and economic costs of holding institutions to the standard of truly equal facilities for both black and white citizens. This strategy required legal challenges to be pursued in the courts, but it also required good evidence about what was equal and what was not.

Houston's first step toward mobilizing NAACP support for this strategy was to lead a film crew in documenting separate and unequal schooling in South Carolina. Houston screened the film as part of his formal address to the association. When a majority of the members voted in favor, the NAACP embarked on a decade-long series of legal challenges to racial segregation. These challenges culminated (shortly after Houston's death in 1950) in the Supreme Court's decision, in *Brown versus Board of Education*, to overturn *Plessy* and call for the abolition of racially segregated public schools.

Field Studies, Experiments and Interviews

With varying emphases on documentation, inquiry, instruction, and advocacy, visual field studies evolved during the mid-century decades as a valued approach in research on education and schooling. Some studies of this sort were closely allied with related work in anthropology, sociology, and psychology. In the 1930s and 1940s, for example, the anthropologists Gregory Bateson and Margaret Mead reported on their extensive photographic studies of Balinese culture, a substantial strand of which focused on adult-child interaction in support of learning and socialization. As a sequel to her work with Bateson, Mead collaborated with Frances MacGregor in analyzing the same photo archives to explore cross-cultural dimensions of child-development theories articulated by psychologist Arnold Gesell.

Image-based education research also drew inspiration from psychological investigations that used visual materials – photographs, drawings, abstract shapes, or artifacts – as prompts for clinical and research interviews. The Rorschach and the Thematic Apperception Test (TAT) were well-known variants of this projective interview genre. In application to education and schooling, however, a more notable example was a series of studies during the late 1930s and early 1940s by Kenneth and Mamie Phipps Clark. The Clarks used a black doll and white doll as visual prompts for interviewing black and white children. With the dolls displayed before them, children were asked which of the two they preferred playing with, which was the good doll, and which doll was most like them. The Clarks interpreted the preference for white dolls among both black and white children, and the visible distress exhibited by the black children in response to the forced-choice questions, as projective evidence of the psychological costs to children of racial segregation and inequality. They testified to this effect in several school hearings – including the Briggs

versus Elliott case that was incorporated into Brown versus Board of Education – and the US Supreme Court made explicit note of their research in its rationale for the Brown decision.

The Clarks' doll studies shifted the focus of projective interviewing from individual personality toward culture and social relations. John Collier, Jr. pushed it even farther in that direction through what he called the photo-elicitation interview, an approach in which photographs of local environs, activities, and materials were used as prompts for discussion with research subjects. Collier noted, in particular, the potential of this approach to elicit accounts from research subjects that reflected their own language, concepts, and priorities rather than mirroring those of the researcher.

Collier had worked as a documentary photographer for the Farm Security Administration in the 1940s and extended the lessons of that experience into his anthropological fieldwork. Through a series of studies in the 1950s and 1960s, he used photo-elicitation interviews to explore perceptions of those he studied and systematic photographic inventories to document their material possessions, homes, and communities. He was keenly interested in studies of both school organization and student experience and affirmed the etic and emic as complementary perspectives. His own interest in education research was apparent in his seminal work, *Visual Anthropology: Photography as a Research Method*, and from his film recordings of native Alaskan classrooms.

Another notable application of image-elicitation techniques to education appeared in the literacy and political education projects Paulo Freire and his associates pursued with indigent populations in Brazil and other Latin American countries. As the first step of a widely imitated intervention protocol, they used traditional fieldwork techniques to identify key circumstances of local culture and social life. As a second step, they shared photographs or drawings of these circumstances with local residents to stimulate community discussions as a foundation for politicization and literacy development. Within the process that Freire called conscientization, social-documentary images functioned as instructional materials. As an intimation of future application of visual data to both research and practice, the subjects of Freire's interventions were also collaborators in analyzing the images themselves.

Microethnographies of Classroom and Language Use

By the mid- to late 1970s, the heritage of these varied approaches had demonstrated the potential value of visual data to studies of the behavior, psychology, social life, culture, and politics of subject populations and to both educational and social reform. Interest in this dual potential

continued as portable videotape recorders and digital media ushered in new forms of visual data and new kinds of visual studies.

One of the most vital applications of portable videorecording emerged among educational anthropologists and sociologists such as Frederick Erickson, Jeffrey Shultz, and Hugh Mehan who were interested in fine-grained investigations of schooling processes and functions. Much of this work focused on different forms of school-related communication – presenting class lessons, teacher–student consultations, classroom interaction, and so on. These phenomena had received prior research attention, but videotape technologies allowed researchers to examine them more systematically and in greater detail. They also made it possible to review the same interaction sequences again and again, code for more subtle cues, observe the interplay of verbal and nonverbal messages, and extend data analysis protocols to colleagues who had no direct involvement in a given field setting.

Many of these studies (but by no means all) were attuned to the ideal of improving experiences and outcomes for students who were disadvantaged in school by their culture, language, race, or social class. Indeed, an enduring contribution of visual studies of this sort was to document how interaction patterns in and around classrooms both reflected and supported structural school inequalities.

Videotape equipment not only made recording easier and more portable, it also made possible new forms of editing, playback, and collaboration. In the mid- to late 1980s, for example, George and Louise Spindler presented videorecordings of classroom interaction as prompts for group discussions in their cross-cultural investigations of schooling in Wisconsin and Germany. As an extension of shared video viewing between researchers and subjects, other researchers engaged research subjects as image-makers in their own right. The work of John Adair, Sol Worth, and Richard Chalfen with native Navaho filmmakers provided a template for subsequent studies in other venues and with other populations, including youth media productions directed toward both education research and youth-development outcomes.

Digital Media and Visual Studies

In the decades just before and after the millennium, the growth of digital media has stimulated additional attention to visual data in education research and in the classroom. For more than a century – at least since Hine's work at the Ethical–Cultural School–teachers and students could pursue image-based field studies as part school curricula, but this practice increased dramatically as digital still and video cameras became increasingly affordable and available. Teachers can now assign students visual-documentation projects and review the results immediately in class. Students can also combine digital image making at

school with related projects in their homes and communities. This expanding genre of student work (including video-based oral history and digital storytelling) includes strands of both documentary and projective imaging and has attracted the attention of researchers interested in literacy, classroom instruction, and youth development.

The capacity of computers to generate visual logs of how individuals use them has also created new possibilities for examining how students learn, what they know, and how they think. In developing the Green Globbs mathematics education software program, for example, Sharon Dugdale designed separate interfaces for students and for teachers and researchers. Within the former, students create algebraic equations to trace a line on their computer screen through predetermined points, or globbs. By presenting different sets of points, the software challenges students to experiment with different coefficients and different kinds of equations. Through the instructor's interface, however, a teacher or researcher can also review hits and misses as diagnostic information about students' mathematical understanding.

Computer-generated visual representations of how students process information have played an increasingly important role in studies of cognition and language development. Neurophysiologists, for example, have used magnetic resonance imaging (MRI) scans to reveal patterns of brain activity associated with learning, memory, and problem solving. As a microbehavioral complement, researchers have used computerized sensing instruments to investigate how students decode and process visual information. In a relatively recent strand of reading research, for example, an eye-tracking device and computer screen operate in sync to generate a visual map of how students scan words on a computer screen.

The instrumentation associated with MRI's and eye tracking seems more closely aligned with experimental research than with fieldwork. However, instrumented interactions with computers are now a common feature of computer-assisted tutoring, social networking, and recreational gaming. In a format that combines elements of both experimental and field studies, some researchers have captured changes in how information is displayed on a computer screen (including changes made by students themselves) in connection with audio-video recordings of students interacting with the computer, either alone or with tutors or peers.

In addition to naturalistic and experimental research studies, digital media and the Internet have precipitated broad changes in how visual materials are distributed and accessed. Online archives from museums, newspapers, historical societies, and libraries have created opportunities for research on school populations, facilities, and rituals as they were photographed and otherwise documented at the time. Websites and networking technologies have also stimulated inquiries into visual dimensions of

adolescent social life, distance and hybrid learning, and student-identity formation.

The Internet has also made it possible to incorporate richer visual data in communication among education researchers and between researchers and practitioners. In form, if not in substance, Collier's photo-elicitation interviews and Freire's efforts to enrich subjects' understanding of key social and political processes can now be pursued online. An early step in this direction was taken when the Child Language Data Exchange System (CHILDES) project created an online archive of audio and videorecordings of children's language use that is now part of a larger TalkBank system. Another step occurred when analysis tools from the Third International Mathematics and Science Study (TIMSS) were reconfigured to support websites where videotape recordings of teaching and learning could be uploaded for review and comment by others engaged in similar pursuits. In a less structured and rapidly evolving way, YouTube has been used by an increasing number of educators and scholars to share visual documents of teaching and learning. As a related, but more structured and officially sanctioned enterprise, annotated video documents of classroom instruction have emerged as an integral feature of teacher credential and licensing programs, including certification by the National Board for Professional Teaching Standards (NBPTS).

Research Contributions and Study Formats

Broadly defined and illustrated by studies such as those noted above, visual data can contribute to education research in four key dimensions:

- extending and enriching observations of natural phenomena that are difficult to document, analyze, and represent with textual and numerical data alone;
- instantiating forms of thinking, feeling, belief, and understanding that are difficult to examine empirically in other ways;
- helping to challenge and refine theoretical constructs for which significant visual dimensions have been overlooked; and
- stimulating and enriching communication among researchers and between researchers, practitioners, and policymakers.

Anne Dyson's study of how children developed literacy skills necessary for successful school performance illustrates several such contributions. Prior studies emphasizing individual linguistic competence represented students as young cogitators trying to apprehend grammar rules and vocabulary presented by teachers. Consistent with this view, policy attention focused on building teacher skills in diagnosing reading and writing difficulties,

designing appropriate lessons, and helping students stay focused on what they could learn from their teachers.

Dyson's direct observations revealed that students' literacy skills might also develop through communication with their peers, that is, within the social worlds they created and found in school classrooms. To explore the depth of these apparent effects, Dyson had to examine not only what children read and wrote, but also what they said to each other and the visual materials they created and responded to in and out of school, including their own drawings a wide range of mass-media imagery. By directly observing how children used these materials and images, she noticed a neglected relationship between mass culture, children's drawings, classroom social life and literacy development – a relationship that the children did not always notice themselves.

The data Dyson collected about the visual materials children attended to in their literacy development made possible a kind of natural scientific inquiry that would be difficult to pursue in other ways, but visual data can also be applied to semiotic analyses and the construction of emic accounts. For a study of cross-cultural perspectives on preschooling, for example, Joseph Tobin, David Wu, and Dana Davidson needed vivid portraits of what some preschools actually looked like. Toward that end, they made videotape recordings at several preschools where they had been conducting fieldwork in Japan, China, and the US. They focused these recordings on activities that were routine for each school, but they also made a special effort to include interactions that reflected conflict, ambiguity, and emotion. They then edited the raw tapes into three 20-min videos portraits, each of which revealed some dimensions of the culture and social organization of one school in each country.

For the second phase of their study, the researchers scheduled public viewings in each country of its corresponding videotape preschool portrait and recorded audience responses, questions, and discussion. These quasi-focus group events helped the researchers to assess the typicality of their video portraits. More importantly, they revealed ideals that adults from each country had about their own preschools. These ideals were refined further through a second round of inquiry in which audiences viewed and commented on preschool video portraits of the other two countries. Taken together, within-country and cross-country video-elicitation activities helped researchers understand how people in each of the three countries regarded the lives of young children and revealed some of the contrasting ideals that supported different preschool configurations among them.

Visual evidence can also provide grounds for challenging the taken-for-granted correspondence between some kinds of data and the phenomena to which they refer, at times in ways that redefine phenomena themselves. Contributions of this sort are illustrated by the three-decade, history of the

International Mathematics and Science Studies. In the first of these studies, national schooling phenomena were defined by standardized test scores, according to which students from some countries did much better than students from others. Critics noted quite rightly, however, that without knowing more about what concepts had been taught to students, and when, comparative assessments of knowledge acquisition and teaching effectiveness were indeterminate. To correct for this shortcoming, a second study in this series combined test-score data with information about the scope and sequence of mathematics curricula in each participating country. The official documents collected as evidence of these variations broadened the conception of schooling being compared but were also somewhat problematic in focusing on espoused curricula that might or might not correspond to curricula in use.

In hopes that it could deepen these international comparisons, a classroom videotape component was included as an adjunct to the Third International Mathematics and Science Study or TIMSS (since extended under the same acronym as Trends in International Mathematics and Science Study). Designed by James Stigler and his associates to sample some of the same classrooms participating in the larger study, the videotape component revealed cross-national differences in how mathematics and science lessons were presented to students, the allocation of class time among different tasks and activities, and patterns of student and teacher interaction. These contrasting features were significant in comparing schooling across different countries, but they were difficult to represent through numerical and textual data alone. The TIMSS videotape study stimulated a cascade of related research and policy investigations focusing on classroom instruction, mathematics and science education, the preparation of teachers, and cultural foundations of schooling. It also challenged the presumption of using either test scores or official curricula as proxies for effective teaching and learning. This outcome prompted the National Research Council's Board on International Comparative Studies to recommend the expanded use of videotape in cross-national studies of schooling.

For each of these three studies, visual images were not only examined as empirical data about the particulars of education and schooling. They also were used to report research findings to external audiences (and in the preschool study, as prompts for eliciting audience commentary). Dyson's writing and presentations typically included photocopies of student work as both evidence and illustrations of her research findings. Tobin, Wu, and Davidson made videotapes not only for interviewing adult subjects but also for stimulating public discussion and policymaking. Visual data generated through the TIMSS research were also integral to both research and public reports about the project. Sample video clips of classroom instruction from countries participating in the initial video study,

for example, were distributed as supplements to written reports. Technologies for analyzing these data were also incorporated into what has become a proprietary lesson lab project for supporting professional development among teachers and other educators.

Symmetry between the analysis of visual data for research purposes and inclusion of visual data in research reports does not necessarily apply to education research in general. Many researchers have analyzed visual data without including them in published reports. In conducting his elementary school ethnography, for example, Jan Nesper reviewed photographs of his own and those made by students and also student-drawn community maps, but only a few of the maps are reproduced in the book based on this work, *Tangled up in School*. The inverse also applies, as many researchers who do not analyze visual data use visual imagery in presenting their work to others.

Diverse Phenomena and Varied Purposes

Education studies are noteworthy for using visual data to investigate a wide range of phenomena and to serve an equally wide range of research and development purposes. Videorecordings of classroom interaction, for example, have been used to study student–teacher interaction, the presentation of course content, and – as interview prompts – to investigate adult views of appropriate school behavior. The same kinds of data have also been used to support professional teaching communities or conduct-certification reviews. Visual artifacts of student schoolwork have been examined to answer questions about student abilities and effort, the cultural knowledge of different school populations, teaching effectiveness, and school–home–community interactions, but they are also used routinely to support parent–teacher conferencing about individual students.

These diverse applications suggest that visual data, analysis tools, and evidence are relatively normalized within the conduct of education research. Visual data in education, for example, have not been subsumed within a separate domain of inquiry that corresponds to visual sociology or visual anthropology. They appear instead as pragmatic, visual dimensions of empirical inquiry in a broad range of studies. The evolution of visual recording technologies, media, and distribution systems could challenge this normalcy. However, for over a century now, education researchers have found ways of using new imaging tools to stimulate research and theorizing about education and schooling and to support fieldwork, pedagogy, and social advocacy. There is every indication they will be adding to this heritage for some time to come.

QUALITATIVE RESEARCH – STANDARDS OF PROOF

Validity: Mapping Diverse Perspectives

G B Rossman and S F Rallis, University of Massachusetts Amherst, Amherst, MA, USA

A M Kuntz, University of Alabama, Tuscaloosa, AL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Connoisseurship (researcher as) – Researcher as expert; asserts evidence as support for expert judgment or interpretation.

Consequential ethics – Actions are judged good or bad because of their results within particular contexts; implies the ends justify the means.

Credible evidence – That which provides justification for researched assertions; reveals researcher's biases concerning what can be known and how one may come to such knowledge.

Nonconsequentialist ethics – Universal standards exist to guide all behavior regardless of consequences related to specific contexts.

Postmodernism – Anti-foundational perspective that explicates historically privileged research practices in order to disrupt commonsensical and unexamined ways of practicing research.

Postpositivism – Argues for truth claims that are plausible and based on testable causal explanations.

Poststructuralism – Questions all authoritative truths and the ability of language to fix meaning. Asserts power and knowledge as intimately linked, knowledges as contingent and historically produced.

Probity – Recognizes holistic truth in need of multiple perspectives for definition; asserts the integrity of the research project above all else.

Realism – Postpositivist perspective that asserts the existence of a real world yet inability for humans to fully observe causal mechanisms and underlying structures of that world. Aims to systematically exclude rival hypotheses as implausible.

Relational ethics – Foregrounds ethical implications of research; questions the meaning of actions and

evidence has for all individuals involved in research projects.

Social constructivism – Meaning is socially constructed, locally situated, and developed through individual experiences.

Trustworthiness – Assumptions about research design, process, and effects that generate assertions of merit, worth, and rigor.

Judging the soundness and credibility of research is central to scholarship, policy development, and program design. What to believe – what to put one's trust in – is foundational to the development of further research, sound policies, and programs that are designed on credible knowledge. The trustworthiness of qualitative inquiry, as with all research, depends on the appropriateness of the study's design for the research questions posed, the depth and rigor displayed in data collection, the richness and integrity of the analyses, and finally on the truth claims put forward, based on the evidence offered. These concerns are subsumed under the criteria or standards for judging the rigor and validity of a study, as well as the reliability with which the data were gathered.

Historically, reliability, validity, objectivity, and generalizability were viewed as the standards against which to judge all research, including qualitative inquiry. However, as the postmodern turn/s and their compelling critiques of normal social science have taken up residence in most social science discourses, these four canonical criteria have been challenged, as has the very notion of criteria or standards itself. Multiple and sometimes conflicting assumptions about the nature of truth (what we claim we know), reality (what we claim we know about), knowledge production (how we produce those claims), and evidence (what we argue supports those claims) now drive theorizing about inquiry as well as on-the-ground research practice. Standards are emergent and often contested, as advocates for a particular genre of qualitative inquiry argue that their are the proper or correct ones. The four canonical standards no longer obtain, at least in their original form. Yeats's (1920) comment is quite appropriate here: "Things fall apart; the

center cannot hold;/ Mere anarchy is loosed upon the world". Thus, judging the quality of qualitative inquiry is no longer a simple process or a formulaic one.

A range of approaches to validity, or trustworthiness, has evolved, reflecting differing assumptions about knowledge, truth, and strategies for observing the agreed-upon canons. We have clustered these into positivism, postpositivism, and postmodernity and poststructuralism. Within the variegated discourse, however, is little explicit discussion of the role of language or narrative form, specifically in terms of argument and evidence, which we discuss next.

The Validity Question: Argument, Evidence, and Authorship

Standards of proof within qualitative inquiry gain meaning and legitimacy from the larger critical contexts from which they emerge. Consequently, the very meaning of validity or truth, for example, is shaped by the assumptions inherent in critical social movements associated with positivism, postpositivism, and postmodernity. The positivist and, to some extent, the postpositivist perspectives focus on procedural rules for establishing the truth claims of research. Phillips (2006) invites us to move beyond methodological procedural rules to a consideration of how the truth-claim argument is constructed from the evidence presented and the warrants that connect the evidence to the assertions. The postmodern critiques offer a challenge to the author-free assumption of traditional social science writing. Central to this critique is the assertion that all texts are authored by a historically situated, political, gendered individual. Thus the notion (which seems obvious today) that the author is present in the text, that, in fact, the author has constructed the text, invites a critical read of the ways in which evidence is brought forward, assertions are supported, and how the evidence warrants those assertions. The focus shifts to the author as well as the content. All this comes under the purview of argumentation which fosters a close reading of the text *qua* text to discern how and in what ways the author has developed a convincing case for the tentative conclusions put forward. Thus, the validity question moves to a more complex place where the soundness/strength/validity of the argument, as well as the soundness/strength/validity of the research itself, becomes paramount. Much of this discussion is without the methodological discourse but, as Phillips (2006) notes, the main question to be asked is:

has the overall case made by the investigator been established to a degree that warrants the tentative acceptance of the theoretical or empirical claims that are being put forward? (p. 24, italics in original).

He notes that building an evidentiary case entails "scientists as making convincing cases, cases that appeal to a wide variety of evidence" (p. 1). The making of a case depends on the argumentation put forward: its logic, clarity, sources of evidence, warrants connecting the evidence to the assertions, and relevance. However, what is convincing varies across time, space, and sociopolitical context.

This article maps this contested terrain by first describing the historical period when the four canonical criteria held sway – the positivist persuasion. Based on the assumptions that one true reality exists and that social scientists can have direct, unmediated knowledge of that social world, this period witnessed the direct application of the canons developed in the natural sciences to qualitative inquiry. Resting on the philosophy of logical positivism, adherents argued for standards for inquiry that provided evidence of cause and effect to foster predictive statements about the social world, as natural scientists could (it was then presumed) do so about the forces of nature. As discussed below, some of these assumptions and normative demands for a positivist kind of validity remain in today's methodological discourse.

We next discuss the reaction – postpositivism – which softened the positivist's belief in a fully apprehensible world and introduced notions of a contingent, tentative knowing of the social world. Those of the postpositivist persuasion argue for inquiry that produces interpretations or truth claims that are plausible, based on the evidence put forward – thus the shift from proof to plausibility. Many nuances can be found within this large category; we discuss realism, social constructivism, connoisseurship, and relational ethics as key perspectives that adopt a less-absolutist ontology and focus more on individual sense making in the research process.

We then shift to the postmodern turn/s more explicitly and the development of poststructural critiques. Within this large, sometimes cacophonous group, are both gentle as well as radical arguments about validity. While some methodological scholars sought to displace the centrality of the term validity within discussion of qualitative inquiry, others utilize poststructural theory to interrogate validity as a contestatory site of multiple and competing discourses. The many contexts inherent in the inquiry process are now investigated with increased urgency as the lines which demarcate the boundaries of the research study blurred to become a site of inquiry themselves.

Historical Perspectives

The positivist period in qualitative inquiry suffered from what could be called physics envy, directing researchers' gaze to the processes and standards of rigor developed in the natural sciences which derive from a correspondence theory of truth. Reliability, validity, and generalizability

became the “holy trinity . . . , worshipped with respect by all true believers in science” (Kvale, 1996: 229). Early texts seamlessly applied these canons from the natural sciences to social science inquiry with little or no critique of the epistemological or ontological assumptions undergirding these standards. For example, Taylor and Bogdan’s 1984 text, *Introduction to Qualitative Research Methods: A Search for Meaning* (2nd edn.), notes that “qualitative researchers emphasize validity” (p. 7), providing procedural rules to ensure validity. These include describing the methods used in some detail (the research design, duration and intensity of fieldwork, number, and type of settings and informants, and analysis procedures including checks of informants’ statements) (pp. 151, 152). Precisely how a researcher is to check on informants’ statements as well as what to check for remain opaque.

A critical moment in the history of qualitative inquiry occurred when Lincoln and Guba published *Naturalistic Inquiry* in 1985. This text engaged with central notions that frame social interactions as well as all research: Do we believe in the claims that a text, a person, or the media put forward? On what grounds do we find these assertions credible? What evidence is put forward? How was that evidence gathered; by what standards do we evaluate it? Are these claims potentially useful for the issues at hand? These questions capture natural-science concerns with validity, reliability, objectivity, and generalizability, but broaden and deepen them. Lincoln and Guba reclaimed ordinary language terms (Kvale, 1996: 231), putting forward the constructs of credibility, dependability, confirmability, and transferability as alternatives to the canon. They argued that standards for trustworthiness should address the credibility of a study, whether it was systematically and rigorously conducted, and whether the study has potential usefulness and significance (see also Rossman and Rallis, 2003). They also offered procedural rules to help ensure that the standards would be met. To help meet the validity/credibility criterion, they urged the qualitative researcher to stay in the setting or with the participants for a long time (prolonged engagement); to conduct member checks where participants validate (or not) the emerging analyses and findings; and to engage in peer debriefing with trusted and yet critical colleagues to ensure that analyses are grounded in the evidence. This latter, along with creating detailed notes of the process for conducting an audit, helps to meet the dependability/reliability and objectivity/confirmability criteria foregrounded by earlier scholars.

Lincoln and Guba’s work was generative. Their arguments directly challenged the positivist cannon, noting specifically that objectivity is a chimera, as all social interactions are mediated by a perceiving individual. Thus, sanitized, person-free inquiry, objective research is not possible. They also introduced a challenge to the traditional canon’s emphasis on generalizability which

was possible only if the probabilistic conditions of randomly selected sampling occurred. Their argument that alternative logics – notably those of comparison and contrast as seen in legal reasoning and medical reasoning on a case-by-case basis – better suited the small sample size of much qualitative research (see also Kennedy, 1979).

Much of the subsequent discourse addressing rigor, validity, and generalizability in qualitative inquiry invokes their work, whether as a starting point for critique or to deepen the ideas that they proposed. In fact, there are few major texts about qualitative inquiry that do not cite this generative text. (See, e.g., Bodgan and Biklen, 2007; Creswell, 2002, 1998; Kvale, 1996; Marshall and Rossman, 2006; Patton, 2001; Wolcott, 2001; Yin, 2003.) Today, calls for meeting the positivist understandings, especially the realist ontology, of these canons continue, but with some softening, as we discuss below. For example, Morse and Richards (2002) assert that “determining reliability and validity remains the qualitative researcher’s goal” (p. 168) and that “claim[ing] that reliability and validity have no place in qualitative inquiry is to place the entire paradigm under suspicion” (p. 168). What is contested is how these crucial constructs are to be defined, by whom, for what research project, and for which audience/s. Addressing these questions, not too long after the publication of *Naturalistic Inquiry* (1985), Guba and Lincoln (1989) critiqued their earlier work as being “parallel, quasi-foundational, and clearly intended to be analogs to conventional criteria” (Schwandt, 1997: 165). They called for an emphasis on the outcomes of research, as well as the politics of both conducting and sharing results.

Postpositivist Perspectives: Keeping the Faith

As introduced above, with its confidence in apprehendible reality and testable causal explanations, positivism promised discovery of truth and a predictable world. The ruling standard of proof was validity; if the study had validity, the results could be trusted (Campbell and Stanley, 1966). The alternative epistemologies of postpositivist perspectives suggest different considerations of what counts as proof and evidence. To a postpositivist, reality is “only imperfectly and probabilistically apprehendible” (Guba and Lincoln, 2005: 195), and any claim to knowledge is both fallible and contingent. Yet, at times the language that some postpositivists use for determining what is legitimate and acceptable research does little beyond borrowing and building on the established positivist criteria. This section begins by discussing what might be called the realist postpositivist perspective, drawing specifically from the work of Maxwell (1996). It then moves to social constructivist perspectives which demonstrate

the shift to the community of discourse or practice as validators of research, then to connoisseurship and its emphasis on transparency of method, then the ethical imperative of probity. All, one way or another, articulate either procedural rules or guiding criteria to help ensure the trustworthiness of the research.

Realist Postpositivism

While the term postpositivism can include various philosophies, each recognizes the role of theory and interpretation in how we define reality and know the world. Realism, for example, asserts that while a real world exists, causal mechanisms and underlying structures are not directly observable; thus, humans use a variety of sense-making techniques to mediate between what is observed and what actually exists. The realist approach, however, still aims to produce an accurate representation of reality; so validity is an exercise to explore “how might you be wrong?” (Maxwell, 1996: 86). From this perspective, the qualitative researcher’s task is to rule out validity threats “using evidence, collected during the research itself, to make rival hypotheses implausible” (p. 88). This language is remarkably similar to that used in the classical positivist text on social science experiments by Campbell and Stanley (1966).

To elaborate, Maxwell (1996) describes distinct threats to validity in qualitative understanding: inaccurate or incomplete data threaten the validity of description; imposing the researcher’s own framework or meaning threatens valid interpretation; and theoretical validity is threatened by establishing vague and abstract propositions without consideration of discrepant data or alternative explanations. Drawing on his realist frame, Maxwell proposes a checklist of validity tests:

- The *modus operandi* method searches for alternative explanations or causes for each event.
- Searching for discrepant evidence and negative cases seeks to falsify any proposed conclusion; and unexplained instances can suggest modifications to a finding.
- Triangulation reduces risk of chance association and systematic biases.
- Soliciting feedback both from those who are familiar with the setting and from strangers may surface biases as well as flaws in logic or methods.
- Member checks offer specific feedback to rule out misinterpretation and to uncover alternative perspectives.
- Rich data (i.e., detailed and complete) provide full and revealing pictures on which to test one’s interpretations.
- Quasi-statistics allow assessment of the amount of evidence that bears on any given conclusion.
- Comparison provides a background against which to test a conclusion (pp. 92–98).

Finally, Maxwell declares that internal generalizability is critical for qualitative case studies. He asks whether descriptive, interpretive, and theoretical conclusions within the setting or group be generalized to the case as a whole. “If you are studying the patterns of interaction between the teacher and students in a single classroom, your account of that classroom as a whole is seriously jeopardized if you have selectively focused on particular students or kinds of interactions and ignored others” (p. 97). In summary, Maxwell, the realist methodologist, seeks to uncover the real arguments or evidence behind an event or interaction.

Social Constructivism

A broad, loosely connected set of perspectives, social constructivists, move away from a strict realist ontology and epistemology: knowledge is local; reality consists of individual experiences, the meaning of which is co-constructed within some community. This perspective stands in contrast with the realist approach above where demonstrating validity lies within the researcher’s and his/her text’s purview. Social constructivists explicitly argue that the strength of a study is determined socially – within a group. Still, many researchers of these persuasions rely on procedural rules for trustworthiness that are reminiscent of approaches to the positivist notion of validity: rigor, systematicity, and competent practice are words used as standards for credible evidence or proof. These approaches still focus on method to ensure interpretive rigor: Are data sources, perspectives, methods, and investigators triangulated? Was there prolonged engagement? Were member checks and peer-debriefing employed?

Some social constructivists, however, offer a somewhat different view of determining trustworthiness. Those of this set of persuasions view knowledge as a set of social artifacts, the reality of which can be observed in social interaction. Trustworthiness, or validation, lies within a “community of scientists” (Mischler, 1990: 422) who identify shared exemplars to guide further research. The essential criterion for judging a study to be trustworthy is “the degree to which we can rely on the concepts, methods, and inferences of a study as the basis for our own theorizing and empirical research” (p. 419). This approach implies an elite discursive validity, socially constructed among and applied by researchers to research.

Another group of constructivists reject any permanent, unvarying, or foundational standards on which knowledge is grounded or by which truth can be universally known; they propose a quite different conceptualization of research as social inquiry. Truth (with a capital T rather than a lower-case one) and any agreement regarding what is valid knowledge is seen as rising from the relationship between members of some stakeholding community and is thus subject to negotiation (Lincoln, 1995). Schwandt

(1996) suggests that instead of criteria to judge social inquiry – which he calls “regulative norms for removing doubts and settling disputes about what is correct or incorrect, true or false” (p. 59) – we practice inquiry as practical philosophy, that is, deep questioning or moral critique. This perspective evaluates the researcher and her research by how well her reports of the inquiry support the “training or calibration of human judgment” (p. 69) and “the capacity for practical wisdom” (p. 70). If this approach uses any criterion, it is the utility of the findings to produce social change (Schwandt, 2008).

Schwandt is not alone in linking credible evidence to use. Spillane and Miele point out that evidence use is an issue of evidence construction: “research does not construct evidence – people do” (Spillane and Miele, 2007: 47). A set of facts becomes evidence only when people interpret the facts as confirming, contradicting or complicating a proposed definition or solution to a problem. The meaning and value of the evidence lies in its use in what they call work practice (p. 58). People construct evidence together within the context in which it is observed or collected, not alone. Credible evidence, then, is a product of collective action while examining practice settings where “new information is encountered (or overlooked), interpreted as evidence of one thing or another (or dismissed as irrelevant), and eventually put to use (or ignored)” (p. 58). This symbolic interaction perspective (Blumer, 1969) assumes that meaning is constructed and reconstructed during human interaction.

Connoisseurship and Critique

The researcher as connoisseur (one who appreciates) or critic (one who discloses) stands as an expert who has had a great deal of experience with the persons, objects, situations, or activities being considered. This researcher questions the need and usefulness, indeed the appropriateness, of the literal and restricted definition of knowledge that the so-called scientific researchers follow: “scientific knowledge is seldom true in the literal sense. Especially in the social sciences where metaphor, analogical reasoning, and hypothetical constructs abound, literal truths are scarce” (Eisner, 1991: 108). As the connoisseur or critic deals with “matters as complex and subtle as the description, interpretation, and evaluation” of human interaction (p. 109), validity is seen as probable or judged by what is reasonable. Eisner (1991), the spokesperson for this perspective, posits that “we can secure no unmediated grasp of things as they ‘really are’”, so “we are ‘stuck’ with judgments and interpretations” (p. 109). The appreciative or critique perspective sees evidence, then, not as providing proof for a given truth but as support for a particular interpretation or judgment. The connoisseur or critic clearly does not believe that anything goes in qualitative inquiry. In fact, Eisner (1991) offers three evidentiary bases

for judging credibility: structural corroboration, consensual validation, and referential adequacy.

The evidentiary bases serve to persuade the reader in favor of the critic’s interpretation. Structural corroboration is, like triangulation, a process “through which multiple types of data are related to each other to support or contradict the interpretation and evaluation of a state of affairs” (Eisner, 1991: 110). The weight and coherence of evidence allows the researcher to build a credible case that is tightly argued and persuasive. Consensual validation implies that competent others agree with the description, interpretation, and evaluation put forth by the researcher or critic. Evidence of the plausibility of the argument, description, and judgment lies in the overlap among those who have described and evaluated the event, object, or phenomenon. The consensus is won among readers who are persuaded by what the critic or researcher has to say. Thus, transparency of method and criteria used is essential to persuade the reader to accept any particular interpretation. A referentially adequate criticism enables the reader to “locate in its subject matter the qualities and the meanings [the critic] ascribes to them” (Eisner, 1991: 114). Put simply, the reader can see what the critic sees and why. Again, transparency of method and criteria is essential. All three of these evidentiary bases work together; a good critic uses multiple sources and types of data, puts forward her methods and criteria so readers can judge their agreement (or not), and offers a picture sufficiently detailed to reveal the grounds for her interpretation.

Relational and Ethics Probity

The previous discussions have considered validity *qua* validity and have addressed ethics as a separate, sometimes equally important consideration for judging the quality of qualitative inquiry. In a departure from this norm, but still within the postpositivist perspective, two of the authors (Rossman and Rallis, 2003; Rallis and Rossman, 2004) argue that the trustworthiness of qualitative research is judged by two sets of standards: Does the study meet agreed-upon canons for acceptable and competent practice (including validity), and does it demonstrate sensitivity to ethical issues? We argue that both considerations are intimately linked because a study might meet accepted standards for practice but, if not ethically conducted, the work falls short. From this perspective, an unethical study is not a trustworthy study. “Bad science makes for bad ethics” (Rosenthal, 1994: 128), and bad ethics makes for bad science. This ethical perspective claims that trustworthiness should depend not only on whether the researcher got the technical matters right, but it must also be judged by how well the researcher got the relational matters right. Relational matters – the long-term, thoughtful, and sensitive interactions, built through probity – are seen as central to ethical considerations.

Probity implies wholeness and integrity; it acknowledges that truth is a holistic concept, is more than meets the eye, and demands multiple avenues toward full understanding. Moreover, probity requires rigorous reasoning through moral principles to determine moral soundness. “The point of moral principles is to regulate interactions among human beings” (Strike *et al.*, 1988: 41) – and what is social science research but an interaction among human beings? Thus, this perspective asks: How are ethical considerations embedded in the demonstration of evidence to support the claims made? What moral principles guide choices for collecting, analyzing, and interpreting the data to inform the findings? What reasoning lies behind the choice of principles? How does the researcher demonstrate and enact the principles in both planning and implementing the study?

This perspective argues that ethical theories, grounded in moral principles, provide direction for researchers to help ensure the overall trustworthiness of a study. Philosophers and ethical theorists have put forward various theories to analyze or direct ethical behavior, and these theories can be grouped into two broad categories – consequentialist and nonconsequentialist – according to the criteria each uses to determine the moral correctness of a particular action, in this case, in a research context.

Consequentialist ethics use the results of actions to determine their rightness or wrongness. Such reasoning implies that ends justify means. Any particular action is either good or bad because of its results in a particular context – its consequences. The best-known example of this category is utilitarianism, “the doctrine that the greatest good of the greatest number should be the guiding principle of conduct” (Brown, 1993: 3534). The moral principle of utilitarianism declares “that actions are right if they are useful or for the benefit of a majority” (Brown, 1993: 3534). Among themselves, utilitarian philosophers debate about what is good and for whose good. Consequentialists may rely on usefulness – both degree and type – as an evidentiary base. They ask: What happens when the research findings are used? Whom do they affect? In what ways? In short, what are their consequences?

In contrast, nonconsequentialist ethical theories derive from the moral principle that universal standards exist to guide all behavior, regardless of the consequences in a specific situation. Three nonconsequentialist moral principles are individual rights and responsibilities, social justice, and care. The ethic of rights and responsibilities upholds the unconditional worth of all human beings and the respect to which they are entitled. This ethic also mandates the corresponding obligations to protect those rights. Reasoning from this moral principle, the trustworthiness of a study is judged by the degree to which and in what ways the conduct of the research and its written product respect the participants’ rights, not by its outcomes or consequences.

The ethic of justice argues for the redistribution of resources and opportunities to promote equity above equality. It relies on principles of fairness and equity to judge the trustworthiness of research decisions and actions. Justice aims to ensure that everyone is better off, even though the allocation of a benefit may differ across groups. Such apparently unequal treatment is justified because not attending to the least is to hurt the whole. Specifically from this perspective, then, the purpose of research is to benefit those who have been excluded or deprived (less to the privileged; more to the needy). This perspective demands that qualitative researchers be diligent in collecting evidence that represents participants who have been marginalized or previously silenced. As noted above, Schwandt (2008) espouses an ethic of justice when he argues that trustworthy research leads to social change whether in the conduct of a study or in its application (resonating with a consequentialist perspective, also).

Finally, this relational perspective draws on another nonconsequentialist moral principle that emphasizes the interdependence of people. Articulated as an ethic of care, this principle addresses the effect any action in a research context is likely to have on human relationships. This ethic honors and respects the intimate connections inherent in human interaction. Gilligan (1982) and Noddings (1984) are two caring theorists who first defined the relational-self in contrast to the individual-self. As they see individuals through their relationships with others, actions have multiple meanings depending upon the particular attachments formed. Rather than relying on general laws or principles, the caring researcher focuses on the particular setting and relationships formed in the research context. Trustworthy research considers what meaning the action and resulting evidence would have for the individuals involved.

These nonconsequential ethical theories are concerned with ongoing actions and interactions. From this perspective, therefore, trustworthy evidence is found not in presumed or hoped-for use but in daily practice from a moral stance. All the postpositivist perspectives discussed above, while there is variation among them, tend to hold to the belief that guiding principles or procedural rules can assure the validity and trustworthiness of qualitative inquiry. We turn now to the postmodern critique and, specifically, poststructural challenges to these more traditional notions of validity and its related questions of truth, reliability, and evidence.

Postmodern Turns and Poststructural Interrogations: Deconstructing, Disentangling, and Reconsidering Validity

The postmodern turn in the humanities and social sciences has spawned an interrogation of traditional forms of all social science inquiry, particularly qualitative inquiry.

Issues of authorship (who is speaking/writing? by what authority?), representation (who is speaking for whom about what?), and truth claims (on what grounds is truth presented?) are entangled in a complex web. Central to these interrogations are issues of evidence and legitimacy, frequently applied to the traditional, highly formalized genre of academic writing. Thus, academic writing itself – the production of text that represents the processes and results of an inquiry project – has come under increasing scrutiny. Much of this critique comes from social theory and literary criticism and is seen in a generative experimentation with alternative forms of representation and evidence. The justification for this experimentation – other than purely for purposes of critique – comes from the insight that, if postmodern and critical perspectives take seriously one of their fundamental assumptions – that the social world is multifaceted, contradictory, confusing, and political in nature – then representations of this multiplicity should be witnessed in multiple, equally legitimate forms.

Specifically, the postmodern turn within qualitative inquiry brings an antifoundational stance and a suspicion of the regulatory norms that govern the true, real, or valid. Consequently, within the postmodern frame, standards of evidence are evaluated based on their reproduction of, or deviance from, historically privileged discourses of truth. In short, postmodernity calls into question the assumptions which make validity possible. As Corbin and Strauss (2007) note:

The notion of judging the quality of research seemed so clear before postmodernist and constructionist thinking pointed out the fallacies of some of our ways. Now I wonder, if findings are constructions and truth a ‘mirage,’ aren’t evaluative criteria also constructions and therefore subject to debate? (p. 297).

Postmodernity has invoked many qualitative researchers, including some of those discussed above, to eschew the terms validity and reliability, due to their historical alliance with quantitative research, and favor credibility and trustworthiness (e.g., Agar, 1986; Corbin and Strauss, 2007). However, some poststructural qualitative methodologists seek to reorient the notion of validity as it pertains to the process of doing research rather than the findings and assertions of the research product (e.g., Beach, 2003; Koro-Ljungberg, 2008; Kvale, 1995; Lenzo, 1995). With roots in postpositivist qualitative methodological writings (see the discussion above on social constructivism, connoisseurship, and relational ethics), this more critical poststructural group situates validity as an historical, power-laden discourse, often used to demarcate a line between science and not-science, and is perhaps best exemplified by the work of Patti Lather.

In her analysis of validity within contemporary times, Lather (1993) asks the simple question, “what do you do with validity once you’ve met poststructuralism?” (p. 676).

Lather (2001) recognizes the question of validity as a continually emergent discourse that can never be avoided or resolved fully. Rather than simply abandoning the notion of validity, Lather (1993) asks qualitative scholars to interrogate the term, questioning what a fluid, context-sensitive understanding of validity might look like. She proposes situated methodologies that convey the complexity of individuals interacting with sociohistorical discourses. Ultimately, Lather and others, who take on a poststructural perspective in qualitative research, focus a critical lens on research practices as a means for evaluating validity within qualitative work.

Poststructuralism carries with it several critical assumptions:

- There is no authoritative truth or reality.
- Binaries, such as true/false, self/other, and researcher/participant are artificial, socially constructed, and usefully collapsed.
- Knowledge is contingent, constructed within sociohistorical contexts.
- Truth claims are limited and partial, never fixed.
- Language insufficiently articulates meaning.
- Power and knowledge are intimately linked, both historically produced and enacted/maintained by discursive practices.
- Prescriptive assertions evoke modernist perspectives of the world as knowable.

One example of how such assumptions alter one’s practices within qualitative inquiry is a shift away from triangulation toward the metaphor of crystallization. The triangle is seen as a rigid, two-dimensional and fixed shape that assumes a static object to be triangulated. As Richardson (1997) writes, the crystal

combines symmetry and substance with an infinite variety of shapes, substances, transmutations, multidimensionalities, and angles of approach . . . Crystals are prisms that reflect externalities *and* refract within themselves, creating different colors, patterns, arrays, casting off in different directions. What we see depends upon our angle of repose (p. 92; original emphasis).

This critical perspective on validity as contingent, a crystal that gains meaning through its variety, calls forth important distinctions between positivist or postpositivist prescriptions for validity and poststructural inquiry. Lather (2001) juxtaposes regulatory validity (that which demarcates the borders of science and not-science) with constitutive practices of validity (those relational and social contexts in which knowledge is claimed) and correspondence validity (emphasizing essential beliefs connected to a broader reality) with transgressive practices of validity (attempts to deconstruct inquiry as a cultural practice) (p. 246). Validity is thus a discursive site, the intersection of diverse knowledge, which never

produces certainty, only the complexity of contextualized truth claims.

Validity in poststructural qualitative research also requires that a methodology incorporate its own mechanisms for self-critique (Lather, 1986, 1993; Lenzo, 1995). Such reflexivity must situate a study within local contexts. Consequently, research practices “cannot be prescribed ahead of time, but can be negotiated in ways that address poststructural problematics involving power, language, representation, politics, and ethics” (Lenzo, 1995: 17). Context, in this sense, builds on Foucault’s (1984) assertion that sociohistorical discourses shape our understanding of language, as well as produce normative interpretations of reality; knowledge is made possible through discursive exercises of power.

Perhaps the poststructural construct of validity that is best known is Lather’s (1986) conception of catalytic validity: the manner in which the process of research re-orientes participants to their reality to stimulate transformative possibilities. Scholars such as Beach (2003) assert catalytic validity as a productive counter to traditional notions of validity, which resists the capitalistic tendencies of current methodological practices. Participants actively collaborate on research projects and co-create the knowledge such projects present. Research projects that take seriously catalytic validity involve the active documentation of researcher and participant interaction with the project context, the types of discourses in which such interactions occur, and the events that give shape to particular constructions of knowledge (Koro-Ljungberg, 2008). Catalytic validity requires that researchers self-reflectively recognize the ontological and epistemological assumptions which govern their interactions with their projects, the very methodological practices they employ.

Final Words

As this article has demonstrated, the markers that determine the worth of qualitative work are contested and set against a larger backdrop of critical social movements. How one determines the validity, trustworthiness, reliability, or even worth of a qualitative study depends on the foundational assumptions that govern the critical tradition to which one subscribes. We have sought to map out how key social movements and scholars have addressed the contested terrain of validity, demonstrating how such perspectives draw their definition in relation to one another. This is not simply an evolving debate – the definitions of such key terms do not systematically become more precise and succinct with the progression of time. Qualitative inquiry takes seriously the complexities of social interaction, the dynamic relations of human meaning making. Consequently, those inquirers who engage in qualitative study necessarily take part in a messy endeavor – a social process heavy with meaning. Whatever theoretical

orientation informs the modes of inquiry, the assumptions guiding the research are diligently articulated through an ongoing set of daily practices. To close, we return to the generative work of Lincoln and Guba (1985) who remind qualitative researchers that a trustworthy study is one whose findings are “worth paying attention to, worth taking account of” (p. 290). As this article has demonstrated, who determines the worth is contested.

QUANTITATIVE AND QUALITATIVE APPROACHES TO RESEARCH – INTEGRATION

Mixed Methods

A Tashakkori and I Newman, Florida International University, Miami, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Inference – A conclusion, understanding, or explanation derived from the results of data analysis in a research study.

Inference quality – The degree to which the interpretations and conclusions of a study are seen as valid, credible, acceptable, and more plausible than other possible explanations of the findings.

Inference transferability – The generalizability or applicability of conclusions made on the basis of the results of a study to other individuals, entities, settings, situations, time periods, or methods of observation/measurement.

Mixed method – A type of research design in which the findings of qualitative and quantitative methods/approaches are integrated in order to gain a fuller understanding of the phenomenon under investigation.

Mixed-methods research systematically integrates quantitative and qualitative approaches to answer complex research questions that might benefit from such a combination. One of its major strengths is that it empowers the researcher to use the most appropriate techniques for answering the research questions. Using an integrated approach has gained increasing recognition in the past two decades. Such recognition is evident in a relatively large number of books (e.g., Bergman, 2008b; Creswell and Plano Clark, 2007; Greene, 2007; Ridenour and Newman, 2008; Tashakkori and Teddlie, 2003; Teddlie and Tashakkori, 2009), numerous articles in professional and academic journals, dissertations, conference presentations, and other outlets (also see the section titled 'Further Reading'). Establishment of the *Journal of Mixed Methods Research*, and the successful continuation of the International Mixed Methods Conference for the 5th year in The School of Healthcare, University of

Leeds, UK (July, 2009), are other examples of the widespread popularity and acceptance of mixed-methods research in the social, behavioral, educational, and health sciences.

Traditionally, quantitatively oriented researchers have worked within the postpositivist worldview in the past few decades, and are predominantly interested in collecting numerical data with structured data-collection methods. They analyze their data using statistical techniques, and maintain a degree of objectivity in their interpretations. On the other hand, qualitatively oriented researchers emerged as a distinct reaction to what was seen, in the 1980s and 1990s, as the dominant and excessive practices of quantitative research. Qualitative scholars follow a constructivist worldview and are predominantly interested in collective narrative data using open-ended (holistic) procedures. They typically analyze their data via thematic analysis, and make holistic, value-based, and subjective inferences on the basis of the findings. Although qualitative research is often assumed to be exploratory, both qualitative and quantitative research may be exploratory/descriptive or explanatory/confirmatory. The dichotomizing based on this aspect of research is too simplistic to be valid (see Bergman, 2008a; Teddlie and Tashakkori, 2009).

Negating the qualitative–quantitative dichotomy, mixed methods has emerged as a third alternative – allowing researchers to take relative stances on a continuum between the two. Mixed-methods researchers identify themselves as integrative and eclectic, work primarily within a pragmatic worldview, collect both narrative and numerical data, employ both structured and emergent designs, analyze their data both via statistical and content analysis, and make meta-inferences as answers to their research questions by integrating the inferences gleaned from their qualitative and quantitative findings.

According to Greene *et al.* (1989) (see the section titled 'Further Reading'), mixed-methods researchers combine the characteristics of quantitative and qualitative traditions that yield answers to questions that neither method alone can answer. Mixed methods potentially enable the

researchers to examine research problems from multiple perspectives and types of (qualitative and quantitative) evidence from multiple sources, leading to conclusions that may be complementary and/or confirmatory. Using an integrated approach allows one to generate new theoretical explanations or expand the current ones, as well as test these understandings in a single study, if needed (Ridenour and Newman, 2008).

Despite the general assumption that integrated methodology has emerged as an alternative to the strict dichotomy of the qualitative and quantitative approaches of the past century, in truth, it is well rooted in the eclectic approaches of social/behavioral science researchers in the first half of the twentieth century (see Brewer and Hunter, 2006; Teddlie and Tashakkori, 2009; Waszack and Sines, 2003 for more details). Consistent with this inherent return-to-roots characteristic, the dominant tenet of mixed-methods research is that the research purpose and question (not the paradigm) dictates the method of inquiry.

Mixed-methods scholars, however, do not ignore the possible impact of investigators' culture, worldview, and sociopolitical context on choosing and formulating research questions. These influences are often inherent in the purposes of the study, which, in turn, shape the research questions, and eventually lead the researcher's methods of study (see Newman *et al.*, 2003). Understandably, only some research purposes and questions are amenable to mixed methods. Many others might be answered more parsimoniously by utilizing either qualitative or quantitative approaches, as appropriate.

Purposes and Utility of Mixed-Methods Research

Admittedly, one of the main reasons for the popularity of mixed methods is that it is more effective for answering some research questions. These are often the type of questions that are not readily answerable by either qualitative or quantitative methods, or the purposes underlying them are not reachable via qualitative or quantitative approaches, "mental models (Greene, 2007)," and techniques. At least seven reasons are often given for using such methods:

- **Complementarity:** Using both mixed methods for the purpose of integrating two expertly different but related answers to the research question, one gleaned from using a qualitative and the other from a quantitative approach.
- **Completeness:** Using mixed methods in order to obtain a fuller understanding of the phenomenon under investigation. The expectation is that such a more

complete understanding will emerge if the inferences from qualitative and quantitative strands of a study are merged effectively (such an effective integration has been called "integrative efficacy" of mixed methods inferences).

- **Development:** Mixed methods is conducted with the explicit (preplanned or emergent) purpose of obtaining research questions, sampling framework, or data sources of a second (e.g., a qualitative) strand of the study from the first strand (e.g., quantitative).
- **Expansion:** Same as 'developmental' discussed above, but with the purpose of expanding the answers already obtained in a previous strand of a study.
- **Corroboration/Confirmation:** Utilizing integrated methods in order to evaluate the credibility of inferences obtained from a (qualitative or quantitative) strand of a study. The research questions of the first strand are often exploratory, while the research questions of the second strand are often explanatory/confirmatory.
- **Compensation:** Utilizing mixed methods with the express purpose of compensating the weaknesses of one approach (e.g., data correction errors/biases) with the strengths of the other.
- **Diversity:** Conducting mixed methods with the hope/purpose of comparing and contrasting divergent pictures of the same phenomenon. (Dialectic approach in which the answers are pitted against each other; Greene, 2007).

Research Questions in Mixed-Methods Research

As we discussed earlier, the main purpose for utilizing a mixed-methods design is to answer research questions that are not effectively answerable by either a qualitative or quantitative approach alone. Such questions often have interrelated components – each following qualitative or quantitative orientations, such as questions including 'what and how', or 'what and why'.

Mixed-methods questions are often seen in two non-mutually exclusive ways: (1) an over-arching question that includes both qualitative and quantitative type of sub-questions, or (2) a collection of separate qualitative and quantitative type of questions, followed by a question with regard to the nature of integration (i.e., how do the answers to the two types of questions relate to each other; see Creswell and Plano Clark, 2007). The first variation is more frequently seen in the literature. For example, one might ask: "What are the effects of teaching method X on achievement and self-perceptions of groups A and B?" Such a question might be followed by three subquestions asking: (1) "Are groups A and B different in achievement and self-perceptions?" (2) "What are the perceptions and constructions of participants in

groups A and B regarding teaching method X and its impact?” and (3) How does teaching method X work differently in the two groups (if it indeed did)?” The subquestions are answered in separate strands (phases) of the study (Teddle and Tashakkori, 2009: 133).

The second approach mentioned above includes explicitly separate qualitative or quantitative type of questions that are clearly interrelated. They are followed by an explicit question about the nature of integration (for more information, also see Tashakkori and Creswell, 2007). Such a question might be stated upfront, or might emerge during the course of a study, such as in emergent sequential designs discussed above. Examples of such preplanned or emergent questions include: “do the findings of the two strand of the study agree?” or “how do the two sets of answers contribute to a comprehensive understanding of the phenomenon under study?”

Design of Mixed-Methods Studies

A grossly simplified framework for classifying mixed-methods designs is to divide them into four families that simultaneously include purposes and expected outcomes, and the sequence of procedures (parallel, sequential, and conversion). Within each family of designs, there is variation on the basis of units of study (e.g., including individuals, social units, or both). Three basic families of design have been described as parallel, sequential, and conversion. A fourth family (fully integrated) includes combinations of the other three basic (simpler) families of designs (see Tashakkori *et al.*, 2009).

Decision to adopt any of these families emerges from an investigator’s answers to two broad questions – one addressing the sequence of strands/phases, and the other exploring the possibility of converting one type of data to another:

1. Which sequence of steps will provide a better opportunity to answer my research questions: Collecting

and analyzing data sequentially (sequential mixed-methods study) or in a parallel manner (parallel mixed-methods design)? In parallel designs, two sets of data (one qualitative and one quantitative) are collected and analyzed independently at the same time or with a time lag (see **Figure 1**), in order to answer a mixed research question. In sequential designs, the second round of data collection and analysis is rooted in (initiated from, made possible by, or modified according to) the results of the first set (see **Figure 2**).

In parallel mixed studies, units of data collection and analysis might be selected in three forms: (1) the sample might consist of two related groups of individuals from the same population (parallel mixed-methods design, multisample); (2) all or a subset of individuals in the first sample are selected for the second strand (parallel mixed-methods design, same/subsample); and (3) the two samples might be at two different levels of organization (parallel mixed-methods design, multilevel). For example, an investigator might decide to select a stratified sample of 30 classroom teachers for in-depth ethnographic interviews, while also administering a structured questionnaire to all students in their classes.

In sequential mixed designs, the purpose, questions, sample, data, or other components of the second strand are rooted in the results of the first strand (see **Figure 2**). For example, based on the results of the first strand of a study that tries to identify the predictors of success in certain groups of economically disadvantaged students, you might also decide to select few highly successful and highly unsuccessful students on the basis of the results, and interview them in depth. The second strand of the study (qualitative in-depth interviews) is conducted in order to explain/expand/confirm the results of the first strand. The second strand of a sequential study might be preplanned, or the need for it might emerge because the results of the first strand are inconsistent, unexpected, or need expansion (see Tashakkori *et al.*, in press for further details).

Similar to parallel mixed studies, in sequential mixed-methods designs the samples might be selected

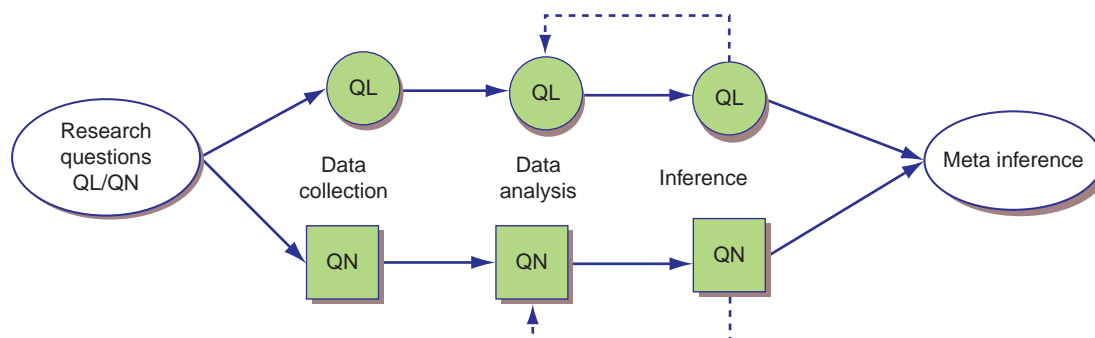

Figure 1 Graphic presentation of parallel (QL + QN) mixed-methods designs with multiple questions, inferences gleaned from the findings of two strands, and a final set of integrated meta-inferences.

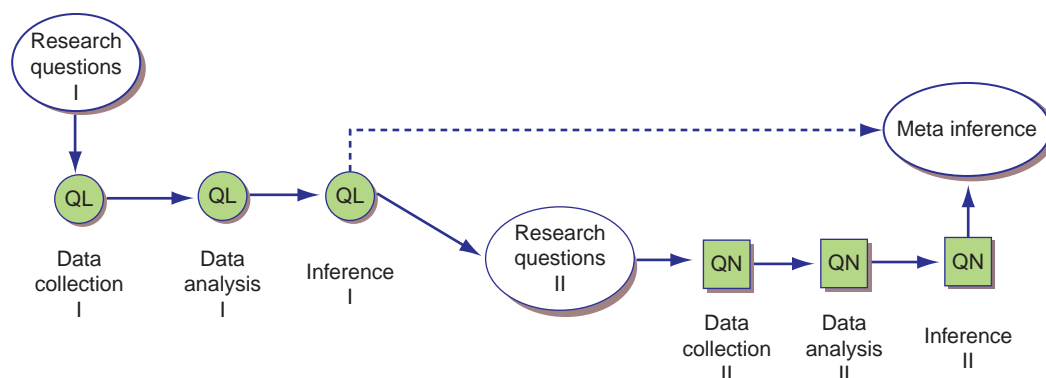

Figure 2 Graphic presentation of a sequential (QL → QN) mixed-methods design in which research questions of the second strand emerge from the findings of the first. A final set of integrated meta-inferences are made on the basis of both sets of findings. (Please note that this family of design also includes a QN → QL sequence.)

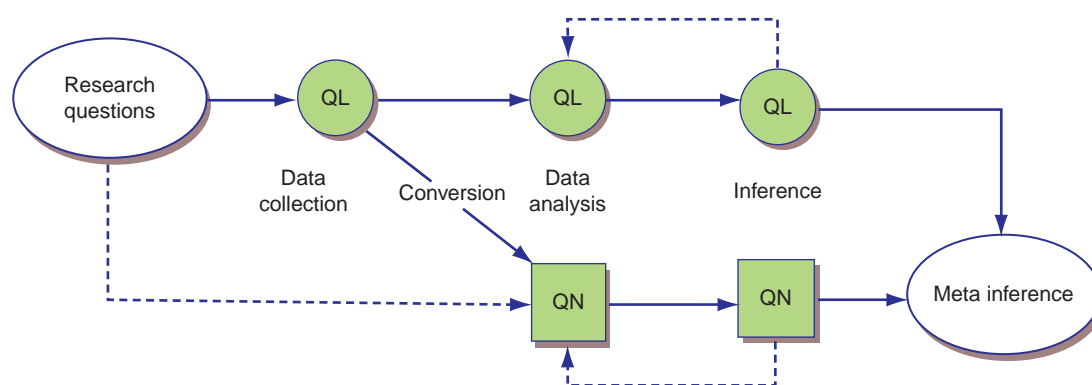

Figure 3 Graphic presentation of conversion (QL ↔ QN) mixed-methods designs with multiple questions – one type of data that are also transformed and reanalyzed. Final integrated meta-inferences are made on the basis of both sets of findings. Please note that this family of design also includes conversion of quantitative data to qualitative (QN ↔ QL).

independently (sequential mixed-methods designs, multisample), one might be the same or a subset of another (sequential mixed-methods designs, same/subsample), or one sample might be at a different level of the same organization (sequential mixed-methods design, multi-level). Unlike parallel studies, in sequential designs the selection of the second sample is dependent on the results obtained from the first. In other words, the second sample cannot be selected until the results of the first are analyzed and evaluated.

2. Will I have an opportunity to convert one type of my data to another, and reanalyze it in order to get more credible answers? If the answer is affirmative, a conversion mixed-methods design is employed (see **Figure 3**). For example, you may collect qualitative data (open-ended interviews, classroom observations, etc.), do a thematic analysis of the narrative, and make conclusions. After this, you may convert the obtained themes to numerical indicators that may be analyzed statistically. In conversion mixed designs, the qualitative data are transformed (quantitized) into numerical indicators that may be analyzed separately using statistical techniques.

Alternatively, in these studies, quantitative indicators (e.g., test results) might be transformed (qualitized) into qualitative data (e.g., profiles) that are analyzed separately as they originated from a separate sample (see Teddlie and Tashakkori, 2009 for more details). Obviously, the findings gleaned from both sets of data analysis are compared, contrasted, and integrated for better understanding of the phenomenon under study.

Depending on the answers to these questions, the investigator might choose one of the three basic (simple) families of designs described above: parallel, sequential, or conversion. In practice, many mixed-methods studies use a combination of these three families – in an iterative and dynamic manner – as needed. These studies have been labeled iterative mixed studies, using a fully integrated mixed-methods design (Teddlie and Tashakkori, 2009), depicted in **Figure 4**. This is the ideal design in mixed-methods studies because it allows the researcher to dynamically utilize both qualitative and quantitative approaches/methods, and use the insights from one type of data/process to modify/enhance the other within and across stages of the study.

Figure 4 Graphic presentation of a fully integrated mixed-methods design with multiple questions, data, data analysis (including data conversion), and inferences within each strand. Elements/stages of the design are iterative both within and across the two strands (i.e., one is modified on the basis of the other). Final integrated meta-inferences are made on the basis of all the findings.

Data-Collection Strategies in Mixed-Methods Research

During the course of a mixed-methods study, an investigator collects a variety of narrative and numerical data, using a combination of qualitative (open-ended, naturalistic, and holistic) and quantitative (close-ended, structured, and variable-specific) data. It is possible to collect both qualitative and quantitative data in a single data-collection strategy. For example, in a mixed-methods study, observations may be recorded by taking extensive notes to record as many of the interactions as possible, while also using highly structured protocols yielding numerical data. Most observations include a combination of both unstructured (open-ended) recording and structured (closed-ended) items to record the behaviors/events. Similarly, interviews and questionnaires may be used to collect both types of data in a mixed-methods study. Open-ended (qualitative) interviews or questionnaires provide qualitative data. Structured (closed-ended) interviews and questionnaires provide quantitative data. Once again, most questionnaires and interviews in research do some of each.

In mixed-methods studies, interviewers conduct funnel-sequenced interviews (Teddlie and Tashakkori, 2009) that start from general questions/topics (“tell me about your school”) and are gradually focused on more specific emerging or preplanned issues. These interviews are conducted individually or in focus groups. Focus groups combine interviews, discussions, and observations of group interactions by the researcher(s), and, often, provide mixed data. Mixed questionnaires provide two types of data as well, although they are less dynamic (interactive) than interviews. Computerized questionnaires provide a greater potential for adapting each item/prompt on the basis of previous responses to close-ended questions.

In addition to using one method of data collection for obtaining both qualitative and quantitative data, mixed data might be obtained through multiple modes of data collection that each provide either qualitative or quantitative data (e.g., close-ended questionnaires with unstructured observations).

Data-Analysis Strategies in Mixed-Methods Research

Highly consistent with the type of design, in mixed methods the qualitative and quantitative data may be analyzed independently, or in an interdependent sequential manner. A detailed discussion of these analyses is beyond the scope of this article. Hence, we gloss over some of the main issues, and refer you to other sources (e.g., Creswell and Plano Clark, 2007; Teddlie and Tashakkori, 2009).

An example of data analysis in parallel mixed designs is when the investigator statistically compares an experimental and control group, while also conducting a thematic analysis of postexperimental interviews (or open observation notes, if the individuals/groups were observed). An example for data analysis in sequential designs might be the formation of groups of people/settings on the basis of qualitative data-analysis results, and then comparing these groups statistically (analysis of variance, discriminant analysis, etc.), using the available (or newly collected) quantitative data.

Integrated Inferences in Mixed-Methods Studies

As mentioned above, integration of the findings and conclusions are the primary objective of most methods studies. Although a degree of consistency between the findings

of qualitative and quantitative strands of a mixed-methods study is desirable, such consistency is not required. Integration in mixed methods denotes elaboration, complementarity, completeness, confirm/disconfirmation, and so forth. Inconsistency is examined carefully by mixed-methods researchers, to see if it might be a result of possible problems in data collection and analysis, or the conclusions derived from the results. If such an examination does not reveal problems in the design or the findings, lack of agreement might indicate that the two sets of findings/inferences are revealing two different aspects of the same phenomenon, one set might provide the conditions for the applicability of the other, or there is a possibility that there are two plausible, but different, answers to the question.

Mixed methodologists have discussed the importance of developing validity criteria and audits that incorporate and expand the qualitative and quantitative concepts. For example, Tashakkori and Teddlie (1998) (see the section titled 'Further Reading') have proposed using the term inference quality as a term to incorporate the term internal validity used by quantitative researchers and credibility used by qualitative researchers. Employing such an umbrella term gives mixed-methods researchers the opportunity to incorporate elements of quality assessment and strategies to deal with possible problems in making inferences (e.g., threats to quality) into a single integrative framework (Tashakkori and Teddlie, 2008). In such a framework, qualitative concepts – such as prolonged engagement, peer debriefing, triangulation, audit trail, negative case analysis, and others – can be used to enhance the quality of inferences gleaned from quantitative findings.

Similarly, concepts such as consistency between elements of the design, design quality, construct validity, investigator expectancy effects, and participant reactivity may be used as safeguards when making inferences on the basis of qualitative findings. In other words, using such an umbrella framework sensitizes the researcher to multiple perspectives when considering the quality/validity of their interpretations. A similar logic is applicable to evaluating and enhancing the quality of data that the findings and inferences are based on (i.e., data quality).

Integrating alternative (but not mutually exclusive) concepts from both qualitative and quantitative traditions, Tashakkori and Teddlie (2008) have offered a broad and twofold definition of inference quality: Design quality, and interpretive rigor. Design quality is the degree to which the interpretations and conclusions made on the basis of the results meet the professional standards of rigor, trustworthiness, and acceptability. Interpretive rigor is the degree to which alternative plausible explanations for the obtained results can be discounted or ruled out (please see Tashakkori and Teddlie (2008) and Teddlie and Tashakkori (2009) for details with regard to the components of these two quality criteria).

Transferability of Inferences in Mixed-Methods Studies

Inference transferability is a mixed-methods umbrella incorporating the qualitative concept of transferability and quantitative concept of external validity. It is broadly defined as the degree of applicability or generalizability of conclusions of a mixed-methods study to other individuals or entities (population transferability), other settings or situations (ecological transferability), other time periods (temporal transferability), or other methods of observation/measurement (operational transferability) (see Teddlie and Tashakkori, 2009 for details).

Conclusions

Mixed methodology puts each component of a research project (questions, data, data analysis, design, inferences, etc.) on a continuum between alternative qualitative and quantitative approaches/conceptualizations. This is consistent with the position of Popper (1959) (also see the section titled 'Further reading' below) – the eminent philosopher of science – who described how information grows scientifically through inductive and deductive approaches. Mixed-methods research is often based on the premise that the research purpose/question – not the paradigm – dictates the method of inquiry.

An advantage of mixed-methods is that it encourages researchers to think in terms of multiple continua rather than a single dichotomy of qualitative and quantitative approaches, employ multiple perspectives as needed, use multiple methods that are rooted in qualitative and quantitative traditions, and interpret the findings freely without the imposed constraints of either of the two broad approaches to research.

A challenge for the mixed-method researcher is that they must learn specific techniques that have been traditionally identified as being qualitative or quantitative. They must also learn how to integrate understandings gleaned from these complementary or competing methods in order to reach meta-inferences that better inform other professionals and stakeholders. There is an underlying assumption that the more perspectives one can get of a particular situation, the more complete the understanding inferences are likely to be. The value of mixed methods to researchers may not solely be in empowering them to use all possible tools for answering their research question, but also in becoming better informed as a result of integrating the findings of these methods.

Glossary

Analog models – Studying a phenomenon in a controlled setting (e.g., scale model of a bridge, animal model of Alzheimer's disease) that mirrors what one would observe in the field (e.g., actual 200 m suspension bridge) or target system (e.g., elderly humans).

Domains of generalizability – Universes of units (*U*), treatments (*T*), outcomes (*O*), or settings (*S*) with regard to which inferences are sought.

Group theory – A broadly applicable and highly abstract mathematical theory designed to describe generalizations of all kinds.

Meta-analysis – Combining findings from many different, yet related, studies to foster empirical knowledge with regard to causal associations that are more trustworthy than those possible from any single study.

Principle of causal explanation – Seeks to strengthen the validity of generalizable knowledge claims by investigating the causal mediating mechanisms that underlie a relationship of interest. Causal explanation is valuable because it explains how and why an effect occurs, and, consequently, provides information about when and where the relationship can be replicated.

Principle of empirical interpolation and extrapolation – Seeks to strengthen the validity of generalizable knowledge claims concerning the unsampled range of values on a particular variable.

Principle of heterogeneous irrelevancies – Seeks to strengthen the validity of generalizable knowledge claims by demonstrating the robustness – or invariance – of a causal association across substantively irrelevant conditions.

Principle of proximal similarity – Seeks to strengthen the validity of generalizable knowledge claims by demonstrating the correspondence between samples and the target universe to foster

generalizability of inferences from sample to universe.

Purposive sampling – Selecting instances from a target universe to make the correspondence between sample and universe an explicit and rational exercise rather than the result of a random process.

Principle of discriminant validity – Seeks to strengthen the validity of generalizable knowledge claims by demonstrating that a finding holds for a target construct and not for a cognate. This involves examining the conditions under which an association changes in magnitude and direction.

Technology-transfer models – Relying on a progression of studies to bridge the gap between the controlled, artificial laboratory conditions and field applications.

Introduction

The term external validity was first introduced more than 50 years ago in a seminal paper by Campbell (1957) titled 'Factors relevant to the validity of experiments in social settings.' For Campbell, internal validity and external validity were the two major criteria for evaluating the validity of research designs examining causal propositions. In his definition, internal validity asked whether an experimental stimulus (e.g., treatment) made some significant difference in a specific instance. In contrast, external validity asked questions about representativeness or generalizability: To what populations, settings, and variables can an effect be generalized?

The distinction between internal and external validity evolved in subsequent writings by Campbell and Stanley (1963), Cook and Campbell (1979), Campbell (1986), and Shadish *et al.* (2002) into a four-partite model of statistical conclusion, internal, construct (treatment and effect), and external validity. The latter two are closely related, in that both involve inferences with regard to more abstract

constructs or universes based on the manifest instances present in a particular study. The following sections briefly define key concepts, review traditional approaches for justifying generalized inferences, introduce Cook's pragmatic principles of generalized causal inferences, and highlight the importance of meta-analysis in justifying the external validity of causal claims. The article concludes by outlining future directions for theory and practice of causal generalization.

What We Generalize About

In Campbell's original formulation, external validity concerned the generalizability of the causal association between a treatment (i.e., experimental stimulus) and an outcome (i.e., response). Following Cook and Campbell (1979) and Cronbach (1982), the external validity of this causal association can be examined with respect to the domains of experimental units (U), treatments (T), outcomes (O), and settings (S).

Carrying forward the notation introduced by Cronbach (1982), U refers to the universe of units with regard to which inferences are sought. Units are the students, classrooms, communities, districts, etc., on which observations are made, that are subjected to different treatments, and for which causal mechanisms are specified to explain the effect of an intervention. In contrast, u represents the specific sample of units in a study.

T represents the universe of treatments about which inferences are sought. The treatments may be interventions, programs, experimentally manipulated conditions, or naturally occurring events. In contrast, t refers to a specific treatment or group of treatments, as realized in a study.

O refers to the universe of outcomes with regard to which inferences are sought. This universe consists of all admissible measures used for collecting data on a particular effect construct. The specific measure or group of measures used in a study is denoted with o .

S refers to the universe of settings in which a study is implemented. Settings include the social, cultural, organizational, and historical context in which a study is conducted. While S refers to the entire universe of admissible settings, s identifies the specific setting of a study.

The Three Main Questions of External Validity

Three major types of external validity questions have been distinguished in the literature. The first – and perhaps most common – is Campbell's original question: To what populations, settings, and variables can an effect be generalized? This question involves inductive inferences from the particular sample of persons, treatment

implementation, outcome measures, and settings (i.e., $utos$) to the universes of interest (i.e., $UTOS$), of which the particular instances included in a study are a part.

The second external validity question asks: Across which universes (or subuniverses) of units, treatments, outcomes, and settings can an effect be generalized? This question concerns inferences about the robustness of an effect and the conditions that moderate its strength or direction. Potential moderators may be found in the characteristics of persons, treatments, outcomes, and settings.

The third question concerns inferences about novel universes of units, treatments, outcomes, and settings that have not been studied yet: To what yet unstudied universes of units, treatments, outcomes, and settings can an effect be generalized? This question asks to make extrapolations or projections from domains in which an effect has been studied to novel domains.

Traditional Approaches to Justifying Generalized Inferences and Their Challenges

Causal Explanation

In the tradition of experimental science, complete knowledge of the mediating and moderating principles provides the strongest justification for generalizing causal relationships to target universes, across subuniverses, and to novel universes (external validity questions 1, 2, and 3). For instance, a complete understanding of the mediating and moderating principles underlying the effects of homework assignments on learning outcomes among seventh graders would allow teachers to identify the optimal homework for a particular group of students to achieve a particular learning objective – given the students' personal characteristics, and family and school support networks. Complete understanding requires substantive theories detailing the explanatory principles, well-specified constructs, valid measurements of these constructs, and the absence of an equal or better-fitting model (Cook, 1993). Unfortunately, complete understanding of a causal association and its mediating and moderating principles is hardly attainable in the social and behavioral sciences, and therefore, cannot provide a solid foundation to justify the generalization of causal inferences.

Statistical Sampling Theory

In the tradition of observational research, generalizations to target universes (external validity question 1) are best justified through the correspondence between samples and the universes they represent. When universes are clearly designated and their elements can be sampled

with known probability, statistical sampling theory provides the strongest justification for this correspondence. Although designating human populations (e.g., students, teachers, classrooms, and schools) to sample from is relatively straightforward (e.g., rosters of students, directory of schools), it is rarely practiced in experimental and quasi-experimental research, in which the primary emphasis is on internal rather than external validity. Further, sampling theory may be outright impossible to apply when selecting instances from the universes of treatment (e.g., homework assignments), outcomes (e.g., learning outcomes), and settings (e.g., sociocultural context). These universes are, often, defined as theoretical constructs with fuzzy – rather than crisp – boundaries (Matt, 2005), generally have multiple and partially conflicting definitions, and lack commonly accepted sampling frames. As valuable as statistical sampling theory can be when it is applied to designated universes and valid sampling frames, it does not provide a panacea for all generalizability domains. It also provides no support for generalizations across subuniverses and extrapolations (external validity questions 2 and 3).

Purposive Sampling

Purposive sampling is a common approach in efforts to validate treatment and outcome constructs. The goal of purposive sampling is to select instances from a target universe that make the correspondence between sample and universe an explicit and rational exercise rather than the result of a random process. The exercise begins with a description of a target construct – including its prototypical and more marginal components, features shared with cognate constructs, and boundaries shared with related constructs. Then, specific instances – which belong to the target construct and demonstrably share most of its prototypical components – are selected. Variants are then purposively selected to rule out the confounding of substantive interpretations and irrelevancies and to better understand potential features that may moderate the association between treatment and effect constructs. Purposive – as opposed to random – sampling ensures construct coverage (Cronbach *et al.*, 1972), and allows researchers to specify and test hypotheses about the nature of treatment and effect constructs. Thus, purposive sampling can be used to justify generalizations from specific instances of a sample to a target universe (external validity question 1) and is widely practiced in construct validation studies of treatments (*T*) and outcome measures (*O*).

Analog Models

Analog models – common in education (e.g., mock classrooms in preservice teacher education programs), engineering (e.g., scale models), biotechnology (e.g., genetic

knock-out mice), medicine (e.g., first-aid practice mannequin, animal studies), and some areas of behavioral science (e.g., computer simulations) – use purposive sampling to justify inferences about a target model drawn from data collected on an analog model. Similar to purposive sampling methods described above, analog systems do not need to provide a probabilistic representation of the target; they must only share relevant properties of the target system. That is, a successful analog system may look very different, but must behave just like a target system.

Analog models make it possible to study a phenomenon in a controlled laboratory setting (e.g., scale model of a bridge, animal model of Alzheimer's disease) that mirrors what one would observe in the field (e.g., actual 600-ft suspension bridge) or target system (e.g., elderly humans). The critical task is to create a valid analog model that corresponds to the actual generalizability target in all relevant features such that findings based on the analog model by extension also apply to the generalizability target. Analog models provide a promising direction to justify inferences about novel universes (external validity question 3).

Technology Transfer Models

Technology transfer models rely on a progression of studies to bridge the gap between the controlled, artificial laboratory conditions and field applications. They are closely related to the idea of analog models and purposive sampling in that earlier studies serve as analogs to justify inferences with regard to yet-unstudied organisms or domains.

A good example of the implementation of the technology transfer model is the approval process that guides the development of new pharmaceutical products in the USA (US FDA (US Food and Drug Administration (FDA)), 1998). Experimental new drugs are first tested in preclinical studies for safety and efficacy in controlled laboratory conditions. These studies often involve cell cultures, computer models, and animal analogs. This is followed by Phase I clinical studies in humans, short-term studies on small samples, focusing on safety, and, often, involve healthy subjects. If these initial studies demonstrate a drug's safety, Phase II studies follow – in which short-term efficacy and drug safety are investigated in larger samples. If Phase II studies continue to demonstrate a drug's safety and efficacy, large-scale Phase III clinical trials are conducted with a focus on drug dosage, long-term effectiveness, and drug safety. Data collected in the preclinical and clinical trials are again reviewed by FDA expert panels to approve, request additional studies, or deny approval of a new drug. Following FDA approval, monitoring systems are put in place to detect adverse reactions.

The technology transfer model is also evinced in the field of education. University-based educational research

centers bring together researchers interested in studying issues surrounding the teaching and learning of mathematics, science, languages, and other subjects. Studies are conducted in controlled laboratory conditions to investigate basic cognitive processes involved in developing new mathematical concepts (e.g., rate of change) or in acquiring a second language through dual immersion. Research findings are then used to inform the development of materials for the professional development of educators, as well as educational curriculum that is ultimately implemented in actual classrooms.

Through a programmatic series of research studies, the technology-transfer model can support inferences with regard to target universes (e.g., target populations, target effect, side effects; i.e., external validity question 1), robustness and moderating conditions (e.g., drug indications and contraindications; external validity question 2), and novel universes (e.g., off-label use; i.e., external validity question 3).

Meta-Analysis

Meta-analysis combines findings from many different – yet related – studies to foster empirical knowledge about causal associations that are more trustworthy than those possible from any single study. This benefit arises for two main reasons. First, combining findings from parallel studies promises to increase statistical power and precision for estimating the magnitude of a causal association. More importantly, however, is the potential of meta-analysis to strengthen external validity by identifying the realm of application of a causal association – that is, meta-analyses are most useful when they allow us to examine whether a causal association (1) holds with specific populations of persons, settings, times, and ways of varying the cause or measuring the effect; (2) holds across different populations of people, settings, times, and ways of operationalizing a cause and effect; and (3) can even be extrapolated to other populations of people, settings, times, causes, and effects than those that have been studied to date – that is, meta-analyses offer opportunities to probe external validity questions 1, 2, and 3.

In 1978, Glass and Smith published a noteworthy meta-analysis examining the relationship between class-size and academic achievement – an issue that was previously surrounded by inconclusive research findings. This meta-analysis synthesized the results of 77 separate studies that included 725 comparisons of academic achievement in smaller versus larger classes. It received considerable attention because it was the first meta-analysis to find clear evidence that reduced student-to-instructor ratios significantly improved academic achievement (Cooper, 1989). Examples from this meta-analysis will be presented to illustrate how Cook's five principles justify generalization in the absence of formal sampling.

Five Pragmatic Principles for Justifying Generalized Causal Inferences

Cook (1991) put forth a pragmatic alternative approach to statistical sampling theory for justifying the validity of generalized causal inferences in the absence of formal probability sampling. The proposed approach relies on five principles, adopted from research on construct validation (e.g., purposive sampling), and existing analog and transfer models of generalization. It can be used to justify generalization to target constructs (e.g., treatment, outcomes), as well as generalization to target populations of units and setting. The approach emphasizes purposive sampling for theoretical ends rather than random sampling to represent a population.

The Principle of Proximal Similarity

The principle of proximal similarity describes the correspondence between samples and the target universe. Proximal similarity requires an explication of which components are – and are not – central to the targets of the generalization (*UTOS*). Because matching cannot be feasibly achieved on all features, it is most critical to demonstrate similarity on prototypical components (Cook, 1993). In research syntheses, proximal similarity is achieved by ensuring that the relevant properties of the target universe are adequately represented by the samples included in the meta-analysis (Matt, 2003). Because Glass and Smith (1978) were interested in generalizing inferences about the effect of reduced student-to-instructor ratios (*T*) on achievement (*O*) among school-aged children (*U*) in elementary and secondary-education classrooms (*S*), they ensured that the prototypical components inherent to each universe were present in the sampled studies.

The Principle of Heterogeneous Irrelevancies

The principle of heterogeneous irrelevancies concerns the robustness, or invariance, of a causal association across substantively irrelevant conditions. Robust empirical findings suggest broad main effects of interventions – the type of effects that are particularly useful for policy decisions affecting large and diverse constituencies (Abelson, 1995). The greater the range of substantive irrelevancies across which a causal association has been found to be robust, the more confident one can be that the causal association will hold under yet-unstudied conditions.

The principle of heterogeneous irrelevancies highlights the importance of probing causal associations under many different conditions, especially those that are deemed irrelevant to the phenomena under investigation. Doing so protects against the possibility a causal relationship is confounded by a factor common to all the studies in which it was examined (Matt, 2003). For example, if all studies

examined by Glass and Smith (1978) administered the same standardized achievement test, then the relationship between class-size and achievement could be confounded by outcome-method invariance. Consistent with the principle of heterogeneous irrelevancies, Glass and Smith (1978) ensured variance in assessment method and subject area, pupil demographics and intelligence quotient (IQ), geographic location, and other irrelevancies across studies. Further, the studies date back to 1900 – indicating that the effect of class-size on achievement was neither confounded by time, nor associated with an event that occurred at a particular point in time. The range of irrelevancies encompassed by the studies in this meta-analysis parallels the heterogeneity of the *UTOS* to which authors intended to generalize the causal inference.

The Principle of Discriminant Validity

In addition to demonstrating robustness of a causal association across substantively irrelevant conditions, external validity is strengthened when we can show that a finding holds for a target construct and not for a cognate. Demonstrating discriminant validity requires exploring the boundaries of target constructs and understanding the conditions moderating an association. The principle of discriminant validity requires identifying the substantively relevant conditions under which an association holds, fails to hold, and changes in magnitude or direction. To illustrate, the relationship between class-size and achievement held across the range of irrelevancies listed above; however, it was slightly weaker in elementary, as compared with secondary classrooms (Glass and Smith, 1978). By examining the relationship across a greater range of *utos* than any single study is capable of, Glass and Smith (1978) pinpointed a moderating factor that might have otherwise gone unrecognized.

The Principle of Empirical Interpolation and Extrapolation

The principle of empirical interpolation and extrapolation addresses the issue of generalizing to an unsampled range of values on a particular variable (Cook, 1993). For example, if the effect was observed in second and fifth graders, empirically bound generalization based on interpolation would infer that the effect would also be observed at unstudied levels in-between (i.e., third and fourth graders). Interpolation relies on the assumption that the relationship between cause and effect is known (e.g., linear) between the studied levels of a variable. In contrast, extrapolation involves generalizing beyond the range of sampled values in either direction (e.g., generalizing findings from second and third graders to first and/or fourth graders). According to Cook (1993), there is greater confidence in generalization based on interpolation than on extrapolation, and there is

stronger justification for either when (1) a greater range of values is studied and (2) the effect is consistent across this range. Further, shorter extrapolations are less problematic than larger inferential leaps. An advantage of meta-analysis is that it encompasses a wider range of person and/or treatment variable values than is typically observed in any single research study (Cook, 1993). Therefore, interpolation is much more common in meta-analysis than is the riskier practice of extrapolation.

The Principle of Causal Explanation

The principle of causal explanation requires investigation into the causal mediating mechanisms that underlie a relationship of interest. Causal explanation is valuable because it explains how and why an effect occurs, and consequently, provides information regarding when and where the relationship can be replicated. Complete understanding of an entire causal mediating process is the holy grail of experimental scientific research because it provides the knowledge necessary to identify the conditions under which a causal association will and will not occur. A complete blueprint of a causal association may be an unrealistic goal; however, even partial knowledge of the causal process can strengthen generalized causal inference. For example, if the causally efficacious component of reduced class-size is one-on-one time with the teacher, then a similar increase in achievement might be attained by scheduling more individualized instruction time in classrooms with fixed student-to-instructor ratios. Similarly, if one-on-one time improves achievement by enhancing self-esteem (i.e., a mediator), then other interventions targeting self-esteem may indirectly affect achievement. Unfortunately, the major limitations of using meta-analysis to identify causally relevant treatment components and mediating factors are that (1) primary studies, often, do not provide sufficient details about the treatment and (2) studies rarely investigate the same mediating mechanism (Cook, 1993). For example, in regard to the latter, in order for Glass and Smith (1978) to infer that the effect of class-size on achievement was mediated by self-esteem, a number of primary studies would have had to similarly investigate this connection.

Outlook

Statistical sampling theory provides a powerful theoretical framework for generalizing from samples to corresponding populations and is most relevant when generalizing to populations of units and settings (external validity question 1) that can be enumerated and are under the control of the researchers. In research practice, however, random sampling from designated universes of students, classrooms, schools, etc. is uncommon in most studies that involve

causal associations and random assignment of experimental units to different treatment conditions. The relevance of sampling theory to generalizations about the treatments and outcomes and to other questions of external validity is less clear. This situation leaves researchers in a difficult position: If sampling theory is not often used or is not able to answer important generalizability questions, how should we justify the external validity of causal relationships? What is needed is a viable new theory of generalization that can guide the design of primary studies and the design of research syntheses.

The principles introduced by Cook (1991, 1993) and further elaborated by Shadish *et al.* (2002) can serve as a starting point. They borrow strategies and techniques commonly used to justify construct-validity claims and have been applied in programmatic approaches to support the transfer of research and technology from labs to applications (US FDA, 1998). They provide practical guidelines for exploring and building arguments around generalizability claims and can be applied very well to research syntheses (Matt and Cook, 2009).

Meta-analysis provides the most promising research design to explore generalizability claims using Cook's five principles as no single study provides as many opportunities as research synthesis to examine the robustness and moderating conditions of causal associations. Matt and Cook (2009) examine, in detail, the validity of generalized causal inferences based on research syntheses.

Another promising direction for a comprehensive theory of generalization comes from a branch of mathematics called group theory. In fact, group theory is a broadly applicable and highly abstract mathematical theory designed to describe generalizations of all kinds (Livio, 2006). A mathematical group is defined as any set whose members obey certain rules with respect to particular operations, and therefore, act similarly in response to such operations. The members of a group may include numbers, words in the English language, a pair of jeans, or a causal association. Operations can be as diverse as 'rotate 120°,' 'do nothing,' 'turn inside out,' and 'followed by,' 'add,' or 'multiply.' A group exists if the operations are applied to the members and the following properties hold: (1) closure, (2) associativity, (3) identity element, and (4) inverse.

In contrast to sampling theory, group theory does not characterize a generalization based on the objects it involves (e.g., a set of exemplars defining a universe settings), but by whether an operation changes it or leaves it unchanged. Similar to Cook's pragmatic principles, group theory relies on studying the invariance to transformation (i.e., robustness) and the identification of moderators (i.e., discriminant validity). Translating the tenets of group theory to the generalizability of causal association could provide important insights into the design of primary studies and the analysis of meta-analyses that facilitate generalizable proposition. Based on Cook's five principles and the

cursorry introduction of group theory, drawing generalizable inferences will benefit from efforts to examine causal associations under many diverse conditions, both substantively irrelevant as well as substantive relevant characteristics of units, treatments, outcomes, and settings. Research synthesis and programs of research bear most promise for providing the empirical warrants for such generalized inferences.

Globalization and Education

Globalization in its generic and literal sense is the process of transformation of local or regional phenomena into global ones. It refers to the idea of the people of the world being connected and unified in multiple ways. It is not a new phenomenon, but the issue has come to the fore in recent decades with economic aspects of globalization receiving the most attention. In the economic context, it refers to the reduction and removal of barriers between national borders in order to facilitate the flow of goods, capital, services, and labor. Another dimension of globalization is cultural integration, again an ancient phenomenon, intensified by recent revolutionary changes in communication and transportation technologies.

Cultural globalization, driven in its recent manifestations by digital communication technology, has led to both a process of homogenization and an enhanced potential for promoting and appreciating cultural diversity. Effective and aggressive marketing of American and Western cultural industries has raised the specter of the global domination of Western culture at the expense of national and indigenous cultural diversity. However, the spread of communication technologies has also supported the emergence of movements in defense of local uniqueness, individuality, and identity (Croucher, 2004).

A critical aspect of cultural globalization, or the influence of the globalizing forces beyond the economic sphere, is the development of a global perspective and global interaction on education. This includes influence of globalization on educational content, objectives, and delivery of services.

A Global Perspective on Education

In the post-World War II era, under the auspices of the United Nations, a different form of globalization, in contrast to economic globalization driven by the free market principles, has developed. This other form of globalization is based on the recognition of the need for an international order to guide action on common interests of humanity. Principal tenets of this order include peaceful resolution of conflicts; common responsibility to promote and protect human rights and human dignity, justice for all, and development of the human potential everywhere; protecting and nurturing the planetary resources for the benefit of the present and future generations; and inculcating a spirit of human solidarity and responsibility.

The establishment of the United Nations itself is a manifestation of the phenomenon of globalization arising from interdependence and connectedness of peoples and nations. Globalization guided by the principle of human solidarity, since the creation of UN, has found a concrete expression in the regime of international treaties and conventions which have emerged to establish and protect human rights and promote human development. International and national NGOs and civil society organizations have played a prominent role in shaping the content of these international agreements and lobbying for the adoption and ratification of these internationally and in countries.

The Universal Declaration of Human Rights adopted in 1948 was the first global statement about the inherent dignity and equality of human beings. In adopting the declaration, the governments representing the international community accepted a set of principles and obligations

covering a wide range of human endeavor, which applied to all nations universally.

The principles directly related to education are set out in the declaration's Article 26, which affirms that: (1) everyone has the right to education, (2) education shall be directed toward the full development of the human personality and to the strengthening of respect for human rights and fundamental freedoms, and (3) parents have a prior right to choose the kind of education that shall be given to their children.

The universal declaration served as the touchstone for subsequent international agreements in the form of declaration, treaties, and conventions addressing common concerns and interests of humanity, which called for collective and global action. For example, the universal declaration directly led to the negotiation and adoption of the two binding treaties in 1966, recognized as the twin pillars of global human rights standards and provisions – the International Covenant of Civil and Political Rights and the International Covenant of Economic, Social and Cultural Rights. These agreements impose a moral obligation, and many place a legal obligation, on the signatory countries to abide by these agreements. They constitute a body of legal and institutional structure of common responsibility for common good of humanity (United Nations, 2002).

Major international treaties include a provision for states to report to a treaty body on progress made and steps taken in implementing the agreements by national governments who have become signatories to these treaties. There are, for example, the Human Rights Committee and the Committee on Economic, Social and Cultural Rights, which serve as treaty bodies for the relevant agreements. Similar bodies exist for reviewing progress in countries on implementation of the Convention to End all forms of Discrimination against Women (CEDAW) and the Convention on the Rights of the Child (CRC). NGOs have often served as an effective watchdog in respect of efforts of countries to implement the agreements and adequate and objective reporting by countries to the treaty bodies. Often, NGOs and other civil society bodies have prepared alternative reports to draw public attention, from their perspective, to lack of good-faith efforts to live by the treaty obligations.

The creation of the United Nations Educational, Scientific and Cultural Organization (UNESCO) itself represents a commitment of the international community “to contribute to peace and security by promoting collaboration among the nations through education, science and culture in order to further universal respect for justice, for the rule of law and for the human rights and fundamental freedoms which are affirmed for the peoples of the world, without distinction of race, sex, language or religion, by the Charter of the United Nations” (Article 1, Constitution of UNESCO).

In the case of education, several international treaties and agreements have been adopted since 1945 by international conferences convened either by the United Nations or by UNESCO. Probably the best-known examples in the field of education are the World Declaration on Education for All, adopted by the World Conference on Education for All (EFA), held in Jomtien, Thailand, in 1990 and, as its follow-up, the World Education Forum in Dakar in 2000. A framework for EFA with specific global goals for 2015 was adopted in Dakar. The framework has served as both the guide for formulation of national plans of action and the focus of advocacy for national and international NGOs. (See below the description of advocacy activities of the Global Campaign for EFA.)

The United Nations General Assembly has from time to time adopted resolutions proclaiming an international day, year, or decade relating to education, the purpose being to focus world opinion on a particular aspect of education considered to be deserving of attention and support. Examples include International Literacy Day (September 8), World Teachers Day (October 5), International Literacy Year (1990), and United Nations Decade for Human Rights Education (1995–2004). These proclamations and events and activities related to these, on the one hand, reflect a broad international consensus on educational issues; on the other hand, these serve as the basis for advocacy and mobilization activities on educational issues by national and international NGOs and other civil society bodies.

Development in education over the years since the beginning of the process of establishing global norms and goals, starting with the proclamation of the Universal Declaration of Human Rights, has been dramatic. In the late 1940s, a little more than 50% of the world's adults were literate at a rudimentary level and less than 50% of the children had access to formal education. Today, most children go to school and the majority has access to beyond primary education. Four out of five of the adults have acquired literacy skills at least at the basic level, although women still lag significantly behind (UNESCO, 2000).

As noted, important contribution of the globalization forces in the progress achieved in education has been in articulating the norms and goals that all shared and in assessing and comparing the country situations in global league tables. NGOs and the civil society have played an important role in advocacy, awareness raising, and capacity building, and, in many instances, extending educational opportunities in creative ways to those left out from the mainstream educational services. What do all these add up to? It is reasonable to argue that the international consensus and expression of commitments, cooperation and sharing of lessons and experience, the global recognition of the right to education and the obligation to fulfill this right, and the work of NGOs in driving the messages home, have considerably strengthened the momentum for the secular trends of educational expansion that existed.

Changing Educational Paradigm in the Context of Globalization

The demands of globalization in terms of competitive market, skills and capabilities that young people must acquire, dramatic changes in knowledge dissemination possibilities, and interdependence of people and nations have altered the conventional centuries-old thinking and models about learning content, objectives, and delivery of educational services. At the same time, it has become more critical than ever that learners are aware of and that they interact effectively with the world in which they live and appreciate and claim the common heritage of human thought, action, and, creativity.

The need for change in the educational paradigm has been argued cogently in the report of the UNESCO-appointed International Commission on Education for the Twenty-first century led by Jacques Delors. The Commission identified four key purposes as the pillars of learning on which the educational systems must be built. These are:

1. learning to know,
2. learning to do,
3. learning to live together, and
4. learning to be.

These pillars refer to the imperatives of acquiring the skills of learning (to learn rather than to accumulate facts), being purposefully productive, being responsible and effective members of the human community locally and in the world, and, at the same time, being confident of one's identity (UNESCO, 1998).

The point is often made that advances in information technology and telecommunications have created unprecedented opportunities for learning for every one; that the barriers of time, distance, language, pedagogic skills, and resources can be less critical. However, this potential can be realized and transformation of learning can happen, only if the new paradigm of knowledge, education, and learning can incorporate components that are neglected in the current models. The Global Information Infrastructure Commission suggests the following key elements as essential components of the new learning paradigm (Cogburn, 1998):

- focusing on concepts and understanding, rather than accumulation of factual information;
- using a holistic and iterative approach in pedagogy, rather than a linear development of knowledge and skills;
- emphasizing on enhancing the learners' ability to manipulate symbols;
- enhancing the student's skills to acquire and utilize knowledge;
- producing an increased quantity of scientifically and technically trained persons;

- blurring the distinction between mental and physical labor;
- encouraging learners to work in teams;
- overcoming the barriers of time and space in learning; and
- developing an agile and flexible system of education.

Recognizing the global implications of local action and vice versa, educational content has been developed, frequently in higher education, and at secondary and primary levels as well, under the label of global education or international education. Global education places particular emphasis on the changes in communication and relationships among people across nations and regions. It sheds light on how major societal phenomena, such as human conflict, economic systems, human rights and social justice, human commonality and diversity, the common legacy of literature and culture, and technological revolution affect people and communities. Without denying the value of traditional branches of specialist knowledge, global education seeks to blur the boundaries between disciplines. It encourages interdisciplinary and multidisciplinary studies, which can help offer solutions of complex human problems.

The term international education, sometimes used as the substitute for global education, may mean different things, but two meanings are generally attached to the concept. The first refers to education that transcends national borders through the exchange of people, as in study abroad. The other meaning reflects a comprehensive approach to education that attempts to prepare students to be effective participants in an interconnected world.

The premise underlying the approach of global education and international education is that the understanding of society, nations, and the human condition is deepened through examination of cultures, languages, environmental situations, governments, political relations, religions, geography, and history of the world. Professionals and students particularly wishing to be engaged in international educational development are mostly the participants in international education academic programs (Cummings and McGinn, 1997).

Commodification of Education

One effect of economic globalization is that education may be treated as a marketable commodity. The traditional view of education as a public good financed largely by public funding is being challenged by the criterion of efficiency of the market. The neoliberal view – the belief that society's needs can be best met and problems can be best solved by the market with minimal government regulation and public sector involvement – has spread from

the economic sphere to what have been generally regarded as public services and the domain of the public sector.

At least three elements of the neoliberal market approach may be found in the design for educational provisions:

1. attempting to make the provision of education cost efficient by designing them as marketable products;
2. standardizing the educational services and experiences as well as assessing their performance by objective and standardized testing of results; and
3. focusing on marketability of outputs.

The three elements are reflected in policies, such as cut-backs in the public sector, closing inefficient programs that do not directly meet market needs, and the use of technology, including distance learning to bring about greater efficiency, comprising courses and degrees that are packaged for delivery over the Internet by for-profit corporations (Tabb, 2007).

The intergovernmental body World Trade Organization (WTO), established in 1994, is dedicated to the goal of removing trade barriers among nations. The General Agreement on Trade in Services (GATS), a product of the WTO, is aimed at deregulating international markets in services, including education. Two key operating principles of GATS are: the most favored nation and national treatment. The former requires that all countries be treated identically with regard to import or export, while the latter enjoins countries to treat foreign companies at least as favorably as their equivalent national competitors. The purpose of these principles is the creation of an open, global market place where education and other services can be sold to the highest bidder.

GATS covers educational services which are not exclusively provided by the public sector, or those which have commercial purposes. Since education systems are rarely exclusively public and many programs are partially commercial, large parts of the education systems of countries fall under the purview of GATS.

Internationally, education is estimated to be a trillion-dollar industry. Corporations have seen the prospects of a deregulated education sector and of having a market share in the industry, to the extent education can be turned into a tradable commodity (Frase and O'sullivan, 2007).

This aspect of globalization is a direct challenge to the public good character of education. It is a crucial political and educational policy issue in many countries to decide how the balance should be struck between the public good character of education and education as a market commodity. Civil society bodies and NGOs have a role in advocacy and awareness raising in respect of molding public opinion about the political choice that must be made (Tabb, 2007).

NGOs and Globalization

There is no one widely accepted definition of the term nongovernmental organization.

The diversity of NGOs, with hugely varied goals, structures, and the driving force behind them, makes it difficult to agree on such a definition.

While NGOs vary widely, their activities often fall into two broad categories: they engage in operational activities related to delivery of services and/or they undertake advocacy activities designed to influence policies and programs. Their size and scope of activities can be limited to a local community or extend across nations. Many NGOs in developing countries receive international funding for their work in areas such as research, advocacy, relief, environment, human rights, and health and education services.

Education is an important arena of public good in which NGOs have played a prominent role both as provider of services and in undertaking advocacy. The scope and nature of their involvement in education and the impact and significance in respect of globalization of education in a particular national, subnational, and international context vary in line with the diversity of NGOs themselves. However, the overall significance of NGOs in shaping globalization of education is impressive, as will be seen below (The Commission and Non-Governmental Organisations, 2000).

Economic globalization and advances in communication and transportation technology have influenced the growth of international NGOs and global civil society institutions. Although international religious and academic networks can be traced back to the Middle Ages, international NGO activity began to spread during the middle of the nineteenth century. They multiplied since the last quarter of that century (Seary, 1996; Charnovitz, 1997). It has been argued that governments followed the lead of international NGOs in addressing international issues (Charnovitz, 1997).

In the 1980s, funding for NGOs from bilateral aid providers, such as the US Agency for International Development (USAID) and the official European donors as well as private Northern donors, grew significantly. The prevailing neoliberal and pro-market policies of US and other Northern governments promoted the reduction of the role of the state and expansion of the role of the private sector, including NGOs.

While economically the role of NGOs was to complement the provisions for public goods, politically NGOs served as building blocks of global civil society (Spiro, 1995; Mathews, 1997). Participation of NGOs in the UN system deliberations on global issues has helped the process of the formation of global civil society. It has been observed that there are often strong differences of viewpoint between Northern and Southern NGOs in these

deliberations. For example, at the UN Conference on Environment and Development (UNCED) in Rio in 1994, Southern NGOs raised concerns about the debt crisis and multinational corporations contributing to environmental destruction, while Northern NGOs were more interested in commitments to preserve certain resources (Clark *et al.*, 1998). This diversity of voices representing genuine stakeholder interests added to the legitimacy and credibility of NGOs.

NGO Response to Globalized Education – Two Examples

Building Resources Across Countries

BRAC (formerly known as the Bangladesh Rural Advancement Committee, renamed in 2008 as Building Resources across Countries, but well known just by the acronym BRAC) illustrates the significant role of NGOs in national development, including the development of education. BRAC, exceptionally among Southern NGOs, has also become an international organization working in several Asian and African countries.

BRAC was established as a relief organization to assist war-displaced people in the aftermath of the Bangladesh Liberation War. It now operates in all 64 districts of Bangladesh as well as in Afghanistan, Sri Lanka, Pakistan, Tanzania, Uganda, Southern Sudan, Sierra Leone, and Liberia. In Bangladesh, BRAC has over 7 million micro-finance group members, 37 500 nonformal primary schools, and more than 70 000 health volunteers. It employs over 120 000 full-time and part-time staff, the majority of whom are women. Among others, BRAC operates its own bank and runs a well-known university. BRAC USA and BRAC UK have been established as affiliates both to generate funding support, especially for the international programs, as well as to operate programs aiming at the disadvantaged immigrant populations in the two countries (BRAC, 2008).

BRAC's Non-Formal Primary Education (NFPE) program provides the 5-year primary education course in 4 years to poor, rural, disadvantaged children and drop-outs, who cannot access formal schooling. These one-room-one-teacher schools are for children between 8 and 14 years of age. Each school typically consists of 33 students who as a cohort are taken through the 4-year program, before another cohort is recruited. Core subjects include mathematics, social studies, and English in line with the national curriculum objectives. The schools also offer extracurricular activities. As of June 2008, 37 500 primary schools and 24 750 pre-primary schools were in operation enrolling nearly 3 million children, 65% of whom are girls. The schools have a dropout rate of less than 5%.

BRAC has set up centers for adolescent girls called Kishori Kendra that provide reading material and serve as a gathering place for adolescents where they are educated about issues sensitive to the Bangladeshi society such as reproductive health, early marriage, and women's legal rights. BRAC has also set up about a 1000 community libraries, 20% of which are equipped with computers (Smilie, 2009).

The Global Campaign for Education

The Global Campaign for Education (GCE) is a civil society movement, established originally with the initiative of Education International, the worldwide federation of teachers' organizations. Its aim is to end the global education crisis. Its mission is to hold governments to account for their promises made to provide EFA and to ensure that they act to deliver the right of children and adults to quality public education.

Since its formation in 1999, organizations and people from over 100 countries – civil society organizations, trade unions, child rights campaigners, teachers, parents, and students – have united under its auspices to demand universal education.

GCE was a strong civil society voice in the World Education Forum in Dakar 2000 in setting the EFA agenda for 2015. The GCE's membership is open to national coalitions and international and regional organizations that advocate for EFA and subscribe to GCE's principles and goals. The main advocacy approaches and activities of GCE are summarized below.

Global action week

GCE coordinates the Global Action Week on education with all its national and international partners in April every year. Activities included the World's Biggest Lesson and Send My Friend to School. In 2008, close to 9 million people took part in the World's Biggest Lesson, including national leaders and celebrities aimed at drawing attention to the state of education and actions that must be taken.

Year-round campaign

GCE represents civil society on education at key education decision-making bodies, including the Education Fast Track Initiative Steering Committee, the EFA UNESCO-led Working Group and High Level Group. It also guides national campaigns to lobby the annual G8 and World Bank and International Monetary Fund (IMF) meetings to demand adequate long-term financing for education.

EFA class of 2015

GCE helped launch the EFA Class of 2015 at the UN high-level meeting on the Millennium Development Goals on 25 September 2008. This class brings together governments, faith leaders, corporations, civil society, and

education advocates who are committed to making sure that the EFA goals become a reality by 2015.

Global advocacy

GCE encourages policy research on different aspects of the EFA agenda, what is needed to achieve EFA and rate the performance of national governments. It has produced a school report that ranks governments' efforts toward achieving EFA.

Recent Developments

There have been always winners and losers from economic globalization. Who the winners and who the losers are from the inexorable forces of globalization are determined by whether people live in the global North or in urban and developed parts of a country, whether they are skilled and educated, whether people have acquired the capacity to adjust to change and new situations easily, whether they possess assets, their gender and ethnic status, and such factors over which people have little control (Streeten, 2001).

Globalization-induced improvements in a nation's standard of living also can promote women's status and raise household income, education, nutrition, and life expectancy, while lowering birthrates. The key issues clearly are: discerning the factors which create the winners and losers; identifying the vulnerable groups affected by these factors; determining the conditions and actions that would reduce the vulnerability of people; and promoting and supporting the creation of these conditions and enabling people to engage in these actions. Enhancement of people's capabilities to discern and assess the options and make the choices can happen through effective access to education, knowledge, and information.

The quality of human resources determines success for a nation in the era of intensified globalization. The intellectual capital of a nation has become more important than natural resources and financial capital to a country's ability to compete in the global economy.

The economic crisis of 2008–9, manifested in the meltdown of the financial market, causing huge contraction of capital, decline in consumption, and increase in unemployment has posed new challenges to the legitimacy of the premises underlying economic globalization. This situation creates new opportunities for the civil society and NGOs to reinforce the international coalitions and compromises that are necessary to mitigate the negative aspects of globalization and enhance the positive effects – putting a higher premium on global human solidarity than on unimpeded global competition. Education and learning, in multiple ways and in the broadest sense, have to be regarded as a critical element in this effort.

Achievement Goal Theory: Definitions, Correlates, and Unresolved Questions

T Urdan, Santa Clara University, Santa Clara, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Research on achievement goals has emerged over the last three decades as one of the most prominent fields of motivational research (Elliot, 2005; Weiner, 1990). Achievement goals are defined somewhat differently by

various researchers, but there is general agreement that goals refer to the perceived purposes of achievement. Two broad categories of purposes have been most commonly examined: the goal of developing competence through

learning, understanding, and building new skills and the goal of demonstrating competence, either to oneself or others, according to social-comparative norms. The first class of goals has been most commonly called mastery goals (or task goals), whereas the second category of goals is currently most often referred to as performance goals (it has also been called ability, relative ability, and ego goals). Achievement goals have also been distinguished according to their valence properties. In the mid-1990s, a number of researchers demonstrated that achievement goals, particularly performance goals, differed according to whether they represented an appetitive desire to approach success (performance-approach goals) or a fear-based desire to avoid appearing incompetent (performance-avoidance goals; Elliot and Harackiewicz, 1996; Middleton and Midgley, 1997; Skaalvik, 1997). A performance-approach goal represents a desire to outperform others, whereas a performance-avoidance goal reflects a goal of avoiding being outperformed by others. More recently, mastery goals have also been divided into approach and avoidance dimensions where a mastery-approach goal represents a goal of gaining competence and skills and a mastery-avoidance goal represents a concern with not doing as well as one could or with deteriorating skills (Pintrich, 2000).

Roots of Achievement Goal Theory

The achievement goal framework grew out of, and in response to, a number of motivational theories prominent in the 1970s. The need-based theories of Atkinson, McClelland, and their colleagues that held sway from the 1950s to the 1970s raised important questions about the stability of motivational tendencies. Need for achievement (nAch) and fear of failure (FOF) were believed to represent stable, personality-like needs of individuals. As social-cognitive theories such as attribution theory and self-efficacy research began to gain footholds, a group of researchers at the University of Illinois (Carole Ames, Carol Dweck, Martin Maehr, and John Nicholls) developed achievement goal theory. They conceptualized achievement goals as motivational dispositions that were not only partly stable orientations but also somewhat malleable and subject to the influence of messages in the achievement context regarding the definition and purposes of achievement in those contexts. Whereas achievement motivation researchers described competitive, avoidance, and achievement orientations as stable aspects of personality, goal theorists generally ascribed greater responsibility to situational factors (Elliot, 2005; Urdan, 1997).

Achievement goal theory also has foundational roots in attribution theory. Carol Dweck and her colleagues examined why elementary school children often differed in their responses to failure. They argued that some children

explained their failure to causes they perceived as stable (i.e., a lack of intelligence or ability), leading to a helpless response to failure. Others attributed their failure to unstable, controllable causes (e.g., a lack of effort), leading to effortful and optimistic responses to failure (Diener and Dweck 1978; Dweck and Leggett, 1988). These different explanations for failure were associated with different achievement goals. When one believes that ability can be improved through effort, the goal of developing ability (i.e., a mastery goal) will be adopted. In contrast, when one believes that ability is trait like, with little hope of altering it through effort, one becomes concerned with demonstrating superior or ability or hiding a relative lack of ability (i.e., performance goals).

The development of achievement goal theory also has strong ties to progressive ideals. Nicholls (1989) was unabashed in his belief that the democratic ideal of American education could best be realized through the pursuit, and promotion, of mastery goals. As mastery goals include a definition of achievement that is internal rather than social-comparative, all children can achieve mastery goals, regardless of their ability. After all, everyone can improve and learn, even if these occur at different rates for different students. Since performance goals define achievement comparatively, any system that promotes performance goals creates a situation where some will lose and others will win. Nicholls argued that although the pursuit of performance goals may lead to achievement in school, such an association is indicative of school systems promoting the wrong (i.e., competitive) values rather than the inherent benefits of performance goals.

The last decade or so has seen a return to the achievement motivation roots of achievement goal research. Elliot and his colleagues have argued that the nAch and the FOF are the causal antecedents of mastery and performance goal adoption (Elliot, 1997; Elliot and Harackiewicz, 1996). According to this model, mastery goals are driven primarily by an nAch, performance-avoidance goals by an FOF, and performance-approach goals by a combination of nAch and FOF. They argue that achievement goals represent the proximal, cognitive influences of achievement-related behavior that channel the more general, unconscious motive dispositions of nAch and FOF.

Correlates of Achievement Goals

A wealth of research, mostly using survey and experimental methods, has revealed a pattern of associations among achievement goals, self-regulatory strategy use, affective and motivational variables, and achievement (for reviews of this research, see Elliot, 2005; Harackiewicz *et al.*, 2000; Midgley *et al.*, 2001; Urdan, 1997). Most of this research has found a generally positive constellation of correlates with mastery goals. For example, when pursuing mastery

goals, students generally persist longer when faced with difficulty, are more willing to attempt difficult or challenging tasks, use more deep-level cognitive processing strategies, are more intrinsically motivated, and feel better about school and school work. Despite these positive motivational, affective, and cognitive correlates of mastery goals, researchers have not consistently found positive associations between mastery goals and achievement, both in school and on experimental tasks (Elliot, 2005). Recent research examining the association between mastery goals and student performance on assessments designed to match instruction in actual classrooms has revealed modest positive correlations between achievement and mastery goals (Linnenbrink, 2005; Nolen, 2003).

In contrast to the correlates of mastery goals, pursuing performance-avoidance goals is usually associated with a negative pattern of motivational beliefs and behaviors. When students are performance-avoidance goal oriented, they are more likely to give up when faced with difficult work or confronted with failure, use more shallow-level cognitive strategies (such as rote memorization), are less likely to seek help when they need it, and are more likely to engage in self-defeating practices like self-handicapping. As performance-avoidance goals represent a concern with being outperformed by others and with appearing incompetent, the primary emotions associated with these goals are shame and fear. Individuals who are able to achieve well despite their performance-avoidance goal orientation are most likely to feel relief rather than pride.

Whereas the maladaptive motivational and achievement consequences of pursuing performance-avoidance goals have been found consistently, the effects of performance-approach goals on motivation and achievement have been ambiguous. Some research has found that performance-approach goals are associated with lower persistence after failure (Elliott and Dweck, 1988), greater use of surface learning strategies and less use of deep cognitive processing strategies (Nolen, 1988), greater feelings of self-consciousness (Roeser *et al.*, 1996), negative affect in school (Urdu and Midgley, 2003), and the tendency to attribute failure to lack of ability (Dweck and Leggett, 1988). However, there is also a substantial body of research that has found significant positive associations between performance-approach goals and adaptive or beneficial motivational and achievement variables, including intrinsic motivation (Elliot and Harackiewicz, 1996), teacher-assigned grades (Harackiewicz *et al.*, 2002; Roeser *et al.*, 1996), achievement motivation (Elliot, 1997; Nicholls *et al.*, 1985), engagement in science class (Meece *et al.*, 1988), valuing of school (Midgley *et al.*, 1996; Wolters *et al.*, 1996), self-efficacy (Roeser *et al.*, 1996; Wolters *et al.*, 1996), and self-regulation (Wolters *et al.*, 1996). Indeed, a number of studies have found that performance-approach goals are positively correlated with mastery goals

(Nicholls *et al.*, 1985; Roeser *et al.*, 1996; Nolen and Haladyna, 1990).

It appears that the effects of a performance-approach goal orientation on motivation, affect, and achievement depend on a number of factors, including how the goals are measured, how they combine with the simultaneous pursuit of mastery goals (Barron and Harackiewicz, 2001; Meece and Holt, 1993; Pintrich, 2000; Wolters *et al.*, 1996), and personal characteristics of students including their gender (Urdu, 1997b), ethnicity (Midgley *et al.*, 1996), culture (Urdu, 2004), and grade level (Midgley *et al.*, 2001). The mixed pattern of associations with performance-approach goals makes global statements about the positive or negative effects of a performance-approach goal orientation difficult to support. Indeed, the ambiguous results have spawned a debate among achievement goal researchers regarding the potential benefits and harms of performance-approach goals (see Midgley *et al.*, 2001; Harackiewicz *et al.*, 2002). Midgley and her colleagues argued that the beneficial effects of performance-approach goals may be limited primarily to older students (i.e., college) with a history of high academic achievement. Molden and Dweck (2000) argued that performance-approach goals are beneficial as long as students are succeeding, but an orientation toward demonstrating superior ability can quickly change to a fear of demonstrating relative incompetence when students encounter failure or difficulty. Recently, Brophy (2005) argued that researchers' focus on the relative merits and drawbacks of performance goals may be misguided as observational and interview research suggests that students rarely mention social-comparative concerns in school settings unless directly prompted by researchers, as through the use of surveys. At present, the most definitive statement that can be made regarding performance goals is that much remains unresolved regarding their definition, operation, and influence on motivation and achievement.

Classroom Goal Structures

The achievement goals that have been discussed so far refer specifically to the personal goals that individuals pursue. In addition to personal goals, there are also goal structures. Goal structures refer to messages in the environment (e.g., experimental situation, classroom, and school) that make certain goals salient. Such goal-related messages can come from a variety of sources in the achievement context, including how the purposes or definitions of success are presented, the types of tasks that are assigned, how much time students are given to complete the task, and how individuals are recognized and rewarded in the classroom, school, work, or athletic context. For example, it is common in experimental manipulations of goals to provide research participants with

instructions that make one type of goal salient, and these instructions constitute the goal structure for that situation. Similarly, in a classroom, teachers can emphasize the ability differences between students (performance goal structure) by grading on a curve or emphasize the development of competence by using portfolio assessment to chart the progress of each student over time (mastery goal structure). Most researchers who have discussed goal structures have referred specifically to the classroom- or school-level goal structures (e.g., Ames, 1992; Anderman and Midgley, 1997).

Researchers examining goal structures have experimentally manipulated the goal messages in the achievement context (most commonly a laboratory setting), assessed students' and/or teachers' perceptions of the classroom goal structure in the classroom or school using surveys, conducted observations in classrooms to see which goals were emphasized, or some combination of survey and observational methods. Experimental manipulations of goals have yielded the most consistent results, generally producing an adaptive motivational pattern when mastery goals were emphasized, lower motivation and achievement when performance-avoidance goals were emphasized, and a mixed pattern of motivation and achievement when performance-approach goals were emphasized (Elliott and Dweck, 1988; Elliot and Harackiewicz, 1996). Some researchers have questioned whether the results of research using experimental manipulations of goals in laboratory settings will generalize to authentic achievement contexts such as classrooms. In the lab, it is easy to emphasize that a single achievement goal and performance on the assigned tasks generally have few, if any, long-term consequences for participants. In the classroom, students receive multiple goal messages and are usually engaged in activities that influence their grades, an outcome of significance for most students.

Research on the influence of classroom goal structures on motivation, affect, and achievement that has been conducted in classrooms and schools has produced much more ambiguous results than has laboratory-based experimental research (see Urdan (2004b) for a review). For example, survey research has revealed that students' perceptions of a mastery goal structure in the classroom are positively correlated with their own personal mastery goals, positive affect in school, self-regulatory strategy use, and sometimes course grades (Ames and Archer, 1988; Urdan and Midgley, 2003). However, other researchers have reported a lack of association between perceived classroom mastery goal structures and a variety of outcomes, including persistence, choice of challenging work, or course grades (Wolters, 2004), between changes in the perceived mastery goal structure and changes in students' valuing of mathematics and English over time (Anderman *et al.*, 2001), or expected negative associations between classroom mastery goal structures and self-handicapping (Urden *et al.*, 1998). Similarly, some research has found a

pattern of associations between perceived classroom performance goal structures and a variety of maladaptive motivational outcomes. For example, classroom performance goal structures have been found to correlate with procrastination (Wolters, 2004), self-handicapping (Urden *et al.*, 1998; 2004a), and attributing failure to lack of ability (Ames and Archer, 1988). However, perceived classroom performance goal structures have also been found to correlate with positive cognitive outcomes, such as attributing success to effort and failure to inappropriate strategy use (Ames and Archer, 1988) and have been found to be unrelated to other variables, such as cognitive and meta-cognitive strategy use (Wolters, 2004), and self-handicapping (Turner *et al.*, 2002).

There are several possible explanations for the inconsistent pattern of results found when examining classroom goal structures. One is that classroom goal structures may simply not be very strong, or clear, in most classrooms. As mentioned previously, genuine achievement contexts such as classrooms usually contain multiple achievement goal messages. Research suggests that students' perceptions of classroom goal structures are largely subjective creations rather than objective realities; therefore, students' existing personal goal orientations may shape their perceptions of the classroom goal structures to a significant degree (Brophy, 2005; Urden, 2001). Observational research and survey research using hierarchical linear modeling reveal that students in the same classroom vary widely in their perceptions of the classroom goal structures. A second plausible explanation for the mixed pattern of results is that researchers vary widely in their operational definition of classroom goal structures. The survey measures employed by Church *et al.* (2001), Ames and Archer (1988), Urden and Midgley (2003), Urden (2004a), Nolen (2003), and Greene *et al.* (2004) are so different from each other that comparisons across these studies are not likely to yield interpretable conclusions. It is not only clear that goal-related messages in achievement contexts can influence the personal goals students adopt, but also clear that research examining classroom goal structures is in its early stages and still needs significant advancement in conceptualization and measurement.

Remaining Questions about Achievement Goals

Although research on achievement goals has grown rapidly to become perhaps the dominant paradigm in the field, a number of important questions remain. Among these, perhaps none is more important than the question of what, exactly, an achievement goal is. A precise definition of achievement goals is critical for understanding the results of past research and to help the field advance. For

example, much of the debate discussed previously regarding the benefits and costs of performance goals may hinge on how performance goals are defined, both conceptually and operationally. For achievement goal research to be useful to educators, coaches, and parents, the definition of achievement goals must be clear.

Elliot (2005) argued that achievement goals have been defined as specific, desired end states (i.e., to master a concept or skill, to outperform other students in a class, to win a competition) and as broader, overarching orientations that include cognitive and affective components (see Ames, 1992; Dweck, 1986). In a recent qualitative study, Urdan and Mestas (2006) found that high school students often reported quite different reasons for pursuing the same achievement goal. For example, some students said they wanted to outperform others (i.e., a performance-approach goal) because they wanted to silence other students who had questioned their intelligence, whereas others said they wanted to outperform others to make their parents proud. Elliot (2005) argued that achievement goal researchers should separate achievement goals from the reasons behind their pursuit in order to define goals as clearly and simply as possible. However, even when goals are separated from their reasons, there is no consensus yet about the defining features of achievement goals. Grant and Dweck (2003) found that performance goals have been operationally defined as a desire to validate one's ability, to outperform others, or as a desire to simply do well on a task, such as getting a good grade. Using factor analysis on a survey measure they designed, Grant and Dweck found that performance goals divided into outcome goals (i.e., doing well), ability goals (i.e., validating ability), and normative goals (i.e., doing better than others and validating superior ability). Goal researchers have not yet agreed about the defining feature, or features, of performance goals. Differences in operational definitions used by goal researchers may explain the different patterns of results researchers have reported when examining the consequences and correlates of personal performance goals. Additional questions about the definition of achievement goals, including whether they are stable orientations or more situation specific, also need resolution.

In addition to the defining features of mastery and performance goals, questions remain regarding how many and which goals count as achievement goals. Several researchers have argued that social goals, including goals such as making or maintaining friendships, being a good citizen in the classroom, pleasing the teacher, and gaining social status among peers, are important goals that students pursue in the classroom (Ryan, 2001; Urdan and Maehr, 1995; Wentzel, 1991). Social goals were included in early goal measures, such as the ego/social goals construct of Nicholls *et al.* (1985). However, others have argued that social goals are fundamentally different from

mastery and performance goals because the latter goals are focused specifically on competence. Although there are dozens of goals that individuals might pursue (to be a good parent, to own a nice home, to lose weight, etc.), only those goals that focus on competence in achievement-related activities – such as school, sport, and work – should be included as achievement goals (Elliot, 2005). Other goals that have sometimes been included in research on achievement goals, including social goals and work-avoidance goals (i.e., the desire to get by with as little effort as possible), may be different in kind than are mastery and achievement goals.

In addition to questions about the precise definition of achievement goals, there remain a number of questions regarding how they operate. Most research has found that mastery and performance goals are either moderately correlated or orthogonal, meaning that individuals can, and do, pursue multiple goals simultaneously. Barron and Harackiewicz (2001) argued that mastery and performance may combine in three different ways: independently, additively, or interactively. In the independent model, mastery and performance goals have unique associations with different outcomes, but these associations are not affected by the presence or absence of the other goals. For example, students with a strong mastery goal may value mathematics more strongly than do students with a low mastery goal, regardless of whether they have a strong or weak performance-approach goal. In the additive model, mastery and performance goals combine to create stronger effects than do either goal alone. For example, students with strong mastery and performance-approach goals may have higher achievement than do students with either strong mastery or performance goals, but not both. Finally, the interactive model suggests that mastery and performance goals interact to influence outcomes. For example, perhaps performance-approach goals are positively related to persistence after failure when mastery goals are high but negatively related to persistence when mastery goals are low.

Research examining the associations between multiple goal configurations and outcomes has not yet yielded consistent results. Some studies have found that the optimal pattern of motivation and achievement is produced when students are high in their pursuit of mastery goals and low in their performance goal pursuit (Meece and Holt, 1993; Pintrich and Garcia, 1991). Others have found that the most adaptive pattern of outcomes is associated with the simultaneous endorsement of both mastery and performance goals (Elliot and Church, 1997; Pintrich, 2000). Barron and Harackiewicz (2001) examined multiple goals among college students in two ways: (1) using an experimental manipulation of goals and (2) simply asking participants to self-report their goals. They found that for self-reported goals, mastery predicted intrinsic motivation variables but not achievement on a math task, whereas

performance goals predicted achievement in success, but not difficult, conditions. They did not find any unique effects of multiple goal pursuit. These results suggest that mastery goals are predictive of some outcomes and performance goals are predictive of other outcomes; therefore, the authors concluded that pursuing both goals is adaptive because it allows students the best opportunity to succeed on multiple outcomes. In the manipulated goals experiment, Barron and Harackiewicz found that holding multiple goals may benefit both high- and low-achievement motivation students when they are in situations that do not match their achievement motive well.

In an ambitious quasi-experimental study, Linnenbrink (2005) conducted an experimental manipulation of the classroom goal structures in ten upper-elementary school classrooms during a 5-week mathematics unit. She discussed achievement goal theory with the five participating teachers and then assigned teachers to one of three conditions: mastery, performance, or combined mastery and performance. Linnenbrink gave teachers a set of strategies they could use to promote the appropriate goal or combination of goals and then observed them to see if they faithfully implemented strategies to promote the appropriate goal emphasis. She also used surveys to assess students' motivation (self-efficacy, interest value, and utility value), emotional well-being (positive affect, negative affect, and test anxiety), cognitive engagement (the quantity and quality of self-regulatory strategy use), and help-seeking behavior before the unit began and again immediately upon its conclusion. An end-of-unit achievement test was also administered pre- and postintervention. Linnenbrink found that scores on the unit test improved the most (from pretest to posttest) among students in the performance and combined performance-mastery conditions relative to the mastery goal condition. This difference between the groups decreased by the time of the follow-up test administered 5 weeks after the conclusion of the math unit. She also found that students in the performance-approach condition increased their use of expedient help seeking (i.e., just asking for someone to give them the correct answer), whereas students in the other two groups decreased slightly in their expedient help-seeking behavior from pre- to posttest. There were no goal-structure-group differences, either in mean level or change over time, for motivation, emotional well-being, cognitive engagement, or adaptive or avoidance help seeking. From the research examining multiple goals, it appears that mastery goals are predictive of some outcomes and performance goals are predictive of others. When combined, their additive and interactive power does not appear to be substantial. More research on the combined effects of mastery and performance goals, over time, under success and failure conditions, and with populations of different ages is needed before firm conclusions can be drawn.

Finally, more research is needed that examines possible differences by age, culture, and achievement level in the definition and function of achievement goals. A limited body of research indicates that cultural factors such as race (Midgley *et al.*, 1996) and generational status (Urdan, 2004a) may influence the way students interpret goal-related messages in the classroom and the association between achievement goals and various outcomes. As noted earlier, some have argued that achievement goals, particularly performance goals, have different consequences for young (i.e., elementary) and older (i.e., college) students (Midgley *et al.*, 2001) and for high achievers compared to low achievers (Dweck and Leggett, 1988). Once clear conceptual and operational definitions of achievement goals have been established, research examining these cultural, age, and achievement level differences should prove most interesting.

Conclusion

The achievement goal framework has produced an incredibly productive and varied body of research. As the field reaches middle age, a number of important conceptual and empirical questions remain. The continuing maturation of research in this area will undoubtedly produce findings of importance to motivation researchers and educators alike.

Affect, Mood and Emotions

S Schnall, University of Plymouth, Plymouth, UK

© 2010 Elsevier Ltd. All rights reserved.

Definitional Issues

Despite a considerable body of literature dedicated to the scientific study of affect, there is surprisingly little consensus on some of the most basic concepts related to affect. To some extent, definitions relating to affective processes are specific to certain research traditions. For example, whereas some theorists consider the conscious experience of emotion one of its central features, others propose that emotional processes can also take place entirely outside of conscious awareness. There is broad agreement, however, that affect comprises both emotion and mood, which differ regarding their object and temporal constraints. An emotion typically follows a specific eliciting stimulus or event, and is intense but limited in duration. Certain action tendencies, such as whether one is more likely to approach or avoid the target of one's current emotional feeling, are associated with specific emotions. These action tendencies do not imply that the person will necessarily engage in that action; however, in principle, a readiness to engage in the action is present. A mood, on the other hand, is usually not attributable to a specific stimulus, is of low intensity, and of longer duration. Since the source of a mood is often ambiguous, the feeling can be incorrectly attributed to a stimulus under consideration, thus leading to various types of affective influences on evaluation and cognitive processing, as are discussed in more detail further below.

Emotions can be classified along two orthogonal dimensions, namely valence and arousal. Valence refers to whether the experience is positive or negative, and thus reflects the value of a given object or situation. Arousal refers to whether the person experiences a state of activation or deactivation, and signifies whether the event is important or trivial. Other classifications of emotions have involved categorizing them with regard to specific action tendencies, such as approach and avoidance. For example, although anger and sadness are both subjectively negative experiences, anger is considered an approach emotion because an angry person is inclined to confront the source of their anger, whereas sadness is considered an avoidance emotion because a sad person is likely to withdraw from other people.

Since affect can either pertain to emotion or mood, affective feelings refer to the subjective experience of emotions or moods. Such affective feelings can be distinguished from those that are nonaffective in nature, such as hunger, thirst, or boredom. Usually, convergent affective cues are

provided by multiple response systems, including subjective experience, cognitive processes, hormonal changes, physiology, motor behavior, and expressive behavior such as facial expressions, postures, and vocal signs. Both cortical and subcortical neural subsystems are thought to coordinate these multiple response systems. Affective processes are scientifically measured by tools closely relating to the different response systems. Such measures include self-reports (e.g., emotion rating scales), observational data (e.g., of facial expressions and instrumental actions), psychophysiological measurements (e.g., heart rate, skin conductance, and electromyography), and brain imaging techniques (e.g., functional magnetic resonance imaging (MRI) and electroencephalogram (EEG)).

Many issues in the study of affect have created great controversy and are still being debated. For example, whether there is a fixed number of basic emotions continues to be a matter of dispute. Some researchers have argued that evidence for culturally universal facial expressions of happiness, sadness, anger, fear, disgust, and surprise suggests a special status for these emotions, relative to others. Other researchers maintain that facial expressions are, however, one of many facets of the emotional experience, and do not provide enough evidence to suggest a privileged status of those relative to other emotions. Indeed, definitional issues of emotion are intricately linked to theoretical positions, with varying emphasis placed on the necessary and sufficient components of an affective experience. As will be reviewed below, different research traditions have emphasized functional, embodied, or cognitive components, and although they differ in the extent to which they consider one or the other primary, they have contributed to the general understanding of affective phenomena.

Components of Affect

Functional Aspects of Affect

Affective processes have historically often been contrasted with rational processes; however, it has become increasingly apparent that this is not a useful distinction because many affective phenomena are, at least in principle, functional in nature. Charles Darwin was among the first to scientifically study emotion from a functional perspective by exploring its evolutionary underpinnings.

There is widespread agreement that the function of emotion is to facilitate social interactions with conspecifics,

and to facilitate rapid responses toward potentially harmful aspects of the environment. As far as social relationships are concerned, comparative research has established that in animals and humans alike, early experiences with the primary caregiver are critical for affective functioning in later life. The attachment system ensures a warm and caring relationship between the child and caregiver, and this primary relationship results with the child developing an internal model of social relationships. Deficits in this early relationship can have detrimental effects on social and romantic relationships later in life. Although the attachment style is relatively stable and can have profound consequences on one's emotional responses within social relationships, it can be altered through specific efforts, for example, in the context of psychotherapy.

Presumably because of their evolutionary origins, affective responses toward certain stimuli are stronger than toward others. For example, human and nonhuman primates are especially likely to develop negative attitudes to snakes and spiders, whereas this is not the case for neutral stimuli such as flowers or mushrooms. The evolutionary argument for this preparedness in learning is that primates who differentially learned to avoid snakes, spiders, and other potentially harmful stimuli had a greater chance of survival than those who did not.

In addition to these basic ways in which affective processes can be considered evolutionarily adaptive, affective influences on cognitive processing have also been discussed as providing useful informational feedback about the state of the environment. On a general level, affective feelings provide feedback about whether something is good or bad. More precisely, they provide one with information about the momentary value of objects and situations. When making evaluative judgments and deciding whether something is desirable or not, people attend to their own feelings, as if asking themselves: How do I feel about it? The experience of these felt evaluations serves as information. Thus, people generally like what they feel good about and dislike what they feel badly about. As a consequence, affective feelings have been shown to influence ratings of life satisfaction estimates of risk, and many other judgments. In addition, many attitudes are shaped by affective processes.

Affective cues, however, are not only informative when interpreted as evaluations of objects and situations, but can also be interpreted as performance feedback while working on a task: positive feelings serve as success feedback, indicating that the current cognitive strategy is adequate, whereas negative feelings serve as failure feedback, indicating that a different cognitive strategy should be pursued. As a result, being in a good mood makes people more likely to process incoming information in relation to easily accessible knowledge, expectations, and heuristics; that is, a good mood facilitates top-down processing. In contrast, being in a bad mood makes people more likely to rely on

uninterpreted perceptions and analytical processing; that is, a bad mood facilitates bottom-up processing. Affective feelings, therefore, directly concern adaptive actions as well as which actions work well in pursuit of a goal or which ones might better be abandoned.

Contextual constraints can qualify emotional experiences on several levels. First, affect is embedded in a social, cultural, and historical context, and the meaning of affective practices is constructed in relation to this context. Modern-day research has confirmed that some aspects of emotion, such as the facial expressions of a number of emotions, are universal. Cultural variability exists, however, with different culture display rules regulating the contexts in which it is acceptable to publicly express an emotion. For example, in Western societies where a considerable emphasis is placed on feeling unique and independent, emotions like pride are more socially acceptable than in some Eastern cultures (e.g., Japan) where fitting into an interdependent community is more important. In these interdependent cultures, emotions that are defined by interpersonal demands, such as shame or guilt, serve to maintain social relationships.

Second, once emotions are experienced within this contextual background, they provide important information to the individual concerning what is good or bad. However, exactly how this information serves as evaluative feedback depends on the situation in which the emotional feelings are interpreted, or more precisely, toward what they are experienced. For specific emotions, such as feelings of anger, fear, happiness, etc., what object they are felt toward is usually clear. In contrast, more subtle moods, such as feeling mildly good or mildly bad, usually do not have a clear object attached to them and, thus, the source of these moods remains ambiguous. Since moods lack specificity and are therefore unconstrained regarding their informational value, they can be misinterpreted, or misattributed in various ways: people tend to report feeling more satisfied with their lives on a sunny day than on a rainy day; that is, people's judgments can be influenced by irrelevant affect from an external source such as the weather, provided they are not focally aware of this irrelevant source as the cause of their feelings. However, simply asking about the weather before obtaining judgments of life satisfaction is sufficient to eliminate the effects of weather on these judgments. Thus, a central finding in the affect literature is that irrelevant affective states influence judgments and cognitive processing only as long as their source is kept ambiguous. When this is the case, feelings are experienced as relevant to whatever is currently on one's mind, and the meaning of affective feelings depends on the current agenda of a person.

Overall, the functionality of affect is evident directly in the way people deal with certain stimuli in the environment, and indirectly in the way people cognitively process information about the environment.

Embodied Aspects of Affect

Emotion research has a long history of studying embodied aspects of experience. William James argued that the experience of emotion reflects the experience of bodily changes. According to this view, bodily sensations determine the subjective experience of emotion. Although this view has been criticized at times, it currently enjoys renewed support as a consequence of recent developments in the research area of embodied cognition. A direct consequence of the view that embodied cues constrain subjective experience is that emotional feelings can be regulated, and even initiated, by intentionally manipulating a person's physical state. For example, when a person is induced to put on a smile, the person is likely to report feeling happy. Similar evidence also has been obtained when research participants are induced to adopt postures characteristic of certain emotional states, such as fear, anger, or sadness. This research suggests that people read their emotional bodily behavior, and may experience their emotional physical states as emotional feelings. In other words, rather than being epiphenomenal to the experienced feeling of emotion, some theorists have argued that these bodily changes actually constitute the emotion and causally influence the feeling.

In addition to obvious emotional bodily cues such as facial expressions and emotional postures, other bodily cues can also be interpreted as providing affective information in appropriate contexts. For example, motor behaviors that are associated with agreement or disagreement have shown to influence attitudes. When research participants were induced to produce a vertical head movement, resembling head nodding, while listening to a communication about increasing tuition at their university, they were later more likely to agree with the tuition increase than participants who had been induced to produce a horizontal head movement resembling head shaking. Similarly, performing simple motor behaviors that are typically associated with approach behavior results in more liking of neutral stimuli than engaging in avoidance behavior. Presumably, people typically approach positive things and avoid negative ones, and finding themselves engaging in these behaviors produces the inference that an attitude object is more or less positive.

Considerations of the physicality of emotional experiences have increasingly involved the study of the brain. In particular, subcortical structures in humans and other mammals are considered fundamental in the subjective experience of emotion because of their direct connections with the hypothalamus, which in turn controls functions of the autonomic nervous system (heart rate, arousal, etc.) and the hormonal system. Subcortical structures are thought to be involved in the primary evaluation of the affective stimulus's valence as either positive or negative, and its importance of being personally relevant or

irrelevant. Although other subcortical structures are also critically involved, the amygdala appears especially important in this respect. The amygdala, which has been studied extensively in the processing of fear-eliciting stimuli, influences the cortex directly in order to provide an initial evaluation of a stimulus situation outside of conscious awareness. Evidence for this notion comes from the finding that whereas fear can be experimentally conditioned in the absence of cortical involvement, a conditioned fear response is absent after damage or removal of the amygdala. In addition, the amygdala activates cortical arousal systems of the brain which alert the organism to prepare itself for appropriate action. In other words, the amygdala serves two purposes at the very onset of an emotional experience: Direct projections to the cortex provide specific information about the stimulus situation, and nonspecific cortical arousal makes the organism ready for potential action.

The notion of cortical involvement in emotional processing is widely accepted, presumably because it has become clear that cognitive appraisals (see below) can modify a person's physical and subjective emotional experience. An early demonstration of the importance of the cortex in emotional experience was the famous case study of Phineas Gage, who, as a consequence of an accident, lost large sections of his prefrontal cortex, leading to profound deficits in emotional functioning for the rest of his life. Other individuals suffering from prefrontal brain damage have been studied using modern brain imaging techniques to localize specific brain lesions, and how these relate to abnormal affective experience. These patients tend to exhibit flat affect, that is, they do not appear to be experiencing any emotions at all, based on what can be inferred from their openly expressed emotions. Although it was initially suspected that perhaps only the expressive, rather than the experiential, component of emotion might be impaired, data regarding physiological reactivity suggested otherwise. Whereas healthy individuals show characteristic physiological reactions to an emotional stimulus, patients with specific damages confined to the prefrontal cortex do not show, for example, skin conductance responses to emotionally disturbing stimuli. However, these patients still indicate that they cognitively know that the stimuli are disturbing and ought to elicit negative emotions. Thus, although the knowledge about appropriate emotional reactions is still intact and accessible, conscious emotional feelings cease to exist in patients with certain prefrontal cortical impairments. Interestingly, in addition to their impaired affective functioning, these patients also show deficits in decision making because they appear unable to generate hypothetical mental scenarios that would help them to selectively choose among several options. Thus, contrary to the assumption that

emotional feelings need to be controlled to allow for rational thinking, the absence of emotional feelings can be even more debilitating as far as efficient, adaptive decisions are concerned.

Cognitive Aspects of Affect

In the 1960s, researchers advanced the notion that emotional experiences involve an evaluation to determine their relevance for the individual. This conception was later expanded to include a primary appraisal of determining personal relevance, and a secondary appraisal that involves assessing one's ability and resources to cope with the emotional situation. Further elaborations of appraisal theories have explicated how specific appraisals lead to the experience of distinct emotional feelings. Cognitive approaches of affect, including appraisal theories, suggest that affective states can be modified by changing the cognitive component of the emotion. Many emotion-eliciting events can be cognitively reappraised or given a different meaning; as a consequence, the quality of the experience changes. For example, the feeling of anger after waiting in vain for a friend can give rise to the feeling of worry after learning that the friend was in a car accident. Thus, the same phenomenological experience, the bodily cues associated with an emotion, can be interpreted differently depending on the situational context and one's cognitive appraisal. Research on the self-regulation of emotion indicates that it is more beneficial to reappraise emotion-eliciting stimuli rather than trying to suppress an emotional reaction once this response has already occurred.

Appraisal processes have been implied as one component of emotional intelligence, which is considered a person's ability to appropriately identify and utilize emotional responses. Emotional intelligence consists of four aspects: (1) perceiving the emotion, and accurately identifying it, both in oneself and in others; (2) using appropriate emotions to solve problems and enhance cognitive processes; (3) understanding the elaborate interconnection of various emotions, and their potential consequences for oneself and others, for example, in the context of flexible planning; and (4) regulating or managing one's emotions effectively, which not only aims at not getting overwhelmed by emotions, but also not suppressing or denying them when they occur. Indeed, suppressing the outward expression of emotion can be associated with impoverished cognitive functioning (e.g., decreased memory performance), presumably because controlling one's emotional responses is effortful and takes up resources that could otherwise be dedicated to cognitive processing.

Modeled along widely used intelligence tests, assessments of emotional intelligence have been developed to test individual differences in the extent to which people understand and utilize their emotions. Such test scores

have been successfully used to predict the quality of social relationships, as assessed by individuals themselves and their family members and peers. In addition, there appears to be a negative relationship between emotional intelligence and various deviant and antisocial behaviors. For example, people scoring high in emotional intelligence are less likely to engage in bullying behavior or abuse drugs than those who score low. Additional research efforts will need to clarify the developmental trajectories of emotional intelligence, and the extent to which it can be taught in schools and other educational settings.

In addition to differences in emotional intelligence, variability in affective styles has been observed, with some individuals apparently being more prone to experience positive emotions than others who are more prone to experience negative ones. Further findings have established that these differences are relatively stable, with some people reporting consistently higher levels of happiness than others throughout the course of their lives. Surprisingly, once the basic human needs such as adequate shelter, food, and social ties are taken care of, wealth, material possessions, and other situational factors appear to only be weakly associated with increased happiness, suggesting that a person's level of happiness has a strong genetic component and is not influenced heavily by contextual factors. These differences in affective style have been documented as being associated with specific types of brain activity. Both in infants and adults, hemispheric dominance has been invoked in the experience of positive and negative emotions, with left-sided activation being associated with higher levels of self-reported positive affect. In general, the left hemisphere of the brain shows relatively greater activation with approach-related, positive emotions, whereas withdrawal-related, negative emotions show greater right-sided activation.

Summary

Although some central definitional issues in the field of affective studies remain to be controversial, the field has been accumulating considerable empirical evidence for certain core findings. This includes emphasizing relative contributions of bodily and cognitive influences and how they might have evolved in the course of evolution. In addition, findings through research with subcortical structures and the influence of bodily cues highlight the embodied aspects of affect. Similarly, approaching affect from a cognitive perspective illustrates how it can be altered through cognitive processes and appraisals. These varying theoretical perspectives of affect and their corresponding findings illuminate its complex nature, and it is only with more research that affect can be fully understood and these findings may be integrated.

Glossary

Cognitive-focused interventions – Emphasize the mediating role of cognitive processes in sustaining or eliminating test anxiety and refer to a wide array of therapeutic approaches directed toward modifying the worry and irrational thought patterns of test-anxious clients.

Emotionality – Consists of perceptions of autonomic reactions evoked by evaluative stress.

Emotion-focused interventions – Primarily aim at reducing the arousal and heightened emotional reactions of test-anxious persons when faced with stressful evaluative situations.

Situation-specific personality trait – In the context of test anxiety research, this trait refers to the individual's disposition to react with extensive worry, intrusive thoughts, mental disorganization, tension, and physiological arousal when exposed to evaluative situations.

Test anxiety – Refers to the set of phenomenological, physiological, and behavioral responses that accompany concern about possible negative consequences or loss of competence on an examination or similar evaluative situation. Test-anxious behavior is typically evoked when a person believes that his/her intellectual, motivational, and social capabilities are taxed or exceeded by demands stemming from the test situation.

Worry – Primarily refers to cognitive concern about the consequences of failure.

typically required to adjust to a variety of novel and challenging academic and social stressors and demands that may evoke anxiety. These include demanding coursework assignments; heavy workload; time pressures in meeting deadlines for submission of papers; insufficient finances and work opportunities; demanding examinations administered under stringent time pressures; poor student–faculty rapport; inadequate and crowded study conditions; and conflict between meeting academic demands, leisure, and extracurricular pursuits, and family responsibilities. The anxiety experienced by many students as a result of school or academic stress is such an unpleasant and painful experience that it is not surprising that anxiety often interferes with student learning, well-being, and health.

Anxiety is a universal human experience, intrinsic to the human condition. The construct is defined by a loosely coupled ensemble of cognitive, affective, somatic arousal, and behavioral tendency components, evoked in response to mental representations of future threat or danger in the environment (Zeidner, 2007). However, the nature of the specific environmental stimuli evoking anxiety appears to have changed considerably over the years (Zeidner, 1998). Whereas in ancient times, wild beasts, natural catastrophes, and the like plausibly served as major sources of environmental stress, in the modern achievement-oriented society, stress and anxiety are evoked largely by a wide array of social-evaluative encounters (e.g., appearing for a college aptitude test, defending a dissertation, and taking a vocational aptitude test battery).

Modern conceptualizations view anxiety as an important adaptation that signals to us what is potentially harmful, dangerous, or threatening in a stressful encounter, with critical value for human survival (Rachman, 2004). Thus, anxiety in educational contexts serves as a call for action, taking precedence before all other activities and shifting attention to the sensed threats and potential losses and dangers at hand. When an individual experiences anxiety this is important information suggesting that something in the environment has been appraised as threatening or harmful to one's well-being and some action needs to be taken to ward off the threat (Lazarus, 1999).

Anxiety is frequently cited as a key villain in the ongoing drama surrounding educational testing and evaluation, and is claimed to be among the factors at play in determining a wide array of unfavorable outcomes and contingencies (e.g., poor cognitive performance, scholastic underachievement, low satisfaction with school or college, and psychological distress and ill health; Zeidner, 1998).

Overview

Anxiety is incontestably the most researched of all emotional states in education (Schutz and Pekrun, 2007). Educational settings are contexts in which students at all levels are ubiquitously exposed to a wide array of potentially stressful and anxiety-evoking experiences. Thus, school-aged students are frequently exposed to stressors such as parental pressures for high achievement, fierce classroom competition for high grades, experiences of frustration and failure, teacher disapproval, peer conflict, social isolation and rejection, and physical and verbal aggression and abuse. Comparably, college students are

Clearly, many students have the potential to do well but perform poorly because of their debilitating levels of anxiety, thus limiting educational or vocational development. The loss to society of the full contribution of potentially capable students through anxiety-related distress and somatic ailments, underachievement and failure at school, or performance decrements constitutes an important problem for educational practitioners.

Conceptualizations

In contrast to early mechanistic views of anxiety as a unified construct, it is currently construed as a complex multidimensional construct embodying a series of interrelated cognitive, affective, and behavioral tendency components and reactions. Its complex nature, coupled with the fact that anxiety encompasses worry and self-preoccupation, physical upset, disruptive feelings, and maladaptive behaviors, makes it particularly difficult for educational researchers to sort out all these components. Anxiety has been variously conceptualized as an antecedent stimulus condition, a latent mediating process (e.g., as a probability of a harmful future outcome), and a response (physiological, affective, behavioral, etc.) to a stressful condition.

Since the early 1950s, the anxiety construct was dramatically advanced by a number of important conceptual distinctions, which helped refine thinking and research in the area. One useful distinction differentiates between anxiety as a relatively stable personality trait and as a more transitory state reaction to specific ego-threatening situations (Spielberger, 1972). Thus, trait anxiety refers to relatively stable individual differences in anxiety proneness, whereas state anxiety is a palpable, temporary reaction to a stressful event (e.g., final examinations) characterized by subjective feelings of tension, apprehension, nervousness, and worry, as well as by the activation or arousal of the nervous system. Whether or not students who differ in trait anxiety will show corresponding differences in state anxiety in the school or college setting depends on the extent to which each of them perceives a specific situation (e.g., college algebra examination) as psychologically threatening, and this is influenced, in turn, by each individual's constitution (e.g., numerical ability) and past experiences (e.g., number of mathematics courses taken).

Another important conceptual and methodological contribution to the evaluative anxiety literature is the distinction between facilitating and debilitating anxiety (Alpert and Haber, 1960). Accordingly, facilitating and debilitating anxiety, respectively, are claimed to lead to task-related and task-irrelevant behaviors during evaluative ego-threatening situations. A particularly useful conceptual distinction differentiates between worry and emotionality components of anxiety (Liebert and Morris,

1967). Worry, the cognitive component of anxiety, was viewed primarily as a cognitive concern about the consequences of failure on evaluative tasks (e.g., college aptitude examinations). By contrast, emotionality, the affective component of anxiety, was construed as perceptions of autonomic reactions evoked by stress. These two components are empirically distinct, though correlated, and worry relates more strongly to performance decrements than does emotionality.

Lazarus's transactional theory of stress and coping (Lazarus and Folkman, 1984; Lazarus, 1991) provides a contemporary and fundamental conceptual framework for the analysis of stress and anxiety in educational settings. According to this perspective, emotions, such as anxiety, reveals something of a person's goal hierarchy and belief system and how events in the immediate environment are appraised by the person. Thus, any evoked emotion reflects a high-level synthesis of several appraisals relating to the individual's adaptational status in the current environment. The core theme in anxiety is a danger or threat to ego or self-esteem, especially when a person is facing an uncertain, existential threat. Thus, the very presence of anxiety in an evaluative encounter is informative because it communicates that an existential threat has not been controlled very well, thus providing the researcher and educational specialists (counselors, school psychologists, etc.) with critical diagnostic information.

Evaluative Anxiety

A host of different types of anxiety may be relevant to specific educational settings (test anxiety, math anxiety, computer anxiety, social anxiety, etc.). These forms of anxiety are frequently encountered in education and share the prospect of personal evaluation in real or imagined social situations, particularly when a person perceives a low likelihood of obtaining satisfactory evaluations from others (Leitenberg, 1990). Next, we discuss two prevalent forms of evaluative anxiety in education – test and math/computer anxiety.

Test Anxiety

Test anxiety refers to the set of phenomenological, physiological, and behavioral responses that accompany concern about possible negative consequences or poor performance on an examination or a similar evaluative situation (Zeidner, 1998). Test-anxious behavior is typically evoked when a student believes that his/her intellectual, motivational, and social capabilities are taxed or exceeded by demands stemming from the test situation.

Test anxiety has taken on a variety of different meanings throughout its relatively brief history as a scientific construct. In the early days of research, the construct was

defined in motivational terms, either as drive level, goal interruption, or a need to avoid failure. Subsequently, it was conceptualized as a relatively stable personality disposition linked to cognitive–attentional phenomena. Accordingly, the highly anxious person is one who attends excessively to evaluative cues concerning personal competence, and to feelings of physiological arousal. Test anxiety may also be a concomitant of self-handicapping employed to preserve one's self-merit in the face of potential failure (Zeidner and Matthews, 2005). Cybernetic self-regulative models have seen test anxiety as resulting from a conflict between competing reference values (Zeidner, 2007).

Recent theorizing (Zeidner, 1998) emphasizes the distinction between test anxiety as an attribute of the person and as a dynamic process. From the first perspective, dispositional test anxiety may be construed as a contextualized personality trait. Accordingly, test anxiety refers to the individual's disposition to react with extensive worry, intrusive thoughts, mental disorganization, tension, and physiological arousal when exposed to evaluative contexts or situations. The more transient-state expressions of anxiety may be assessed separately from the more stable trait. From the second, process-oriented perspective, test anxiety depends on the reciprocal interaction of a number of distinct elements at play in the ongoing stressful encounter between a person and certain parameters of an evaluative situation. These elements include the specific educational context, individual differences in vulnerability (trait anxiety), threat perceptions, appraisals and reappraisals, state anxiety, coping patterns, and adaptive outcomes.

Math and Computer Anxieties

Both math and computer anxieties, respectively, are conceptually related to test anxiety through a common theme of concerns about evaluation (e.g., Rosen and Maguire, 1990). Math anxiety is defined by feelings of tension, helplessness, mental disorganization, and associated bodily symptoms that are evoked in mathematical problem-solving situations (Ashcraft, 2002). Math anxiety is claimed to interfere with the manipulation of numbers and the solving of complex mathematical problems in a wide variety of ordinary life and academic situations. Statistics anxiety, referring to the feeling of anxiety encountered when taking a statistics course or working on statistical analysis, has frequently been construed as a subset of math anxiety (Zeidner, 1991). Math anxiety, coupled with objective cognitive difficulties experienced in learning mathematics, may lead people to reject goals, such as scientific career choices, for which studying mathematics is instrumental.

Computer anxiety (sometimes termed computer phobia, technophobia, or cyberphobia) may be decomposed into anxiety about present or future interactions with computers or computer-related technologies; specific

negative cognitions or self-critical internal dialogs when interacting with the computer or when contemplating future computer interaction; and negative global attitudes about computers, their operation, or their societal impact (Weil *et al.*, 1990). The effects of computer anxiety on the utilization of computer-based technology may incur serious economic costs estimated at the level of billions of dollars per year (Bozionelos, 2001).

Math and computer anxieties may relate not just to the obvious stimulus attributes of mathematics/numbers and computers, but also to deeper personal concerns. Thus, math anxiety focuses not only on the evaluative nature of mathematics tests, but also concerns mathematical content (symbols, operators, etc.), its distinctive features as an intellectual activity (inductive and deductive reasoning, problem solving, etc.), and its meanings for many persons in our society (Richardson and Woolfolk, 1980). Similarly, computer anxiety is evoked by the consideration of the broader implications of computer use for perception of the self, society, and culture. Computer-anxious persons may also suffer from a more generalized technophobia, which itself is evident before adulthood (Weil *et al.*, 1990).

Similar to the state-trait distinction for test anxiety, trait math anxiety reflects relatively stable individual differences in the tendency to perceive situations involving the manipulation of numbers and the use of mathematical concepts and data as threatening or harmful. Persons high in trait math anxiety respond to these situations with elevations in state anxiety, involving both heightened emotion and interfering worry responses (Anton and Klisch, 1995). State math anxiety refers to elevations in worry, apprehension, and arousal in a situation involving mathematical content or reasoning. Likewise, in contrast to the dispositional nature of trait computer anxiety, state computer anxiety is aroused by specific objects (personal computer, scanner, printer, etc.) or situations (computer error). Individuals high in trait computer anxiety are especially vulnerable to state anxiety responses (Gaudron and Vignoli, 2002).

All forms of evaluative anxiety are quite common, with prevalence estimates in adults ranging from 20 to 50% for math and computer anxieties (e.g., Bozionelos, 2001). Experiencing various forms of evaluative anxiety in educational settings is a near-universal phenomenon across people differing in age, gender, and culture. Thus, meta-analyses of test anxiety data from various national sites show that although mean test anxiety levels vary to a certain extent across cultures, test anxiety is a prevalent and relatively homogenous cross-cultural phenomena. Furthermore, women tend to report higher levels of evaluative anxiety (test, math, and social) than men; however, the gender difference often does not translate into objective performance differences. In addition, as discussed below, evaluation anxiety has frequently been linked to performance decrements in educational settings.

Table 1 Tentative typology of test-anxious students

Type	Brief description
I. Students deficient in study and test-taking skills	Characterized by a major deficiency in study and test-taking skills. Their poor examination performance results from deficits that include problems in acquisition (encoding), organization/rehearsal (study skills), and retrieval/application during a test.
II. Students experiencing anxiety blockage and retrieval problems.	These students have efficient study skills but suffer from anxiety blockage, consequently encountering problems in retrieving information during the examination. These anxious students study effectively, but cannot handle the stresses and pressures of evaluative situations.
III. Failure-accepting students	Failure-accepting students are characterized by a personal history of repeated test failures. They come to accept low ability as the primary explanation of their failures. As a consequence, they become accepting of failure, exhibiting apathy, resignation, and a sense of defeat, not unlike reactions traditionally associated with learned helplessness.
IV. Failure-avoiding students	Failure-avoiding students are driven to achieve primarily as a means of protecting themselves against beliefs that they lack ability. For these students, effort is truly a double-edged sword. They may strive for success through meticulous preparation; yet, failure despite high efforts increases the probability that one's ability will be considered low, thus inducing anxiety reactions.
V. Self-handicappers	These students avoid diagnostic information about intellectual tasks by reducing effort or avoiding the test situation. Accordingly, if a low score is obtained, the self-handicapping student can rely on the debilitating effects of anxiety as an excuse to escape responsibility for actions, thus reducing otherwise burdensome expectations others hold for that person.
VI. Perfectionistic overstrivers	These overstriving perfectionists are characterized by high personal standards of academic success, perception of high or even exaggerated expectations, perceived doubt regarding the quality of academic performance, and a need for order and organization in their academic work. No effort is ever sufficient as the perfectionistic examinee seeks approval and acceptance and tries to avoid errors and failure through an endless cycle of self-defeating overstriving.

Discussions of evaluative anxiety in the literature are commonly guilty of a uniformity myth, conveying the impression that evaluative anxiety is a rather homogeneous category. In the domain of test anxiety research, Zeidner (1998) has sketched some distinct, yet potentially overlapping categories, of subjects with test anxiety (see **Table 1**). In fact, as this tentative typology of test-anxious students demonstrates, test anxiety has a variety of sources and, similarly, its behavioral consequences vary with contextual and personal factors.

Measurement and Assessment

We now briefly discuss a number of issues in anxiety assessment, focusing on subjective self-reports, which are by far the most popular observational procedure for mapping out the phenomenology of anxiety in educational settings.

Subjective Self-Report Measures

Subjective reports include any direct report by the person regarding his/her own anxiety experience and responses in a particular setting (learning mathematical operations, using new computer programs, taking examinations, engaging in social interactions, etc.). These assessments typically employ single-item rating scales (e.g., "Please indicate how anxious you were speaking before the entire

class, employing the following 7 point rating scale: 1 = not at all anxious, 7 = extremely anxious"); multi-item questionnaires (e.g., Spielberger's 20-item Test Anxiety Inventory, 1980); or oral interviews before, during, or after an important stressful event in the educational context.

Self-report instruments are now popular because they are considered to provide the most direct access to a person's subjective experiences in ego-threatening situations, possess good psychometric properties, are relatively inexpensive to produce, and are simple to administer and score (Zeidner, 1998). Self-report paper-and-pencil questionnaire measures of state anxiety ask individuals to report which of the relevant symptoms of anxiety they are currently experiencing in a particular situation, whereas trait measures ask subjects to report symptoms they typically or generally experience in a particular class of situations (e.g., public speaking, classroom examination, social interaction, and sports competition). Unfortunately, many studies use self-report data exclusively, without any attempt to measure salient behavior (e.g., through observational procedures), thus either under- or overestimating anxiety levels.

Rather fortunately, most popular anxiety inventories have satisfactory reliability coefficients, typically in the high 0.80s to low 0.90s. Among the factors influencing reliability are test length, test-retest interval, variability of scores, and variation within the test situation. However, at present, we have no infallible or perfectly objective criterion against which to validate anxiety scores. Scores

Table 2 Some alternative measures for assessing anxiety

<i>Type of assessment</i>	<i>Examples</i>
Physiological measures	Accretion levels of corticosteroids, adrenaline products, sugar, cholesterol, and free fatty acids.
Performance measures	Examination scores, semester grade point averages, and latency and errors in recall of stress-relevant stimulus materials.
Systematic observations of specific behaviors	Perspiration, excessive body movement, hand wringing, fidgety trunk movements, and inappropriate laughter when subjects were engaged in examination situations.
Trace measures	Amount of chewed traces on the pencil or ruler, sweat smudges on examination papers, and personal diaries.
Think-aloud procedures	Relating thoughts and emotions following or during stressful experience (e.g., "Please list as many thoughts and feelings as you can recall having during this algebra examination").

on ability tests, grade point average, observer ratings, behavior in structured evaluative situations, and the like have been employed as measures of criterion behaviors. A number of alternative measures of anxiety appear in Table 2.

Anxiety and Cognitive Performance

Scores of studies have investigated the complex pattern of the relations between anxiety and different kinds of performance. Various forms of evaluative anxiety (test, mathematics, computer, statistics, etc.) have been found to interfere with competence both in laboratory settings as well as in true-to-life test situations in school or collegiate settings. Processing deficits that relate to test anxiety, including general impairments of attention and working memory, together with more subtle performance changes, such as failure to organize semantic information effectively.

Hembree's (1998) meta-analytic study, based on 562 North American studies, demonstrated that test anxiety correlated negatively, though modestly, with a wide array of conventional measures of school achievement and ability at both high school and college levels. Data collected on students from upper elementary school level through high school show that test anxiety scores were significantly related to grades in various subjects, although the correlation was typically about -0.2 . Cognitive measures (i.e., aptitude and achievement measures combined) correlated more strongly with the worry than the emotionality component of test anxiety. Higher effect sizes were reported for low-rather than high-ability students and for tasks perceived as difficult rather than those perceived as being easy. Another meta-analysis reported by Ackerman and Heggestad (1997) showed a mean correlation of -0.33 between test anxiety and general intelligence test performance. Test anxiety was also correlated in the -0.20 to -0.30 range with other broad intellectual abilities including fluid and crystallized intelligence, learning and memory, visual perception, and mathematics ability.

There is a large literature on anxiety as a predictor of information processing in laboratory studies. The information-processing components sensitive to anxiety relate to input (encoding and acquisition of information), central processing (e.g., memory, language processing, conceptual organization, judgment, and decision-making), and output (e.g., information retrieval, response selection, and execution). These anxiety-related deficits, at various stages of processing, suggest some general impairment in attention and/or working memory. These various performance deficits are often attributed to high levels of worry and cognitive interference.

Both cognitive interference and cognitive bias appear to be pervasive in evaluative anxiety, influencing various stages of information processing (Eysenck, 1992). Anxiety often leads to scanning of the environment for threat (generating distractibility and attentional impairment), followed by focusing of attention on sources of threat (generating attentional bias). In addition, competence deficits may also be a consequence of poor skill acquisition. For example, deleterious effects of test anxiety may reflect not just cognitive interference, but also deficits in study habits and test-taking skills.

Behavioral avoidance generated in part by performance-avoidance goals plays a key role in the maintenance of evaluative anxiety and concomitant skill degradation. Evaluative anxiety leads to procrastination, motivated by fear of failure in learning specific subject matter or the aversiveness of the test situation or material. Procrastination, such as failure to complete homework assignments or study for the test, leads to failure to acquire the knowledge required. In turn, this lack of preparation leads to poor performance and anxiety in the test situation (Naveh-Benjamin, 1991), increasing subsequent test anxiety and avoidance of study.

Studies also identify moderator variables that accentuate or reduce deficits in performance. For example, negative feedback appears to be especially detrimental to anxious students, whereas providing reassurance and social support may eliminate the deficit. However, there have been sufficient instances of nonconfirmation of predicted deficits to suggest that high anxiety does not

automatically generate lower achievement outcomes. Generally, anxiety is more detrimental to attentionally demanding tasks, and may even facilitate performance on easy tasks. There may also be more subtle effects related to the qualitative nature of the task.

Interventions

A bewildering array of anxiety-treatment programs has been developed and evaluated over the past three decades. Current attempts to reduce debilitating levels of anxiety and enhance scholastic performance have typically focused either on treatments directed toward the emotional (affective) or cognitive (worry) facets of evaluative anxiety.

The emotionally oriented therapies primarily aim at reducing the arousal and heightened emotional reactions of anxious persons when faced with stressful evaluative situations. Based on the assumption that anxiety comprises a physiological component, attempts to alleviate anxiety symptoms should prove successful, in part, if they focus on reducing levels of arousal or on altering ways in which people appraise their arousal in evaluative situations.

In general, these emotion-focused treatments rely on key behavioral learning principles (counterconditioning, reciprocal inhibition, extinction, observational and coping skill learning, etc.) They also draw from an arsenal of behavioral techniques, such as deep muscle relaxation, guided imagery, and graduated hierarchies. For example, relaxation and guided imagery are not unique to a particular behavioral intervention method, but are employed in several methods, including relaxation as self-control, systematic desensitization, and anxiety management training. Procedures designed to reduce emotionality, while clearly useful in modifying subjectively experienced anxiety, by these methods, appear to have little effect on cognitive performance. Overall, emotion-focused treatments appear to be relatively ineffective in reducing evaluative anxiety unless these treatments contain cognitive elements.

Recent years have witnessed a proliferation of cognitively oriented intervention programs that emphasize the mediating role of cognitive processes in sustaining or eliminating anxiety. Cognitive therapy is a generic term that refers to a wide array of therapeutic approaches directed toward modifying the worry and irrational thought patterns of anxious clients. Broadly speaking, cognitively oriented approaches to anxiety intervention are quite similar in assuming that cognitive processes are determining factors in anxiety, although they differ in terms of actual intervention procedures. A fundamental assumption shared by contemporary cognitive models of test anxiety is that cognitive processes mediate the person's emotional and behavioral responses to stressful evaluative situations. It follows that to modify the negative emotional reactions of anxious clients to evaluative

situations, therapy needs to be directed at reshaping the faulty premises, assumptions, and negative attitudes underlying maladaptive cognitions of anxious subjects. A brief summary of key emotion-focused, cognitive-focused, and skill-focused treatment techniques and methods, and their reported effectiveness, is presented in **Table 3**.

The choice of which therapy to use will be influenced not only by the diagnosis of the specific nature of the client's problem and type of test anxiety, but also by the broader diagnostic picture, the immediate and long-term goals of treatment, and the therapeutic orientation adopted. For example: although relaxation may not increase the performance of test-anxious students with study-skill deficits, it may be prescribed by the school psychologist in order to help the student achieve the immediate goal of achieving control over test anxiety – as a first step toward academic problem solving. Thus, once the anxiety that interferes with learning new study skills is removed, the following step would be training the student in efficient study skills. Furthermore, there are different ways that a therapist may view his/her students' problem (distorted thinking styles, poor problem-solving skills, etc.) In addition, each of these views may give rise to different treatment procedures.

Summary and Conclusions

Anxiety is one of the most ubiquitous and researched emotions in education. Anxiety is a multifaceted construct, involving cognitive, affective, and behavioral components. Although different forms of anxiety discussed above are distinguished by the antecedent conditions and contexts evoking the anxiety (e.g., tests, and mathematics/computers), they have important structural similarities (worry and arousal) and are governed by similar cognitive and motivational processes (apprehension of being evaluated and fear of not meeting standards).

The nature of the anxiety–performance relationship is best viewed as reciprocal in nature. Thus, high levels of anxiety, accompanied by elevated levels of worry and cognitive interference, absorb part of the capacity needed for attention, working memory, problem solving, or other cognitive processes required for successful completion of a task. Evaluative anxiety also produces certain aversive patterns of motivation, coping, and task strategies that interfere with learning and performance. The result is that competence and self-efficacy suffers, thus leading to further anxiety over time and generating a vicious circle of increasing anxiety and degrading competence.

Overall, the assessment of anxiety in educational settings has not kept pace with the theoretical advances in conceptualizing the construct. Thus, much of the construct domain (e.g., task-irrelevant thinking, off-task thoughts, and poor academic self-concept) is underrepresented in current measures of anxiety. Stressful situations

Table 3 Some focal emotion-focused and cognitive-focused anxiety intervention techniques

<i>Treatment</i>	<i>Description</i>	<i>Effectiveness</i>
<i>I. Emotion-focused interventions</i>		
Biofeedback	Use of instrumentation (e.g., a physiograph) to provide a person with immediate and continuous information about one or more physiological processes (e.g., skin conductance, temperature, heart rate, blood volume pulse, respiration, and electromyograph). Biofeedback teaches highly test-anxious persons to monitor and modify the physiological processes associated with their emotional reactions.	A large body of literature supports the notion of increased physiological control when using physiological feedback and self-regulation. However, biofeedback alone is not effective in reducing anxiety (nor does the addition of biofeedback training improve the efficacy of other forms of treatment). Given the potential cost and inconvenience of using biofeedback training, it may not be the treatment of choice for anxiety intervention.
Relaxation training	Recommended on the premise that maintaining a relaxed state, via deep breathing and muscle relaxation exercises, would counteract a person's aroused state. Presumably, if a person knows when and how to apply relaxation, it will be applied directly as a counterresponse to anxiety.	Meta-analytic research tends to support the effectiveness of relaxation therapy. However, the effects on performance tend to be negligible.
Systematic desensitization	Situation-specific anxiety is viewed as a classically conditioned emotional reaction resulting from a person's aversive experiences in aversive situations. Systematic desensitization proposes that anxiety reactions to threatening situations may also be unlearned through specific counter-conditioning procedures. The anxious client is typically trained in a deep muscle relaxation procedure and, while relaxed, instructed to visualize an ordered series of increasingly stressful scenes (an anxiety hierarchy). The client imaginably proceeds up the hierarchy until he/she is able to visualize the most stressful scenes on the list without experiencing anxiety. Through repeated pairings of imaginal representations of threatening evaluative situations with deep relaxation, the bond between the threatening evaluative scenes and anxiety is expected to be weakened.	Meta-analytic data lend support to the effectiveness of systematic desensitization in reducing anxiety, particularly test anxiety, in school children and college students. It is shown to be as, if not more, effective in reducing test anxiety than a variety of other treatments, including relaxation training, hypnosis, and skills training. However, systematic desensitization fares less well when cognitive performance (e.g., academic achievement) is the criterion or when outcome is being assessed.
Anxiety management	Teaches highly anxious subjects to recognize their situation-specific related arousal responses as they are building, and then to use them as cues for initiating the coping response of relaxation in threatening situations.	A body of research supports the effectiveness of this technique in reducing anxiety. Thus, anxiety management training appears to be as, if not more, robust and effective than related interventions. Reductions in debilitating anxiety were maintained for follow-up periods ranging several weeks to months.
Modeling	Involves the live or symbolic (e.g., through videotape) demonstration of desired coping behaviors in a stressful situation such that they can be subsequently imitated by the anxious person. It is assumed that exposure to models displaying adaptive behavior may play a positive role in facilitating performance. Clients are instructed to vividly imagine the stressful evaluative scene and focus on the anxiety and associated response-produced cues (e.g., racing heart, neck and shoulder tensing, dryness of the mouth, and catastrophic thoughts). Clients are then trained to use these cues to prompt adaptive coping skills to actively relax away tension, and reduce anxiety before it mounts too severely.	A body of research lends support to the effectiveness of modeling in treating anxiety. In particular, exposure to models who are task oriented and provide attention-directing cognitive structuring clues is beneficial to the performance of anxious persons. Of additional benefit is evidence in the behavior of the model that he/she is successfully coping with the worry and tension associated with anxiety.

Continued

Table 3 Continued

<i>Treatment</i>	<i>Description</i>	<i>Effectiveness</i>
<i>II. Cognitive-focused interventions</i>		
Cognitive-attentional training	Cognitive attentional training provides specific training in the redirection of attention to task-focused thinking and emphasizes the inhibition of task-irrelevant thinking and nonproductive worry. The cognitive attentional approach relates performance decrements to the diversion of attention to self-focused thinking, coupled with the cognitive overload caused by the worry component of anxiety. By redirecting attention to the task and reducing worry and task-irrelevant thinking, cognitive resources are freed and, when redirected to the task, performance is improved. Attentional training programs traditionally provide clients with instructions to attend fully to the task and to inhibit self-relevant thinking while working on a variety of academic tasks.	The beneficial effects of attentional instruction on the anxiety and cognitive performance of highly anxious students is supported by some empirical research. Task instructions that provide examinees with information about appropriate problem-solving strategies, and away from self-preoccupied worry, may be particularly helpful to the anxious individual's cognitive functioning.
Cognitive restructuring	The rationale is that anxious persons will be able to master their anxiety by learning to control task-irrelevant cognitions that generate their anxiety and direct attention from their task-directed performance. The two most prominent cognitive therapeutic methods in test anxiety intervention are Rational Emotive Therapy and Systematic Rational Restructuring. Both forms of treatments are based on the premise that anxiety or emotional disturbance is a result of illogical or irrational thinking. Two key irrational beliefs that maintain anxiety are that one must succeed at all costs, and that success is equivalent to self-worth. Anxious individuals are taught how to recognize, vigorously challenge, question, and dispute their irrational beliefs, and replace their maladaptive internal dialog with more rational structures and beliefs. Presumably, by modifying irrational beliefs and schemas, negative emotional reactions will be reduced, and performance improved. Systematic Rational Restructuring aims at helping test-anxious clients to discover the worrisome task-irrelevant thoughts they entertain, to eclipse such thoughts, and to substitute positive self-statements that redirect their attention to the task at hand.	Research indicates that whereas cognitive restructuring reduces anxiety, there is no concomitant improvement in performance. A number of studies provide evidence showing that these techniques may be effective in reducing anxiety. However, concomitant improvements in cognitive performance are observed with far less consistency.
Cognitive Behavioral Modification	A multifaceted program merging both cognitively-focused and emotionally focused techniques (as well as skill training in many cases), thus offering the test-anxious client the best of many worlds, so to speak. This multimodal treatment attempts to deal with the multiple manifestations of anxiety, including negative motivational or affective tendencies, irrational thought patterns, and skills deficits, and emphasizes the application, and transferring of acquired coping skills to <i>in vivo</i> test situations. Given its dual emphasis on modifying both emotional processes and irrational thoughts and cognitions, this results in a powerful approach that merges emotionally oriented and cognitively oriented techniques to alleviate clients' anxiety and enhance their performance. This procedure is based on the premise that reducing a person's level of anxiety involves both anxiety-reduction training as well as detailed cognitive restructuring of certain faulty beliefs or misconceptions.	Multimodal treatment packages, such as cognitive-behavior modification, are most likely to be effective by their support for the inclusion of multiple domains related to anxiety. These procedures are relatively effective in reducing self-reported levels of debilitating anxiety, and are equally effective, more or less, in reducing both cognitive and affective components of anxiety. These procedures increase test performance, on average, by about half a standard deviation in school-aged samples, and elevate grade point average by close to three-quarters of a standard deviation.

would typically have effects on various response systems (i.e., verbal, physiological, and cognitive performance), and each measurement method possesses unique functions in anxiety assessment and is characterized by specific and unique limitations. It is desirable to obtain measures from a number of systems and triangulate any observed effects by means of converging operations.

Evaluative anxiety is more than a combination of physiological arousal, negative self-preoccupation, deficit in stress-related coping skills, and poor study habits. It is the complex interaction among these diverse components that seems to define anxiety. As the cognitive, affective, and behavioral components of anxiety interweave in contributing to the problem of evaluative anxiety and its treatment, it is predicted that an induced change in one system would generally be followed by a change in the other. Therapeutic approaches, which emphasize cognition, often extend to the emotional life too, and vice versa. For example, it is likely that emotion-focused training (e.g., progressive relaxation) may make the client less anxious and result in a decrease in anxiety-focused, task-irrelevant ideation. Similarly, some forms of cognitive therapy may provide anxious subjects with an increased sense of perceived control, which might spill over into the emotional domain and result in lower emotional arousal in an evaluative situation.

Anxiety assessments need to be understood within the context of a student's life and social milieu. Thus, understanding the results of a score on an anxiety measure requires an appreciation of the possible multiple and interactional influences on anxiety. These include the subject's past affective and academic history, and current social, emotional, vocational, and economic adjustments, as well as behavior during the examination. When a life history (no reported math anxiety in the past) is in disagreement with the results of a math anxiety scale, it is best to pause before making a diagnosis or decision on the basis of the anxiety scale alone, as the former is generally a more reliable criterion.

It is now readily apparent that interventions should be based on a careful theoretical analysis of the nature of evaluative anxiety and its key components and manifestations. Traditionally; however, interventions have mainly evolved from interest in specific behavioral treatment techniques rather than from an analysis of the nature and effects of anxiety. Indeed, most investigators who have applied behavioral methodology to the reduction of evaluative anxiety have generally paid little attention to relating the treatment process to important theoretical conceptions. The current diversity of treatments, while supplying the clinician with a rich variety of treatment

options to choose from in rendering services, also reflects a state of uncertainty marked by the lack of consensus regarding the most effective method for treating anxiety in educational settings.

Attribution Theory

B Weiner, University of California, Los Angeles, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

An amalgam of assumptions, beliefs, data, hypotheses, and theories related to phenomenal causality fall under the rubric of attribution theory. Hence, attribution theory refers to a field of inquiry rather than to a specific scientific conception. Inasmuch as the focus of study concerns inferences about the causes of events and outcomes, including achievement-related success and failure, and the consequences of these beliefs, the field of attribution is of central concern to educators. Indeed, a great deal of life in the classroom can be examined from an attribution perspective.

The origin of attribution thinking for psychology was Fritz Heider and his seminal book: *The Psychology of Interpersonal Relationships* (Heider, 1958). However, there had been a traditional philosophic interest in the study of causal reasoning and even prior to Heider a number of empirical studies were concerned with perceived causality (e.g., Michotte, 1946). Heider's contribution was relatively neglected prior to the influential attribution analyses offered by Jones and Davis (1965) and Kelley (1967). In addition to these contributions, the book *Attribution: Perceiving the Causes of Behavior* (Jones *et al.*, 1972) was also responsible for ushering in nearly two decades (1970–90) of attribution dominance in the field of social psychology. Attribution theory, often associated with naive psychology, replaced in impact the noncommon sense theory of cognitive dissonance, and subsequently was supplanted within social psychology by a focus on unconscious processes and priming. During and following its ascendance, attributional thinking penetrated other fields of study as well, including educational psychology.

This article presents aspects of attribution thinking that are of relevance to education, confining this discussion to the perceived causes of success and failure in achievement-related contexts. In so doing, a great deal of attribution-related literature is omitted, particularly from cognitive psychology pertaining to causal reasoning, from clinical psychology related to coping and mental health, and from social psychology concerning interpersonal attitudes and behavior.

The article proceeds as follows. Initially, the perceived causes of success and failure and their underlying properties or characteristics are considered. This is followed by a presentation of some antecedents of causal beliefs, and then a more extensive examination of their cognitive, emotional, and behavioral consequences.

The Perceived Causes of Success and Failure

Explanations may be based on reasons or causes, which need to be distinguished, although this differentiation is at times murky and fraught with philosophical intricacies (see Buss, 1978). If a student is asked why he or she enrolled in a particular course, he or she might call forth reasons such as: "I need it for my major" "I heard the teacher is great" "It meets at the perfect time;" and so forth. These explanations or justifications make the choice understandable and intelligible. In explaining everyday action, people typically call forth current reasons, which are associated with incentives (costs and benefits) and volitional choice (see Malle, 2004).

Attribution theory, on the other hand, is centered on causes. Causes are invoked to explain outcomes or end results, such as success and failure, rather than actions; they are antecedents instead of (in addition to) justifications and can apply to intended or unintended outcomes and to factors that may or may not be controllable. Failing in mathematics because of perceived poor aptitude is considered here to be an attribution, or a causal antecedent, rather than a reason, while enrolling in a class to be with a friend is a reason (incentive) and is not regarded a cause.

It must also be noted that not all outcomes elicit a search for understanding and causality, for this requires cognitive work. For example, if one succeeds at a simple puzzle in the newspaper, it is unlikely that time is taken to answer the question: "Why did I succeed?" On the other hand, unexpected failure at an important task is particularly likely to give rise to a search to identify the cause (see Gendolla and Kolle, 2001). Attribution analyses thus are subsumed within cognitive functionalism in that future successful actions often depend on perceiving the causes of past failures.

What, then, are the causal ascriptions for success and failure? First, it must be remembered that attribution theory is concerned with phenomenal causality, rather than seeking the true causes. Perceived causes vary as a function of situational context. For example, the perceived causes of success and failure at sports (e.g., strength, a windy day) differ from the causes of success and failure at math (e.g., math aptitude). Math outcomes may even elicit different dominant causal beliefs (e.g., aptitude) than do performance results at a history quiz (memorization effort). Causal beliefs also vary between age groups,

cultures, and depend on whether the causal target is the self or someone else.

The potential causes of achievement-related outcomes therefore are numerous, diverse, and often idiosyncratic – one must be wary of generalizations. Nonetheless, there is a set of causal beliefs that appears in many contexts. The most common causes of success and failure are aptitude, ability (or a learned skill), immediate and long-term effort, task characteristics (such as ease or difficulty), intrinsic motivation, teacher characteristics (such as competence), mood, and luck (see Weiner, 1985, 1986). Furthermore, within this delimited list, aptitude (which is presumed here to include ability) and effort dominate causal beliefs. Hence, one succeeded because one is smart and/or tried hard, and failed due to being incompetent and/or not exerting effort. At the very heart of the contribution of attribution theory to education is a conceptual analysis of the distinction between ability and effort and the contrasting linkages of these two causal beliefs to other cognitions, emotions, and actions.

Causal Properties

Inasmuch as causes are diverse and numerous, there have been attempts to identify their underlying properties or characteristics. For example, although it is evident that ability and effort are not the same, in what ways do they differ? Progress from description to classification allows causes to be compared and contrasted quantitatively, rather than merely indicating that they differ qualitatively.

Certainly three, perhaps four, causal dimensions have been isolated (see Weiner, 1985, 1986). One characteristic of causes is their locus, or location, within or outside of the actor. This causal property is most associated with Julian Rotter (1966), the originator of the concept referred to as locus of control. The locus label grew from research on skill-versus chance-determined tasks and is most associated with a scale used to classify individuals according to their beliefs regarding personal causality. Aptitude and effort are similar in locus, both being internal to the actor (although aptitude is likely to be regarded as more internal than effort), and differ from causes such as chance or task ease, which are regarded as located in the environment, or external to the actor.

A second property on which causes can be compared and contrasted is controllability. Aptitude, which is internal to the person, is not subject to volitional control and change, whereas effort expenditure is considered subject to personal control – it could be otherwise.

Endurance or stability is the third known property of causes. Some causes, such as aptitude, are viewed as stable over time, whereas others, such as chance, are not

enduring. Effort also is typically considered unstable, although recall attribution theory deals with phenomenal causality so that labeling another lazy, or industrious, implies stability in effort expenditure.

Yet, a fourth causal characteristic relates to the globality of the cause, or the extent to which the cause generalizes across situations. For example, it could be contended that perceived general intelligence exerts an influence over a wide array of academic outcomes, whereas perceptual reasoning ability has more limited application.

All causes, then, have multiple properties and can be classified within a taxonomic system. Aptitude, for example, is internal to the actor, stable, uncontrollable, and often considered global, whereas effort also is internal to the actor, but likely believed to be unstable, controllable, and specific. In a similar manner, chance tends to be perceived as external to the actor, unstable, uncontrollable, and specific. These groupings are important because causes that differ qualitatively (e.g., aptitude and chance) may share some consequences but differ on others. For example, failing in math because of perceived lack of aptitude or due to bad luck both capture the belief that “I could not do anything about it” and give rise to the results of uncontrollable thinking. On the other hand, these causes are linked to different expectations about the likelihood of future success because ability is stable whereas luck is unstable.

Causal Antecedents

Attributional accounts of the determinants of causal beliefs have been derived from an analysis of reasoning processes. The concepts most invoked are covariation, conditional probabilities, causal rules such as necessary and sufficient causality, and the like (see Kelley, 1967). Discussions also often consider prescriptive or correct reasoning, which is contrasted to the flawed conclusions reached by the person on the street. This body of knowledge, related to epistemology, has applicability in educational settings but is not discussed in this context.

More pertinent here is a consideration of some psychologically based antecedents that give rise to causal beliefs, particularly hedonic concerns. In addition, causal determinants that involve communications from teachers to their pupils also are of central importance in educational contexts. Finally, in the following section I consider impression management techniques that attempt to alter the causal beliefs of others.

Biases in Causal Reasoning

It has been repeatedly documented that individuals overestimate themselves on virtually all positive characteristics.

Just as 75% of the mothers believe that their children are in the upper 25% of the class, individuals regard themselves as smarter, more moral, better drivers, having more common sense, and so on, than others and compared to what they really are (see Dunning *et al.*, 2004). A similar conclusion can be reached regarding causal reasoning: individuals relatively believe that they caused their own success, whereas failure was due to outside forces. This phenomenon has been given various labels, including the self-serving attribution bias, ego-enhancement, and most prominently, the hedonic bias. It is to be expected, then, that children and their parents blame the teacher or the school for failure, while the teacher holds the child and/or his or her parents responsible. Disagreement and conflict regarding the causes of success and failure are normative.

Other biases have been hypothesized and have been very popular topics for attribution research. One considered determinant of causal beliefs is labeled the actor–observer perspective. It has been suggested that actors attribute their behavior to the situation, whereas observers ascribe an action to a characteristic of the actor. For example, if I hit someone it is because that other person provoked me (situational causality), whereas when someone else acts with aggression it is because that person is hostile. Associated with this discrepancy is a dispositional bias, or the fundamental attribution error, which is the tendency to underestimate the situational influence on the behavior of others and overestimate the importance of traits or perceived characteristics of the person.

These presumed tendencies, however, are now being called into question (see Malle, 2006). One factor undermining these hypotheses is the established hedonic bias. If individuals tend to take personal credit for success, then positive behaviors will not be ascribed by the actor to the situation. On the other hand, in situations of failure, both the hedonic bias and an actor–observer discrepancy go hand in hand, with over-attribution by the actor to the situation, relative to an observer.

Teacher Communications

Teachers may inadvertently communicate causal information to their pupils. This information can be conveyed through expressed emotions, praise and blame, and help giving.

As will be elaborated later, emotions are linked with causal beliefs. Anger following the failure of another tends to be elicited by controllable causes, such as lack of effort, whereas uncontrollable causality, such as lack of aptitude, elicits sympathy. Compare, for example, parental reactions to the failure of their child due to lack of studying as opposed to being caused by a mental handicap. Teachers who express anger following failure convey to the pupils that the failure was their fault and is changeable, whereas heightened sympathy, and particularly pity, conveys “it is

not your fault and nothing could have been done.” Thus, a positive or pro-social emotional expression could have negative behavioral consequences (see Graham, 1990).

In a similar manner, praise for success at an easy task, and the absence of reprimand for failure at such tasks, are cues that one has low ability. Furthermore, uncalled-for help may be a low-ability signal from a teacher. In sum, a variety of causal information regarding ability and effort has the teacher as its source.

Impression Management Techniques

It is intuitively evident that individuals do not want others to blame them for failure or untoward actions. To manipulate the causal beliefs of others, disparate impression management techniques are used. Four impression management strategies have been identified: denial, excuse, justification, and confession. In denial, the actor does not acknowledge a particular outcome (e.g., “I did not fail the test”; “I was not smoking”). This is a rather primitive technique, often used by younger children, for it can be readily disconfirmed if untrue.

A more common strategy is to provide an excuse to change causal beliefs (ex = from; cuse = cause). The actor attempts to shift the perceived controllable cause (e.g., lack of effort) to an uncontrollable one (e.g., the bus was late). In so doing, it is anticipated that blame and personal responsibility will be averted. Justification, a third identified impression management strategy, has a similar goal, although in this case allegiance to a higher moral goal is invoked (“I did not study because I had to take my father to the hospital”). Finally, confession of a misdeed is possible. In so doing, the wrongdoer acknowledges a bad behavior; however, confessing puts forth the impression that he or she is a good person who will not engage in the act in the future (“I did not study for the test; I am sorry and it will not happen again”).

Teachers and their pupils at times disagree on the acceptableness of various excuses and justifications. For example, pupils believe that their alarm failing to ring is a reasonable cause for missing an appointment, whereas teachers do not regard this as acceptable to promote forgiveness and lack of anger (see review in Weiner, 1995). It also is the case that some apparent excuses are truthful. However, an observer cannot conclude with any accuracy whether a student in fact missed the test because the bus was late, or had the flu, as opposed to being negligent.

Causal Consequences

Of particular relevance to educators are the consequences of causal thinking on the expectations, emotions, and behavior of pupils. These are addressed in turn.

Expectancy of Success

Motivation theorists have established that behavior is in part guided by future expectancy of success. Regardless of the intensity of a need, if the expectancy of goal attainment is low, then instrumental action directed toward that goal will not be undertaken. For example, regardless of how hungry one is, a restaurant known to be closed will not be a target of choice.

To a great extent, expectancy of future success in achievement contexts is determined by causal beliefs about the cause of prior failure. Stable or enduring causes give rise to the conviction that the future will be no different than the past. Hence, attributions of failure to lack of aptitude, an uncaring school environment, an absence of support, and so on promote expectancy of future failure. This lowers motivation and results in a tendency to leave that setting. On the other hand, ascription to changing factors provides hope that the future may differ from the past. Attribution to lack of effort, or to a teacher who is leaving, promotes positive expectations of the future inasmuch as the perceived causes of the prior failures are unstable or changing.

In an attribution-based change program designed to keep first-year college students from dropping out, it was merely communicated that grades increase the longer the student remains in school (Wilson and Linville, 1982). That is, over time, there is grade inflation. There was no attempt to change the study habits, attendance, note taking, or any other instrumental actions of the pupils. The data suggest the effectiveness of this program in improving school performance and decreasing dropout rates, presumably because expectation of success had increased.

Emotions

The appraisal approach to the understanding of emotion is based on the simple assumption that feelings are determined by thoughts, that is, thoughts are necessary and sufficient determinants of affective states. For example, negative self-related beliefs such as “I am a bad person” or “I am incompetent” are sufficient to promote negative feeling states and decrease personal esteem.

Causal beliefs have far-reaching emotional consequences, both in regard to the self and feelings about others. To understand the emotional lives of school children, it is essential to invoke causal ascriptions. Here, I present an overview of the implications of causal thinking for some feeling states (see Hareli and Weiner, 2002).

It has already been indicated that hope for the future and, similarly, the opposing feeling of hopelessness are guided by the perceived stability of a prior cause of failure. The other causal properties also have affective implications. Attribution of success to the self gives rise to pride in accomplishment and increments in self-esteem, whereas this is not the case for external causal

beliefs. Hence, ascriptions of success to ability or effort both promote pride and positive views of the self, whereas attribution to luck, or to help from others, does not contribute to these self-directed affects. Indeed, attribution of success to others fosters gratitude (if the help provided by the other was volitional). One consequence of the simultaneous influences of the hedonic bias as well as the desire to manage the thoughts of others is that public expressions of gratitude exceed private beliefs about the deservedness of this expression.

Perceived causal controllability, the third property of causes, has a complex relation to feeling states, with the linked affects dependent on the target of the emotion. Ascription of failure to a controllable cause such as lack of effort, given a desire to reach the goal, elicits guilt and regret. On the other hand, lack of aptitude as the cause of failure promotes humiliation and shame, which also involve social comparison with competent others.

These same attributions for the behavior of others, however, elicit a different set of emotions. If another failed due to controllable causes, then anger tends to be elicited. On the other hand, nonattainment of a goal due to uncontrollable causes tends to promote sympathy. Self- and other-related emotions are entangled within a complex interconnected system – communicated anger, if accepted, implies a controllable cause, which should promote guilt, whereas communicated pity implicates uncontrollable causality and promotes feelings of humiliation.

A number of other achievement-related affects also depend on causal thinking. Envy, for example, tends to be elicited by internal and uncontrollable causality for the success of others. One is envious of another’s intellectual capabilities, or beauty, but not of their hard work, since one can also work hard. Admiration, on the other hand, can be evoked by the effort as well as the ability of successful others.

Affect-related personality inferences also are linked to perceptions of the causal role of effort and ability. For example, if the success of another is perceived as due to ability, while the other communicates effort or external factors as the cause, then modesty is inferred. Modesty is a desirable inference associated with liking. On the other hand, if ability is conveyed as the cause of success, then arrogance is inferred, even if it is the true cause. If Einstein says “I am an Einstein,” he nonetheless will be regarded as arrogant, which is an unfavorable trait. Thus, school-based competence has some negative consequences in that others may be envious and perceive the capable person as arrogant. This is perhaps responsible for pejorative labels, such as nerds and geeks, which convey negative attitudes toward competence.

Behavior

Expectancy of future success, along with affective states, guides future action. That is, goal anticipations and

feelings bridge the gap between causal thinking and behavior. For example, assume that a student failed in an exam and ascribes that failure to lack of ability. Inasmuch as ability is a stable cause, expectancy of future success is low; and being an internal and uncontrollable cause, self-esteem decreases while shame and humiliation are experienced. Low expectancy of success, low self-esteem, and humiliation are motivational inhibitors that contribute to a decision to leave the setting.

On the other hand, lack of effort is an unstable, controllable cause, so that attribution to this factor maintains hope and positive anticipations, while arousing guilt, which is a motivator to make amends for the past. Thus, an attribution of failure to lack of effort tends to be adaptive and functional.

Along with the attributions, emotions, and behaviors of actors, this same sequence also describes observers of the actor. An observer making attributions of failure of another to lack of ability tends to experience sympathy, which promotes help-giving. On the other hand, ascriptions to lack of effort evoke anger and an antisocial reaction (see Weiner, 1995, 2006).

As the attributions of ability versus effort are linked with disparate reactions, attribution-change programs have focused on having students make insufficient effort rather than low-ability ascriptions in situations of failure (see Perry *et al.*, 1993). These programs vary but often provide models in film clips portraying adaptive attribution patterns. The attribution interventions have proved successful and provide promising tools to improve school-related performance.

Some Concluding Comments

Attribution theory was developed and nurtured by social psychologists. However, the centrality of thoughts about causality in everyday life transported this body of knowledge to other fields of study. For education, attributional analyses provided a ready fit inasmuch as parents, pupils, and teachers focus so much attention on evaluation and the causes of good and poor performance.

Two broad questions emerge from this approach: How does one know or determine one's level of ability, the adequacy of effort expenditure, and the like? Thus, existential questions, such as "Who am I?" (as well as, "Who are you?"), are addressed. In this article, three inferential sources were pointed out: biases that enhance the self, communications from teachers, and impression management techniques used by others.

The second extended question asked is: "So what? What difference does it make if success or failure was caused by low ability, as opposed to lack of effort?" These questions point out the functional and motivational significance of causal thinking. Here, the classification of

causes into fundamental properties was introduced. These underlying characteristics were shown to influence expectancy of success, emotional reactions, and personality inferences. Of special note is the array of affects linked to causal thinking: admiration, anger, envy, guilt, gratitude, hope, hopelessness, pity, pride, regret, self-esteem, shame, and sympathy were mentioned, and this is not the full list of causally linked feelings.

Expectancy and affect, in turn, are two key mediators of achievement-related behavior. Thus, increased school motivation and decreased school dropouts can be affected by alteration of perceived causality. In sum, the study of education processes is intimately linked with attributional analyses.

Children's Friendship

S R Asher, Duke University, Durham, NC, USA

Friendship is a close dyadic relationship characterized by a shared history, mutual affection, and a recognition by both participants that the relationship has a special status, which sets it apart from mere acquaintanceship or colleagueship. Friendship carries with it certain expectations, such as companionship, cooperation, instrumental help, loyalty (reliable alliance), confiding, and emotional support. Furthermore, friendships tend to be characterized by relatively equal power between relationship partners, especially compared to the parent-child relationship. For most people, a close friendship is their first nonfamilial intimate relationship that is freely chosen. A comparison between friendships and sibling relationships is also instructive. When siblings argue or have a falling out, they continue to be siblings even if they do not engage in relationship repair. On the other hand, as friendships are typically voluntary, friends need to work at maintaining the relationship or they risk the friend withdrawing from the relationship.

Although being a friend inevitably carries expectations, these expectations differ somewhat as a function of age. When interviewed or surveyed, young children report friendship expectations that center on play and companionship. In middle childhood, there is an increased emphasis on sharing, cooperation, and helpfulness, and in adolescence young people report greater expectations for intimacy, shared confidences, and emotional support. However, interviews and surveys may underestimate the richness of even young children's friendships. When children as young as 3 years of age are observed playing with their best friend, many examples arise of children cooperating with one another, providing emotional support, and sharing confidences. The fact that some of these processes occur within the context of fantasy play adds to their charm but does not detract from the evidence that even young children can display more developmentally advanced friendship processes.

Characteristics of friendships may differ to some degree as a function of gender. Girls and boys do not differ in their reports of how much companionship or conflict they have in their friendships; however, girls do report more help and guidance, emotional support, intimacy, and ease of conflict resolution. Yet boys and girls do not differ in the number of close friends they have in their class, their satisfaction with their friendships, or their loneliness in school, suggesting that we need to more extensively observe the friendships of boys, in order to better understand interaction processes in their friendships.

Characteristics of friendships also vary across cultures. In many cases, friendships are voluntary relationships that children choose to form and can terminate if they wish. However, in some cultures, friendships may become formalized relationships that are unbreakable, such as ceremonial friendships or 'blood brotherhoods.' In addition, the expectations held of friends and the importance placed on certain features of friendships can vary widely from culture to culture. For example, Indonesian children describe instrumental aid as a more central feature of their friendships than do American children, whereas American children describe enhancement of worth, companionship, and reliable alliance as being more important in their friendships than do Indonesian children.

Measuring Friendship in School and Distinguishing Friendship from Peer Acceptance

There is a long tradition extending back to the late 1920s of using sociometric measures, or measures of interpersonal attraction, to identify classroom friendships. Typically children are asked to name their best friends in their class or grade. Researchers can ask children for a limited number of nominations (e.g., their best three friends) or can use an unlimited nomination measure in which children can name all their friends in their class or in their grade. Several improvements have taken place in sociometric friendship assessment over the years. First, children are typically given a roster with names of schoolmates to circle rather than relying on children's ability to recall and write down their classmates' first and last names. Second, for young children, photographs of schoolmates are used instead of a class roster, again to overcome literacy or memory constraints. Third, researchers have distinguished between unilateral and reciprocal nominations, and most typically define a friendship as existing when two children mutually nominate one another as opposed to one child nominating the other but the other failing to reciprocate the nomination. With this methodology, children can be assigned a score based on the number of reciprocated friendship nominations they have.

Note that the number of friends that children have does not speak to the stability or the more qualitative features of their friendships. To measure the stability of a friendship, repeated sociometric surveys are needed to learn whether friendships are maintained. Furthermore, to learn about

the qualitative features of friendships (e.g., levels of companionship, emotional support, or conflict), children can be observed or interviewed about their friendships. Research on stability and qualitative features of friendship indicates that these are extremely important dimensions. For example, children who have more stable friendships and higher-quality friendships are less lonely at school.

Furthermore, it is also important to distinguish children's participation in friendships from their overall acceptance by the peer group. Peer acceptance refers to how well a child is liked by the group as a whole. Peer acceptance is typically measured in one of two ways. One approach is to ask children to nominate three children in their class or grade they like the most and three children they like the least. Researchers then typically calculate a social preference score, which is the number of liked least nominations subtracted from the number of liked most nominations a child receives. This score can be standardized by grade or class and can also be standardized within gender. Alternatively, children can be asked to complete a sociometric rating-scale measure of acceptance in which they rate each of their classmates or grademates on a Likert scale in terms of how much they like each person, or how much they like to play or work with each person. With this measure, acceptance scores are the average ratings received by peers, typically standardized within classroom or grade and gender.

Research using a rating-scale measure of acceptance and mutual friendship nominations to index friendship indicates that children can be well-liked by their peers but not have close friendships at school. Likewise, children can be generally disliked by classmates but still have one or more friends (subgroups of highly aggressive children are likely to be in this situation). Overall, the correlation between the number of mutual friends children have and their acceptance by peers is approximately 0.50, suggesting that there is unique variance associated with each index of peer adjustment. Evidence in support of the friendship-acceptance distinction comes from several lines of inquiry. First, having friends and being liked by peers make distinct contributions to children's early school adjustment. Second, having friends and being accepted by peers independently predict to feelings of loneliness at school and to whether or not children are victimized by peers. Third, children are less likely to form friendships with peers of a different race than they are to like or accept them. Finally, social skills intervention studies have repeatedly found that children can make gains in peer acceptance yet not make gains in their number of good friends.

In the section that follows, the focus is on the effects of friendship on school adjustment; however, several of the supplementary readings may be useful for readers interested in learning more about acceptance and school adjustment.

The Effects of Friendship on School Adjustment

Children's friendships provide validation, emotional support, a context for self-disclosure, companionship, help and guidance, and reliable alliance. These provisions in turn serve protective functions in children's lives at school. Indeed, children with friendship difficulties are at risk for a variety of social-emotional adjustment problems in school, including increased social anxiety, lower self-esteem, and increased likelihood of loneliness and depression. One reason that children lacking friends may feel worse than children with friends is that having friends can protect children from being victimized by peers. Children with friends at school are less likely to be victimized, especially when their friends are strong and protective.

It should be noted, however, that the benefits of friendship may be moderated by friendship quality and stability. Having friendships that are high in positive qualities and that are relatively stable is associated with increases in self-esteem over time for children; however, if friendships are high in negative qualities, this is less likely to be the case. Further, if children are in friendships in which their friend is treating them badly, it can be particularly distressing. When friends interact in negative or hostile ways with one another, children show increases in internalizing problems such as anxiety, social avoidance, and loneliness.

One of the compelling findings about friendship and school adjustment is that children who are not nominated by any of their peers as being a friend are much more likely to drop out of school years later. Undoubtedly, having friends is part of the glue that keeps children connected to school. The academic benefits of friendship are evident as early as in the first years of school. Kindergarten children who enter school with friends or who make friends during the school year are better adjusted to school (on indexes such as attitudes toward school, school anxiety, and absenteeism) at the end of the year than children who do not.

Here, too, the association of friendship with school-adjustment may be moderated by the quality of a child's friendship. For example, kindergartners who report receiving help from a friend increase in their liking for school more than those children who did not receive help from a friend. Further, children who report more positive qualities in their friendships also report being more involved in class and feeling more accepted by peers. Conversely, having friendships that are high in unresolved conflict is predictive of being more disruptive in class and being less involved in school.

The characteristics of a child's friends may also affect the child's academic success and achievement motivation. The academic performance of a child's friends is associated with the later academic performance of the child. For instance, if a child's close friends get higher

grades then the child is more likely to improve, but if a child's close friends perform poorly, then his or her performance is also likely to suffer. This influence may occur through a variety of processes, such as tangible help (or lack thereof) that friends provide each other, discussions about schoolwork, or through increasingly similar beliefs and attributions about academic achievement and the causes of academic success and failure. It is also important to note that even though being friends with children who are high achievers may increase a child's academic performance, this friendship may also increase the child's negative self-evaluations due to social comparison between the self and the friend.

Just as friends influence the achievement orientation of one another, they also influence children's tendencies to be prosocial or antisocial in their behavioral orientations in school. Children who affiliate with antisocial peers are more likely to engage in antisocial behavior themselves. Antisocial children positively reinforce each other for antisocial behavior even in their conversations about previous delinquent behavior. Since high levels of antisocial behavior are predictive of school dropout, friends who engage in 'deviancy training' with one another are, in effect, contributing to one another's eventual withdrawal or suspension from school.

As children move into adolescence, their friendships are embedded in cliques and larger groups called crowds (e.g., athletes, academic nerds, populars, and druggies). Children within cliques and crowds have shared interests in particular activities and also frequently share beliefs about the value of school achievements. Schools, too, can differ markedly in the extent to which the peer group values achievement. Accordingly, cliques, crowds, and overall peer culture at schools make their own independent contribution to school adjustment.

The Social Tasks of Friendship

Since acceptance by peers and participation in friendship are positively correlated, many of the interpersonal skills related to getting along with peers are also related to being able to make and maintain friendships. In general, it benefits children to be prosocial (i.e., friendly, cooperative, kind, and helpful), to be competent academically and athletically, and to have a good sense of humor. Nonetheless, friendship is a rich and complex context that poses specific kinds of challenges for children that go beyond the social tasks involved in maintaining harmonious relationships with the group as a whole. The friendship tasks that children face include forming a friendship (which means moving a relationship beyond an acquaintanceship or colleagueship), managing conflict and responding to friendship transgressions, providing help and reliable alliance, and self-disclosure.

Forming Friendships

At the core of friendship is companionship, recreation, shared activities, and having fun together. Children who are good at generating enjoyable activities, are good at games and sports, knowledgeable about peer culture, have a good sense of humor, and interact with a spirit of fairness are more likely to be enjoyable play partners.

Forming friendships often calls upon children to initiate interactions and a relationship with another child. This task involves being able to approach another child in a positive manner, to be able to initiate conversation, and/or suggest a joint activity. Part of the social task of initiating interaction is coping with the task of group entry. Children in school contexts are faced with the continuing problem of how to get access to a group of children who are playing together. Children who are skillful at taking the perspective of other group members and thereby gently easing their way into the ongoing interaction are generally more successful than children who more egocentrically attempt to plow ahead and disrupt the ongoing activity. Successful initiations of interactions also involve being responsive to others' initiations. Children who respond warmly and positively to others' initiation attempts are more likely to be sought out to play by peers. Even in infancy and toddlerhood there are large individual differences in how children respond to the initiations of others.

In the early childhood years, parents are likely to play a more active role in initiating contact with other children outside of the school context. For example, they may arrange a play date at home or at a local park. Indeed, parents who are skillful planners of their children's social world and engage in indirect, nonintrusive but competent monitoring of children's play, have children who are more successful at making friends. As children grow older, however, initiating play dates becomes more of their responsibility, although parents maintain an important role by providing transportation or enrolling children in programs such as youth sports, church groups, or dance classes. Neighborhood characteristics also play important roles. For example, where heavy concentrations of children live in close proximity, less scaffolding by parents is required. Furthermore, environmental features such as access to neighborhood parks, public transportation, and safe bike routes affect the extent to which children can initiate their own friendship contacts.

It should also be noted that friendship formation between children is facilitated by physical propinquity. When children are asked to name their 'best friends in the world,' a high proportion of the children named are actually in their classroom or neighborhood. Physical propinquity is a powerful force in children's friendships, much the same as in adults' friendships. With regard to similarity, the role of demographic characteristics is not to be underestimated. For example, the great majority of

elementary-school-age children's friendships is with children of the same gender. Likewise, children tend to form friendships with children of their own race and social class. Similar interests and activities (a shared interest in sports, video games, music, etc.) are also bases for friendship formation. Indeed, children whose interests are highly discrepant from the interests of the mainstream peer group may have difficulty forming friendships within that group. In relation to this, one important role that parents play in their children's social lives is fostering interests in their children that help them connect with other children and thereby form friendships.

Beyond initiation, children need to be able to sustain interaction with peers to form friendships. Even in the preschool years, children can be observed engaging in extended play bouts, often in the context of shared fantasy (e.g., playing firefighters or playing house). For play to continue harmoniously as children grow, they need to develop increased communication skills, such as listening well to their partner, communicating in a contingent way (such that their utterances relate in a meaningful and relevant way to those of their partner), and amicably resolving disagreements.

Managing Conflict and Responding to Friendship Transgressions

Children can be successful at initiating friendships but are still not successful at maintaining friendships. Conflicts are virtually inevitable in friendships and friendships often rise or fall based on how well the parties resolve disputes when they arise. Responding to conflict is particularly challenging for some children and there are large individual differences in the goals and the behavioral strategies that children enact in conflict situations. Children who focus on maintaining a good relationship with their partner and who engage in cooperative and compromising strategies are more successful in their friendship than those who focus exclusively on getting their way. Further, children who are vengeful in conflict-of-interest situations with friends have fewer friendships and, if they do have a friend, their friendships are of lower quality. Indeed, children's goals and strategies in conflict situations predict success at friendship even when statistically controlling for children's levels of peer acceptance. Here, again, adults (both as parents and teachers) can play a valuable role by helping to mediate disputes or, better still, by teaching children conflict-resolution strategies.

Just as conflicts are virtually inevitable in friendship, it is not possible for friendships to extend over time without incidents of minor, or even major, friendship transgressions. As discussed above, friendship carries expectations for companionship, cooperation, instrumental help, loyalty, confiding, and emotional support. These expectations, usually strongly held, mean that children are vulnerable to feeling

sad, hurt, or angry when a friend violates a core expectation of friendship. Examples of transgressions include friends canceling play dates, preferring to be with another friend on a particular day, refusing to provide help when help is needed, or sharing a secret with others. When transgressions occur, children make inferences about the meaning behind the action of the friend. A fundamental question is whether the friend meant to cause harm or simply had other needs, goals, or external pressures that were temporarily interfering with the ability to be a good friend. Children who attribute hostile intent or infer that the other person's actions are a sign of lack of caring, rejection, or disregard are far more likely to want to get even or terminate the relationship. As part of this reaction they are also more likely to engage in negative behavior, including physical, verbal, and relational aggression (intended harm through the damage of another person's relationships or social standing).

Friendships are embedded in the larger peer network of cliques and crowds. Knowing how to effectively manage dyadic relationships in this larger peer context may be particularly challenging for some children. For instance, friends have other friends and if children have high expectations of exclusivity in their friendships they may become jealous. Jealousy is a cognitive, emotional, and behavioral reaction set off by the perception that one's partner prefers a relationship with someone else. Young adolescents who are more jealous in their friendships report lower self-worth and more loneliness. The jealous child conceives of friends having other friends as a friendship transgression rather than an expected part of social life.

Providing Help and Reliable Alliance

As children move into the primary school years, there is an increasing expectation that friends will provide help, guidance, and tangible forms of assistance. This can range from small things such as loaning a friend a pencil in class to larger tasks such as helping a friend with homework or a chore. It also involves providing advice and/or emotional support when a friend is coping with familial, school, or peer relationship difficulties.

Help-giving requires special cognitive and social skills. As in the task of group entry, perspective taking plays a key role. In addition, children need effective communication skills to elicit important information before offering advice. They also need a broad knowledge base of effective solutions to problems that can arise in everyday life. Further, when no easy solution is in sight, friends can help by distracting a child by providing reliable and enjoyable companionship.

Friends also help each other by serving as reliable allies. Friends count on each other, stand up for each other in threatening (e.g., bullying) situations, and have each other's best interests at heart. Having both emotional

and instrumental support from friends can increase children's sense of belonging in school, protect children from stress, and foster a sense of security which in turn facilitates the self-disclosure that occurs when friends confide in one another.

Self-Disclosure

Self-disclosure, or the sharing of personal information with another person, is a central feature of many friendships, particularly in adolescence. This is consistent with a major concern that arises at this stage of development, namely self-exploration and the development of identity. Sharing high levels of intimate information can be risky unless the friend can be relied upon to treat information as confidential and not share it with others. Through reciprocated self-disclosure, children form a sense of emotional closeness and acquire extensive knowledge about one another. Part of a shared history of a friendship is not just the activities or events that friends share together but the detailed and intimate knowledge they have of the other person. As a result, friends know far more about one another than do nonfriends.

One interesting complexity about self-disclosure deserves comment. Although friendships that are high in self-disclosure are more likely to be close friendships, co-ruminating with friends, or excessively discussing problems and focusing on the negative feelings associated with those problems, may have negative emotional consequences for children and adolescents, especially girls. To illustrate, although co-rumination is associated with higher-quality friendships for boys and girls, it is also associated with higher levels of anxiety and depression for girls.

Interventions to Promote Friendships

Given the powerful role of friendship in children's social-emotional and academic adjustment, effective intervention methods are needed for helping children who lack friends and for children whose friendships are of lower quality. Interventions to promote friendship have taken various forms although, on the whole, far more research is needed. Evidence exists that placing children in cooperative work groups can lead children to form friendships across racial lines, although the long-term maintenance of newly formed friendships has not been investigated. There is also evidence that children who lack friends can make a friend when put in a school context where they get to interact with classmates during a pleasurable activity (e.g., planning for and putting on a skit for the class). However, in this case, follow-up assessments suggest that the positive friendship outcomes of this type of intervention do not endure once the activity has ended. This evidence, along with other research indicating that children who lack friends are less socially skilled, suggests

that providing opportunities for enjoyable interaction may not be sufficient and that instead some form of social relationship skill learning opportunities is needed.

Interestingly, several social skills training studies carried out with 8- to 10-year-old children in elementary schools have found that teaching certain social relationship concepts leads to significant gains in overall acceptance by peers, but not necessarily gains in best friendship. In these studies, children were taught core concepts of social interaction (e.g., staying involved in the game or activity, cooperating, and being friendly and supportive) and given opportunities to try out the ideas by playing a game or doing an activity with a peer. Following these interactions, the child was given the opportunity to reflect further on the concepts in light of his or her immediately preceding peer interaction experiences. A potential next step for educational researchers could be to learn whether this kind of direct instruction approach for promoting social competence could be successfully adapted to help children develop friendships and to achieve friendships that have positive qualities. Such research is certainly needed given the important role that friendship plays in children's academic success and emotional well-being.

Coping with Stressful Situations: An Important Aspect of Self-Regulation

M Boekaerts, Leiden University, Leiden, The Netherlands

© 2010 Elsevier Ltd. All rights reserved.

Coping with stressful situations includes coping with difficulties, obstacles, impediments, failure, shortcomings, impairments, handicaps, and liabilities. Several attempts have been made to classify the stressors that children and adolescents encounter in daily life. A distinction was made between acute and chronic stimuli that exert a taxing demand on the individual and require an adaptive response (Compas, 1987). Acute demands are caused by cumulative life events (e.g., parental divorce) and specific events, such as irritating, frustrating, and anxiety-provoking situations that occur in the classroom, at home, and on the way to school. These new demands may disrupt ongoing and upcoming activities, because the youngster must meet a sudden stream of threats and challenges. A successful attempt to cope with the acute source of stress signifies that a bridge has been built between the stressor and the existing coping repertoire. By contrast, several unsuccessful coping attempts may turn a situation into a chronic stressor.

Chronic stressors refer to recurring stressful life events that cause aversive conditions in the home (such as poverty, maternal depression, sibling rivalry) or the school environment (suboptimal learning conditions, teacher harassment, peer rejection, and feelings of academic inadequacy). Specific personal conditions may also create an enduring handicap or liability for the student, such as suffering from a chronic disease, physical handicaps, or learning problems.

Several questionnaires have been constructed to explore the major life events and daily hassles that students encounter in a school context. The data collected revealed that school stressors can be divided into social conflicts (e.g., unpleasant social exposure: rejection, bullying, harassment, and jealousy) and academic stressors (e.g., failures, overloads, exam stress). Both acute and chronic stressors impact on students' functioning, but the degree of the impact depends on the students' interpretation of the stressor and the coping strategies that they can bring to bear on the stressor. Research has described various adverse outcomes that are associated with lack of effective coping strategies, including several types of psychosomatic complaints (e.g., insomnia, headache, tummy ache, nervousness, feeling dizzy, and low back pain), absenteeism, fatigue, drop-out, and maladaptive social behavior. Interventions have been designed to help teachers and educators coach students' coping attempts. Before discussing some of these interventions, some the components of the coping process are discussed.

What Does Coping with Problematic Situations Entail?

When under stress, students report that their ongoing behavior is interrupted suddenly. They experience increased levels of arousal. Often they report negative emotions, such as anxiety, irritation, disappointment, shame, guilt, and sadness. They also report intrusive, repetitive thoughts about the event that caused the stress, and about the possible consequences of not being able to reduce the threat. They might inform about bodily changes as well, such as increased heart rate and perspiration, and about behavioral changes (e.g., aggressive or passive behavior).

It is important to realize that stress does not lie in the problematic situation itself. Rather, it concerns the way a potential stressor is interpreted. Each person comes to a stressful situation with either direct or vicarious experiences with the stressor. These prior experiences are activated at the time the stressor occurs and form a sort of internal context to interpret the problematic situation. At the same time, the person perceives and interprets the situation in which the stressor is currently embedded (external context). The significance that youngsters attach to a stressor and the way they interpret it depends on both the internal and external context.

An interesting question that was raised in this respect is: what is effective coping and which external and internal conditions promote (in)adequate coping? Questions such as these will never find a definite answer, because no solution is valid for all individuals at all times. An answer that sounds plausible is that personal functioning, development, and well-being are rooted in personal resources (e.g., self-efficacy, competence, resilience) and contextual affordances that facilitate the pursuit of one's salient goals and helps one to be resistant to life stressors and daily impediment.

Later in this article, some interesting issues about the effect of socialization and context on the development of (mal)adaptive forms of coping are discussed. For now, it is sufficient to understand that there are several conditions that should be met for a youngster to cope adaptively with classroom stress. In the first place, students should be able to appraise a problematic situation and determine whether that situation is changeable and controllable. Two other important conditions that should be met have to do with the selection of adequate coping strategies.

On the one hand, students need to regulate their emotional arousal. On the other hand, they should come up with a solution that produces a sense of mastery (Compas *et al.*, 1999). These important conditions are addressed next.

Appraising a Problematic Situation

Lazarus and Folkman (1984), the founders of transactional stress theory, view stress as the transaction between a person and the environment. They defined stress in terms of the individual's appraisal of the situation. More specifically, Lazarus and Folkman argued that any new, unexpected situation triggers a primary and a secondary appraisal. The primary appraisal determines how significant the situation is for well-being. Is it benign, threatening, or harmful? Does it harbor a loss of some kind? Situations are appraised as problematic when individuals detect a discrepancy between the perceived task demands and their own resources to meet these demands. Secondary appraisal determines the degree of the threat, challenge, harm, or loss. More specifically, the person assesses whether his or her coping resources are sufficient to deal with the situation. The degree of stress that is experienced depends on the balance achieved between primary and secondary appraisal processes.

Perrez and Reicherts (1992) proposed a way to explore the mental representation that a person makes of the stressor. They described five objective characteristics that individuals use to describe and categorize a stressful situation. These are: valence (how stressful or intense is the situation?), re-occurrence (will the situation re-occur in the future?), changeability (will the stressor go away by itself, without any actions being undertaken?), controllability (do I have control over the situation), and ambiguity (is there sufficient information to interpret the situation?).

Selecting a Coping Strategy

Based on their mental representation of the stressor, students select one or more coping strategies from their repertoire. What types of coping strategies can they select from? Lazarus and Folkman (1984) proposed a basic dichotomy between problem-focused and emotion-focused coping strategies. The former refers to efforts to change the situation by acting on the source of stress (e.g., work harder, problem solving). Emotion-focused coping refers to efforts to reduce the emotional distress by moving away from the source of stress either mentally or actually (e.g., denial, distraction). Other researchers described two slightly different universal ways of dealing with stressors, such as approach versus avoidance; active versus passive forms of coping; and primary versus secondary control coping strategies. They all argued that individuals tend to use habitual and preferential ways of dealing with specific types of

stressors, but that there is no way of telling which coping mode is most effective for a specific stressor. It is almost impossible to make any comments on the effectiveness of a person's coping strategies without knowledge of his or her coping goal. This issue is discussed further, later in the article.

Stress researchers working in educational psychology have used an empirical approach; they factor-analyzed the different coping strategies that students report using. The literature can roughly be divided into how students cope with unspecified stressors and with specific daily hassles. One of the most valid coping questionnaires is that of Frydenberg (2004). Frydenberg and her colleagues reported that 18 coping strategies are commonly used by adolescents, namely seek social support, social action (join people with the same concerns), seek to belong (improve relationships), invest in close friends, wishful thinking, worry, work hard, keep to oneself, seek relaxing diversions, physical recreation, focus on the positive, ignore the problem, tension reduction, seek professional help, spiritual support, self-blame, and not coping. Summarizing the results of several studies, Frydenberg reported age and gender differences. The younger students in her samples (11–13 years of age) reported more hard-work strategies and less self-blame and tension-reduction strategies than did the older students (15–16 years). Girls tended to address problems immediately and used more social support seeking, wishful thinking, and tension releasing than did boys. Boys adopted a wait and see strategy, preferring to manage by themselves rather than seek social support.

Bridging the Gap between New Stressors and One's Coping Repertoire

Children and adolescents are in a period of cognitive, emotional, physical, and social development. It is clear that situations that they consider problematic at one point in time may not be problematic a few weeks or months later. For example, at major transition periods (e.g., changing body image, changing schools) most youngsters appraise their daily life as chaotic and problematic. They cannot form an adequate mental representation of the new situation and find it difficult to deal adequately with the stressor. Often, they characterize the stressor as highly significant, re-occurring, unchangeable, uncontrollable, and ambiguous (e.g., I cannot find my way in the new school; I do not know the rules). Although such transitions are part of normal development, prior experiences of uncertainty and insecurity may be activated at the time the stressor occurs, thus forming an unfavorable internal context to interpret the new situation. At the same time, the student may perceive and interpret the actual situation in which the stressor is currently embedded as suboptimal (e.g., I do not have any friends here).

Fortunately, most students will pass these transitions smoothly, mainly because their habitual coping strategies prove to be adequate in the new context.

It is important to realize, however, that selecting a coping strategy to deal with a new stressor is not a one-shot selection process. It is a dynamic process that involves a series of transactions. For example, it is plausible that a student, who is confronted with a social conflict in class, uses emotion-focused coping before switching to problem-focused coping, or vice versa. In stressful situations, students have – very often – a direct, urgent need to restore their well-being, as well as a long-term intention to resolve the problem or conflict. During the coping episode, these short-term and long-term goals compete for dominance in the goal system as the following example illustrates.

Emily's teacher has just given class a challenging group assignment. Emily wants to start right away, but Maggie pressurizes group members to work in a manner they do not like. Emily protests and asks Maggie to explain why her method is better. Maggie ignores her and starts to give directions. Emily protests again, raising her voice. Other group members avert her gaze. Emily starts chatting with Lucy about her new skirt. They seemed to enjoy the interaction for a while and then joined the group in the problem solving process.

In order to interpret Emily's successive ways of dealing with the social stressor, we need to know the functions that different coping strategies serve during the coping episode. At first, Emily's focus was on the learning process, but Maggie's social pressure triggered negative emotions. Emily wanted to stand her ground and argued against the proposed working method, because she felt that one of her long-term goals was frustrated (not to let other students make decisions for her). At the same time, she felt a strong urge to avoid conflict and tension in her group, particularly when she noticed that the rest of her group did not openly support her protest. Hence, Emily opted for problem-solving coping initially but switched to emotion-focused coping later on. Research has shown that youngsters who rely on both types of strategies exhibit better overall adjustment than those who are limited to a single type of coping.

Coping and Volition: Two Essential Aspects of Self-Regulation

The notion of the purpose and function of coping processes is fundamental to the distinction that Lazarus and Folkman made between emotion-focused and problem-focused coping strategies. However, we need to know more than the students' appraisal of the stressor and their choice of coping strategies. We also need to consider

their intentions and goals in relation to the stressor, as well as their intentions and goals concerning the activity that was interrupted by the stressor.

At this point in the discussion, with a little digression, a point to note is that there are moments in the history of a discipline when concepts and models, stemming from a neighboring discipline, start penetrating into one's own theories and models. At this junction in time, a great deal of confusion, due to the simultaneous use of old and new labels, might be prevented if somebody compares and contrasts these different models and brings order into the multitude of constructs.

Elsewhere (e.g., Boekaerts, 2006), it is proposed to blend constructs and research findings from the coping and volition literature and integrate them into the self-regulated learning model. There is a distinction made between three types of self-regulation, namely top-down, bottom-up, and volition-driven self-regulation. Top-down self-regulation refers to goal pursuit that is driven by the students' own values, needs, interests, and goals. Bottom-up self-regulation occurs when specific cues in the learning environment create a mismatch with the students' current learning intention. Perception of a mismatch triggers cue-driven self-regulation with the purpose of engaging in activities to explore the nature of the mismatch. Discovery of obstacles and difficulties that are a threat to well-being elicit negative emotions. At that point, students' attention is drawn away from the activity they were previously engaged in. They either get involved in activities, which serve the purpose of regulating their emotional arousal, or engage in efforts to continue goal pursuit. The former strategies are called emotion-regulation strategies. They are akin to the emotion-focused coping strategies that are described in the coping with stress literature. The latter strategies, which are called volition-driven strategies, are akin to the problem-focused strategies that were described previously.

The three self-regulation strategies are visualized in Boekaerts' (2006) dual processing self-regulation model. The top part of **Figure 1** represents the formation of a mental representation, or appraisal, of a learning situation. The bottom part depicts the three self-regulation pathways. The broken line visualizes top-down self-regulation. Students start activity on the mastery pathway, when their appraisal of the learning situation is such that the learning goal is congruent with their personal goals. This match elicits dominantly positive emotions (e.g., Emily is interested in the task. She wants to increase her competence).

Activity on the well-being pathway (dotted line) begins when students initially appraise the learning situation as problematic or when they detect cues that signal a threat to well-being during the learning process. In our example, the pressure that Maggie put on the group created a mismatch with Emily's current learning intention and with her need for autonomy. This triggered negative

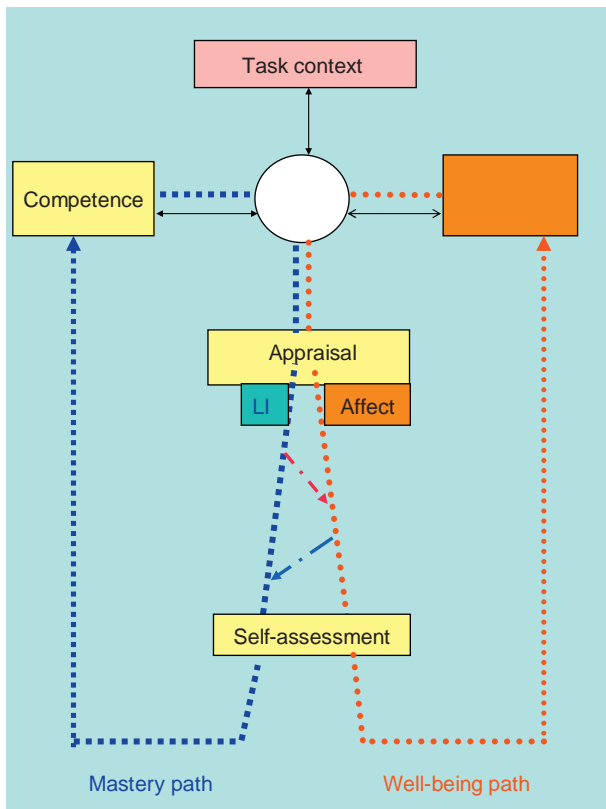

Figure 1 The dual processing self-regulation model. From Boekaerts, M. (2006). Self-regulation and effort investment. In Sigel, E. and Renninger, K. A. (eds.) *Handbook of Child Psychology, Vol. 4, Child Psychology in Practice*, pp 345–377. Hoboken, NJ: Wiley.

emotions and initiated a coping episode. At first, Emily stayed task-focused and tried to re-negotiate the working method (i.e., she used volitional strategies to stay on the mastery pathway). Her emotional arousal increased when she observed that Maggie ignored her and that the group did not support her either. Emily raised her voice, but when that did not help she opted for a different coping strategy, namely looking for distraction. Emily experienced positive emotions while chatting with Lucy and this gave her enough energy to redirect her attention to the learning process. This re-routing is visualized in **Figure 1** by a path that runs from the well-being pathway to the mastery pathway.

Emily's example illustrated that she made use of different strategies to regulate her emotions and to re-fuel the learning process. The next two sections review briefly what is known about these two types of bottom-up strategies.

Regulating Emotional Arousal

Emotions are an inherent part of human functioning. Emotions are tightly linked to the context and what the student is trying to do. Experiencing negative emotions signals to the

individual that something is wrong and that it is important to monitor the context carefully. By contrast, positive emotions signal that everything is fine and that there is room for exploration and play. Why can some students regulate their emotions more effectively than others? The ability to regulate one's emotions refers to the capacity to understand one's own emotions and their expression. Students may or may not understand that emotions are sources of energy and they may or may not be able to override them when salient goals should be pursued.

Inability to temper the intensity and duration of one's emotional arousal (e.g., worry, self-blame) hinders functioning in a social context, whereas the capacity to temper one's emotions (e.g., tension reduction, relaxation, and distraction) facilitates functioning in a social context. It helps students to feel self-efficacious, appraise the classroom environment in a positive way, and the learning and problem-solving process as constructive. It is important to realize that modulating one's emotions does not necessarily imply that one has to play them down. At times, it may be beneficial to express one's emotions, amplifying them so that people present in the situation can take account of one's feelings. Children realize that the way they communicate their emotions affects their peers' subsequent reactions to their behavior. For example, Emily raised her voice, hoping that Maggie would listen to her protest. Maggie's reaction informed her that this was not a good strategy to use and she switched to distraction.

Eisenberg and Spinrad (2004: 4) showed that not all students are able to regulate their emotions strategically. They cannot temper their emotions in such a way that they can continue the (social) activities that they were engaged in at the moment the emotion was triggered. Research shows that parental modeling and coaching plays an important role in the way children regulate their emotions. Children who grow up in families with intense marital conflict develop either aggressive coping strategies and externalizing behavior problems (particularly boys) or acute distress reactions (particularly girls). Ramsden and Hubbard (2002) showed that the way children rated their own emotion regulation predicted aggressive behavior best. Interestingly, the overall degree of negative expressivity in the family coincided with a low rating of emotion regulation, whereas family acceptance of the child's emotions was associated with higher emotion regulation. These researchers pointed out that children, who grow up in families with moderate structure and availability of social support, have a larger repertoire of coping strategies to choose from.

Volitional Strategies: Finding a Solution That Produces a Sense of Mastery

Many common educational practices reduce students' intrinsic interest in academic learning, such as a focus on evaluations and grading, and presenting tedious, ambiguous,

and uncontrollable tasks. Why can some students remove obstacles to intrinsic sense making and persist in the face of difficulties whereas others cannot? Volition-drive self-regulation refers to the ability to maintain focus and effort toward learning goals despite obstacles and distractions. The capacity to get started on learning tasks or continue working on them, when one gets sidetracked by competing goals, facilitates functioning in a classroom and homework context. For example, it helps students to protect their intentions, specifically when difficult work must be completed. It is important to realize that having access to volitional strategies, which Randi and Corno (2000: 5) call good work habits, is essential for re-routing activities from the well-being to the mastery pathway. These include, how to organize one's work, keep distractions at bay, make a time schedule and stick to it, how to resolve conflicts, how to set goals and sub-goals and prioritize them, and how to monitor progress. Socialization practices impact on the development of volitional strategies and it is important that teachers and parents enhance will-power by modeling it and discussing its effectiveness with students. An interesting study by Hill and Craft (2003: 5) reported that parental involvement in school tasks also affects performance. They found that the effect of parental involvement on math performance was mediated by emotional regulation, the children's tendency to accept authority, and their ability to initiate activities and stay on track.

How Can We Help Students Cope with Stressful Situations in the Classroom?

In the previous sections, it has been argued that students need to know which conditions trigger stress and need to practice how they can deal strategically with increased levels of arousal. Often, initial attempts to deal with a stressor fail because students do not know which strategies are most effective in a given context. Alternatively, they might have this knowledge but fail to generate productive strategies at the point of use. In the remainder of this article, two intervention studies that provided insight into how teachers and educators might coach students' coping attempts (for a more extensive review, see Pincus and Friedman, 2004) are described.

Stress Interventions Coach Students' Coping Attempts

Cunningham *et al.* (2002) argued that many adolescents manage their coping resources ineffectively. They hypothesized that low coping efficacy is associated with a pessimistic attributional style (i.e., positive outcomes are viewed as specific, temporary, and caused by luck) and nonproductive coping strategies. These researchers set up an intervention to decrease nonproductive, emotion-focused coping

strategies (worry, wishful thinking, tension reduction, ignoring the problem, self-blame, and keeping to oneself). After an 8-week training period, the students had a greater sense of control over their internal states as compared to controls, showed significantly less depressive attributions, and a decrease in nonproductive coping strategies. Contrary to expectation, no change was found in the use of productive strategies. The reason could be that the researchers' focus was on what the students should not do, rather than on the use of productive coping strategies.

An interesting study by Zimmerman and Kitsantas (2002) showed that students need to have the chance to build up conditional knowledge about the types of obstacles they may encounter during skill development and about the coping strategies that are effective to deal with these obstacles. They found that students, who had observed how a model flawlessly performed a new skill (here: dart throwing and writing-revision strategies) surpassed students who did not have the chance to observe a model perform the task. However, students, who had been exposed to a coping model before they had to practice the skill, outperformed the former group. Why? Watching a coping model struggle to implement emotion regulation and volitional strategies informed the students that the new skill is complex and difficult to implement and that stressors may come in one's way, yet realize that the stressor is changeable and controllable. This information is stored as conditional knowledge and allows students to bootstrap their strategy use and efficacy beliefs. Zimmerman and Kitsantas reported that the coping model condition produced not only better observational learning but also more effective practice experiences and superior acquisition during post-testing than the mastery model or no model condition.

It is easy to implement the coping model condition in the classroom, allowing students to build up information about the personal resources that are necessary and sufficient to deal with the obstacles that may come on their way and about the contextual affordances that facilitate the pursuit of the learning goals. The final point is that there is an urgent need to train teachers to coach volitional and coping strategies.

Culture in Motivation Research: A Challenging and Enriching Contribution

K Kimmel and S Volet, Murdoch University, Murdoch, WA, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Culture – In its broad, ethnographic sense, culture, or civilization, is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by people as a members of society.

Emic/etic – An emic account of behavior is a description of behavior in terms that are meaningful (consciously or unconsciously) to the actor, whereas an etic account is a description of a behavior in terms that are familiar to the observer. Scientists interested in the local construction of meaning and local rules for behavior rely on emic accounts, while those interested in facilitating comparative research and making universal claims rely on etic accounts.

Motivation – Commonly defined as an internal state or condition and sometimes described as a desire or want that drives people's behavior and gives it direction. Based on the expectancy-value theory, what motivates behavior is a function of the expectancies one has and the value of the goal toward which one is working.

Aim, Focus, and Structure

This article aims to capture the current zeitgeist of research on culture and motivation, embedded in its historical development. Key motivational constructs have been selected and reviewed to illustrate the diversity and richness of culture-based theorizing as well as the range of empirical studies that have examined motivation from a cultural perspective. The article also highlights the salient research trends that have emerged in the last decade and the significant contribution that culture has made to motivation research.

As a background to understanding the development of recent research on culture and motivation, the first section provides a brief overview of critical milestones in the development of culture research in the broader field of psychology. The following section examines five key motivational constructs that have attracted a significant amount of research from a cultural perspective. The choice of constructs and the grouping of studies are, to a

large extent, arbitrary, the aim being to illustrate a range of unique theoretical and empirical contributions that a culture-based perspective has made to motivation research. Two examples of cultural psychology research have been added to show that emic research from non-Western settings can make a unique contribution by unveiling new dimensions of learning and motivation. The article concludes with a brief discussion on the shortcomings of research and future directions.

Background and Historical Development of Culture-Based Research

The modern epoch of cross-cultural psychology with a coherent research agenda began only in the mid- to late 1960s. Earlier, according to Adamopoulos and Lonner (2001), cultural studies were largely the domain of anthropologists. The main purpose of early cross-cultural psychology research was to test theories, initially developed and validated in Euro-American contexts, in a range of other cultural contexts so that they could claim universality. This culture-label research (typically using a country or an ethnic group as the independent variable) has revealed numerous cross-cultural differences in target variables. However, inherent to their research design, studies representing an essentialist conceptualization of culture could not explain the variations that were observed.

To address this issue, many cross-cultural psychologists have shown interest in identifying and measuring cultural variables that may account for cross-cultural differences. The most well-known cultural variables involve individualism/collectivism (Hofstede, 1980; Triandis, 1994), basic human values (Schwartz, 1994), and independent/interdependent constructions of the self (Markus and Kitayama, 1991). Methodological problems have also been addressed, for example, the psychometric equivalence of data from cross-cultural settings (Van de Vijver and Poortinga, 1982). Overall, however, and regardless of whether the research involves a culture label or adopts a culture-measured approach, this research is problematic according to cultural psychologists because there is an underlying assumption that culture is static and homogenous, and that it can be treated as an antecedent of psychological phenomena.

For cultural psychologists, differences across cultures are the product of unique cultural contexts, where culture

and mind can only be conceived as inextricably connected since they mutually constitute each other (Adamopoulos and Lonner, 2001). It is argued that cultures need to be treated as dynamic processes (Greenfield, 1997) or open systems (Kitayama, 2002) that spread across geographical borders, evolve over time, and are constantly in flux due to changing contextual characteristics (Hong and Chiu, 2001; Kagitcibasi, 1996; Kashima, 2001; Zusho and Pintrich, 2003). The dynamic, complex interface of culture, context, and social cognition is a relatively new trend in cultural and educational psychology research. Accordingly, mainstream motivation research has just begun to explore how the interplay of the cultural aspects of contexts and personal dimensions co-contribute to producing different motivational patterns.

Additionally, similar views to the position of cultural psychologists have been expressed from an indigenous psychology perspective. Although the main motive of the indigenous psychologists is to address the prevailing dominance of the Euro-American mainstream cross-cultural psychology research, their position is consistent with that of cultural psychologists. Their call for the development of theories from within, that is, those developed within non-Western contexts that are therefore more appropriate for such milieus (Sinha, 1998; Yang, 2000), is consistent with the view that cultural systems should be the unit of analysis (Kim and Berry, 1993) in psychological research.

Overall, the major shift in culture-based research from a static, homogenous, decontextualized conceptualization to a dynamic, complex, and contextualized perspective has emerged almost in parallel to recent developments within mainstream research on motivation and learning (Volet, 2004). In the latter, the shift is from studying psychological phenomena with an exclusive focus on the individual (cognitive) toward a person-in-context perspective (sociocognitive), taking account of the location of mental processes in social activities that are embedded in broader social, cultural, and historical contexts (situative, sociocultural perspective) (Pintrich, 2000; Turner and Meyer, 2000; Volet, 2001). In addition, this perspective (situative, sociocultural) stresses the significance of mutual, dynamic interactions between individuals and culturally constituted contexts for the emergence of cognitive, motivational, and learning orientations. Thus, both cultural psychology and the situative perspective highlight the emerging, complex, dynamic, and contextualized nature of culture and motivation.

Motivational Constructs Investigated from a Cultural Perspective

The search through conceptual and empirical material for this article revealed that motivation research from a

cultural perspective is very diverse and spans across a range of theoretical perspectives and constructs. Here, we provide illustrations of the type of theorizing and empirical work that has emerged in recent years with the view to highlighting its richness and significance. As mentioned in the introduction, the selection of motivational constructs and the grouping of studies are, to some extent, arbitrary; therefore, this article does not represent any systematic mapping of the field.

Achievement Motivation, Its Relationship to Effort and Ability

In the 1960s and 1970s, extensive cross-cultural research related to achievement motivation (McClelland, 1961) was conducted in Asian contexts. The purpose was to investigate the roots of achievement motives to better understand the essential underlying psychological mechanisms of achieving societies. A number of empirical studies (e.g., McClelland, 1961, 1965) revealed that Asian samples scored lower on achievement motivation compared to American samples, which was conceptualized at the time as a relatively stable personality disposition learned through independence and mastery training. This type of research was highly criticized in the 1970s for being unable to provide insight into the specific cultural context in which achievement motivation was generated. Maehr (1974), for instance, proposed “a framework . . . that stresses the importance of contextual conditions in eliciting achievement motivation” (p. 887). Similarly, Salili *et al.* (1976) pointed out that motivational patterns could manifest differently across diverse cultural contexts due to varying sociocultural influences. In the 1990s, Yu and Yang (1994) also criticized McClelland’s work on the ground that this achievement motivation theory was based on Western middle-class values, which are not generalizable to an Asian setting. Similarly, Salili’s (1994) research using a repertory grid technique (based on Kelly’s 1955 personal construct theory) suggested that different cultures could share the same dimensions of achievement, but their conceptions of achievement, for example, the meaning attached to success, could vary.

This illustration shows how, in early research on achievement motivation, culture was viewed as the unique, contextual frame for the development of motivational patterns. These patterns, therefore, were assumed to reflect the values and beliefs of the specific sociocultural setting. Simply stated, the view that culture is context was used to explain why motivational orientations and processes have different manifestations across distinct cultures.

Recent work related to achievement motivation (Hufton *et al.*, 2002a) has also endeavored to reveal causal relationships between culture and motivation; however, culture and context have been treated as distinct, and deliberate efforts have been made to interpret the

meaning of the findings in relation to the characteristics of the cultural context. The empirical work of Hufton *et al.*, conducted with American, English, and Russian students, revealed ambiguous relations between the self-perception of academic competence and attribution of achievement to effort and ability. The former two groups appeared more likely to view effort as the cause of high achievement, although they significantly displayed lesser endeavor than their Russian counterparts, who, in contrast and despite working significantly harder, were more likely to ascribe high achievement to ability.

It is noteworthy that Hufton *et al.* (2002b) did not limit the interpretation of their findings in light of the prevailing culture alone. Context was treated separately from culture in terms of schooling and classroom practices, on the grounds that these are expected to shape and build the basis for the emergence of distinct motivation and learning patterns. The authors, moreover, highlighted the significance of not only understanding the meanings attached to the notions of effort, ability, and achievement, but, more importantly, also acknowledged that these may vary within and between cultures. To this effect, they combined their survey with an in-depth qualitative component. Their exploration of the meanings attached, by Russian students, to effort and ability revealed that although a strong emphasis was laid on effort, working hard or effort was considered to be the norm, leading the authors to conclude that "individual differences in ability may be a more salient and discriminating factor" (Hufton *et al.*, 2002b, p. 282). However, based on their additional findings of the conceptions of ability as the result of effort in Russian students, the authors criticized any simplistic and dichotomous conceptualizations of effort/ability.

The value of combining cross-cultural surveys with qualitative studies has also been advocated by Bempechat and Drago-Severson (1999), who called for a qualitative shift in cross-cultural research on achievement motivation. They stressed the significance of exploring the context and culture-specific beliefs about learning, achievement, and motivation to elicit the underlying meanings that individuals attach to these constructs. In their view, subjective perspectives are critical to gaining a deeper and fuller understanding of why learning and motivation patterns are consistent or vary inter- and intraculturally.

The following section pursues the examination of the dichotomous conceptualizations of motivational constructs in a cultural perspective, this time in regard to the self-determination theory, and the constructs of extrinsic and intrinsic motivation.

Self-Determination Theory, and the Constructs of Extrinsic and Intrinsic Motivation

From a Western perspective, the bipolar construct of extrinsic and intrinsic motivation is traditionally conceived

in terms of intrinsic motivation being more beneficial and efficient for learning as it serves as an antecedent for deep learning strategies (Watkins, 2000). This widely shared belief was recently contradicted by Ramburuth and McCormick's (2001) findings, which revealed evidence that the surface strategies were connected with intrinsic motivation for Asian students, whereas extrinsic motivation was linked to deep strategies for Australian students.

Other studies, such as Iyengar and Lepper's (1999), contributed to raising doubts about the Western-based conceptualization of intrinsic motivation rooted in the self-determination theory (Deci and Ryan, 1985, 2000). In short, the self-determination theory postulates that an individual's intrinsic motivation will be higher in situations where options of personal choice are given. Iyengar and Lepper's study found that while this assumption did hold true for their American participants, it failed to predict the motivational tendencies of their Asian sample. The latter group displayed higher intrinsic motivation when task choice was made by significant others, such as their mothers or a valued in-group member, than when they were given the opportunity to choose a task themselves. The authors interpreted their findings in light of Markus and Kitayama's (1991) theory of independent and interdependent self-construal. They argued that while free choice for people from independent societies corresponds to their need for autonomy and personal control, it might harm the need for relatedness of people coming from interdependent societies. In other words, it entails the risk that their personal choice may not be in line with the beliefs and values of important others, and therefore may cause conflict or jeopardize group belongingness.

In this regard, Katz and Assor (2007) argued that having a choice could be motivating when the options meet the choosers' needs for autonomy, competence, and relatedness. Of these, relatedness refers to congruence with the values of the cultures of the choosers, which, as discussed above, is of special importance for members of interdependent/collectivist societies. This assumption is supported by the research of Roth *et al.* (2006), which revealed that on the relative autonomy continuum theorized by the self-determination theory, conformity exists as an intermediate level between external regulation and introjection. The authors concluded that the need for autonomy might be less compatible with Eastern cultures that embrace collectivist values. They suggested future research to examine the relations between conformity, well-being, and performance in collectivist societies.

In light of these findings, which also explored the significance of culture as context in terms of pan-cultural dimensions and self-systems (independence/interdependence), it may be timely to reconsider the bipolar construct of extrinsic-intrinsic motivation. If choice does not play a critical role for people coming from more socially interdependent societies, the fundamental assumptions underlying

this concept can no longer be viewed as appropriate to explain human motivation across cultural contexts. It seems rather, that while the pursuit of self-determination may enhance intrinsic motivation in more independent societies, pursuit of social conformity fulfils that same function in more interdependent societies. However, and as alluded to in the introduction, caution needs to be exercised when explaining differences in motivational tendencies exclusively in light of a global cultural dimension, as it has only limited potential to acknowledge the dynamic nature of motivation across contexts and situations within cultures.

This issue is addressed in the following section when discussing the impact of culturally specific self-beliefs on achievement and motivational orientation.

Attribution Theory, Self-Beliefs about Achievement and Motivation Orientation

In the Euro-American literature, there is a widely shared belief that having confidence in oneself and thinking positively essentially helps and enables people to be successful and to perform at their best. The validity of these beliefs was supported, for example, by Bandura's (1982) research, which revealed that a positive sense of self-efficacy often results in enhanced achievement.

In recent years, however, a number of researchers active in cultural research have cast doubt on this perspective. They suggested that the positive impact of self-confidence might not sustain in cultural contexts other than the Euro-American one (e.g., Fiske *et al.*, 1997; Heine and Lehmann, 1997). Their empirical work in East Asian settings, such as Japan, revealed that, in contrast to the aforementioned shared assumption, it was a person's self-critical view that was positively associated with achievement and motivation.

These findings suggest that motivational beliefs may play out differently across contexts depending on culturally specific self-views. Again, this research treated culture (national culture) as one form of context and assumed it would provide specific opportunities, constraints, and affordances for the development of motivational orientations. For instance, research by Kitayama *et al.* (1997) and Heine *et al.* (2001) provided strong evidence that while the independent self-view (e.g., predominant in the United States) is positively related to self-enhancing motivational strategies, the interdependent self view (e.g., prevalent in Japan) is more likely to be associated with self-improving motivational approaches. Heine *et al.* found that their Japanese participants worked harder on a second task if they had failed to complete the first one successfully, which implies that they were strongly focusing on their weaknesses (self-criticism). In contrast, their American participants worked harder the second time if they previously succeeded in task completion, which suggests that they were motivated by their strengths (self-enhancement).

Notably, the authors' interpretation of these findings was not exclusively based on cultural dimensions of self-construal. Some attention was also given to each group's respective cultural-educational environment, in terms of school culture and university entrance qualification systems, on the grounds that these would have shaped people's lay theories of the self. Dweck and colleagues (e.g., Chiu *et al.*, 1997; Hong *et al.*, 1999) have coined the terms entity theory and incremental self-theories. They argued that while the former refers to the cultural belief that the self is relatively fixed and stable, the latter views the self as adjustable, fluid, and improvable. These culturally based self-beliefs may help explain the different motivational strategies displayed by American and Japanese participants following failure. While the American participants attributed their failure to lack of ability, a fixed, inherited characteristic, the Japanese participants thought that task completion was just a matter of more effort.

Despite these striking differences, it is important to highlight that although diverging motivational strategies were adopted, both groups were striving toward the same goal, namely to do their best. To sum up, it suggests that humans may share similar goals, needs, and desires. However, while the strategies that people adopt in pursuit of these, and the ways in which these are constructed, may depend on cultural elements to some extent, the multiple contextual factors prevalent in specific contexts are also significant. These were only minimally taken into consideration in the research examined so far. The importance of culture and context as distinct constructs is discussed in the following sections on goal orientation as well as agency and self-efficacy.

Goal Orientation, Social Diversity, and Educational Practices

Culture-based research on goal orientation has revealed that the basic constructs of the goal theory show remarkably similar structures across cultural groups (e.g., McInerney, 2003; McInerney *et al.*, 1997; Nelson *et al.*, 2006). Based on that research, it would appear that goal orientation and achievement motivation may not be that dissimilar around the globe.

However, research conducted in the context of multicultural classrooms, for example, by Kaplan and Maehr (1999), showed strong evidence that while task goals were positively related to the sense of school belonging, perceived competence, and self-esteem in minority students, by contrast, ego goals correlated negatively. In this regard, Maehr and Yamaguchi (2001) argued that school cultures that stress and encourage task goals may play an important role in reducing negative and inhibiting aspects associated with social diversity. Most importantly, this strengthens the view that motivational orientations are

malleable, and thus may change in response to specific educational practices.

The respective significance of culture and multiple contextual variables on students' learning and motivational orientations has been investigated by, for example, Salili *et al.* (2001). The authors conducted research with three groups of students, namely Chinese in Hong Kong, European-Canadian, and Chinese-Canadian. The findings were interpreted in light of the sociocultural setting as well as the context of schooling practices (e.g., grading and assessment systems). The study revealed that Chinese-Canadian and European-Canadian students who participated in the same learning environment displayed different learning attitudes and goals. For example, Chinese-Canadian students spent more time studying, received higher marks, and indicated family-oriented goals more often than European-Canadian students. Importantly, observed differences in self-efficacy scores between Chinese-Canadian and Hong Kong Chinese students could not simply be explained by culture alone. Different schooling practices, such as assessment processes and success criteria, were found to play a vital role, with a significant impact on students' self-efficacy beliefs and motivational patterns. Hong Kong students doubted their self-efficacy because despite working very hard, they only received low marks. In contrast, the efforts made by Canadian students were reflected in their examination results.

The findings of this study by Salili *et al.* (2001) illustrate the importance of interpreting motivational orientations in light of the specific cultural milieu and the multiple contextual characteristics that afford and constrain particular learning and behavior patterns. Moreover, the study highlights that a contextualization of research has the potential to reveal stability and change in individual motivation patterns across situations and over time.

The final section addresses the situated nature of individuals' agency and self-efficacy beliefs, and discusses how these evolve differently within and across cultures and contexts.

Agency and Self-Efficacy, Separating Culture and Context

In recent years, a number of researchers, for example, Hernandez and Iyengar (2001) and Kitayama and Uchido (2005), have suggested that cultural differences in motivation may be best explained in terms of distinct agentic modes. The idea is that people coming from cultures that stress independence and autonomy are more personally agentic and their behaviors attributed to dispositional characteristics, whereas people from cultures that emphasize interdependence are more collectively agentic and their behaviors attributed to situations or are even viewed as directed by groups. More specifically, it is argued that

personal agents view the self as the source of agency and essentially display higher intrinsic motivation in situations that involve self-initiated and self-directed actions. In contrast, collective agents perceive agency as emerging from the collective and, in turn, exhibit higher intrinsic motivation for behaviors that are rooted in and directed toward the collective (Kitayama and Uchido, 2005; Markus and Kitayama, 2004).

In the same line of thought, three modes of agency are distinguished in the sociocultural theory: personal, proxy, and collective agency. While personal agency is exercised individually, proxy agency is in operation when individuals influence others to take actions for them. In collective agency, individuals act in accordance with each other to produce collectively desired outcomes (Bandura, 2002). However, Bandura made it explicit that it is of utmost importance to realize that although "the determinants and agentic blends of individual, proxy and collective agency vary cross-culturally . . . all these agentic modes need to be enlisted to make it through the day, regardless of the culture in which one happens to reside" (Bandura, 2002, pp. 269–270). Consequently, he also argued that cultural variations in the behaviors of individuals may be best explained in terms of the relative importance attributed to each type of agency in a particular cultural context, rather than the result of entirely bipolar individualist or collectivist modes of agency. Moreover, Bandura stated that regardless of which mode of agency is exhibited, one underlying mechanism is omnipresent, namely efficacy beliefs. The core belief that one has the power and the ability to achieve desired outcomes serves as a baseline for a range of factors that may guide the behaviors of individuals. In other words, cognitive, motivational, affective, and decisional processes are viewed as essentially shaped by an individual's self-efficacy beliefs. However, again according to Bandura, although efficacy beliefs have generalized functional meanings, their emergence, structure, exhibition, and purpose vary across cultural contexts. Additionally, as mentioned above, not all efficacy beliefs are limited to an individual perspective. Collective efficacy beliefs refer to situations where group members act in accordance to a shared belief that a desired outcome can be achieved by joint actions. Again, however, although the focus shifts from the individual to the collective, the basic underlying functions and processes of efficacy beliefs are the same. Consequently, based on Bandura's position, it can be argued that regardless of the cultural context, there is universal commonality in human agency and mechanisms of operations. It is the ways these mechanisms are put in practice and the shapes they adopt that can vary cross-culturally.

Furthermore, researchers such as Bandura (2002), Hernandez and Iyengar (2001), Hong and Chiu (2001), and Kashima (2001) have stressed the contextualized nature of human behavior. They view context as a combination of

a variety of contextual attributes and situational factors that can engender or inhibit human motivation, regardless of the prevalent cultural milieu. For instance, depending on whom a person is interacting with and what the interaction is about, intra-individual differences in behavioral and motivational patterns can emerge. This idea is supported by Freeman and Bordia's (2001) findings that depending on the reference group (e.g., peer, family, academic, and national), participants exhibited different levels of individualistic and collective orientations.

These findings therefore support the significance of situational and contextual factors on the development of behavioral and motivational orientation. Furthermore, they highlight the importance of taking intra-individual as well as within-culture variations into account. Thus, focusing on context and situation-specific characteristics as fundamental for the thoughts and actions of the individuals, rather than exclusively relying on the global construct of culture, essentially enhances the understanding of the dynamic nature of social behavior. In this regard, Volet's (1999) research provided strong support for the benefits of systematically separating culture and context, allowing for the examination of stability and change in the motivational patterns of Singaporean and Australian students in the same educational context and over time. The characteristics of the specific learning settings as well as students' subjective perceptions of these settings were assumed to afford and constrain particular learning and motivational patterns, regardless of the students' cultural backgrounds. Volet found that while the overall achievement motivation remained relatively stable in the group of Singaporean students, more contextualized aspects of their motivation, such as self-efficacy and goal orientation for particular learning activities, changed over time in the new academic setting with its unique configurations of contextual features. Thus, macro-(sociocultural background) and micro-(classroom and instructional practices) level contextual influences, as well as students' subjective perceptions of these, crucially shape the development of motivational orientations and processes that consequently become congruent with the particular cultural-educational context.

Kitayama and Uchido (2005) stated that motivation is universal in all cultures and the ways in which it is constructed depends on cultural values and characteristics. However, while traditional theories of human motivation have postulated personal agency and self-determination as the central drive of all human actions, a growing body of culture-based research suggests that these fundamental assumptions may not be as relevant among members of more interdependent cultures. As elaborated above, it seems that motivational variations may be best explained in light of prevailing sociocultural factors and the interplay of multiple contextual variables, rather than in terms of static, bipolar cultural dimensions that cannot account

for the dynamic nature of culture and motivation, which constantly change over time and across situations.

In the following section, we briefly illustrate how indigenous psychology research can make a unique contribution to expanding and enriching mainstream theories of motivation through unveiling culturally specific conceptions of learning, motivation, and achievement.

Cultural Research from Within

Two Asian scholars, Li (2002) and Ho (1998), provide examples of cultural research from an indigenous perspective. Li's (2002) research, situated in China and focused on indigenous, traditional conceptions of learning and achievement, proposed a new dimension of motivated learning that cross-cultural research had not captured. Her model of "heart and mind for wanting to learn" stresses that knowledge seeking and the cultivation of lifelong learning is of greater value for Chinese learners than achievement itself. The overall aim of Chinese learners, according to her, is to achieve breadth as well as depth of knowledge and, simultaneously, to personally and morally grow through the learning process. Furthermore, the meanings attributed to success/failure and effort/ability in her model remarkably differ from the commonly shared understanding of these notions in Western models. The difference, according to her, emerges as a result of the dialectical reasoning style characteristic of Chinese culture; thus, failure and success are both perceived as essential components of the learning experience. From this perspective, failure is not perceived negatively, but as a sign to work on and improve particular skills, which in turn will help to achieve success in the future. Consequently, Li's Chinese model of learning stresses the impact of effort to achieve learning outcomes. Innateness of ability is not neglected; however, it is also not viewed as a determinant factor because lack of ability can be compensated by substantial effort (Li, 2002). Interestingly, Li's conception of effort/ability appears consistent with the findings by Hufton *et al.* (2002b) in a Russian educational context.

While Li recommends the accommodation of the Chinese conceptions of learning and achievement in existing frameworks for theory enhancement, she does not claim the universality of these dimensions. In contrast, Ho (1998) proposed methodological relationalism as a universally generalizable approach to consider human relationships as culturally defined and, thus, to interpret individual behavior more accurately. Ho grounds his idea of methodological relationalism and the significance of relational dimensions in Asian social psychology. According to Ho, the methodological relationalism approach is critical to capture the inherently social nature of human actions that are invariably embedded in relational contexts. Ho (1998) recommends person-in-relations and persons-in-relation as

useful, universal units of analysis to acknowledge the impact of relational contexts on the thinking and actions of individuals.

These two constructs, postulated by Ho, explain how cultural research from within can provide a unique insight into indigenous perspectives on learning and motivation. This insight is viewed as a crucial prerequisite for understanding and explaining cross-cultural variations because it unveils how participants themselves construct and value the phenomena under investigation.

Research Shortcomings and Future Directions

Focusing on the five key motivational constructs was useful for providing an illustrative picture of the challenging and enriching contribution of culture in motivation research. It highlighted how current theories of motivation, mainly developed and validated through Western lenses, are not always useful for explaining and predicting motivational orientations in cultural milieus different from those in which they originated. For example, the relatively simplistic, dichotomous conceptualizations of ability/effort, success/failure, and extrinsic/intrinsic motivation appear unable to adequately explain cultural variations across contexts, and therefore need to be reexamined and redefined. The moderating influence of culture on relationships between variables was revealed, and emic positions were found useful to highlight how variables can differ across cultures.

The research on culture and motivation is characterized by a number of methodological shortcomings. These involve a dominance of single-context studies that use cross-sectional designs and rely on questionnaire data. Such studies have limited potential to capture the complexity and interacting nature of personal, cultural, and situational influences on emerging motivational patterns. In contrast, studies that involve longitudinal designs and that investigate motivation in multiple contexts have greater potential to reveal stability and change in motivational orientations over time, within and across contexts (e.g., Volet, 1999). This is important because it is only if cultural variations are found across diverse contexts that we can be confident that these represent a real main effect. Acknowledging the moderating influences of culture on the relationships between variables as well as the dynamic, situated nature of both culture and motivation require research designs and methodologies that reflect these more complex conceptualizations. Such approaches also have the potential to unveil intra-individual as well as within-culture differences (e.g., Bandura, 2002).

The current undue reliance on questionnaire data will also need to be reexamined and complemented by other approaches. Van de Vijver and Poortinga (2002) have

argued that multiple approaches are needed to progress with the daunting task of studying the relationship of development and cultural context. They recommend combining qualitative and quantitative research methodologies as well as the use of a variety of models, ranging from simple main effects to dynamic interaction models. A similar approach would benefit research on culture and motivation. There is little doubt that questionnaire data are not well suited to the task of capturing the significance of culturally constituted contexts for individuals' processes of understanding and meaning making of the phenomena under investigation (e.g., Elliott and Bempechat, 2002). Two possible ways of empirically examining and improving the validity of survey methodology in cross-cultural contexts are Rasch measurement (e.g., Andrich, 1978) and cognitive pretesting (Karabenick *et al.*, 2007). While the former allows for the measurement of qualitative differences in the responses of individuals to psychometric items, the latter empirically examines the extent to which respondent's interpretations of items are consistent with the meaning that a particular construct is intended to capture.

To conclude, both sociocognitive and situated theoretical perspectives on motivation have stressed that achievement, self-efficacy, and agency beliefs (to name just a few) are socially constructed. Social constructions include cultural constructions, and both call for qualitative, ethnographic, and emic approaches to complement traditional survey methodologies. As discussed in this article, culture has already made a challenging and enriching contribution to motivation research. Further enhancement in our understanding of the respective contribution of culture and contextual dimensions on motivation requires continuous reexamination of theoretical assumptions within and across multiple cultural contexts, and a variety of research approaches that reflect the complex and dynamic nature of culture and motivation.

Glossary

Conflict management skills – Conflicts are part of friendships between peers. Conflict management skills are associated with forming and maintaining friendships, and therefore with increased social understanding.

Context – The immediate setting, such as neighbourhood, school, and community, and different types of interpersonal relationships, that is, peers, family, and school-based.

Friendships – A special form of peer relationship when children engage in many more positive interactions with each other that are characterized by talking, cooperation, and positive affect, than they would with other peers.

Joint Attention – The ability to share attention with others.

Peer relationships – The degree that children are liked by children in the larger peer group, and to peer friendships, that apply to dyadic relations between two children.

Social Competence – A combination of effective use of social skills, absence of maladaptive behaviour, positive relations with others, and accurate, age-appropriate social cognition, or social understanding.

Social Development – A set of behavioural patterns, feelings, attitude, and understanding of the relationship to others that becomes apparent over time. It is the result of both intrinsic child characteristics and socialization.

Socialization – Guiding the child in such a way that reciprocal compliance, a child that is willing to be guided by parent directives and a parent that aims at fostering socialization, results in a social competent child.

Social play – Collaborative interactions of peers during play.

Social understanding – Accurate, age-appropriate social cognition.

Temperament – The whole of an endogenously organized personality trait that has a persuasive effect on the quality and frequency of social exchanges and interpersonal relations.

Transactional model – A continuous attunement between intrinsic child characteristics and elements

in the child's environment, such as circumstances in the home, the school, the neighbourhood, and former life experiences.

Introduction

This article deals with social development, which refers to a set of behavioral patterns, feelings, attitude, and understanding of the relationship to others that becomes apparent over time. We consider social development as a result of transactions between child characteristics and environment. This transactional view on social development means that we look at social skills as abilities that develop during socialization. Processes of socialization are related to the child's parents and the cultural habits of the parents, and contextual influences, for example, family relations, and neighborhood. Social development starts at birth when the child's skills to share attention with others increases. The results of joint attention and increasing skills to use language allow the child to share actions and emotions with his caregivers. The child's interactions with caregivers gradually develop to more sophisticated verbal and nonverbal interactions. These allow the child to turn his attention to other adults and peers gradually. Both the results of socialization and the child's characteristics, especially temperament, add to increased social development. When the child goes to school, the results of socialization up to that point in time, and the child's achieved social skills further influence his social understanding to become a socially competent member of his culture.

The very first sign of social awareness is sharing attention. This capability is typically human as opposed to chimpanzees, and it refers to the first social behaviors that children show shortly after birth. The meaning of this skill is therefore the first topic that we present as one of the main elements of social development with regard to children aged 0–6 years. The other elements are development of peer interactions, social play, and social competence with regard to school. We based the choice for these essential factors upon extensive literature searches related to issues on social development. First, we define each of the items, and we describe recent theoretical insights, which are based upon recent findings of studies related to the theme. We consider temperament as a factor, which

relates to all of the items, and we therefore present it in a separate paragraph. We will start with a historical overview of interest in social development to offer a frame for the article content, thereafter we present the elements of social development one after the other. In the conclusive remarks, we draw attention once again to early social development as a concept that is related to effective schooling.

Historical Overview of Interest in Social Development

Social development is the result of both intrinsic child characteristics and socialization. Both elements have received considerable attention over the years. The theoretical considerations and studies to test hypotheses derived from these theories reflect a growing insight in the way children become socialized given the genetic traits, and the environment in which they grow up. A first concept of socialization was that children are reinforced to form habits by their parents: As the child observes his parents, and as his parents deliver continuous feedback on intentional and nonintentional behavior while being together, the child develops increasing insight in how to behave. Later on, psychodynamic views came into focus. Children are active learners as they initially experience control by their parents but they gradually develop internal social control. This growing ability to understand social behavior, in turn, affects how they perceive social events. Studies on visualizing social behaviors showed that both parenting style and attachment affect socialization, and that the reciprocal nature of these factors leads to ongoing changes over time. Next, a new element of socialization came into view. This was the capacity to self-regulate, and it added a new series of studies to understand processes of socialization. It became clear that both child characteristics and environmental influences decide the outcome of socialization. Parents need to guide their child in such a way that reciprocal compliance, a child that is willing to be guided by parent directives, and a parent that aims at fostering socialization, results in a socially competent child. Consequently, research methodologies became more sophisticated to address bidirectionality in the study of social behaviors, especially with regard to the sequential properties of social interactions between child and parent. This sense of bidirectionality guides the description of the elements considered as main factors in early social development and schooling.

Main Factors in Early Social Development and Schooling

Joint Attention

The ability to share attention with others is a developmental task that precedes social competence. Behaviors

that are indicative of the capacity for joint attention begin to emerge about 3 months after birth. Infants at that age already show visual preference for members of their own race compared to members of a different race. They also favor the sound of the native language when spoken to, since they tend to look longer at the person who speaks their language, and they are attracted to movements of the human face. More elaborated and differentiated forms of attention develop in the next 15 months. The tendency to fixate social stimuli and to engage in social interaction is socially motivated: The child seeks a broader context that provides comfort, security, and satisfaction. Perceiving what another person is looking at facilitates referential communication, which includes three distinct skills of joint attention: responding to joint attention, or proto-imperative behavior; initiating joint attention, or proto-declarative behavior; and initiating behavior regulations. Successful joint attention is socially rewarding for the child, although individual children may differ in tendency to share positive affect with others. Moreover, eye contact marks awareness that others have powers of perception as well.

Joint attention is a skill that develops gradually based upon child and caregiver characteristics. Being motivated for interpersonal and emotional dyadic sharing is reciprocally rewarding, and the relationship between the child's daily social interactions and later social understanding is strong. Studies about joint attention by 12-month-old infants showed that the more frequent these children responded to, and initiated joint attention with an unfamiliar tester, the more often parents reported that their child showed optimal social competence at 30 months of age. As these results came forward even after excluding measures of cognition and language, it indicates that joint attention as a skill is an important predictor of later social competent behavior.

Studying joint attention is often included when investigating how children develop shared intentionality as part of cognitive development. In several studies, young children and chimpanzees have been compared with regard to the way they develop skills to share intentions. This information seems important to understand the meaning of developing joint attention for the human species. Four skills were compared between young children and young chimpanzees: The first one is gaze following and joint attention. Young children and chimpanzees know what others see, but only children attempt to share attention with others, and they know that they are doing this whereas chimpanzees do not. A second skill is that both young children and chimpanzees gesture in order to communicate with others, but only children understand its underlying cooperative motive. Group activity and collaboration can be observed with young children and chimpanzees, but only children actively encourage the adult to assist them to take part in the activity. Finally, social learning occurs only with young children and an adult as he or she demonstrates or teaches them. However, adult

chimpanzees do not demonstrate things to their youngsters. Instead, the young animals observe and copy the adult's behavior. Joint attention as an expression of shared intentionality therefore, is "a direct expression of the biological adaptation that enables children to participate in the cultural practices around them" (Tomasello and Carpenter, 2007). At the same time, these cultural practices alert to child to "specific conditions under which the built-in default assumption of universal knowledge and omniscient other minds must be suspended or inhibited" (Gergely *et al.*, 2007). Joint attention, therefore, is a first step in social referencing which develops gradually and is experience driven. Improved social referencing allows children to build peer relationships.

Peer Relationships

From a relational perspective, the child's early relationships with his parents initiate the child into a system of reciprocal and mutual interactions. These affect the child's connection to his parents and later on to his brothers and sisters, and to his peers. Three features of relational quality seem to be meaningful to successful socialization: warmth, security, and mutual reciprocity (Laible and Thompson, 2007). Secure attachment, or a positive relational quality between parent and child, predicts the child's competence in peer relations. As secure attachment is a main result of early parenting, adults play a significant role in the socialization of their child. Children become interested in peers throughout the second year. At first, these interactions mainly include looking, offering, and taking toys. By the 14th month, toddlers start using objects to lengthen the time of interacting, and to increase opportunities to reciprocal communication. During the preschool years, children's improved opportunities to use language for communication with peers allow longer and more intensive interactions, which enhance the development of interpersonal understanding. This understanding characterizes peer relationships and it proceeds along four levels that can be observed when pairs of preschool children are invited to play together. The first level is that immediate will is pursued with little consideration for any other factors; unilaterally expressing one's own needs or wishes is the second level; then reciprocal strategies which includes coordinating perspectives through persuasion occur, and finally collaboration by developing mutual understanding of both partners' perspective shows up. Social sensitivity of preschool peers is not the same between pairs of children. A range of developmental levels occurs while watching preschoolers playing together. Moreover, children differ remarkably in the way they profit from each other's social developmental level.

Peer relations refer to peer acceptance, which is the degree that children are liked by children in the larger peer group, and to peer friendships, that apply to dyadic relations between two children. Core aspects of the

dynamics of interaction processes in peer interaction are the child's effectiveness in social interaction, and his social power, or status of popularity. Both elements of peer interaction are reflected by sociometric status. Measuring a child's status allows expressions of the child's social competence: The children are nominated by their peers to derive scores for social preference and social impact. Next, sociometric categories are computed to decide the category that a child belongs to. These are popular, rejected, neglected, controversial, or average. The findings of recent studies question whether sociometric status is an attribute of individual children. Studies on revealing how social development of rejected children unfolds over time show that rejected children who are not aggressive are less at risk for poor social development outcomes than their peers who are both rejected and aggressive. The same accounts for the other categories of sociometric status. Therefore, an increased emphasis on the fit of the child's characteristics in relation to the expectations of the larger group is taken into account in studies on identifying processes of peer functioning.

A special form of peer relationship is friendship. Children can have dyadic relationships with peers, but it is called friendship only when they engage in many more positive interactions with each other, and these are characterized by more talking, cooperation, and positive affect, than those of other peers. Friendships start early in childhood. Toddlers can be observed in showing specific interest in one child, and spending time with that child by frequent initiatives to share playthings, being close to one another, and share laughs and actions. During preschool, friendships show up in sustained coordinated play and role play. In kindergarten, playing together is still an important part of friendship but there are also more often verbal interactions. These are characterized by many positive and animated exchanges including sharing of preferred activities. Making and keeping friends requires several social skills, such as perspective taking, self-regulation, and understanding desires and beliefs of the other. Having friends is not a critical determinant of social competence, however, as it also depends upon the child's other close relationships in the family, or the level of stressfulness in the child's life. For children who grow up in unstable families, friendships often serve as socialization agents that are indispensable for healthy social development. School is an important place to develop friendships. Studies show that adjustment to school requirements is most important in the early school years "when classrooms are relatively self-contained and being able to interact effectively with a variety of peers is significant" (Gifford-Smith and Brownell, 2003). The role of context, therefore, is more important than earlier presumed.

Conflicts are part of friendships between peers. Conflict management skills are associated with forming and maintaining friendships, and therefore with increased social understanding. The skills develop from simple

skills, which is insisting to one's own strategy or using a strategy that does not allow compromise and conciliation, to elaborate skills. In that case, a child reasons with his peer and attempts to compromise by giving the peer information about his perspective, and offering resolutions that the peer may find acceptable. A study with 5-year children from preschool showed that they use simple assertion and compliance as main strategies in a conflict situation. However, these strategies are situated: simple assertion is mainly used when the opponent insists, and compliance is used more often when the opponent uses a justification, or gives an alternative proposal. Children apply aggressive assertion when their opponent uses physical aggression. Conflict strategies are, however, part of the social skills that children develop while interacting with peers. Episodes of physical aggression decline over the period from 2 to 4 years of age. Use of aggressive behavior is, therefore, an expression of age-related behaviors that are part of becoming more socially competent. These skills are used in relationship to the peer they are interacting with. It follows that being able to develop relationships with peers allows children to enjoy playing together with peers, and to develop further understanding of one's own mind and that of others during social play.

Social Play

Social play refers to collaborative interactions of peers during play. The interactions are the result of productive engagement through the sharing of knowledge, and they provide opportunities to engage in role taking and social perspective taking. These activities lead to adjustments in inter-individual cooperation. As a result, children jointly develop rules that guide their activity, as peers are often approximately equal in status and competence during social play. Acquiring social skills that result in successful interactions during social play is primarily a developmental task. Social play develops from including social bids, such as smiling to the partner and smiling back, to role reversals in which children take over the role of their play partner, to pretend-play when children act as if, and finally, to meta-play when the children discuss the next step of a story line, and discuss changes of roles. The lowest level of social play occurs by 13 months, and the highest level can be observed from 30 months and onward. The more children are experienced to play with peers, the higher is their level of engagement in social play. There is also a significant effect of age with respect to length of sequences of social play. A longer history of shared social play leads to more successful role play. Moreover, child-directed play or free play in groups without external interventions leads to significant longer social play.

There are, however, individual differences in the degree to which children initiate social play, and are willing to take part in play. Child characteristics, such as

temperament, and parental influences, for example, parenting style, and cultural background, influence whether and how children play together. Experience in social play also increases a child's ability to interact with peers while playing together. The more partners are involved in social play, and treat it as a joint act and understanding, the more likely they will learn from it, resulting in positive adjustment, and consequently, improved social competence of each of them. By the time a child visits school 5 days a week, skills that allow him to understand and cooperate with peers and his teacher in the classroom offer opportunities to respond to social demands successfully.

Temperament

Temperament is visible from the child's earliest years. It is defined as the whole of an endogenously organized personality trait that has a persuasive effect on the quality and frequency of social exchanges and interpersonal relations. There are clear associations between temperament and immediate and later adjustment. Three dimensions of temperament are widely accepted: the first dimension is reactivity, which refers to irritability or distress to limitations, and distress to novelty; the second one is self-regulation consisting of effortful control of attention and of emotions; and the final one is sociability, or the tendency to approach novel situations. Temperament determines a child's adjustment as it is moderately stable over time. It contributes strongly to the development of abilities to cope with emotions; it directly and indirectly affects social behavior; it is an antecedent of collaboration quality, and is gender specific. Four models explain the developmental processes through which temperament affects social development. The first one is that temperament has direct linear effects on social development (e.g., since the child is upset easily by novel situations, he tends to withdraw from them; therefore, the child misses out opportunities to practice social skills that foster peer acceptance and play with peers). In the second model, temperament has an indirect effect on social development (e.g., the child's mother is distressed easily by novel situations, and consequently tends to keep her child away from these situations, which in turns affects the child's behavior toward novel situations). The third model refers to an interaction between temperament and social development, and includes a goodness-of-fit hypothesis (e.g., the child's mother is highly sociable while the child is easily distressed by novel situations. The possibility that the child is overexposed to situations that unnerve him is therefore big and affects the child's emotional stability in a negative way). A transactional model of the relationship between temperament and social development refers to a continuous attunement between intrinsic child characteristics and elements in the child's environment, such as

circumstances in the home, the school, the neighborhood, and former life experiences. In these continuous and long-lasting transactions, temperament is either a risk or a protective factor for adequate social development.

Social Competence in School

The results of social development by the time that children enter preschool and kindergarten are reflected in skills that children apply in social interactions with peers and adults surrounding them. We refer to these skills as a part of social competence. Adequate social competence is defined as a combination of effective use of social skills, absence of maladaptive behavior, positive relations with others, and accurate, age-appropriate social understanding. Social competence refers to “a long term characteristic as opposed to social effectiveness which accounts for short term interactions mainly” (Steenbeek and Van Geert, 2007). Socially competent children succeed in integrating the behavior of the self with others during interactions, and they are able to self-monitor and correct errors during interactions. The higher a child’s social competence is, the more positive his developmental outcomes are, since successful interpretation and response to other’s affective communications, elicits positive interactions with peers and others.

School settings require specific skills related to social competence. These are engaging in prosocial interactions, regulating behavior to complement that of others, and delaying personal gratification. Moreover, children’s relationships with teachers are less personal and intimate than those of their parents, and finally, evaluations of children’s academic and social skills are ongoing (Wentzel and Looney, 2007). Social competence in school is related to the school as a context that affords skills to be and to become skilled as a social individual. An example of the relevance of context is that, especially for younger children, mixed age groups in preschool are beneficial in affecting their abilities to communicate, and to socialize with classmates. This advantage disappears by the age of 4–5 years. This suggests that older children profit more from same-age experiences than younger children, as these allow sharing of thoughts and activities that stabilize ongoing relationships with peers. Social competence, therefore, is an ability that is contingent upon opportunities and affordances that allow a child to become and stay socially integrated as well as self-assertive.

Task behavior is a specific form of social competence as it refers to being able to listen and follow instructions, show adequate behavior in the classroom, and staying task oriented. It is a skill that improves by practicing. It follows that children who have attended childcare are more experienced to interact with adults who are not their caregivers, tend to be more skilled to communicate with peers, and more easily show task behavior. Moreover,

children who like school at the start of entering school are more receptive to the role of being a student, and they more often express behaviors related to being a good student, such as complying with classroom rules, and responsibilities as a student. Classmates are important sources of information about ways to be socially effective.

Teachers play a central role in structuring learning environments that afford social goals for the students in their class. Preschool programs that offer combinations of child-initiated and teacher-initiated programs are more successful in fostering social competence. Teachers that apply a combined approach in their classroom are more sensitive to children who are not yet able to self-regulate activities. These teachers compensate for differences between children, and promote social skills by teaching them explicitly to children who tend to avoid situations in which they are to use social skills. Teachers can promote social competence by educating children about emotions. They can tell stories in which the characters experience conflicts, invite them to use feeling words that express the character’s feelings, and discuss strategies that regulate these feelings in appropriate ways to deal with the conflict.

Conclusive Remarks

This article dealt with social development as a set of behavioral patterns, feelings, attitude, and understanding of the relationship to others that become apparent over time. We described social development from a transactional developmental perspective to allow inclusion of both processes of socialization and of development of social skills. We identified four main elements in early social development starting at birth when the child’s skills to share attention with others increases as a very first sign of social awareness. The other elements we presented were development of peer interactions, social play, and social competence related to school. We based the choice for these essential factors upon extensive literature searches related to issues on social development. As we considered temperament as a factor, which relates to all elements of social development, we described this child characteristic in a separate paragraph. In the final paragraph on social competence, we again emphasized the important role of context for social skills developing in the school.

Emotion in Educational Contexts

Emotions in Educational Contexts

Educational activities tend to generate affective experiences for those involved in such activities. As such, emotions permeate educational contexts and affect everyone in the schooling process. A recent example is the accountability movement in the United States that has brought with it an increase in the use of high-stakes testing and associated emotional experiences (pleasant and or unpleasant) for students, teachers, and parents (Nichols and Berliner, 2007). Specifically relating to teachers, the current high attrition and early retirement rates of teachers in a number of countries around the world have been linked to unpleasant affective states such as anger, stress, anxiety, and burnout (Wilhelm *et al.*, 2000; Wisniewski and Gargiulo, 1997). Thus, understanding the nature of emotions in educational settings may be a key to successful educational experiences for students, teachers, and parents.

The increased interest by scholars in issues related to emotions in education has resulted in a growing number of educational journals devoting special issues to this topic (e.g., *Educational Psychologist*, 2002; *Learning and Instruction*, 2005; *Teaching and Teacher Education*, 2006; *Educational Psychology Review*, 2007) and several recently published books regarding emotions in education (Boler, 1999; Schutz and Pekrun, 2007; Zembylas, 2005). This suggests a perceived need to better understand the nature of emotions in education.

In this article, we describe some current inquiries related to emotions in education. We begin by discussing the concepts we used to describe emotional experiences and explicate some of the current research on student emotions. This is followed by a discussion of the current work concerning teachers' emotional experiences. We conclude with suggestions for potential future directions for research on emotions in education.

What Are Emotions?

Due to the variety of terms used in the academic literature and everyday speech, we must first clarify our approach on emotional experiences. We currently conceptualize affective experiences as being organized into three interrelated constructs – affective tendencies, core affects, and emotional experiences.

Affective Tendency

Affective tendency is a predisposition toward certain ways of being in the world (Lazarus, 1991; Rosenberg, 1998). This propensity for particular ways of being tends to develop through transactions among a variety of sources such as socialization, individual beliefs, temperament, approach/avoidance motives, and personality. These affective tendencies provide a lens through which individuals view their transactions in the world. Thus, if one is predisposed to view the world as a scary place, one is more likely to interpret various situations as being potentially frightening and may have more frequent fear-type emotional experiences.

Core Affect

Core affect is essentially how we feel at any particular point in time. Researchers in this area suggest that core affect is fundamentally a combination of two types of feeling continuums – valiance (pleasant to unpleasant) and arousal (low activation to high activation) (Linnenbrink, 2007; Russell, 2003; Russell and Barrett, 1999). Thus, at any particular point in time we may feel calm (low activation and pleasant), tense (high activation and unpleasant), or happy (pleasant, high activation). Mood, which is one example of core affect, can be viewed as a prolonged core affect without an object. Russell (2003) suggests that core affect is object free but can become directed at an object through attributions or appraisals. In these instances, the affect experience is usually described as an emotional experience.

Emotional Experience

Schutz *et al.* (2006) described emotional experiences as “socially constructed, personally enacted ways of being that emerge from conscious and/or unconscious judgments regarding perceived successes at attaining goals or maintaining standards or beliefs during transactions as part of social-historical contexts” (p. 344). There are two key aspects of this definition that are relevant to our discussion here.

Appraisals and emotional experiences

First, emotions involve judgments or appraisals (Boekaerts, 2007; Pekrun *et al.*, 2007; Schutz *et al.*, 2007). As suggested above, core affect tends to become an emotional experience

via appraisal or attribution regarding what is happening during a particular episode. Individuals' goals, values, and beliefs, as well as their social network are the referent points used to judge where they are in relation to where they want to be (Carver and Scheier, 2000; Schutz and DeCuir, 2002; Schutz and Davis, 2000; Powers, 1971). These goals, values, and beliefs represent ways individuals, as members of social groups, position themselves during a particular life event (Boekaerts, 2007; Ford, 1992; Markus and Nurius, 1986; Schutz *et al.*, 2001).

Thus, appraisals involve students' or teachers' perceptions of how the pursuit of a goal progresses during an academic transaction. In most cases, these judgments tend to occur outside of the students' or teachers' awareness, yet these judgments are seen as being key to the emotional experience (Frijda, 1993; Lazarus, 1991; Pekrun *et al.*, 2007; Schutz and Davis, 2000; Smith, 1991). Lazarus (1991, 1999) made a distinction between primary and secondary appraisals. He indicated that primary appraisals deal with how important the outcome is perceived to be by the teacher or student. For example, if a student does not see homework as important, there is probably little potential for emotions related to homework. For primary appraisal, Lazarus (1991, 1999) talks about judgments related to goal relevance (i.e., is it important to the student's goals?), goal congruence (i.e., is it going how the student hoped it would?), and the type of ego involvement (i.e., how much of the student's self or one's identity is involved?).

Secondary appraisals are the judgments a student or teacher would make about their potential to handle the particular situation. Key secondary appraisals are related to agency or control (Lazarus, 1999; Pekrun *et al.*, 2007; Schutz and Davis, 2000) and problem efficacy (Bandura, 1997; Schutz and Davis, 2000), or what Lazarus (1991) referred to as coping potential (i.e., the person's confidence about their ability to handle the situation). These secondary appraisals help differentiate among potential emotions. Consequently, a situation that has been appraised as goal important (i.e., "It's vital for my students to do well on this standardized test") and goal incongruent (i.e., "My students did really badly on that test"), with secondary appraisals of self-blame (i.e., "I knew I should have done a better job of teaching") may result in shame (Turner and Waugh, 2007). Alternatively, the same situation with secondary appraisals of other blame (i.e., "These standardized tests don't measure what my students know") may result in anger.

Social construction of emotional experiences

Schutz *et al.* (2006) also suggest that emotions are socially constructed and emerge from particular social-historical contexts. In other words, emotions are relational, such that emotional experiences do not exist as exclusive features of a person or of an environment (Denzin, 1984; Lazarus, 1991; Lazarus and Folkman, 1984; Meyer and Turner,

2007; Op 'T Eynde *et al.*, 2007). Particular emotional experiences involve person-environment transactions. Consequently, in most cases there are both a social dimension of an emotional experience, and the person's enactment of the particular emotional way of being.

Emotional experiences are also influenced by the particular social-historical context in which the transaction occurred (DeCuir-Gunby and Williams, 2007; Markus and Kitayama, 1994; Ratner, 2007; Schutz *et al.*, 2007; Stearns and Stearns, 1985). For example, the emotional experience we label guilt is based upon developing knowledge of the ethical and legal values of a culture (Ratner, 2007; Weiner, 2007). As such, the student or teacher must adopt the cultural value or belief of personal responsibility in order for a guilt emotional experience. This suggests that the appraisals and attributions that students and teachers make are reflective of the social-historical context in which they and their social groups are embedded.

As such, when there are emotional experiences in the classroom, they reflect person-environment transactions as well as the social-historical contexts in which those transactions occur. Illustrative of this concept is an emotional school situation described in a study by Decuir-Gunby and Williams (2007). After attending an assembly featuring a local civil rights leader, some students had intensive emotional experiences, including guilt, anger, and sadness. One student, in particular, described her classmate as being "upset, and crying. She was upset that he was saying she was a bad person simply because she was white". This student was experiencing an emotion (sadness) as a result of both an environmental transaction (listening to the civil rights leader's speech) and her own social-historical context (the perceived meaning of being white).

Educational Research on Students' Emotional Experiences

Researchers' efforts to study students' emotional experiences can be broadly organized into two general areas – students' self-regulation and motivation and the related area of students' learning and achievement.

Students' Self-Regulation, Motivation, and Emotional Experiences

In the motivation and self-regulation literature, students' emotional experiences emerge during activities that are embedded within personal as well as social-historical contexts. This personal history includes students' goals, values, and beliefs regarding academics in general as well as their beliefs about the subject and the particular activity (Op 'T Eynde *et al.*, 2007; Schutz *et al.*, 2006).

For example, a student may possess a general affective tendency to avoid a challenging task for fear that it may

show ignorance relative to his/her peers (i.e., performance avoidance goal orientation) (Elliot and Pekrun, 2007; Linnenbrink, 2007). In this situation, the student may begin an activity fearful and anxious and, as a result, may attend more closely to aspects of the activity that may be interpreted as a lack of understanding. Thus, through fear and anxiety the student may look to the teacher for help (i.e., external regulation) (Linnenbrink, 2007; Pekrun *et al.*, 2004).

Researchers have also found that pleasant emotional experiences tend to be associated with perceived self-regulation, intrinsic motivation, and the tendency to engage in meta-cognitive or self-regulatory strategies (Linnenbrink, 2007; Meyer and Turner, 2007; Pekrun *et al.*, 2002). This suggests that emotional experiences (pleasant or unpleasant) tend to provide multidirectional feedback for other processes involved in self-regulation (Turner and Waugh, 2007). For example, having successful experiences that students attribute to themselves may result in pleasant emotions, which can increase interest and focus on the activity (Ainley, 2007; Efklides and Petkaki, 2005). This link between emotional experience and self-regulatory processes was demonstrated by Boekaerts (2007), who found that pleasant affect was associated with increases in competence and value judgments as well as effort, whereas unpleasant affect lowered competence and value judgments and was associated with less effort.

The influence of emotional experiences on self-regulation and other motivational and learning processes has resulted in researchers investigating the process involved in emotional regulation. Emotional regulation involves various processes that are directed at monitoring, evaluating, and modifying emotional experiences (Schutz and Davis, 2000; Schutz and DeCuir, 2002; Thompson, 1994). In the area of testing, Schutz *et al.* (2004) were able to explain 55% of the variance in the Worry subscale of the Revised Test Anxiety scale (Benson, 1998) with the emotional regulation during test-taking scale (ERT). In a follow-up study Schutz *et al.* (2007) accounted for 56% of the variance in pleasant and 87% of unpleasant test emotions. These results suggest what students do during tests or other classroom activities may influence their emotional experience.

Students' Learning, Achievement, and Emotional Experiences

Interest in relationships among learning, achievement, and emotional experiences has a long history. The focus of much of this research has been on the test anxiety construct. Test anxiety has been associated with a number of adverse effects on students: poor cognitive performance, scholastic underachievement, psychological distress, and ill health (Zeidner, 2007). Zeidner (2007) goes as far as to suggest that:

Indeed, a student's performance on a classroom exam may be as much an indicator of the students' ability to cope with high levels of evaluative stress and anxiety in the classroom as a reflection of the ability or achievement the exam aims at measuring. Thus, the measurement of any particular ability or proficiency will be confounded with anxiety. (Zeidner 2007: 160)

Recently, researchers interested in emotions in education have also begun to examine other emotional experiences. They paint an interesting, yet complex, picture of the role of emotional experiences in the classroom. As expected, in general, pleasant emotional experiences tend to be associated with the use of more effective learning strategies, task-focused attention, and academic performance (Pekrun *et al.*, 2002, 2004), whereas unpleasant emotional experiences, such as anxiety, boredom, and hopelessness tend to reduce academic performance (Pekrun *et al.*, 2002; Zeidner, 2007). However, other research suggests that unpleasant emotional experiences can also improve achievement. In one such study, Pekrun and Hofmann (1996) found that for some students anxiety was not related to improvement in achievement-related agency over time but for others, there was a positive relationship.

Others have obtained similarly inconsistent findings. Linnenbrink (2007) indicated that general measures of pleasant affect tended to be consistently unrelated to students' learning. This suggests that emotional experiences do not occur in a personal vacuum. As indicated, emotional experiences emerge out of the appraisals students make regarding where they perceive themselves to be in relationship to their goals, values, and beliefs. As a result, what is key to the nature of a particular emotional experience, as well as the potential learning and self-regulation during and after an activity, are the students' perceptions of control and efficacy as well as the attributions they make during and after the activity (Pekrun *et al.*, 2007; Weiner, 2007).

Thus, emotional experiences occur in real time and therefore, are susceptible to changes that occur during an event (Turner and Waugh, 2007). As such, an emotional experience can change very quickly (e.g., joy can rapidly become frustration or anger), which may explain some of the inconsistent findings reported. This also reinforces the need for researchers to continue looking at emotional experiences as they are occurring (Ainley, 2007; Meyer and Turner, 2007; Op 't Eynde *et al.*, 2007; Turner and Waugh, 2007).

Educational Research on Teachers' Emotional Experiences

Researchers who foreground teacher emotions in educational contexts have tended to focus on issues related to teachers' efforts to cope with unpleasant, difficult

emotional experiences, and the related topic of emotional rules and labor.

Unpleasant Emotional Experiences

Researchers suggest that emotions tend to be pervasive within the service of teaching (Meyer and Turner, 2007; Williams *et al.*, in press). Meyer and Turner (2007), demonstrated that teachers who care tend to be sensitive and use humor to create classrooms where students are less likely to avoid tasks and increase performance. However, similar to most professions that require a positive work relationship with the public, teachers must juggle their own emotions, while trying to contend with their students' needs and attend to other administrative duties. As such, teaching is an emotionally charged situation and, if not regulated appropriately, may lead to anxiety, depression, anger, or simply becoming burned out on teaching.

Liljestrom *et al.* (2007) reported that some teachers become angry when required to carry out additional administrative duties that interfere with their curriculum and teaching, although the subsequent behavioral reactions varied across individuals. For instance, some teachers will rebel by becoming less cooperative with administrators, while some advocated for policy changes to higher-level administrators. Still others choose to leave the profession entirely.

The prevalence of unpleasant emotions was demonstrated by Sutton (2007) who, in a diary of teachers' anger and frustration, found that each week teachers reported a median of two anger experiences and seven emotional experiences labeled as frustration. Even more illustrative of the nature of teaching was that many of the teachers reported that these were experiences that sometimes lasted for more than an hour (Sutton, 2007). Reports such as these have resulted in researchers focusing on emotional labor and the emotional rules associated with teaching.

Emotional Rules and Labor

While researchers agree that some emotions are universal, it is important to keep in mind that emotions are socially constructed and therefore behavioral, emotional, and physiological reactions tend to fluctuate across cultures. To understand these social-historical influences, researchers have suggested that there are normative emotional rules that indicate what emotional displays are or are not appropriate (Hargreaves, 2001; Liljestrom *et al.*, 2007; Morris and Feldman, 1996; Zembylas, 2007). Thus, when examining normative rules for teachers, it is important to keep in mind that institutions such as schools embody norms that have been established historically and culturally. Because of the normative nature of these rules, teachers often feel they must conform to socially acceptable standards of displaying emotions or be perceived as deviant. This can be illustrated

by comparing a teacher who teaches to the test and shows neutrality of emotions to a teacher that embodies pedagogical practices that engage students in authentic learning. Depending on the particular school context, each of these teachers could be considered deviant.

Normative rules and consequences related to emotions are not only affected by environmental factors, but also reinforce a reciprocal relationship. Continuing with the above example, a teacher who deviates from the institutionally constructed norm of emotional neutrality and teaching to a standardized test, may be emotionally affected by feeling shame and doubt about how they are teaching. Williams *et al.* (2008) found evidence of this when they found that many teachers deem it necessary to suppress or avoid the display of emotions in the classroom. As such, teachers' emotional experiences are tied to construction of their own teachers' identities (Schutz *et al.*, 2007). The dynamic and transactional nature of emotional experience is influenced by current teachers' identities; this may restrict their affective displays based on how they want to be seen, they will tend not to exhibit emotions that contradict this image.

The idea that teachers are expected to display different emotions in particular ways has been associated with the idea of emotional labor (Hargreaves, 2001; Hochschild, 1990; Morris and Feldman, 1996; Zembylas, 2007). Morris and Feldman (1996) define emotional labor "as the effort, planning, and control needed to express organizationally desired emotions during interpersonal transactions" (p. 987). Emotional labor, under some circumstances, has been associated with emotional exhaustion (a key component of burnout), job satisfaction, and adverse health symptoms (Hochschild, 1990; Morris and Feldman, 1996) thereby demonstrating again the importance of understanding the nature of emotional experiences in the classroom.

Where Do We Go from Here?

As indicated, we currently view emotional experiences as transactional processes that occur in real time. In addition, these transactional processes are embedded within particular, ever-changing social-historical contexts. Given this perspective, it would seem important to approach the study of emotions in education using multiple methods and methodologies (Pekrun and Schutz, 2007) at the various levels of research (Schutz *et al.*, 2004).

One crucial problem area in need of exploration is how issues of class, race, and ethnicity, and gender transact with emotional experiences within the educational setting. In many societies, such as the United States, issues such as race and gender often impact the learning and development that occurs within the school context (DeCuir-Gunby and Williams, 2007; Liljestrom *et al.*, 2007; Steele, 1997). Further exploration of these issues

may help demonstrate the impact class, race, and ethnicity, and gender prejudices have in the educational setting, as well as provide an avenue for researchers and educators to help address these issues.

A second area in need of attention is the area of emotional development. Psychologists have researched the nature of emotional development (Aviles *et al.*, 2006); however, developing an understanding of how unpleasant and complex emotional experiences develop within the school context will require more contextual and domain specific approaches.

A related topic is the development of ways for teachers to scaffold emotions in the classrooms (Meyer and Turner, 2007). It seems clear that by scaffolding and encouraging students' emotions in class, a teacher can help to forge a trusting bond with the student, demonstrate and model respect for the student, and facilitate better engagement with learning tasks. Therefore, more research and eventually implementation research is needed in this area.

Another area involves the emotional labor associated with teaching. Emotional labor has been associated with job satisfaction, adverse health symptoms, and emotional exhaustion – key components of burnout and teacher attrition (Schutz *et al.*, 2007; Zembylas, 2007). A better understanding of the nature of emotional labor and the emotional display rules for teachers will be important to facilitate teachers' emotional well being.

The final area related to teaching is the area of skills at reading emotions of others or other directedness (Nowicki and Carton, 1993; Snow *et al.*, 1996). As mentioned earlier, for the most part, goals and our self-directed attempts at accomplishing them are predominantly social endeavors. They emerge from transactions in a social environment and we pursue them within our social-historical context. The expression of emotions and our ability to read others' emotions are key components of the self-regulation process. For example, the ability of a teacher to tell when students are anxious or frustrated about a task or not understanding the questions, may be the first step in helping students to learn how to regulate those emotions. This is an area where there has been very little inquiry but which has tremendous potential to help the educational process.

Conclusions

Emotions are an integral part of the educational activity setting and, therefore, an understanding of the nature of emotions in the school context is an important goal. In this article, we have attempted to examine some current research on emotional experiences in education. As this area matures, we see the continual examination of the theoretical foundations of emotions in education as fundamental to healthy development of our program of inquiry as well as for that of the larger community.

Empathy

R Arnold, University of Sydney, Sydney, NSW, Australia

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Attunement – Actively listening to, observing, and focusing on another to resonate with their thoughts and feelings.

Empathy – An act of heartfelt, thoughtful imagination to help determine another's cognitive and affective experience.

Intersubjective experience – Engaging with the internal and expressed thoughts and feelings of others.

Intrasubjective experience – Engaging with one's own internal thoughts and feelings through reflection.

Mirroring – The affirmation of one's feelings and thoughts by another through their words, facial gestures, tone of voice, or other expressive features.

Introduction

For a long time, effective educators and others have known tacitly that the relationships and contexts within which humans learn are significant to the quality of that learning. It is timely to elaborate the nature of such aspects, particularly, but not exclusively, as they relate to school learning. Mindful that much significant learning of language and socialization occurs before children enter formal education, the nature of infant learning is relevant to understand early influences on attitudes to learning and self as a learner. In early childhood, affective and inter-/intrasubjective templates are formed which influence learning readiness and interpersonal responsiveness (O'Connor and McCartney, 2007; Repacholi and Meltzoff, 2007; Stern, 1985; Winnicott, 1965).

Empathy through inter-/intrarelatedness, developed as empathic intelligence (Arnold, 2005), is a useful frame for reflecting how social and emotional experiences can affect pedagogy. In the pedagogical framework of this article, empathy is theorized as a function of mind, brain, and feeling within contexts of care and relatedness. By creating a dynamic between thinking and feeling in a climate perceived as caring by students, teachers can mobilize learners' intrasubjective experiences in the service of learning. Similarly, understanding the nature of empathy and how quality relationships can influence learning intensifies educators' attunement to their own

thoughts and feelings and those of others to whom they relate and influence.

Intrasubjective engagements are the thoughts and feelings which come into play as we try to make sense of experience. For example, understanding ambivalent reactions to a situation, or discerning in order to make an important decision are processes which touch on internalized prior experiences. Since we are all influenced in our psychic development by significant others in life, such as parents, siblings, teachers, and friends, our internalized thoughts and their emotional aura continue to influence present thoughts, feelings, and responses.

Empathic intelligence posits that in educators and those involved in interpersonal and intrapersonal work, particular desirable behaviors, such as attunement, warmth, sensitivity, and capacity for mirroring, can have positive effects on those with whom they engage. Importantly, educators' empathic disposition needs to be matched with other abilities, such as a capacity to engage, an ability to create a dynamic between thinking and feeling, coupled with professional expertise, enthusiasm, and intelligent caring. While empathic intelligence is particularly apt for those involved in teaching, training, and educating, it is equally applicable for those involved in a range of professions engaged in relationships and learning. Education is conceptualized here to include formal and informal teaching and learning in public and private settings across all age ranges. In learning contexts and organizations, which function within a climate of empathic intelligence, participants' tacit abilities to learn and relate effectively can be mobilized.

Some background to the development of empathy is outlined here, but the focus of this article is on empathy and empathic intelligence in teaching and learning. Theorization of the concept of empathy has been influenced by work in disciplines such as philosophy (Buber, 1965; Greene, 1995; Kohlberg, 1978; Noddings, 1984, 1988, 1992; Nussbaum, 1995, 1997; Polanyi, 1959, 1969, 1974, 1983; Verducci, 2000), biology (Darwin, 1965), psychology (Barnes and Thagard, 1997; Barnett, 1987; Bruner, 1972, 1986, 1990; Csikszentmihalyi, 1990; Eisenberg and Strayer, 1996; Feshbach and Feshbach, 1987; Freud, 1922; Gardner, 1983, 1993, 1997; Goleman, 1995; Isen, 1984; Kincheloe *et al.*, 1999; Mayer and Salovey, 1997; Piaget, 1926, 1981; Wadsworth, 1989; Vygotsky, 1978), psychoanalysis (Kohut, 1959, 1971, 1979, 1982, 1985; Winnicott, 1965), and infant studies (Lichtenberg, 1983, 1984; O'Connor and McCartney, 2007; Repacholi and Meltzoff, 2007; Stern, 1985; Trevarthen, 1977, 1979). The relevance of empathy to learning has only recently surfaced in

education though it has been foreshadowed in liberal, democratic, student-centered educational practice, influenced by Dewey (1916, 1963, 1971). The brain-based research of Damasio (1994, 2000, 2003), LeDoux (1992), and Williams (2001) offers important insights into the complexity of cognitive/affective interplays in the mind, signaling that learning is not primarily a cognitive task but very much influenced by social and emotional aspects.

Historical Antecedents

Research on the nature of empathy (Barnett, 1987; Barnes and Thagard, 1997; Davis, 1994; Duan and Hill, 1996; Ekman, 2003; Eisenberg, 1989; Eisenberg and Strayer, 1996; Kohut, 1971, 1982, 1985; Verducci, 2000) serves to highlight some of its conceptual complexity. Some salient features of the concept will be highlighted, particularly as they relate to education as an outcome of interpersonal relatedness.

Apart from a reference in Aristotle's *Rhetoric* to *empathiea*, as Verducci (2000a) points out, empathy first appears in nineteenth-century German esthetics in the work of Friedrich Vischer (1847–1933), and following them, Martin Buber and Theodore Lipps. Friedrich Vischer called empathy as a process of 'symbolic interjection of emotions into objective forms', such as engaged in by viewers of works of art. Verducci (2000: 67) notes that Vischer's son Robert named the process *Einfubling*, which was later translated as empathy. Robert Vischer described the process as projecting one's own life into the lifeless form, "only ostensibly do I keep my own identity... I am mysteriously transformed into this Other" (Friedrich Vischer 1994: 19–20). The philosopher Martin Buber (1965) describes the experience of feeling strong connectedness with subjects or objects,

To glide with one's own feeling into the dynamic structure of an object... to 'transpose' oneself over there and in there. Thus it means the exclusion of one's own concreteness, the extinguishing of the actual situation of life, the absorption in pure aestheticism of the reality in which one participates (Buber, 1965: 97).

Although Buber's description of empathy here is far removed from the concept of empathy in human relatedness, it does describe a capacity for imagination for decentering and opening up to and trusting experience which is part of empathic responsiveness.

Lipps (1851–1914) went further than the Vischers and Buber, saying "empathy is the fact here established, that the object is myself and by the very same token this self of mine is the object... the antithesis between myself and the object disappears, or rather does not yet exist" (Verducci, 2000: 68). He saw the phenomenon of empathy as projective, imaginative, and primarily affective. Verducci (2000: 67) notes that in these early ideas of empathy,

"The seed of this process lies in the imagination, the flower in the viewer's affective life. The imagined mental representation of an object and the viewer's feelings become inseparable." In these rudimentary views of empathy, concentration and the capacity for absorption are also functioning. What is not identified is a capacity for cognitive distancing or awareness of a self engaging in the experience, arguably, necessary predispositions for those engaged in educating others. The experience as described by these philosophers is esthetically pleasing though no judgment or cognition is identified in the process. Nor is empathy associated with unpleasant feeling such as disgust or rage which can be mobilized, along with other unpleasant feelings such as shame and distress, in an empathic response to the events witnessed. As Verducci (2000) notes "empathy as sole grounding for the aesthetic experience cannot account for the phenomenon of aesthetic judgment" (Verducci, 2000: 69), signaling the cognitive aspect present in some empathic experiences.

Empathy in Psychoanalytic Literature

It is surprising that Freud had little explicitly to say about empathy, apart from acknowledging that it "plays the largest part in our understanding of what is inherently foreign to our ego in other people" (Freud, 1922: 69–144). Here Freud seems to be suggesting empathy as an ability to recognize what and which we perceive in others to be different from ourselves. Earlier followers of Freud such as Theodor Reik and Robert Fliess regarded empathy as essentially a cognitive process of identifying the feelings of their therapy patients, while attempting to maintain an emotionally distanced therapeutic relationship with them. Little is reported about patients' responses to what might well seem like dissonant engagements where therapists encourage patients to express or disclose their emotions, while rigorously suppress their own.

In common parlance, empathy means being able to imagine, often intuitively, how the other thinks and feels. Heinz Kohut (1959) described empathy as "vicarious introspection". As a more complex process than identification, vicarious introspection includes both affective attunement and the cognitive capacity to judge best how to respond insightfully and feelingly to the other's psychic state. Kohut argued that empathy should be examined and evaluated 'in an empirical context as a mental activity' (Kohut, 1982: 397). He differentiated two levels of empathy, one an "information-gathering activity" and the other "a powerful bond between people" (Kohut, 1982: 397). This differentiation is a useful precursor to the development of empathy as both a cognitive and an affective process, capable of both developing and reflecting relatedness and understanding. Kohut argues that the presence of empathy is beneficial both in a clinical setting and in human life,

as it “suggests an explanation for certain observable contents and/or sequences of events in man’s (*sic*) psychic life” (Kohut, 1982: 397). Most importantly, the self-soothing and empathic responses of parents and others, promotes the development of a nuclear self into a mature, cohesive self (Kohut, 1971). In psychotherapeutic terms, the task of being empathically responsive is complex. Guided by empathic attunement, the therapist’s capacity for introspection and sensitivity to the state of the therapeutic alliance functions to soothe the client’s feeling state (if he/she is responsive to the therapist’s mood), and to stimulate awareness of masked feelings, in the expectation that understanding and even insight can be developed. Kohut warned, “empathy is used non-intuitively, ploddingly, if you wish, by trial and error. I did not write about empathy as being always correct and accurate” (Kohut, 1982: 396). Arguably, it is not the accuracy, or otherwise, of the empathic response which is necessarily therapeutic as much as the therapist’s perceptible wish to be attuned and responsive which cues patients’ feelings of positive self-regard. Similarly, children with positive attachment experiences with caretakers, particularly mothers, are likely to enter preschool and formal schooling, and are able to develop positive relationships with responsive teachers and peers.

Empathy and Infancy

A number of infant studies (Lichtenberg, 1981, 1983; Stern, 1977; Trevarthan, 1979, 1980) support the view that infants are programmed to seek engagement with others and with their environment. These studies focus attention on the infant’s development of a subjective self. The work of Daniel Stern (1985) on the role of empathy in infancy illuminates the importance of empathic attunement in early learning, emotional development, and socialization. Stern writes about the development of “the domain of inter-subjective relatedness” (Stern, 1985: 27), that ability to experience one’s self as a separate being from others, but as a dependent being too whose sense of self can shift according to others’ responsiveness or otherwise.

Stern theorizes that in dyadic engagements between infant and mother in which the mother’s empathic responsiveness (or otherwise) amplifies, soothes, validates (or deadens) the infant’s affect states, there develop what Stern theorizes as representations of interactions that have been generalized (RIGs), (Stern, 1985: 99). These might be thought of as psychically coded emotional experiences which provide the infant with a unified sense of a core self and awareness of a core other: “The existential bedrock of interpersonal relations” (Stern, 1985: 125). The degree to which the major affect states (interest, joy, surprise, anger, distress, fear, contempt, disgust, and shame) are mirrored back to the child by the mother and other caretakers influences how they are encoded psychically.

Thus codified, they become available as emotional templates influencing responsiveness to events experienced as similar by the child. These social and emotional templates can be reinforced, modulated, and nuanced throughout life, depending upon one’s ability to be self aware and deeply reflective. Emotional response to a stimulus can range from the mild pleasure of cursory attention to the intense pleasure of deep absorption in it, or flow (Csikszentmihalyi, 1990). Angry feelings can range from mild irritation to intense rage or fury, shame can be experienced as mildly embarrassing or searingly humiliating, distress can be momentarily discomforting or completely terrifying.

Stern’s point is that in early childhood and beyond, the way others reflect back or mirror the child’s emotional states, affects the internalization and elaboration of those states. The infant’s initial pleasure in throwing food on the floor is modulated by the caretaker’s response to that behavior, hence relatedness and emotional responsiveness influence learning. Stern’s concept of RIGs is helpful in explaining how early experiences influence children’s attitudes and predispositions to learn. The child for whom learning language, listening to stories, and exploring through play is associated with pleasurable relationships and emotions is likely to be predisposed to learning. Long before children enter school, they have developed feelings about learning and themselves as learners, modulated by their sense of relatedness with those modeling behaviors and attitudes. This is evidenced in the experimental work of Repacholi and Meltzoff (2007) who demonstrated that infants’ actions were influenced by their memory of the affect of adults’ behavior. Furthermore, “the infants’ actions varied as a function of whether they were currently in the Emoter’s visual field” (Repacholi and Meltzoff, 2007: 503). The researchers concluded that infants “learn from emotional eavesdropping and their subsequent behaviour depends on the Emoter’s orientations toward them” (Repacholi and Meltzoff, 2007: 503). By 12 months of age, infants can use emotional cues such as tone of voice and facial expression to regulate their own actions (see Feinman *et al.*, 1992, cited in Repacholi and Meltzoff, 2007: 50 for a review of the literature on infant social referencing).

Teachers and schooling can amplify or dampen feelings of expectation, joy, anxiety, or dread around learning experiences. Empathic teachers can attune to these feelings and relate with their students in constructive and emotionally engaging ways. While students may not necessarily articulate the qualities of effective teachers in complex ways, they will experience them in felt ways depending upon the teachers’ emotional sophistication and attunement to their needs. How do we know this? As research into infant social referencing indicates that infants in their early stage know how to read emotional cues and can use such cues to modify their behavior. Repacholi and Meltzoff’s (2007) study provides important insights into what might be called as infants’ capacities to learn in social contexts through

affective experiences. O'Connor and McCartney's (2007) study of 1364 children from birth to sixth grade found positive associations between quality of teacher-child relationships and achievements. In addition, they found that high-quality teacher-child relationships buffered children from the negative effects on achievement of insecure or other maternal attachment issues. Secure attachments "are marked by high levels of maternal sensitivity and child trust in maternal availability and support" (O'Connor and McCartney, 2007: 343). The effect of quality teacher-child relationships on achievement was mediated through child and teacher behaviors in the classroom.

Several studies show that children develop attachment relationships with teachers which are associated with their long-term achievement (Birch and Ladd, 1997; Pianta, 1994; Pianta and Nimetz, 1991). Peer relationships also influence achievement (Azmitia and Montgomery, 1993; Birch and Ladd, 1996; Ladd *et al.*, 1999). As O'Connor and McCartney (2007) concluded from their study:

Educating teachers as to how to develop high-quality relationships with children may provide strategies for teachers working with children who are at risk of lower levels of achievement. . . Informing teachers as to the influence of relationship quality on classroom behavior may increase teacher awareness and in turn prevent children with low quality relationships from engaging in harmful behaviors in the classroom. (O'Connor and McCartney, 2007: 364)

Narratives and Empathy

Maxine Greene argues passionately and persuasively for the role of imagination in education. She says,

One of the reasons I have come to concentrate on imagination as a means through which we can assemble a coherent world is that imagination is what, above all, makes empathy possible. It is what enables us to cross the empty spaces between ourselves and those we teachers have called "other" over the years. . . of all cognitive capacities, imagination is the one that permits us to give credence to alternative realities. (Greene, 1995: 3)

Narratives offer particular social and emotional experiences which can promote empathic development. Martha Nussbaum (1997) argues that three capacities, above all, are essential for the cultivation of humanity in today's world:

First is the capacity for critical examination of oneself and one's traditions-for living what, following Socrates, we may call "the examined life". . . (Second) Citizens who cultivate their humanity need. . . an ability to see themselves not simply as citizens of some local region or group but also, and above all, as human beings bound to all other

human beings by ties of recognition and concern. . . The third ability of the citizen, closely related to the other two, can be called the narrative imagination. This means the ability to think what it might be like to be in the shoes of a person different from oneself, to be an intelligent reader of that person's story, and to understand the emotions and wishes and desires that someone so placed might have. (Nussbaum, 1997: 9-11)

Nussbaum (1997: p. 14) says empathy means "learning how to be a human being capable of love and imagination." Further, she argues that when a child and a parent learn to tell stories together, sharing a sense of wonder, the child is acquiring essential moral capacities "...stories interact with (children's) own attempts to explain the world and their own actions in it. A child deprived of stories is deprived, as well, of certain ways of viewing other people. For the insides of people, like the insides of stars, are not open to view" (Nussbaum, 1997: p. 89). "The habits of wonder promoted by storytelling thus define the other person as spacious and deep, with qualitative differences from oneself and hidden places worthy of respect" (Nussbaum, 1997: 90).

Narratives (and metaphors/symbolic experiences) can function to develop empathic attunement and perspective taking. Some stories draw us back into the past; others project us into the future. Some illuminate the day; others take us into the darkness of human behavior. The best storytellers lighten and enlighten the paradoxes and ambiguities of life. In narratives, the past and present exist in a seemingly timeless realm in which human characters confront physical challenges, emotional and moral dilemmas in some form, and tacitly suggest to us, as readers, how we might best choose to conduct our lives.

Empathic Intelligence

Empathy is defined here as an ability to understand the thoughts and feelings of self and others. It is a sophisticated ability involving attunement to one's own thoughts and feelings, a capacity to decenter and distinguish between projection and introjection and a capacity for deep introspection. It is, fundamentally, an act of thoughtful, heartfelt imagination whereby understanding of the other is provisional and nonintrusive. Empathy seeks to understand rather than to judge.

Empathic intelligence is more complex than empathy itself but necessarily includes it. Empathic intelligence theorizes how an empathic disposition and associated qualities of enthusiasm, expertise, and capacity for engagement can be enacted in the effective practice of pedagogy. Empathic intelligence articulates aspects of intersubjective and intrasubjective phenomena of pedagogy.

Empathic intelligence is a sustained system of psychic, cognitive, affective, social, and ethical functioning derived from:

- an ability to differentiate self-states from others' states ("who owns what in the interaction");
- an ability to engage in reflective and analogic processing to understand and mobilize a dynamic between thinking and feeling in self and others;
- attunement to the potential integration (or disintegration) of experiences created through that dynamic (recognizing whether learning occurs or not);
- an ability to use mirroring and modeling to good effect; and
- a commitment to the care, well-being, and development of self and others.

In various combinations and with different strengths according to context, these qualities inform the enactment of empathic intelligence. Since these social, emotional, and personal qualities are complex and often subtle in their manifestations, they can be evidenced often in the enthusiasm, capacity to engage, expertise, and empathy of teachers. In a sense, these four qualities provide a shorthand way of thinking about empathic intelligence and recognizing it in professional practice.

It is helpful to conceptualize empathic intelligence as manifest in five behaviors: enthusiasm, expertise, capacity to engage, intelligent caring, and empathy itself. While all these behaviors, and the values and attitudes consistent with them, can help to identify an empathically intelligent educator, it is important to consider them as having some distinctive qualities but sharing in common an informing belief that they function in the service of the other, albeit they can also provide important substance to the professional well-being of their adherents. This is because they are inherently intra/intersubjective behaviors which function in the interpersonal domain of experience and thrive upon mirroring, rigorous self reflection and sensitivity to dynamics.

Enthusiasm

Enthusiasm reflects a sense of inner spiritedness. In a pedagogical context, it can convey pleasure in the act of teaching and influencing, along with pleasure in engaging with students. Such spiritedness can have a positive effect on students, provided it is modeled sensitively and not overwhelmingly. It signals commitment, a sense of purpose and belief in the worth of the persons and enterprise of teaching and learning, which can be emotionally affirming for students and help to engage their attention.

Enthusiasm is easy to recognize in this highly expressive form where the enthusiast is demonstrative physically, and perhaps vocally. In a more subtle form, it can manifest itself

also in quiet concentration upon a task or purpose, or even in a centeredness which can be as captivating to observe as its more demonstrative forms.

Engagement

The skill of engaging others can depend on all kinds of personality factors and even the use or abuse of power and status factors. In this model of empathic intelligence, engagement depends on the ability to create within the other, a justifiable belief in the worth of paying attention to the one seeking the engagement. Experienced writers know the importance of engaging readers in the first couple of paragraphs of a book, mindful that readers are not particularly forgiving or enthralled with writers who fail to draw them into the web of language early on. Surprise, a tone of authority, a description of an interesting time, place, or character, or similar strategies, can work well to keep the reader believing there is something for them in the pages which follow. Similarly, the engaging educator needs to be sophisticated in choosing from a repertoire of strategies, those likely to keep the audience believing in the worth of the engagement. It certainly helps if that expectation of worth in the engagement is honored and fulfilled. Not only does it satisfy the audience, it also provides the engager with positive feedback about the strategies selected, and indeed, about the worth of the enterprise.

Expertise

In teaching and learning, expertise requires a range of educative abilities and qualities (Berliner, 1994, 2002; Bucci, 2003; Hattie, 2003) but particular ones are highlighted here as they relate to empathic intelligence. In the model of empathic intelligence, the expert can mobilize students' imagination and encourage them to look at experience from a number of perspectives in order to hypothesize about cause and effect.

The expert educator is theoretically informed about professional practices and discipline content. This includes understanding child development and the nature of learning. Such educators understand that learning occurs in complex ways and progress is not always straightforward or easily discernible. An expert educator has an expansive repertoire of professional practices, tested and modified through reflection on practice. The expert educator can model best practices and can tolerate own and others' mistakes.

Intelligent Caring

Intelligent caring can identify the right balance between dependency and independence. It offers the other close

attention and sustained engagement, providing an awareness of possible outcomes. It positions the welfare of the other at the heart of the engagement but seeks to mobilize the other's psychic energy, thought, and feeling in constructive ways (Arnold, 2005: 57). It establishes reasonable boundaries to promote autonomy. The function of care in moral development has been extensively theorized (Hoffman, 2000; Noddings, 1984, 1988, 1992).

Empathy and Brain-Based Research

The work of Antonio Damasio (1994, 2000, 2003) provides strong support for the argument here that empathic intelligent teaching mobilizes a dynamic between thought and feeling, recognizing the complementarity of thought and feeling in intellectual and personal development. He argues that human consciousness is actually consciousness of the feeling and experiencing of self.

"Contrary to traditional scientific opinion, feelings are just as cognitive as other percepts" (Damasio, 1994: p. xvii). "(Emotion and feeling) provide the bridge between rational and nonrational processes, between cortical and subcortical structures" (Damasio, 1994: p. 128).

Laboratory work on brain-based research shows that emotion is integral to the processes of reasoning and decision making. As Damasio says,

The neurological evidence simply suggests that selective absence of emotion is a problem. Well-targeted and well-deployed emotion seems to be a support system without which the edifice of reason cannot operate properly. . . . These (results) also made it possible to view emotion as an embodiment of the logic of survival. (Damasio, 2000: 42)

Damasio (1994) illustrates the story of one of his patients, Elliot, whose brain damage affected his normal ability to generate response options to social situation and to consider spontaneously the consequences of particular options. Damasio remarks that when treating Elliott,

I began to think that the cold-bloodedness of Elliot's reasoning prevented him from assigning different values to different options, and made his decision-making landscape hopelessly flat. (Damasio, 1994: 51)

I found myself suffering more when listening to Elliot's stories than Elliot himself seemed to be suffering. In fact, I felt I suffered more than he did just by thinking of those stories. (Damasio, 1994: 44)

Damasio's own philosophical and ethical commitment to both understanding and enhancing the lives of his patients, even those whose mental functioning is very minimal, reflects a professional functioning applicable widely in professional practice. His willingness to engage in a sensitive and feeling way to his patients provided a source of significant scientific insights.

Furthermore, he embodies the capacity to create and to understand a dynamic between thinking and feeling, in a climate of care. The care is characterized as intelligent caring for the well-being of the patient and for the realization of the truth of the situation. It suggests that the phenomena of each individual experience are created uniquely in each particular context. As he remarks,

Were it not for the possibility of sensing body states that are inherently ordained to be painful or pleasurable, there would be no suffering or bliss, no longing or mercy, no tragedy or glory in the human condition. . . . Feelings form the base for what humans have described for millennia as the human soul or spirit. (Damasio, 1994: xvii-xviii)

Steven Rose, a practicing scientist working at the forefront of medical research, provides a similar perspective. He describes his experience of discovering that his feelings interfered with his game of chess, a game which he previously believed involved purely cognitive and logical skills (Rose, 1993: 36). From his scientific work and his reflections upon his own learning experiences, he argues that cognition cannot be divorced from affect, try as one might (Rose, 1993: 36). He continues,

The problems that it (the link between affect and cognition) illuminates are fundamental to my research strategy, just as much as their resolution. However, even today I find myself frequently in danger of forgetting that lesson, though it ought to be fundamental to a strategy for living. (Rose, 1993: 36)

Howard Gardner, arguing for a more complex view of intelligence than commonly prevailed, remarked:

The roots of a sense of self lie in the individual's exploration of his (*sic*) own feelings and in his emerging ability to view his (*sic*) own feelings and experiences in terms of the interpretative schemes and symbol systems provided by the culture. (Gardner, 1983: 294)

Many educators work tacitly in sympathy with these neurological insights but it is affirming and encouraging to professional practice to understand why certain processes are effective. Learning is equally an affective, cognitive, imaginative, and empathic enterprise, and teaching practices need to reflect that. It is important to recognize that it is within the intersubjective and intrasubjective experience of imagined worlds that feeling and reason can psychically engage, deepening one's sense of self and consciousness of others. The empathically intelligent teacher harnesses social and emotional experiences in the service of students' learning.

Glossary

Flow – A state of optimal experience characterized by total absorption in the task at hand; a merging of action and awareness in which the individual loses track of both time and self.

Brief Definition and History

Nearly every educator holds the primary, though often elusive, goal of facilitating students' deep engagement in learning activities. In recent decades, Mihaly Csikszentmihalyi's flow model has advanced our understanding of the experience of deep engagement, as well as the individual and contextual factors that may promote it. The model has implications for both research and practice, and has seen application in fields, including education, psychology, psychiatry, anthropology, and business. This article provides a description and analysis of the flow model, and summarizes the potential and actual applications of flow in education.

Born out of a desire to understand intrinsically motivated activity, flow refers to a state of optimal experience characterized by total absorption in the task at hand; a merging of action and awareness in which the individual loses track of both time and self. The flow state is experientially positive, and out of the flow experience emerges a desire to replicate the experience. The concept of flow was developed nearly four decades ago by psychologist Mihaly Csikszentmihalyi while he was observing students at an elite art school in the United States. In an effort to understand what led individuals to be passionate about their creative pursuits, Csikszentmihalyi observed the students as they worked on their artistic creations. He quickly noted that students often became so engrossed in their work that they would effectively tune out any outside distractions or obligations. Students would lose track of time, missing meetings or mealtimes, working well into the night, apparently sustaining deep levels of both concentration and enjoyment for extended periods. Almost paradoxically, once the painting or sculpture was completed it seemed to lose its value to the student: The creation was often hauled back to a dark corner of the studio where it would sit indefinitely. It became clear that for these art students, the value in art was not to be found in the final product so

much as it was in the process of creating it: once the final brush stroke was applied students rarely took the time to admire their own creation, but instead were eager to get involved in a new project. Csikszentmihalyi came to characterize these experiences as autotelic, where the goal (telos) lies in participation itself (auto). In the nearly four decades that have elapsed since this initial discovery, Csikszentmihalyi and colleagues have studied the flow experience in multiple contexts, and have identified a shared phenomenology in that participants consistently describe optimal states of complete absorption, focus, and enjoyment (for reviews see Csikszentmihalyi, 1990; Nakamura and Csikszentmihalyi, 2002).

The Flow Model and Its Use in the Study of Education

Studies of the flow experience have revealed consistency in the conditions under which these optimal states most often occur. Numerous researchers have confirmed commonalities both in optimal experiences and in their underlying conditions (Csikszentmihalyi, 1975/2000, 1990, 1996; Jackson, 1995, 1996; Massimini and Carli, 1988; Perry, 1999).

The Flow Experience

The optimal state described by individuals is most commonly characterized by: (1) intense concentration on the task at hand; (2) a deep sense of involvement and merging of action and awareness; (3) a sense of control over one's actions in dealing with the task at hand; (4) enjoyment or interest in the activity; and (5) a distorted sense of time (usually that time has passed very quickly). During the process of gathering these descriptions, several interviewees described themselves as being in flow or flowing. Thus, experiences characterized by such descriptions have become known as flow experiences or flow states.

The Flow Conditions

The specific activities from which individuals derive flow experiences vary widely. Interviews with males and females of different ages, classes, and cultural backgrounds have revealed that the flow state can emerge from involvement in a variety of activities, including athletics, performing surgery, tending cattle, haggling in the marketplace, working

on a factory line, reading, and writing. While there is considerable variation in the particular activities that lead people to experience flow, there are a number of phenomenological conditions that are typically present when flow does occur, regardless of the specific activity in which one is engaged. These conditions include: (1) engagement in activity chosen for its own sake – not a necessary, but a facilitative condition; (2) perceived challenges of the task at hand that are relatively high and in balance with one's perceived skills; (3) clear proximal goals that are regarded as important; (4) immediate feedback indicating one's success at meeting these goals; and (5) highly focused, rather than divided or scattered, attention.

Over the years, challenge and skill have emerged as two primary conditions for the flow experience: research has consistently shown that when challenges and skills are relatively high and in balance, the experience of flow likely ensues (Csikszentmihalyi and Csikszentmihalyi, 1988; Csikszentmihalyi, 1990, 1997). The flow model is often depicted by a chart similar to that shown in **Figure 1**. The figure describes four different channels of experience, each defined by the relative relationship between challenge and skill. When challenges and skills are both high, individuals tend to experience flow. Instances marked by high challenges but low skills tend to produce anxiety, while instances marked by low challenges but high skills produce relaxation (or at the extreme, boredom). Finally, instances of low challenges and low skills tend to produce feelings of apathy. Some researchers have further parsed these basic four channels of experience into 8 or even 16 channels (see Massimini and Carli, 1988), but in the interest of simplicity, and to preserve the focus on the flow state, only the more basic model is presented here.

The flow model itself is dynamic and is designed to account for changes in ability and circumstance: as an individual becomes more skilled, a given activity becomes decreasingly challenging, with the result that a person may cease to experience flow. In order to maintain one's

state of flow, the challenges of one's activities must be increased by choosing a more difficult task, setting a higher goal, or otherwise manipulating one's circumstances to bring challenges and skills back into a state of balance. Likewise, an individual may take on a task that is more challenging than one's skills are able to address at the moment, producing a state of anxiety. This anxiety can be relieved either by taking action to rapidly improve one's skills and bring them into alignment with the current challenges, or by adjusting one's activities and/or goals downward, so that the challenges of the activity are more in line with one's current skills. When viewed in an educational context, this dynamic nature of the flow model is similar in many ways to the zone of proximal development (Vygotsky, 1962; Gray and Feldman, 2004).

Some activities by their very nature are structured in such a way that proximal goals and feedback are more salient, challenges can be manipulated to best match one's skills, and distractions are minimized to focus attention. Indeed, there is some evidence that certain activities (e.g., making music and competitive athletics) are more likely than others to produce flow (Csikszentmihalyi, 1990). Nevertheless, flow refers only to a subjective phenomenology, suggesting that what matters most is that these conditions are salient to the individual, not necessarily inherent to the activity itself. Individuals have the capacity to identify challenges in seemingly unchallenging situations, define proximal goals and rules for engagement, and focus attention in such a way as to create the conditions for flow even when such conditions are absent from the task at hand. What is most essential for the experience of flow appears to be one's subjective perception of challenge, skills, goals, feedback, autonomy, and focused attention. Accordingly, numerous investigations have documented the flow state among individuals while doing daily household chores (Csikszentmihalyi, 1990), working in factory jobs (LeFevre, 1988), living in concentration camps (Logan, 1985), and in other situations that might appear on the surface to be counterproductive to the experience of flow (for a review, see Csikszentmihalyi, 1990).

The experience of flow may be related to personal characteristics. Adolescents who are highly optimistic and those with higher self-esteem generally report higher levels of flow than their peers (Schmidt *et al.*, 2007). Adolescent females tend to report more flow than males (Shernoff *et al.*, 2000). Turning specifically to individual characteristics related to flow in classrooms, American 12th graders report more flow in school than 10th graders, ethnic minority students report more flow than white students, and students from lower socioeconomic backgrounds appear to report more flow in school than their more advantaged peers (Shernoff and Schmidt, under review).

The momentary experience of flow is also linked to sustained engagement in tasks. Individuals who experience flow are likely to seek out these optimal experiences again,

Figure 1 Channels of subjective experience.

with the result that they develop commitments to certain tasks or fields of engagement. This phenomenon has been referred to as emergent motivation, because one's desire to continue to pursue an activity emerges from the very experience of engaging in the activity. This perspective has been applied to the study of long-term academic pursuits. For example, Csikszentmihalyi, *et al.* (1993) demonstrated that students who have positive subjective experiences in a particular academic domain demonstrate greater commitment to that domain several years later. Csikszentmihalyi and Schneider (2000) demonstrated similar links between classroom experiences and students' future aspirations.

The Paradox of Flow in Educational Contexts

While the flow model was developed as a model of engagement more generally, it is not difficult to see the numerous applications to academic engagement. Many of the conditions that facilitate flow are present and manipulable in most classroom environments. While most academic activities are not freely chosen, there is some room to offer choice in learning activities. The balance between challenges and skills can certainly be adjusted to promote a state of optimal balance for students. Goal setting and feedback are both regular parts of most classroom settings. Finally, teachers can minimize distractions to promote attention to the task at hand. According to the model, if some or all of these conditions could be facilitated in classrooms, several things would be more likely to occur; students would likely experience flow when engaged in academic tasks, having positive subjective learning experiences. These positive experiences would motivate students to continue their deep engagement in tasks, as they would desire to maintain their positive flow state. As it is a dynamic process that keeps one in a flow state, learning would occur in order to keep one's skills in balance with the ever-increasing challenges presented by the classroom environment. Over time, such engagement would develop into long-term commitments to particular academic endeavors, and ideally, to increased success with related academic tasks.

Research has confirmed that some of the conditions that tend to promote flow are often present in educational settings. Specifically, adolescents experience high levels of challenge and skill more often in school than in any other context of their lives (Csikszentmihalyi, 1990). Recent research in American schools has suggested that while the challenge and skill conditions are often present in schools, students generally do not feel the deep concentration, involvement, and enjoyment that typically follow from these conditions. (Schmidt, *et al.*, 2007) Similar findings were obtained in a study of Italian students (Delle Fave *et al.*, 2002). The context of school is a unique setting in that the flow experience does not seem to follow from these two basic conditions as is the case in other contexts.

It appears to be academic classes, in particular, where the link between the flow conditions and the flow experience fails to exist. Research examining traditional middle and high school classrooms from the perspective of flow theory suggests that the instructional practices that are typically used in classrooms may lack certain other conditions for flow. Most high school students still spend a majority of their classroom time doing individual seatwork or listening to lecture, and while these activities may present significant challenges in which children can apply their skills, they tend not to be very involving for students (Shernoff, *et al.*, 2003).

Turner and colleagues (1998), similarly, have argued that specific instructional practices may promote flow experiences more often than others. They found that middle school students experienced the most flow when their teachers provided more scaffolded instruction (thus manipulating the balance of challenge and skill) and when they used instructional practices that fostered intrinsic motivation, such as providing choices and taking interests of students into account. The problem is that at the middle and high school level, the practices that produce the flow experience tend to be few and far between.

Schweinle, *et al.* (2006) provide further explanation for this disconnect between the flow conditions and the experience of flow in classrooms. In a study of elementary school mathematics classes, the researchers found that activities generally perceived by students to be challenging, were largely viewed as a threat to students' self-efficacy and were not seen as an opportunity to develop new skills. The authors speculate that children in elementary grades may have a different and more negative definition of challenge than older individuals. It may not be until individuals are older that they can view challenges more positively, after they have experienced the opportunities that optimal challenges can provide.

These studies suggest that while challenges and skills are often present, some of the other conditions for flow tend to be lacking in classrooms. Conditions for the flow experience also include: recall that focused attention, clear short-term goals, and the feeling that one is engaged in an activity that is freely chosen. Arguably, many traditional classroom environments might be characterized as places where students have little choice about their learning activities, and where the focus is on longer-term goals (e.g., completing the assignment, getting a good grade) rather than short-term goals (e.g., completing one small step at a time). In addition, a bustling classroom where students shift their attention from subject to subject after only a short period of engagement may not be the ideal place to promote focused attention. Indeed, there is some empirical evidence that in the rare cases where these additional conditions are present in classrooms, the flow experience is more likely to occur (Shernoff *et al.*, 2003, Schmidt *et al.*, 2007).

There are certain settings that do appear to consistently promote flow. When in nonacademic classes like fine arts or music, students experience greater levels of flow than in almost any other context, inside or outside of school (Schmidt, *et al.*, 2007). Similarly, in those relatively rare instances where students are involved in more hands-on, collaborative work in their academic classrooms, the experience of flow is more frequent (Shernoff *et al.*, 2003). Given that the flow state is more likely when students are engaged in these active learning environments, it is not surprising that students in nontraditional learning environments that emphasize active learning tend to experience more flow. Rathunde and Csikszentmihalyi (2005a, 2005b) compared the experience of students in traditional public middle schools to students in a Montessori school. While students in the two school types did not differ from one another in their subjective experience of nonschool activities, their experience of school was very different in that Montessori students experienced flow much more often than students in a traditional school. In 2004, Johnson obtained similar results in a study that compared the experience of students in a traditional American high school with that of students in an alternative high school with greater emphasis on student autonomy.

Andersen (2004, 2005a, 2005b, 2007) has conducted comparative studies in several Scandinavian countries and in Japan in which he observed classrooms and interviewed students about their flow experiences. Primary-grade students in Denmark experience particularly high levels of flow in school compared to students in other countries. These findings may be due to an emphasis on student autonomy, interest, and an appropriate balance between teacher-led and student-led learning activities (Andersen, 2004). These observations are consistent with the findings discussed earlier in which challenge and skill alone appear to be insufficient to produce flow in school contexts. Autonomy and control appear to be particularly critical conditions for fostering flow in school. It is important to note, however, that although Danish students were by far the most engaged in school, they lagged behind students from other countries (specifically Finland) in their performance of basic academic skills (Andersen, 2005a). These results suggest that schools should be warned against promoting engagement in school at the expense of demanding competence when it comes to basic skills.

Anderson's (2005b) work in Japan has identified several elementary schools and afternoon programs that are specifically designed to promote optimal learning among students. Central to these programs is a collaborative learning environment in which both students and teachers are expected to learn and develop through the use of computer-based activities and other advanced problem-solving activities. Classroom activities require frequent changes not only in activity, but also in students' physical

placement in the room, moving from group discussions, to hands-on projects, to teacher lecture-discussions, to computer sessions, all focused on the same subject matter. Andersen reports that students who participate in these programs not only experience a high degree of flow, but also develop deep understanding of the academic material. Unlike the Scandinavian programs studied, these Japanese programs have achieved a balance between the promotion of engagement and focus on learning outcomes.

Putting Flow theory into Practice: The Key School

While researchers have been able to identify those moments when students experience flow in school and link them to specific personal characteristics, instructional practices, or academic programs, most of the work presented thus far does not represent intentional application of flow theory *per se*. However, there are individual teachers, and indeed entire schools or school programs that have done substantial work to incorporate the conditions for flow into their learning environments. One of the longest-standing and most successful models of this is the Key Learning Community in Indianapolis, Indiana in the United States. The Key School is a magnet school that is part of the Indianapolis Public School System. Begun in 1987 as an elementary school, Key now serves elementary, middle, and high school students on two separate campuses. From its inception, the school has been structured to promote flow and intrinsically motivated behavior among its students. This mission has been carried out in several ways, including the development of courses and curricula that place equal emphasis on Gardner's (1993) multiple intelligences.

Perhaps the most intriguing application of flow theory has been the school's Flow Center. Students are scheduled to spend time in the Flow Center each week, just as they would spend time in any other class. The purpose of the center is to provide students with the opportunity to experience flow, so that they may recognize the positive nature of this state and be motivated to seek it out in their other scholastic activities. Knowing that many of the conditions for flow are themselves highly individual and subjective, the designers of the Flow Center recognize that the flow experience simply cannot be created for all students in a classroom context by the manipulation of activities or expectations by some external person (usually the teacher). What is more valuable then is to provide students with the tools to create flow for themselves, so that they can facilitate their own flow in a variety of environments. In order to help students experience flow, the Flow Center is equipped with a variety of games, puzzles and challenging activities for students to engage in. Students are free to choose their own activities in the Flow Center on the one condition that

the time spent in there is not treated as recess or downtime but is intended for problem-solving activities. The mission of the flow room is to help students realize that they can become deeply engaged in activities that are educational, and that the same processes they used in the flow room (whatever they are) can be applied in other areas of their studies (see Whalen and Csikszentmihalyi, 1991 for further description).

Evidence suggests that these modifications in the school environment translate into academic success. In addition to an uncommon sense of excitement about learning observed by visitors to the school, more standard measures point to success as well. Standardized test scores for students at the elementary and high school level are consistently higher than those of students at other schools in the district, though it is important to note that the high school program has existed only a short time, with the first students graduating in 2003. While only time will reveal the long-term success of these students, all initial indications are positive. In the years for which data are available, the school posts graduation rates at or near 100%, with the vast majority of graduates pursuing postsecondary education.

Looking Back, Looking Ahead

An examination of students' educational experience from the perspective of flow theory is informative to both researchers and educators in that it helps us understand the personal and situational factors that promote students' deep engagement in learning. There is enormous potential for students to experience flow in schools, but this potential is often thwarted because some key conditions for flow are largely missing from many of today's classrooms. While students generally experience two of the main conditions in that they are using their skills to address increased levels of challenges in the classroom, they often fail to experience flow. This may be because school environments generally offer few opportunities for choice. Moreover, the goals and feedback in classrooms may be focused on a target that is less immediate than the goals that are usually salient in flow experiences. Finally, classrooms may need to be structured in a way that helps students focus their attention on the tasks at hand.

Most encouraging is the fact that flow is consistently observed in a number of unique school contexts. Students often feel flow in their nonacademic classes, most of which provide a number of flow conditions like choice, autonomy, and focus that are typically absent in academic subjects. Likewise, students tend to experience flow when engaged in hands-on learning tasks. Additionally, a number of non-traditional schools and school programs are very successful in facilitating flow among their students – this appears to

be attributable to greater focus on many of the conditions that produce flow. Teachers interested in increasing their students' engagement in classrooms may learn a lot by examining the structure of nonacademic classes, as well as the nontraditional programs mentioned here, to take some cues about how to create more of the conditions for flow in students' everyday experience.

Looking to the future of research on flow in education, there is still much work to be done. First, more research needs to be done linking the experience of flow in academic pursuits with a variety of learning outcomes, as the few studies that have addressed this issue have produced mixed results. Future research must further examine the nature of links between the experience of flow and specific learning outcomes. Additionally, more research is needed to understand the link between flow in a given subject area, and long-term commitment to that field.

Second, relatively little work has been done to examine the role of flow in learning environments beyond the classroom. One emerging application of flow theory in education concerns the use of computers and video games. Children and adolescents frequently experience flow when engaged in video and computer games (Bassi and Delle Fave, 2004). In recent years, researchers and educators alike have attempted to use the appeal of videogames to construct interactive computer technology for learning. A growing body of evidence suggests not only that these e-learning environments can be intensely engaging, but also that such engagement is linked to a variety of positive learning outcomes (Coller and Shernoff, 2006; Pearce, 2005; see Scoresby and Shelton, 2007 for a review). An examination of the e-learning experience from the perspective of flow theory will assist in the understanding and design of these increasingly used educational tools. Likewise, researchers should continue to examine the role of flow as it relates to learning in other extracurricular environments.

Third, the vast majority of research on flow in education has involved children and adolescents. While the experience of flow appears to be consistent across age groups, it is possible that certain conditions for flow, similar to challenge or autonomy, might be differentially salient to learners of different ages. Thus, examining a broader age range of learners, including adults, would be informative. In general, research on flow in schools should take into consideration the developmental stage of the students under investigation.

Finally, we must not forget that teachers play a key role in educational processes – an examination of teachers from the perspective of flow theory would be informative as well. Dissertation work by Di Bianca, in 2000, suggests that when teachers report the most flow, students generally report the least. In other words, those moments that are most engaging to teachers are least engaging to students. Further research is needed to corroborate and explain these findings.

The flow model and related research provides a solid base of knowledge regarding how students might become more engaged in their learning and how they feel when they are so engaged. This knowledge base is of practical use to educators interested in increasing student engagement. There is, however, much work remaining to be done in this field in order to more fully understand the complexities of flow's role in educational processes.

Glossary

Avatar/animated pedagogical agent – An agent within a computer game or simulation; in game environments avatars are usually the players game character; in learning software animated pedagogical agents are humanoid assistants or animated characters who facilitate learning.

Deep processing strategies – Processing strategies that require transformation and elaboration of learning material; require more processing effort than strategies relying solely on rote memory or surface processing.

Engagement – Connection and involvement; used to denote active, positive connection with schooling; task engagement; school engagement; distinctions made between behavioural, cognitive and affective engagement.

Mastery achievement goals – Learning goals where the purpose is to improve skills, achieve understanding, or expand competencies; cf, performance achievement goals.

Seductive details – Task information or details that students find highly interesting but which is not part of the important information content of a task.

Seeking system – An evolutionary emotional brain system that gears the animal for goal seeking action including exploration and information seeking; interest is an expression of this system (see Panksepp, 2000).

Self-regulated learning – Learning that is controlled and regulated by the learner; a self-regulated learner has clear learning goals, monitors progress toward achievement of their goals, and reflects on the quality of their own learning achievements.

Trait curiosity – Curiosity from the perspective of an individual disposition or personality trait; distinguishing between individuals on the basis of their typical style of reaction to novel and puzzling phenomena; cf, state curiosity.

A couple of years prior to the publication of the last volume of the encyclopedia, Suzanne Hidi published a seminal paper describing interest as a mental resource for learning (Hidi, 1990). Although Hidi was not the only person writing about interest at that time, her paper struck a chord in the educational community and is widely cited.

Two complementary perspectives on interest were identified and this distinction has formed the basis for most of the research and thinking on the nature of interest and the role it plays in learning and development. Hidi's review article was followed up in 1992 with a volume that presented a collection of the major writers and researchers who were addressing the issue of interest and its contribution to learning (Renninger *et al.*, 1992). Another significant feature of this volume was the bringing together of researchers from around the world. The work emanating from the school of German researchers (Hans Schiefelé and Erhardt Todt) with their person-object (POI) model of interest was presented alongside work that had been growing in the US and Canada. What followed has been an intense research focus on the characteristics of interest and its role in learning.

Interestingly, the resurgence in attention to the role of interest in learning and development claimed heritage from Dewey's writings in the early twentieth century. For example, in *Interest and Effort in Education* Dewey wrote: "the root idea of the term seems to be that of being engaged, engrossed, or entirely taken up with some activity because of its recognized worth" (1913 cited Boydston, 1979, p. 160); another work referred to interest as the "vital union between the student and his study" (p. 253). Berlyne's work in the 1940s and 1950s was another important influence on the development of ways of thinking about interest. Berlyne defined three ways in which the term interest was used in psychology: a state of the organism, a quality of the stimulus, and a relation between organism and stimulus (Berlyne, 1949). As will become clear, each of these has in some way influenced current thinking. We will consider current perspectives on interest by focusing on the three most widely used perspectives; interest as psychological state, situational interest, and individual interest.

The Character of Interest

What exactly does interest mean? One of the simplest ways to represent the range of usage of interest terminology is to look at the level of generality in the behavior mentioned. At the most specific level, interest refers to a psychological state in which attention is focused on a particular object or event. For example, a student has her gaze fixed in concentrated attention on a computer screen where she has just discovered a website showing the first images of a newly discovered planet. Close observation reveals that

she is absorbed by what is in front of her and as we watch she continues to explore the website and other images of the planet, ignoring the conversation of her friends at the next table. In this example, we are witnessing interest as a state and this phenomenon raises a number of questions that contemporary research programs are addressing. What specific processes are involved? What function does it serve in learning and achievement?

Interest as State

The state of interest has been shown to involve positive affect. There is still some debate over whether this state of positive affect is an emotion. Some current neuropsychological theories of emotion suggest that interest is the information-seeking strand of a basic seeking system (Panksepp, 2000). We know that positive affect is an important element in the state of interest and that it may also be accompanied by other feelings which are not necessarily positive. For instance, most people can appreciate the mix of positive and negative affect associated with students watching their first animal dissection in biology classes. The state of interest is predictive of persistence, exploratory, or information-seeking activity, and has been shown to be associated with knowledge acquisition and performance. Interest is a dynamic state and so can be expected to change over relatively short periods of time. Students' persistence with curriculum tasks often depends on whether the task sustains interest. When interest in a task is sustained or even increased, students are more likely to persist with the task and show higher levels of learning and performance.

Situational Interest

Shifting the lens slightly directs the focus to the character of interest as determined by sources or factors that trigger interest. Specific kinds of events or contextual factors can trigger a state of interest and, when triggered in this way, interest has been referred to as situational interest. The young female student described above happened upon the planet images by chance. She was searching for a site on the Internet featuring a popular music group and happened to click on the planet link by chance. Immediately, her attention was caught by the colorful swirls of the orbiting planet and she investigated it further. Her interest in the planet is appropriately described as situational interest.

Situational interest can be triggered by a wide range of environmental events. Physical properties of an event, such as change, novelty, ambiguity, and uncertainty, have all been linked with the triggering of situational interest. This fact has often been used in educational settings to engage students with curriculum tasks. It is clear from a large number of research findings that interactive

computers and digital information can be used to trigger situational interest in a variety of tasks for a wide range of students. In relation to learning and development, the problem then becomes one of holding or sustaining students' interest so that they engage with the learning content. There is no doubt that the new medium captures interest of the students. However, very often that interest rapidly wanes, and often disappears when what follows does not match the enticing first impressions. The interest triggered by the swirling color and movement of the planet in orbit is likely to dissipate if our student is reminded of her intention to find the music group's website.

A substantial proportion of the research on situational interest has investigated the influence of interest on reading text. General findings provide clear evidence of a significant effect of interest on performance indicators, for example, comprehension and recall of text information. It is also well documented that interest affects deeper processing as shown by scores on learning measures that require processes such as elaboration, transfer, or application of information to a new setting. These effects imply that techniques for increasing situational interest might be employed to improve learning outcomes. There are a number of text features that can be used to influence situational interest. Structural features of the text, such as novelty, coherence, ease of comprehension, and vividness, can be modified to increase interest. At an individual level, personally meaningful or valued content can be used to increase interest, while at the broader group level, themes of universal personal significance (e.g., life, death, or sex), sometimes referred to as absolute interests, have predictable effects on interest (Schraw and Lehman, 2001; Wade, 2001).

While providing some guidance for teachers, there are also some cautions to be heeded. When not connected to the important informational content of the text these themes may take on the character of seductive details. Rather than improving performance they may interfere with it by diverting attention away from significant text themes and meaning. It is when interest and important text elements coincide that interest has a positive influence on learning. Similar findings have been reported in other learning domains, for example, learning from science texts and learning with multimedia resources.

Individual Interest

At a more general behavioral level, personal or individual interests have been identified as an important type of interest that influences students' learning. Individual interests are predispositions or trait-like personal organizations that have been developed over time. A topic, a domain, a school subject, or a type of activity, may each become the object or content of an individual interest. For example, a second young student has also landed on the website displaying the first images of the new planet. He also

shows the unmistakable signs of experiencing interest; his demeanor leaves no doubt that he is enjoying what he is seeing. His attention is concentrated on the screen and he looks as if he will be glued to that website for some time. However, the interest being observed in this student is different from that of the young girl who discovered the planet images by accident. This student came to the site with a well-developed interest in astronomy. He had heard that the images of the new planet had just been released and was eager to check them out. From as early as 6 years of age, he was attracted to pictures of planets, has learnt their names, and details of their composition and orbits. Hence, although displaying a similar state in response to the images of the new planet, his interest is different. He is seeking different kinds of information about the new planet, information that will expand his already well-developed knowledge of the universe. Hence, the characteristics of individual interest, sometimes referred to as personal interest, are that there is a well-developed personal organization of knowledge, value, and affect. Our astronomy enthusiast has a well-structured core of knowledge about the domain. The subject is important to him and his feelings, when pursuing his interest, are likely to include some or all of fascination, excitement, enjoyment, surprise, wonder, and delight.

Clearly, when the object of interest is a school domain or has close links with a school domain, problems of motivation and engagement or problems with achievement outcomes are likely to be minimal. But by the same token, when individual interest in school domains is lacking or is lower than required for effective learning, this is soon reflected in low achievement levels and lack of motivation. It is well documented that in many developed countries significant numbers of young adolescent students are showing low interest in schooling domains. Awareness of this problem has prompted questions concerning the development of individual interest which will be taken up in a later section.

Vocational Interests

One form of interest, not yet considered in this article, concerns interest at a level more general than individual interest – generic interests. These interests are the broad personal organizations of preferences for types of activities and experiences that constitute vocational interests. Vocational interests are generally treated as personality traits. They can be observed in children's preferences early in their schooling and function as organizing themes in the way children and adolescents react to new situations, to people and to tasks (Betz and Borgen, 2000). Holland's classification of vocational interests into realistic, investigative, artistic, social, enterprising, and conventional (RIASEC) themes is used in a wide range of research and in practical settings as a model of vocational

interests. In the same way that individual interests develop through experience over time, it has been proposed that vocational interests are based on two main forms of self-perceptions that accrue over time. These are individuals' self-perceptions of efficacy or confidence in relation to pursuing tasks and activities, and their perceptions of the likely outcomes of those tasks and activities. Schooling experiences at all levels contribute to and consolidate students' vocational interests.

Development of Interest

How interest in schooling domains develops is central to educational philosophy and practice. If interest, in any or all of its forms, is a key component of learning as our review suggests, then understanding the factors that initiate and support the development of interest are essential for successful educational outcomes. This question has come to prominence recently and a number of models of interest development have been proposed. All emphasize an important role of experience in supporting the development of interest. Hidi and Renninger (2006) have proposed a four-phase model of interest development that identifies a sequence which begins with the triggering of situational interest by a specific feature of the environment. When this or similar experiences occur a number of times, the situational interest is maintained or strengthened. External support, for example in the form of teacher encouragement, is important at this stage of interest development. Further experiences over time strengthen and deepen the intrapersonal organization of thinking and feelings associated with the activity. By now, a wider range of similar activities or even a broader domain has become the content of the interest. It has progressed through phases of being an emergent individual interest to being a well-developed individual interest with stronger and deeper knowledge, value, and feeling components. Although still responsive to external support, it is not essential at this stage. If we go back to the two students who were observing planet images on the computer screen, we can locate them at different positions in their development of an interest in the solar system. The young girl who happened on the planet images by chance would be identified as being at the earliest phase, a triggered situational interest. This may be the start of a new interest or it may be an event that is never repeated and her interest in the solar system may go no further. On the other hand, the young boy already has a well-developed interest in the solar system and his experience is about consolidating and extending his knowledge within that domain.

A three-stage model of development from situational to individual interest (situational interest, a stabilized situational interest, and an individual interest) based on

the POI theory of interest (Krapp, 2003) has also been advanced. This theory is used to map developmental trajectories of interest, especially in relation to schooling domains and to explore the basis for the typically lower levels of interest in school that occur as students move from childhood to early adolescence.

Gender patterns of interest development have also been investigated. Besides showing specific relationships with school subjects domains, gender patterns of interest have also been shown to influence the way students respond to specific topics within school subjects and to ways that topics are presented. These patterns have important implications for teachers. For example, in physics classes it has been shown that the interest levels of boys and girls are influenced by the way that physics topics are presented. When learning the principles of a pump, girls showed higher levels of interest when the topic was pumping the blood around the human body than when the topic was pumping gas out of the ground (Hoffmann and Haussler, 1998). These findings raise a number of important questions for educators and researchers. What are the limits to this approach? Can all of the physics content that is important in a school curriculum be presented in ways that trigger interest for all students? Can interest triggered in this way provide the basis for the development of individual interest in physics, sufficient to sustain further exploration and involvement with a wide range of physics concepts and topics?

Yet, another perspective on interest development focuses on its contribution to knowledge acquisition and the development of expertise in specific domains. Alexander (2004) links situational and individual interest to different stages in a model of domain learning (MDL) that describes the trajectory from novice to expert. At the novice stage, situational interest supports knowledge and skill acquisition. However, later in the knowledge-development sequence individual interest in conjunction with deep-processing strategies is more likely to support development of skill and expertise.

These models signal the potential of interest theory and research to contribute to understanding how students learn and to identify how teachers might use their understanding of interest processes to support and deepen students' learning.

Interest and Related Motivational Concepts

Interest is only one of a number of motivational concepts currently being researched and some comment is needed on the place of interest among motivation concepts. Most commonly, interest is grouped with concepts such as engagement, curiosity, flow, and intrinsic motivation. All refer in some way to students becoming involved

with an activity such that they are focused on the task or activity for its own sake rather than simply as a means to some other end outside of the task. In education, the contrast is drawn between interest in the activity (intrinsic motivation) and working on the activity to achieve some external end, such as a high grade, or to receive some form of praise (extrinsic motivation). One significant direction in contemporary thinking on motivation is the articulation of how these concepts contribute to self-regulated learning. Hence, an important question in relation to interest is an understanding of how it is related to the many processes that contribute to adaptive, self-regulated learning.

Self-regulated learning has been defined in terms of the processes whereby personal learning goals are translated into action. While there are a number of specific models of self-regulated learning, they all imply a sequence from activation and task planning, to monitoring and control of on-task behavior, and finally reflective evaluation of task outcomes. Interest, whether considered from the perspective of on-task state, situational interest or individual interest, plays an important role in the sequence of processing, that is, self-regulated learning.

At the task level, the general pattern emerging is that positive orientations to learning (e.g., trait curiosity, mastery achievement goals, or individual interest in a cognate domain) make it more likely that the new task will trigger student's interest. Once interest has been triggered it is then more likely that students' will experience positive affect, will choose to persist with the task, and are more likely to use deep-processing strategies. Another self-regulatory variable that has been shown to be closely linked with the triggering of interest is self-efficacy. When students feel confident about their ability to perform the task, they are more likely to have their interest triggered.

Similar patterns of association have been shown when the research is focusing on individual interest. For example, in college students mastery achievement goals have been shown to be associated with higher levels of individual interest in the subject and this in turn is associated with further participation by choosing courses within that domain. Hence, individual interest is an important component in student engagement over extended time intervals or students' continued participation with the domain content.

Yet, another aspect of the self-regulatory function of interest is operating when students actively make a boring task interesting. It has been shown that when students are committed to continuing with a boring task, they will find ways of making the tasks interesting and in this way regulate their task motivation (Sansone and Thoman, 2005). In the next few years, investigations of exactly how these variables combine to produce effective self-regulated learning will expand our current understanding of ways to support and enhance student learning.

Measurement of Interest

In interest research, as with many areas of educational processes, there is a great reliance on questionnaire measures and this is likely to continue to be an appropriate way to measure individual interest and vocational interests. However, recent developments especially in the measurement of the state of interest are capitalizing on the potential of interactive computer technologies in innovative ways. For example, measures inserted into a task requiring a quick response and minimal interruption to the flow of the task are being used to monitor how the state of interest changes across a task. Using these techniques with reading tasks, it has been demonstrated that gender interacts with text topic to influence whether interest is maintained or extinguished across the course of reading passages of narrative and expository text. Using interactive technologies, complex problem scenarios from domains such as mathematics, social issues, and biology, have been used to identify complex relationships between sets of motivational characteristics (including interest) and to determine how they function in sequences of task behavior connecting persistence, processing strategies, and performance. Simultaneously, these new technologies are also being investigated as a medium for learning and their impact on students' interest in their learning is one of the important factors being addressed.

Educational Technologies and Interest

Part of the appeal of using modern informational technologies as an instructional medium is the often reported observation that students find this medium, more interesting. The assumption is then that students will learn more effectively using modern information technology than when using more traditional media. This assumption has been tested in research comparing information technology and more traditional instructional media (e.g., textbooks) and a number of important findings have been reported. There is no doubt that many of the features of multimedia presentations that are possible by using the latest information technology trigger student interest. Complex combinations of color, movement, and sound have a powerful effect on students. Interest is triggered and in the same way as our earlier student had her interest triggered by the color and movement of the planet images, instructional materials that make use of the potential of new information technologies have a ready audience. At one level, the state of interest is a response to novelty. Interest is triggered and the students' attention is focused on the novel event. However, this effect is short lived and the student is then prey to the next novel event that triggers their interest.

It has been widely shown that students will engage further with the instructional content, that is, their interest will be sustained if what follows the initial novel experience is personally meaningful. However, what is personally meaningful will vary according to the age and experience of students. Instructional content that builds on students' personal or individual interests is likely to sustain the interest initially triggered by the novel medium. As with the research on student interest and text learning, the introduction of seductive details into the multimedia instructional content to hold interest has a harmful rather than beneficial effect on learning. Using scientific text material supported with graphics, it has been demonstrated that seductive details function by diverting the reader. Seductive details prime the student by bringing to mind prior knowledge that is not the main content of the task which then guides selection and organization of new content. In this way, important content is likely to be overlooked (Harp and Mayer, 1998).

On the other hand, some features of new technologies have the potential to improve learning through their effects on student interest. For example, instructional systems have incorporated social agents (referred to as avatars or animated pedagogical agents) who support students' learning. When students reach a plateau in their problem solving, the social agent becomes active and through utterances and/or actions they provide scaffolds for the student's learning. One of the ways this facilitation effect operates is through an increase in students' interest in the task (Moreno *et al.*, 2000). With the rapid expansion in use of information technology, the role of interest as one of the important processes underlying the effectiveness of these technologies in student learning will be a priority question for further investigation.

The Next Decades of Interest Research

The relationship between interest and academic achievement has been referred to a number of times in this article. Although there is variability across studies using different learning domains, different students, and different schooling levels, interest typically accounts for approximately 10–15% of the variation in achievement. It is also clear that interest is associated with deeper processing. As has already been suggested, the next decades are likely to see increased attention on the ways that interest processes combine with other motivational variables to contribute to effective self-regulated learning. In addition, modern information technologies will continue to expand our knowledge of how interest processes can support students' learning as well as being an important tool for learning.

Intrinsic and Extrinsic Motivation

C Levesque, K J Copeland, and M D Pattie, Missouri State University, Springfield, MO, USA
E L Deci, University of Rochester, Rochester, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Individuals are motivated for different reasons. Throughout the day, and over a lifetime, individuals act and behave differently depending on the circumstances surrounding their decisions. One who feels supported in an educational environment might feel satisfied and challenged with a difficult class project. On the other hand, one who feels controlled in an educational setting might consequently miss a lot of classes and appear disengaged while in class. When one feels supported and engaged, positive forms of motivation such as intrinsic motivation are likely to be sustained. In a supportive context, individuals are more likely to value what they do and feel satisfied while doing the activity. In contrast, when one feels controlled and pressured, negative forms of motivation such as external regulation are likely to be triggered. In a controlling context, individuals are more likely to do only what they are told and feel dissatisfied and disengaged while doing so.

The difference between intrinsic and extrinsic motivation is a well-known dichotomy between motivational types that has been discussed in the psychology literature for almost four decades. The following examples illustrate this dichotomy. Tommy likes reading, and he reads every chance he gets. His room is filled with books! Tommy's parents encourage his reading and get involved whenever they can. On the other hand, Melanie does not like to read, and she only does so when she is forced by her teacher and parents to read for an upcoming book report. The difference in their environments fosters different types of motivation which supports different learning outcomes.

Intrinsic Motivation

Intrinsic motivation is the most self-determined, or autonomous, form of motivation. It underlies activities that are performed purely for the joy gained from the activities themselves. In other words, individuals who are intrinsically motivated choose to engage in activities solely for the pleasure, interest, enjoyment, and satisfaction derived from performing those very activities. A child who plays with construction blocks for hours at a time, fully absorbed in the process of building towers and houses, is intrinsically motivated toward that activity (Deci, 1971, 1975). He does not do it in order to gain something from it, but only for the simple, pure pleasure of the activity itself.

deCharms's (1968) notion of perceived locus of causality speaks directly to the autonomous nature of intrinsic

motivation as it describes the tendency of individuals to be motivated to feel like they are at the origin of their behaviors. That is, individuals want to perceive themselves as choosing to perform behaviors out of their own volition. For example, students are more likely to feel like the behavior originated from within if they were encouraged to develop their projects and worked on them at their own pace. In contrast, students are more likely to feel their behavior is controlled if a certain project topic were imposed upon them with a very strict deadline. deCharms' concept of perceived locus of causality is, furthermore, linked to the basic psychological need for autonomy discussed in self-determination theory (SDT) (Deci and Ryan, 1985, 2000). The need for autonomy does not signify independence. Autonomy signifies choice and volition. The need for autonomy is satisfied when individuals feel they have choice and volition while engaging in a particular behavior. The need for autonomy underlies the development of intrinsic motivation.

Another basic need that supports intrinsic motivation is the need for competence. The concept of competence derives from White's (1959) assertion that people often engage in activities simply because they want to experience themselves as competent or efficacious. This is linked to the basic psychological need for competence as described in the SDT (Deci and Ryan, 1985, 2000). The need for competence is satisfied when individuals feel like they are developing skills and mastering the activities they are performing.

The satisfaction of the basic psychological needs for autonomy and competence are instrumental for the maintenance and enhancement of intrinsic motivation. Environments that provide support for competence and autonomy will foster intrinsic motivation. For example, a classroom environment that encourages students to become involved in how they will learn new materials and that provides them with the opportunity to frequently experience small successes will foster intrinsic motivation. In contrast, a classroom environment that is dictated, and, therefore, does not provide support for autonomy and competence will diminish intrinsic motivation and not encourage student involvement. The provision of rewards has been found to decrease an individual's level of intrinsic motivation when the rewards are salient and given for performing an activity that the individual finds interesting. This is the case because rewards are usually seen as an attempt to control one's behavior, thus jeopardizing one's sense of autonomy. Take

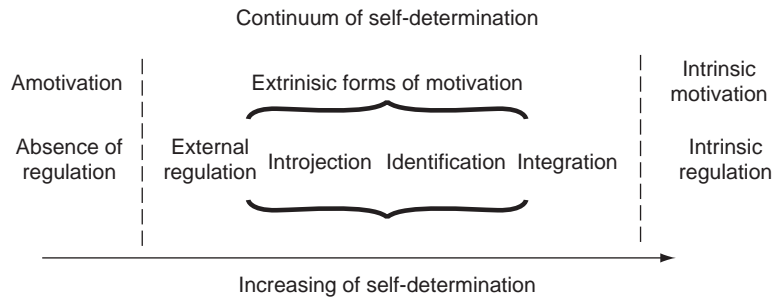

Figure 1 Visual representation of the self-determination continuum.

for example 6-year-old Lisa who really likes to read *The Cat in the Hat* book. Just to showcase her reading skills at the next family reunion, Aunt Sally begins to give money to Lisa for reading the book to family and friends. After a few family reunions and a few dollars spent, Lisa does not want to read *The Cat in the Hat* on her own anymore. She will only read it if she is given money for doing so. This is a book that Lisa used to enjoy reading, on her own, without any external incentives. In other words, she was intrinsically motivated toward reading the book. From a motivational perspective, the provision of the reward for doing an enjoyable activity shifted the perceived locus of causality from internal to external, making Lisa feel less autonomous about reading the book – feeling less like an originator of her behavior. Lisa is no longer doing the activity because she enjoys it but because she wants to obtain the reward. Reading this book is now more extrinsically motivated than intrinsically motivated, and it was her environment that triggered this change.

Extrinsic Motivation

Extrinsic motivation refers to the forms of regulation that underlie activities that are performed as a means to an end. Little Lisa who is now reading *The Cat in the Hat* because she wants the money is extrinsically motivated toward reading that book. A fifth grader who does his homework in order to gain the privilege to go see a movie at his friend's house afterward is extrinsically motivated toward doing his homework. This child is doing homework in order to obtain a reward. The same would be true of a teenage girl who cleans her room in order to avoid losing car privileges over the weekend. She is cleaning her room because she does not want to lose the car for the weekend, not because she just wants to clean and because she enjoys a clean room. Taken as a whole, extrinsically motivated activities are performed to attain a goal, to obtain a reward, or to avoid a penalty or a negative consequence. When extrinsically motivated, individuals perform the activities not because they simply derive enjoyment from them, but because the activities are instrumental in reaching a goal, or avoiding an undesirable outcome or

consequence. The activities may still be valuable to the person engaging in them, but the motivator is not the enjoyment but rather what can be obtained by engaging in the activity.

Although motivation can be dichotomized as intrinsic and extrinsic, SDT (Deci and Ryan, 1985, 2000) further specifies four types of extrinsic motivation. The different types of extrinsic motivation vary in terms of the degree to which they have been internalized and thus are self-determined. **Figure 1** depicts the placement of the four forms of extrinsic motivation and the one form of intrinsic motivation along a continuum of self-determination.

External Regulation

This is the form of motivation commonly referred to as extrinsic motivation, for it involves behaving to obtain a reward or avoid a punishment. This form of extrinsic motivation is the least self-determined and is thus located on the far left end of the continuum. Behaviors that are externally regulated are performed because of pressures, obligations, and constraints coming from external sources. When externally regulated, individuals try to obtain a reward or positive consequence, or they try to avoid some undesirable consequence. Externally regulated behaviors are only performed in the presence of specific external contingencies, such as controlling teachers, strict school requirements, and pressures from peers that are maintaining the behaviors themselves. In the absence of these contingencies, individuals will not remain engaged in the activity, will eventually quit or abandon the activity, or will not be able to persist when the task becomes more difficult. For example, students who show up for an eight o'clock physics test may do so because they do not want to fail the class and are trying to get a good grade on the test. If external regulation is their main motivation for being in class at eight in the morning, many students will not show up for class unless attendance is required or there is a test on a certain day. As constraints, pressures, and rewards shift the perceived locus of causality outside of the individual, external regulation is opposite to intrinsic motivation and consequently not self-determined (Deci *et al.*, 1999).

Introjected Regulation

This underlies behaviors that are performed out of guilt, ego involvement, or other kinds of internal pressures. Similar to external regulation, powerful pressures maintain these behaviors; however, unlike external regulation, the pressures associated with introjection are internal as opposed to external. Introjected regulation is not self-determined because the behaviors are pressured and controlled even though that pressure and control come from an internal source. Individuals who behave mainly out of introjection engage in behaviors because they want to avoid feeling guilty or bad about themselves or because performing the behavior will allow them to aggrandize themselves. For example, a young man is asked to perform in a spelling bee because of how well he would represent the school. Although he does not feel very comfortable with the idea of competing in front of a lot of people, he accepts because he would feel guilty for not participating. He does not want to disappoint his teacher. With introjection, the contingencies maintaining the behaviors have been partially internalized. That is, they are within the person but not fully endorsed by the self. The regulation of the behavior is not yet fully integrated with the individual's motivations, cognitions, and affects into a coherent whole, reflected by the fact that the individual does not really want to perform the activity and does not choose to do it.

Identified Regulation

This exists when the contingencies maintaining a certain behavior become endorsed by the self and the behavior itself becomes valued, thus no longer requiring the specific contingencies. At this point, the behavior is said to be regulated through identification. When individuals are motivated mostly out of identification, they identify with their behaviors, value them, and find them important. The identified regulations are endorsed by the self, which means that although the behaviors are still instrumental in attaining goals (thus still extrinsic), the goals are valued by the individual who identifies with the importance of the activities performed. At this point, the behaviors are considered to be self-determined or autonomous though they are not considered intrinsically motivated. For example, a student might be working on an extracurricular project requiring him to stay after school 3 nights a week. Even though the activity is demanding and might interfere with other things going on at that time, he gladly participates because this extracurricular project is important to him. He does not necessarily find it interesting (and thus not intrinsically motivated) but it is valued.

Integrated Regulation

This is the form of motivation that represents the most self-determined form of extrinsic motivation. When a behavior

is regulated through integration, it is not only valued but also integrated within the self and is in harmony and coherence with other aspects of the self. A graduating senior might talk about her academic experience by discussing the growth she has experienced over the years, the friends she has made, the connections she now has with faculty members, and how all these experiences will benefit her in her chosen career and in becoming the person she aspires to be. The motivation that underlies such statements is a fully self-determined extrinsic motivation. The motivation is still extrinsic because the experiences discussed are in the service of the goal of her future life and career, but these experiences are fully integrated within the self.

By further examining the continuum of self-determination, one can see that intrinsic motivation is located at the far right of the continuum and is also separated from the other types of motivation on the continuum. This is so because intrinsic motivation is inherent to the person rather than resulting from internalization and is based on interest in the activity itself rather than on the importance of the activity for self-selected values and goals. Intrinsic motivation is the prototype of self-determination signifying engagement in activities because the activities themselves are rewarding.

Process of Internalization

Considering the various forms of motivation, including intrinsic and extrinsic motivation, is very useful when trying to explain why someone would behave or act a certain way. Distinctions between the different types of motivation allow researchers to explain a considerable range of human behaviors and experiences. Understanding these various forms of motivation also enables researchers and practitioners to identify antecedents that will foster these different types of motivations and the consequences that may follow these motivated behaviors.

According to SDT, individuals have a natural inclination toward growth and toward integrating the different aspects of the self into a single unified sense of self. The process of internalization is an example of the functioning of this natural movement toward a greater integration of the self and toward more self-determined forms of extrinsic motivation to accompany people's intrinsic motivation. Integration refers to the natural propensity of individuals to take in or internalize the contingencies underlying their behaviors and then to integrate them into their core self.

Antecedents of the Development of Intrinsic and Extrinsic Motivation

Certain social and environmental contexts provide what is essential for the development of self-determination and

intrinsic motivation. In addition to individuals' natural propensity toward internalization, autonomy-supportive settings foster the development of intrinsic motivation. Social and environmental contexts that are autonomy supportive acknowledge people's perspective and provide them with choices and encouragement. Such settings allow self-initiative and provide a rationale for performing requested behaviors. In addition, and very importantly, settings that are autonomy supportive rarely use pressures, controlling strategies, and external contingencies to motivate behaviors; rather, in these settings, empathy for others is frequently expressed and appropriate and timely feedback is offered in order to confirm competence within behaviors or tasks.

Controlling contexts make use of explicitly pressuring and coercive strategies to motivate behavior. For example, these strategies may include salient rewards, competition, deadlines, the threat of punishment, imposed goals, surveillance, and controlling language such as words and phrases like *should*, *have to*, and *ought to* (see Deci *et al.* (1999) for a review). These strategies are most often perceived as controlling because they force individuals to engage in behaviors rather than inviting their engagement. They shift the locus of causality from being perceived as internal to external leading the individual to no longer perceive himself or herself as the causal agent of the behavior.

Environmental factors and social contexts that foster the development of intrinsic motivation and self-determination are also the ones that satisfy the basic psychological needs for autonomy, competence, and relatedness. To be psychologically healthy, individuals must be engaged on a daily basis in activities that contribute to the satisfaction of these three needs.

As mentioned earlier, autonomy signifies choice and volition rather than independence. Autonomy means the endorsement of one's behaviors even though these behaviors might not reflect independence. A girl could decide to get involved in a group project where she will have to share the decision-making power. She will be working with others, not independently, and yet because it is by her own choice, she may feel completely volitional about her decision. In contrast, a boy could feel pressured to study by himself in the library for an important test. Though this behavior would be done independently, he would not want to perform it and would, therefore, not feel a sense of autonomy while doing so.

Competence refers to a sense of mastery. Students need to feel competent while engaged in various academic and nonacademic activities. A sense of competence increases the level of interest and involvement in the activities performed. The need for competence is most likely to be satisfied when students work on developing and mastering skills. An adequate level of challenge, often referred to as an optimal level of challenge, is also necessary in order to

satisfy the need for competence. Again, when this need is satisfied, as when any of the three needs are satisfied, the development of intrinsic motivation and self-determination is furthered.

Relatedness refers to the need to connect with and relate to other people. Students derive a lot of satisfaction from seeing their friends at school everyday, meeting new people, and getting to know their professors. Being with friends in school becomes an important part of going to school and contributes to the extent to which students find school satisfying and enjoyable (Ryan *et al.*, 1994). Furthermore, when students develop healthy relationships with their teachers and other staff members, their productivity and interest level in the classroom improves. This also leads to greater satisfaction and actual enjoyment within a student's academic experience.

Consequences of Intrinsic and Extrinsic Motivation

In general, individuals who behave out of intrinsic motivation or self-determined extrinsic motivation (identification and integration) have been found to experience a greater proportion of positive outcomes with their behaviors. In contrast, individuals who mostly behave out of non-self-determined extrinsic motivation (introjection and external regulation) have been found to experience a much greater proportion of negative outcomes. For example, intrinsic motivation, integration, and identification have been associated with a variety of benefits including academic achievement, school competence, and in general, higher levels of well-being (Boggiano *et al.*, 1993; Levesque *et al.*, 2004; Soenens and Vansteenkiste, 2005). In contrast, introjected regulation and external regulation have been found to lead to a host of negative outcomes including anxiety, burnout, school dropout, and in general, lower levels of well-being and vitality. Paradoxically, the harder the teachers and parents attempt to push students to do their homework, perform well in school, and achieve, the more negative outcomes are experienced without improvements in academic achievement (Deci and Ryan, 2002). By trying to force and push students to perform in school, the opposite results are often obtained. When parents and teachers are autonomy supportive, however, and foster choice and self-determination regarding school-work, students then tend to be more creative, perform better in school, and achieve more academically.

Interplay Between Intrinsic and Extrinsic Motivation

If the movement toward greater internalization and more self-determination is innate, why is it that we do not see

self-determined behaviors to a greater extent in school? A recent meta-analysis summarizing the literature on the effects of rewards on intrinsic motivation highlighted the powerful effects of using rewards to motivate behavior (Deci *et al.*, 1999). Providing rewards for behaviors that are intrinsically motivated or self-determined has been found to undermine the motivation for the activity by shifting the locus of causality outside the self (Deci *et al.*, 1999). To illustrate this process, take the example of Mary, a 5-year-old girl about to begin kindergarten. She has been talking about going to school for the past year, and she is very excited about finally being able to go to school everyday. After her first day at school, she can not stop talking about all the fun games, the school, the teachers, and all that she has done that day. She can't wait to go back! Mary shows intrinsic interest in school for the entire year and is very excited to go back to school and start first grade the following year. However, during that year, something changes. Her teacher begins talking about doing well more often. She makes use of conditional regard in the classroom and has a tendency to compare the students with one another. The teacher offers plenty of rewards for good behaviors and at the beginning of the year instituted a strict behavior-management plan in order to prevent bad behavior in the classroom. Good behavior is rewarded and bad behavior punished. In third grade, Mary is introduced to standardized tests and is constantly reminded by her teacher how important it is to do well on these tests. If asked, Mary would now say that she does not like school and does not want to go anymore. She is afraid and worried on test dates and becomes physically ill sometimes. More generally, the emphasis on standardized tests is perceived as controlling and fosters an external locus of causality, thus the development of non-self-determined extrinsic motivation. The students in Mary's class are criticized when they attempt to find the solution to a problem in a way that differs from the teacher's expectations or the predetermined answer in the textbook. Students in this class feel forced to perform well on assignments and tests, but they do not yet fully understand the concepts they need to apply. As a result, they do not feel comfortable asking questions. They refrain from asking for help because they are afraid they will be perceived negatively. This dynamics will obviously lead to poor performance on assignments and/or tests.

The emphasis on rewards in the traditional school system often works to undermine students' level of intrinsic motivation and self-determination toward school. There is less room for creative activities and exploration because the emphasis is on teaching the standardized tests to the students. The creation of autonomy-supportive learning environments, where choices and options are offered and where creativity is encouraged, would foster the development and maintenance of intrinsic motivation

and self-determination (Levesque *et al.*, 2006). Autonomy supportive environments would enable satisfaction of the needs for autonomy, competence, and relatedness which would then help students to better engage in materials, feel better about themselves, and perform better in the long run (Boggiano *et al.*, 1993; Grolnick *et al.*, 1991). The connection with teachers that is fostered in an autonomy-supportive environment allows students to feel comfortable asking more questions which then leads to overall better performance.

Looking Ahead

There is no doubt that within our education system there is an environment that is inherently restricted by rules and regulations. Grades need to be assigned, skills need to be mastered, and performance needs to meet certain standards of proficiency. However, if the environment in which these constraints are present is consciously crafted to be more autonomy supportive, then intrinsic motivation and self-determination will be more likely to flourish. This in turn will allow students to grow and develop, to reach their potential, and to experience greater levels of well-being (see Vansteenkiste *et al.*, 2006, for a review).

Motivating Students in Classrooms

J Brophy[†]

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article focuses on the challenges facing teachers seeking to motivate their students to learn, along with the strategies they might use for doing so. Research on motivation in education has mushroomed, yielding many principles that are both well grounded in good theory and well supported in empirical research. Unfortunately, most of these are difficult to implement consistently in classrooms, so guidelines for teachers emphasize managing conflicting agendas and achieving the best possible compromise, rather than creating and sustaining the ideal.

Motivation in Classrooms as Expectancy \times Value Reasoning within the Social Context of a Learning Community

Much of what has been learned about motivation can be organized within an expectancy \times value model (Wigfield and Eccles, 2000), which holds that the effort that people are willing to expend on a task is a product of the degree to which they (1) expect to be able to perform the task successfully if they apply themselves and (2) value the task itself or whatever rewards successful task performance will bring. Effort investment reflects the product rather than the sum of the expectancy and value factors because both factors must be present to at least a threshold level. People do not invest in tasks that do not offer enjoyment or valued outcomes, even if they know they can perform the tasks successfully. Nor do they invest in even highly valued tasks if they believe that they cannot succeed, no matter how hard they try.

In addition to their subjective expectancy and value reasoning, students' motivation is affected by their interactions with teachers and classmates. Some classroom climates are supportive of motivation to learn, but others interfere with it. Several recently developed lines of theory and research converge on the conclusion that it is important for teachers to establish their classrooms as collegial learning communities in which students focus on collaborating and supporting one another's learning rather than on self-aggrandizement and competition.

Sociocultural theorists speak of learners as novices undergoing cognitive apprenticeship, under the supervision of mentors, within communities of practice. Everyone

in the community both mentors and learns from others as they collaborate in carrying out the community's activities (Rogoff *et al.*, 2001; Tharp *et al.*, 2000; Wells, 1999). Social constructivist models of learning also depict it as a socially collaborative activity, in which students strive to make sense of new input by relating it to their prior knowledge and collaborating in dialog with their teacher and peers to construct shared understandings (Brophy, 2002; Moll, 1990; Newman *et al.*, 1989). Achievement goal theorists talk about establishing mastery goal structures in classrooms (which focus students on developing knowledge and skills) but avoiding performance goal structures (which encourage students to become more concerned with preserving their self-worth and competing with peers than with mastering the curriculum) (Ames, 1992; Covington, 1992; Ryan and Patrick, 2001; Turner *et al.*, 2002).

These and many other emerging ideas about optimal social contexts in classrooms center around the concept of learning community. Common definitions point to the two key ideas emphasized in the term itself. First, learning implies something more than merely completing academic tasks or even passing tests. School learning is supposed to be enriching and empowering for students, equipping them with important knowledge, skills, values, and dispositions. Second, this learning occurs within a community in which people have social connections and responsibilities toward one another and the group as whole. This implies that the learning will be collaborative as community members encourage and support one another's efforts. Within such a social context, students can feel comfortable asking questions, seeking help, and responding to questions when unsure of the answer because confusion and mistakes are understood as natural parts of the learning process (Baker *et al.*, 1997).

Challenges Facing Teachers in Motivating Students to Learn

Students are motivated to learn when they find classroom lessons and learning activities worthwhile and try to gain the intended learning benefits from them. They may not find these activities pleasurable, exciting, or even interesting, but they engage in them seriously with the intention of pursuing learning goals because they perceive it as worth the effort to do so.

Learning can be enjoyable, but is not fun in the sense that recreational activities are fun. It requires sustained

[†] Deceased

concentration and goal-oriented mastery efforts. In classroom settings, learning situations are complicated in ways that create special motivational challenges for teachers.

First, school attendance is compulsory and the curriculum reflects what society wants students to learn, not what students would choose for themselves. Consequently, teachers often are faced with trying to motivate students to engage in activities they do not value. Second, teachers working with 20 or more students cannot always meet individuals' needs. Some students are often bored while others are often frustrated. Third, classrooms are social settings, so failures often produce not only personal disappointment but also public embarrassment. Fourth, assignments and tests are graded, and reports are sent to parents, which magnifies the consequences of poor performance for struggling students. Finally, teachers and students often settle into familiar routines that become the daily grind. Attention is focused on what must be done to complete activities rather than the knowledge or skills that the activities were designed to develop. Task completion and performance replace motivation and learning as focal concerns (Brophy, 2004).

Expectancy Issues: Supporting Students' Confidence as Learners

The expectancy aspects of motivation involve students' beliefs about their own capabilities. Dweck (1991, 1999) showed that students' engagement in learning activities is affected by their implicit theories about learning ability. Those who subscribe to the entity theory think of ability as a fixed entity over which they have no control, so they are prone to give up and develop helplessness perceptions when they do not succeed easily. In contrast, those who subscribe to the incremental theory believe that ability can be increased incrementally through effort, so they are more likely to persist in their efforts to attain learning goals. Dweck's work implies that teachers should portray learning activities as opportunities to acquire (not just display) knowledge or skill, remind students that mistakes are part of learning, and talk about achieving mastery through successive approximations rather than attaining it quickly and easily.

Weiner (1992, 2001) focused on students' causal attributions – the explanations they generate to explain their successes or failures. Effort and persistence are greater when students attribute their performance to internal and controllable causes. Concerning successful performance, optimal patterns of motivation are associated with attributing success to the combination of sufficient ability and reasonable effort. When students believe that they possessed whatever abilities the task required and were able to meet its demands by applying reasonable effort, they can be confident that they will be

successful on similar tasks in the future. They would have less reason for confidence if they attributed their success to more external, less controllable causes (e.g., the task was easy, I lucked into the solution, I got unexpected help that I probably will not get again).

Concerning unsuccessful performance, effort and persistence are greater when students attribute failures to internal but controllable causes such as insufficient knowledge (of task-relevant information or response strategies) or insufficient effort (they did not prepare or concentrate as much as they should have). These failure attributions enable students to believe that they can improve and ultimately achieve success (by acquiring the needed knowledge or increasing their level of effort). They would have less basis for confidence if they attributed their failures to external causes (e.g., poor textbook or teacher), or worse, to the internal cause of low ability (especially if they had an entity theory of ability). Teachers can encourage productive attributions by portraying learning as acquired gradually through persistent efforts and avoiding any suggestion that failures are due to fixed ability limitations or other factors beyond their students' control.

Self-efficacy perceptions are beliefs in one's capabilities to meet the demands of achievement situations. Students who possess self-efficacy perceptions believe that they can accomplish what the situation calls for, whereas those who lack these perceptions are unsure whether they can succeed or even convinced that they cannot (Bandura, 1997; Bong and Skaalvik, 2003; Pajares, 1996). Teachers can support self-efficacy perceptions by encouraging their students to set specific and challenging but attainable goals, modeling and cueing effective response strategies, providing informative feedback, and helping them to appreciate that they are developing their abilities by accepting challenges and applying consistent effort (Schunk and Ertmer, 2000).

Teachers can support their students' confidence as learners and dispositions to approach learning activities with productive goals and strategies through their approaches to curriculum, instruction, and evaluation.

Curriculum: Program for Success

The simplest way to ensure that students expect success is to make sure that they achieve it consistently. This requires setting tasks at the appropriate level of difficulty (challenging but doable) and then scaffolding their learning efforts through guidance and feedback. Comments on students' progress should stimulate appreciation for their accomplishments to date and imply confidence that they will attain ultimate goals. Both goal setting and feedback are more effective if they focus on the processes or strategies needed to accomplish the task, especially during earlier stages of learning (McNeil and Alibali, 2000; Schunk and Ertmer, 2000; Zimmerman and Kitsantis, 2002).

Instruction: Teach Goal Setting, Performance Appraisal, and Self-Reinforcement

Students may not fully appreciate their accomplishments unless teachers help them to identify and use appropriate evaluation standards. The process begins with setting goals that are proximal rather than distal, specific rather than global, and challenging rather than either too easy or too hard (Locke and Latham, 2002). Students may need help in formulating challenging but reachable goals, especially when perfect performance is unlikely. Richly specified goals help learners to focus on important aspects of the task, motivate their mastery efforts, and empower them with criteria they can use to assess and if necessary adjust their strategies as they work (Page-Voth and Graham, 1999).

In giving feedback, teachers can help students evaluate their performance appropriately, comparing it with absolute standards or their own previous performance rather than with the performance of classmates (Shih and Alexander, 2000). Students who have been empowered with concepts and language needed to evaluate accurately are in a position to reinforce themselves for their successes (that is, attribute them to their willingness to make the needed effort). Students should be taught to think of effort as investment rather than risk: learning may take time and involve confusion or mistakes, but persistence and careful work build knowledge or skills and prepare them to handle more challenging tasks in the future.

Assessment: Emphasize Informative Feedback

Getting and following up productively on informative feedback are integral parts of the learning process, but classroom evaluation and grading systems often undermine students' motivation and learning strategies. If testing and grading are not well matched to everyone's knowledge and skill levels, some students can obtain high grades without exerting much effort and others cannot no matter how hard they try. Assessment information should measure progress toward major instructional goals. Ordinarily, this requires authentic tasks that call for students to integrate and apply what they are learning, not just respond to matching or fill-in-the-blank items (Ames, 1992; Butler, 1987; Crooks, 1988; Wiggins, 1993).

Most motivational researchers advise teachers to include safety nets by allowing failing students to take an alternative test (following a period of review and relearning) or to earn extra credit by producing some product to indicate that they have overcome the deficiencies identified in their test performance. This encourages struggling students to make the extra efforts needed to accomplish the instructional goals (Brophy, 2004).

Certain students become highly anxious and perform considerably below their potential in tests or during any test-like situation in which they are monitored and

evaluated. Several strategies have been developed for minimizing these test anxiety problems: Explain each test's general scope and nature, and how students can best prepare for it; be friendly and encouraging when administering the test; avoid time pressures unless they are truly central to the skill being taught; portray tests as opportunities to assess progress rather than as measures of ability; and teach students effective test-taking skills and attitudes (Hembree, 1988; Hill and Wigfield, 1984; Neveh-Benjamin, 1991; Wigfield and Eccles, 1989; Zeidner, 1998).

Value Issues: Helping Students See Learning Activities as Meaningful and Worthwhile

Whereas the expectancy aspects of motivation surround the question, "Can I do this?", the value aspects surround the question, "Why should I?" Eccles and Wigfield (1985) suggested that subjective task value has four major components: (1) attainment value: the importance of attaining success on the task in order to affirm our self-concept or fulfill our needs for achievement, power, or prestige; (2) intrinsic or interest value: the enjoyment we obtain from engaging in the task; (3) utility value: the role that engaging in the task may play in advancing our career or helping us to reach other larger goals; and (4) cost: the time, effort, and other resources that must be committed to the task, as well as the lost opportunities to devote these resources to other agendas.

Addressing the value aspects of motivation involves inducing students to view their engagement in lessons and learning activities as worthwhile (benefits exceed costs). Traditionally, teachers have been advised to accomplish this either by offering incentives for good performance (extrinsic motivation approach) or by emphasizing content and activities that students find enjoyable (intrinsic motivation approach).

Extrinsic Motivation Approaches

Extrinsic rewards are popular because teachers enjoy giving them and students enjoy receiving them. However, they support motivation to learn only under certain circumstances. First, it is important to deliver rewards in ways that provide students with informative feedback and call attention to significant achievements. This encourages students to apply themselves to their studies because doing so empowers them with knowledge and skills, not just because it can lead to extrinsic rewards (Sansone and Harackiewicz, 2000).

In addition, rewards can act as motivators only for those students who believe that they have a chance to gain them. Opportunity to earn a reward by obtaining a high grade will be motivating to high achievers, but demotivating to

students who have little chance to earn such a grade. Thus, using rewards effectively requires individualized success criteria that allow all students to have comparable access to the rewards. An alternative that avoids this problem is to give rewards only to the class as a whole (“I know that you all put a lot of work into your projects. As a token of my appreciation for your efforts. . .”). Celebrations of everyone’s efforts and progress also are more in keeping with the spirit of a learning community.

Teachers’ praise is another potential source of extrinsic motivation, but again, it is important to deliver it effectively. Students are likely to be motivated by sincere praise delivered privately or through notes on returned assignments, but not by being singled out publicly, especially for things that are not significant achievements (such as sitting up straight and paying attention). Effective praise and encouragement communicate appreciation and informative feedback (not evaluative judgments). They focus on the effort and care that students put into their work, their gains in knowledge or skill, or their achievement’s noteworthy features (meanwhile avoiding attributions of success to high aptitude) (Brophy, 1981; Caffyn, 1989; Henderlong and Lepper, 2002).

Intrinsic Motivation Approaches

The intrinsic motivation approach involves emphasizing content that students are interested in and activities that they enjoy. Interesting activities provide learners with forms of input or opportunities for response that they find rewarding and want to pursue (Renninger and Hidi, 2002; Schraw and Lehman, 2001). This may be because the activities are perceived as relevant or useful; are simply enjoyable or sources of fun; provide self-actualization potential by allowing students to feel empowered or creative; are meaningful or satisfying because they allow students to experience new understandings or gain new skills that they value; or provide opportunities for identification or self-projection (as when they identify with the hero of a story). For example, most students enjoy collaborating in pairs or small groups, activities that provide opportunities to use a wide variety of skills (e.g., conducting and reporting research) rather than limiting them to boring repetition (e.g., filling in blanks on a worksheet), and activities that allow them to create a product that they can point to and identify with (e.g., a display or report) (Alleman and Brophy, 1993–94; Askill-Williams and Lawson, 2001).

Other intrinsic motivation approaches involve adapting school content or activities to students’ interests (Renninger, 2000; Schraw *et al.*, 2001). For example, Hidi and Baird (1988) found that interest in texts was enhanced when their main ideas were elaborated through insertions that featured: (1) character identification (information about people with whom the students could identify, such as the inventors whose discoveries led to the knowledge under

study); (2) novelty (content that was new or unusual); (3) life theme (connections to students’ lives outside of school); and (4) activity level (intense activities or strong emotions). Teachers also can stimulate students’ curiosity or whet their anticipation by introducing content in ways that create a need to resolve some ambiguity or obtain more information about the topic, or by asking questions to put students into an information-processing or decision-making mode (Blank and White, 1999; Reeve, 1996).

Teachers’ beliefs about effective motivation strategies emphasize intrinsic approaches: cooperative learning, stimulating tasks, opportunity to make choices, simulations, projects, learning games, relating content to current events, hands-on activities, and personalized content (Hootstein, 1995; Nolen and Nicholls, 1994). However, teachers typically focus on finding enjoyable activities or adding interesting elements to content rather than on helping students to develop appreciation for the content itself (Zahorik, 1996). Hands-on activities will not produce important learning unless they include minds-on features that engage students in thinking about big ideas.

The self-determination theory of Deci and Ryan (1985, 2000) has been a major source of ideas about supporting intrinsic motivation in classrooms. As part of developing their core thesis that in order to experience a sense of well-being, people require social contexts that meet their three basic needs for autonomy, competence, and relatedness, self-determination theorists have been exploring what is involved in creating autonomy-supportive contexts in classrooms. Operating from intrinsic motivation typically involves exercising autonomy and making free choices. In contrast with controlling contexts, which pressure students to think, act, or feel in particular ways, autonomy-supportive contexts minimize extrinsic performance pressures, provide students with choices, encourage them to solve problems in their own ways rather than insisting on a single method, and invite them to ask questions and suggest ideas for learning activities. Autonomy-supportive teachers empathize with the student’s perspective, seek to facilitate independent thought and decision making, and provide meaningful rationales when choice is constrained. In contrast, control-oriented teachers overmanage their students using detailed instructions backed by rewards, grades, and threats (Reeve *et al.*, 1999; Valas and Sovik, 1994; Vansteenkiste *et al.*, 2006).

Teachers often can allow their students to choose among task alternatives or to exercise autonomy in pursuing alternative ways to meet curricular requirements. For example, they might allow students to select topics for book reports, composition assignments, or research projects, and perhaps also to select from alternative ways of representing their work. When students are likely to make undesirable choices if left completely on their own, teachers can provide a menu of choices to select from or help them make choices that are well suited to their interests and reading levels (Starnes and Paris, 2000; Worthy *et al.*, 2002).

Motivating Students to Learn

Mitchell (1993) distinguished between catching students' interest and holding it. He found that presenting students with brainteasers or puzzles or allowing them to work on computers or in groups were effective for catching initial interest, but not for holding that interest in ways that led to significant learning. The best outcomes were associated with meaningful content (students could appreciate its applications to life outside of school) and instructional methods that fostered involvement (active learning and application activities, not just watching and listening). Other research similarly concluded that the key to motivating students to learn is to structure the curriculum around big ideas and develop them with emphasis on their connections and applications to life outside of school (Hickey *et al.*, 2001; Newton, 2000; Pugh, 2002; Reeve *et al.*, 2002).

Students do not need to enjoy school activities in order to be motivated to learn from them, but they do need to perceive these activities as meaningful and worthwhile. Therefore, teachers need to make sure that their curriculum content and learning activities are in fact meaningful and worthwhile, and then develop the content and scaffold students' engagement in the activities in ways that enable students to appreciate their value.

This begins with content selection and representation. If planning is guided by purposes and goals phrased in terms of desired student outcomes, the curriculum should feature content that students can appreciate as worthwhile and activities that they can appreciate as authentic. The bulk of such a curriculum will consist of coherent networks of connected content structured around powerful ideas. These ideas will be developed in sufficient depth to promote deep understanding of their meanings and connections, appreciation of their significance, and exploration of their applications to life outside of school. As much as possible, this learning will occur through engagement in authentic activities that require using what is being learned for accomplishing the very sorts of life applications that justify inclusion of the content in the curriculum in the first place.

Good content development includes conveying reasons why the content's big ideas are worth learning, explaining when and why they might be used, and modeling how it looks and feels when we use them. Coaching should include goal reminders and encouragement of students' appreciation for the learning domain, and feedback should call attention to developments in students' knowledge or skills, to signs of artistry or craftsmanship in their work, or to unique signature elements that reflect their personal style of operating in the domain (Brophy, 2004).

Optimally mediated learning experiences raise students' consciousness of the purposes and goals of each activity and help them learn not only with understanding but also with

appreciation and life application. Appreciation connotes that students not only understand what they are learning but also value it because they realize that there are good reasons for learning it. These reasons may include not only practical applications but also ways that the learning might enrich the students' repertoires of insights and recognitions or otherwise enhance the quality of their inner lives. Life application implies that the students experience authentic activities that will enable them to apply what they are learning to their lives outside of school.

Conclusion

In conclusion, most discussions of motivation in classrooms emphasize extrinsic praise and rewards or intrinsic motivation strategies for making learning fun, but research findings point to structuring the content around big ideas developed with emphasis on their connections and applications as the key to motivating students to learn. The best results will occur when teachers combine this approach to the value aspects of motivation with an approach to the expectancy aspects that supports all students' confidence as learners and an approach to classroom management that emphasizes learning community principles.

Introduction

Students' motivation within academic tasks is consistently viewed as a critical determinant of their learning and achievement. Students who report increased levels or more adaptive forms of motivation tend to exhibit greater learning and higher levels of achievement. Unfortunately, academic tasks are replete with obstacles that make it difficult for students to be motivated. Students complete cognitively challenging academic tasks, learn material that has little personal relevance, and repeatedly practice basic decontextualized skills. Further, the classroom environment within which these activities are situated is often characterized by multiple tasks occurring at one time, a high level of noise and distractions, and many opportunities for off-task behavior. Hence, even students who begin academic tasks eager to work and be successful may suffer declines in motivation. Motivational demands for completing academic work outside the classroom can be even more burdensome. Students may have to complete homework perceived as difficult, unimportant, or boring, and do so without the guidance or social supports available in the classroom. Despite these problems, many students do exhibit high levels of motivation for academic tasks both in school and outside the classroom context.

Motivational regulation is one explanation for how students' are able to rise above these obstacles and sustain or increase their own motivation for learning. The purpose of this article is to review the conceptual understanding of motivational regulation and to explain its importance to students' academic functioning. To achieve this goal, the article is divided into five sections. In the opening section, we provide a basic conceptual definition of motivational regulation and distinguish it from the process of motivation. In the following section, we identify the theoretical roots of motivational regulation within models of volition and self-regulated learning. Next, we discuss three major dimensions of motivational regulation. Finally, we touch on research examining the antecedents and the outcomes associated with students' motivational regulation.

General Definition and Distinction from Motivation

At the broadest level, the term motivational regulation could be used to describe any efforts to manage students'

achievement motivation. From this perspective, teachers and parents engage in motivational regulation on a regular, if not daily, basis when they purposefully design interesting tasks, promise rewards for hard work, or make statements to bolster students' self-confidence. This more expansive viewpoint, however, is typically supplanted by one that focuses on regulatory efforts that are initiated and directed by students themselves. In line with this focus, the emphasis here is on motivational regulation that is purposeful and is initiated and directed by the student. We define motivational regulation or the regulation of motivation generally as the process through which individuals purposefully manage either their level of motivation or the underlying processes through which motivation is determined. Motivational regulation, therefore, includes thoughts and behaviors through which students act to initiate, maintain, or supplement their willingness to start or to provide effort toward completing academic activities (Wolters, 2003).

Motivational regulation is closely related, but conceptually distinct from motivation itself. Achievement motivation most often refers to students' willingness or desire to engage in, persist, or work hard at academic tasks or to account for goal-directed behavior. Motivation also encompasses the cognitive or affective processes through which this willingness is determined (Anderman and Wolters, 2006). Behaviorally, theories of achievement motivation seek to explain students' choice of activities, the intensity or quality of their effort, and their persistence at academic activities. Most contemporary models explain these outcomes using cognitive constructs such as students' causal attributions, perceptions of self-competence, goals, values, interests, feelings of self-determination, or reasons for engaging in an activity.

Motivation and the regulation of motivation differ most acutely with regard to the awareness and purposefulness of students' thoughts and actions. Regulation of motivation describes the thoughts and actions through which students consciously and intentionally manage their motivation regarding a particular activity (Boekaerts, 1996; Wolters, 2003). This process has a deliberateness or plan-fullness that is unnecessary and absent in most explanations of motivation. Cognitive theories of motivation do not typically propose that students must ever be aware of the underlying processes that determine their motivation. In addition, models of motivation do not advocate that students ever purposefully intervene in these processes.

As an example, students in a class may experience a heightened level of personal interest based on the topic of a particular lesson. This increased interest may, in turn, foster greater attention and persistence for tasks associated with that lesson. Students may not and need not be cognizant of their increased interest for it to affect their behavior. In contrast, motivational regulation would postulate that students understand the positive effects of increased interest and intentionally take steps that will facilitate the interestingness of the lesson. Boekaerts (1992) described this distinction as subjective versus active control. The former refers to actions influenced through motivational beliefs and perceptions, and latter refers to actions determined more by a conscious intent to manipulate.

Theoretical Roots of Motivational Regulation

Research on motivational regulation has emerged from a number of different theoretical traditions. Parts of this process have been investigated by researchers interested in volition, personality, language development, delay of gratification, cognitive and emotional development, behavioral conditioning, and self-regulated learning. These diverse and extensive theoretical roots speak of the importance of motivational regulation as a fundamental aspect of effective functioning in both academic and nonacademic settings. Space limitations prohibit a full and comprehensive consideration of the contributions from each of these perspectives to the overall understanding of motivational regulation. We focus our discussion on volition and self-regulated learning, the two theoretical frameworks most frequently used to understand this process within academic settings.

Motivational regulation is a prominent feature within the research and theory of examining volition. Historically, theories of volition focus on understanding how people are able to maintain the pursuit of goals they have selected in light of competing opportunities and behavioral obstacles (e.g., Corno, 2001; Kuhl, 1985). Corno (2004; Corno and Kanfer, 1993) has served as a primary ambassador for using a volitional framework to understand students' learning and achievement behaviors in academic settings. As a whole, this work emphasizes a distinction between motivational and volitional processes. Motivational processing is viewed as responsible for identifying which goals or behavioral outcomes students decide to pursue. Volition, in contrast, is viewed as critical for protecting those intentions once they have been formed. For example, motivation would account for a student's decision to sit and begin a homework problem set. Volition would account for the student's efforts to remain engaged in this activity until it was finished despite distractions in the environment and/or difficulty with the task. Within this perspective, the switch from

forming intentions to protecting those intentions is considered an important qualitative change that is difficult to undo.

According to volitional theories, students maintain their intention to pursue goals they have selected through various regulatory or control strategies. Based on which aspect of the learning process is being controlled, these strategies have been divided into strategies associated with motivation, as well as attention, encoding, cognition, emotion, and environmental distractions (Corno, 2001). A student who has adopted a goal of preparing for an upcoming exam might go to a quiet place to study (environmental control), use flashcards to memorize course material (encoding control), and reduce anxiety through self-talk (emotion control). Most relevant to the current discussion, students' control of motivation has been described as one type of volitional strategy central to students' efforts to increase their persistence or time on task (Corno, 2004; Kuhl, 1985).

Models of self-regulation emphasize individuals' active, purposeful, and reflective role in their own functioning and behavior within domains that include employment, clinical well-being, chronic illness, and general physical health. The term self-regulated learning is most often applied within social cognitive models that articulate how this process operates in academic contexts. In these contexts, self-regulated learners are viewed as autonomous and efficient learners who have the cognitive abilities as well as the motivational beliefs and attitudes needed to understand and direct their own achievement-related behaviors (Boekaerts, 1996; Pintrich, 2004; Zimmerman, 2000). In particular, these students are knowledgeable about many different cognitive learning strategies and have the metacognitive skills needed to select, monitor, and control their use of these strategies effectively. They also have motivational beliefs and attitudes that drive their engagement and persistence in academic tasks.

Regulation of motivation has become a key feature within several social cognitive models of self-regulated learning (Boekaerts and Cascallar, 2006; Pintrich, 2004; Wolters, 2003). For instance, Pintrich (2004) argued that self-regulated learning entails students' ability to have forethought, monitor, control, and reflect on four areas of academic functioning one of which was motivation. Models advanced by Zimmerman (2000) and Boekaerts (1996) also depict students' understanding and active management of their own motivational processing as an important part of self-regulated learning. Within each of these major models of self-regulated learning, motivation or motivational processing can be the target of students' efforts to plan, monitor, control, and reflect. These efforts, furthermore, are thought to pay dividends to students in terms of increased attention, effort, and persistence that ultimately lead to improved learning and higher achievement.

Dimensions of Motivational Regulation

Drawing from across theoretical perspectives, there appears to be at least three distinguishable dimensions to motivational regulation. One facet reflects the meta-level knowledge or understanding needed to regulate motivation (Boekaerts, 1996; Wolters, 2003). In the research on metacognition, this type of knowledge has been differentiated based on whether it relates to the person, the task, or strategies (Pintrich *et al.*, 2000). Students' knowledge of what topics, domains, or activities they personally find interesting, fun, or motivating in general would reflect person-related meta-motivational knowledge. Insight into the types of tasks that are more or less motivating in general or that may make it difficult to be motivated because they are boring, frustrating, or lack usefulness would be task-related meta-motivational knowledge. Consistent with views of metacognition, meta-level knowledge related to motivational regulation strategies is likely to include declarative, procedural, and conditional forms of knowledge. Some students, for example, have been found to use self-talk to highlight features of completing the task that they find motivating (Wolters, 1998). Before engaging in this sort of strategy, however, students must know about it as a potential strategy, must know how to enact the steps needed to accomplish it properly, and must believe that using the strategy will lead to some desired effect on motivation within a particular situation. Students lacking any of this knowledge are unlikely to use this particular motivational regulation strategy.

A second dimension of effective motivational regulation is the monitoring of one's level or state of motivation. Students can become aware or self-assess their motivation before a task begins (prediction of motivation), during a task (experience of motivation), and after a task has been completed (reflection on motivation). This consideration of one's level of motivation is necessary to identify when motivation is waning, and is thus a prerequisite to any active intervention designed to bolster one's motivation. As an example, a person is unlikely to take steps that will make a task more enjoyable if he/she does not first become aware that he/she is bored and losing interest in finishing the task. This type of self-awareness may include monitoring both the level of motivation as well as the nature of one's motivation. The former ensures that the willingness or quantity of effort needed to complete a task is available whereas the latter may be necessary to ensure that the type of motivation driving one's engagement will lead to the desired outcomes. Much like the monitoring of one's comprehension or understanding outlined as part of metacognition, this process may continue without much conscious effort until a problem is encountered. Nonetheless, without effective monitoring, students may not successfully regulate their motivation for academic tasks.

A third dimension of effective motivational regulation is the purposeful or active efforts to intervene and control

one's own motivation for a task. This process encompasses the actual strategies one engages in, to control the level or nature of motivation. For instance, once a student recognizes that she has little interest in tackling a required task she must do something to increase her interest, or to foster some other form of motivation. Given the diverse nature of motivation, the particular methods that might be used to affect motivation for a task are likely to be quite varied. Prior work examining motivational regulation, in fact, has identified a number of strategies that students might use to control their motivation (Wolters, 2003). These strategies include attempts to regulate various motivational beliefs that have been discussed in the achievement motivation literature such as goal orientation, self-efficacy, task value, and interest in the task. When initiated in order to control outcomes such as effort and persistence, students' management of their affect, environment, and behavior might also be considered forms of motivational regulation (Boekaerts, 1996; Wolters, 2003).

Antecedents of Motivational Regulation

The consideration of factors that determine or influence whether students engage in motivational regulation is important for both its theoretical and practical implications. Consistent with views about self-regulation and volition more generally (Boekaerts and Corno, 2005; Pintrich, 2004), motivational regulation is likely a function of both stable individual differences among students, as well as more situational influences within the instructional context and the broader environmental context. Recent work in this area also argues that all aspects of self-regulation, including motivational regulation, are developed through social and cultural interactions/influences. In this section, we briefly identify factors from within each of these areas that have been discussed as potential influences on students' motivational regulation.

Individual differences among students, including aspects of their cognitive development, personality, gender, and ethnic identity may affect the extent to which they regulate their motivation. Developmentally, research suggests that forms of motivational regulation may emerge at a very young age. Children as young as 3 years old use strategies to creatively modify academic tasks to regulate their motivation, and even before reaching school age there is evidence that children use strategies to block distractions in order to complete tasks (Corno, 1994; Metcalfe and Mischel, 1999). Still, as suggested by the extant research on metacognition and self-regulated learning, the most sophisticated forms of motivational regulation may not develop until adolescence. Moreover, students who are more conscientious or who identify more closely with doing well in school may be more apt to regulate their motivation for academic tasks.

Another determinant of students' efforts to regulate their motivation is likely the motivational beliefs and attitudes they bring to a particular situation or task. Past work on the more cognitive aspects of self-regulated learning has firmly established that motivation impacts students' use of meta-cognitive regulatory strategies. As motivational regulation represents a similar expression of self-management, it follows that students who hold more adaptive motivational beliefs would be more apt to utilize motivational-regulation strategies than students who hold less-adaptive motivational beliefs (Boekaerts, 1996; Corno, 1994). The view that motivation can be both a cause and an outcome of students' regulatory processing is consistent with the view of self-regulated learning as a complex, iterative process. Further, prior research provides some evidence supporting this additional link between motivation and motivational regulation. Wolters and Rosenthal (2000), for instance, found that students who viewed the material they were learning as more important or useful, or who focused on mastery goals tended to report greater use of motivational regulation strategies. In this same study, however, self-efficacy was not an important predictor of students' motivational regulation. Hence, a more complete understanding of these relations remains an important goal for future research.

Situational factors, including the instructional environment specifically, represent another possibly potent influence on students' motivational regulation. For instance, teachers can structure their classrooms to encourage motivational-regulation strategies by allowing students time to reflect, the autonomy needed to control aspects of the task, and by providing opportunities for students to observe models of this process. In addition, parents can foster the different facets of motivational regulation through modeling and by providing opportunities for self-management, and through other parenting practices. Students can be trained to use strategies for motivational regulation, like other forms of volition and self-regulation, through more direct interventions.

Broader sociocultural processes can also be viewed as an important influence on the development of motivational regulation. For instance, Jarvela and Volet (2004) describe motivation as a dual psychological-social phenomenon because it involves the development of individual abilities through shared, social, or interactive processes. Others have argued that motivational regulation and other similar processes are best conceptualized using the term co-regulation because they grow from the scaffolding, intersubjectivity, and cultural supports provided through social interactions (McCaslin *et al.*, 2006). Overall, these views emphasize that the knowledge, beliefs, attitudes, and skills individuals need to regulate their motivation emerge from shared, dynamic, and socially supported experiences within culturally meaningful contexts.

Outcomes Associated with Motivational Regulation

Successful motivational regulation should, of course, have a positive influence on students' engagement, effort, or persistence for academic tasks. Ultimately, students who regulate their motivation most effectively should also exhibit better academic outcomes than students who fail to self-regulate their motivation. These benefits may be even more acute when a situation is particularly detrimental to ongoing motivation. Empirical evidence that expressly documents these anticipated relations, however, continues to be in short supply.

Some evidence for these links comes from research investigating more global indicators of students' regulatory activities. For instance, prior research has shown a link between overall measures of volitional control and positive educational outcomes (Corno and Kanfer, 1993; Kuhl, 1992). These studies have not, however, tended to assess and test motivational control or the regulation of motivation separately from other forms of volition. Moreover, these models have assumed a fairly broad view of motivational regulation. They have not accounted for potential differences in the types of motivational-regulation strategies that students use.

Two studies by Wolters (1998, 1999) contribute more direct evidence for the positive effects of motivational regulation. The college students studied by Wolters (1998) reported using many different types of motivational-regulation strategies. Findings from this study indicated that students who reportedly exerted some purposeful control over their level of motivation for academic tasks tended to have more positive academic outcomes than other students. Similarly, Wolters (1999) found that adolescent students' motivational regulation was related positively to their use of learning strategies, effort, and classroom performance. Not all studies examining these relations, however, have found a positive relation between indications of students' motivational regulation and achievement (Xu and Corno, 2003). An increased understanding of the specific motivational-regulation strategies students use at different ages, and how these strategies are related to other self-regulatory processes and to academic performance is an important goal for future research.

Conclusions

Motivation is an important process that undergirds students' engagement and achievement in academic contexts. Students' ability to understand and purposefully influence their motivation, therefore, is a potentially critical influence on their learning and achievement. Motivational regulation

has emerged and proven useful as a model for conceptualizing and understanding this process. Further, evidence specifically documenting the nature and importance of this process has begun to emerge. Students' ability to regulate their motivation has not, however, received the same level of attention as their ability to manage their cognitive processing and there is much left to investigate. More attention is needed for a better understanding of the different components of motivational regulation, as well as the most critical antecedents and substantial outcomes of this process both in the classroom and in academic tasks completed in other contexts.

Peer Learning in the Classroom

Peer Learning in the Classroom

Recognizing that students can learn by working with and helping each other, school districts, state departments of education, national research organizations, and curriculum specialists recommend, and sometimes mandate, the use of peer-based learning. Undergirding these recommendations is a large research literature showing positive effects of peer-based instructional methods on student achievement, compared with other forms of instruction that involve little interaction between students such as teacher-led whole-class instruction or individual work.

However, simply placing students in small groups does not guarantee that learning will take place. Rather, the extent to which students benefit from working with other students (variously referred to as cooperative learning, collaborative learning, peer tutoring, and peer-based or peer-directed learning) depends on their interaction. This article explores the mechanisms by which working with other students is thought to benefit student learning, and the many ways in which small-group work might be orchestrated to bring about those benefits.

Social-Behavioral Perspectives on the Benefits of Peer Interaction

Social-behavioral perspectives hypothesize that working together, helping each other, and supporting each other's contributions will lead to increased effort, greater learning, and more liking of the task and other students than instructional settings without such opportunities for student interaction.

Motivational Perspectives

One way to motivate students to collaborate is to have groups work toward a common goal (Deutsch, 1949). In a group or cooperative goal structure, group members can attain their own personal goals only if the group is successful. A group goal may be based on rewards or incentives. In Slavin's (1992) Student Teams-Achievement Divisions (STAD), for example, teams are rewarded based on the improvement of group members' achievement. Since the team's success depends on the progress of all group members, these group rewards ensure individual accountability, a feeling of personal responsibility for what happens in the

group. This motivates students to work hard toward the group goal and encourage and help others do the same.

To limit undue focus on the reward itself and maintain focus on learning and task performance, the group incentive (e.g., a team certificate or a mention in a classroom newsletter) is not designed to be highly desirable or have high stakes. To ensure student effort and reduce pressure on less-capable group members, task difficulty is tailored to the capabilities of individual team members and no one is assigned overly difficult tasks. Cooperative learning methods that use both group rewards and individual accountability show positive effects on achievement compared to cooperative learning methods that include only one or neither of these components.

Social Cohesion Perspectives

Creating socially cohesive groups is also thought to motivate students help each other because they care about the group and its members. To promote a sense of group identification and concern for others, some cooperative learning methods, for example, Johnson and Johnson's (1994) *Learning Together and Alone: Cooperative, Competitive, and Individualistic Learning* uses teambuilding and development of social skills. Teambuilding activities help students get to know each other and experience success as a team. Training in social skills such as active listening, stating ideas freely, accepting responsibility for one's behaviors, taking turns, sharing tasks, making decisions democratically, and trying to understand others' perspectives helps group members trust, accept, and support each other, communicate accurately and effectively, and resolve conflicts constructively.

Another way to build group cohesion is to provide feedback on group functioning. By discussing their respective group's interaction and how they might improve it (group processing), groups can identify and solve general communication problems (e.g., disruptive or bullying behavior) and reinforce each other's collaborative efforts.

Cognitive/Developmental Perspectives on Learning from Peers

Piagetian Perspective

According to Piaget (1932) and his followers, cognitive conflict leads to higher levels of reasoning and learning. The conflict arises when learners perceive a contradiction between their existing understanding and what they hear

or see in the course of interacting with others. To resolve the conflict, learners reexamine and question their own ideas and beliefs, seek additional information, and try out new ideas. Exchanges with peers are more likely to promote learning than exchanges with adults because students are more likely to cooperate as equals and challenge each other, exercise mutual control over the interaction, and share each other's language and point of view.

Supporting evidence of the benefits of cognitive conflict comes from research on the cognitive development of pairs of children working on conservation tasks to discuss whether some characteristics of objects (e.g., the volume of liquid) remain the same when others (e.g., the width or height of the container) change. When children who have not yet learned the principle of conservation are paired with children who have mastered it, the former often gain whereas the latter rarely regress to giving nonconserving responses. Moreover, pairs of nonconservers progress when they hold conflicting, but still incorrect, ideas, but not when they hold the same incorrect conception. Benefits of resolving conflicting perspectives also appear in studies of larger groups in which students initially hold different conceptions.

Vygotskian perspective

According to Vygotsky (1978), learning can occur when a more-expert person helps a less-expert person. With the help of a more-skilled person, a process of negotiation and transformation enables the less-competent person to carry out a task or solve a problem that the latter student could not perform without assistance, a process sometimes referred to as scaffolding or guided participation. Through this process, the less-proficient student can internalize skills and knowledge that he/she has practiced and developed such that they become part of his/her individual repertoire.

Students can often provide effective scaffolding and support due to their understanding of, and familiarity with, each other's misunderstandings and their ability to explain concepts in familiar terms. Students being helped will benefit most when they have, and use, opportunities to apply explanations received to solve the problem or carry out the task for themselves.

Co-Construction of Knowledge

Students can also learn by co-constructing knowledge with their peers, for example, when students contribute different pieces of information or build upon others' explanations to jointly create a complete idea or solution. Students can collaboratively build knowledge and problem-solving strategies that no group member has at the start by acknowledging, clarifying, correcting, adding to, building upon, and connecting each others' ideas and suggestions.

Such interactions have been shown to help children co-construct and internalize strategies and concepts in a wide variety of areas including, for example, identifying chemicals in chemical reactions, understanding of place value, learning how to multiply numbers, and constructing mental models of the nature of matter.

Co-construction may require a high degree of coordination among group members. In highly coordinated interaction, students acknowledge each other's ideas, repeat others' suggestions, and elaborate on others' proposals (Barron, 2000). Speakers' turns are tightly connected, and group members pay close attention, and respond, to what other members do and say, give space for others' contributions, and monitor how the unfolding contributions relate to the problem-solving goal.

Cognitive Elaboration Perspective

From a cognitive elaboration perspective, interacting with others may encourage students to restructure their own knowledge and understanding. Specifically, explaining the material to others may promote learning by encouraging explainers to rehearse information, reorganize and clarify material, recognize misconceptions, fill in gaps in their understanding, strengthen connections between new information and previously learned information, internalize and acquire new strategies and knowledge, and develop new perspectives and understanding. When formulating an explanation, students may think about the salient features of problems and generate self-explanations that help them internalize principles, construct specific inference rules for solving problems, and repair imperfect mental models (Chi, 2000). This process may help students monitor their own understanding and develop a metacognitive awareness of what they do and do not understand.

The social component of explaining to others is important. Consistent with the idea that the process of explaining to someone else leads to more differentiated, complex, unified, and organized cognitive structures than does merely learning the material for oneself are findings that vocalizing to a peer (presumably to teach that person) produces greater concept attainment than vocalizing to an experimenter (presumably only to demonstrate mastery of the material). By accommodating explanations to the difficulties of other students, helpers may construct more elaborate conceptualizations than they would when solving the problems for themselves.

The strong relationship between giving explanations and achievement in small groups has been well documented (Webb and Palincsar, 1996). Moreover, giving more-elaborated explanations may be more effective for learning than giving less-elaborated explanations, for example, providing multiple reasons versus a single reason about the role of resistors in electric circuits.

Debilitating Interpersonal Processes

Groups may not function in ways that are optimal for learning. A number of detrimental processes have been documented.

Unequal Participation

Some students participate more than others due to personality characteristics (extroverted and energetic members may do most of the talking) or status characteristics. High-status students, especially on academic standing or popularity, tend to be more active and influential than low-status individuals, while low-status individuals tend to be less assertive, talk less, and give fewer suggestions and less information than high-status individuals. Both real and artificial differences in task-related competence (e.g., classifying students' competence on the basis of fictitious test scores) can create imbalances in activity and influence. Status may also be linked to social characteristics, such as gender or race, with boys and white students being more active than girls and colored students.

Sometimes, students choose not to participate. One or more group members may sit back and let others do the work (referred to as social loafing or diffusion of responsibility). Individuals may go along for a free ride if they believe that their efforts cannot or will not be identified or are dispensable. The free-rider effect can turn into the sucker effect when the group members who were doing all of the work discover that they have been taken for a free ride and stop working to avoid being suckers.

Students who are not involved in group interaction will not experience the benefits of active participation described earlier. Students who do participate will not benefit from the knowledge and perspectives of the passive students.

Many cooperative learning methods encourage participation of all group members. In *The Jigsaw Classroom* (Aronson *et al.*, 1978), students are assigned responsibility for mastering a portion of the material, discussing that material with other students assigned the same topic, and teaching their topic to the other members of their groups. The group-investigation method by Sharan and Hertz-Lazarowitz (1980) requires students to carry out research on a piece of a group project and then work together as a team to integrate their findings and plan their class presentations.

Failure to Seek and Obtain Effective Help

Another set of debilitating processes concerns the failure of students to seek help when they need it or to obtain effective help when they seek it. Students may fail to seek help because they lack the metacognitive skills necessary to monitor their own comprehension, or may watch their

teammates solve a problem or accomplish a task and assume that they can do it too (Nelson-Le Gall, 1992).

Students may decide not to seek help for fear of being judged academically or socially incompetent, or they may not want to feel indebted to those giving the help (Newman, 1998). Alternatively, students may believe that help seeking is undesirable (as a result of classroom norms to be quiet and work alone without disturbing others) or may have received antagonistic or unsatisfactory responses to previous help-seeking attempts. Students may believe that no one in the group has the competence or resources to help, or they may lack a sense of responsibility or motivation to do the work. Finally, they may believe themselves to lack the competence to benefit from help that others may provide.

Even if students do seek help, their help-seeking strategies may be ineffective. Students may select helpers who are nice or kind, or who have high status, rather than those who have task-relevant skills. Conversely, they may ask vague, indirect, or unfocused questions, which are not likely to elicit explanations, rather than questions that are explicit, precise, direct, and targeted to a specific aspect of the problem or task. Asking precise questions makes it easier for other group members to identify the student's misconceptions or areas of confusion and formulate effective help accordingly. Precise questions may also signal to the group that the help seeker wants to learn, and has sufficient understanding to be able to profit from explanations provided, and thus motivate the group to help. General questions, in contrast, may signal a lack of ability or of effort (it takes less effort to declare general confusion than to formulate precise questions), or both. Students who appear to be loafing or who give up easily may be less likely to receive help than those who appear to be working hard.

Even if students are willing to help their teammates, they may not have the skills to provide effective explanations. Help givers may have misconceptions themselves, not be able to translate their thinking into appropriate language, use confusing language, not provide enough detail, dictate how to solve a problem or complete a task without referencing the needs of the help seeker, or they may not monitor other students' comprehension and thus be unaware of specific misconceptions that need to be addressed.

Whether students obtain help may depend on the group's composition and a student's relative position in the group. For example, in groups that are academically heterogeneous, middle-ability students may be left out of teacher-learner relationships that emerge between high-ability and low-ability group members.

Too Little or Too Much Cognitive Conflict

Although students can learn by resolving discrepancies in ideas, too little or too much conflict may be detrimental. Infrequent conflict may reflect suppression of

disagreements, either from the domination of one group member over the others or from social pressures not to challenge others. Too much conflict may prevent group members from moving forward, especially if group members engage in an adversarial or conflictual style of argumentation instead of a co-constructive style in which group members work together to critique suggestions and create new solutions.

Lack of Coordination

Group functioning may also suffer from uncoordinated communication (Barron, 2000), marked by low levels of attention to, and uptake of, members' suggestions (even correct ones), and by students advocating and repeating their own positions and ideas, ignoring others' suggestions, rejecting others' proposals without elaboration or justification, interrupting others, or talking over them simultaneously. Lack of coordination and joint attention may undermine many of the processes by which individuals can gain by collaborating with others, such as resolving conflicts and co-constructing knowledge, as well as reduce group cohesion and students' motivation to work together.

Other Negative Socioemotional Processes

Other negative socioemotional processes, such as rudeness, hostility, and unresponsiveness, may also impede the participation and learning of group members. Rudely disagreeing with others and ignoring their suggestions may prevent groups from solving problems correctly. Aggressiveness, hostility, and insulting behavior may lead to unconstructive and bitter arguments and may cause students to withhold knowledge and ideas from the group or decide not to seek help.

Approaches to Promoting Beneficial Peer Interaction

Researchers have designed a variety of collaborative approaches to promote beneficial peer interaction and inhibit detrimental group dynamics. Many, if not most, peer-based methods incorporate one or more of the strategies described here.

Preparing Students to Work Collaboratively

Altering expectations and status relationships

To promote equal participation among students in heterogeneous (especially multiracial) groups, Cohen and Lotan (1995) developed methods of minimizing status effects by altering high-status students' expectations about low-status students' competence. By training low-status students on academic and nonacademic tasks which they then teach to

high-status students, high-status students change their perceptions about low-status students' competence. A related approach is the multiability intervention, which raises students' awareness of the multiple skills necessary to perform the task. The teacher discusses with students the multiple abilities needed to solve complex problems (e.g., visual thinking, intuitive thinking, and reasoning) and, when groups work on these tasks, points out the particular contributions of specific students (particularly of low status) and how these are important and valuable.

These approaches have shown success in reducing the relationship between status (based on language background, race, socioeconomic status, and academic ability) and behavior in small groups. For example, the more frequently teachers talk about the multiple abilities needed for a task (and the fact that no one has all of the abilities) and assign competence to low-status students (e.g., observing and commenting on a non-English speaker's ability to build structures based on drawn diagrams), the greater is the participation rate of low-status students, and the smaller is the gap between the participation rates of high-status and low-status students.

Instruction in explaining and group reasoning skills

As an adjunct to providing social skills training designed to improve communication in groups, a number of studies have incorporated instruction in academic helping, explaining, and help-seeking behaviors, such as asking clear and precise questions, giving explanations instead of answers, monitoring understanding of teammates, checking others' answers, and giving specific feedback on the problem-solving strategies of their teammates. Some training approaches focus on helping students make their reasoning explicit and engage constructively with others' ideas (e.g., sharing relevant information, reaching agreement, taking responsibility for decisions, providing reasons, challenging others, and discussing alternatives before making decisions). Compared to untrained groups, this preparation for working in groups has been shown to produce more explaining and often higher achievement (Gillies and Ashman, 1996).

Structuring Peer Interaction

To supplement training in communication and explaining skills, some peer-based methods structure group interaction in specific ways or implement activities to guide groups' collaboration. These methods require groups to carry out certain strategies or activities, or assign students certain roles to play, or both.

Reciprocal teaching

Palincsar and Brown (1984) developed teacher scaffolded instruction, referred to as reciprocal teaching, to help students carry out certain strategies designed to improve comprehension of text: generating questions about the

text they have read, clarifying what they do not understand, summarizing the text, and generating predictions. Teachers initially take the leadership in explaining the strategies and modeling their use, and gradually help students become proficient (by asking students to demonstrate the strategies and giving them feedback) so that they can carry out the strategies in their groups. Students using reciprocal teaching methods have shown improvement in reading comprehension and better performance than students receiving other kinds of instruction with and without peer interaction.

Explanation prompts

Some peer-learning approaches give students specific prompts to encourage them to exchange elaborated explanations. Students may be prompted to describe what happened in their experiments, find patterns in their results, and explain why their results occurred. Alternatively, they may be prompted to construct explanations, justify answers and beliefs, relate what they learned in class to the task at hand, use distinguish between scientific and everyday definitions and explanations, and to compare real-world experiences to class learning. The use of these explanation prompts produces conceptually advanced explaining and more accurate and complete understanding of the material.

Guided reciprocal questioning

In guided reciprocal questioning, students ask each other high-level questions about the material to help them monitor their own and each others' comprehension and encourage students to describe and elaborate their thinking. King (1992), for example, gave students how and why question stems to guide their discussions of text (e.g., "Why is . . . important? How are . . . and . . . similar?"; p. 113). In problem-solving contexts, students may ask each other questions to help them reflect on problems before solving them (e.g., identifying known and unknown information), make connections between current problems and previous ones, and generate and defend their choice of problem-solving strategies. The use of high-level questions by the groups increases the frequency of elaborated explaining and student achievement.

Structured controversy

To promote the benefits that arise from resolving conflicts, Johnson and Johnson's (1995) structured controversy approach subdivides groups into teams, requires them to master material on different sides of an issue and debate the issue with the other team, and then to work as a group to synthesize the two positions. Groups required to debate the issues often carry out more high-level discussion of material and show higher achievement than groups required to seek concurrence by working cooperatively and compromising.

Cognitive role specialization

Some approaches assign students roles to play (usually alternated or rotated) based on specific cognitive activities. Students may play the role of recaller (also referred to as learning leader or summarizer) or listener (also referred to as active listener, learning listener, or listener/facilitator), which are sometimes incorporated into scripts for groups to follow (O'Donnell, 1999). The recaller summarizes the material and the listener is responsible for detecting errors, identifying omissions, and seeking clarification. Students work together to elaborate on the material, and then change roles for the next part of the task. A large body of research shows that such scripted cooperation usually produces greater elaboration of ideas and higher student achievement than does unstructured cooperation.

Tutor and tutee roles are widely used. In reciprocal peer tutoring, students receive training in how to model strategies such as summarizing text, and how to give explanations, corrections, and feedback about other students' work, and then alternate tutor and tutee roles during pair work. Some approaches pair more-skilled and less-skilled learners, whereas others pair students randomly or with similar proficiency. Some approaches specifically focus on promoting a high-level of discourse during paired discussions, such as training tutors to give highly elaborated conceptual rather than algorithmic explanations to their partners, or training tutors to push tutees to give high-level explanations that make connections among ideas.

Manipulating the group-work task

Equal student participation can also be encouraged through the use of complex tasks or open-ended problems without clear-cut answers or procedures that require the combined expertise of everyone in the group. Such tasks encourage groups to value the different contributions that students can make, whereas narrowly defined tasks or problems, especially those that can be completed by one student with the requisite skills, may limit the participation of some students.

The Teacher's Role

Developing Classroom Goal Structures and Norms

The teacher can influence peer interaction by working with students to mutually construct norms for student engagement. He/she can raise the level of discussion by monitoring and intervening in small-group dialogs to remind students about their obligations (e.g., to share their thinking and solution methods with others and to challenge each other's solutions) and make specific suggestions for (e.g., stop another student and ask for help), and by using actual and hypothetical situations to initiate

discussions with the class about students' responsibilities in collaborative work, and to show examples of genuine dialog between students (Yackel *et al.*, 1991).

Modeling Desired Discourse

Teachers also communicate their expectations for students' behavior through their own discourse. When teachers use a recitation approach in which they assume primary responsibility for solving the problem, ask students to provide only answers to discrete steps, and rarely encourage students to verbalize their thinking, groups may adopt an interactional style in which help-givers do most of the work and infrequently monitor other students' level of understanding. In contrast, training teachers to use specific skills to challenge students' thinking encourages students to probe each other's opinions, acknowledge each other's ideas, and attempt to relate new information to ideas previously discussed.

Further Research

While much is known about how and when students learn from their peers, as well as how small-group work might be orchestrated to produce desired learning outcomes, a number of issues have received less attention or are only beginning to be studied systematically. Some of these topics include how to use student characteristics (e.g., ability, gender, cultural or racial background, and personality) when creating group assignments to optimize group functioning for all students; the correspondence between mechanisms that promote academic and nonacademic outcomes (e.g., interpersonal attitudes, liking of the task, and values); the impact of different task structures (e.g., division of labor) on learning outcomes; peer interaction and learning in computer-mediated environments; and how to help teachers modify their teaching practices and classroom environments to facilitate peer learning.

Poverty, Effects of on Social and Emotional Development

N Philipsen Hetzner, A D Johnson and J Brooks-Gunn, Columbia University, New York, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Absolute poverty measure – In the United States, it is a threshold determined by a number generated in 1960 that has been carried forward to the present while accounting for increases in cost of living.

Attention – The ability to maintain arousal, disengage and refocus attention, and to resist competing demands for attention.

Cross-sectional study – An observational study that examines a subset of the population at a single point in time.

Delay of gratification – The ability to inhibit impulse behavior and shift attention away from tempting objects to forgo an immediate reward in order to gain a more substantial one later.

Empathy – The ability to experience thoughts and feelings from the perspective of another person.

Environmental chaos – Generally refers to the level of noise, degree of crowding and foot traffic, the routine, predictability, and organization of the home environment.

Exogenous shock or Natural experiments – An observable phenomenon that happens naturally and approximates the properties of a controlled experiment.

Experiments – A method of investigating causal relationships in a controlled environment. Participants are randomly assigned to treatment and control groups that differ only on the variable of interest.

Fixed effects study – Fixed effects methods attempt to control for all stable characteristics of an individual in order to minimize or eliminate selection bias.

Inhibitory control – The ability to control one's behavior by inhibiting responses to irrelevant stimuli while pursuing a goal.

Longitudinal study – An observational study that examines a subset of the population over more than one point in time. If a variable of interest is measured at many points in time, it can be controlled for at an earlier point in order to determine change in the outcome over time.

Relative poverty measure – The extent to which a household's financial resources fall below the

median income of the all the other households in the measurement area.

Selection bias – Spurious associations between variables of interest in a research study often due to unmeasured characteristics.

Introduction: Poverty and Child Development

In 2005, nearly one-fifth of America's children were living in poverty. American individuals and families are considered to be living in poverty if their total household pre-tax income is less than the federal poverty threshold for a family of the same size and composition.

In the United States, the federal poverty threshold is defined in absolute terms based on a number generated in 1960 that has been carried forward accounting for increases in the cost of living. However, in Europe, a measure of relative poverty is used. Relative poverty is the extent to which a household's financial resources fall below the median income of all other households in that measurement area. Regardless of what standard of poverty is used, it is clear that child poverty in the US is alarmingly high. On a measure of relative poverty, the US ranks 24th out of the 25 industrialized countries with respect to child poverty; using an absolute poverty measure, the US occupies the 12th place (see **Figure 1**).

Within the US, a family of three living at 100% of the federal poverty level in 2005 had an annual pre-tax income of \$15 720 (US Census Bureau, 2006a). Those living with incomes below 50% of the federal poverty level experience extreme poverty; in 2005, 7.2% of families with children were living in extreme poverty. Although the number of minority children in the general population is smaller than the number of white children, black and Hispanic children are overrepresented in the poverty population; approximately 25% of black children and nearly 22% of Hispanic children were poor in 2005, compared to 8.3% of white children (US Census Bureau, 2006b).

The prevalence of child and family poverty in the United States has contributed to a flurry of research in recent years around the impact of economic deprivation on the developmental trajectories of children. Not surprisingly, studies have found negative associations between poverty and child development in families who cannot

Figure 1 Percentage of children living in poverty in industrialized nations using relative and absolute measures. Relative poverty rate is 50% of overall national median income for survey year. Absolute rate is \$15 299, based on 1995 US official poverty line for a two-parent family with two children. Adapted from Bradbury, B. and Jäntti, M. (1999). Child poverty across industrialised nations. *Innocenti Occasional Papers, Economic and Social Policy Studies*, no. 71. UNICEF International Child Development Centre, Florence, Italy.

afford basic goods and services such as food, clothing, and healthcare (e.g., Aber *et al.*, 1997; Brooks-Gunn and Duncan, 1997; Betson and Michael, 1997; Havemen and Wolfe, 1994). (The majority of poverty research is based on correlational work which largely limits the ability to draw causal conclusions. Therefore, debates occur as to whether income matters at all, or whether income effects can be attributed to selection bias – spurious associations due to some unmeasured characteristics. For this reason, researchers place more credence on some research designs than others; in order from least to most: cross-sectional studies, longitudinal studies where initial outcomes are controlled at an earlier time point so a change in outcomes is analyzed (Duncan *et al.*, 1994), studies looking at change in income and in outcomes (Chase-Lansdale *et al.*, 2003), fixed effects or sibling effects, exogenous shock or natural experiments, and experiments (Fauth and Brooks-Gunn, in press). A number of studies have examined the negative role that poverty plays in shaping children's cognitive skills and school achievement outcomes. In particular, such research

suggests that poor children are more likely to score lower than their middle-class peers on standardized achievement tests (Smith *et al.*, 1997), and more likely to experience developmental delays and disabilities than their nonpoor classmates (Brooks-Gunn and Duncan, 1997). In fact, the achievement gap between low-income children (as young as 2 years) and their middle- and upper-class peers persists and even widens as children grow older (Baydar *et al.*, 1993; Phillips *et al.*, 1998; Rouse *et al.*, 2005).

As links between income and children's cognitive outcomes have generally been more consistent than links between income and children's social and emotional outcomes (Bradley and Corwyn, 2002), and because socio-emotional outcomes tend to be more difficult to measure than cognitive skills, much of the research on poverty and development has focused on school readiness and achievement skills. However, a growing body of literature suggests that poverty also hinders the healthy development of social and emotional skills in children of all ages (e.g., Bradley and Corwyn, 2002; Brooks-Gunn and Duncan, 1997; Evans,

2004; McLoyd, 1998; Duncan *et al.*, 1994; Korenman *et al.*, 1995; McCabe *et al.*, 2004; McLeod and Shanahan, 1993; Sameroff *et al.*, 1987).

This article explores links between poverty and children's social and emotional development. We begin with a brief definition of social and emotional development as it is currently understood in the research literature along with its association with poverty. Next, we examine the moderating role that depth, persistence, and timing of poverty have on the association between income and socio-emotional development and the mechanisms through which poverty and its correlates impinge on early development: parents, the home environment, early education and care settings, and neighborhoods (Romano *et al.*, 2005). Finally, we conclude with a brief discussion of the policy implications that extend from research findings on the impact of poverty on social and emotional development, as well as suggestions for future reading.

Poverty and Child Social and Emotional Development

Developmental psychologists and researchers generally agree on a broad definition of social and emotional development that includes a host of behaviors, typically grouped along two dimensions: internalizing behaviors such as anxiety, withdrawal, and depression (three distinctive behaviors that are often combined when studying children) and externalizing behaviors such as aggression, fighting, and acting out (Brooks-Gunn and Duncan, 1997). In addition, the definition of social and emotional development also includes emotion regulation (including inhibitory control, a child's ability to control one's own behavior, and delay of gratification, a child's ability to inhibit impulsive behavior and shift attention away from tempting objects (Blair, 2002; Cole *et al.*, 2004; Eisenberg, 2001; Eisenberg and Fabes, 1998; Fantuzzo *et al.*, 2005; Li-Grining, 2007; McCabe *et al.*, 2004; Raver, 2004) and attention. Attention refers to a child's ability to maintain arousal, ability to disengage and refocus attention, and the ability to resist competing demands for attention (Posner and Rothbart, 2000).

Data collected on children's social and emotional development are often based on observations of children in structured situations in order to elicit inhibitory control, delay of gratification, emotional knowledge, attention, and empathy. Data may also be collected through parent and teacher reports of children's emotional and behavioral symptoms. Symptoms generally fall on a continuum, allowing researchers to study children who may at some point have mild or moderate levels of psychopathological symptoms in order to determine how they influence particular outcomes. Although less common in large-scale, representative research, classifications of social and emotional diagnosable disorders allow

researchers to study people in terms of groups based on a set of criteria. Some studies have found that the effect of symptoms is as meaningful as psychiatric diagnosis for later consequences of childhood disorders (Jensen *et al.*, 1999).

As the associations between poverty and child outcomes can emerge as early as pregnancy (Wood, 2003), longitudinal studies help us understand links between early environmental conditions and subsequent developmental consequences that emerge over time. On average, children in poverty display more internalizing and externalizing social and emotional developmental problems (Brooks-Gunn *et al.*, 1999; Duncan *et al.*, 1994; McLeod and Shanahan, 1993; McLeod and Shanahan, 1996), as well as decreased emotional regulation and attention (Izard *et al.*, 2008).

Although income is positively correlated with child outcomes, the trend is not linear. Deep poverty is indeed associated with the most negative child outcomes; however, the slope of the line is steeper at the bottom of the income distribution, meaning that one dollar matters more for those children than it does for those higher on the income distribution (Duncan *et al.*, 1998). Exploring how poverty matters differently for social and emotional outcomes based on the depth (or severity) of poverty, the timing of poverty during childhood, and the persistence or length of time poverty is experienced, leads into a discussion of the moderators between poverty and child social and emotional outcomes (Brooks-Gunn and Duncan, 1997).

Depth of Poverty

The finding that deep poverty is especially deleterious for early development is bolstered by evidence from different studies demonstrating that children at the lowest end of the income distribution are most dramatically affected by limited resources (Dearing *et al.*, 2001; Duncan *et al.*, 1998). As mentioned earlier, those in deep poverty are less likely to have access to basic resources and services such as healthy food, safe shelter, medical care, transportation, and stimulating home environments. Children living in deep poverty are likely to encounter a greater number of risk factors than are their less- or nonpoor peers, therefore enduring accumulating risks on development. Research on the National Longitudinal Survey of Youth (NLSY), a national survey spanning from 1986 to 1994 with an overrepresentation of economically disadvantaged respondents, suggests that young children in deep poverty display increased anxiety, withdrawal, and depression compared to less- or nonpoor children, and that the gap between children of different socioeconomic levels widens as children age. For slightly older children (5–8-year-olds), deep poverty was associated with increased aggression, fighting, and acting out (Brooks-Gunn *et al.*, 1999). However, increases in income may also have the greatest positive impact for children living in the deepest poverty. Data from the National

Institute of Child Health and Human Development Study of Early Child Care (NICHD SECC), a longitudinal study designed to follow the childcare experiences of more than 1000 families and their children from birth, reflect that children in poverty who experience a rise in income during the first 3 years of life scored similarly to nonpoor children on behavioral outcome measures. While increases in income seem to have little association with the outcomes of children who were not living in poverty, a small (10%) increase in family income was associated with a decline in negative behavior of children who were poor (Dearing *et al.*, 2001; Taylor *et al.*, 2004), also suggesting that monetary increases are most important for families with the lowest incomes.

Persistence of Poverty

Similarly, the associations of poverty and development vary with the length of time poverty is experienced, such that families in chronic poverty face more prolonged and extensive negative life events and stressors than do families living in transitory poverty (Linver *et al.*, 2002). Children in the NLSY who experienced long-term poverty demonstrated increased internalizing problems (dependence, anxiety, and unhappiness), while those who experienced transient poverty displayed hyperactivity and headstrong behavior (McLeod and Shanahan, 1993). Additionally, the internalizing problems were observed in a follow-up study by the same authors several years later, regardless of further changes in income, suggesting that the negative impact of poverty on social and emotional development may endure over time (McLeod and Shanahan, 1996). The finding that long-term poverty was linked to internalizing problems in children of the NLSY is supported by evidence from another longitudinal study, the Infant Health and Development Program (IHDP; a randomized, multisite early intervention program for premature, low birth-weight children from families of varying socioeconomic levels). IHDP children who experienced enduring poverty demonstrated increased externalizing and internalizing behavior problems (Duncan *et al.*, 1994). Conversely, when families are lifted out of poverty, children may experience improvements in social and emotional outcomes. Income over time was studied using a natural experiment that evolved during a longitudinal study of American Indian and predominately white children living on a reservation in a rural community. Unlike the longitudinal, nonexperimental studies described thus far, this study was able to examine the links between poverty and child outcomes under experimental conditions, therefore ruling out many alternative explanations and spurious associations often characteristic of longitudinal data. After a casino opened on the Indian reservation, the incomes of the American Indian families increased while those of the white families stayed the same. Increased family income was associated with a significant decrease in observed psychiatric symptoms for those children whose

families moved out of poverty as a result of the introduction of the casino. Moreover, children whose families were lifted out of poverty with the additional income demonstrated reduced behavioral problems such that they matched children whose families had never been poor. Children's emotional problems, however, were unaffected by the change in income (Costello *et al.*, 2003).

Timing of Poverty

Research findings on the impact of the timing of poverty on development have been mixed. On the one hand, there is evidence that poverty in early childhood is more harmful to long-term behavioral outcomes than is poverty in later childhood or adolescence (Duncan and Brooks-Gunn, 2000). Some have hypothesized that, because very young children are biologically vulnerable, early deprivation has particularly negative consequences. Evidence suggests that, as a period of rapid and neurological development occurs between the ages of 0 and 3, children who do not have access to rich, stimulating environments during this crucial period are more likely to demonstrate deficits in healthy development (Shonkoff and Phillips, 2000).

On the other hand, there is evidence that implies children who experience poverty later in life have less favorable developmental outcomes than do their younger counterparts. For instance, research suggests that children who experienced poverty in middle childhood (between the ages of 4 and 9) demonstrated increased social and behavioral problems (Hofferth, *et al.*, 2000; NICHD Network, 2005), while a study on the well-being of children whose mothers returned to work after the 1996 welfare reforms found heightened social and emotional problems in the adolescent children of welfare recipients (Gennetian *et al.*, 2004). Therefore, it remains unclear what the impact of timing of poverty may be.

Mechanisms/Pathways

The pathways (or processes) of poverty refer to the mechanisms that explain how poverty works to produce negative child outcomes, and offer points of intervention for policies and programs. Research on these pathways can be organized into four categories: parenting, the home environment, education and care settings, and neighborhoods.

Parenting: The family stress model

Positive child outcomes typically flow from warm parent-child interactions, cognitive stimulation, clear limit-setting, and adequate monitoring (Bornstein, 2002). However, the psychological stress that accompanies poverty, resulting from the disruption of family relationships, unpredictable work schedules, and unstable income, can negatively affect parenting behavior which may subsequently contribute to poor child outcomes. Families that experience either

short-term financial loss or persistent poverty struggle to supply food, shelter, safety, and clothing; these struggles lead to increased levels of depression and anxiety for parents (McLoyd, 1990); notably, linkages between parenting stress and poor parenting practices are more pronounced for families in deep poverty (Petterson and Albers, 2001). In general, poverty has been connected to harsh parental behaviors associated with risk such as physical disciplining practices (Dodge *et al.*, 1994; Linver *et al.*, 2002), decreased attentive and responsive parenting (Dodge *et al.*, 1994; Jackson *et al.*, 2000; Smith *et al.*, 2001), and decreased levels of parental support (Jackson *et al.*, 2000). These parenting behaviors can lead to the deterioration of the parent-child relationship, especially in disadvantaged families (Petterson and Albers, 2001). In sum, the links between financial strain, parental stress, the disruption of family relationships, and ultimately negative child outcomes represent the crux of the family stress model.

Researchers have applied the family stress model to low-income adolescents, school-aged children (McLeod and Nonnemaker, 2000; Sampson and Laub, 1994), and young children (Dodge *et al.*, 1994; Duncan *et al.*, 1994; Jackson *et al.*, 2000; Linver *et al.*, 2002; McLeod and Shanahan, 1993; Yeung *et al.*, 2002), and have found evidence that families in stress can either exacerbate or serve as buffers against the negative child outcomes associated with poverty. For instance, a study by Linver *et al.* (2002) documented that income was associated with behavior problems and that authoritarian and harsh parenting, resulting from maternal emotional distress, accounted for the link between income and behavior problems for 3- and 5-year-olds in the IHDP sample. Similarly, in a study on 93 working mothers (who were poor) and their children, financial strain was found to be associated with increased depressive symptoms which were negatively linked with parenting quality and in turn led to negative child behavioral outcomes (Jackson *et al.*, 2000).

On the other hand, parents who engage in positive parenting despite stress factors due to poverty can buffer the negative association between poverty and child outcomes. In a classic study from the Great Depression, Elder and Caspi (1988) report that emotionally stable fathers were less likely to resort to negative parenting despite dramatic income loss, in turn positively influencing their children's self-esteem. In a second study, findings from parents in a poor rural community who were classified as nurturing and involved suggest that such positive parenting buffered the association between income stress and their children's development (Conger and Conger, 2000). Fortunately, social services, community-based programs, and early intervention programs, including home visiting components, are all potential sources of support, assistance, and information for parents that can improve parenting and, as a result, the child socio-emotional well-being (although results differ as a function of the intervention, with some

programs not finding effects; Barnes *et al.*, 1995; Benasich *et al.*, 1992; Brooks-Gunn *et al.*, 2000; Brooks-Gunn and Markman, 2005). Thus, the family stress model addresses an important pathway through which poverty operates on child social and emotional outcomes, and offers an opportunity for intervention and enhancement through social programming.

The home environment

While the family stress model emphasizes the association between income, parenting, and family relationships, the home environment itself is another pathway through which poverty may impact child development. As mentioned earlier, poverty almost certainly limits a family's ability to purchase material goods and experiences, to spend quality time with children, and to provide a safe and calm living environment that is conducive to healthy social and emotional development.

Research suggests that children from economically impoverished families have limited access to a variety of learning materials, such as books and educational toys (Bradley *et al.*, 2001), but that exposure to print materials and stimulating games may mitigate some of the negative links between poverty and child outcomes (Yeung *et al.*, 2002), as well as provide an opportunity for social exchanges between children and adults (Bradley and Corwyn, 2002).

In addition to having limited access to resources, a study using data from the NLSY found that the physical environments of families in poverty are generally less safe, less clean, darker, and more cluttered than those of nonpoor families (Bradley *et al.*, 2001). Furthermore, the lack of structure and routine, combined with increased environmental chaos that is more prevalent in low-income households, has been shown to have negative associations with child social and emotional development (Evans *et al.*, 2005).

Unfortunately, low-income households often lack important learning materials and resources in the home environment associated with positive child social and emotional outcomes. However, balancing monetary and time-related needs is especially challenging for low-income families because poor parents who work sacrifice time with their children without gaining much buying power from income in exchange (Ryan *et al.*, 2006).

Early childhood education and care

Yet a third pathway through which poverty may impact child development is by way of children's early childhood education and care (ECEC) environments. Specifically, there is promising evidence that quality ECEC settings are linked to improved child outcomes (e.g. Schweinhart *et al.*, 2005). Quality in ECEC refers to aspects of developmental environments recognized by researchers to promote and enhance early learning, including, but not limited to, low child-to-adult ratios, high levels of caregiver

education and qualification, stimulating and responsive interactions between the child and caregiver, and the availability of appropriate toys and learning materials; such aspects of quality in ECEC settings have been linked to improved cognitive and social outcomes for young children (Blau, 2001; Burchinal and Cryer, 2003; Lamb and Ahnert, 2006; NICHD Network, 2000; Shonkoff and Phillips, 2000). For children in poverty, high-quality ECEC may improve school readiness and subsequent chances for school success, financial independence, and social stability (Heckman and Lochner, 2001), and studies have found that the poorest children may benefit the most from high-quality ECEC programs (Brooks-Gunn, 2003; Brooks-Gunn *et al.*, 1993). Unfortunately, not all ECEC environments are of high quality. Recent findings from the Early Childhood Longitudinal Study Birth cohort (ECLS-B), report that 75% of infants and toddlers in center-based care were in care that was of low-to-medium quality, while only 24% were in high-quality centers (Mulligan and Flanagan, 2006). For poor children, low-quality care may add to the multitude of risk factors already present in a child's life.

Despite discouraging evidence regarding the quality of available care, there is reason to believe that when care is of high quality, low-income children experience long-term benefits. As space does not allow for a comprehensive review of the ECEC literature, we highlight findings from random-assignment experimental evaluations of high-quality model ECEC programs. When studies involve random assignment of subjects to treatment conditions (in this case, to receive or not to receive quality ECEC services), the possibility that noted differences after the conclusion of the study are due to the program being tested is higher than it would be if subjects chose, or selected themselves into, the different conditions. Thus, observed differences in performance or outcomes between subjects who were randomly assigned to a given condition or to the control group (children who did not participate in the high-quality ECEC program) are less likely to be due to unobserved, preexisting differences between groups and more likely to be attributed to effects of the program itself.

Beginning in the 1960s, researchers have conducted several experimental evaluations of the so-called model ECEC programs. These programs, which enroll low-income youngsters, typically offer children cognitively stimulating educational curricula directed by qualified staff in classrooms with low child-to-staff ratios, and often include parenting classes, health and nutrition components, and a home-visiting dimension. Low-income children who participated in the Infant Health and Development Program (IHDP) exhibited short-term positive changes in behavior; however, there is evidence that participation in high-quality ECEC programming can contribute to sustained socio-emotional benefits as well. For instance, children who attended Perry Preschool demonstrated fewer conduct and behavioral problems than did control-group children

up to 15 years after the conclusion of the intervention (Schweinhart *et al.*, 1993). Program children continued to experience lower rates of criminal arrest and decreased delinquent behavior through age 40 (Schweinhart *et al.*, 2005). Children who received ECEC services from the Carolina Abecedarian Project were less likely than those who did not to demonstrate the negative social and behavioral outcomes typically associated with childhood poverty, such as teen pregnancy and delinquent behavior, at ages 15 and 21 (Campbell and Ramey, 1994).

The neighborhood

Families, homes, and ECEC settings all exist within communities or neighborhoods and are inextricably linked to the characteristics of that area. However, aside from these elements, other neighborhood characteristics are also linked with child development. Therefore, the neighborhoods in which families reside are another possible pathway of influence through which income operates on child social and emotional outcomes.

The structural and demographic features of neighborhoods and communities are likely to affect child and adolescent outcomes, through community-level social and cultural processes such as community monitoring, the number and quality of social ties, organizational participation, and value consensus. For example, neighbors may serve as role models and exercise social control, helping young people to internalize social norms and learn the boundaries of acceptable behavior (Gephart, 1997; Jencks and Mayer, 1990; Xue *et al.*, 2005). Alternatively, low-income families are often limited in their choice of neighborhoods and find themselves in areas with social disorganization such as crime, unemployed adults, and few resources such as playgrounds and parks (Brooks-Gunn and Duncan, 1997). Overall, research has found that living in areas of concentrated poverty is linked with a negative impact on child and adolescent development (Brooks-Gunn *et al.*, 1997; Jencks and Mayer, 1990; Leventhal and Brooks-Gunn, 2000), as residence in low-income neighborhoods has been associated with increased child behavior problems, anxiety, and depression over and above family poverty (Chase-Lansdale *et al.*, 1997).

The ways that neighborhoods function to impact children in poverty have been studied using two large, longitudinal data sets. The Project on Human Development in Chicago Neighborhoods (PHDCN) is a multi-level, longitudinal study of a representative sample of children aged 5–11 years recruited from 80 neighborhoods and conducted in the late 1990s. In the PHDCN sample, concentrated neighborhood disadvantage was associated with more frequent and more severe mental health problems than other neighborhood socio-demographic characteristics after controlling for family demographic characteristics, maternal depression, and earlier child mental health scores (Xue *et al.*, 2005). This finding is

consistent with prior research on the same sample, linking concentrated disadvantage to neighborhood violence (Sampson, *et al.*, 1997), and suggesting that the social emotional health of children in poverty who reside in neighborhoods of concentrated disadvantage may suffer. However, data from the Moving to Opportunity Program, another randomized study of low-income families living in poor neighborhoods, found mixed results in terms of neighborhood wealth or poverty and social and emotional development (Leventhal and Brooks-Gunn, 2005).

Policy Implications

Childhood is a time of great vulnerability, in part because the developing social and emotional competencies of poor children are especially susceptible to the obstacles that growing up in poverty presents. However, childhood is also a time of great opportunity; the developmental trajectories of children and young adolescents are malleable, and thus these sensitive periods offer windows for intervention. Given what we know about the depth, persistence, and timing of poverty, programs that increase household income even modestly, that intervene to break up what would otherwise be extended cycles of poverty, and that offer social safety nets for children at all stages of development would be beneficial investments for society.

Moreover, research that has illuminated the range of pathways through which poverty presents obstacles to the healthy development of poor children has also highlighted a variety of options for enhancing the lives of poor children. With respect to parenting, the federally funded Early Head Start (EHS) program, which includes parenting classes, parental support groups, and home-visiting components targeted at improving parenting practices, shows some promise regarding more supportive parent-child interaction and increased episodes of parent-child reading compared to families who did not receive EHS services (Love *et al.*, 2005). Likewise, programs that incorporate home-visiting elements may also enhance the home environment of children in poverty.

With respect to ECEC, it is clear that high-quality ECEC programs that begin early, offer a comprehensive set of services, and that adhere to recognized standards of quality have a great deal of potential to boost developmental outcomes of children in poverty. Increased access to subsidies for childcare would increase the purchasing power of low-income families so that they might be able to buy into higher-quality care. In the meantime, continued support for the federal Head Start Program is crucial; begun in the 1960s, the comprehensive, wrap-around, center-based services offered by Head Start include ECEC that is, on average, of higher quality than a majority of other preschool programs (Currie, 2001). Additionally, recent research suggests that Head Start does have the

potential to substantially decrease the school readiness gap that exists between minority children (who tend to be low income), and their white peers (Magnuson and Waldfogel, 2005). However, a concern for those interested in intervening early in the lives of poor children is that only families below the federal poverty line are eligible for childcare subsidies and Head Start enrollment; families who are near-poor and endure many of the same stressors as poor and deep-poor families are nonetheless ineligible for many of the social services that would enhance their children's development. Thus, making ECEC programming universally available is an approach to intervention that can benefit extremely poor as well as near-poor children. Indeed, state-level initiatives, such as those in Oklahoma and Georgia to implement universal prekindergarten to all 4-year-old children, have demonstrated positive impacts on child development (Gormley and Phillips, 2005; Henry *et al.*, 2001). More effort is needed on behalf of policymakers to increase accessibility and affordability of quality care for children too young for programs like Head Start and universal prekindergarten.

Regarding the impact of neighborhoods as a conduit between poverty and child socio-emotional development, community development initiatives and programs that seek to build social capital in communities have great potential for alleviating many of the negative dimensions of poverty prevalent in low-income neighborhoods. For instance, high degrees of collective efficacy and community cohesion are associated with reduced violent crime and disorder; research findings reflect that collective efficacy within a community mediates the association between concentrated disadvantage and violence (Sampson *et al.*, 1997). As the association between both depression and anxiety in children, and exposure to violence, is well established and collective efficacy may protect children from these neighborhood threats (Xue *et al.*, 2005), a viable goal for community interventions and initiatives may be to increase efficacy.

In sum, it is imperative that policymakers attend to the extensive body of research literature emphasizing linkages between poverty and social and emotional development, as well as the range of options for intervening in and enhancing the lives of poor children. One possibility suggested by recent research is to apply an investment model to early childhood, where dollar-for-dollar increases in societal investments in children are linked to equal or greater pay-offs in terms of societal benefits. Indeed, some have argued that viewing social programs that support early childhood development as economic development initiatives may be the most effective way to marshal resources for interventions critical in setting healthy developmental trajectories (Rolnick and Grunewald, 2003; Schweinhart *et al.*, 2005). Regardless of the approach to intervention, policymakers must implement programs that help, rather than hinder, children's development by supporting families and

children. Without appropriate support mechanisms and intervention strategies, it is likely that poor children will continue to lag behind their nonpoor peers.

Seeking Help as an Adaptive Response to Learning Difficulties: Person, Situation, and Developmental Influences

S A Karabenick, University of Michigan, Ann Arbor, MI, USA

R S Newman, University of California – Riverside, Riverside, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Adaptive help seeking – Help seeking which is self-regulative, strategic, and ‘smart’.

Autonomous help seeking – See also adaptive help seeking.

Excessive help seeking – See also expedient help seeking.

Executive help seeking – See also expedient help seeking.

Expedient help seeking – Help seeking which is effort-avoidant and unnecessary.

Instrumental help seeking – See also adaptive help seeking.

Mastery-oriented students – Students motivated by a desire to learn, understand, and master difficult tasks.

Performance-avoid goals – Desire to avoid an appearance of incompetencies.

Social affiliation goals – Desire for friendship and intimacy.

Social status goals – Desire for peer approval and popularity.

Help Seeking and Learning: An Evolving Perspective

Students experience and deal with difficult academic tasks in diverse ways. Some exert little effort, sit passively, and give up prematurely, whereas others respond to failure with extra resolve and resourcefulness. One manifestation of such resolve involves seeking help. Indeed, recent research and theoretical advances indicate that help seeking can be an important form of behavioral self-regulation (Pintrich and Zusho, 2002), part of the tool kit of cognitively, behaviorally, and emotionally engaged learners (e.g., Butler, 1998; Karabenick, 2003, 2004; Karabenick and Knapp, 1991; Karabenick and Newman, 2006; Nelson-Le Gall and Resnick, 1998; Newman, 2000; Skinner and Zimmer-Gembeck, 2007; Zimmerman and Martinez-Pons, 1990; Zusho *et al.*, 2007). Seeking help may contribute to a general pattern of student resilience in overcoming obstacles to learning and achievement (see Newman, 2000, 2002).

This characterization of help seeking challenges the belief that it should be discouraged out of concern that it perpetuates dependency. Continued dependence on others could be a consequence of less adaptive help seeking (also referred to as expedient, excessive, or executive), which is effort-avoidant and unnecessary (Nelson-Le Gall, 1981, 1987). More adaptive help seeking (also referred to as instrumental, strategic, or autonomous; Butler, 1998; Karabenick, 1998; Nelson-Le Gall, 1981; Newman, 2000), however, can have just the opposite effect by increasing students’ capacity to surmount learning difficulties when encountered subsequently. Just as seeking help that is work avoidant or excessive may not be in students’ long-term best interests, avoiding seeking help when that help is truly necessary also can be nonadaptive (see Marchand and Skinner, 2007; Newman, 2007). The distinction between more and less adaptive forms (or goals) of help seeking must be considered as we examine the person characteristics and features of the learning context that influence its effective use.

Toward that end, we begin with a normative, or ideal, description of learners who employ adaptive help seeking. Such learners carefully monitor how they are doing academically, are attuned to difficulties they cannot overcome independently, and have the skills, motivation, and emotions to address those difficulties by approaching a potential helper and requesting what is needed. Resources required for adaptive help seeking include: (1) cognitive competencies (e.g., knowing when help is necessary and knowing how to formulate linguistically a specific question that yields exactly what is needed); (2) social competencies (e.g., knowing which instructors and classmates are more knowledgeable and can potentially help them and communication skills, such as how and when to approach helpers and how and when to thank them); (3) affective–motivational resources (e.g., academic and social goals, self-beliefs, and emotions that allow the student to tolerate difficulty and uncertainty and the ego strength required to withstand possibly negative perceptions in the eyes of classmates); and (4) contextual and interpersonal resources (i.e., classroom and home affordances such as teachers’ goals, grading system, collaborative activities, rules of student–teacher engagement, and teachers’ and parents’ expectations for the student) that support students’ cognitive and social competencies and affective–motivational resources.

Person and Contextual Influences

As in other areas of self-regulation, help seeking has been extensively studied within the framework of achievement goal theory, which differentiates between mastery-focused and performance-focused approaches to learning (Arbreton, 1998; Butler, 1998; Butler and Neuman, 1995; Karabenick, 2003, 2004; Newman, 2002; Pintrich, 2000; Ryan *et al.*, 1997; Ryan and Pintrich, 1997, 1998). At the individual level, studies have consistently shown that instrumental/adaptive help seeking is more likely among mastery-oriented students, who tend to construe seeking help within the broader goal of understanding and self-improvement (i.e., developing competence). Theirs is a learning orientation, which lends itself either to seeking help adaptively, or to working independently when that would be more effective (Butler, 1998). Adaptive help seeking is less likely, however, for students who are concerned about appearing incompetent (i.e., a performance-avoid orientation). If such students do seek help, it is often in the form of expedient or executive help seeking (e.g., Karabenick, 2004; Karabenick *et al.*, 2005).

Students' achievement goals at any point in time are a function both of past experiences and features of the contemporaneous learning context. Achievement goal structure refers to how students construe their classrooms and courses of study in terms of the contextual emphasis on mastery and/or performance goals (Ames and Archer, 1988; Midgley, 2002). Studies using hierarchical modeling consistently have found that students' perceptions of their classes' achievement goal structure influence their tendencies to seek or to avoid seeking help when needed (Church *et al.*, 2001; Midgley, 2002; Urdan *et al.*, 2002). Elementary school classes that students collectively judge as more focused on mastery are less likely to avoid seeking needed help (Turner *et al.*, 2002). Although young children are concerned about not appearing incompetent by asking for help, not until middle school do such concerns influence whether they will ask (Newman, 2000). Presumably a consequence of increased evaluation pressures that begin with the transition to middle school (Eccles and Midgley, 1989; Ryan and Pintrich, 1997, 1998), performance goal-related classroom characteristics, in addition to perceived classroom mastery goals, affect middle school students' tendencies to seek or to avoid seeking help (Karabenick *et al.*, 2005; Newman, 2002; Ryan *et al.*, 1998). By the time students are in college, available evidence suggests that classroom mastery goals are not as relevant to help seeking; rather, students in classes they perceive to be focused on avoiding demonstrations of incompetence (performance-avoid goals) are less likely to seek needed help, or they seek expedient help (Karabenick, 2004).

Cultural Influences

Culture can influence whether and in what situations students seek help, in particular, the degree of stress on individualism versus collectivism (Triandis, 1994). Learners in the US especially are socialized to idealize individualism and deplore dependency (Fischer and Torney, 1976; Sears *et al.*, 1957), which adds to the threat posed by help seeking. Individualistic values were codified in early theories of achievement motivation in which seeking help was considered incompatible with an achievement motive (Beller, 1957; Winterbottom, 1958). Learners in collectivist societies presumably are not as subject to the same prohibitions and should accordingly be less reluctant to seek help. This prediction was verified in that Israeli students raised collectively on kibbutzim were more likely to seek help than those socialized in individualistic-oriented cities (Nadler, 1998). Such cultural influences extend to learning and performance in the workplace as well, as evidence indicates that collectivistic (vs. individualistic) norms facilitate help seeking due to the perceived safety that results from collectivist organizational norms (Sandoval and Lee, 2006).

When examining the effects of culture on help seeking, however, it is important to avoid essentialist generalizations. This means taking into consideration characteristics of tasks, specific learning contexts, and whether the help is sought in public (as in classrooms) or privately (after class or in faculty offices) (Karabenick and Knapp, 1988a). For example, the cultural differences found by Nadler depended on whether students worked on tasks individually or in groups. Japanese college students' collectivistic acculturation, which stresses cooperation, dependency, and empathy, does facilitate seeking assistance from peers outside of the classroom. However, due to culturally induced deference to authority in the form of relationships with instructors, students are hesitant to ask their instructors questions in class (Shwalb and Sukemune, 1998). The same deference to authority occurs in other collectivist societies such as Malaysia (Hashim *et al.*, 2003). Situation influences have also been demonstrated among US and Australian college students whose intentions to seek help from peers decreased as the cultural difference between them and their peers increased (Volet and Karabenick, 2006). The more students were culturally unlike other students, the less likely they would approach them for needed assistance with their studies. The effect of cultural difference between those in need of assistance and help providers was moderated, however, by students' perceived support from their teachers for intergroup acceptance: cultural differences were minimized to the extent their teachers supported intercultural interactions among students in their classes.

Fostering Adaptive Help Seeking in the Classroom

Teacher Influences

Help seeking in the classroom is a social transaction (Newman, 1998a). Teachers establish – and students internalize – patterns of discourse in the classroom. Teachers who respond to requests for help with hints and contingent instruction (vs. direct and controlling answers) are likely to have students who not only accomplish difficult tasks but, in addition, learn that questioning is an invaluable academic strategy. In contrast, teachers who take on the role of expert (e.g., who present to the class an explanation without discussion and then expect students simply to practice) are likely to support overly dependent executive/expedient help seeking. When teachers personally demonstrate that uncertainty can be tolerated – and perhaps even transformed into intellectual challenge – students are likely to realize it is normal not to be able to solve all problems independently (McCaslin and Good, 1996). It is expected that, when teachers scaffold learning experiences and socialize the normalcy of academic difficulty, need for collaboration, and expectation of answers to their questions, students internalize a personal sense of empowerment and voice (Nelson-Le Gall and Resnick, 1998).

Ideally, students learn the value, usefulness, and skills of questioning that are important for monitoring, diagnosing, and fixing misconceptions. The frequency with which teachers call on students, the amount of time they wait for a response, and the amount and type of praise they give vary from student to student (Eccles and Wigfield, 1985). Teacher feedback helps students know when they need help. Giving no more assistance than is necessary may help students learn the difference between adaptive and nonadaptive (i.e., expedient) help seeking. Encouraging students to go back to an incorrect problem and try to re-solve it may convince them of the importance in determining if they need further assistance. Further, it may be instrumental in students' coming to appreciate the function of questioning and help seeking in the ongoing process of self-monitoring and learning.

As noted above, when both classroom and personal goals emphasize learning and developing competence, students are especially likely to seek help adaptively, whereas when both types of goals emphasize performance, students are reluctant to do so. When students who are concerned about grades and looking smart are placed in a learning-goal classroom, they may tend to overcome – and compensate for – their personal tendencies to avoid help. Thus, by being attuned to individual students' personal goals, teachers can assist those who otherwise might give up in the face of adversity (Newman, 1998b). Teachers can also try to accommodate students' social goals

(e.g., social affiliation, social status) that influence help seeking (Ryan *et al.*, 1997). The task of goal-coordinator is not easy, as multiple personal (i.e., both achievement-related and social) goals and multiple classroom goals can complement or conflict with one another. Things become even more complex when one considers that responsive teachers try to support student autonomy while at the same time satisfying their own personal (i.e., both achievement-related and social) goals and need for autonomy within the constraints of public school settings (Butler, 2006). In classrooms in which teachers share with children their time, energy, and nurturance, students tend to be attentive, effortful, self-expressive, and interested in learning.

Teachers who are interpersonally involved with students and attuned to the student's purpose typically establish classrooms that facilitate adaptive help seeking. When teachers and students are on the same page, teachers are especially able to take the student's perspective and understand his or her thinking (e.g., regarding a particular academic task) and, based on this understanding, appropriately guide the student's learning. Teachers who are perceived as friendly and caring tend to demonstrate democratic interaction styles, with lines of communication open to students; they listen, ask questions, inquire if students need help, make sure students understand difficult material, and provide help in a nonthreatening way (Wentzel, 1997). When they experience this type of communication, students learn that teachers are trustworthy helpers. Low achievers, who often have poor self-perceptions of ability and low self-esteem, typically are reluctant to seek academic help in class (Karabenick and Knapp, 1988b, 1991). For these students, especially, teachers who believe their responsibility is to attend to students' academic as well as social and emotional needs can counter student disengagement (Ryan *et al.*, 1998).

Teacher involvement forms the basis of students' beliefs and feelings about the benefits – and costs – of help seeking. Early-elementary-aged students generally feel comfortable approaching their teacher for assistance because of global, affective traits of the teacher (e.g., niceness and kindness). By the middle of elementary school, students tend to view teachers as helpful when they show an awareness of their problems and give them advice, time, energy, and encouragement to ask questions in class (Newman and Schwager, 1993). In classes where teachers are perceived as supporting collaboration, student questioning, teacher fairness, respect, and caring, middle and high school students are especially likely to seek adaptive help and not avoid seeking help (Karabenick *et al.*, 2005). Their approaches to teaching, in terms of their own achievement goals, can also influence how supportive they are perceived by students (Butler, 2007). Perceived support for student questioning facilitates help seeking, in particular, at the

college level (Karabenick and Sharma, 1994). However, as early as grade 2, students often are fearful of teachers' negative reactions (e.g., I think she might think I'm dumb if I ask for help) if they ask for help (Newman and Goldin, 1990). Perceived costs are heightened when teachers are unwilling to help (e.g., if you had paid attention, you wouldn't need to ask that question). Children weight the relative benefits and costs of help seeking, with the integration process becoming increasingly complex over the school years, whereas older students increasingly struggle in deciding what to do when they need academic assistance (Newman, 1990).

The Influence of Peers: Social Relations and Comparison Processes

Generally, classroom goals and task structure determine how students influence one another's competence and self-perceptions of competence required for adaptive help seeking. In some learning contexts, students are allowed to collaborate – asking and answering one another's questions – but in other contexts, they are not. In contrast to individual classroom activity (where teachers usually expect students not to need assistance) and whole-class activity (where questions generally flow in the direction of teacher-to-student rather than student-to-teacher), small-group activity generally reduces social comparison and promotes peer collaboration. During small-group collaboration, children can turn to one another when they need assistance.

With experience working together, children gradually become better at asking each other good questions in good ways. Adaptive help seeking requires that students skillfully request help from one another, for example, checking to see if the potential helper is paying attention to them before actually making a request. Ideally, students make requests that are direct, sincere, polite, and clear about what exactly is being requested (Cooper *et al.*, 1982). Requests are often revised and clarified if they are initially unsuccessful in obtaining a response. When students make vague requests but persist by reformulating and clarifying the requests, academic performance tends to improve. Also, when they ask for – and receive – elaborated help (e.g., explanations rather than direct answers) and when they then use the help in a constructive way, children are most likely to learn (Webb and Palincsar, 1996).

Especially at upper-elementary and middle school, collaborative activity provides students a chance to think in public and exchange with one another their thoughts. Built into many collaborative activities are opportunities for students to ask – and be asked – questions for purposes of monitoring their own and others' understanding and for requesting clarification, justification, and elaboration of other students' ideas. Questions potentially allow an exchange of perspectives among individuals who are

working on relatively equal footing. As students observe the effectiveness of peers' questions in resolving difficulties, they are likely to learn that different individuals contribute unique skills and knowledge. They may learn how, in the future, to choose helpers according to both their own needs and others' competencies (Webb *et al.*, 2006).

Although social comparison can be detrimental if that process facilitates performance-avoid goals, comparing one's performance with that of others can have a positive influence on help seeking. Social comparison offers information about others' strengths and weaknesses and thus helps children evaluate peers' capacity to be effective helpers (Ruble and Frey, 1991). It helps children make realistic judgments about whether they personally have tried enough before turning to others. With development, children are increasingly able to judge when assistance is truly necessary so they can request the right amount of help – not too little and not too much.

Typically there are concomitant changes in how children conceptualize ability; students come to believe that smart children who do not have to try very hard and dumb children who have to work extra hard can get a similar grade on an assignment. Thus, students come to perceive children who need help as not very smart (Nicholls and Miller, 1984). By publicly seeking help, adolescents put their self-worth at risk (Covington, 1992). Social comparison strongly influences one's achievement motivation, for it affects why one works hard, or cheats, or gives up: Is it to satisfy one's personal desire to learn, or to prevent others from seeing a weakness, or to impress classmates and parents (see self-determination theory; Ryan and Deci, 2000). By managing positive and negative aspects of social comparison (e.g., according to grading practices, types of classroom activity, goal structures), classroom teachers can potentially affect the extent to which students influence one another's sense of autonomy needed for adaptive help seeking (Newman, 2000).

Friends, by definition, assist and support one another (Berndt and Keefe, 1996). Quality friendships are characterized by mutual support as well as certain features (e.g., reliability, affection, intimacy, and lack of conflict and rivalry) that tend to mediate efforts to seek help. In close relationships, children are relatively unconcerned about self-disclosure, threat to self-esteem, and indebtedness to those who help them. In a friendly context, children find it easier to manage and negotiate social demands of interactions and focus their shared efforts on learning and problem solving. In contrast, children in conflictual relationships typically are reluctant to disclose difficulties to one another and probably would not expect help to be forthcoming even if they requested it.

Social goals are related to academic help seeking. The more strongly they strive for goals of social affiliation (i.e., desire for friendship and intimacy), the more students value and use help seeking as a strategy for dealing with academic difficulties (Ryan *et al.*, 1997). These goals

however do not guarantee that help seeking is adaptive. Children may appear to work together and request help from one another but really just goof off. Indeed, requests among friends are sometimes socially inappropriate (e.g., shouting questions across the room) and cognitively inappropriate (e.g., requesting unnecessary help). The more strongly students strive for goals of social status (i.e., desire for peer approval and popularity), the more they are embarrassed to ask for help in the classroom (Ryan *et al.*, 1997). At the transition to middle-school, when students typically are concerned about their self-image in addition to the increase in evaluation pressures, social status goals are likely to inhibit help seeking, especially if an individual's self-esteem is easily threatened and his or her peer group does not value academic success. Importantly, however, inhibition is likely to be minimized if the student has a strong sense of self and a peer group that does value learning. Such influences may also play a role when students transition to college. If nothing else, their peers during that time are a convenient and even preferred source of assistance (Knapp and Karabenick, 1988).

The Role of Technology

Help seeking increasingly takes place by other than face-to-face contact. More so than voice, computer-mediated communication (CMC) potentially affords students an unlimited landscape of individuals, virtual communities, information, and intelligent systems as resources (Keefer and Karabenick, 1998). Such availability can dramatically reduce the cost of seeking help both in terms of sheer time and effort but also in creating safe contexts by virtue of increased (or total) anonymity, which reduces the threat to self-worth and increases the likelihood that students will seek help (Karabenick and Knapp, 1988a). The wide availability of resources, however, also increases the potential for seeking help that is expedient and work avoidant and raises significant concerns that technology-assisted help seeking may tend to be less adaptive. Recent work is exploring this issue in students' use of online tutoring systems, which employs comprehensive models of the help-seeking process to provide context sensitive help (Aleven *et al.*, 2003, 2006). One emerging concern is that students tend to game the tutoring system in order to quickly complete online tasks rather than gain greater understanding of the material. It appears that the technology-mediated help-seeking process is subject to the same motivation-related characteristics of contexts in which it is situated (Schofield, 1995). Accordingly, whether learning occurs in a mastery-versus performance-focused instructional setting may be just as important when seeking help using advanced technologies as it is from teachers in the classroom.

Summary

Help seeking is a unique social and behavioral strategy of self-regulated learning that involves a social transaction with teachers, classmates, parents, and resources that may be technologically mediated. Its social dimension renders seeking help more complex than other regulation strategies such as rehearsing, organizing, self-checking, and self-testing, strategies that students can carry out independently. The promotion of strategic help seeking necessitates that teachers and other help providers such as counselors, tutors, or parents understand the distinction between help that is instrumental or adaptive from that undertaken to avoid work (expedient), such as seeking help excessively (Alexitch, 2006; Collins and Sims, 2006).

Teachers and peers play important roles in children becoming self-regulated learners. Adaptive help seeking is facilitated by fostering mastery goals. When teachers stress the intrinsic value of learning in their classrooms rather than just getting good grades (or avoiding bad grades), students tend to ask task-related questions in order to truly understand their work. Knowing how one is doing in relation to classmates can have both positive (e.g., it's normal to need help) and negative (e.g., concern about social status). Teachers can potentially affect processes of social comparison. Sensitive and responsive teachers buffer students from factors (e.g., potential embarrassment) that typically inhibit help seeking. They play an instrumental role in the development of children's personal beliefs about the costs and benefits of help seeking. They can help establish collectivistic (vs. individualistic) classroom norms and facilitate the degree to which peer involvement provides children opportunities to experience social aspects of learning. Teachers need to be aware of how technology, in the form of communications or online tutoring, can facilitate help seeking by reducing costs (time, effort, and embarrassment), but they also need to be aware of the potential for its excessive misuse. Increasingly, learners as well need to develop better adaptive help-seeking strategies, which would be important for teachers and other providers of help to foster as they would other cognitive and metacognitive learning strategies.

Self-Concept in Learning: Reciprocal effects model between academic self-concept and academic achievement

H W Marsh and L F Scalas, Oxford University, Oxford, UK

© 2010 Elsevier Ltd. All rights reserved.

Self-concept is one of the oldest and most important constructs in the social sciences, dating back to at least the seminal work by William James (1890/1963). Today, self-concept enhancement is a major goal in many fields, including education, child development, health, sport/exercise sciences, social services, and management. This concept is a multidimensional hierarchical construct with highly differentiated components such as academic, social, physical, and emotional self-concepts in addition to a global self-concept component. It is also an important mediating factor that facilitates the attainment of other desirable outcomes. Particularly in education settings, a positive academic self-concept (ASC) is both a highly desirable goal and a means of facilitating subsequent learning and other academic accomplishments.

Multidimensionality of Self-Concept

Definition of Self-Concept

Historically, self-concept measurement, theory, research, and application have been plagued by the poor quality of both theoretical models and self-concept measurement instruments (e.g., Shavelson *et al.*, 1976; Wells and Marwell, 1976; Wylie, 1974, 1979). In an attempt to remedy this situation, Shavelson *et al.* (1976) reviewed existing self-concept research and instruments, proposed a new theoretical model of self-concept, and provided a blueprint for the development of multidimensional self-concept instruments (see review by Marsh and Hattie, 1996).

Self-concept, broadly defined by Shavelson *et al.* (1976), is a person's self-perceptions formed through experience and interpretations of one's environment. It includes feelings of self-confidence, self-worth, self-acceptance, competence, and ability. It is influenced especially by evaluations by significant others, reinforcements, and attributions for one's own behavior. Self-concept is not an entity within the person, but a hypothetical construct that is potentially useful in understanding individuals and how they behave. Shavelson *et al.* noted that self-concept is important both as an outcome and as a mediating variable that helps to explain other outcomes. Self-perceptions influence the way important outcomes and these outcomes in turn influence one's self-perceptions.

Multidimensional, Hierarchical Model of Self-Concept

Shavelson *et al.* (1976) identified seven features that were critical to their definition of the self-concept construct. The most important for present purposes are that self-concept is multifaceted and hierarchically organized with perceptions of personal behavior in specific situations at the base of the hierarchy, inferences about self in broader domains (e.g., social, physical, and academic) at the middle of the hierarchy, and global self-concept (also known as self-esteem) at the apex (see **Figure 1**).

Remarkably, at the time Shavelson *et al.* proposed their model, there was little support for the multidimensionality of self-concept. The resistance to the multidimensional aspect of the model in particular was so strong that leading researchers of that period (e.g. Coopersmith, 1967; Marx and Winne, 1978) argued that self-concept was either a unidimensional construct or that the facets of self-concept were dominated so heavily by a general factor that they could not be differentiated adequately. Recently, Byrne (1984: 449–450) noted that: “Many consider this inability to attain discriminant validity among the dimensions of SC to be one of the major complexities facing SC researchers today.” In retrospect – as clearly articulated by Shavelson *et al.* (1976) – the renaissance of self-concept research was floundering due to the lack of a solid basis of measurement to support it.

However, the Shavelson *et al.* model provided a blueprint for the development of a whole new generation of multidimensional self-concept instruments that have provided overwhelming support for the multidimensionality of self-concept. There are several widely used inventories for measuring multiple dimensions of self-concept that, to some extent, differ in the self-concept dimensions included (e.g., Bracken, 1996; Harter, 1998; Marsh, 1990b; see review by Byrne, 1996b). Typically, however, these instruments include at least one or more factors representing the specific academic (e.g., mathematical and verbal self-concept), social (e.g., relations with friends and relations with parents), physical (e.g., physical competence and attractiveness), and emotional domains of self-concept, and a global self-esteem scale as posited in the Shavelson *et al.* (1976) model. Among the various instruments, external reviews (see Boyle, 1994; Byrne, 1996b;

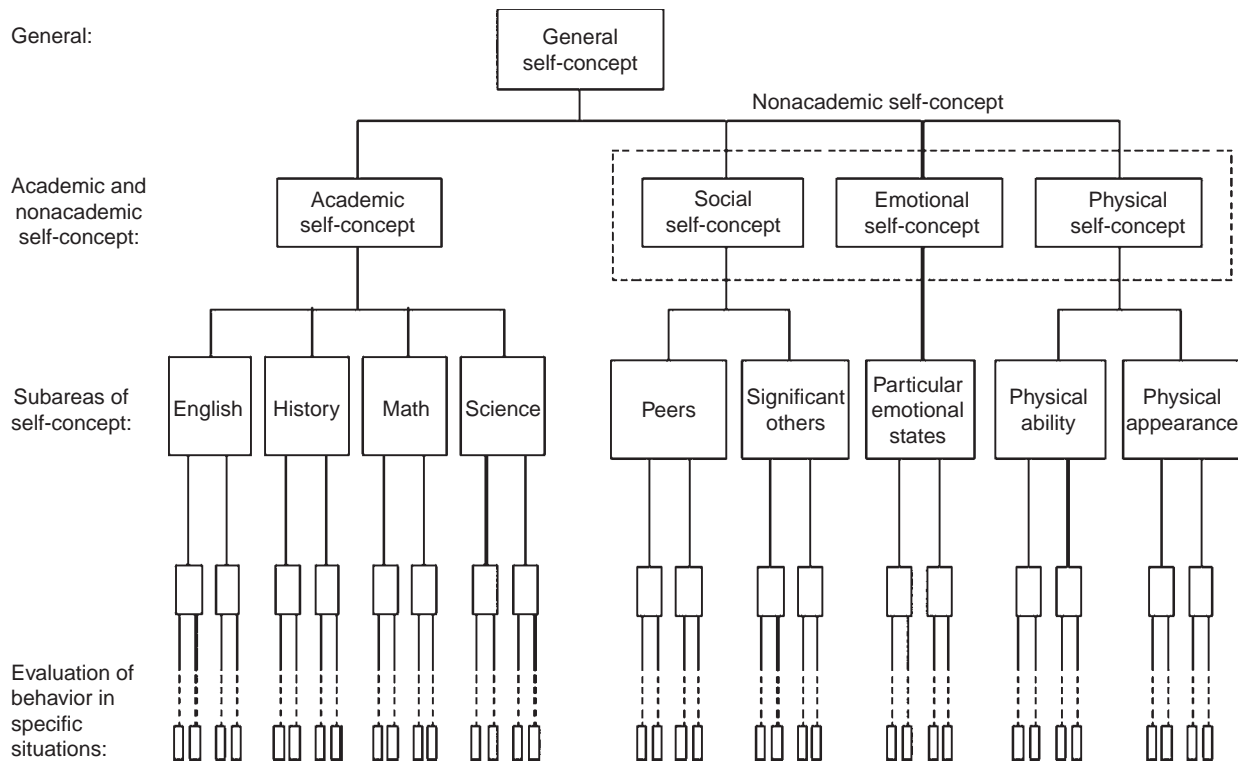

Figure 1 Pictorial representation of the multidimensional, hierarchical model of self-concept posited by Shavelson *et al.* (1976) and Marsh and Shavelson (1985). The box consisting of dashed lines around the nonacademic self-concept factors is used to distinguish these from the academic self-concept factors, but does not imply that there is a single higher-order nonacademic factor, as is hypothesized for the academic factors. The unlabeled boxes in the bottom of the hierarchy are used to show that the model posits additional levels in the hierarchy and even more domain-specific components of self-concept than those that are explicitly presented (e.g., mathematical self-concept might be broken into different mathematical topics such as algebra, trigonometry, or calculus, and each of these could be further subdivided into specific components relevant to each of the mathematical subjects). Reprinted from Shavelson, R. J., Hubner, J. J., and Stanton, G. C. (1976). Validation of construct interpretations. *Review of Educational Research* 46, 413.

Hattie, 1992; Wylie, 1989) suggest that the Self Description Questionnaire (SDQ) instruments are the strongest multidimensional self-concept instruments for children (SDQI), adolescents (SDQII), and young adults (SDQIII), respectively. In less than a decade, the accepted wisdom in self-concept research moved from a unidimensional perspective in which the multidimensionality of self-concept was all but dismissed to a multidimensional perspective that was particularly embraced in educational research (see reviews by Marsh and Hattie, 1996; also see Byrne, 1996a, 1996b; 2002). The hierarchical aspect of the Shavelson model linked these two approaches, including both a global component of self-concept at the apex of the model and increasingly differentiated multiple dimensions of self-concept at lower levels of the model.

Marsh and Craven (2006) argued that the acceptance of a multidimensional rather than a unidimensional perspective of self-concept varies substantially across various social science disciplines and within subdisciplines in psychology. However, its broadest acceptance and strongest

support comes from educational psychology with its focus on ASC (Marsh, 1993) and its relation to academic achievement, school grades, student learning, and other academic outcomes.

Support for Multidimensionality: Correlations between ASC and Achievement

Various measures of academic achievement are substantially correlated to corresponding measures of ASC, but are nearly uncorrelated (or even negatively correlated) with nonacademic components of self-concept and self-esteem (Marsh, 1993; Marsh and Craven, 2006). Thus, for example, Marsh and O'Neill (1984) related mathematics and English achievement to responses by high school students to the SDQIII instrument. Mathematics achievement correlated 0.58, 0.27, and 0.11 with math, general academic, and verbal self-concepts, respectively, whereas English achievement correlated 0.42, 0.24, and 0.19 with verbal, general academic, and math self-concepts,

respectively. Remarkably, none of the nine nonacademic scales – including global self-esteem – was significantly related to either of the achievement scores. Demonstrating the generalizability of these effects, Marsh *et al.*, (1988) found that correlations between math and English self-concepts based on each of three different instruments were close to zero, that math achievement was substantially correlated with math self-concept but not English self-concept, and that English achievement is substantially correlated with English self-concept but not math self-concept. Similarly, Marsh (1992) established that relations between ASCs in eight specific school subjects were substantially related to school grades in the matching school subjects ($r_s = 0.45\text{--}0.70$), offering support for the external validity of specific facets of ASC. In contrast, self-esteem was nearly uncorrelated with school grades in all the school subjects, indicating that it had no validity in relation to this criterion. More recently, Marsh *et al.* (2006) demonstrated a predictable pattern of substantial relations between eight academic criterion variables (grades, test scores, and coursework selection in different school subjects) and corresponding ASCs, whereas self-esteem was nearly uncorrelated with all these criteria ($r_s = -0.03$ to $0.05 >$).

Although self-concept and school grades are substantially correlated, there are also important differences between the two constructs. Thus, for example, academic achievements in different school subjects are substantially correlated, indicating a strong hierarchical ordering in which much of the variance in specific subject areas can be explained by a global achievement factor (or intelligence quotient (IQ)). In contrast, self-concepts in different school subjects are highly differentiated. In fact, even though math and verbal achievement are highly correlated (r_s of $0.5\text{--}0.8$), math and verbal self-concepts are nearly uncorrelated. Marsh and Hau (2004) demonstrated support for a theoretical model designed to explain this juxtaposition between ASC and achievement domains generalized across nationally representative samples of students from 26 different countries. This extreme differentiation among math and verbal self-concepts also led to the Marsh/Shavelson revision of the original Shavelson model in which self-concepts in core academic subjects are represented by two higher-order ASC factors (math/academic and verbal/academic) rather than one (Marsh, 1992; Marsh *et al.*, 1988).

Furthermore, consistent with this distinction between self-concept and achievements in different school subjects are relations between ASC, achievement, and other academic criteria. For example, Marsh and Yeung (1997) demonstrated that whereas self-concepts in different school subjects and matching school grades were substantially correlated, the specific components of ASC predicted subsequent coursework selection much better than did school grades or more general components of self-concept. These results provide empirical evidence calling into

question the usefulness of a general self-esteem construct in educational psychology research, and offer strong support for the multidimensional perspective. In summary, ASC and achievement are not only systematically related, but also very distinct constructs.

ASC/Learning Relationship: Reciprocal Effects Model

Causal-Ordering ASC and Achievement: Reciprocal Effects Model

Do changes in ASC lead to changes in subsequent academic performance? Correlational studies provide convincing evidence of the strong relations between ASC and various measures of academic accomplishment, achievement, and learning. However, a much more demanding question is whether ASC causes achievement or achievement causes ASC. Historically, the causal ordering of self-concept and performance has been, perhaps, the most vexing question in self-concept research (Byrne, 1984; Marsh, 1993; Marsh and Craven, 2006). This critical question has important theoretical and practical implications, and has been the focus of considerable research – particularly in educational settings.

Byrne (1984) emphasized that much of the interest in the ASC/achievement relation stems from the belief that ASC has motivational properties such that changes in ASC will lead to changes in subsequent academic achievement. As self-concept and academic achievement are not readily amenable to experimental manipulations, most research relies on longitudinal panel data in which both self-concept and achievement are measured on at least two occasions (i.e., a two-wave, two-variable design) and preferably three or more (see **Figure 2**). Calsyn and Kenny (1977) contrasted self-enhancement and skill development models of this relation. The self-enhancement model posits self-concept as a primary determinant of academic achievement (i.e., self-concept \Rightarrow achievement) and would support self-concept enhancement interventions. In contrast, the skill development model implies that ASC emerges principally as a consequence of academic achievement (i.e., achievement \Rightarrow self-concept) so that the best way to enhance ASC would be to develop stronger academic skills.

In a review and critique of this research, Marsh (1990a, 1990b, 1993) argued that much of this research was methodologically unsound and inconsistent with self-concept theory (Marsh *et al.*, 1999). He emphasized that according to both common sense and theory, prior academic achievement was one determinant of ASC. Hence, the critical question was whether there also existed a significant path from prior ASC to subsequent achievement – regardless of whether or not this path was larger than the path from prior academic achievement to subsequent ASC. Marsh (1990a)

Figure 2 Prototype causal-ordering model for testing self-enhancement, skill development, and reciprocal effects models. In this full-forward, multiwave, multivariable model, multiple indicators of academic self-concept (ASC) and achievement (ACH) are collected in three successive waves (T1, T2, and T3). Each latent construct (represented by ovals) has paths leading to all latent constructs in subsequent waves. Within each wave, academic self-concept and achievement are assumed to be correlated; in the first wave, this correlation is a covariance between two latent constructs, and in subsequent waves, it is a covariance between residual factors. Curved lines at the top and bottom of the figure reflect correlated uniqueness between responses to the same measured variable (represented by boxes) collected on different occasions. Paths connecting the same variable on multiple occasions reflect stability (the solid gray paths), but these coefficients typically differ from the corresponding test-retest correlations (which do not include the effects of other variables). Dashed lines reflect effects of prior achievement on subsequent self-concept, whereas solid black lines reflect the effects of prior self-concept on subsequent achievement.

further argued that a more realistic compromise between the self-enhancement and skill development models was a reciprocal effects model (REM) in which prior self-concept affects subsequent achievement and prior achievement affects subsequent self-concept (Marsh and Craven, 2006; Marsh *et al.*, 1999). He further argued that this early emphasis on an either/or model of causal ordering was due largely to limitations in statistical techniques for testing these models in the 1980s that are no longer relevant.

Bringing together stronger theoretical and statistical bases for addressing these issues, Marsh (1990a) proposed the REM of ASC. **Figure 2** presents a prototypical REM designed to test the causal ordering of ASC and achievement. Self-concept and academic achievement are each measured at least 3 times in this longitudinal panel design. The critical issue is whether there are statistically significant paths leading from prior self-concept to subsequent achievement (in support of self-enhancement predictions) and from prior achievement to subsequent self-concept (in support of skill development predictions). Support for the

REM requires that both sets of paths are statistically significant; however, from the perspective of self-concept theory and practice, the linkages from prior self-concept to subsequent achievement are particularly important.

A growing body of research, reviewed by Marsh and Craven (2006), has established support for the REM of relations between ASC and academic achievement (Marsh *et al.*, 1999). In a recent meta-analysis of relevant research, Valentine *et al.* (2004) also concluded that there was clear support for predictions based on the REM over those derived from self-enhancement and skill development models.

This reciprocal pattern of relations between self-concept and performance posited in the REM is also represented in many other theoretical accounts of self-concept and related self-belief constructs (e.g., Bandura, 1997; Byrne, 2002; Eccles, 1983; Eccles and Wigfield, 2002; Harter, 1998, 1999; Hattie, 1992; Skaalvik, 1997; Valentine and DuBois, 2005; Valentine *et al.*, 2004; Wigfield and Eccles, 2002) as well as in the broader themes of reciprocal patterns of relation in developmental psychology (e.g., Lerner, 1982, 1996). Thus, for example, expectancy-value theory (Eccles, 1983; Eccles and Wigfield, 2002) hypothesized academic self-beliefs to be a function of prior academic successes and to affect subsequent academic success directly or indirectly through their influence on other mediating constructs. More generally, in their review of theoretical research and meta-analysis of empirical research, Valentine and DuBois (2005) concluded that the posited reciprocal effects relating academic self-beliefs and achievement are consistent with theories of learning and human development that view the self as a causal agent (e.g., Bandura, 1997; Carver and Scheier, 1981; Deci and Ryan, 1985). Indeed, Valentine and DuBois concluded that support for the REM was equally strong for domain-specific ratings of ASC and self-efficacy.

Extensions of the REM

In their review of theoretical and empirical support for the REM, Marsh *et al.* (1999; also see Marsh and Craven (2006)) argued for the need for further research to test the generalizability of the REM over nationality and culture (support was based largely on studies done in Western, English-speaking countries), age (support was based primarily on research with adolescents), and content area (research was based largely on studies in a limited number of academic domains – particularly mathematics).

Cross-cultural generalizability

Partly in response to Marsh *et al.* (1999), recent research demonstrated that this support for the REM of ASC and achievement generalized to different cultural/national settings in a large nationally representative sample of

Hong Kong students (Marsh *et al.*, 2002) and large samples of East and West German students at the time of the fall of the Berlin Wall (Marsh and Köller, 2003; Marsh *et al.*, 2001). Support for the generalizability also comes from research based on French-speaking Canadian primary students (Guay *et al.*, 2003) and the German high school students (Marsh *et al.*, 2005). Hence, there is strong cross-national and cross-cultural support for the REM.

Generalizability over age

Based on developmental theory, some researchers have suggested that the reciprocal pattern of relations in support of the REM found with adolescents is unlikely to generalize to preadolescents (see Wigfield and Karpachian, 1991). However, two reviews of this literature (Marsh *et al.*, 1999; Valentine *et al.*, 2004) concluded that there was not sufficient good-quality research with young children to support this conclusion. Guay *et al.* (2003) addressed this issue about developmental trends in REM research. They used a multicohort–multioccasion design for responses by students in grades 2, 3, and 4 (i.e., three age cohorts aged 8–10 years of age, each with three measurement occasions). The structural equation model (SEM) for the total sample supported an REM for the first two waves of data (paths leading from prior self-concept to subsequent achievement, and from prior achievement to subsequent self-concept) and a self-enhancement effect (paths leading prior self-concept to subsequent achievement) between the second and the third waves. This pattern was replicated in tests of the invariance of the SEM across the three age cohorts, demonstrating support for the generalizability of the REM across these preadolescent ages.

Generalizability to the physical domain

Although there is a growing body of research based on ASC and academic achievement, Marsh *et al.* (1999) noted that there were few tests in nonacademic domains. More recently, Marsh and colleagues have undertaken a number of studies evaluating the generalizability of the REM to the physical domain for both general populations and elite athletes.

Marsh *et al.* (2005) evaluated the generalizability of the REM for gymnastics self-concept and gymnastics performance (independently evaluated by expert judges viewing videotapes of a standardized performance test). Consistent with *a priori* predictions in support of the REM, the effect of T1 gymnastics self-concept on T2 gymnastics performance (0.20) and the effect of T1 gymnastics performance on T2 gymnastics self-concept (0.14) were both highly significant. Consistent with the REM, gymnastics self-concept and gymnastics performance were both determinants and consequences of each other.

Recognizing the critical importance of health-related physical self-concept in children and adolescents,

Marsh *et al.* (2006) adapted the REM in a study of the causal ordering of physical self-concept and exercise behavior. The study was based on a large sample of primary and secondary Greek physical education students (2786 students, 200 classes, 67 teachers) and data collected early (T1) and late (T2) in the school year. There was clear support for the REM as there were significant effects of T1 physical self-concept on T2 exercise behavior and T1 exercise behavior on T1 physical self-concept. Physical self-concept is both an effect and a cause of exercise behavior.

Does physical self-concept influence subsequent physical performance during preadolescence? Marsh *et al.* (in press) combined the need to test the generalizability of the REM with children and in the physical domain. They used longitudinal data for young boys and girls ($N = 1135$; M age = 9.67 years) to show that physical self-concept is both a cause and a consequence of physical accomplishments. After controlling for prior physical performance (physical-performance-based test and teacher assessments in grade 3, primary school), physical self-concept had a positive effect on subsequent physical performance in both grade 4 and, following the transition to secondary school, grade 6. Despite the fact that physical self-concept is a gender-stereotyped construct (with boys having systematically higher physical self-concepts; Crain, 1996; Marsh, 1989), support for the REM generalized over gender. In addition, gender differences favoring boys in grades 4 and 6 were largely mediated by prior differences in grade 3. Coupled with previous REM research based largely on studies of adolescents in the academic domain, this study supports the REM's generalizability over gender, self-concept domain, preadolescent ages, and the transition from primary to secondary school.

How well does support for the generalizability of the REM generalize to elite athletes? Marsh and Perry (2005) tested the effects of sport self-concept on subsequent performance in 270 elite swimmers from 30 countries participating in the Pan Pacific Swimming Championships and the World Short Course Championships. Whereas subsequent championship performance was highly related to prior personal best performances ($r = 0.90$), SEMs demonstrated that elite athlete self-concept contributed significantly to the prediction of subsequent championship performance, explaining approximately 10% of the residual variance after controlling for personal best performances. As each swimmer typically competed in at least two different events, we were able to show that support for the REM was nearly identical for both events.

Marsh and Craven versus Baumeister *et al.* Debate

Support for the importance of self-concept and the REM is part of a revolution sweeping psychology, one that

emphasizes a positive psychology focusing on how healthy, normal, and exceptional individuals can get the most from life (e.g., Seligman and Csikszentmihalyi, 2000). Positive self-beliefs are at the heart of this revolution (Hunter and Csikszentmihalyi, 2003; Marsh and Craven, 2006).

In a potentially serious threat both to this positive psychology movement and to the REM, Baumeister *et al.* (2003, 2005) challenged the prevailing optimistic perspective of the value of positive self-beliefs in a highly influential review commissioned for *Psychological Science in the Public Interest*. In their reviews, they posed the question: “Does high self-esteem cause better performance, interpersonal success, happiness, or healthier lifestyles?” Drawing a negative conclusion to their question, Baumeister *et al.* (2003) concluded that “self-esteem per se is not the social panacea that many people hoped it was” (p. 38), a point reiterated by Baumeister *et al.* (2005) in their *Scientific American* article in which they concluded “that efforts to boost people’s self-esteem are of little value in fostering academic achievement or preventing undesirable behavior” (p. 84).

Particularly in relation to models of causal relations between self-concept and academic achievement – a major focus of the Baumeister *et al.* (2003, 2005) reviews – Marsh and Craven (2006) provided convincing evidence for the consistent positive effects of ASC on subsequent achievement after controlling the effects of prior achievement. They argued that conclusions drawn by Baumeister and colleagues were based largely on research studies, statistical methodology, and theoretical conceptualizations of self-concept that are no longer current. Although there were many points of agreement between the reviews by Marsh and Craven (2006) and those by Baumeister and colleagues (e.g., the need for longitudinal studies, cross-lagged designs, and appropriate statistical analyses), they differed particularly in relation to Baumeister *et al.*’s sole reliance on self-esteem and an implicit unidimensional perspective of self-concept compared to the explicitly multidimensional perspective taken by Marsh and Craven. Integrating the two apparently contradictory perspectives, Marsh and Craven argued that it was quite reasonable and consistent with their multidimensional perspective that there are almost no reciprocal relations between academic achievement and self-esteem (as reported by Baumeister *et al.*), whereas there are consistent reciprocal relations between ASC and achievement (as reported by Marsh and Craven). Indeed, there was almost no overlap between the older, multiple regression studies of self-esteem considered by Baumeister *et al.* and the more recent SEM studies of ASC emphasized by Marsh and Craven. Consistent with this rapprochement, Valentine and Dubois’ (2005) meta-analysis showed that the effect on subsequent school performance was stronger for academic self-beliefs, such as ASC, than for more global self-belief constructs, such as global self-esteem,

and even stronger when the self-belief construct logically matched the achievement construct in terms of domain specificity (i.e., mathematics achievement and math self-concept).

Summary and Implications

The results of the causal modeling studies in particular provide a clear affirmative answer to the question: Do changes in ASC lead to changes in subsequent academic achievement? This research is critically important in that it has established that increases in ASC lead to increases in subsequent academic achievement and other desirable educational outcomes. Hence, not only is self-concept an important outcome variable in itself, but it also plays a central role in mediating the effects of other desirable educational outcomes. These findings have significant implications for international educational policy and practice. It is important to emphasize that the direction of causality between ASC and achievement also has very important practical implications for educators. If the direction of causality were from ASC to achievement (the self-enhancement model), then teachers might be justified in placing more effort into enhancing students’ self-concepts rather than fostering achievement. On the other hand, if the direction of causality were from achievement to self-concept (the skill development model), then teachers should focus primarily on improving academic skills as the best way to improve self-concept. In contrast to both these apparently overly simplistic (either-or) models, the REM implies that ASC and academic achievement are reciprocally related and mutually reinforcing. Improved ASCs will lead to better achievement and improved achievement will lead to better ASCs. For example, if teachers enhance students’ ASCs without improving achievement, then the gains in self-concept are likely to be short lived. However, if teachers improve students’ academic achievement without also fostering students’ self-beliefs in their academic capabilities, then the achievement gains are also unlikely to be long lasting. If teachers focus on either one of these constructs to the exclusion of the other, then both are likely to suffer. Hence, according to the REM, teachers should strive to simultaneously improve both ASC and achievement.

Glossary

Outcome expectations – Beliefs about the expected outcomes of actions.

Reciprocal determinism – Interacting influences of cognitions, behaviors, and environmental variables.

Self-efficacy – Perceived capabilities to learn or perform behaviors at designated levels.

Social cognitive theory – The theory of behavior emphasizing cognitive, vicarious, self-regulatory, and self-reflective processes in human adaptation and change.

Overview of Social Cognitive Theory

With the publication of *Social Foundations of Thought and Action: A Social Cognitive Theory* in 1986, Albert Bandura advanced a view of human functioning that accords a central role to cognitive, vicarious, self-regulatory, and self-reflective processes in human adaptation and change (Bandura, 1986). From this social cognitive perspective, human thought and action are viewed as products of a dynamic interplay among personal, behavioral, and environmental influences. How people interpret the results of their own behaviors informs and alters their environments and the personal factors they possess that, in turn, inform and alter subsequent behaviors. The view that (1) personal factors in the form of cognition, affect, and biological events; (2) behaviors; and (3) environmental influences create interactions that result in a triadic reciprocity is the foundation of Bandura's conception of reciprocal determinism.

The reciprocal nature of the determinants of human functioning in social cognitive theory makes it possible for therapeutic and counseling efforts to be directed at personal, environmental, or behavioral factors. Strategies for increasing well-being can be aimed at improving emotional, cognitive, or motivational processes; increasing behavioral competencies; or altering the social conditions under which people live and work. In school, for example, teachers face the challenge of improving the academic learning and confidence of their students. Using social cognitive theory as a framework, teachers can work to

improve their students' emotional states, correct their faulty self-beliefs and habits of thinking (personal factors), improve their academic skills and self-regulatory practices (behaviors), and alter the school and classroom structures that may work to undermine student success (environmental factors).

Social cognitive theory is rooted in a view of human agency in which individuals are proactively engaged in their own development and can make things happen by their actions. Individuals are imbued with certain capabilities that define what it is to be human. Primary among these are the capabilities to symbolize, plan alternative strategies (forethought), learn through vicarious experience, self-regulate, and self-reflect. For Bandura, however, the capability that is most distinctly human is that of self-reflection; hence, it is a prominent feature of social cognitive theory. Through self-reflection, people make sense of their experiences, explore their own cognitions and self-beliefs, engage in self-evaluation, and alter their thinking and behavior accordingly.

Self-Efficacy Beliefs

Of all the thoughts that affect human functioning, and standing at the very core of social cognitive theory, are self-efficacy beliefs, or individuals' judgments of their capabilities to learn or perform courses of action at designated levels. In essence, self-efficacy beliefs are the self-perceptions that individuals hold about their capabilities. These beliefs of personal competence provide the foundation for human motivation, well-being, and personal accomplishment. This is because unless people believe that their actions can produce the outcomes they desire, they have little incentive to act or to persevere in the face of difficulties.

Self-efficacy should not be confused with constructs such as self-concept or self-esteem, which are broad evaluations of one's self, complete with judgments of self-worth that accompany such evaluations. Self-efficacy beliefs revolve around questions of can (Can I write this essay? Can I solve this problem?), whereas self-concept/self-esteem beliefs reflect questions of feel (Do I like myself? How do I feel about myself as a writer?). Moreover, one's beliefs about what one can do may bear little relation to how one feels about oneself. Many bright students are able to engage their academic tasks with

[†]Deceased.

strong self-efficacy even while their academic skills are a source of low self-esteem, having been labeled by their classmates as nerds or geeks.

Research examining the empirical properties of these two constructs has shown that they differ in important ways. Self-efficacy beliefs are cognitive, goal-referenced, relatively context-specific, and future-oriented judgments of competence that are relatively malleable due to their task dependence. Self-concept beliefs, on the other hand, are primarily affective, heavily normative, typically aggregated, hierarchically structured, and past-oriented self-perceptions that are relatively stable due to their sense of generality. Self-efficacy acts as an active precursor of self-concept development.

People's self-efficacy beliefs should not be confused with their judgments of the consequences that their behavior will produce, or outcome expectations. Typically, self-efficacy beliefs help determine the outcomes one expects. Confident individuals anticipate successful outcomes. Students confident in their academic skills expect high marks on examinations and expect the quality of their work to reap personal and professional benefits. Conversely, students who lack confidence in their academic skills envision a low grade before they begin an examination or enroll in a course. The expected results of these imagined performances will be differently envisioned: greater academic success and subsequent career options for the former and curtailed academic possibilities for the latter. However, self-efficacy beliefs also can be inconsistent with the outcomes one expects. A high sense of efficacy may not result in behavior consistent with that belief, for example, if the individual also believes that the outcome of engaging in that behavior will have undesired effects. A student highly self-efficacious in his/her academic capabilities may elect not to apply to a particular university whose entrance requirements are such as to discourage all but the hardest souls.

The notion of perceived control also differs from self-efficacy. People who believe they can control what they learn and perform are more apt to initiate and sustain behaviors directed toward those ends than are individuals who hold a low sense of control over their capabilities. Perceived control is generic; thus, it is meaningful to speak of this control over learning or performing and over outcomes. Further, it is only one aspect of self-efficacy. Other factors that influence self-efficacy include perceptions of ability, social comparisons, attributions, time available, and perceived importance. People may believe that they can control their use of learning strategies, effort, and persistence, yet hold a low sense of self-efficacy for learning because they feel that the learning is unimportant and not worth the investment of time.

Since individuals operate collectively as well as individually, self-efficacy is both a personal and a social construct. Collective systems develop a sense of collective

efficacy – a group's shared belief in its capability to attain goals and accomplish desired tasks. For example, schools develop collective beliefs about the capability of their students to learn, of their teachers to teach and otherwise enhance the lives of their students, and of their administrators and policymakers to create environments conducive to these tasks. Organizations with a strong sense of collective efficacy exercise empowering and vitalizing influences on their constituents.

Sources of Self-Efficacy Beliefs

Individuals form their self-efficacy beliefs by interpreting information primarily from four sources. The most influential source is the interpreted result of one's previous performances, or mastery experiences. The process of forming self-efficacy beliefs from mastery experiences is simple and intuitive: individuals engage in tasks and activities, interpret the results of their actions, use the interpretations to develop beliefs about their capability to engage in subsequent tasks or activities, and act in concert with the beliefs created. Outcomes interpreted as successful raise self-efficacy; those interpreted as failures lower it.

In addition to interpreting the results of their actions, people form their self-efficacy beliefs through the vicarious experiences of observing others perform tasks. This form of efficacy information is particularly powerful when people observe models who they believe possess similar capability as themselves. Observing the successes of such models contributes to the observers' beliefs about their own capabilities (If they can do it, so can I!). Conversely, watching models with perceived similar capabilities fail can undermine the observers' beliefs about their own capabilities to succeed. When people perceive the model's capabilities as highly divergent from their own, the influence of vicarious experiences is greatly minimized. It is noteworthy that people seek out models with qualities they admire and capabilities to which they aspire. Significant models in one's life can help instill self-beliefs that will influence the course and direction that life will take.

Individuals also create and develop self-efficacy beliefs as a result of the social persuasions they receive from others. These persuasions can involve exposure to the verbal judgments that others provide. Persuaders play an important part in the development of an individual's self-beliefs. However, social persuasions should not be confused with knee-jerk praise or empty inspirational homilies. Effective persuaders must cultivate people's beliefs in their capabilities while simultaneously ensuring that the envisioned success is attainable. Just as positive persuasions may work to encourage and empower self-efficacy beliefs, negative persuasions can work to defeat and weaken the same. It is usually easier to weaken self-efficacy beliefs

through negative appraisals than to strengthen such beliefs through positive encouragement.

Physiological and emotional states such as anxiety, stress, arousal, and mood states also provide information about efficacy beliefs. People can gauge their degree of confidence by the emotional state they experience as they contemplate an action. Strong emotional reactions to a task provide cues about the anticipated success or failure of the outcome. When they experience negative thoughts and fears about their capabilities, these affective reactions can lower self-efficacy perceptions and trigger additional stress and agitation that help ensure the inadequate performance they fear. One way to raise self-efficacy beliefs is to improve physical and emotional well-being and reduce negative emotional states. As individuals have the capability to alter their own thinking and feeling, enhanced self-efficacy beliefs can, in turn, powerfully influence the physiological states themselves.

The sources of self-efficacy information are not directly translated into judgments of competence. Individuals interpret the results of events, and these interpretations provide the information on which judgments are based. The types of information people attend to and use to make efficacy judgments, and the rules they employ for weighting and integrating them, form the basis for such interpretations. The selection, integration, interpretation, and recollection of information influence judgments of self-efficacy.

Effects of Self-Efficacy Beliefs

Self-efficacy beliefs enhance human accomplishment and well-being in countless ways. They influence the choices people make and the courses of action they pursue. Individuals tend to select tasks and activities in which they feel competent and confident and avoid those in which they do not. Unless people believe that their actions will have the desired consequences, they have little incentive to engage in them. How far will an interest in architecture take a student who feels hopeless in geometry? Irrespective of the factors that operate to influence behavior, they are rooted in the core belief that one has the capability to accomplish that behavior.

Self-efficacy beliefs also help determine how much effort people will expend on an activity, how long they will persevere when confronting obstacles, and how resilient they will be in the face of adverse situations. People with a strong sense of personal competence approach difficult tasks as challenges to be mastered rather than as threats to be avoided. They set challenging goals and maintain strong commitment to them, heighten and sustain their efforts in the face of failure, and recover their sense of efficacy more quickly after setbacks. High self-efficacy helps create feelings of serenity in approaching difficult tasks and activities. Conversely, people with low

self-efficacy may believe that things are tougher than they really are, a belief that fosters anxiety, stress, depression, and a narrow vision of how best to solve a problem. As a consequence, self-efficacy beliefs can powerfully influence the level of accomplishment that one ultimately achieves. This function of self-beliefs also can create the type of self-fulfilling prophecy in which one accomplishes what one believes one can accomplish; that is, the perseverance associated with high self-efficacy is likely to lead to increased performance, which, in turn, raises one's sense of efficacy and spirit, whereas the giving in associated with low self-efficacy helps ensure the very failure that further lowers confidence and morale.

Of course, human functioning is influenced by many factors. The successes and failures that people experience as they engage in the myriad tasks that comprise their life naturally influence the many decisions they must make. In addition, the knowledge and skills they possess play an important role in what they choose to do. However, because past attainments, knowledge, and skills are always interpreted by the individual, it is the interpretations that form the foundation for the beliefs that are developed about subsequent capabilities. As a consequence, people's accomplishments are generally better predicted by their self-efficacy beliefs than by their previous attainments, knowledge, or skills.

Development of Self-Efficacy Beliefs

The first influences on an individual's self-efficacy take place within the family. Parents and caregivers provide their children with the first experiences that differentially influence self-efficacy beliefs. These home influences that help children interact effectively with the environment positively affect self-efficacy. When the home environment is rich in activities and materials that arouse the children's curiosity and offer challenges that can be met, children are motivated to work on the activities and learn new information and skills.

Parents who provide a warm, responsive, and supportive home environment, encourage exploration and stimulate curiosity, and provide play and learning materials, accelerate their children's intellectual development. Parents also are the key providers of self-efficacy information. Since mastery experience is the most powerful source of self-efficacy information, the parents who arrange for their children to experience varied mastery experiences develop more efficacious youngsters than do parents who arrange fewer opportunities. Such experiences occur in homes enriched with activities and in which children have the freedom to explore. With respect to vicarious experiences, parents who teach children diverse ways to cope with difficulties and model persistence and effort strengthen their children's self-efficacy. Family members are also

prime sources of persuasive information. Parents who encourage their children to try different activities and support and encourage their efforts help to develop children who feel more capable of meeting challenges.

As children grow, peers become increasingly important. Parents who steer their children toward efficacious peers provide further vicarious boosts in self-efficacy. Peers themselves influence children's self-efficacy in various ways. One means is through model similarity. Observing others, who are similar to the observers, succeed can raise the self-efficacy of the observers and motivate them to perform the task if they believe that they, too, will be successful. Conversely, observing others fail can lead students to believe that they lack the competence to succeed, and dissuade them from attempting the task.

Self-efficacy beliefs tend to decline as students advance through school. There are several reasons for this, including greater emphasis on competition, more norm-referenced grading, less teacher attention to individual student progress, and the stresses associated with school transitions. These and other school practices can weaken academic self-efficacy, especially among students who are less academically prepared to cope with increasingly challenging academic tasks. Lock-step sequences of instruction frustrate some students who fail to grasp skills and increasingly fall behind their peers. Ability groupings can lower self-efficacy among those relegated to lower groups. Classrooms that allow for much social comparison tend to lower the self-efficacy of students who find their performances inferior to those of their peers.

Periods of transition in schooling also bring other factors that affect self-efficacy into play. As elementary students remain with the same teacher and peers for most of the school day, children receive much attention, and individual progress is stressed. Typically, however, several elementary schools feed into the same middle school, and children begin to move from class to class for specific subjects. Thus, middle school students become exposed to peers whom they do not know. Evaluation becomes normative, and there is less teacher attention to individual progress. The widely expanded social reference group, coupled with the shift in evaluation standards, requires that students reassess their academic abilities. As a consequence, perceptions of academic competence typically begin to decline during middle school.

In self-efficacy research, it is not uncommon for children to report overconfidence about accomplishing difficult tasks. Even being provided with feedback indicating low performance may not decrease self-efficacy. The incongruence between children's self-efficacy and their actual performance may be due to various causes. Children often lack task familiarity and do not fully understand what is required to execute a task successfully. As they gain experience, their accuracy improves. Children may also be unduly swayed by certain task features and decide based on these that they can

or cannot perform the task while ignoring other features. In subtraction, for example, children may focus on how many numbers the problems contain and judge longer problems to be more difficult than those with fewer numbers, even when the longer ones are conceptually simpler. As their capability to focus on multiple features improves, so does their accuracy.

Children sometimes do not know what they are capable of accomplishing. In writing, for example, it is difficult for them to know how clearly they can express themselves or whether their writing skills are improving. A teacher's feedback – especially at the elementary level – is intended to encourage and stress what children do well. Children may believe they can write well when, in fact, their writing is below normal for their grade level. As they develop, children gain task experience and engage more often in peer social comparisons, which improve the accuracy of their self-assessments. The correspondence between self-efficacy and performance also can be increased by providing children with instruction and opportunities to practice self-evaluation and with instructional interventions that convey clear information about children's skills or progress.

Self-Efficacy, Motivation, and Academic Achievement

Bandura situated self-efficacy within a social cognitive theory of personal and collective agency that operates in concert with other sociocognitive factors in regulating human well-being and attainment. He also addressed the major facets of agency – the nature and structure of self-efficacy beliefs, their origins and effects, the processes through which such self-beliefs operate, and the modes by which they can be created and strengthened. Bandura has reviewed a vast body of research on each of these aspects of agency in diverse applications of the theory. Researchers have demonstrated that the self-efficacy beliefs of individuals powerfully influence their attainments in diverse fields.

A search for the term self-efficacy in most academic databases reveals that, at the start of 2007, nearly 4 000 articles have been written on this important psychological construct. In a Google Internet search, the term returned over 1 million webpages. Self-efficacy has generated research in areas as diverse as life-course development, education, business, athletics, medicine and health, media studies, social and political change, moral development, psychology, psychiatry, psychopathology, and international affairs. Self-efficacy has been especially prominent in studies of educational outcomes such as academic achievement, attributions of success and failure, goal setting, social comparisons, memory, problem solving, career development, and teaching and teacher education. Researchers have established that self-efficacy beliefs and behavior outcomes

are highly correlated and that self-efficacy is an excellent predictor of academic motivation and performance.

Researchers also have demonstrated that self-efficacy beliefs mediate the effect of skills, previous experience, mental ability, or other motivation constructs on subsequent achievement, which implies that they act as a filter between prior determinants and subsequent accomplishments. Meta-analyses have found that the average weighted correlation between self-efficacy and work-related performance was $(G)r = 0.38$, which transforms to an impressive 28% gain in task performance. In education, a meta-analysis of studies published between 1977 and 1988 revealed that efficacy beliefs were positively related to academic achievement. Self-efficacy beliefs were related to academic outcomes ($r_u = 0.38$) and accounted for approximately 14% of the variance. Correlations between self-efficacy and academic performances in investigations, in which self-efficacy is analyzed at the item- or task-specific level and corresponds to the criterial task, have ranged from 0.49 to 0.70; direct effects in path analytic studies have ranged from $\beta = 0.349$ to 0.545. Self-efficacy beliefs have also been found highly predictive of college students' selection of majors and career choices. Variables such as perceived control, outcome expectations, value, attributions, and self-concept are types of cues used by individuals to assess their efficacy beliefs.

In general, empirical evidence amply supports Bandura's contention that self-efficacy beliefs touch virtually every aspect of people's lives – whether they think productively, self-debilitatingly, pessimistically, or optimistically; how well they motivate themselves in the face of adversities; their vulnerability to stress and depression; and the life choices they make. Self-efficacy is also a critical determinant of how individuals regulate their own thinking and behavior. Particularly in psychology and education, self-efficacy has proven to be a more consistent predictor of behavioral outcomes than have other motivational variables.

Summary

Bandura's social cognitive theory of human functioning emphasizes the critical role of self-beliefs in human cognition, motivation, and behavior. Social cognitive theory gives prominence to a self-system that enables individuals to exercise a measure of control over their thoughts, feelings, and actions. In putting forth this view, Bandura reinvigorated the nearly abandoned focus on the self in the study of human processes that William James initiated nearly a century earlier. Social cognitive theory is an agentic and empowering psychological perspective in which individuals are proactive and self-regulating rather than reactive and controlled either by environmental or biological forces. Instead, the beliefs that people have about themselves are key elements in their

exercise of control and of personal, cultural, and social achievement. It is because of their beliefs about their own capabilities – their self-efficacy beliefs – that people are able to exercise the self-influence required to contribute to the types of persons they become and their achievements.

Social and Emotional Outcomes of Learning

J Vorhaus, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

In this article, evidence on the social and emotional outcomes of learning, causal and other explanations for their development, and the frameworks in which explanations and outcomes are located, are reviewed.

The relationships between learning and outcomes in health, well-being, citizenship, parenting, and criminality are explored. Attention is also paid to social relations, and these relationships over the life-course and across generations are explored.

This study is not a systematic review. Three sources of evidence are treated with particular interest: (1) Heckman and colleagues on cognitive and non-cognitive development over the life-course; (2) Eccles and Roeser on schools and adolescent development; and (3) Wilczenski and colleagues on social and emotional learning outcomes. We also draw heavily on the evidence the author and his colleagues at the Centre for Research on the Wider Benefits of Learning (WBL) collected and reviewed over the last 7 years. The first three sources are given priority: first, because the authors have themselves conducted substantial reviews of the literature; second, because each has made a significant contribution to the field; and third, because together they represent a variety of disciplines and methods – including interdisciplinary methods – that are necessary to call upon to produce a sound theoretical framework for understanding the relationship between learning and its social and emotional effects.

This article is organized as follows: we first deal with explanatory frameworks. These provide the context for the presentation of evidence in sections that follow. Priority is given to the drivers of the outcomes for individuals from and within the experience of learning, categorized according to whether their primary source lies in compulsory or post-compulsory schooling.

A review of this kind is bound to be strictly circumscribed: we say nothing about the closely related subject of economic returns; in the main we consider social and emotional variables as outcomes and not determinants of learning, and the range of acknowledged learning activities is largely confined to formal environments.

Several omissions deserve notice. Description of method is kept to a minimum; there is no discussion of pre-school or out-of-school programs; and several prominent lines of enquiry are barely touched upon. For example, Heckman *et al.* (2004) present evidence that both

cognitive and non-cognitive skills affect the returns to schooling: increasing non-cognitive ability over the same decile range as cognitive ability has a greater effect on many outcomes than increasing cognitive ability over the same range. This applies, for example, to a reduced likelihood of smoking, spending time in jail by the age of 30, and nonmarital pregnancy outcomes (Cunha: 19). But the literature on the returns to enhancing non-cognitive skills cannot be surveyed.

Many other issues are also omitted, including race, learning difficulties, and bilingualism. In these cases also, there is a large literature attached to each, and that is more than this article can begin to do justice to. That should not be taken to imply that outcomes of these kinds are any fewer or matter any less than those that are explored.

A Framework for Analysis

Complementarity, Self-Productivity and the Skill Multiplier

Cunha *et al.* (2005) consider the life cycle as the proper context in which to interpret evidence on the development of outcomes. As against the influential work of Becker and Tomes (1979), childhood is conceived as a multi-stage process during which early investments feed into later investments.

Over the life-course, genetic, environmental, and personal inputs are variously productive of outputs, in the form of achieved levels of skill. Points of greatest productivity are sensitive periods, and these become critical if one stage alone is productive of a given skill or ability. Skills produced at one point augment skills achieved later on (self-productivity), and skills produced at one stage raise the productivity of investment at subsequent stages (complementarity). Levels of skill at different ages bolster one other, producing a skill multiplier.

This framework explains significant findings from the literature: that skill begets skill and abilities beget abilities (*ibid.*: 5), and that the formation of skills is a dynamic process, whereby those formed at one stage in the life cycle affect the productivity of learning in the next stage (*ibid.*: 12).

Multi-Level Contexts

The work of Heckman and colleagues illuminates research by Eccles and the WBL, whose two models for

conceiving and analyzing learning outcomes are mutually complementary.

Eccles and Roeser examine how schools promote academic, social, and psychological competence. Following Bronfenbrenner, schools are conceived as comprising multi-level contexts; these influence adolescent social-emotional and behavioral development, through organizational, social, and instructional processes, each of which operate at different levels. (Eccles and Roeser, 2003)

The school context is conceived as a “series of hierarchically-ordered, interdependent levels of organization,” beginning at the level of the classroom and moving up in complexity to the school as “an organization system embedded in a larger cultural system” (*ibid.*: 3). There are multiple levels of regulatory processes, usually dynamic, interrelated across levels of analysis, and which develop or change as children move through different school levels. These multi-level processes are interwoven into one another, and relations between different levels of organization in the school can be complementary or contradictory (*ibid.*: 4).

A central point is that the influence of schools on adolescent development is by means of multiple dynamic impacts of different levels of school interacting with each other, rather than the static resources or characteristics of the curriculum, teachers, or school *per se* (*ibid.*). These are not specified in this article (see Eccles and Roeser for a detailed conceptual framework).

The specifics of school-related processes change across the course of children’s and adolescents’ development as they progress through primary, secondary, and tertiary education, and beyond into learning in adulthood. However, throughout development and maturation, interactions between the learner and the learning environment are essential to learning (Eccles and Midgley, 1989; Eccles: 5).

In parallel with the work of Eccles, the WBL has developed a broadly similar multi-level framework for analyzing the wider benefits of learning, recognizing social and emotional outcomes at the level of the individual, family, community, and nation. The model highlights the range of outcomes influenced by education, the multiple, dynamic relationships operating at and between the different levels, and the formative significance of the multiple contexts in which they operate (Preston *et al.*, 2005 and WBL Research Report, No. 11).

A distinguishing feature of the WBL analysis is the concept of social productivity. This concept denotes the capacity of education to support outcomes of social value at each of the levels mentioned above, and to prevent outcomes such as crime, intolerance, mental health problems, disengagement, and social immobility.

Socially valuable outcomes developed in the educational process include skills, capabilities, and social networks. These emerge from interactions in numerous

contexts; they are not simply the product of attendance at educational institutions. Hence, the effects of education will depend on interactions with peers, teachers, and others; on the impact of identity, beliefs, and values; and on the ethos, pedagogy, and curricula comprising the learning environments. The socially productive capacity of learning is evidenced by its impact on variables such as self-concept, self-efficacy, and social capital.

So, for example, Putnam (1993) views education as a valuable source of social capital formation. At the level of primary education, learning can promote societal cohesion and strengthen citizenship when individuals of all socioeconomic backgrounds are enrolled in the public education system. Learning experience can provide opportunities to gain and practice social capital skills, such as participation and reciprocity; to extend and deepen social networks; and to support the development of shared norms and the values of tolerance, understanding, and respect. Learning experience can also provide a forum for community activity and for students to learn how to participate responsibly in their society (Heyneman, 1998; Schuller *et al.*, 2004 and WBL Research Report No. 3).

Organizing the Evidence

In keeping with the framework set out in this section, the evidence in sections 3–7 are considered in relation to the primary levels of analysis – the individual, family, and community – and the primary stages of lifelong learning: childhood, adolescence, and adulthood. No level or stage is intrinsically more important than any other but for reasons of space priority is given to individual-level outcomes for children and adolescents. And while some themes are treated in the context of one level or stage rather than another, this is largely because the evidence reviewed tends to adopt that temporal focus; it is not meant to imply that the themes themselves do not prominently feature at other points in the life-course.

Individual-Level Effects: Childhood and Adolescence

Introduction

The effects treated in this section have been hypothesized as sources of causal impact on social and emotional outcomes. They are individual level effects in the sense that they are construed as the effects of individual agents, operating, for example, as managers, teachers, or deliverers of a curriculum. At the same time it is also recognized that there are alternative legitimate construals, according to which these effects operate at other levels, such as the level of the school or at a level involving other social and organizational agents.

Teacher Expectations

When students are aware of teachers' high expectations, students achieve more, experience higher esteem, and are less involved in problem behavior during childhood and adolescence (Eccles *et al.*, 1993; Rutter, 1983; Roeser *et al.*, 1998; Weinstein, 1989). Teachers who believe they can, reach out to the most difficult students, communicate positive expectations to those students, thereby enhancing the students' confidence in their ability to master academic material (Ashton, 1985; Midgley *et al.*, 1989). When teachers have a low sense of their effectiveness, this can lead to students exhibiting helpless responses to failure in the classroom, and to the development of depressive symptoms (Cole, 1991; Roeser *et al.*, 1999).

Teachers often have varying expectations from students in any one class. Rosenthal (1969) argues that teacher-expectancy effects depend on whether teachers structure activities differently, and interact differently, with high- and low-expectancy students, and on whether these differences are perceived by the students (Brophy, 1985; Parsons *et al.*, 1982; Weinstein, 1989). One focus of research is differential treatment in respect of gender, ethnicity, and social class. Studies report small but consistent undermining effects of low-teacher expectations from girls (mathematics and science), minority groups (all subject areas), and children from low social-class backgrounds (all subject areas). (Eccles and Roeser, 2003; Brophy and Good, 1974; Ferguson, 1998; Jussim *et al.*, 1996; Valencia, 1991).

Classroom Management

Research on classroom management gives evidence of the effects of orderliness and predictability. Student achievement and conduct improves when teachers provide feedback, and establish smoothly run and efficient procedures for monitoring student progress and work completion (Blumenfeld *et al.*, 1983; Eccles *et al.*, 1998; Pintrich and Schunk, 1996).

Boggiano, Deci, and Ryan suggest that overly controlling, autonomy-inhibiting environments undermine intrinsic motivation, ability self-concepts, and self-direction, and, instead, encourage a learned helpless response to difficult tasks. Laboratory and field-based studies provide support for this view (Boggiano *et al.*, 1992; Deci *et al.*, 1981; Grolnick and Ryan, 1987).

While direct instruction has a positive impact on student achievement, research also suggest that students exhibit more stress in didactic as compared with student-centered contexts (Dunn and Kontos, 1997). More open classroom contexts encourage students to be more creative, hold better self-concepts, and more positive attitudes toward teachers and school, and to demonstrate greater independence and curiosity (Dunn and Kontos, 1997; Peterson, 1979; Reynolds, 1975).

The Curriculum

The significance of providing learning materials that are meaningful to students is borne out by the association between low interest in and perceived irrelevance of the school curriculum on the one hand, and poor attention, disengagement, and alienation from school on the other (Jackson and Davis, 2000; Finn, 1989; Larson and Richards, 1989). Curricula that fail to represent the voices and experience of traditionally underrepresented groups can also explain the alienation of some group members from the educational process (Fine, 1991; Sheets and Hollins, 1999; Barton).

Many school programs aim to improve outcomes by supporting students' self-image and self-esteem. But Wilczenski argues that enhancing social and emotional outcomes requires a focus on mastery in the classroom rather than student self-perceptions (Wilczenski *et al.*, 2001: 4). Socioemotional learning cannot be separated from the instructional mission of schools, because social and emotional adjustment mediates academic competence and resilience (Shapiro, 2000).

Peer Collaboration, Tutoring and Mentoring

Collaboration among peers fosters socioemotional development (Slavin, 1980; Sharan, 1980), including better attitudes toward learning, better self-concepts, better attitudes toward others, and better racial relationships (Bossert, 1988/1989; Slavin, 1990). Peer-tutoring programs frequently show socioemotional gains: tutees are described as more cooperative and respectful toward peers and teachers, while also exhibiting higher self-esteem (Gensemer, 2000; Phillips *et al.*, 1994; Roswal *et al.*, 1995).

There is evidence of the effectiveness of mentoring and motivational programs for disadvantaged teenagers, largely stemming from the benefits of fostering motivation and improving non-cognitive skills (Karoly *et al.*, 1998; Currie and Blau, 2005; Heckman, 2000). Studies of Big Brothers/Big Sisters (BB/BS) and Philadelphia Futures sponsor-a-scholar (SAS) programs show positive social effects on school-aged children and adolescents. BB/BS paired unrelated adult volunteers with young people from single-parent households. Tierney and Grossman (1995) found that 18 months after being matched with a mentor, Little Brothers and Sisters (aged 10–16 at the time of the match) were less likely to have used drugs or alcohol, to skip class or a day of school, or to lie to their parents; they were more likely to feel competent in their school work and to report a better relationship with parents (Cunha, 2005).

Ability Grouping

Individuals may be grouped by ability either within a class or between classes. The evidence on socioemotional outcomes appears to favor ability grouping for high ability

but not low-ability students (Fuligni *et al.*, 1995; Gamoran and Mare, 1989; Kulik and Kulik, 1987).

The argument in favor of ability grouping includes the point that students are more likely to learn when material is well matched to their competence. There is evidence consistent with this for children in high-ability classrooms and high within-class ability groups (Dreeben and Barr, 1988; Fuligni *et al.*, 1995; Pallas *et al.*, 1994). Shields (1996) found that, compared to heterogeneously grouped gifted students, homogeneously grouped gifted students showed higher self-concepts, self-acceptance, and independence. Feldhusen and Moon (1992) argue that heterogeneous grouping for gifted students leads to lower motivation and poorer attitudes toward school.

Eder and Felmlee (1983, 1984) explored attention patterns in low- and high-ability first-grade reading groups. They controlled for individual characteristics that included personal attention patterns, and found that students in low-ability groups became inattentive at four times the rate of students in high-ability groups. Eder and Felmlee observed that teachers of high-ability groups quickly managed inattentiveness or disruption whereas teachers of low-ability groups tended to ignore this. Peer effects were observed: high-ability groups applied pressure to maintain attention during interruptions, while low-ability groups tended to use interruptions as an opportunity to distract attention from the current task. Schwartz (1981) observed the behavior in low-ability classes among elementary and junior high school students, and found it to be characterized by challenges to teacher authority, obstruction of academic activities, and misuse of educational resources. These findings indicate that social influences in low-ability groups may overwhelm any instructional advantages to grouping (Wilczenski, 1981: 10).

The Lou *et al.* (1996) meta-analysis of studies of within-class grouping found small but positive effects of placing students in groups; they were more positively disposed toward schools and had higher self-concepts than students in ungrouped classes. However, the same studies show negative socioemotional effects of grouping low-ability students together, in part owing to the low-expectations of teachers and the absence of positive role models. Being placed in between-class low academic groups is also associated with poor attitudes toward school, feelings of incompetence, and problem behaviors (Oakes *et al.*, 1992), effects often accounted for by inferior educational experience (Dreeben and Barr, 1988; Pallas *et al.*, 1994; Vanfossen *et al.*, 1987).

School-Level Effects: Childhood and Adolescence

Social Climate

The academic focus of a school can affect mental health. A series of studies found that a belief that school is

ability-focused can lead to a decline in students' self-esteem, and an increase in anger, depressive symptoms, and school truancy when moving from seventh to eighth grade (Roeser and Eccles, 1998; Roeser *et al.*, 1998). An emphasis on ability can alienate many of those students unable to perform at the highest levels, leading to anxiety, anger, and disenchantment (Eccles and Midgley, 1989; Finn, 1989). Schools emphasizing effort, improvement, and the expectation that all students can learn, appear to include more adolescents in the learning process, while also reducing depression and the anxiety that achievement settings can give rise to (Eccles and Roeser, 2003: 18).

Figueira-McDonough (1986) compared two high schools that were similar with respect to intake and achievement rates but different with respect to academic orientation and rates of delinquent behavior. The school putting more emphasis on competition and high grades had higher delinquency rates and delinquent behavior was predicted by low grades. For the school with more diverse goals, taking a greater interest in students' non-academic needs, school attachment was greater on average, with higher delinquency rates associated with low-levels of attachment. The emphasis on motivation and diversity may have promoted an attachment to school, thereby discouraging delinquency.

Transitions

There is evidence that academic motivation and achievement decline during early adolescence (Eccles, 1994; Eccles and Midgley, 1989; Eccles *et al.*, 1993; Maehr and Midgley, 1996), often coinciding with the transition into middle school or junior high school. There is a decline in some early adolescents' school grades as they move into junior high school (Simmons and Blyth, 1987), and similar declines occur for interest in school (Epstein and McPartland, 1976), intrinsic motivation (Harter, 1981), and self-concepts (Eccles *et al.*, 1989; Wigfield *et al.*, 1991). There are also increases in test anxiety (Wigfield and Eccles, 1989) and both truancy and school dropout (Rosenbaum, 1976). Eccles and Midgley (1989) suggest that junior high schools typically lack educational environments that are developmentally appropriate for early adolescents.

Teaching practices

Researchers observe the combination of increasing maturity of high school students and greater teacher emphasis on control and discipline, providing fewer opportunities for student decision making as compared with elementary school teachers (e.g., Brophy and Evertson, 1978; Midgley and Feldlaufer, 1987; Moos, 1979). The evidence confirms what stage-environment fit theory suggests: the discrepancy between the wish for autonomy and control, and the actual opportunities for students in the classroom, leads to

a decline in motivation and interest in school (Mac Iver and Reuman, 1988).

Students entering junior high school face more in the way of whole-class task organization and between-classroom ability grouping (Eccles and Midgley, 1989; Oakes *et al.*, 1992). This is likely to increase social comparison and competitiveness (see Eccles *et al.*, 1984; Rosenholtz and Simpson, 1984), while the use of grading and public assessment has a negative affect on early adolescents' self-perceptions and motivation.

Classroom practices can be distinguished by the priority given to either task mastery or to performance goals. Teachers and learners testify that, as adolescents move from elementary to middle school, the school environment is increasingly focused on performance – competition, relative ability, and social comparison (Midgley *et al.*, 1995; Roeser *et al.*, 1994). How far teachers were task-focused at both levels predicted students' and teachers' sense of personal efficacy, this being lower among middle school participants than among elementary school participants.

Anderman *et al.* (1999) compared two groups of young adolescents: the first moved into a middle school emphasizing task-focused instructional practices, the second into a middle school emphasizing performance-focused instructional practices. The two groups of students were found to differ in their motivational goals following the transition, although these had not differed beforehand; the adolescents moving into the first school were less likely to show an increase in extrinsic motivational and performance-oriented motivational goals.

Eccles and Midgley argue that changes in school environment are often harmful for young adolescents: "the nature of these environmental changes, coupled with the normal course of individual development, is likely to result in a developmental mismatch so that the 'fit' between the early adolescent and the classroom environment is particularly poor, increasing the risk of negative motivational outcomes, especially for adolescents who are having difficulty succeeding in school academically" (Eccles and Midgley, 1989).

Individual-Level Effects: Adult Learning

Introduction

The term adult learning refers to the learning that follows the years of compulsory schooling. In the United Kingdom this is referred to as post compulsory or post-16 learning, and includes, among other contexts, higher education, further education, the workplace, and adult and community learning.

Health, Well-Being, and Social Inclusion

Analysis by the WBL (WBL Research Report No. 6) of the 1958 National Child Development Study (NCDS)

and the 1970 British Cohort Study (BCS70) suggests considerable health advantages associated with having higher-level qualifications. For example:

- Graduates are less likely to smoke: those educated to level 2 or below are 75% more likely to be smokers at age 30, compared to similar individuals educated to degree level or higher.
- Those educated to degree level or higher are between 70% and 80% more likely to report excellent health, compared to a similar individual educated to level 2 or below.
- Graduates are between 35% (women) and 55% (men) less likely to suffer from depression, compared to a similar individual educated to level 2 or below.

The WBL also found in the British Household Panel Study (BHPS), a strong relationship between educational success and progress at 16 and uptake by women of recommended cervical smear tests (WBL Research Report No. 12).

Civic engagement

Feinstein and Hammond (2004) and WBL Research Report No. 8) used the 1958 cohort to examine the contribution of adult learning to a wide range of health and social-capital outcomes. Analysis focused on changes between the ages of 33 and 42 in life outcomes for adults, controlling for their development and context up to age 33.

It was found that participation in adult learning has positive effects on a wide spectrum of health and social-capital outcomes with statistically significant effects of participation on nine of the 12 outcomes looked at. These outcomes are changes in smoking, exercise taken, life satisfaction, race tolerance, authoritarian attitudes, political cynicism, political interest, number of memberships, and voting behavior.

Research on race tolerance combined with authoritarianism (Preston *et al.*, 2005 and WBL Research Report No. 11) found that adult education may be important in sustaining non-extremist views, but it does not appear to be associated with a transformation away from extremist positions.

School-age signals

The WBL has explored how far-emerging aspects of child development have implications for their long-term health and well-being as adults. Using the 1958 cohort, eight proxy measures were used for failure to flourish at secondary school. These encompass attainment, attendance, social adjustment, and attitudes. The adult variables covered aspects of well-being and mental health and some physical conditions and health behaviors. The WBL estimated the associations between failure to flourish at secondary school and health and well-being at age 33,

controlling for social, psychological, and economic factors up to the age of 7.

Those who flourished at school had better outcomes in all main aspects of well-being than those who did not flourish. The magnitudes of adjusted associations were substantial and apply to well-being, mental and physical health, and health behaviors.

Both attainment and engagement at secondary school were markers of adult health and well-being. Those with poor attainment but who were quite engaged at school had relatively poor levels of health and well-being in adulthood compared to cohort members who had attained well at school, but those with poor attainment and poor engagement had worse adult health and well-being than either group.

Literacy and numeracy

The National Research and Development Centre for Adult Literacy and Numeracy (NRDC) analyzed literacy and numeracy data from the 2004 survey of 9664 members of BCS70 (NRDC reports: *New light on literacy and numeracy*; *Illuminating Disadvantage* 2007).

Substantial differences in life chances, quality of life, and social inclusion were evident between individuals at or below entry level 2 in the English National Qualification Framework compared with others at higher levels of literacy and numeracy. Entry level 2 skills were associated with poor health prospects and lack of social and political participation. Gender differences were marked in some of these relationships including the tendency for men with poor skills to lead a solitary life without children in their mid-30s. In contrast, women with the same levels of skills were also more likely to be without a partner, but more typically were parents and often with large families.

At age 16, men and women with entry level skills were the most likely to be alienated from school and to have parents with low aspirations for them. 20% of women with entry level 2 literacy and 10% with entry level 2 numeracy had experienced a spell of homelessness compared with 6% women at level 1 or higher. Women with entry level 2 skills were more than twice as likely as women with level 1 or higher skills to have been a teenage mother (18% to 8%) and three times more likely to have four or more children by age 34 (11%–3%).

Self-efficacy and confidence

Hammond and Feinstein (LRE) investigated links between participation in adult learning and self-efficacy, particularly for adults with low levels of achievement at school. Analyses of data from NCDS, controlling for a range of features of the individual and their context up to the age of 33, found an association between taking courses and transformations from low to good levels of self-efficacy between ages 33 and 42 for all cohort

members. The association is greatest for those who had low achievement levels at school.

This correlational evidence does not prove that adult learning causes these positive changes; there remains the need to identify how far adults who are motivated to participate in adult education are already more likely to have higher levels of confidence and self-efficacy.

Family-Level Outcomes

Intergenerational Effects

The WBL reviewed the evidence on the role of parental education in child development (WBL Research Report, No. 10) and hypothesized that parental education is transmitted inter-generationally through six pathways:

1. by impacting on key distal factors such as income and poverty;
2. by moderating the effect of each distal factor, acting protectively and providing resilience in the family so that they can better deal with difficulties such as poverty;
3. by impacting on the characteristics of contexts, such as parents' cognitions or their mental health and well-being;
4. by supporting individuals and families in managing a set of characteristics and hence moderating their effects;
5. by impacting on proximal processes such as learning behaviors in the home; and
6. by moderating the effects of proximal processes.

The WBL found strong support for the view that education influences most of the factors that have been found to affect children's attainments. Besides having a direct influence on most of the characteristics and parent-child interactions, parental education can also moderate the effects of risk factors and ease the effect of them on interactions between parents and children.

Post-16 Participation and Benefits for the Next Generation

Although, there is considerable evidence to suggest that parenting is an important mediator, WBL research found that the association of educational participation and parenting skills and educational behaviors does not appear to be causal.

Using data from over 11 000 members of the 1958 British Cohort Study (WBL Research Report) the WBL estimated the causal effects of education on parenting skills. In the analysis that did not take account of the possible endogeneity of education, there was evidence of a clear gradient between educational background and elements of parenting. However, this relation between

education and parenting disappeared under a more robust causal instrumental variable specification. The WBL concluded that ability and positional ambition in society could be strong confounders of the relation between staying on in post-compulsory education and subsequent parenting skills.

WBL (Research Report) investigated the relationship between a mother's education and her parenting using data from the child supplement of the 1958 NCDS. By considering data across generations, the dataset allows for an estimation of the size of the bias in the relationship between education and parenting from failing to account for background characteristics, early cognitive development, and mother's own parenting experiences. Results indicate a confounding bias of 73% for cognitive stimulation and 89% for emotional support. This confounding bias is larger for females than for males.

The evidence on the effects of education on parenting skills and educational behaviors is insufficiently robust to problems of selection bias. It cannot be assumed that years of schooling is an appropriate measure for the formation of the identity capital skills that underlie parenting skills.

Community-Level Outcomes

At the community level, outcomes that indicate good functioning and well-being include community cohesion, low levels of crime and anti-social behavior, and trust and other aspects of social capital. A significant issue at the community level, not always apparent at lower levels of aggregation, is that social networks start to matter more explicitly in the determination of outcomes.

Individuals live and learn in multi-faceted and related contexts and these contexts interact. For example, family background interacts with schooling, and these interactions are important for the attainment and engagement of young people and the wider benefits that follow. Other contexts are also important, such as peer groups, child-care, and neighborhoods.

Crime

A US study (Lochner and Moretti) showed that a ten percentage point rise in the rate of high school graduation would cut the murder (arrest) rate by between 14% and 27%. A one percentage point increase in the graduation rate would lead to a reduction in crime of between 34 000 and 68 000 offences.

The WBL (Research Report No. 14) evaluated the impact on male juvenile burglary conviction rates of two UK government interventions, the reducing burglary initiative (RBI) and educational maintenance allowances (EMAs). The EMA program was piloted in some local education

authorities of England, creating a quasi-experimental setting. The RBI was introduced by the Home Office between 1999 and 2002. The aim of this initiative was to reduce burglary nationally by targeting areas with the worst domestic burglary problems. The WBL found that in areas where both initiatives were introduced convictions for 16- to -18-year-olds for burglary fell between 1.1 and 1.5 per 1000 relative to areas where neither program was introduced. This was also a much greater crime reduction than for areas that introduced the EMA or the RBI singly.

National-Level Benefits: Educational Inequality

At the national level, the benefits of learning are manifest as impacts on a wide range of outcomes, such as crime rates, health mortality and morbidity rates, levels of social cohesion, and engagement with public life.

Using international datasets the WBL (Research Report No. 7) explored the relationship between education and social cohesion. Education was found to be a powerful generator of social capital in some contexts, and the most significant predictor of individual propensity to trust, join, and engage in politics, even when controlling for other factors such as age, gender, and income. The report found that there is no significant relation between mean levels of education and societal cohesion. However, excluding the outliers, Norway and Germany, there is a negative and significant correlation of -0.765 between societal cohesion and education inequality. Creating a more cohesive society is likely to require policies which are designed to increase educational equality.

Final Thoughts

There is evidence of significant learning outcomes along all the socioemotional dimensions explored, including health, well-being, social cohesion, social capital, and citizenship. The best explanations situate outcomes in the context of the life-course, emphasizing the dynamic, interrelated and multi-level nature of context and process in relation to which outcomes materialize. The longitudinal aspect permits analysis of how learning outcomes are later built upon, neglected, or undermined. The dynamic aspect draws attention to the interactivity between contexts, whose causes and effects are shaped by factors variously proximate or distal, and which operate at many more levels than one.

We can only illustrate the many questions for further research: social and other types of capital theory promise further insight; there is scope for exploring further how far a model emphasizing self-productivity and complementarity (Heckman) supports or contradicts a model emphasizing context, process, and interactivity (Eccles

and the WBL). And the identification of learning outcomes often runs ahead of a secure explanation of their genesis, including the profile and direction of causality.

Glossary

Collaboration, Collaborative learning – In this article, mostly referred as construction of shared understanding, coordination, co-construction of knowledge.

Content and relational space of communication – Content space refers to cognitive aspect of collaborative communication, for example, how the subject in hand is reasoned, relational space refers to social aspect of collaborative communication, for example, how students orientate towards each others in interaction (collaborative, individualistic or competitive orientation).

Social aspects – Social dimension in collaborative interaction, social relationships (friendship, status).

Status – (1) Academic status: perceived academic ability or knowledge level; (2) Peer status: perceived attractiveness or popularity.

The ideas presented in this article are based on the recent research on collaborative learning. This research demonstrates the dual nature of collaboration, in which cognitive and social processes of learning interact with each other in a dynamic manner. The article first discusses the central concepts and research trends related to the social dimension of collaborative activity. Further, research results on social relationships in collaborative learning are summarized. Particular emphasis is laid on the friendship and status. Finally, the main findings on social aspects of collaborative learning are synthesized, and some critical challenges for this research field are raised.

Social Dimension in Collaborative Activity

The most widely used definition of collaboration describes it as a construction of shared understanding through interaction with others, where the participants are committed to or engaged in shared goals and problem solving (Dillenbourg, 1999; Littleton and Häkkinen, 1999; Roschelle and Teasley, 1995). In addition to the construction of shared understanding, collaboration is commonly referred to as the co-construction of knowledge (e.g., Rafal, 1996; Baker, 2002), building collaborative knowing (Stahl, 2004), co-argumentation (Baker, 2002), negotiating of shared meaning (Pea, 1993), construction of common

knowledge (e.g., Elbers and Streefland, 2000; Crook, 2002), exploratory talk (Mercer, 1996), or coordination (Barron, 2000). However, on closer inspection, the core of all these terms seems to refer to interaction of a similar type – one that calls for specific qualities from cognitive, social, and emotional perspectives.

According to Barron (2000), the extent to which a group works collaboratively depends on the degree of coordination among the group members. In her study comparing the interaction of successful and less-successful student triads, Barron (2000) found three forms of coordination – shared task alignment, mutuality, and jointly focused attention – by which the interaction of these groups differed. The group activity is coordinated in a situation where the students have shared task alignment. In such a situation, the students have collaborative orientation toward problem solving, and the activity is organized around joint problem-solving efforts. In the activities of groups, this is manifested in the co-construction of solutions and referring to and expanding each other's ideas as opposed to individual solution paths and reference to one's own ideas. The success presupposes that participants have achieved a common ground (Clark, 1996) or alignment in the sense that students work in phase at the same conceptual level (Baker, 2002). Barron (2000) adds that there may be some complementary role division in the activity as in a situation where one person is generating ideas while writing and the other is monitoring the documentation. Thus, there is some horizontal division of labor while the first person is acting at the task level and the other, at the meta-(communicative) level (Dillenbourg, 1999).

Mutuality, Barron's second form of coordination, refers to the extent to which there is reciprocity and balance in the interaction with potential of all members to meaningfully contribute and be heard. Mutuality is reflected in the nature of dialog; how the contributions of others are treated in the discussion and how the ideas offered are engaged by others. Barron refers to transactive dialogs, introduced by Berkowitz and Gibbs (1985), where one partner's reasoning operates on another partner's reasoning. In interaction, the content of the other person's turn of speech is taken into account and acknowledged, for example, by acceptance, clarification, or elaboration, instead of rejection without an explanation. Even the conflicts that arise in the situation are productive (Barron, 2000). It is also typical of mutuality that the turn-taking norms are respected. Barron's (2002) mutuality comes close to Baker's (2002) notion of symmetry. According to Baker (2002), interaction is symmetrical if the participants adopt certain roles equally throughout the

interaction, that is, participate equally in problem solving. Even though Baker (2002) does not refer to symmetry of knowledge, a certain degree of knowledge symmetry is essential to enable equal roles (Dillenbourg, 1999). If the knowledge level of the participants is very different, it easily triggers different (permanent) statuses and roles in the learning situation (Cohen, 1994). In addition, Van Boxtel (2000) observes that the essential prerequisite for co-construction is that all participants equally contribute to the elaboration and solution of the problem at hand. In her work, she describes co-construction as an elaborative episode in which both (all) participants make a verbal and propositional contribution to the elaboration.

The third dimension of coordination is the degree to which the attention is jointly focused during solution-critical moments. In the interaction, there is high sensitivity to one another's attentional states. According to Barron (2000), joint attention is closely related to the notion of mutuality. In addition, the notion of joint attention has similarities with Baker's (2002) term, alignment, in the sense that, in the occasions of joint attention, all the students are working in phase with respect to the activities, and there is not even a horizontal division of labor. As a whole, the three dimensions of coordination – shared task alignment, mutuality, and jointly focused attention – can be regarded as different intertwined aspects of collaborative interaction. For example, the co-construction of knowledge is not possible unless group members have joint focus or mutuality in the situation.

The descriptions presented above well illustrate the dual nature of collaborative interactions. According to Barron (2003), in collaborative activity, the participants have to develop and monitor both the content space and the relational space or, as Sfard and Kieran (2001) put it, the object and meta-level of communication. The content space refers to the cognitive aspect of collaboration: how the subject at hand is reasoned, how the ideas are developed in discussion, and how the shared understanding is constructed. Relational space refers more to the social aspect of collaboration and to the way in which participants in dialog (or monolog) orientate toward each other (and how willing they are to engage in interaction) (Barron, 2003). In the joint activity, the students may have collaborative orientation in their working, or the situation can be competitive, individualistic (Barron, 2003; Mercer, 1996; Sfard and Kieran, 2001), or asymmetrical (Baker, 2002). In a competitive situation, individual participants define themselves through their difference from the others, each having his or her own competing interests, which they try to drive through (Wegerif and Mercer, 1997). Thus, the participants easily end up with disputing rather than arguing for their case. In an individualistic orientation, each student follows his or her own paths of reasoning. In this case, the interaction is more monological than dialogical. For example, in Barron's (2003) study, each of the students in failed groups tried to present and

construct his or her own solutions for the problem. In asymmetrical situations, participants have no possibility to make an equal contribution to the discourse. Reasons may relate, for example, to knowledge (Dillenbourg, 1999) or status differences (Cohen, 1994). In their study, Kumpulainen and Mutanen (1999) distinguished between individualistic, dominant, and collaborative modes of interaction according to the perceived degree of co-construction.

The content and relational spaces are negotiated simultaneously and, thus, compete for limited attention. For example, if the relational space is more focused on competitive interaction or self-focused (individualistic) problem solving, it prevents the participants from gaining joint attention and mutual engagement, and from reaching a common ground on the same topic. At the same time, success in the content space requires success in the relational space. The content and relational spaces thus have a reciprocal relationship, being part of the same collaborative process, and are hard to separate.

Social Relationships in Relation to Collaboration

There is not much research about how students' preexisting relationships within their peer group influence the nature and quality of their interaction in collaborative contexts (Miell and MacDonald, 2000). The study of collaboration has focused more on interactions as opposed to relationships (Azmitia, 1998). However, it has been suggested that students' relationships affect their emotional and social responses to the cognitive working conditions, which show in their willingness to participate in collaborative learning contexts (Crook, 1999; Kutnick and Manson, 1998). Thus, processes and outcomes of collaboration are embedded within the larger context of peer relationships (Azmitia, 1998). Azmitia (2000) points out that collaboration-related research relying on problem-solving tasks that have one correct solution or can be solved through systematic hypothesis testing has contributed to a rosy, calm picture of collaboration placing emphasis on cognitive development. However, in more open-ended and ill-defined problems, collaboration is more stressful because there is no clear script on how to proceed. In these kinds of tasks, collaborators' personalities and relationships as well as the affective elements of interaction play an important role in managing collaboration.

Friendship

There are reports about the positive effects of friendship on collaboration (e.g., Hartup, 1996; Azmitia and Montgomery, 1993; MacDonald *et al.*, 2000). Azmitia and Montgomery (1993) found that collaboration between friends leads to more transactive discourse, greater equality in roles, and

larger increases in knowledge than collaborations between acquaintances. In their study, friends justified their proposals, elaborated on their partners' proposals more often, and also engaged in transactive conflicts more frequently than acquaintances did. In addition, MacDonald *et al.* (2000) found out that, in creative tasks, friends engaged in more transactive discussions than nonfriends, and their musical compositions were rated more highly than those of the latter. Hartup (1996) drew a synthesis on studies comparing friends and nonfriends during collaborative problem-solving tasks. According to these studies, friends tend to engage in more extensive discourse and task-oriented talk, offer suggestions more readily, and are more supportive and critical than nonfriends. In addition, mutuality is more evident and interaction is more positive and equally balanced between friends than between nonfriends. Thus, according to Hartup (1996), social interaction between friends is of the type that is considered to facilitate cognitive development.

However, Berndt *et al.* (1988) did not find differences in the processes and outcomes of the collaborations of friends and acquaintances. One possible reason for the controversy between different studies is that the varied nature and difficulty of tasks may show in differences in the processes and outcomes of the collaborations (Azmitia, 1998). In their study reported above, Azmitia and Montgomery (1993) found out that friends outperformed acquaintances in a posttest only on the most difficult tasks because most friend pairs were able to sustain and repair the collaboration in dealing with difficult tasks, whereas the acquaintances were not. In addition, MacDonald *et al.*, (2000) suggested that, in open-ended creative tasks, nonfriends have more difficulties than friends because they lack the advantage of shared knowledge and accustomed patterns of interaction that would help them maintain interaction and construct knowledge.

The relationship between friendship and successful collaboration is suggested to be due to different reasons. According to Azmitia (1998), mutuality, trust, respect, equality, and fairness, often associated with friendship, are qualities that help friends to be attuned to each other's needs, goals, and points of view, and let them expose their views and also challenge each other. These qualities are beneficial in negotiating shared understandings. According to MacDonald *et al.* (2000), friends are used to establish and maintain a shared social reality in their everyday relationship and also to generate and develop ideas together. Thus, friends have a shared history to lean on (Crook, 1999). On the one hand, this shared history shows in automatized interaction routines that help maintain interaction even in highly demanding tasks (Azmitia, 1998); on the other hand, it shows as shared experiences and prior knowledge (Costin and Jones, 1992; Faulkner and Miell, 2004) that facilitate establishing a common ground (Clark, 1996). In addition, it has been suggested that friends are more motivated and willing to work together (Barron, 2003).

There are, however, age-related developmental differences in the friends' ability to collaborate (see Azmitia, 1998) as well as gender-related differences in the friends' quality of collaboration (e.g., Faulkner and Miell, 2004; Kutnick and Kington, 2005). For example, Kutnick and Kington (2005) found that girl friendship pairs outperformed boy friendship pairs in a scientific reasoning task at the primary level of education. The pupils' interviews revealed that the boys excluded school collaboration as a legitimate activity within the context of their friendships, whereas the girls did not. The boys' friendships were action oriented and based on activities with others outside the school classroom. The study demonstrated that male and female friendship pairs had distinct, culturally (gender related) defined approaches in their cognitive problem-solving activity. These approaches were tied to the experiences they shared with friends in the classrooms and outside the school (Kutnick and Kington, 2005). This is in accordance with Faulkner and Miell's (2004) suggestion that effective collaboration between friends occurs only when it is situated in an activity setting that is meaningful in the context of their relationship.

Status

Several authors (e.g., Dillenbourg, 1999; Baker, 2002) have argued that in order to be capable for true collaboration, the participators must play symmetrical roles in the conversation. They must have the same opportunity to participate, and their level of knowledge must broadly be the same (Dillenbourg, 1999). When the knowledge level among the participants is very different, it easily leads to different roles in the learning situation. These different roles, in turn, can have profound effects on the quality of interaction and learning (Basili and Sandford, 1991; Cohen, 1994; Linn and Burbules, 1993; Richmond and Striley, 1996). For example, Richmond and Striley (1996) found several leadership styles, each with different effects on group interaction. An alienating leader had a negative effect on students' interaction because the leader disregarded the input of others and restricted the discussion process. A democratic leader, however, prompted interaction owing to the open communicative atmosphere that he or she created.

Differences in the perceived academic ability or knowledge level show as academic status differences between students. Academic status is a powerful status characteristic in the classroom because of its obvious relevance to the classroom activities (Cohen, 1994). According to Cohen (1994), students with a higher status easily dominate group interaction and are more likely to be perceived as leaders. Knowledge differences do not even have to be real in the actual situation to raise differences in the roles assumed by the participators, as Cohen (1994) has noted. Differences in the persons' general academic status may

affect interaction; therefore, the power order of the group reflects the initial differences in status, even if the participants share the same level of knowledge in the actual situation, or if the task does not require the academic ability in question. Thus, students with academically high status are expected to be more competent than others, and this status may be generalized to a wide range of school tasks.

Peer status – that is, perceived attractiveness or popularity – may also act as a basis for inequalities in participation in the context of collaborative activity (Cohen, 1994). Popular children tend to get their voice better heard in the group work context. However, the study by Murphy and Faulkner (2000) with preschool children also demonstrated that unpopular children benefited from interacting with popular children. The former had more elaborated disagreements when interacting with the latter than when interacting with other unpopular children. Cohen (1994) relates popularity to academic status, but it has been found (Juvonen and Wenzel, 1996) that, at secondary-level education, popularity depends on qualities other than academic ability, whereas, at the primary level, popularity is often associated with academic ability. Social status factors such as gender can also affect interaction in the collaborative situation. For example, some studies have demonstrated that boys tend to dominate the work in science tasks (Petersen *et al.*, 1991) as well as in computer tasks (Underwood and Underwood, 1990) based on their alleged superiority compared to girls (Underwood and Underwood, 1990). There are contradictory results about the affect of gender *per se* on students' collaboration. Some studies indicate that the interaction of same-gender pairs is qualitatively better and more collaborative compared to mixed-gender pairs (Fitzpatrick and Hardman, 2000; Tolmie and Howe, 1993). Howe and Tolmie (1999) suggest that social unease occasioned by gender can have an influence on the qualitatively lower-level interaction of mixed-gender pairs. However, some studies also fail to demonstrate significant differences in interaction according to gender pairing (e.g., Howe and Tolmie, 1999). These mixed findings can be due to different reasons; a difference in tasks and instructions, in the way performance is measured, as well as a difference in wider classroom culture and context (Fitzpatrick and Hardman, 2000). In other words, these findings can be attributable to the difficulty of gaining context-free results.

Barron (2003) further argues that research on status has concentrated excessively on studying status as a static phenomenon. Therefore, such research has failed to reflect the complexity of interaction and account for dynamic shifts in students' power relations during interaction, as was observed in Barron's (2003) study. In addition, Arvaja *et al.* (2002) noticed in their case study on secondary school students' collaborative science task that the knowledge power held by one student was triggered only occasionally. Hence, it was dynamic in a sense that it did not turn into a permanent role, but was negotiated

throughout the students' activity. Knowledge asymmetry was manifested either in tutoring or a leadership role, which was also in relation with the students' friendship status. The student group consisted of four students: two boys and two girls. The girls were best friends, whereas the boys were classroom peers. It seemed that the non-constructive leadership occurred only when the whole group was present. Altogether, it seemed that when the girls were working with the boys, the social tension between group members contributed to hasty, nonreflective discussion and nonengagement with the task itself. The interaction between the girls was more equal when they were not working with the boys. Only the girls, who were friends, were able to really reason, explain, wonder, and argue, and were able to engage in the problem solving and the task at hand. The only asymmetrical interaction between the girls was tutoring, which, however, promoted collaboration and shared knowledge construction.

In addition, the nature of the task may affect the power relations of the group. According to Cohen (1994), complex tasks with ill-defined problems can be featured as group tasks. A group task is one that requires resources (e.g., knowledge and heuristic problem-solving strategies and skills) that no single individual possesses and is, therefore, probably unable to accomplish the task alone (Cohen, 1994). In group tasks, students are interdependent in a reciprocal fashion (Cohen, 1994). Thus, exchanging ideas and information is vital to success. However, problems with one identifiable correct answer could often be accomplished by single individuals and the interaction would be, in its nature, more like helping each other understand concepts without a need for deeper-level discourse. In addition, according to Chizhik (2001), a single-answer task more easily leads to one participant, perhaps a more knowledgeable person (Cohen, 1994), dominating the discussion. Instead, variable-answer tasks, which elicit knowledge from a wide subject domain, increase the possibility of many participants contributing to the discourse. In another study, Chizhik (1999) found out that gender differences in the participating group's working also diminished in variable-answer tasks.

Summary

Collaborative learning is a fashionable phenomenon nowadays; however, collaboration among students in various learning settings (e.g., in classrooms) is a much more complex phenomenon than has often been thought. While aiming to understand the diverse viewpoints to collaborative learning, we have to consider an extremely complex set of variables, that is, cognitive, social, emotional, motivational, and contextual ones, interacting with each other in a systemic and dynamic manner. This article has particularly focused on the social aspects of collaborative learning.

It has become clear that the line between individual and social processes of learning is blurring, and the main message of many researchers is that we should see individual minds in interaction with group understandings (Stahl, 2004). It is important to support not only the content, but also the social level of interaction (see Barron, 2003). It seems that learners face a dual problem space of this kind as they are supposed to work and learn collaboratively. Furthermore, collaborative situations reflect previous social activities, and are transformed by current interactions and projections of the future. In this process, social relationships deriving from friendship or status are also in a crucial role. For example, Azmitia (1998) has stated that qualities such as mutuality and trust, often associated with friendship, are beneficial in negotiating shared understanding.

Most of the results cited in this article come from studies where relationships – such as status or friendship – in relation to collaboration are explored experimentally by manipulating the group composition according to different status or friendship qualities. The gain for learning is measured in posttests at the individual level. These studies fail to reflect the complexity of interaction and dynamics in shifts in students' relations during interaction. There is a great need for studies that focus on social relationships from the sociocultural perspective, illuminating their dynamic, changing, and negotiated nature in the context of collaboration as well as their historical nature in the form of practices and relations (Arvaja, 2007).
