new move toward excellence in education may increase the likelihood that low-performing students will be referred to as potentially disabled and appropriate for special education. For the African American learner, it will, most often, be based on behavior; therefore, they will be referred for the emotionally disturbed or the mentally retarded classification. The second problem includes the high rate of referrals, with a shortage of individuals well prepared and certified to conduct the necessary evaluation. The third problem is that over 90% of students referred, and over 70% of those tested are then placed in special education programs.

The diagnosis of LD, as stated earlier, can be difficult, especially in the very early grades. However, if one follows some practical guidelines, the diagnosis can be easily substantiated. In order to diagnose a child with a suspected LD, the following procedures and criteria should be considered.

Clinical Interview

Clinical interview involves a series of interviews with the child to assess where the ultimate problem may lie. When interviewing the child with a suspected LD, one may want to look and listen for confusion over questions, poor use of vocabulary, problems expressing ideas and thoughts, awkward gait, poor memory, short attention span, lack of focus, poor fine-motor skills, and a history of academic difficulties.

Ecological Assessment

Ecological assessment involves observing the child in a variety of settings such as the classroom, playground, and other structured and nonstructural settings to determine where the student manifests the greatest difficulties. In the case of a child with a suspected LD, one may observe social withdrawal, alienation from peers, inability to focus in unstructured setting, and class-clown-type behavior as a means of being removed from academically stressful setting.

Parent Interview

Parent interview requires a personal meeting with parents to determine background history that may be essential for appropriate diagnosis. In the case of a child with a suspected LD, a parent might observe behaviors such as (1) has difficulty dressing him or herself, (2) avoids house work, (3) is disorganized, (4) has a short attention span, (5) forgets easily, (6) forgets to bring books home, (7) gets stomachaches in the morning before school, (8) gets frequent headaches, (9) has few friends, (10) is unwilling to try new things, and (11) gives up easily.

Teacher Interview

Teacher interviews may require several meetings with the classroom teacher to ascertain the child's basic intellectual, social, and academic performance. In the case of a child with potential LD, the interviewer should be aware of certain LD symptom clusters that may appear in the classroom. Some examples may include poor memory, gross-motor coordination difficulties, lack of focus, short attention span, procrastination, failure to hand in written work or homework, lack of confidence, self-derogatory statements such as "I'm so stupid," consistently low academic performance in certain subjects over time, social difficulties, lack of motivation for schoolwork, poor handwriting, and poor fine-motor skills.

Review of Cumulative Reports and Records

Review of report cards, attendance records, standardized tests, and so forth – to determine possible patterns of behavior – can be helpful. In the case of the child with potential LD, a review of cumulative records may reveal consistently low group of achievement scores in certain subjects over a period of years, past teacher comments showing a pattern to what the child's present teacher reports, a historical pattern of academic difficulties, frequent absences (which may occur when the child feels frustrated and overwhelmed by the work), and a discrepancy between ability and class performance as indicated by report card patterns.

Intelligence Testing

In the case of a child with a suspected LD, the psychologist will administer an individual intelligence test to look for an average to above average intellectual level. This does not mean that the child's IQ need be in the average range, but analysis of the profile indicates that greater potential be shown through significant uneven pattern between scores within the same test. Many children are commonly misdiagnosed as having a LD when, in actuality, they may be slow learners, children with emotional issues, or underachievers not performing for reasons other than a LD.

Achievement Testing

Children with LDs usually exhibit a severe discrepancy between potential ability (as measured on an individual IQ test) and academic achievement. This is a debatable criterion because it is possible that a child functioning on grade level – according to standardized achievement tests – may actually have a severe discrepancy if one takes into account ability levels (Pierangelo and Giuliani, 2002). Turnbull *et al.* (2002) reported that, in diagnosing LD, it is necessary to use a nondiscriminatory approach to

insure compliance with the mandates of the IDEA. An important aspect of nondiscriminatory evaluation for students with LDs is establishing a discrepancy between ability, as measured by an IQ test, and achievement – as measured by a standardized test.

Instructional Considerations for Students with SLD

One of the best ways for teachers to address the needs of students with LDs is to adopt instruction and materials. Many textbooks include teacher's manuals to assist in the presentation of instruction. Too often, however, the lessons in the manual are brief and potentially confusing. Teachers and service providers need to modify these lessons before presenting them to the class. (see Hunt and Marshall, 2002). They should understand that individuals with LDs have different learning styles – find how best a child learns, and teach to his/her strength. It is important to involve parents and extended family in the education of the child to increase the opportunity for the child to learn at the maximum level.

In addition, competent teachers and service providers should understand:

- Students with SLD are most likely to have reading difficulties, followed by math and writing problems.
- Students with SLD have learning strengths and weaknesses.
- Instructional goals must be comprehensive and unified.
- Intervention needs to be based on a diagnostic-prescriptive approach that includes assessment, planning, implementation, evaluation, and modification as needed.
- Students with SLD required intense and sustained interventional activities.
- There is a need for active learning to overcome the inactive learning of students with SLD.
- Best practice is predicated on using research-supported materials.
- Students with SLD will, likely, require specialized methods for teaching basic skills.
- Content-area instruction should be based on the use of learning strategies and study skills.
- There is a necessity for modifying the pace of instruction and providing organizational cues.
- There is a need for students with SLD to experience success.

Solutions to remedy problem confronted by students with SLD lies with good teachers, understanding administrators, and sound family, and extended family support. The key points to remember are:

- Family support is a must.
- Caring teachers are essential.

- Good teachers are crucial.
- In-school support systems are a necessity.
- Understanding how children learn is a major component.
- Adapting the classroom environment is necessary to meet the needs of the student.
- Adapting material to help students understand it.
- Using peer tutors to increase opportunity helps to increase chance of friendship in the classroom.
- Patience is a must.
- Allowing students to be creative in their presentation of information – to be practiced always.

Conclusion

This article explores many areas of specific LDs. It is understood that the judgment of whether a LD is a difficult one involves consideration of the students intelligence, achievement, past educational experience, age, rate of learning with various instructional approach, quality of present and past teaching, motivation and many other personal curriculum, and environmental factors. It is clearly understood that students with SLDs are bright enough to have learned the basic skills and information required by their school. The learning strategies and information-processing skills of most individuals with LDs are typically expressed, but they do so at a much slower pace.

The role of pollutants and teratogen (aspects of the environment that causes development mental malformation in humans) in causing LDs is well-known research; however, Murphy and Oei (1999) noted that we continue to expand our understanding of how exposure to chemicals during pregnancy and early developmental years contribute to LDs in a newborn or young children. This is a body of research that cannot be ignored based on the influences of our ever-expanding technological development today. With the passing of special education laws P.L. 94-142, in 1975 (The education of all handicapped children act), and amended to P.L. 101-76, in 1990 (ADA), the effectiveness of our teacher-training programs, regarding the treatment, care, understanding, and education of these children have made an impact on their lives as professionals have learned to work with and help them to overcome this disability. At present, the focus is on achieving the expectation of serving these children in what is presently considered to be the least restrictive environment – the regular education classrooms.

Educating Children with Speech and Language Disorders

S L Green and C D Qualls, State University of New York College at Buffalo, Buffalo, New York, USA

© 2010 Elsevier Ltd. All rights reserved.

The numbers of school-age children with speech and language disorders (SLD) in the US and Canada have continued to rise. Advances in medicine, genetics, and technology as well as recent changes in the laws affecting services to individuals with disabilities contribute to these increasing numbers, particularly as more students with disabilities attend school. According to the American Speech–Language–Hearing Association (ASHA) “communication disorders are among the most common disabilities in the United States.” (ASHA, 2008). A communication disorder can be manifested as a unitary speech, language, or hearing disorder, or as a combination disorder with one or more of these aspects of communication being affected. The National Information Center for Children and Youth with Disabilities (NICYD) reported that one in every ten people in the US have a communication disorder, and that over “one million of the students served in the public schools’ special education programs in the 1997–98 school year were categorized as having a speech or language impairment” (NICYD, 2008). The Canadian Association of Speech–Language Pathologists and Audiologists (CASLPA) reported that (CASLPA, 1996) the prevalence of SLD in children between birth and 19 years of age was as high as 10%. In some countries other than the US and Canada, for example, in China and Africa, the numbers may be even greater.

Approximately 50% of the 135 000 members of ASHA (2009) work as speech–language pathologists (SLPs) in an educational setting, many of them in the public schools. An SLP receives training on the nature, and causes, identification, prevention, assessment, and treatment of SLD. Also trained in interviewing and counseling, SLPs work closely with other educational and health professionals to ensure that individuals with SLD and their families receive the highest-quality services.

This article focuses on how those individuals can maximize their fullest potential. In addition, the roles of assessment, referral, intervention, and follow-up in the academic and social success are discussed.

Speech and Language Disorders

Speech is verbal expression for human communication. Students with good expressive abilities can produce or articulate the different sounds of speech, they can speak clearly and without difficulty (e.g., with ease and appropriate rhythm), and they are able to produce good voice

(e.g., adequate volume and no hoarseness/breathiness) for articulate/intelligible speech. A speech disorder may be present in the absence of one or more of these characteristics. Childhood speech disorders are categorized as childhood apraxia of speech (CAS), orofacial myofunctional disorders (OMD), speech sound disorders, articulation and phonological processes, stuttering, and voice (ASHA, 2008).

Childhood Apraxia of Speech

ASHA’s *ad hoc* committee on CAS defines CAS as a neurological childhood speech sound disorder that affects the precision and consistency of the movements necessary for smooth, articulate speech. A child with CAS has normal muscle tone and normal reflexes, yet has difficulty producing the sounds of speech. It is believed that the core impairment is in planning and/or programming the spatio-temporal movement sequences for the sounds and the rhythm of speech.

Orofacial Myofunctional Disorders

OMD affect the muscles (myo) of the mouth (oro) and face (facial). Children with OMD have difficulty with speech and swallowing because the tongue-thrust behaviors seen in the normal infancy fail to disappear as the child develops. Tongue thrust occurs when the tongue moves forward in an exaggerated way between the upper and lower teeth during speech and/or swallowing. School-age children with OMD tend to experience social isolation because they may be self-conscious about their physical appearance and their speech.

Speech Sound Disorders: Articulation and Phonological Processes

As children develop, many will typically make some mistakes in their speech, particularly in early childhood when they attempt to learn new and complex words. A speech sound disorder exists when such mistakes continue beyond the development age at which the child should correctly produce the sound(s). The prevalence of children with speech sound disorders range from 2% in older children (8 years old) to 24.6% in younger children (5 years old). The sound errors will render the child’s speech unintelligible to those unfamiliar with the child. Children with speech sound disorders can have problems with articulation

(making sounds) and/or phonological processing (sound patterns). An articulation disorder is characterized by speech sound production errors (e.g., rabbit is pronounced wabbit). A phonological disorder is characterized by the inability to follow the rules that govern production of sound combinations (e.g., sounds that require the tongue to be placed in back of the mouth are produced with the tongue in the front of the mouth (e.g., cat is pronounced tat) or vice versa (e.g., ball is pronounced gall). Early phonological disorders are related to later/subsequent reading, writing, spelling, and mathematical abilities.

Stuttering

Stuttering occurs when the easy onset and continuous flow of speech (termed fluency) are disrupted. Disruptions, or disfluencies (e.g., hesitations, or repetitions and prolongations of sounds or words), in the flow of speech occur in the speech of most people at times. However, when a person produces too many disfluencies, as seen in persons who stutter, communication often suffers. Stuttering begins in early childhood and, for some people, lasts a lifetime. Further, stuttering behaviors greatly vary across individuals and situations. The impact of stuttering for a child in the school setting is affected by his/her own speech and associated behaviors (e.g., avoidance of certain activities and rearranging the words in their sentence), coupled with others' reaction to their speech. Some children who stutter have other speech or language problems. In some cases, the coexisting speech or language problem will be the impairment that is treated first and, as time permits, the stuttering may be addressed (Blood *et al.*, 2003). These children often experience social isolation and are sometimes bullied by others (see Blood *et al.*, 2003).

Voice Disorders

Childhood or pediatric voice disorders are more common than one might expect. Voice disorders are characterized by aphonia (no voice), abnormal vocal quality (i.e., hoarseness, harshness, and breathiness), pitch that is too high or low, volume that is too loud or soft, impaired nasal resonance, and/or inadequate voice support to produce intelligible speech. A reported 6–23% of school-age children have hoarse voices; hence, the most common voice problem in school-age children is hoarseness related to vocal hyperfunction (i.e., yelling, screaming, crying, loud volume, and excessive talking). Children with voice disorders respond positively to treatment that addresses the source of the voice abuse/misuse and strategies to reduce those behaviors. Early identification and treatment of a childhood voice disorder is recommended to avoid a lifelong communication impairment, particularly because it is thought that the majority of adult voice disorders begins in childhood. Few school-age children receive direct

voice rehabilitation because their difficulty is not considered to be serious enough to be placed on the active caseload (Hooper, 2004). Children with voice disorders can experience difficulties in their academic performance and socialization.

Language Disorders

Language consists of socially shared rules and students who understand and appropriately use these shared rules will be successful not only academically, but also in their social interactions. Students with age-appropriate language:

1. have a good working knowledge of vocabulary;
2. understand that some words have multiple meanings (i.e., literal and figurative meanings); and
3. know how to make new words, put words together, and know what word combinations are best in what situations.

A language disorder impairs one's abilities to comprehend and/or use spoken or written language or other symbol systems (e.g., gestures or sign language). Language impairments may be manifest in the form (grammatical rules), content (e.g., understanding word meanings and creating words, and the ability to follow commands), and/or function (i.e., conversational skills, eye contact, turn-taking, and appropriate use of emphasis) of language in communication. A child's language can be delayed or disordered. A language delay means that the child will develop language skills at a later time than their age peers. A language disorder occurs when, as stated above, one or more language skills are impaired. Childhood language disorders are classified as language-based learning disabilities (LBLD), specific language impairment, and selective mutism.

Language-Based Learning Disabilities

Learning disabilities represent "a heterogeneous group of disorders manifested by significant disabilities in the acquisition and use of listening, speaking, reading, writing, reasoning, or mathematical abilities" (Hammill *et al.*, 1981: 336). Approximately 80% of all school-age children with learning disabilities have language impairments that substantially characterize their disorder (Wiig and Secord, 1998). Language and reading problems in children with LBLD result largely from impairments in vocabulary and comprehension (McCormick and Becker, 1996; Minskoff, 1982; Wright and Newhoff, 2001). Students with LBLD often show average to superior intelligence, but have difficulty in one or more aspects of language, such as spelling, reading, and/or writing. For instance, a child with dyslexia has trouble almost exclusively with reading, whereas a child with an expressive language disorder has

significant difficulty communicating their thoughts although they understand what has been said. These students also have difficulty with figurative (nonliteral) language, such as idioms and metaphors (Qualls *et al.*, 2004).

Children from Linguistically Diverse Backgrounds

Children from culturally and linguistically diverse (CLD) backgrounds are placed in special education at a much higher rate than their white counterparts. Majority of these children are referred for services related to speech, language, and/or reading disorders. African Americans represent more than 30% of the students in special education, yet they make up only 17% of the total school-age population (Obiakor, 2007; Rochon, 2007). Native Americans represent less than 1% of the school population and 1% of the special education population. Asian Americans represent less than 2% of all students in special education, while they make up 4% of the school-age population. White students are the most proportionate of all of the groups relative to the overall school-age population (67%), with placement in special education at 43.2% (National Center for Education Statistics, 2005; Obiakor, 2007). Traditionally, Latino American students have been overrepresented in all categories of special education, particularly SLD and learning disabilities; they are 16% of the national school population and 14% of the children in special education.

African-American English Dialect Speakers

Language is essential in the transmission of culture (Gollnick and Chinn, 2002; Hughes *et al.*, 2002). Through the process of enculturation, children learn their first (home) language and culture, which often differs from learning a second (school) language and culture. When methods for facilitating the learning of the school language do not take into consideration the child's home language/culture as a basis, as well as his/her interests and capabilities (Gay, 2002; Rickford, 2001), the psychological and social consequences can be profound because they can influence how they learn and interact with their peers (Saville-Troike, 1976).

Historically, African-American students' have been overidentified for placement in specific categories of special education, such as speech, language, and reading disorders (National Reading Center, 2002; Obiakor, 2007). This may be due, in part, to the dialect spoken by many African-American students, African-American English (AAE). Graham (1997) noted that AAE speakers comprise a significant percentage of US public school students, many of whom are placed in special education at a disproportionate rate (68% higher) compared to their white peers (National Center for

Education Statistics, 2005). AAE has its own system of sound, word and sentence structure, meaning, structural organization of vocabulary items, and lexical, phonological, and syntactic as well as semantic patterns intertwined with structures in Standard American English (SAE; Green, 2002). SLPs and special education teachers who have a thorough understanding of the distinctions between a language difference (vis-a'-vis, a dialect such as AAE) and a language disorder are key in reducing the numbers of inappropriate placement of AAE speakers in speech and language therapy. In particular, these professionals must have an understanding of the ways in which AAE differs systematically from SAE. Qualls (2007) stated that "speech-language pathologists, educators, and neuropsychologists who are responsible for testing and assessing the speech, language, and cognitive abilities of African Americans should have adequate knowledge about AAE. This is crucial for differentiating one's dialect from disordered speech" (p. 133). These professionals will also reduce the chance that AAE speakers, who are in need of speech and language services, will not be overlooked. SLPs and special education teachers must have (1) the ability to defer their own biases, (2) an appreciation for the range of linguistic and cultural variations in their students, and (3) the sensitivity to any inherent bias in standardized assessments. In their small sample study of 88 self-selected informants from five secondary schools in New York City, Blake and Culter (2003) reported that the majority of the teachers did not support bidialectal education and felt that federal funds should not be allocated for such programs (this is in contrast to their overwhelming support for bilingual education).

Bilingual Students

In 1974, California gave us bilingual education. The United States Supreme Court ruled that California had to provide some type of special educational assistance for linguistically diverse students. The original objective of bilingual education was to ensure students would not fall behind academically because of a poor command of English and to gradually teach them English as a second language. The Federal Bilingual Education Act (1968 and 1974) mandates and provides Title VII funding for local educational agencies to establish, implement, and sustain programs for the transition of children and youth of limited English proficiency (LEP; US Department of Education, 2007). Students from linguistically diverse backgrounds are a large percentage of school-age children in the United States and in California. Over the last 25 years, students from linguistically diverse backgrounds have increased rapidly comparative to mono-English speakers in California and in the rest of the US. In 2005 in the United States, more than 10 million children, between the ages of 5 and 17, spoke a language other than English. This population of students represented 20% of school-age children (US Census, 2005).

For example, in California, 44% or 3.9 million school-age children spoke a language other than English. This population increased by 187%, while mono-English speakers increased by only 8%. Similarly, national statistics for linguistically diverse students increased by 130%, while mono-English speakers decreased by 1.3 %. As a result, the majority of the 5 million additional school age children in the United States over the last 25 years were from linguistically diverse backgrounds (University of California Linguistic Minority Research Institute, 2005).

Disturbing numbers of these bilingual students underachieve in US public schools (Garcia and Domínguez, 1997) and are placed into special education programs. Largely due to language differences, English-language learners continue to be overidentified in special education. In an effort to compensate for such overidentification, there is a new trend of underidentification that has emerged for this population (Ovando and Collier, 1985). Because of the heightened awareness of cultural and linguistic diversity for SLPs and special education teachers, there seems to be more sensitivity when assessing speech and language skills of linguistically diverse students. However, due to personnel shortages, there still appears to be few trained skilled bilingual SLPs and certified bilingual special educators. Consequently mono-lingual SLPs and special educators are engaged in discussions that may not be appropriate for bilingual students. This may be due to the alternative placements of many English-language learners with disabilities in bilingual education instead of special education services (Baca and Cervantes, 1989, 1991). To ensure that this population of students receives a more appropriate placement, many districts implemented bilingual special education programs. Apparently, bilingual special education utilizes an instructional social system that involves active teaching of cognitive skills that takes into account the student's disabilities (e.g., an SLD), developing language skills at the same time as focusing on the acquisition of English (Baca and Cervantes, 1991). Regarding bilingual students with SLD, one assumption is that students learn best in their preferred language. It is therefore imperative that the SLP understands the most appropriate approach to assessment and treatment of the child and his/her family through interpreters, translators, and cultural brokers (ASHA, 2004). The goal is to provide all students with educational experiences that allow them to develop lifelong learning skills (Baca and Payon, 1989).

The Individuals with Disabilities Education Act and Students with SLD

The Individuals with Disabilities Education Act (IDEA) is the federal special education law (IDEA, 1997), that is an amendment to the 1975 Education of All Handicapped

Children's Act (PL 94-142). IDEA provides federal financial assistance to state and local education agencies to guarantee special education and related services to eligible children and youth ages 3 through 21. The IDEA '97 was reauthorized as The Individuals with Disabilities Education Improvement Act (IDEIA) of 2004. This reauthorization provides some guidance in planning and implementing assessment procedures for all students, including CLD students who may or may not have a disability. IDEA stipulates that testing and evaluation procedures should be nondiscriminatory and requires that all children be fairly assessed in their dominant (native) language (US Department of Education, 2007). It is important to note that existing special education referral practices consider primarily the culture and language of mainstream English speakers and do not take into account nonstandard dialect speakers and/or non-English speakers.

A large proportion of nonmainstream students have LEP or are speakers of nonstandard English dialects. These students may not fully benefit from classroom English instruction. Further, some classroom teachers may not be able to distinguish SLD from linguistic differences (Garcia and Domínguez, 1997).

It is well known that standardized assessments are used to determine placement or nonplacement into special education. It is also known that many, if not all, standardized assessments show some level of bias in favor of the culture, language, and cognitive learning styles of speakers of mainstream English. Hence, these assessments will disadvantage anyone who does not possess those characteristics of the mainstream population. For example, speakers of AAE perform more poorly on these assessments; besides, students with cognitive and learning styles that are field dependent and associative have similar outcomes. However, while it is not known to what extent AAE directly affects the placement of African Americans in special education for SLD, researchers assert that AAE among a multitude of variables impacts the attitudes, expectations, and perceptions that often lead to special education referral for SLD and placement (Anderson, 1992; Hilliard, 1992). In an effort to alleviate the number of non-mainstream English speakers' overidentification in the category of SLD, the Diagnostic Evaluation of Language Variance (DELV) was developed. The DELV is a norm-referenced test designed to assess children's language abilities by not penalizing those whose language may differ from mainstream English on test performance. The DELV is responsive to cultural and linguistic differences of many African-American children and is used frequently to assess this population. However, it is an effective assessment tool for children of all races and ethnicities because the DELV examines language structures common to different varieties of English (Harcourt Assessment, 2007).

Responding to Individualized Education Plans

According to law, an individualized education plan (IEP) is required for all students who have been identified as requiring special education services, including those receiving services for SLD. A multidisciplinary team (e.g., students, general education teachers, special education teachers, guardians, counselors, principals, social workers, and SLPs) determines students' eligibility in one or more of the 13 disability categories and the need for special education and/or related services (Figure 1).

Clearly, an IEP assists the school in meeting the student's learning needs as well as helps plan educational goals for him/her. Where a student has been diagnosed as having a speech and/or language disorder, the SLP would lead the IEP team in setting objectives and educational goals for him/her and help to determine any adaptations on approaches to services (e.g., where the student would receive his/her therapy and whether it is in the classroom with the other students or individually). The teacher, the speech pathologist, and parents/guardians must work collaboratively to provide necessary services for the student to successfully meet their annual IEP goals. Parents are considered as equal partners to school professionals. In addition, they provide pertinent information to the team about the child's development, including social and medical history, assist with ensuring he/she is practicing strategies at home, and report on his/her progress from the perspective of the home environment.

Figure 1 Percentage of students in special education by disability category. Other disabilities include multiple disabilities (2.2 %), hearing impairments (1.2 %), orthopedic impairments (1.1%), visual impairments (0.4 %), autism (2.3%), deaf-blindness (0.03%), traumatic brain injury (0.4%), and developmental delay (1.1%). From US Department of Education, Office of Special Education Programs, Data Analysis System (DANS), OMB #1820-0043: Children with Disabilities Receiving Special Education Under Part B of the Individuals with Disabilities Education Act, 2003. Data updated as of 31 July 2004. Also tables 1–3 in vol. 2 of this report. These data are for the 50 states, District of Columbia, BIA schools, Puerto Rico and the outlying areas.

Future Perspectives

School-based SLPs and special education teachers provide invaluable services to children with SLD. IDEA, in conjunction with the school-based curriculum, guides legal and ethical decisions regarding assessment for and assignment into the different categories of special education that include SLD. SLPs are highly trained in the acquisition and development of speech and language; they are supposed to know the nature, causes, and best practices of SLD. In addition, they work with classroom teachers, special educators, social workers, psychologists, interpreters, cultural brokers, and families to ensure that children with SLDs from a range of social, linguistic, and cultural backgrounds can be academically and socially successful.

There are a number of future trends and needs that require the attention of professionals working with school-age children with SLD, three of which are summarized as follows: testing/assessment; technology, and evidence-based practice.

Testing/Assessment

Evidence is incomplete in the area of predicting future functioning:

- large-scale studies are needed to increase the predictive validity of instruments used to assess SLD in children;
- normative samples should be representative of the populations of interest and of sufficient size to demonstrate the instrument's ability for valid, reliable interpretation;
- appropriate instruments are needed for reliable and valid assessment of language in population subgroups, defined in terms of language, dialect, and cultural differences (e.g., English/Spanish proficiency scales in oral and written language, and acculturation and assimilation scales);
- resources are needed to encourage research among teams of professionals with expertise in SLD, cultural experts/brokers, professionals with expertise in disorders that often co-occur with speech and language impairment, and psychometric experts;
- research is needed relative to the applicability of speech and language assessment instruments for individuals with different disorders such as autism, severe physical impairment, mental retardation, CAS, learning disabilities, and hearing impairment.

Technology

Technology is very important in working with students with speech and language problems. Efforts must be made to:

- Assess the efficacy of using technology in the assessment and treatment of children with SLD. There must be research on the efficacy of incorporating technological applications such as, personal digital assistant (PDA) texting, and blogging. It is important to understand the impact of attitudes, perspectives, and beliefs relative to technology.
- Expand the classroom teachers' knowledge base about technology transfer for those children with SLD.
- Refine the use of augmentative-alternative (AAC) devices for children with SLD, including funding, training and education, use in the classroom/at home, and security.

Evidence-Based Practice

As a result of personnel shortages, many SLPs working in the schools are seeing larger numbers of children with SLD. They are consequently spending less time per student per therapy session and feeling the pressure of increased accountability (see IDEA and No Child Left Behind Act of 2001) and consumer demand for high-quality services. Further, rising costs to provide services to children with SLD have led to the need for school-based SLPs to present evidence that their services are efficacious, effective, and efficient.

Evidence-based practice represents the nexus between the best available evidence, clinical expertise, and client/patient perspectives. There is a major movement in the field of communication sciences and disorders to define, understand, adopt, and employ evidence-based practice. However, to fully implement this practice requires a paradigm shift for how clinical decisions are made. To date, the complexities of this practice are yet to be fully understood, although significant resources are being devoted to this important approach to assessing and treating individuals with communications disorders (ASHA, 2008).

Johnson (2006) noted that much of the current research in speech-language pathology is that of basic research, addressing "theoretical or etiological questions and [employing] designs and methods that do not permit direct applications to clinical issues" (p. 21). She further states "to inform practice, research must address clinically relevant questions using particular designs and methods" (p. 21). On the other hand, Brackenbury *et al.* (2008) argue that the particular designs and methods necessary for evidence-based practice may be problematic for a child's language because most treatment approaches for language disorders do not work quickly. Consequently, the child's life circumstances may influence treatment outcomes (e.g., general development). A second conundrum for treatment research pointed out by Brackenbury *et al.* (2008) deals with the trade-off between external validity and internal validity. Increased controls increase internal validity, but decreases external validity, the penultimate goal for intervention research – real-world applicability.

Conclusion

The numbers of school-age children with SLD in the US and Canada have continued to rise and many of these children are from CLD backgrounds. CLD students are placed in special education at a much higher rate than their white counterparts and the majority of these children are referred for services related to speech, language, and/or reading disorders. For example, English-language learners were traditionally overidentified in special education, but are presently underidentified (Ovando and Collier, 1985). It is imperative that SLPs and special educators have a heightened awareness and adequate knowledge of what cultural and linguistic diversity entails. Moreover, they must employ culturally appropriate practices when identifying, referring, assessing, and treating the speech and language skills of CLD students. School-based SLPs and special education teachers are responsible for providing services to children with SLD that are curriculum based, evidence based, and that are guided by legal and ethical tenets that include consideration of the student's cultural and linguistic experiences. Future research should inform, more specifically, best practices for working with CLD children with SLDs and their families. Further, as the change in demographics of school-age children continues to evolve in the US, educational professionals will need to participate in professional development activities that will enable them to more fully engage in culturally competent practices that ensure the success of their students.

Glossary

Asperger syndrome – It is a developmental disorder which significantly impacts the qualitative nature of social interaction, along with a restricted and repetitive repertoire of behavior, interests, and activities, with no general delay in language or cognitive development.

Autism – It is a developmental disorder which significantly impacts the qualitative nature of social interaction and communication, along with a restricted and repetitive repertoire of behavior, interests, and activities.

Pervasive developmental disorder – It is a general diagnostic umbrella term under which five disorders are present: autism, Rett syndrome, childhood disintegrative disorder, Asperger disorder, and pervasive development disorder – not otherwise specified.

Pervasive developmental disorder – not otherwise specified – It is a developmental disorder in which severe and pervasive impairments exist in social interaction or communication skills, or when restricted behaviors, interests, and activities are present, but criteria are not met for other PDDs.

Historical Perspective of Autism Spectrum Disorders

The term autism, taken from the Greek *autos* meaning self, was used in the early 1900s by Swiss psychiatrist Eugen Bleuler to describe idiosyncratic behavioral symptoms of patients with schizophrenia who exhibited fundamental disturbances in contact with the social world. However, it was not until 1943 that autism became recognized as a distinctive condition when Leo Kanner, an Austrian-American and John Hopkins University psychiatrist, published his seminal article *Autistic Disturbances of Affective Contact*. One year later, Austrian pediatrician Hans Asperger published his pioneering paper *Autistic Psychopathy in Children*, in which he described children with severe difficulties with social integration. He chose the label autism to characterize these children; however, the children he was describing clearly differed from those described by Kanner. Asperger's work was not widely

known until after his paper was translated from German to English in 1981 by Lorna Wing, and English psychiatrist who suggested Asperger syndrome to be a separate entity from autism, with less-severe symptoms and much better prognosis.

Prior to the identification of autism as a distinct disorder, children with autism were diagnosed as having mental retardation, childhood schizophrenia, or other psychiatric disorders. Accounts of children with characteristics now accepted as being associated with autism have been reported for hundreds of years, the most famous being Victor of Aveyron. Victor was found in 1797 and originally assumed to have been raised in the wild. In spite of the education and training efforts of Jean-Marc Gaspard Itard, Victor did not learn to speak, yet he did gain the ability to understand spoken language and to conform to some social norms. Scientific study in the 1950s and 1960s investigated possible psychopathological roots of autism. Child psychologist Bruno Bettelheim blamed 'cold, refrigerator mothers' for causing their children's autism and suggested removing these children from their mothers. This psychogenic view was in direct contrast to Kanner's description of inborn autistic disturbances. In the 1960s, strong evidence against the psychogenic theory of autism changed the focus of etiological study. In his book, *Infantile Autism* (1964), Rimland's denouncement of psychogenesis and support for biological etiology led to the widely accepted view that family interaction patterns do not contribute to the occurrence of autism. While this claim discounts psychogenic etiologies, it still neglects the genetic liability that is gaining widespread empirical support, as autism is considered to be a highly heritable condition. Also, beginning in the 1950s, research began to focus on the education and treatment of individuals with autism, with an emphasis on psychotherapy. However, in the 1960s when techniques based on the principles of applied behavior analysis were used successfully to teach children with autism, the educational landscape changed, and more children were educated in research studies and in schools. With the passage of the Education for All Handicapped Children Education Act in the USA in 1975, children with autism were guaranteed a free and appropriate public education. In 1990, this law was reauthorized as the Individuals with Disabilities Education Act (IDEA), and autism was added as a specific educational classification. Since then, the number of students classified under this category has increased dramatically. Similar laws govern the education of students with autism in many countries; however, in a

large number of places throughout the world, individuals with autism are not guaranteed a free and appropriate public education or other publicly funded services.

Characteristics of Autism Spectrum Disorders

The *Diagnostic and Statistical Manual of Mental Disorders IV-TR* provides diagnostic criteria for pervasive developmental disorders (PDDs), which are similar to those listed in the *International Statistical Classification of Diseases and Related Health Problems* (ICD-10). PDDs are pervasive, meaning they are persistent and all-encompassing, affect normal development, and have disabling effects on the lives of individuals. While there is some dispute regarding symptom boundaries for these disorders, the most common standard is to view five distinct and related disorders under the umbrella of PDD (see **Figure 1**):

- Autistic disorder (known also as autism)
- Asperger disorder (Asperger syndrome)
- Rett's disorder (Rett syndrome)
- Childhood disintegrative disorder

Figure 1 Pervasive developmental disorders.

- Pervasive developmental disorder – not otherwise specified (PDD-NOS; autistic-like, autistic tendencies, or atypical autism).

Autism spectrum disorders (ASDs) is a term which is generally accepted to include autism, Asperger syndrome, and PDD-NOS. These disorders have similar characteristics but vary in their expression of a triad of symptoms: social skill deficits, communication disorders, and restricted behaviors, interests, and activities. However, the spectrum of autism can also be manifested in various intellectual abilities, sensory sensitivity, and motor skills (see **Figure 2**).

Autism

Autism is a developmental disorder with neurological origins, present from birth or early development. Considered to be a lifelong disorder, autism impacts an individual's social interactions, communication skills, and behavior patterns. Delays and/or abnormal functioning are apparent by the age of 3 years, particularly in social interaction, social language, or symbolic or imaginative play. Autism is manifested along a broad spectrum, meaning the skills and deficits vary considerably among affected individuals. For example, while earlier research reported that approximately 70% of individuals with autism had intellectual disabilities, more recent epidemiological studies indicate rates as low as 40%. Social symptoms may vary from social quirkiness to severe self-absorption. Some children with autism are highly verbal, while approximately 50–75% have little or no functional speech. Also, some have mildly odd patterns of behavior or interests, while many have persistent destructive and disruptive behavioral challenges.

While neurological dysfunction is not a diagnostic marker, it is a common characteristic of autism. Many individuals with autism have abnormalities in chromosomes,

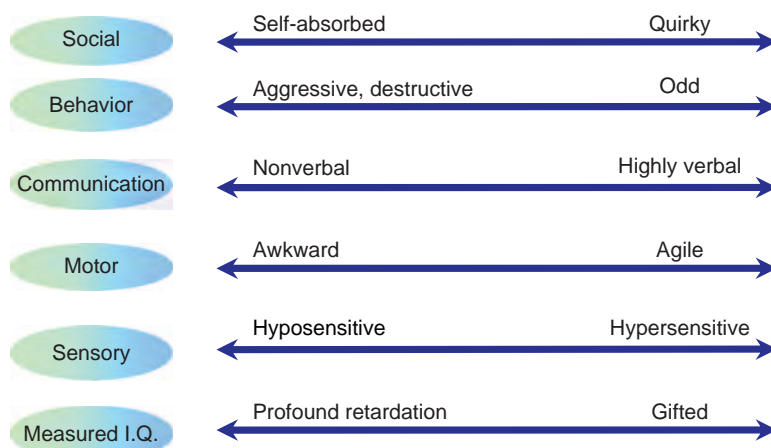

Figure 2 Continuum of symptoms in autism spectrum disorders.

brain structure, and brain chemistry. Approximately 25% of individuals with autism develop epilepsy, often during adolescence. Common symptoms of autism include a triad of impairments:

1. Social skills
 - Delayed development of appropriate peer relationships
 - Impaired spontaneous sharing (e.g., interests and achievements)
 - Lack of social/emotional reciprocity
 - Impaired nonverbal behavior (e.g., eye contact and facial expressions)
2. Behavioral repertoire
 - Inflexible, nonfunctional routines or rituals
 - Repetitive motor actions (e.g., hand flapping and body rocking)
 - Persistent preoccupation and restricted, intense patterns of interest
 - Abnormal mood/affect
 - Hyperactivity
 - Odd responses to sensory experiences
3. Communication
 - Delay or lack of spoken language
 - Conversational impairment
 - Repetitive and stereotyped language
 - Poor receptive language
 - Impaired play skills.

Asperger Syndrome

Individuals with Asperger syndrome have similar symptoms of autism in the areas of social interaction and behavior patterns; however, they show no clinically significant delays in language. According to diagnostic criteria, children with Asperger syndrome use single words by the age of 2 years and communicative phrases by the age 3 years. Further, children with Asperger syndrome have no clinically significant delay in the development of cognitive processes, self-help skills, adaptive behavior, or curiosity about the environment.

For an individual to be diagnosed with Asperger syndrome, the symptoms must significantly impair him or her in social, occupational, or other important areas of functioning. Associated features include mild motor clumsiness, hyperactivity, inattention, and other mental disorders such as depression. Individuals with Asperger syndrome may be overlooked because their high verbal skills may mask the severity of their social dysfunction, and their unusual behaviors may be interpreted as stubbornness. Prognosis for individuals with Asperger syndrome is generally much better than for those with autism. Many are able to complete college degrees, obtain meaningful employment, marry, and interact as contributing members of their communities. Some individuals with Asperger syndrome prefer to be

considered different rather than disabled, rejecting the notion that Asperger syndrome is a condition that needs to be remediated or cured.

Pervasive Developmental Disorder–Not Otherwise Specified

PDD-NOS is a diagnosis given by a physician when an individual exhibits a significant and pervasive impairment in social development, communication, or behavior, but does not meet the criteria for autism, Asperger Syndrome, or other pervasive developmental disorders. Failure to meet criteria includes a later age of apparent onset, atypical symptoms, or symptoms that do not significantly impair the individual quantitatively or qualitatively. A diagnosis of PDD-NOS is also referred to as atypical autism.

Screening and Diagnosis of Autism Spectrum Disorders

Early detection of autism is critical for obtaining early intervention services, yet ASDs are typically not diagnosed until after 3 years of age. However, physicians and parents of children as young as 2 years old should be alerted to the following developmental red flags: poor eye contact, diminished responsive smiling, low occurrence of babbling, reduced social responsiveness; and delayed or disordered development of language, play skills, and ability to initiate or sustain social interaction. At later ages, children who are suspected of having autism exhibit symptoms in the three areas of concern: communication, social interaction, and behavior. Often, when parents are concerned about their child's development, a pediatrician may conduct a screening evaluation. If warranted, the pediatrician refers the child to a child psychologist, child psychiatrist, pediatric neurologist, or other diagnostician. A full medical evaluation is conducted, during which information is gathered about the child's developmental history, along with many evaluations and diagnostic tests in areas such as medical and neurologic conditions, communication skills, cognitive development, adaptive behavior, academic abilities, behavior patterns, and fine and gross motor skills. Further, the family's strengths, resources, and needs are evaluated. This information is used not only to aid diagnosis of a possible disorder, but to guide recommendations for services that are responsive to values and cultures of the family.

Generally, children who have been diagnosed with an ASD are also evaluated by school professionals – not for diagnostic purposes, but for educational classification. Prior to 1990, special education law did not include an educational classification for autism. Children with these diagnoses were often educated under a classification of

mental retardation, severe emotional disturbance, or multiple disabilities. While school multidisciplinary teams determine how to best serve individual students with autism, most students with this diagnosis receive special education services under the autism classification; however, students with Asperger syndrome or PDD-NOS may be educated under the label of other health impaired or another classification which the team determines to be appropriate. If their disability does not warrant special education services because it does not significantly impact their progress in the general curriculum, these students are often served under Section 504 of the Rehabilitation Act of 1973. Students who qualify under Section 504 are served by general educators, who make adaptations and accommodations according to the plan designed by a multidisciplinary team.

Etiology of Autism Spectrum Disorders

Since Leo Kanner first brought the disorder to public attention in 1943, professionals have debated the extent to which autism is a biological condition or the result of environmental or psychosocial factors. There is agreement that autism is a complex, brain-based developmental disorder in which multiple areas of functioning are affected. The specific causes of ASD remain unknown. However, it is widely accepted that there is no single designated cause. Recent clinical and biological research has demonstrated that autism is a neurological disorder which may begin before birth. The strongest evidence to date supports a genetic component. However, investigations into environmental toxins, immune system dysfunction, and other biological factors are being conducted. Autism is not caused by poor parenting, failure of a mother to bond with her child, or a child's willful retreat into his own world. To a large measure, the genetic role in autism has been evident for decades, with the well-documented overrepresentation in males and the evidence since the 1950s of higher concordance rates in monozygotic than dizygotic twins. Further, family studies indicate higher rates of autism among siblings than expected, as well as higher rates of the broader autistic phenotype (e.g., social difficulties and depression) among first-degree relatives of individuals with autism. While there are studies which suggest a relationship between autism and a few select chromosomes, it is clear that genes are an influential but not the sole factor in the development of autism.

Prevalence

Precise prevalence rates for ASD are difficult to obtain due to the variation in the ways epidemiological research is conducted and data are analyzed. However, current research reports a range from 0.7 to 72.6 cases of autism

per 10 000, with a median rate of 13 per 10 000. Prevalence estimates have increased significantly since 1987. Epidemiological studies regarding the rate of PDD-NOS are difficult to interpret due to inconsistent labeling across studies; however, current evidence suggests a median prevalence estimate of 20.8 per 10 000, ranging from 1.9 to 36.1. Data regarding the prevalence of Asperger syndrome are sparse and imprecise, ranging from .3 to 48.4 per 10 000. Best estimates of the prevalence of Asperger syndrome is 2.6 cases per 10 000. The combined global estimate of prevalence for autism spectrum disorders is at least 36.4 per 10 000, yet when most recent prevalence surveys are isolated, this rate increases to 60 per 10 000. Clearly, proper epidemiological surveys are warranted to determine accurate prevalence estimates for each diagnostic category. The dramatic increase in prevalence estimates from the early estimates of four to five cases of autism per 10 000 reflects the impact of changes in diagnostic criteria for autism and other PDDs, improvements in societal awareness, and increases in service availability. No consensus has been reached in the professional community of whether there is a true increase in prevalence.

Treatment/Intervention Approaches for Individuals with Autism Spectrum Disorders

There are innumerable treatment/intervention approaches for individuals with autism spectrum disorders, and these can be educational, biomedical, therapeutic, or family centered. Individual approaches are varied and some are experimental, resulting in different outcomes for children with ASD. Some treatments/interventions claim to cure the child, while most are designed to reduce the effects of the disorder. The most common treatments/interventions include the following:

1. Educational approaches
 - applied behavioral analysis: breaking tasks into small, manageable parts and reinforcing success
 - structured teaching: providing visual and structural support to prevent failure
 - relationship development: developing a positive and nurturing relationship with the child with autism
 - social skills training: teaching appropriate social interactions by modeling, scripting, role-playing, and using personalized stories
2. Biomedical approaches
 - nutritional/dietary
 - wheat/milk-free diets
 - vitamin, herb, and mineral supplements
 - psychopharmacology (medication)
3. Therapeutic approaches
 - speech/language

1. speech training
2. augmentative and alternative communication
3. sign language
4. picture-based systems
5. computerized communication devices
- occupational
- Physical
- sensory integration
 1. visual
 2. tactile
 3. auditory
 4. relaxation techniques
4. Family support approaches
 - parent training
 - respite care
 - support groups.

The recommendations made by the National Research Council in 2001 along with meta-analytic research and syntheses indicate that several components of educational programs are supported by empirical research. Although various education approaches may be grounded in contradictory theories of child development, if the primary components of effective programs are present, it is likely that successful outcomes for children with autism will occur. The following recommendations for young children with autism are among those based on empirical evidence (See **Figure 3** for an evaluation tool which incorporates these recommendations):

- Early intervention into an educational program.
- Active and intense educational programming, up to 5 h per day for 5 days per week for a full year.

Evaluation of educational programs for students with autism

School/program: _____ Teacher: _____

Evaluator's name: _____ Date: _____

Early entry into the intervention program	Average age at which students enter this program:		
	Average age at which students begin receiving services:		
Individualized supports and services for students and families, based upon family and student preference	Support for students:		
	Support for families:		
Active engagement in effective instructional programming	0–2 Hours/day	Half-day	Full school day
	Various sites:		
	Days per week: 1	2	3 4 5
	Less than 9 months	9–10 months	Full year
Systematic instruction based upon valid educational goals, effective delivery of planned instruction (using principles of applied behavior analysis), and frequent evaluation and adjustment of instruction	Educationally and socially valid goals:		
	Type of instruction:		
	How learning is evaluated:		
	How often learning is evaluated:		
Comprehensible and/or structured environments , where students and staff can understand what is happening, predict what will happen, and know what is required of various settings	Curriculum is clear to students: Yes Sometimes No		
	Curriculum is clear to all personnel: Yes Sometimes No		
	How is curriculum communicated to students and staff?		

Figure 3 (Continued)

Specialized curriculum content that addresses core deficits and increases functional skills that can generalize across environments	Do IEPs include goals for core deficits of autism? Social: Yes No Behavioral: Yes No Functional Communication: Yes No Cognitive/Academic: Yes No How frequently are these goals addressed? Daily Weekly Monthly Are skills generalized across environments? Yes No
Adult attention sufficient to meet IEP goals	1:1 1:2–3 1:4–10 Large groups Are goals being met: Yes No
Functional approach to problem behaviors (i.e., positive behavior support), with a focus on replacing rather than merely eliminating problem behaviors, through teaching appropriate replacement behaviors	Evidence of functional assessment of behavior: Evidence of functional analysis of behavior: Evidence of appropriate behavior support plan:
Family involvement	Evidence of family involvement in aspects of educational program: Pre-referral process

- Planned teaching opportunities organized around brief periods of time.
- Adult attention either individually or in small groups to facilitate mastery of educational goals.
- Multicomponent interventions that target individualized supports and services in the core deficit areas of social–emotional skills, cognition, language, and behavior.
- Comprehensible and/or structured environments.
- Intensive behavioral interventions using positive behavior support principles.
- Family involvement.

Clearly, essential components of effective programs for children and adolescents with autism include (1) emphasis on functional activities and skills needed to be successful in the real world, (2) activities that are appropriate for the individual's chronological age, (3) instructional decisions that are data based, (4) instruction in school and non-school environments, and (5) social integration to the maximum extent appropriate.

Currently, meta-analytic research has not found sufficient evidence for treatments that claim to produce

significant outcomes for students with autism (e.g., social stories and school-based social skills intervention); and furthermore, studies have not been examined empirically or they have produced unclear results (e.g., facilitated communication, chelation therapy, dolphin therapy, auditory integration therapy, dietary interventions, and magnets). As it appears, educational treatments/interventions occur across a wide variety of settings, as determined by the child's Individual and Family Service Plan (IFSP) team (ages 0–2 years) or Individualized Education Program (IEP) team (ages 3–21). Some children and youth with ASD are served in their homes, while others are served primarily in schools, ranging from full participation in general education classes to placement in self-contained schools for students with disabilities. The IFSP/IEP is a legal document which designates annual goals for the child with autism. The individualized goals, supports, and services offered are based on student and family needs. All IEP goals must be assessed and documented regularly in order to evaluate whether a child is benefiting from a particular intervention. If the child is not showing sufficient progress, environmental conditions and teaching strategies should be

evaluated for their potential to impact the student's learning. Student progress should be monitored frequently and learning objectives adjusted accordingly. In addition, parents and practitioners are advised to evaluate their programs for children with autism based on high-quality research.

Summary

Recognition of autism as a specific disorder occurred when Leo Kanner published his landmark work describing children with autistic disturbances in their affective contact. Since that time, hundreds of thousands of individuals throughout the world have been diagnosed as having autism or related conditions such as Asperger syndrome and PDD-NOS. These three conditions are generally accepted to be ASDs; however, there is no universal consensus regarding specific boundaries for each diagnostic category. Nevertheless, these ASDs have similar core features which classify them as PDDs. Screening for ASD begins when a child is young, often before age 2 years. Parents and physicians are counseled to attend to markers which may indicate a developmental delay or disorder. Early screening generally leads to early diagnosis, which in turn leads to early intervention services.

A single specific cause for ASD is not known. It is widely accepted that there is not one single cause, but that the etiology of the disorders derives from many sources, with a strong genetic component. Current research has begun to investigate the role of environmental factors in the development of ASD. According to most recent epidemiological studies, the prevalence of autism, Asperger syndrome, and PDD-NOS combined is 60 cases per 10 000 individuals. However, prevalence rates must be interpreted with caution due to imprecise methods of collecting and reporting diagnostic data from multiple studies. Recent increase in prevalence is likely due to increased awareness, broader diagnostic criteria, and increased service availability. Many treatment/intervention approaches are available for helping individuals with ASD, including educational, biomedical, therapeutic, and family-based supports. Meta-analytic research indicates several core features that should be in place for obtaining positive outcomes for students with ASD. Finally, parents and professionals are advised to support practices which are validated by rigorous research.

Educating Students with Cognitive Disabilities

J P Bakken, Illinois State University, Normal, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Cognitive disability – An intelligence quotient (IQ) standard score of approximately 70 or below, with concurrent deficits in adaptive skill areas.

Community-based training – It provides functional-skills training in an integrated business setting, addressing the production, quality, and social demands of the natural work environment.

Image rehearsal – A form of visualization wherein the individual is taught to associate aspects of a task with pictures of events what will help to recall them.

Integrated settings – Settings which have students with and without disabilities.

Least prompts – These are also referred to as a response–prompt hierarchy, because the trainer progresses from the least amount of assistance (usually a verbal prompt) to the most intrusive (usually a physical prompt) until one prompt simulates correct responding.

Reinforcers – These strengthen the probability of (a response to a given stimulus) by giving or withholding a reward.

Self-determination – A person's ability to set and navigate his or her own life course.

Self-reliance – A person's ability to take care of himself or herself.

Systematic instruction – The organized and planned content that is directly taught to students.

Time delay – A procedure that allows the teacher to gradually fade assistance until the student performs without prompting.

Verbal rehearsal – It relates to the concept of self-instruction and refers to labeling aspects of a task, and verbalizing these labels aloud or silently while the task is being performed.

By definition, individuals who have cognitive disabilities are different from people who do not have cognitive disabilities based on intellectual functioning and adaptive skills. According to the most recent American Association on Mental Retardation (AAMR, 1992) definition, the assessed intellectual functioning of individuals who have cognitive disabilities is an intelligence quotient (IQ) standard score of approximately 70 or below, with concomitant deficits in adaptive skill areas. Traditionally, IQ has been described along a continuum of mild (IQ of 55–70),

moderate (IQ of 40–54), severe (IQ of 25–39), and profound (IQ less than 25), according to the degrees to which a person's measured general intelligence deviates from the average range. The term adaptive behavior historically has been used to convey the nature of one's personal independence and social responsibility.

For students with more severe cognitive disabilities, extensive supports are provided on a constant basis, across all environments, and are potentially life sustaining in nature. Supports may be provided to assist with basic and/or complex tasks of daily life, with management of emotional or psychological concerns, or with physical health needs. Persons with extensive support needs are likely to have difficulty acquiring new skills, applying the skills they have already learned to new situations, and communicating their wants, needs, thoughts, and feelings. However, these skills are helpful in functioning successfully in the social world. For this reason, persons with severe cognitive disabilities are likely to concentrate a great deal of time on learning adaptive skills so they can function in society.

Generally, characteristics of individuals with cognitive disabilities include short attention spans, problems with short-term memory, speech and language difficulties, generalizing information to new situations, motor difficulties, and frustration tolerance, especially with regard to academic learning and abstract instructional activities. For students with cognitive disabilities, their different characteristics may impact their learning. These characteristics are tied to attention, memory, speech and language, transfer/generalization, and strategies usage. See Table 1 for examples and descriptions of these.

Teaching Students with Cognitive Disabilities

To teach students with cognitive disabilities, instructional techniques that include drill and practice with flashcards and pictures and repetition of content and skills are often implemented. In addition, the transfer of knowledge learned in the classroom and on community trips where the focus is on generalization of skills is also important. Effective classroom teachers have direct control of instructional strategies they employ. These teachers not only have a large array of such strategies at their disposal, but are also adept at determining which strategies to use with specific students and content (Marzano, 2003). Interventions must be sufficiently

powerful to improve the performance of students with disabilities and lend themselves to integration with current teaching practices and conceptions. How do we know, as teachers, if an intervention is effective? Research indicates that effective interventions should be supported by outcome data (Gersten *et al.*, 1995). Guidelines for the evaluation and implementation of effective instructional practices include consistent and regular monitoring of students (daily and periodically), and implementing of informal and formal assessment strategies (as appropriate). All accountability measurements are usually aligned with content and processes involved in the practice, and trouble-shooting and/or interventions are immediately available in response to low performance.

Effective Teaching Behaviors

When presenting material to students with cognitive disabilities, it is more beneficial to the learner to present material in a group or cluster form than in random order. Grouping is perhaps the simplest method of organizing information (Spitz, 1973, 1979). Material may be grouped spatially (in different visual arrangements), temporally (with a pause or time lapse between items), perceptually (with certain items enclosed in a shape or configuration), or categorically (by content or commonality of items).

Verbal learning mediation refers to the process by which an individual connects a stimulus and a response. It can be used to work with students with cognitive disabilities. Verbalizing the connection between two stimulus words seems to enhance performance. The meaningfulness of the material and the use of stimulus words or objects familiar to the subjects also facilitate learning in paired associate tasks (Estes, 1970). Verbal rehearsal can also be used with such students. It relates to the concept of self-instruction and refers to labeling aspects of a task and verbalizing these labels aloud or silently while the task is being performed. This strategy allows the student to hear or think about all the steps needed to perform a task. In image rehearsal, a form of visualization, the individual is taught to associate aspects of a task with pictures of events that will help recall them. This strategy allows the learner to connect abstract information to concrete information to aid in the learner's recall of the material (Mercer and Snell, 1977).

Modeling, imitation, and learning through observation play fundamental roles in the education of students with cognitive disabilities. These are terms most often associated with observation learning, which refers to learning from the demonstration of others. Suggestions for using observational learning as a teaching tool include: (1) being aware that any behavior may serve as a model, (2) using prompts or cues to direct students' attention, (3) calling attention to students exhibiting desirable behaviors, (4) ignoring undesirable

Table 1 Learning related characteristics

Characteristics	Description
Attention variables	<ul style="list-style-type: none"> • Difficulties with attention span (length of time on task), focus (inhibition of distracting stimuli), and selective attention (discrimination of important stimulus characteristics) • Students need to be trained to be aware of the importance of attention and to learn how to actively monitor its use
Memory	<ul style="list-style-type: none"> • Short-term memory (STM) is more difficult for students • Students typically have a strong long-term memory (LTM) • STM problems involving nonacademic tasks are associated with the lack of spontaneous use of mediation strategies • Strategy production is difficult for students with cognitive disabilities, but improves in recall can be achieved when they are shown how to proceed in an organized, well-planned fashion
Speech and language	<ul style="list-style-type: none"> • Tend to be passive learners • Speech and language problems occur with greater frequency among individuals identified as cognitively disabled • Language disorders that commonly accompany cognitive disabilities include delayed language development and a restricted or limited vocabulary • The speech problems often seen are difficulties in articulation, voice, and stuttering • Children who do not have the verbal communication skills of their peers may withdraw from interpersonal relationships or seek attention in inappropriate ways. These children may misbehave because they cannot clearly distinguish between acceptable and unacceptable standards of behavior. Problem behavior can also result from the frustrations of scholastic failure or as an attempt to gain acceptance from other children, who might encourage inappropriate behavior
Transfer/generalization	<ul style="list-style-type: none"> • Tend to show deficiencies in the ability to apply knowledge or skills to new tasks, problems, or situations • In particular, they may fail to use previous experience to develop rules that will help solve future problems that are similar
Strategies	<ul style="list-style-type: none"> • Less likely than normal learner to employ effective techniques for organizing information for later recall • Mature learners implement effective strategies like verbal rehearsal and repetition, and imagery • Students with cognitive disabilities have difficulty producing effective strategies

behaviors so that others do not model it in an attempt to gain attention, and (5) rewarding imitation of appropriate behavior.

The majority of the literature on teaching vocational tasks to individuals with cognitive disabilities focuses on the use of least prompts (Cuvo *et al.*, 1978; Test, *et al.*, 1988). This strategy is also referred to as a response-prompt hierarchy, because the trainer progresses from the least amount of assistance (usually a verbal prompt) to the most intrusive (usually a physical prompt) until one prompt simulates correct response. The use of a least-prompting strategy can be very effective for teaching skills on community job sites and may also be effective for training students who have long been dependent on teachers for verbal instruction. In addition, gestures can be used instead of a full-model prompt or partial physical assistance such as touching the student's arm. Clearly, regardless of the types of prompts selected, the teacher should establish a latency period or time that he/she will wait for the student to respond before providing the next level of assistance. Usually a student should be given approximately 3–5 s to respond independently. Students with physical disabilities, however, may require longer latency periods based on their movement limitations, and this requirement should be determined on an individual basis (Inge, 1992; Sowers and Powers, 1992). Finally, the teacher is cautioned to deliver each prompt only once before moving to the next, more intrusive prompt. See **Table 2** for the guidelines for implementing a least-prompt hierarchy and **Figure 1** for an example of a data recording sheet. Before this is begun, a task analysis of the to-be-learned behavior must first be completed.

The use of time delay on vocational training sites is an option for teachers of students with cognitive disabilities (Inge *et al.*, 1993). There are several critical components to a time-delay procedure (Gast *et al.*, 1988; Snell and Gast, 1981). First, the teacher must select a prompt that will consistently assist the student to perform the task correctly. Initially, the prompt is given simultaneously with the request to perform the job duty. Gradually, increasing amounts of time (usually seconds) are awaited between giving the request to perform the task and providing the prompt to complete the task correctly. The number of trials at each delay level and the length of the delay should be determined prior to initiation of the program. By the teacher's pairing of the prompt with the request to perform a work task, the student is not allowed to make errors initially. The delay procedure allows the teacher to gradually fade assistance until the student performs without prompting. For example, trials are designated for 0-s delay, the next at 2 s, the next at 4 s, and so forth, until the student performs without assistance. Unlike the system of least prompts, time delay requires that the teacher select one prompt for use during the instructional program. Therefore, the procedure would be particularly useful if

Table 2 Least-prompt hierarchy guidelines for students with cognitive disabilities

Guidelines for using a least-prompt hierarchy

1. Have the student move to the appropriate work area unless movement is part of the task analysis (TA)
2. Stand behind or beside the individual so that you can quickly provide prompts when necessary
3. Provide the cue to begin the task (e.g., clean the white board, pass out the papers, etc.)
4. Wait 3 s for self-initiation of Step 1 of the TA
5. If the student completes the step independently, provide reinforcement and proceed to Step 2 of the TA. Score + or – on the data sheet
6. If the student is incorrect or does not respond within 3 s, provide a verbal prompt specific to Step 1 of the TA (e.g., pick up the eraser)
7. If the student completes the step with a verbal prompt, provide reinforcement and move to Step 2. Record V (for verbal) on the data sheet
8. If the student is incorrect or does not respond within 3 s, model the response (e.g., teacher picks up the eraser)
9. If the student completes the step with a model prompt, provide reinforcement and move to Step 2. Record M (for model) on the data sheet
10. If the student is incorrect or does not respond within 3 s, physically guide him or her through the response (e.g., teacher guides the student's hand to pick up the eraser). Record P (for physical) on the data sheet
11. Begin instruction on Step 2 of the TA
12. Repeat this procedure for each step in the TA until the task is completed. Always interrupt an error with the next prompt in the least-prompt system.

a student has consistently demonstrated a preference for one type of prompt. If an error occurs during time delay, the teacher should implement an error-correction procedure. Usually error correction consists of immediately interrupting the student's mistake and providing the prompt. If the student makes three or more errors in a row, the teacher may consider reverting to a number of trials at 0 s before again delaying the prompt. Monitoring of the training data is not constantly making errors during the procedure. See **Table 3** for a detailed description of time delay.

The selection of reinforcers and the systematic delivery of reinforcement are critical for student success on community-based vocational sites. The most effective reinforcers are those that arise as a natural consequence to a given task or situation within the work environment (Wilcox and Bellamy, 1982). Therefore, the teacher should begin by attempting to identify items that are available in a specific community-based setting. However, it should be remembered that not all individuals will be reinforced by the same items and that even the most preferred reinforcer used too frequently might lose its effectiveness (Falvey, 1989). Only after failing to identify a

Figure 1 Sample data recording sheet.**Table 3** Time-delay explanation, types, and examples*What is time delay?*

Time delay is a prompt-fading strategy. With time-delay prompting, you fade instructional prompts by inserting a delay between giving an instruction and stepping in and prompting. Time delay is considered to be an error-minimizing prompting method. That is, we use this method to prevent a child from making a lot of errors while learning a new skill.

There are two types of time-delay prompting:

Progressive time delay:

The time between giving the instruction and giving a prompt is gradually increased

Constant time delay:

A fixed amount of time is always used between the instruction and the prompt

What types of skills can be taught using time delay?

Time delay can be used to teach almost any type of skill, including:

Communication skills

Imitation, academic skills (e.g., number identification or sight word reading)

Daily living skills (e.g., grocery shopping)

Leisure skills

natural reinforcer should the teacher select more artificial items. Teachers are also cautioned to select only age-appropriate material for use on community sites. See **Table 4** for steps to identify student reinforcers.

Table 4 Identifying potential student reinforcers

1. Survey people familiar with the student (i.e., parents, siblings, and grandparents) to determine likes and dislikes. Include leisure activities, tangible items, types of verbal reinforcement, and so forth.
2. Observe the student in several natural environments during his or her free time and record what he or she does.
3. Offer the student a chance to interact with several novel items and record what he or she does. Repeat the experience over several days and determine if there is a pattern to item selection.
4. Select an item and use it as a reinforcer for a behavior the student already performs independently. Observe to see if that behavior increases.

Strategic Educational Programming for Students with Cognitive Disabilities

Educational programming for persons with cognitive disabilities has made great strides in the last 25 years. Specifically, systematic instruction of students with severe cognitive disabilities has provided empirical data to illustrate that learning actually occurs (Snell, 1993). Optimal educational programs are generally community referenced, or related to actual incidents that naturally occur in the environment. Clearly, the most useful learning activities are both functional and age appropriate. Education is designed

to enhance the student's ability to function successfully in a world inhabited largely by people without disabilities and, therefore, it is important that instruction be delivered in integrated settings. Consider this example. There is a difference between a person from Illinois who took a class in German as a high school sophomore and a person from Illinois who spent his sophomore year as an exchange student in Germany. Although it is possible to learn about another culture without experiencing it firsthand, opportunities for learning are greatly enhanced through direct experience. There are four reasons that all school-aged children should be educated in the same settings (Brown *et al.*, 1989). First, students without disabilities who are educated alongside students with disabilities are more likely to function as responsible adults in a pluralistic society. Second, integrated schools provide more meaningful instructional environments. Third, families have greater access to activities in neighborhood schools. Finally, integrated schools offer more opportunities to develop a wide range of social relationships. Integrated learning settings are as important for adults as they are for children. When teaching a person who has pronounced difficulties learning new information, it is very important to give the person every advantage. For adults, this means that job skills are better taught on the job, and domestic skills are better taught in the person's home.

The determination of a curriculum is overwhelmingly important for learners with cognitive disabilities. Skills are typically found in the domains of communication, domestic, leisure, self-help, social/friendship, and vocational. Recently, self-determination skills have been added to the best-practice curricula. The need to teach self-determination was first documented in the literature related to employment (Moon *et al.*, 1990). Although persons with cognitive disabilities are able to complete requisite job skills, they are frequently dependent on their job coaches to cue them to begin and end tasks. The development of self-determination competencies challenges students to become actively involved in their learning and decision making. Ultimately, self-determination and overall student empowerment improve the quality of students' adult lives. Increasing students' self-determination may increase their success in transitioning from high school to adult living. See **Table 5** for some other effective research-based strategies.

The Use of Assistive Technology

Assistive technology is defined by the Technology-Related Assistance Act (Tech Act) of 1988 (P. L. 100-407), and the Individuals with Disabilities Act (IDEA) of 1990 (P. L. 101-476), as "any item, piece of equipment, or product system, whether acquired commercially off-the-shelf, modified, or customized, that is used to increase, maintain or improve the functional capabilities of individuals with disabilities."

It can describe both devices and services that aid an individual. Assistive technology allows a person with disabilities (in this case, a person with cognitive disabilities) to become an integral part of the school or community (Hasselbring and Peabody College of Vanderbilt University, 1998). Examples of commonly used assistive-technology devices that illustrate the formal definition include positioning equipment, mobility devices, computer applications, adaptive toys and games, adaptive environments, electronic interfaces, homemade battery-powered toys, medical equipment, prostheses, and alternative and augmentative communication aids (Parette *et al.*, 1996). There are two purposes of assistive technology. First, technology can augment an individual's strengths by counterbalancing the effects of a disability; and second, it can provide alternative methods for performing a task so that disabilities can be compensated for or bypassed entirely (Lewis, 1998). For example, an individual with difficulties in reading who possesses good listening skills can listen to books on tape rather than read the print version. Persons with poor computational skills but with good fine-motor skills may use a hand-held calculator. Those with poor spelling abilities but with a measure of computer literacy may write with a word processor that offers assistance in spelling. See **Table 6** for assistive-technology options.

To determine the type of technology or support a particular student may need, it is critical to address the issues of individual needs and differences. Applying technology involves matching the individual's exhibited needs with the potential benefits possible through the rise of the technology (Parette and Murdick, 1998). In addition, less emphasis should be placed on the categorization of the devices as being low or high-tech. Considering that students with disabilities possess individual interests, strengths, and weaknesses, one may conclude that a device appropriate for one person may be inappropriate for another. In a similar way, a device that may assist in one setting may be inappropriate in a different situation or environment (Bryant *et al.*, 1998). Once individual needs have been targeted and appropriate technology has been applied, then the technology has the potential to provide a variety of needs for a person with a disability such as a cognitive disability.

Instructional modifications include changes to teaching procedures, curricula, management materials and technology, and the physical environment to facilitate learning (Bryant and Bryant, 1998). Specifically, assistive technology may require simple, low-tech modifications. Off-the-shelf technologies can become adaptive when they are used to enhance the learning of a student with a cognitive disability (Lewis, 1998). For example, an audiotape becomes assistive when it is used to compensate for an individual's memory or note-taking problems. In addition, low-tech modifications such as sticky notes, flags, and highlighters can enhance a student's organizational skills. Such modifications require minimal time and

Table 5 Other strategies for students with cognitive disabilities

<i>Strategy</i>	<i>Description</i>
Mnemonic strategy	The keyword method is a mnemonic (memory-enhancing) technique used to increase the initial learning and retention of facts and fact systems of the kind often encountered in schools. The method incorporates both auditory and visual cues to enhance meaningfulness of the information to be learned and to promote strong associations between questions and answers.
Self-instruction	Self-instructional training has been employed to increase general behaviors required for academic success, such as student attention to task as well as to develop specific academic skills, such as handwriting, reading comprehension, and math performance. Specifically, the teacher first models what to say and do by verbalizing task-relevant strategies while performing a task. Responsibility is then gradually faded to the students by requiring them to perform the task while the teacher continues to verbally direct the student's performance. Next, the teacher fades responsibility further by requiring the students to verbally cue their behaviors while performing the task. The final steps of self-instruction training consist of the student being told to convertly cue their behaviors. At this point, teacher direction has been completely faded, and students are self-regulating their performance.
Visual supports	Visual supports are any visually perceived stimuli that assist us in comprehending environmental information and demands. In the classroom, visual supports help students understand direction, schedules, rules, and instructional materials. Pictures are universally understood and, therefore, can be generalized to most every functional setting. Combining visual cues with speech can help some children better understand what is verbally said to them.
Empowerment strategies	Choice boards give students a visual representation of their options at any given time. By pointing to or handing a picture or icon to another person, the student is able to communicate what he/she wants: what activity to do, what materials to use within an activity, whom to work with, and when to conclude the activity. Token boards serve as conditioned reinforcers for positive behaviors. This fundamental concept of a token board is that it serves as a visual display for students who can earn a specified number of tokens contingent on their behavior or performance.
Information-gathering strategies	Social stories give students precise information about what is happening in a given situation, concrete descriptions of relevant thoughts or feelings of other directly involved in the situation, and instruction to the student for behaviors that might come with those changes. A strategy similar to social stories is comic strip conversations. Comic strip conversations teach children with autism the art of conversation. This version is a conversation between two people that is illustrated on paper as the conversation evolves.
Simultaneous prompting	Visual schedules use pictures, photos, or words to create the order of events or activities. Simultaneous prompting is a systematic form of the antecedent prompt and test procedure because all trials are conducted with 0-s delays between the discriminative stimulus and the teacher prompts. A very effective strategy to teach grocery store sight words.

Table 6 Assistive-technology solutions

- *High-tech* solutions involve the use of sophisticated devices, such as computers and interactive multimedia systems.
- *Medium-tech* solutions use less-complicated electronic or mechanical devices, such as videocassette players and wheelchairs.
- *Low-tech* solutions are less sophisticated, such as adapted spoon handles, Velcro fasteners, or raised desks that can accommodate a wheelchair.
- *No-tech* solutions require no devices or equipment. These might involve the use of systematic teaching procedures or the services of related services personnel such as physical or occupational therapists.

training to be implemented in the classroom. Simple and uncomplicated modifications are sometimes all that are needed to allow a student to use a computer software program (Olson and Platt, 2000). Standard computer

keyboards pose a number of problems for some students with cognitive disabilities (Kincaid, 1999). Various modifications may need to be considered so that students with limited hand and finger mobility can access computer technology. Before a student can use computer technology for a given task, an appropriate method for inputting information must be available.

To a large measure, word processing has the capability of helping individuals improve their writing skills (MacArthur, 1996). Students with cognitive disabilities often possess limited conceptualization of editing and revising; thus, such students limit their revision to minor errors that fail to strengthen a written document as a whole. Therefore, using word processor may not only teach students who are cognitively delayed to edit their writing better but also can help them to make frequent revisions without labored rewriting. Word processing reduces resistance to revising as a whole and eliminates errors due to transcription (MacArthur *et al.*, 1991).

Table 7 Maximizing assistive technology for students with cognitive disabilities

- Use open-ended devices that permit customizing the user and/or task, are generally the most useful.
- Find the lowest technology solution that can provide a level of performance or function rather than a complex, high-technology device or system. Simply changing a student's angle of view of a computer monitor (e.g., placing the monitor at eye level as opposed to hairline level or above) could reduce strain and improve performance.
- Collaborate with other teachers. There are too many technologies developing too quickly for one teacher to monitor advancement in technology independently. Sharing expertise can help.
- Collaborate with parents to ensure that assistive-technology devices that go home are properly used and maintained. Parents can also be an excellent source of evaluative information on how effectively a device or piece of software is working.
- Do not believe that you have to master a device or software application completely before you begin using it. Many times an application can be used successfully early in the learning curve, and learning by doing can prompt eventual mastery.
- Assistive devices should match the age, gender, and preferences of the user to promote acceptance and use.
- The arrangement and separation of controls should be predictable and natural. Feedback to the user must be meaningful.
- Be sure that your school or school system has a comprehensive policy covering assistive technology, including the protection of student and teacher privacy, the repair and maintenance of equipment, and the home use of the school purchase equipment. Be sure also that the policy states who is the assistive-technology resource for the individualized education plan (IEP) team.
- Simply purchasing assistive-technology equipment will not ensure its use. Funds must also be allocated to ensure that teachers and other potential assistive-technology service providers receive training in the use of the equipment.
- Do not be afraid to experiment. Assistive technology is a very young field, and everybody is learning.

In addition, it has the potential to facilitate other operational revisions such as moving content and deleting material.

It has been proved that computers can help young children with cognitive disabilities develop language (MacArthur, 1996). The goal of any language development program is to provide young children with the tools for independent communication. Some children will learn to speak, some will learn sign language, and others will need the assistance of augmentative communication. Augmentative communication refers to a set of approaches used to improve the communication skills of persons who do not speak or whose speech is not intelligible (Olson and Platt, 2000). Aided systems require the use of a picture or word board, a notebook, or a computerized aid. An unaided system requires the individual to use only hand or body motions to communicate (e.g., sign language). Augmentative communication options can range from

high- to low-tech devices including aids such as a symbol system, manual communication boards, electronic communication devices, speech synthesizers, and communication-enhancement software. Communication boards, a low-tech alternative to augmentative communication, assist young children in language expression. Communication boards are usually made of cardboard or any other material used to display choices for children who cannot speak (Ysseldyke and Algozzine, 1990). See Table 7 for ways to maximize the use of assistive technology.

Moving Forward: For Persons with Cognitive Disabilities

Independence is a broad construct that encompasses self-reliance and self-determination of persons with cognitive disabilities. Self-reliance refers to a person's ability to take care of himself/herself. Skills that reflect self-reliance range from feeding oneself to living in a home alone. Educational programs offer many opportunities to encourage self-reliance. As described earlier, self-determination refers to a person's ability to set and navigate his/her own life course. Skills that educators may help to develop include making choices, communicating preferences, setting achievable goals, and self-advocating (Wehmeyer, 1993). In any society, independence is largely tied to productivity, which is generally defined as holding a job and being economically self-sustaining. Therefore, the most desirable outcome for all individuals, including those with cognitive disabilities, is competitive employment. For this to occur, education and training must focus on vocational instruction and on-the-job skill development. Research generated during the past 20 years demonstrates that competitive employment is a visible outcome for persons with cognitive disabilities (Hill *et al.*, 1987; Moon *et al.*, 1990). For successful school-to-work transitions, there must be individual transition plans, improved work opportunities, job placement in competitive, integrated settings, and documentation of progress in employment-related skills.

Good quality of life is an important educational outcome for persons with cognitive disabilities. Although it is important that persons with cognitive disabilities see and are seen by their nondisabled peers, interventions are sometimes necessary to ensure true social involvement and quality of life. Possibilities include teaching the person with cognitive disabilities where and how to find others with common interests and educating nondisabled peers about the person with the disability (Schoeller, 1997). In addition to focusing on quality of life, it is important to focus on person-centered planning. Although the two constructs are based on a philosophy that people with cognitive disabilities are entitled to live well-rounded lives, some differences do exist. Whereas the interest in quality of life has largely been

based on a desire to define and analyze its components, proponents of person-centered planning adhere to the notion that outcomes are diverse and individualized. In other words, the person should be enabled to express his/her own goals. Person-centered planning begins by asking the person what he/she wants life to be like. People who care about the individual are invited to join the process; their role is especially important when planning with a person who has severe cognitive disabilities. They are sometimes called on to speak for the person or to translate the person's attempts to communicate. The planning process involves service providers and educators who are able to identify resources for attaining goals (Gaylord, 1997). The goal is to make sure that outcomes are clear, individualized, and easily measured.

Conclusion

This article discussed ways that teachers can best educate children and youth with cognitive disabilities. The characteristics of effective interventions (e.g., least prompts, time delay, and identifying reinforcers) are discussed along with specific curriculum and teaching strategies (e.g., systematic instruction, integrated settings, and assistive technology). Additionally, educational outcomes (e.g., quality of life and personal outcomes) are highlighted. Clearly, persons with cognitive disabilities are humans; and as humans, every effort must be made to maximize their fullest potential.

Educating Students with Emotional and Behavioral Disorders

S W Smith and G G Taylor, University of Florida, Gainesville, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Cognitive behavioral interventions – Strategies used to teach the use of self-talk or inner speech to regulate overt behavior.

Externalizing behavior – Constant and destructive acting out behaviors such as verbal and physical aggression, arguing, chronic outbursts, and general unpleasant behaviors.

Functional behavioral assessment – A measure used to identify the purpose of a student's behavior by focusing on the function of the behavior in relation to its environment or context.

Internalizing behavior – Covert behaviors that are often concealed from plain view such as withdrawal, sad affect, excessive fears, and phobias.

Negative reinforcement – The removal of an aversive condition to serve as a form of reinforcement to increase desired behavior.

Overcorrection – Requiring the students to engage in repetitive action as a penalty for inappropriate behavior.

Positive reinforcement – A reward that is positive, or pleasing, to a student presented after an appropriate behavior.

Pre-referral – Systematic and collaborative efforts to prevent formal referral and placement of students in special education programs.

Punishment – The presentation of an aversive condition to decrease undesired behavior.

Response cost – The removal of a reinforcer when undesired behavior is displayed.

For professional educators, providing a quality public education for all children and youth has always been a challenge. Even in the best of circumstances, effectively delivering academic, social, and emotional learning can be complicated and frustrating, yet at the same time, it can be professionally rewarding. The educational enterprise, however, becomes especially difficult and perplexing when children and youth display behaviors that can be described as disruptive, deviant, violent, antisocial, aggressive, destructive, and/or noncompliant. Despite years of conceptual and empirical progress in understanding and successfully serving school-aged children and youth with emotional and behavioral disorders (EBD), there continues to be a host of perpetual problems that the field of special

education continues to work through and will for decades to come. This article focuses on how students with EBD are identified, the prevalence and characteristics of the disorder, and the complex issues related to where students with EBD are taught. Evidence-based prevention and intervention strategies that can maximize the potential of students with EBD are described and, finally, several special issues that confront the field of special education in the education of students with EBD are explored.

Defining EBD

Behavior exists on a continuum with no clear delineation between what is considered normal and what is abnormal or disordered. Indicators used to identify or diagnose disordered behavior include how frequently and severe undesired behavior is displayed. Defining disordered behavior is inherently subjective and the task to determine what intolerable and disordered behavior is often falls to authority figures such as medical personnel, teachers, or mental health professionals (Kauffman, 2005). While there is concern about the stigmatizing effects that assigning labels to children may have, the use of labels and accompanying terminology is a means from which to secure the necessary financial resources to diagnose and provide treatment. Terminology used across the education and related fields such as mental health and social services may vary to some extent, and, at times, they may signify the conceptual approach taken by a field. The legal term used in the special education federal definition of children with significant behavioral problems is emotionally disturbed. Various states use differing labels ranging from emotionally handicapped to socially impaired. Professionals in the field of special education commonly use the term EBD because they feel it more accurately describes the condition.

The Individuals with Disabilities Education Improvement Act (IDEA) of 2004 defines emotional disturbance as:

a condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree, which adversely affects educational performance:

- A. An inability to learn which cannot be explained by intellectual, sensory, or health factors.
- B. An inability to build or maintain satisfactory interpersonal relationships with peers and teachers.
- C. Inappropriate types of behavior or feelings under normal circumstances.

- D. A general pervasive mood of unhappiness or depression.
- E. A tendency to develop physical symptoms or fears associated with personal or school problems.

The term includes schizophrenia. The term does not apply to children who are socially maladjusted, unless it is determined that they have an emotional disturbance. (US Department of Education, 2006)

Problems with the Federal Definition

Vague language and undefined terms included in the federal definition have led to dissatisfaction among professionals. Criticisms include the subjective nature of phrases such as to a marked degree or over a long period of time, the potential exclusion of children and youth who do not qualify because they are not academically delayed, or exclusion of children who are labeled socially maladjusted. Interpretation of the definition has been left to the states which some professionals describe as creating “at best a great potential for inconsistency across referred children and, at worst, conditions allowing unchecked bias, inequity, and prejudice” (Knoff, 1995: 852).

Years ago, the National Mental Health and Special Education Coalition attempted to improve the definition by including more up-to-date terminology, using language that was sensitive to ethnic and cultural differences, excluding problems due to temporary stress, acknowledging multiple disabilities, and not arbitrarily excluding the full range of emotional or behavioral disorders (Forness and Knitzer, 1992). While proponents are advocating for change, the proposed definition has not been adopted or incorporated into federal laws and regulations.

Characteristics of EBD

In general, students served in programs for EBD display highly visible and chronic externalizing maladaptive behaviors (e.g., verbal/physical aggression, noncompliance, excessive teasing, and classroom disruption) that are against universal social norms and behaviors expected for a safe learning environment. When engaging in aggression and disruption, peers may look elsewhere for companionship and positive social interactions and may elicit negative counter responses creating a negative spiral of aggression and continued rejection. At times, peers may reinforce a student's aggressive behavior unintentionally by attending to it or complying with the aggressor's demands. What is most problematic, however, is that students who exhibit aggressive, maladaptive behaviors associate with peers who act in similar ways, thus perpetuating their aggressive behavior and increasing their rejection by nonaggressive peers (Bierman *et al.*, 1996). For those students in EBD programs, who exhibit more covert maladaptive behaviors (e.g., depression, anxiety, excessive fears, and phobias),

their behaviors may also elicit social rejection that can contribute to withdrawal from lasting, positive social relationships.

Cognitive Characteristics

In general, students placed in special education programs for EBD have intelligence quotients (IQs) in the low average range, although scores can be below 70 (often considered mental retardation) and in the upper range that could be considered gifted. As might be expected, students with EBD in the low average IQ range, often experience academic difficulties. Since these students engage in classroom disruption and often lack motivation to complete tasks, they may experience increasing deficits in their academic performance as they progress through the school years. Students who are placed in EBD programs may have academic deficits in all areas, and may have more extreme deficits in reading and math (Bos *et al.*, 2002). Interestingly, researchers have found that 30–40% of students who exhibit EBD also have learning disabilities (LD; Fessler *et al.*, 1991).

Behavioral Characteristics

What most readily comes to mind about students with EBD is their externalizing behaviors, or constant and destructive acting-out behaviors such as verbal and physical aggression, arguing, chronic outbursts, and general unpleasant behaviors. What often goes unrecognized, however, are student behaviors such as withdrawal, sad affect, or excessive fears and phobias that are more covert or internalizing, and are concealed from plain view.

Externalizing behaviors

Externalizing or overt behaviors are characteristically interpersonal and are more easily identified by teachers and others professionals than the internalizing type. Externalizing behaviors are typically the acting-out and noncompliant type. Students who exhibit EBD are often described as aggressive and tend to experience continual negative interactions with authority figures at school and in the community. Externalizing behavior problems may be part of a student's escalating spiral of conflictual relationships with family members, peer group, and, in later years, with fellow workers and in marital situations. As these overt and undesired behaviors frequently elicit negative responses, they can limit the much-needed positive interactions with others and contribute to a deleterious pattern of opposition and negative social status.

Internalizing behaviors

Teachers and other professionals often overlook students who have significant internalizing or intrapersonal problems. As students with internalizing disorders do not

typically display more noticeable disruptive behaviors in the classroom, they become less frequently noticed as those with externalizing problems. Internalizing problems can take the form of childhood depression, anxiety, fears and phobias, and obsessive-compulsive disorder. Students' internalizing problems can sometimes negatively affect their academic success, socialization with peers and adults, and overall development.

Prevalence and Causes of EBD

The issue of prevalence of EBD is closely linked to its definition. The criteria used to judge the presence of any disorder is sometimes subject to a changing consensus. Therefore, it is difficult to make precise statements about the overall prevalence of children with behavioral disorders considering differing criteria across states and decades. Prevalence estimates, from the most recent Office of Special Education Programs, 25th Annual Report to Congress (US Department of Education, 2007), indicate that students ranging in age from 6 to 21, who received special education services for EBD, remained steady at about 0.7% from 1993 to 2003 and was approximately 8% of the total students in 2003 who received special education services. Identification of EBD is more likely for students who are racially and ethnically diverse. The US Department of Education (DOE) also reports that black students are 2.3 times more likely to receive special education services related to EBD than all other racial/ethnic groups combined.

The causes of EBD are complex and interrelated. Most behavioral problems occur in combination with other problems, thus causal influences can be viewed from both biological and environmental perspectives. According to Kauffman (2005), the causes of EBD can be arranged around four general categories: (1) the individual child, (2) family, (3) school, and (4) culture.

Individual Child

All behavior is a dynamic mix of biological dispositions and environmental contexts. Some biological factors suspected to contribute to emotional or behavioral disorders are: (1) genetics, (2) brain damage or dysfunction, (3) nutrition, (4) biochemistry, (5) physical illness or disability, and (6) temperament (Kauffman, 2005). Each of these factors may contribute individually or intermix with others to help explain the presence of EBD.

Family

Various influences, such as family structure, socioeconomic status, and styles of parental discipline, may serve as contributing factors to the development of EBD.

Complex interactions between conditions suggested by social demographic indicators and family dynamics have been shown to correlate with the presence of EBD. These indicators include poverty, absent fathers, divorce or separation, and hostile family relationships (Rutter, 1985). Researchers, however, suggest that while these factors may increase the risk for developing EBD, they may not be causes in, and of, themselves (Kauffman, 2005).

School

There are several factors found in schools that could contribute to the presence of EBD. Researchers indicate there is a strong correlation between poor academic performance and the presence of EBD. Disordered behavior and poor academic performance may result in social consequences that may cultivate more undesired behaviors. Kauffman (2005) suggested six ways schools may contribute to academic failure and disordered behavior, namely:

1. insensitivity to students' individuality,
2. inappropriate expectations for students,
3. inconsistent management of behavior,
4. instruction in nonfunctional and irrelevant skills,
5. poor reinforcement contingencies, and
6. undesirable models of school conduct.

In addition, the difficulty of finding qualified teachers for students with EBD places immense pressure on district personnel to provide quality instruction to those students who are often the most difficult to manage as well as the most difficult to teach. Chronic teacher shortages in special education and the fact that many teachers are ill-equipped and underqualified, especially in the area of EBD (Blake and Monahan, 2007; Hampton and Hess-Rice, 2003), can compromise the high-quality teaching necessary in academic instruction and social and emotional learning.

Culture

Aside from the cultural factors that influence a student's behavior in families and schools, standards and values of the larger cultures in which they live can have effect. The effects of popular culture with advertising, mass media, videogames, and violent movies may all play a role in increasing inappropriate behaviors (Coyne *et al.*, 2006). The culture of peer groups, communities, ethnicity, and social class are all factors that may also influence the development of a behavioral disorder. Rarely can the development of EBD be attributed to a single particular cause. Most significant behavioral problems, such as EBD, are due to a combination of factors that occur on many levels and locations. Physiology, parenting, teaching, and culture may all play a part in the development of a disorder but must be considered uniquely for each individual.

Assessment and Eligibility of Students with EBD

Regular education teachers who may experience significant problems with a student's behavior may think seriously about the referral of the student for special education services. Referral requires a significant assessment process designed to collect enough information by a team of professionals (including parent(s) and sometimes the student) to make an informed judgment about eligibility, determine an effective instructional program through an individualized education program (IEP), and agree upon the best placement option. To prevent formal referral, prereferral strategies are often generated as an attempt to keep students in the least-restrictive educational environment.

Prereferral

Prereferral strategies are systematic and collaborative efforts to prevent costly and time-consuming formal referral and placement of students in special education programs. For students with significant behavioral problems in the classroom, prereferral is a way for teachers to systematically approach behavioral issues to mollify their effect on the educational environment. Prereferral usually involves a team of education professionals who can approach carefully, in a collaborative manner, a student's behavioral issues. From this collaborative approach, specific action plans are developed to facilitate the student's success in the regular education environment, such as designing reinforcement programs for appropriate behavior, enlisting parent help, or enlisting other professionals' support such as school psychologist or school counselor. Before formal referral, prereferral efforts must be documented indicating that the student fails to respond positively to reasonable accommodations.

When Congress reauthorized IDEA in 2004, the law included a response to intervention (RTI) approach for the identification and eligibility of students with high-incidence disabilities. IDEA (2004) encourages schools to "... use a process that determines if the child responds to scientific, research-based intervention as part of the evaluation procedures..." (Section 1414(b)(6)). While this change in law was written specifically for determining eligibility of students with specific LD, the RTI model has found support for use across special education, including EBD.

RTI is a model used by school systems to systematically guide the prereferral process and ensure the provision of scientifically based intervention strategies. The three-tiered model provides increasingly intense services to students based on student outcome data. Tier-one universal interventions are based on core curriculum and address the needs of approximately 80% of the school population. Tier-two group interventions typically serve

approximately 15% of a school population and involve more intensive instruction. The third tier of intervention serves approximately 5% of a school population and provides services for the small number of students who need individualized instruction (Hawken *et al.*, 2008). While implementation differs across settings, the key components of RTI include a process that screens for at-risk students, monitors responsiveness to scientifically based instructional interventions, and uses outcome data to determine a course of action (Elliott, 2008).

Cheney *et al.* (2008) reported that tier-two instruction with at-risk students for EBD reduced the students' at-risk status and helped prevent the development of EBD. RTI data may also be taken into consideration when determining student eligibility for EBD services. The influence and implementation of the RTI model have had a positive impact on prereferral and other educational services for students with EBD.

Referral and Determining Eligibility

If prereferral strategies fail to provide a student the necessary supports for success, special education referral procedures become necessary. Referral for placement in special education, because of a suspected EBD, would include all of the typical evaluation procedures, such as measures of intelligence and achievement, but might also include assessment of social competence and peer relations through interviews, self-reports, anecdotal reports, behavior rating scales, and direct behavioral observations. For students being referred for EBD, direct observation, a method of recording specific behaviors, is typically conducted by someone other than the student's teacher, and the use of behavior rating scales insure that the assessment of students is based on numerous informational sources (i.e., people and behavioral instruments). As part of the assessment process, multidisciplinary team members must also assess the effect of a student's behaviors on peers, teachers, and family members and assess the effect of the teacher's behaviors. A teacher's interactions with a student may make a student's behavioral problems worse; hence, teacher and student interaction observations can significantly influence classification, placement, and treatment recommendations.

After all the necessary information is collected, students referred for EBD services become eligible if they exhibit behavioral problems as specified in the special education law to a marked degree and over a long period of time, and if their educational performance is affected. At the same time, the multidisciplinary team makes an eligibility decision and considers the need for related services (e.g., counseling and social services). For those students identified and requiring special education and related services, there exist a variety of placement options

along a continuum that ranges from least (e.g., regular class with supports) to most restrictive (e.g., hospital or homebound instruction). Other placements could include regular class placement with some programming in a special education resource room, a separate special education class for students with EBD for most of the school day, a separate school for students with EBD, or a residential setting. It is up to the multidisciplinary team to decide what setting is in the best interest of the student and what programming best meets their academic and social needs.

Functional Behavioral Assessment and Behavioral Intervention Plans

IDEA mandates that a functional behavioral assessment (FBA) be conducted for those students whose behaviors necessitate a change in school placement or represent a chronic pattern of misbehavior. Professionals use FBA to identify the purpose of a student's behavior (e.g., getting social approval from peers for inappropriate behavior and escaping a teacher's demand to complete work). FBA focuses on the function of the behavior (the why of the behavior) in relation to its environment or the context. When the function of a particular behavior problem is determined through a series of FBA steps, a behavioral intervention plan (BIP) is developed to assist a student in achieving the same or a similar goal (e.g., gain something or escape a demand) through more socially acceptable behaviors. Through FBA procedures, general and special education professionals can identify causes that may contribute to a student's inappropriate behaviors and design programs that can result in academic and social success.

Placement of Students with EBD

Nearly 70% of students with emotional disturbances spent more than 21% of their time outside regular education classes (US Department of Education, 2007). Nearly 47% of the students spent more than 60% of their day outside of regular education and some (16.9%) spent their entire day in a separate environment. Students with EBD are served in separate environments more often than any other categorical area except for deaf-blind and multiple disabilities (US Department of Education, 2007). The issue of where to best serve students with EBD has endured serious and long-term debate. The IDEA (2004) and other federal regulations mandate a continuum of alternative placements (CAPs), while some experts suggest that CAP segregates students from their more typical peers and access to the regular education curriculum. Kauffman and Smucker (1995) purported that specialized environments for students with EBD serve the following purposes:

1. protecting others (family, community, and schoolmates) from students' uncontrolled or intolerable behavior;
2. protecting students from themselves or others;
3. educating or training students in academics and other life skills and appropriate emotional responses, attitudes, and conduct;
4. educating or training children's families or teachers and peers to provide a more supportive environment;
5. keeping children available and amenable to therapies; and
6. providing opportunities for observation and assessment of children's behavior and its contexts.

There are, however, some special education advocates who disagree with Kauffman and Smucker (1995). Van Dyke *et al.* (1995), for instance, argued that all students with emotional and behavioral disorders are best served in the general education classroom. These advocates have noted that placing students in the general education classroom promotes a sense of belonging, provides opportunities to make friends, and more efficiently provides exposure to the regular education curriculum alongside nondisabled peers. They believe instead of providing separate environments, resources, and supports are better allocated for students with EBD to be successful in regular education classrooms. In addition, they argue that it prepares all students, with and without disabilities, to participate in a diverse world where interaction with people of differing abilities and behaviors is commonplace. In fact, this debate about the best placement model for students with EBD is ongoing. Professionals and advocates on both sides of the issue agree that children with disabilities should be educated in as typical an educational experience as possible. The discussion continues however, as to how this can best be accomplished.

Strategies to Prevent EBD

The prevention of problem behavior is an issue that receives much attention in politics and the national media. Traditionally, the procedures for identifying students with EBD are reactive and tend to occur after children's deviant behavioral repertoires are well established. Prevention of EBD is complicated by poor collaboration between service agencies, disjointed screening and eligibility criteria, and lack of funding for research and program implementation (Conroy *et al.*, 2004). This lack of coordination among agencies, such as schools, social welfare, and juvenile justice, is a fundamental obstacle toward prevention (Quinn and Poirier, 2004). Young children at risk for EBD are sometimes denied access to services due to eligibility restrictions and the lack of coordination is compounded by the fact that funding for prevention research is limited. Despite these barriers to

prevention, special education professionals and researchers are recognizing the value of prevention at the school, classroom, and individual student levels.

School-Wide Discipline

Media exposure and public perception of violence in schools have influenced administrators and policymakers to adopt rigid standards and a position of zero tolerance toward students who exhibit problem behavior in school (Quinn and Poirier, 2004). Researchers (e.g., Skiba, 2002) indicate that discipline practices that rely primarily on punishment and exclusion are ineffective and may actually contribute to an increase in problematic behavior. Recent prevention efforts, such as school-wide discipline strategies, use systematic processes to foster proactive solutions by implementing research based and validated practices. While there are several programs available to assist schools in the implementation of a unified school-wide supportive approach to discipline, many share similar elements such as:

1. a shared vision by the school staff on how to best prevent and minimize problematic behaviors based on evidence-based practices;
2. consistent and visible support by administrative leaders;
3. academic and social expectations are developed and implemented collaboratively by all staff; and
4. program change decisions are informed by evaluation of effectiveness data collected at the school (Colvin, 2007).

Prevention Strategies in the Classroom

Gresham (2002a) asserted that adopting an approach to prevention that begins with whole-class strategies and moves to addressing individual student needs may reduce over identification of children for special education. Witt *et al.* (2004) suggested the necessary components for prevention include solid academic instruction, explicit instruction of positive behavioral expectations to students, and consistent and effective teacher responses to inappropriate behavior. The emphasis should be to create a supportive classroom environment that promotes academic participation and achievement for all students. In addition to effective academic instruction, the promotion of positive behavioral expectations increases the length of academic engagement and decreases problem behaviors (Witt *et al.*, 2004). Positive behavioral expectations should be explicitly taught to students allowing adequate time for practice and feedback. Once students are aware of and can perform to expectations, careful monitoring of student behavior by teachers, coupled with the consistent delivery of effective contingent consequences, is central to maintaining behavioral compliance. Clearly, emphasis on proactive practice has led to procedures that identify environmental

contingencies that promote problem behaviors and the adaptation of those variables to reduce future misbehavior. A focus on class-wide effective academic instruction and proactive instruction of behavioral expectations are promising approaches for the prevention of behavioral problems. Sometimes, however, school-wide and classroom strategies are insufficient to address the needs of individual students who may require services that are more intensive.

Individual-Student-Centered Prevention Strategies

If school-wide and classroom attempts to promote desired behavior are ineffective, interventions based on a functional assessment of an individual student's behavior is the most effective evidence-based strategy currently available (Iwata *et al.*, 1993). Evidence in support of its use is so strong that the requirement to functionally assess chronic problem behaviors was added to the reauthorized IDEA in 1997. While functional assessment is used to identify the causes of behavior and to develop effective interventions for students with EBD, it can also be used as a strategy for prevention with individual students at risk for EBD. To a large measure, functional assessment examines the effects of specific environmental variables on a student's maladaptive behavior. Direct manipulation of these variables through intervention along with consistent monitoring of the effect on behavior reveals which contingencies may be supporting the enactment of the problem behavior. Interventions can then be adapted, based on the empirical evidence collected during the assessment. Once these interventions are implemented, progress is monitored and adaptations are made relevant to the performance of the individual as determined by ongoing data collection.

Intervening to Reduce Extreme Problematic Behaviors

While prevention efforts at school, classroom, and individual levels are foundational for effective management of student behavior, students who exhibit EBD may still require extensive behavioral programming to mollify the effects of their behavioral excesses and deficits. Reducing maladaptive behaviors and increasing appropriate ones can be achieved through the use of behavioral principles, such as reinforcement and punishment procedures, and appropriate replacement behaviors can be taught to students using social skill instruction, self-management techniques, and through the use of cognitive-behavioral interventions (CBIs).

Using Behavioral Principles

Teachers and service providers typically use behavioral strategies such as reinforcement to increase positive and

desirable behaviors and punishment to reduce unwanted and maladaptive behaviors. Positive reinforcement is a reward that is positive, or pleasing to a student presented after an appropriate behavior. Reinforcers can be of four types:

1. tangibles (e.g., toys, school supplies, posters, and magazines);
2. activities contingent on acceptable behavior (e.g., playing board games and listening to music);
3. social reinforcement (e.g., high five for work completion and verbal praise); and
4. token reinforcement (e.g., points to reach an established goal or imitation money exchangeable for some valued object or activity).

Conversely, negative reinforcement is the removal of an aversive condition and can also serve as a form of reinforcement to increase desired behavior. For example, a teacher may say to a student who is off task that if the work is not finished on time, he/she will have to finish it in detention. If the student completes the assignment on time, then he/she was negatively reinforced because he/she finished the work to avoid detention.

Punishment is used to reduce the future occurrence of problematic behaviors. Teachers and service providers may use reprimands, response cost, time out, and overcorrection. A reprimand is a short verbal scolding or correction that is designed to reduce inappropriate behavior. Response cost would be the removal of something the student has earned, such as points or privileges, when inappropriate behavior is displayed. Time out is usually associated with removing a student from a reinforcing activity or environment. Sending a student back to his/her desk as a result of inappropriate behavior during group work, sending a student into the hallway or to another room, or sending a student to the principal's office can be considered time out from reinforcement. Overcorrection typically happens when a teacher has a student engage in repetitive action as a penalty for inappropriate behavior. Although overcorrection has many forms, examples would include asking an unruly student to practice getting in line calmly and orderly a few times, and directing the pick up of refuse after a student kicks a trash can with additional cleanup of the rest of the floor. Using punishment, however, should always be a teacher's last resort to decrease unwanted behaviors from happening in the classroom. There are more positive techniques than punishment to help students decrease socially undesirable behaviors with more socially appropriate ones.

Teaching Appropriate Replacement Behaviors

Not only do teachers have to reduce problem behaviors of students with EBD, but they also need to explicitly teach more appropriate and positive replacement behaviors that

can lead to more successful long-term outcomes. Teaching replacement behaviors can be accomplished through social skills training, CBIs, and teaching self-control techniques to students.

Social skills training

There are a number of reasons to teach social skills to students who exhibit EBD. Social skills are arguably the most important skills students learn, not only in school, but also as they grow into adulthood. The ability to get along successfully with other people is a criterion for success for students with EBD whether at school, in the work world, family, or community. Before social skill instruction, assessment of a student's social strengths and weaknesses must occur. Assessment can help identify individual student needs, monitor progress, and evaluate the viability of a teaching strategy. Behavior rating scales or peer rating scales might be useful to assess student social skills. A teacher can identify a student's social strengths and determine areas that need some instructional intervention by combining direct observation of a student's social behavior and functional assessment of behavior (Gresham, 2002b).

Typically, social skills are taught by defining and modeling the skill to be learned, setting up role-plays for students to learn the skill steps, giving performance feedback, and, most importantly, providing opportunities for practice (see Goldstein and McGinnis, 1997). The teacher can also provide homework so that learned skills can be practiced and generalized to situations outside of the learning setting. Students have generalized or transferred their learning when they reliably perform the social skill in new and novel places, with a variety of people and situations, and with variations of the learned skill.

Cognitive-behavioral interventions

CBIs are designed to teach the use of self-talk or inner speech (verbal self-regulation) to regulate overt behavior. Simply, verbal self-regulation is talking to oneself to guide problem solving or some other behavior. CBIs are often described as stop-and-think strategies. Problem solving, one type of CBI, is a useful cognitive process that can help students with EBD analyze in a better manner their social encounters during the day and to exercise self-control. Problem solving consists of a series of mental steps designed to identify and define problems, generate a menu of appropriate responses or solutions to solve the problem, select an efficient and effective solution, and make a plan to carry it out successfully (Smith and Daunic, 2006).

Self-control

As students become older and enter into the world of work, the ability to successfully regulate or self-manage their own emotions and behavior becomes critical. Self-regulation begins when students take responsibility for their own behavior and learn to use internalizing or

cognitive processes that will enable success when external systems, such as reinforcement and punishment, are unavailable. Teaching self-regulation represents a critical step in reducing or fading a teacher's participation in controlling a student's behavior. Teachers and service providers can help students with EBD learn self-management strategies and use CBIs to increase self-regulatory functions (see Polsgrove and Smith, 2004). Self-regulation or self-management strategies include self-assessment of problematic behaviors and the necessary replacement behavior, self-monitoring of those behaviors, and self-reinforcement when the student experiences success. Self-management strategies are often recommended for students who are manipulative or oppositional when confronted and for facilitating the success of students who are mainstreamed into less-restrictive placements.

Special Issues: Looking at the Future

Providing a quality educational experience for students with EBD is and will continue to be problematic; however, despite the immense gains in providing successful programming for these students, there are complex issues that professionals still confront. Students with EBD exhibit such extreme behavioral deficits and excesses that issues related to suspension and expulsion and placement in alternative school settings differentially affect this population. Of special note is that minority students are disproportionately represented in EBD programs.

Suspension and Expulsion

Disciplining students with EBD who violate acceptable standards of student behavior is (and will continue to be) complex and often a contentious issue. Since students with disabilities are guaranteed a free and appropriate public education (FAPE), as outlined in case law and in IDEA (2004), long-term suspension (more than ten consecutive school days) or expulsion of students (removal from a current educational setting) with EBD can violate a student's right to FAPE. Any long-term suspension for violating acceptable standards of behavior or expulsion for egregious violation of the code of student conduct (e.g., weapons, drugs, and serious bodily injury) is considered a change of placement and can occur only after a meeting of the student's child study or IEP team. At that time, the team is to make a determination about the relationship between the student's misconduct and disability. Since students with EBD are served in special education because of their significant behavior problems, determining whether or not the misconduct is related to the disability is sometimes uncertain and confusing.

Placement in Alternative Educational Settings

Alternative educational settings are designed for students who are at risk for school failure. Alternative schools typically are small, personalized settings that emphasize individualized educational, vocational, and general living skills. Researchers have found that about 12% of students who are attending alternative schools are students with disabilities, mostly students with LD or EBD (Lehr, 2004). Students with EBD may be placed in alternative settings after a disciplinary removal or expulsion for violating the code of student conduct (e.g., weapons, drugs, and serious bodily injury). This placement option can only be considered when all procedural safeguards are followed as outlined in IDEA.

Overrepresentation of Minority Students in EBD Programs

Using data from the US Department of Education (2006), analyses suggest that minority students are disproportionately placed in EBD programs. For instance, black children are 1.92 times more likely than white students to be labeled EBD (Losen and Orfield, 2002). These researchers suggest that stereotypes, racial bias in implementing discipline policies, and education practices that are culturally non-responsive may contribute to the overidentification and placement of many minority students. Minority students who exhibit EBD are often subject to low expectations, are educated in separate settings, and excluded from many educational opportunities. While minority populations are at great risk of living in poverty, Losen and Orfield refute the myth that racial overrepresentation in special education can be explained away by factors associated with poverty. This undoubtedly will continue to influence future educational programming for students in EBD programs.

Conclusion

Educating students with EBD is a complex endeavor that requires careful consideration and deliberate action. Those professionals who are dedicated to serving children and youth with EBD are constantly trying to identify and develop strategies and techniques that will help this population of students maximize their potential in school and beyond. There are ongoing efforts in the field of special education to define and assess in a better manner the disorder to intervene effectively and efficiently on behalf of students. There is also an emerging technology to prevent student placement in EBD programs and, when required, there are powerful techniques to teach replacement behaviors for those students who exhibit antisocial and maladaptive behaviors that preclude school success.

Notwithstanding the tremendous progress that has been made over the past few decades, some issues remain, such as

where best to serve students with EBD, policies about suspension and expulsion, placement in alternative educational settings, and the overrepresentation of students from minority racial and ethnic backgrounds. Despite these unresolved problems, education professionals continue to work tirelessly in an effort to serve this unique population.

Educating Students with Special Needs: An Overview

Educating Students with Special Needs: An Overview

From time immemorial, individuals with special needs have lived in our midst. They have existed, functioned, and participated in our societal functions in one way or another. For instance, the Jewish Talmud, Moslem Koran, and Christian Bible made particular references to persons who were atypical in nature. In fact, all societies have continued to focus on how to take care of their less fortunate, less powerful, disenfranchised, and disadvantaged (Obiakor and Algozzine, 1995). From these contexts, it appears that efforts have concentrated on how to tolerate and/or be nice to persons with special needs rather than on how to truly educate them with real pedagogical power. Hillard (1992) explained that real pedagogical power means that “all children who may have disabilities receive sophisticated, valid services that cause them to do better than they would have done if they had not received special services at all” (p. 168).

In the late eighteenth century, Jean Marc Itard, a French physician believed in real pedagogical power when he decided to take on the task of educating Victor, the wild boy of Aveyron, France. Even this wild boy was able to acquire some skills, an indication that special education works. In the early parts of the twentieth century, Dr. Alfred Binet, the brain behind the current Stanford-Binet Intelligence Scale, noted that human knowledge and/or intelligence can be improved. Binet (1909) warned against the over reliance in his intelligence quotient tool. In speaking about his special class, he remarked, “It is parochial sense, the only one accessible to us, that we say that intelligence of these children has been increased. We have increased what constitutes the intelligence of a pupil: the capacity to learn and to assimilate instruction” (p.104). More than two decades ago, Gould (1987) decried the mismeasure of people and argued that “if Binet’s principles had been followed, and his tests consistently used as he intended, we would have been spared a major misuse of science in our century” (p. 155). In addition, he warned against the blind following of the theory of biological determinism (i.e., the belief that human attributes are only genetically based) because it hampers human valuing and the ability to engage in real pedagogical power. Goodlad (1993) corroborated Gould’s premise and noted that:

We appear incapable of getting beyond individuals as the units of assessment with the accompanying allocation of

responsibility for success and failure. We must adopt as standard practice the kind of contextual appraisal that tells whether schools have in place the curriculum, materials, pedagogy, and other conditions necessary to the good education of individuals. The absence of these exposes and brings inequities that are the moral responsibility of a caring people in a just society to correct. (p. 20)

We strongly believe students with special needs can and must be educated. The entries in this section reveal that efforts have been made and continue to be made in this regard. As scholars and practitioners, our broad goal must be to provide education that is different from, additional to, and supplementary with those provided in the regular classroom with a systematic modification and adaptation of instructional techniques, materials, and equipment (Obiakor *et al.*, 2003a). To achieve this broad goal, we must know who these students with special needs are. Not surprisingly, these students fit into broadly or globally recognized categories of exceptionalities, namely: cognitive disabilities, learning disabilities, emotional/behavioral disorders, communication disorders/speech and language impairments, visual impairment/blindness, hearing impairment/deafness, autism, traumatic brain injury, gifted and talented, physical disabilities, and other health impairments. While some of these categories are fewer in some countries, every country wants to demonstrate its interest in helping students with special needs to maximize their potential. Clearly, the entries in this section reflect dynamic special education methods and techniques that mirror our changing times in our complex world. In addition, through their entries, the contributors have demonstrated their multidimensional interests and exceptional knowledge in the world of special education. To a large measure, they have shown global and specific characteristics of the field of special education.

Historical Impacts and Contexts

It is common knowledge that people like to associate with those who behave, look, speak, and act like themselves. Anyone who does not fall in that norm is perceived and treated differently (Obiakor, 2008, 2009). Clearly, students with special needs have been discriminated against, ostracized, labeled, and called demeaning names (e.g., stupid,

imbecile, and retarded). Today, it has become increasingly clear that differences are a part of life. Advocates of students with special needs have pressed for ways to positively respond to their needs in quantifiable ways (Obiakor *et al.*, in press). In the United States, it is impossible to divorce the education of students with special needs from the Civil Rights Movement and the subsequent events that followed. To a great extent, the education of these students has been greatly influenced by social developments and court decisions in the 1950s and 1960s. For example, the landmark *Brown v. Board of Education of Topeka* (1954) case was a civil rights case that declared separate education as unequal education and unconstitutional (Obiakor, 2009). This was significant because it had the goal of ending racial segregation in schools. Logically, this opened doors of advocacy for students with special needs. The ruling of this case became a catalyst that prompted parents and professionals to lobby for equitable education for their students.

The *Brown* ruling, in the United States, encouraged parent groups to petition the courts to allow students with special needs to be educated in public schools. The *Pennsylvania Association for Retarded Children v. Commonwealth of Pennsylvania* (1972) (PARC) case held that children could not be denied access to public schools, and entitled them to a free and appropriate public education (FAPE). In the *Mills v. Board of Education* (Mills, 1972) case, a class action lawsuit was filed on behalf of 18 000 children with varied exceptionalities in the Washington, DC schools. In this case, the court ordered the district to educate all children, including those with special needs and further clarified that specific procedures had to be followed to determine whether a student should receive special services. Generally, these cases and other subsequent cases formed the framework for the legislation that currently guides the field (Yell, 2004).

In the United States, the Civil Rights Act (1964) (PL 88-352) provided legal rights to equality in education and other sectors of human interactions. In 1973, Section 504 of the Vocational Rehabilitation Act (PL 93-112) was passed to provide persons with special needs with (1) free and appropriate public education, (2) civil rights, (3) accessibility of programs, and (4) employability rights. The Education of All Handicapped Children's Act (1975) (PL-94-142) was passed with the following fundamental ingredients: (1) education for students from 3 to 21 years, (2) free and appropriate public education, (3) identification of students, (4) nondiscriminatory assessments, (5) placement in the least restrictive environment (LRE), (6) confidentiality of information, (7) procedural safeguards, and (8) development of individualized education plans (IEP). In 1986, PL 94-142 was amended to accommodate young children from birth to 3 years. This law Education of All Handicapped Children's Act (1986)(PL 99-457) was enacted to provide not just IEPs for children but also individual family support programs (IFSPs) for parents and guardians. In 1990,

PL-94-142 was renamed as the Individuals with Disabilities Education Act (IDEA, 1990, PL101-476). This Act involved funding for states to provide educational services to students from birth through 21 years, and ensured procedural safeguards for parents that guarantee meaningful participation in the evaluation process (Katsiyannis *et al.*, 2001). Additionally, IDEA guaranteed improvement in the education of students with special needs through research training and technical support and transitional supports for students when they are 16 years of age. To challenge the private sectors, the 1990 Americans with Disabilities Act (ADA, 1990; PL101-336) was passed to provide more societal opportunities for persons with special needs. In 1997, IDEA was reauthorized as PL 105-17 (IDEA, 1997) to facilitate disciplinary procedures and reduce litigation costs. In 2001, the No Child Left Behind Act (NCLB, 2001; PL 107-110) was passed to educate all learners and quantifiably account for their progress at all levels. Later, in 2004, IDEA was again reauthorized as the Individuals with Disabilities Education Improvement Act (IDEIA, 2004; PL 108-446). This law mandated that teachers of students with special needs be highly qualified, meaning they must be certified in the content areas that they are teaching (Smith, 2005).

Staying the Course, Resisting Change, or Moving Forward

The goal of any educational program is to maximize the fullest potential of students. In other words, the goal must be to truly leave no child behind despite his or her ability or disability. The critical question remains: Do we stay the course, resist change, or move forward in the education of students with special needs? Without a doubt, the dream is to move forward! More than a decade ago, Schrag (1993) confirmed that "the proportion of students being served within special education programs today and in the future is changing, which requires closer integration and coordination of services within the educational system and with a broader array of health and social services" (p. 208). The response of the federal government with regard to these imperatives has been accountability without accountability (i.e., accountability that focuses narrowly on the exclusion of students via assessment). Sadly, some accountability measures are already hurting the spirit of special education. In his piece titled, 'The death of special education,' Lieberman (2001) remarked that:

Special education has been swallowed by the beast: the school system, with its mandated curriculum, mandated tests, and mandated standards. Now, children with disabilities are entitled – no, are practically required – to have the same education as every other child, regardless of whether or not that education is of high quality or is appropriate for a child with a disability. (p. 39)

While it is iconoclastic to believe special education has been swallowed by the beast because of accountability challenges that are forced upon it, it is equally unrealistic to assume that we should just stay the course in special education. Any field or profession that does not believe in positive change is dead. Clearly, recent demographic changes in our society have challenged general and special educators and leaders to look for innovative ways to maximize all students' potential in school programs (Obiakor, 2007; Rueda, 2007). As Rueda argued, "given the long-standing but continuing controversy over the issue of overrepresentation of diverse students in special education, the future implications for identification, referral, assessment, and instructions are abundant" (p. 292).

Of late, there have been some aggressive moves to silence critics of the current system of special education that overrepresents culturally diverse students (e.g., African American learners) in programs for children with emotional/behavioral disorders and underrepresents them in programs for students with gifts and talents. Kauffman (2002, 2003a, 2003b, 2004), Mostert *et al.* (2003), and Sasso (2003) agreed that it is wrong to criticize the current system of special education. In fact, in their works, they were less receptive on the issue of the disproportionate representation of culturally and linguistically diverse students in special education. For instance, Kauffman (2003b) argued that:

The assumption that special education, which is at its best the fair treatment of disability, *creates* stigma is not just wrong; it is perverse. It confuses treatment with cause, just as if we were to make the assumption that identifying and treating cancer caused the stigma that used to accompany having it. Without willingness to talk about disabilities in a simple and straightforward way, we cannot address the problem of stigma. Euphemisms are cloaks that hide nothing effectively. Always and inevitably, they are stumbling rags that trip up prevention. (p. 196)

There is no doubt that the current special education system works for some children. However, the question is: Do critics of the current system of special education believe in the spirit of special education? Sure, they do! The reality is that special education has become an important educational phenomenon that works well when it does not misidentify, misassess, miscategorize, misplace, and misinstruct students who are racially, culturally, linguistically, and socioeconomically different. It seems unprofessional and immoral to hide under the cloak of special education to get rid of students just because they exhibit different behavioral and learning styles. Again, while there is great need for evidence-based practice in special education, we strongly disagree with Kauffman's (2003a) assertion that "if you discount science as a way of finding things out and believe that special education is fundamentally flawed, second rate, ineffective, unfair, and oppressive, then you're not going to use it for prevention" (p. 206).

We believe science is necessary; however, the indiscriminate use of a scientifically proven medication to cure all illnesses is dangerous, unethical, and immoral (Obiakor, 2004). The heart or respect for humanity must be incorporated into whatever we do as professionals even though one's heart or spirituality cannot be measured. Science may not always be the only answer; feelings matter too! Even in the medical field, the touch of the doctor and the feelings of the patient can facilitate and advance the healing process. Why should special education be any different?

In their study titled, Do race of student and race of teacher influence ratings of emotional and behavioral problem characteristics of students with emotional disturbance?, Cullinan and Kauffman (2005) concluded that "results did not support the position that, among students with ED [emotional disturbance], overrepresentation of African Americans arises from racial bias in teacher perceptions of emotional and behavioral problems" (p. 393). Coupled with the study's limitations and weaknesses as identified by Cullinan and Kauffman, there is the presumption of innocence of teachers just because of their race or culture. In many urban schools in the United States, there are culturally and linguistically diverse professionals who through their actions have devastated the lives of students and their parents (Obiakor, 2001b, 2003). Also in the United States, there are many Black policemen or women who wrongfully arrest, brutalize, shoot, and kill fellow Blacks in strange attempts to maintain law and order. Their race or culture must never be an alibi that exonerates them from being criticized or sued for violating the civil rights of others (Prater, 2006). Clearly, on issues of misidentification, misassessment, miscategorization, misplacement, and misinstruction of students, a poorly prepared general and special educator will not advance the education of all students (Obiakor, 1999, 2001b, 2003, 2004, 2007, 2008, 2009; Obiakor and Beachum, 2005; Obiakor and Ford, 2002; Obiakor *et al.*, 2002; Utley and Obiakor, 2001).

We believe we must move forward to advance creative strategies for educating all students, their special needs notwithstanding. As it appears, we cannot help all students unless we tap on the energies of all stakeholders (Obiakor, 2003, 2007, 2008, 2009; Obiakor *et al.*, 2002). Though there are no magic solutions, we must explore the multidimensional nature of the Comprehensive Support Model (CSM) to tap into the contributions of individual students, families, schools, communities, and governments. The individual self is important because without personal responsibility or self-improvement, it will be difficult to manage behavior and learning problems. The family is important because it is the cornerstone of the special student and the bridge that connects the student with the school. The school is important because it has general and special education teachers

and professionals who have the power to shift their paradigms regarding demographic changes. The community is important because it provides a variety of opportunities and choices for our children and youth who have been labeled as trouble makers or problem students because of their different styles. Finally, the local, state, and federal governments are important because they generate equitable policies that strengthen the multiple voices of all students. Evidently, a responsible government must be worried about the civil rights of its people, even those of people who have special needs or exhibit nonproductive and antisocial behaviors (Obiakor *et al.*, 2002).

To move forward in the whole process of special education for all students, it is imperative that general and special educators and leaders:

- Develop and use identification, assessment, and instructional strategies that function within the context of cultural competence.
- Create a collaborative system of community support that focuses on eradicating social stereotyping based on race, ethnicity, national origin, gender, and socioeconomic status.
- Develop an awareness and appreciation for the many family forms that value individual differences and strengths.
- Thwart conditions that lead to violence in the home or community and cultivate a sense of safety for children and families.
- Advocate economic policies and human services that are pro-family by virtue of proven outcomes.
- Promote culturally competent practices in schools and in the larger society to respect differences in worldviews and learning styles among individuals.
- Advocate expanded services that provide for affordable quality childcare to meet the varied needs of all families and children.
- Develop collaborative community approaches to problem solving that involve students, parents, schools, and community leaders.
- Recognize that the focus of the problem in at-risk situations is not only in the individual but also in institutional barriers in the environment.
- Reconfigure curricula that incorporate culturally sensitive variables.
- Reestablish rites of passage and service opportunities that cultivate a sense of belonging and resiliency in youth.
- Broaden visions in educational reform that include economic reform and the investment in human capital.

Apparently, by moving forward in this age of change, general and special educators can assist all students in school programs. For instance, they can prevent and manage violent behaviors that have created psychological setbacks for students by shifting their own personal paradigms.

In contrast to the get-tough no-nonsense approaches (e.g., zero tolerance or three-strikes-you-are-out disciplinary models), school personnel can teach prosocial skills and educate children to manage interpersonal conflicts nonviolently (Goldstein, 1999; Long, 1997; Obiakor, 2001a). After a lifetime of experience with youth with emotional/behavioral disorders, Long simply suggested using kindness or what we call the heart. General and special educators employing caring transitional strategies must focus on a variety of communication skills that enable young people to manage their behaviors and respond to others in ways that do not provoke confrontations. They must revisit the traditional emphasis on intelligence or academic achievement that seems to downplay the emotional intelligence and resiliency needed to survive in a changing society (Gardner, 1993; Goleman, 1995; Obiakor *et al.*, 2004, 1997). As Goleman remarked, emotional intelligence entails “abilities such as being able to motivate oneself and persist in the face of frustrations; to control impulse and delay gratification; to regulate one’s moods and keep distress from swamping the ability to think; to empathize and to hope” (p. 34). He added:

Academic intelligence offers virtually no preparation for the turmoil – or opportunity – life’s vicissitudes bring. Yet even though a high IQ is no guarantee of prosperity, prestige, or happiness in life, our schools and our culture fixate on academic abilities, ignoring emotional intelligence, a set of traits – some might call it character – that also matters immensely for our personal destiny. (p. 36)

Some proactive measures have been found to foster emotional intelligence in all learners, including those with special needs! These measures incorporate partnership programs, prosocial skills instruction programs, and mentorship programs. How can students value differences if differences are not valued in their homes, schools, and communities? How can they work together if adults and communities fail to work together? People who have emotional intelligence skills can help dissipate some of the cultural forms of heartlessness that permeate schools, for example, putdowns based upon race, ethnicity, gender, or disability. Students must work together, their families must cooperate with each other, their schools must work collaboratively, and their communities must work together (Obiakor *et al.*, 2002, 2004). These collaborative and consultative behaviors frequently lead to cooperative resolutions of situations at all levels and help students, parents, and professionals to maximize their potential.

Implications for Teacher Preparation

Clearly, all students exhibit special and different learning and behavioral patterns. As a consequence, they are intentionally or unintentionally misidentified, misassessed,

miscategorized, misplaced, and misinstructed in school programs (Mukuria and Obiakor, 2004; Obiakor, 1999, 2001b, 2003a, 2003b, 2007; Obiakor and Beachum, 2005; Obiakor and Wilder, 2003; Utley and Obiakor, 2001). What then are the roles of teacher-preparation programs for learners who are different? Even with the best intentions, many colleges and universities have failed to satisfactorily prepare educators for today's classrooms. Earlier, Haberman (1995) asserted that upon completion of traditional teaching programs teachers and service providers are as prepared for today's classrooms as a swimmer who prepared for the English Channel by training in the university swimming pool. It is important that teacher educators and leaders take the bull by its horns! They must be professionally responsible – they must prepare general and special educators and leaders to respond to demographic changes. They must shift their own paradigms to prepare teachers and leaders who can shift their paradigms (Smith *et al.*, 2001; Winzer and Mazurek, 1998). For those engaged in research, they must broaden their horizons in their understanding of nature versus nurture and other human behaviors and attributes. As scholars, they must go beyond the archaic theory of biological determinism and the myth of socioeconomic dissonance to make sense of their research (Gould, 1981; Weikart, 1977). For instance, Weikart warned that the deficit model of thinking, when applied to a certain population, “seems to limit potential assistance to that group because it channels thinking in ways that emphasize weaknesses rather than strengths, and it interprets differences from the norm as individual deficits” (p 175). The logical extension is that:

We cannot limit ourselves to the identification of trait dimensions or typological classifications across individuals without also considering the characteristics of the environments within which individuals function. Nor can we limit ourselves to an analysis of the environmental determinants of human differences without also considering the hereditary determinants. Finally, we have to ask ourselves what kind of society is most desirable for the expression of human diversity – for the opportunity for each of us to grow as individuals and at the same time not infringe on the rights of others to develop their own individuality. (Minton and Schneider, 1985: 489)

Minton and Schneider's (1985) statements have far-reaching implications for research, policy, and practice in general and special education and leadership. For instance, first, research that focuses on behavior problems of children and youth needs to address measures that will help us to understand them. When we understand them, we assist them to be functional, goal-directed decision makers in our complex society. Put another way, research that focuses on underlying pathological attributes of students needs to be valued with caution because such a research is deficit-oriented and lacks measurable or

observable solution-based attributes. Second, research, policy, and practice ought to go hand in glove. Many years ago, Keogh (1990) noted that “from this perspective, policy should follow research, and change should be found in evidence” (p. 186). It is apparent that something is wrong with our intervention strategies for culturally diverse students with special needs. Third, research that divorces itself from the fundamental principles of individualized instructional programming fails to appreciate or value individual differences in people. In the end, we need redirection in research funding and projects to reflect culturally sensitive proactive measures. Research studies with skewed divisive, emotionally loaded, political underpinnings must be discouraged in special education. Any research that does not lend itself to common-sense problem-solving interpretation and practice must be viewed with caution. Fortunately today, most scholarly publications (e.g., *Exceptional Children*, *Journal of Special Education*, *Multicultural Learning and Teaching*, *Multiple Voices*, and *Teacher Education and Special Education*) are demanding practical implications to works. Consequently, scholars, educators, and leaders must begin to broaden their definitions, theories, and intervention models to reduce illusory conclusions, perceptual assumptions, and prejudicial generalizations (Obiakor, 2007). Special students need specialized training of professionals. Strategies that empower all students must be developed if education is to get its desired respect. For instance, teacher educators and leaders must begin to realign themselves with new ways of thinking that go beyond games and politics.

We are convinced that poorly prepared teachers teach poorly. It is important that teacher educators and leaders practice what they preach. In this age of change, they must use divergent techniques to prepare future educators who will, in turn, use divergent techniques to teach learners who exhibit different styles and express special needs. To look for the magic pill that can cure educational problems of all students is not realistic. However, the key is for teacher educators and leaders to prepare those who value individual differences and special needs (Ford *et al.*, 1995; Obiakor, 2001b, 2003, 2007; Obiakor and Beachum, 2005; Obiakor and Ford, 2002; Obiakor *et al.*, 1999, 2003b; Wilder *et al.*, 2003). By so doing, they become aware of emotional first-aids needed to address crises confronting their students (Obiakor *et al.*, 1997). From our perspective, it is nonproductive to bemoan new multicultural paradigms that incorporate quality and equity in educational programming (Price, 1991). We must avoid any kind of multiculturalism that tends to project goodness with underlying negative intentions, and phony sense of community that hampers ways to increase knowledge about the interactions between human behaviors and cultural styles. To this end, teacher educators and leaders must make efforts to recruit and retain culturally sensitive students, faculty, and staff to remain competitive in this age of change (Obiakor, 2001b,

2007; Obiakor and Beachum, 2005; Obiakor and Utley, 1997; Wald, 1996).

Conclusion

While the United States and other countries have done a commendable job of putting legal mandates to protect students with disabilities and provide them with equal public education, the interpretation and implementation of those laws have many loopholes that need to be sealed. Overrepresentation of students from culturally and linguistically diverse background in special education has caused great concern. If students have been misplaced, it means that their educational needs cannot be met. Appropriate placement should be in least restrictive environments in which students' cultures and language do not result in misidentification, misassessment, miscategorization, and misplacement. The heart and soul of quality service delivery for students with special needs must include nonrestrictive environments and settings that maximize their potential. Finally such environments must be culturally, linguistically, and socioeconomically accepting.

Educating Students with Traumatic Brain Injury

S Burkhardt and A Rotatori, Saint Xavier University, Chicago, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Injury factors – Common causes of traumatic brain injury in children, including accidents and assault.

Mental functions – Cognitive capabilities which support academic achievement and behavior, including attention, memory, executive functions and response time.

Multidisciplinary planning – Educational programming which includes goals and strategies from various learning specialists.

Positive behavioral support – Behavior management programming that relies on reinforcement and strengths as the means of increasing adaptability.

Recovery factors – Post-trauma elements of recovery from traumatic brain injury that affect prognosis, including severity of injury and environmental supports.

Secondary attention-deficit hyperactivity disorder (SADHD) – The development of attention deficit disorder following traumatic brain injury.

School readiness factors – Teacher and school preparedness for post-injury support of students.

Traumatic brain injury (TBI) – Open and/or closed head injury that is acquired after birth and is caused by external physical force.

Educating the Student with Traumatic Brain Injury

In 1990, traumatic brain injury (TBI) was added as a disability category within the Individuals with Disabilities Education Act (IDEA) in the United States (see Code of Federal Regulations, Title 34, Section 300.7(b) (12); (NICHY, nd)). TBI is defined, in the IDEA, as an acquired open or closed head injury to the brain, caused by external physical force. TBI results in total or partial functional disability and/or psychosocial impairment that have an adverse impact upon the student's educational performance. Specifically excluded from the term TBI are congenital or degenerative brain dysfunction as well as brain injuries caused by birth trauma (NECCYD, 1997).

Brain injury affects more than 1 million children every year, with about 30 000 of them sustaining a lifelong disability

due to the brain injury (NICHY, nd). Although children and teenagers are more likely to survive TBI than adults (US Department of Health and Human Services, 1999), it is the most common cause of death and disability among children in the United States (Keyser-Marcus *et al.*, 2002), with African Americans having the highest fatality rate (Arroyos-Jurado and Savage, 2008). A review of the National Trauma Data Base, by Haider *et al.* (2007), indicated that black children “experience worse clinical and functional outcomes following TBI” compared to white and Hispanic children. Socioeconomic status (SES) and availability of postinjury services were associated with these findings. In terms of gender, males are more likely to sustain TBI than females (Arroyos-Jurado and Savage, 2008).

TBI may affect the way a student thinks, speaks, remembers, pays attention, and behaves. **Table 1** identifies the mental functions that may be affected by TBI. The learning characteristics of students with TBI may differ significantly from their learning characteristics prior to TBI (NICHY, nd). Understanding their characteristics and methods to maximize the learning potential of students with TBI is very important. This is the focus of this article.

Categories of Factors Related to TBI

To educate students with TBI, it is important to consider a framework to meet their needs. Four general categories are considered. Injury factors are those aspects of TBI that constitute the basis of the educational difficulties experienced by a student with TBI. School-readiness factors refer to programs and personnel available in the general education setting who can accommodate the learner with TBI. Coordination of services refers to various intervention strategies and accommodations provided on behalf of a student with TBI. Lastly, recovery factors are discussed as the basis for addressing the continuing needs of students with TBI (**Figure 1**).

Injury Factors: Causes of TBI

The top ten categories of head injury among children, age 14 or younger, are the following: bicycle accidents; football injuries; baseball/softball injuries; powered skateboard and scooters; basketball injuries; unpowered skateboards and scooters; winter sports; powered recreational vehicles; and water sports and trampolines (American Association of Neurological Surgeons, 2007). Additional causes of injury

Table 1 Mental functions affected by traumatic brain injury

Cognition
Speech and language

include falls, assaults, other violence, child maltreatment, and child-passenger injury (CDC, 2008). Sports injuries are a common source of head injury for high school and college students, with football, ice hockey, and soccer being most frequently associated with concussion – a form of head injury that does not include loss of consciousness (Moser *et al.*, 2007; National Academy of Neuropsychology Planning and Policy Committee, 2007).

The National Academy of Neuropsychology Planning and Policy Committee (2007) highlighted concerns with regard to mild brain trauma and young athletes. School sporting events seldom have medical personnel in attendance and injured student players do not always receive immediate medical attention. Brooks (2004) discussed pertinent legal cases with regard to the liability for school districts related to

student-athlete head injuries, including differing policies for benching a player who complains of dizziness following a play. Clearly, schools are well placed to address brain-injury prevention for all students. The Centers for Disease Control and Prevention (CDC, 2007) made the following suggestions for prevention education: reminding students to wear seat belts at all times when in motor vehicles; encouraging parents to place children in the back seat to avoid air-bag injury; and promoting the wearing of helmets when riding a bike or horse, skateboarding, snowboarding, and playing sports.

School Readiness Factors

Two types of school readiness factors are identified. First, the role of the school in supporting the re-entry of students to the school environment following TBI is considered; and, second, the preparedness of the general education teacher for including a student with TBI is discussed.

The Role of the School in Re-Entry of Students with TBI

A report of best practices for the rehabilitation of TBI in children and adolescents was compiled a decade ago (US Department of Health and Human Services, 1999); however, the information is currently deemed archival. The 1999 report indicated that data with regard to special education placement, services, and outcomes for students with TBI was limited. The report offered analysis of several studies from the 1990s, including the estimate that between 9% and 38% of students with TBI were referred to special education after returning to school.

Keyser-Marcus *et al.* (2002) promote the creation of a student learning profile for a student with TBI upon return to school. Such a profile emphasizes student strengths while suggesting instructional interventions that are effective for the individual. Bowen (2005) identified instructional methods for students with TBI which include adapted school environment and special education supports. Direct instruction (i.e., Glang, 1993) and cognitive strategy intervention, were determined to assist students with and without disability (Glang *et al.*, 2008). Both methods have shown promise with students with learning and behavioral characteristics similar to those of students with TBI (Bowen, 2005; Glang *et al.*, 2008). Assessment emerges as an essential best practice for the support of students with TBI (see North Carolina State Department of Public Instruction, 1997). Bowen emphasized the need for functional assessments of learning and behavior, in addition to formal assessments of cognition and achievement, to capitalize on remaining strengths and to minimize the impact of diminished capabilities. Assessment measures for students with TBI, often, include neuropsychological evaluation, with assessment of numerous domains: information processing, sensory-motor

integration, reaction time, mental flexibility, memory and learning, language comprehension, speech fluency, and social-emotional responses. Interview of family members and review of pre-injury academic performance are necessary, in light of the findings that post-injury achievement is associated with pre-injury performance (Arroyos-Jurado *et al.*, 2006).

Teacher Preparedness for Students with TBI

Educators may struggle with school programming that meets educational and psychosocial needs of students with TBI and their families. A report by Mohr and Bullock (2005) based upon focus group discussion with educators identified potential difficulties regarding teacher preparedness for students with TBI: lack of teacher awareness with regard to the characteristics of TBI and the course of recovery, poorly defined educational goals, and few specific accommodations for students with TBI.

Useful information for the classroom teacher needs to be as real world as possible (Keyser-Marcus *et al.*, 2002). The types of problems experienced by students with TBI may include difficulty remembering the previous day's lecture or the location of a locker; disorganization; losing track of conversation; inflated estimate of academic performance; and difficulty naming familiar objects. Thus, it is critical to provide a classroom observation checklist to assess functional domains and problems experienced by the student in the classroom environment. The checklist includes functional assessment of the following domains: memory, attention and concentration, executive functioning, self-awareness, and language. The checklist helps to identify significant indicators associated with TBI, such as losing track of conversation, poor time management, and limited meta-cognition (i.e., overestimating knowledge or preparation for academic tasks). In the end, Glang *et al.* (2004) recommended a TBI Team Model that provides for peer consultants to assist schools with the education of students with TBI. This model involves the following components: an assessment of student needs, recruitment of an intervention team, training of the team members, and evaluation of implementation and outcomes. Team members serve as consultants to school staff and the classroom teacher.

Coordination of Services

Two aspects of coordination of educational services for students with TBI are identified. Multidisciplinary planning is presented as a needed component of educating the student with TBI who is, often, returning to school as a transition from rehabilitation services. Additionally, although TBI is a special education category of eligibility, it is a category that does not encompass specific educational programming. Thus, the role of the Individual Education Plan (IEP) for the student with TBI is considered.

Multidisciplinary Planning

Mohr and Bullock (2005) defined specific elements of a school prepared to support successful re-entry of students with TBI. Excellent communication among school, family, and rehabilitation staff should be established prior to the student's discharge from rehabilitation programming. Communication may be enhanced by identifying a liaison from the school knowledgeable in TBI and transition from rehabilitation. Involvement of parents in planning is needed, particularly utilizing the family's successful strategies at home to support transition back to school. Continued use of strategies from home and the rehabilitation facility provide continuity and avoid confusion for the student making post-injury adjustments.

Since 1990, students with TBI are eligible for special education services within the TBI category. Despite this, few unique, coordinated, and comprehensive services are designated specifically for TBI. Thus, students with TBI are likely to receive special education services by learning disabilities specialists, occupational therapists, speech pathologists, and school social workers (Arroyos-Jurado and Savage, 2008). Common accommodations for students with TBI include shortened school day or modified school schedule, with most rigorous classes attended during the student's alert and rested periods of the day. Continuous monitoring and assessment of not only the learner with TBI but also the suitability of the learning environment is needed. Clearly, instructional methods and materials that build on the student's strengths and avoid areas of deficit are particularly appropriate (Bowen, 2005). Harvey (2006) recommended coordinated services that are both variable and flexible.

The Individualized Education Plan

The individualized education plan (IEP) should reflect the best practices of each professional supporting students with TBI (Arroyos-Jurado and Savage, 2008). Reports of specific IEP accommodations are lacking in systematically reviewed outcome studies; however, special education services and an IEP are associated with increased success in transition to post-secondary education (Bowen, 2005; Todis and Glang, 2008). Adjusted schedule was a frequent accommodation for students with TBI following return to school (Gfroerer *et al.*, 2008). Strategies associated with best practices for students with TBI include positive behavioral support, interventions designed to compensate for memory loss, customized supports for organization, and social regulation (Bowen, 2005). A positive behavioral support approach focuses on the replacement of inappropriate behaviors with more appropriate behaviors that allow learners with TBI to achieve their social-emotional and academic needs. Positive behavioral support encompasses a variety of behavioral strategies such as: environmental

scans (Mukuria and Obiakor, 2008), functional behavioral assessment, positive reinforcement, behavioral momentum (Ylvisaker *et al.*, 2003), and structured environment (Bowen, 2005). The successful implementation of these strategies allows teachers and service providers to tailor a learner's environment based on his/her preferences, strengths, and needs so that more functional behavior occurs. (see Mukuria and Obiakor, 2008). Customized programming is dependent upon the special education staff's familiarity with TBI. Keyser-Marcus *et al.* (2002) recommended strategies for teaching the student, with TBI, in the general education setting. Strategies include multimodal instruction, frequent use of review and repetition, task analysis to support skill acquisition, and breaking down assignments into smaller components. Instructors are encouraged to patiently answer questions and encourage independent thinking, memory notebooks, tape recorders, color coding of instructional materials, and customized checklists may be needed to support the learner with TBI (Bowen, 2005).

NICHY (nd) provided a list of tips for teachers that target the residual effects of TBI with regard to education-related behaviors, such as information processing, response time, and psychosocial adjustment. Suggestions include allowing extra time for schoolwork and tests, the use of simple, short, and/or written instructions to clarify directives; the use of demonstration to teach how to perform new tasks; ample opportunity to practice new skills; establishing a routine and warning with regard to changes in the routine. Planned rest periods to address fatigue may be needed. Reduction of distractions in the learning environment is, often, helpful. Finally, educators are encouraged to have flexible expectations and patience in their efforts on behalf of students with TBI.

Recovery Factors

Two elements of recovery from TBI are discussed as they relate to educating the student with TBI. Although children survive TBI and make good progress, the risk of abnormal post-injury development remains. In a similar vein, problematic behaviors related to TBI may require continuous positive behavior management for students with TBI in order to support education in the least restrictive environment.

Post-Injury Development of Students with TBI

Although recovery continues following TBI, post-injury development of students who have sustained brain injury may be affected. Arroyos-Jurado *et al.* (2006) determined that severity of TBI was associated with post-injury loss of nonverbal intelligence quotient (IQ) performance, impaired encoding, and difficulty recalling information. Max *et al.* (2005a) determined that 22% of children in the age range of 5–14 years, who sustained TBI, exhibited personality changes in the 6 months following injury. Poor post-injury

regulation of emotion was determined to be related to the severity of the brain injury and not psychosocial factors. In addition, secondary attention-deficit hyperactivity disorder (SADHD) is a common complication following pediatric TBI (Max *et al.*, 2005b). SADHD includes personality changes, behavioral problems, cognitive deficits, and impairments in adaptive functioning. Up to 21% of children experiencing TBI develop SADHD by 24 months post-injury. The findings of Max *et al.* (2005b) suggest the development of SADHD occurs in students who, prior to injury, did not display ADHD.

Max *et al.* (2005a) found that, of 143 children with no pre-injury ADHD who sustained mild-to-severe TBI, 15% developed SADHD within 12 months of injury. Additionally, a minority of the children with SADHD also developed personality changes as well as other disorders including oppositional defiant disorder, obsessive-compulsive disorder, conduct disorder, and dysthymia. Analysis of risk factors associated with the development of SADHD identified not only biological features related to injury (severity and location), but psychosocial risk factors as well (Max *et al.*, 2005b). Pre-injury SES correlated with the development of SADHD, although the specific mechanisms underlying such correlations remain unknown (Max *et al.*, 2005a). Family history of ADHD was not predictive of SADHD – suggesting a genuine distinction between primary ADHD and SADHD. At 6 months post injury, lesion location and SES predicted SADHD. However, by 18 months post injury, family adversity and personal pre-injury functioning were the strongest predictors of the extent of SADHD. These findings suggest that TBI – combined with psychosocial disadvantage – predicts the development of SADHD. By 18 months post injury, severity of injury was not associated with SADHD. Thus, there is evidence to indicate that while severity of injury is an important determinant of post-injury functioning, post-injury environment may influence post-injury recovery. As return to school constitutes a major feature of the post-injury environment, special care must be taken to provide an optimal environment for a student who is experiencing learning and behavioral changes due to TBI. Additionally, demands of learning may need modification for these students as they transition back to the school environment.

Continuous Positive Behavior Supports

TBI encompasses the possibility that the student with TBI may continue to display difficulties with self-regulation and emotional expression (Dykeman, 2003). Constructive management of behavioral difficulties related to TBI, SADHD, and/or organic personality changes is necessary to support recovery and inclusion in the school setting. Behavioral contracts that emphasize positive reinforcement for appropriate behavior should serve as the central feature of a behavioral management plan for a student with

TBI. The need to accept the slow rate at which desired behavior can be shaped following TBI requires patience and persistence; and disciplinary approaches that include punishment and response cost for undesirable behavior may impede adjustment to the school setting. Reduced expectations for work load, stamina, and participation set the stage for the student with TBI to experience success for that which is accomplished rather than anxiety or discouragement for that which is not readily achieved.

Rules and routines may need to be directly taught and practiced. Activities that require prolonged concentration may need to be avoided. Verbal interactions may require longer processing time; the student with TBI should not be reprimanded for delayed response to directives. The IEP is likely to be a working document that is flexible and allows for unique and changing needs of a student with TBI. Clearly, the student may need direct and ongoing assistance with organizational skills.

Conclusion

Learning is supported by good mental functioning, thus, TBI in many cases has a significant adverse impact upon a student's ability to learn. Impairment in many of the mental processes, including attention, memory, language, and regulation of emotion, is frequently related to TBI. Educators and service providers may find themselves underprepared for the return to school of their student with TBI. Since students with TBI, often, differ greatly in terms of the severity and type of impairment, individualized assessment, and service plans are needed.

TBI is an acquired disability in which injury factors, such as severity, influence the degree of impairment, and course of recovery. In order to educate a student with TBI, the school must be ready to meet his/her needs, with instructional methods and educators who are knowledgeable with regard to learning and behavioral characteristics of TBI during recovery. Educational services for TBI include multidisciplinary teams who employ best practices in assessment and intervention. Emphasis upon a flexible IEP is needed in order to identify and utilize the student's remaining and emerging strengths. Finally, education of the student may require patience; by its very nature, TBI continues to affect development and functioning. Thus, students with TBI may need continuing services, including behavioral management plans to promote restoration of adaptive behavior while effectively managing residual post-injury dysfunction.

English Language Learners with Special Needs

R Rueda and G Ragusa, University of Southern California, Los Angeles, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

English learner – English learners are those individuals whose primary language is other than English and who is in the process of acquiring English language skills in the areas of listening comprehension, speaking, reading, and writing necessary to succeed in the school and in the workplace.

IDEA – The Individuals with Disabilities Education Act (IDEA), which is the current version of the federal special education law that was first enacted in 1975 and was originally known as the Education for All Handicapped Children Act of 1975 or Public Law 94-142. It outlines the provisions to be followed in the education of students with disabilities.

Response to intervention – Response to intervention refers to a family of approaches which aim to prevent unnecessary assignment to special education. With RTI, low-performing children are offered intense, individualized academic intervention. Student progress is monitored to see if response to this intervention yields adequate academic growth. A key aspect of the approach is the provision of services to students with academic delays using one or more research-validated interventions. The student's academic progress is monitored frequently to see if those interventions are sufficient to help the student to catch up with his or her peers. If the student fails to show significantly improved academic skills despite several well-designed and implemented interventions, this failure to respond to intervention can be viewed as evidence of an underlying learning disability.

This article discusses the challenges and dilemmas associated with placement and service provision for English language learners (ELLs) in special education systems and provides recommendations for improved assessment practices and service provisions. These issues represent a range of factors, including inappropriate assessment and psychometric issues, overrepresentation in special education programs, ambiguities in special education categorization, questionable pre-referral intervention practices, inadequate practitioner preparation related to language and cultural factors, and ineffective instructional practices both within and outside of the special education system

(McCardle *et al.*, 2005). These challenges are not new to the special education field as they have been described in the literature since the 1970s.

The difficulties associated with meeting the needs of ELLs appear to remain in spite of new reauthorizations of federal special education legislation that was originally prescribed by Public 94-142 (IDEA, 2004). An extensive review of the literature reveals a continuing issue with practitioners' beliefs and discrepancies in their understanding of the needs of ELLs in public education that may lead to biased assessment practices, overreferral to special education systems, and ineffective instructional practices. In this article, we provide a brief review of these and related issues.

The English Language Learner Population

In order to fully understand the needs of ELLs in education systems, it is important to describe the unique characteristics of the population. Linguistic diversity has dramatically increased in the past decade in the United States. The most recent United States Census data reveals that nearly 47 million US residents comprising nearly 18% of the total US population speak languages other than English. This growth is reflected in both the elementary and secondary school population. According to the US Department of Education, National Center on Educational Statistics (NCES), services related to ELLs were provided to 3.8 million students (11% of all students) during the 2003–04 school years. California and Texas had the largest reported number of students receiving ELL services during this period. In California, there were 1.6 million students (26% of all students) who received ELL services, and in Texas, there were 0.7 million students (16% of all students) who benefited from ELL services.

Not only do ELLs face challenges related to language barriers, they are also adversely affected by persistently low teacher expectations and struggles associated with national and state achievement tests (McCardle *et al.*, 2005). According to the National Assessment of Educational Progress (NAEP) data, the academic achievement of ELL students has not kept pace with their English-speaking peers. In 2007, NAEP data revealed that 7% of ELLs read at or above the proficient level in fourth grade, in contrast to 36% of English-speaking students.

Research has revealed a variety of reasons for why ELLs do not fare well on NAEP and related types of

standardized assessments. Test biases, misinterpretation of student needs, inadequate teacher training related to language assessment and instruction, and inconsistent teacher beliefs about the needs and expectations for ELLs all affect the achievement of this group, in particular those who are referred for special education services (Artiles *et al.*, 2004). These difficulties and misperceptions have been cited as factors contributing to overrepresentation of ELLs in special education programs nation-wide. Overrepresentation of ELLs in special education presents significant challenges to families, students, and educational systems nationally (Rueda and Windmueller, 2006).

Range of Special Education Programs

Currently, special education offers a range of programs in the United States. This range has increased as a function of each reauthorization of the federal special education legislation. In particular, the federal mandate for placing students in the least restrictive environment (LRE) has been an important factor in increased number and type of special education program options. Current program options include services for children beginning at birth and extending through to the age of 22 years and ranging in service intensity from full inclusion in general education with minimal consultative special education support to residential, segregated special education services.

While access to special education services is expected to be equitable and universally available to all students who qualify, national statistics have illustrated that service choice, particularly when inclusion is warranted, is inequitable and racially divided. The most recent reauthorization of the Individuals with Disabilities Education and Information

Act (IDEIA) included legislative revision that increased the number of students included in general education classroom for a portion of their day.

While inclusive settings have become more common, inequities abound. Researchers recognize that inclusion has benefited many students, particularly students identified with specific learning disabilities (SLDs). In the 2003 US Department of Education, Office of Special Education Report to Congress, underrepresented groups including ethnic minorities were placed in special education at significantly higher rates than white students. Moreover, students of color have been found to spend less time in inclusive settings. While Hispanic and Black K-12 students make up the largest population of special education learners, it appears from the national statistics that these subgroups spend more of their educational experiences in more restrictive special education settings than their peers. According to the National Center on Educational Statistics, (2005) approximately 50% of all disabled students in 2003–04 spent 80% or more of their day in a regular classroom, up from 45% in 1994–95. In contrast, Black and Hispanic students with disabilities spent less time in a regular classroom on average than their peers of other races/ethnicities with disabilities. This inequity suggests that particular ethnic groups are not provided with the full range of service options available to students with special needs. **Table 1** provides an illustration of this representation by ethnic group and federally recognized disability category.

As indicated by **Table 1**, in 2003, the percentage of students receiving special education with SLDs (the largest reported category) is highest for Hispanics (many of whom are ELLs). Hispanics represent 57.3% of all students with SLDs served.

Table 1 Disability distribution, by race/ethnicity, of students aged 6 through 21 receiving special education and related services: Fall 2003

<i>Disability</i>	<i>American Indian/ Alaskan Native</i>	<i>Asian Pacific Islander</i>	<i>Black (not Hispanic)</i>	<i>Hispanic</i>	<i>White (not Hispanic)</i>
Specific learning disability	54.5	39.5	44.5	57.3	45.6
Speech language impairments	16.0	26.0	14.3	18.3	20.1
Mental retardation	7.5	8.9	16.1	8.1	7.9
Emotional disturbance	8.0	11.6	11.2	4.9	7.9
Multiple disabilities	2.0	2.7	2.2	1.9	2.3
Hearing impairments	1.0	2.8	1.0	1.5	1.1
Orthopedic impairments	0.7	1.7	0.8	1.2	1.2
Other health impairments	5.7	5.3	5.9	4.1	9.1
Visual impairments	0.4	0.8	0.4	0.5	0.4
Autism	1.1	5.7	1.8	1.5	2.7
Deaf-blind	0.0	0.1	0.0	0.0	0.0
Traumatic brain injury	0.4	0.4	0.3	0.4	1.4
Developmental delay	2.6	1.4	1.2	0.6	1.2
All disabilities	100	100	100	100	100

Total may not sum to 100 because of rounding.

27th Annual (2005) Report to Congress on the Implementation of the Individuals with Disabilities Education Act, vol. 1. Washington, DC.

Overrepresentation of ELLs in Special Education

For nearly four decades, minority students have been overrepresented in special education. As a recent example, Artiles *et al.* (2005) conducted a study of within-group diversity of disproportionate representation of ELL students in special education. They discovered that ELLs identified as having limited proficiency in both their primary language (L1) and English (L2) showed the highest rates of identification in the special education categories investigated. Moreover, these students were consistently overrepresented in programs for students with learning disabilities and language and speech disabilities, and had significantly greater chances of being placed in special education.

Because of the long-standing overrepresentation of certain groups of students in special education, federal legislation now requires states to collect and examine data on disproportionality related to race and ethnicity. Wherever, states identify disproportional representation, they are mandated to plan services and to develop policies and procedures to adjust proportionality (US Department of Education, Office of Special Education and Rehabilitative Services, Office of Special Education Programs, 2007).

In addition to examining referral and identification data, the legislation requires that states adjust their identification criteria for students with SLDs and adopt a policy of pre-referral intervention with a process of response to intervention (RTI). RTI is defined as “the use of strategies used by classroom teachers to target instructional interventions to children’s areas of specific need as soon as those needs become apparent” (US Department of Education, 2007), and before referral to special education is formally commenced.

Inappropriate Referrals Based on Language Differences

NCLB and the massive demographic changes of the student population have placed a tremendous demand on school districts to educate all students to proficient levels. One challenge is that in response to these conditions, educators increasingly inappropriately refer ELL students for special education (Rhodes *et al.*, 2005). In addition to these pressures, biases in the referral process have been implicated in disproportionality. This bias impacts other steps in the process such as pre-referral interventions and assessment practices.

English Language Learners and Issues of Education Assessment

Researchers have suggested that inappropriate assessment practices account for much of the disproportionality of English language learners receiving special education

services. Various studies have demonstrated that standardized achievement tests present significant challenges for ELLs. Differentiating between typical second language acquisition and learning disabilities is an important and continuing educational challenge (Gonzalez *et al.*, 1997). Another stems from the difficulty that the educational field has with development of assessment measures and procedures that adequately determine when a child with a primary language other than English is ready to be tested in English only, the primary language currently used to assess learners for special education (Abedi, 2006). Students often appear to be orally proficient in English long before they have fully developed cognitive academic language proficiency (CALP), the linguistic proficiency required for comprehending and effectively utilizing academic informational text. Bailey and Butler (2004) propose that effective inclusion efforts must begin with equitable exposure to and learning of the academic language required in the classroom and on content examinations.

Macswan and Rolstad (2006) documented a significant discrepancy between ELLs’ performance on commonly used language assessment measures and qualitatively coded natural language samples completed by the study’s research team. This led the researchers to question the construct validity of widely used language tests, and they noted that practitioners should use them with caution when considering special education status.

In a related large-scale national study that included analyses of standardized assessment data from K-12 settings, Abedi (2006) found a significant performance gap between ELL and non-ELL students in reading and writing assessments. The gap was less for science assessment measures, and lowest for math problem solving, for which the test items were less linguistically challenging for ELL students. The performance gap virtually disappeared in math computation, where the language demands of the test items were minimal. These results suggest that language-rich tests have significant potential for misidentifying students into special education when they are factored into students’ special education eligibility profiles.

Research suggests that test biases and validity issues are highly plausible factors related to the overrepresentation of ELLs in special education. These findings suggest a need to develop assessment measures that fairly, validly, and reliably assess the needs, abilities, and achievements of ELLs with special needs. Additionally, the assessment research suggests that multiple measures that create comprehensive student assessment profiles should be used to assess ELL students for special education eligibility and placement so that the students’ educational future is not determined by a single assessment measure (Rueda and Windmueller, 2006). The practice of developing assessment profiles that include both standardized and holistic community specific measures is a viable option for decreasing misidentification of ELLs for special education placement.

Language and Cultural Considerations in Pre-referral and RTI

Assessment is not the only step in the special education referral process that may contribute to inappropriate placement and overrepresentation of English learners in special education services. In response to the ineffectiveness of the discrepancy model for special education eligibility, the RTI process has been established. RTI focuses on pre-referral interventions to address the overrepresentation of minority groups in special education groups (Fuchs *et al.*, 2003). RTI is defined as the practice of providing high-quality instruction/intervention matched to student needs and using learning rate over time and level of performance in advance of formal referral to make important educational decisions about special education eligibility and service provision. That is, instead of relying on a score as an index of or predictor of learning potential, RTI assesses actual response to high-quality treatment or intervention as a pre-referral metric.

Recognizing the potential of pre-referral intervention, researchers, practitioners, and policymakers established RTI to systematically improve and articulate levels of support and intervention provided to students in at-risk conditions (Artiles and Klinger, 2003). The IDEIA legislation requires educators to measure students' RTI before referring the students for special education assessment and services.

A widely used model for RTI includes a three-tiered process. The first tier consists of quality instruction in a general education classroom based on evidence-based practices; the second tier is implemented only with students who do not reach expected benchmarks using an assessment instrument; and the third tier refers to students that are going to engage in the special education referral and assessment processes. While RTI is designed to alleviate disproportionate representation of students of color and English language learners in special education by increasing opportunities to learn, it may at the same time be subject to the same challenges related to cultural and linguistic differences that have plagued the special education system historically (Klinger *et al.*, 2005).

The National Center for Culturally Responsive Educational Systems suggests that RTI implementers consider the following four critical areas in designing and delivering educational intervention: (1) culturally meaningful task criteria, (2) teacher–student shared understandings of the purpose of tasks and activities, (3) culturally inclusive participation frameworks in classroom discourse, and (4) deficit-based ideologies about low-income racial minority students used in referral and placement practices. These considerations are sparsely evident in many RTI programs or in the RTI research. It has been noted that practitioners and researchers are in conflict around effective interventions in RTI (NCCRESt, 2005). In general, practitioners

conducting RTI use a problem-solving approach to intervention, while researchers often favor the use of standardized treatment protocols.

Intervention Strategies and Cultural Appropriateness

Not only are many special education assessment practices inappropriate for ELLs, there are also problems with intervention and instructional practices. In an effort to alleviate inequity in RTI-related services, Gersten and Dimino (2006) recommend that the three RTI tiers be fully implemented with the focus on preventing referral to special education by identifying at-risk factors in students early on in the process. They propose using a combination of national benchmarks and local and classroom norms to identify students at risk for failure. Gersten and Dimino describe the need for immediate, specific one-on-one small group intervention aligned with data that teachers consistently monitor in general education classrooms.

In addition, appropriate intervention with ELLs requires training nonspecial education teachers to recognize risk factors in students and to have proficiency in a range of strategies for providing remediation for at-risk learners. Often, teachers' beliefs, expectations for students, skills sets, and efficacy are challenged at levels that they are not prepared for in their teacher preservice preparation program (Tyler *et al.*, 2004). This situation may contribute to the disproportionality in special education noted earlier in this article.

In addition to the potential problems associated with pre-referral (RTI) intervention, researchers note that intervention strategies in full service special education are often culturally and linguistically inappropriate for ELLs. Inflexible implementation of commercial and undifferentiated instruction is of primary concern to researchers in their quests for finding effective intervention strategies for ELLs in intervention programs. Unfortunately, there are relatively few intervention programs specifically designed for ELLs with special needs. Yet even these efforts to deliver early and individualized help may provide benefit to these students.

As an example, Williams (2005) conducted a study using a reading-related intervention often found in RTI Tier 3 (as described earlier in this article), focused on text structure and gradual introduction of reading comprehension strategies. The content was introduced to learners in small increments, moving from simpler to complex while providing (1) modeling by the teacher, (2) scaffolding that faded as instruction progressed, (3) substantial guided followed by unguided practice with texts specifically structured for instruction with feedback, and (4) a thematic along with feedback instructional approach. The goal for this intervention was the development of automaticity of

the comprehension strategies in addition to transfer of the strategies to real life situations. This study revealed significant improvements in reading scores for both Hispanic and African American students, with the resulting treatment effect sizes between 1.64 and 4.06. This finding is consistent with other studies on this issue.

While reading has been identified as a primary intervention need for ELLs, many ELLs also receive mathematics instruction through RTI or through ongoing special education service provision. Fuchs and Fuchs (2005) identified mathematical problem solving (MPS) as a primary instructional need for students at risk for special education identification. They identify skill transfer as a primary difficulty and suggest that many math interventions have focused on basic skills rather than real life problem solving. Fuchs and Fuchs designed an intervention drawing on schema-based instruction and self-regulation strategies to address the transfer problems in mathematics problem solving. These math intervention strategies have yielded promising results.

As previously stated, intervention studies do not have to focus specifically on the needs of ELLs. This is quite unfortunate as the recent NCES statistics (2005) reveal that ELLs continue to be overrepresented in special education and in the special education pre-referral process. While some small-scale studies reveal promising intervention results for ELLs, few studies have focused on the unique cultural and linguistic needs of ELLs in designing interventions. Additionally, at the pre-referral stage in the special education system, the bulk of responsibility for identification and intervention is placed on general education teachers who have little, if any, training at preservice or in-service levels in working with and assessing learners with special needs who are ELLs.

Teacher Qualification, Beliefs, Expectations, and Practices Associated with ELLs in Special Education

Teacher education research suggests that teachers' beliefs influence instructional practices and influence the expectations that they have for students. Other factors such as teachers' self-efficacy may be important in the quality of instruction provided to students. Research has revealed that many teachers are often uncertain about how to determine whether ELLs are having difficulties due to language differences or due to learning challenges. For example, Obiakor (1999) identified low teacher expectation for ELL students as a significant factor in inappropriate referral to special education. Obiakor suggested that teachers' beliefs about the abilities and needs of ELL students inform their expectations and in turn inform their instructional practices. These beliefs and assumptions are informed both by personal experiences as well as by formal preservice and

in-service teacher education. A significant limitation of teacher training programs nationally is that they overemphasize knowledge acquisition to the detriment of equipping teachers with practical skills for teaching to a diverse range of students, including those with disabilities (Edelen-Smith *et al.*, 1993). Additionally, in most states, preservice teacher preparation programs require only one course in special education (NCATE, 2002), and special educators are often not required to take courses on meeting the needs of ELLs (NCATE, 2002). The shortcomings of teacher preparation programs contribute to the challenges faced by teachers in their professional educational practices. As an example, Richardson *et al.* (1989) studied two elementary schools and investigated the reasons for teachers referring students for special education assessment. They concluded that often referrals are more a reflection of teacher stress and inadequate training than a result of the students they teach having an identified learning disability.

Tyler *et al.* (2004) suggest that general education teachers often interpret culturally diverse students' performance through European American middle-income normative parameters of competence. Because culturally diverse students' performance does not always align with such parameters, it is often regarded as deficient. In many cases, a deficit perspective perpetuates low expectations for ELL students by teachers, and likely contributes to the overrepresentation of ELLs in special education.

Summary and Conclusions

While progress has been made in reducing ELLs' overrepresentation in special education, it remains a problem. Few interventions have been designed specifically to address the linguistic and cultural needs of ELLs at both the pre-referral and service provision levels. Also problematic are teacher preparation programs and teachers' misunderstanding and misattribution of the needs of ELLs. These challenges have existed for nearly four decades and have not been comprehensively addressed. It appears that without significant changes in the special education system, the needs of ELLs will continue to be unmet.

Recommendations for Research and Practice

Significant changes are needed in order to meet the needs of ELLs. Particularly needed are strategies to address the needs of ELLs at the pre-referral stages and in special education. However, the issues are multidimensional (Rueda and Windmueller, 2006) and must be addressed from various avenues. It is critical to address the training needs of general education teachers at both in-service and preservice levels

so that they fully understand the needs of ELLs in their classroom. The language, cultural, and socioeconomic-related dimensions of students' experiences need to be considered in special education referral processes. This requires a significant overhaul of accreditation standards for teacher preparation programs so that colleges and universities are required to include comprehensive coursework and meaningful supervised preservice practice for all general and special education teacher candidates. This may help address the challenges associated with over-referral to the special education system. Training related to instructional strategies should be provided to effectively teach ELLs using culturally, linguistic, and developmentally appropriate practices. Training of special education teachers is needed in this area because statistics reveal that ELLs in special education are less likely to exit special education once placed in this system.

Additionally, assessments that are psychometrically appropriate for validly assessing ELLs are needed. Culturally and linguistically appropriate pre-referral strategies must be developed to address the RTI requirements of the new special education legislation so that ELLs can fully benefit from RTI approaches. The legislative mandates associated with monitoring disproportionality statistics and action plans associated with changing the disproportionality must be fully implemented (IDEA, 2004). These recommendations are critical for ELLs to be insured educational equity.

Functional Behavioral Assessment

J P Bakken, Illinois State University, Normal, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Antecedent – An event that precedes the behavior.

Assessment – The act of judging or assessing a person or situation or event.

Behavior – The manner in which one behaves; the actions or reactions of a person or animal in response to external or internal stimuli.

Consequence – An event that follows a behavior.

Discipline – Punishment inflicted by way of correction and training.

Intervention – This is provided to improve an academic or behavioral situation; it can also be referred to as strategies.

Observable – Capable of being or liable to be observed; noticeable; visible.

Functional behavior assessment (FBA) is a systematic method of “generating information on events preceding and following behavior in an attempt to determine which antecedents and consequences are reliably associated with the occurrence of the behavior” (Miltenberger, 1997: 563). FBA is the process of identifying the events that reliably predict and maintain problem behaviors before an intervention is determined (Scott *et al.*, 2003). The purpose of functional assessment information is to improve the effectiveness and efficiency of behavior support (Horner, 2000). Functional assessment is a key aspect of behavior intervention strategies mandated for IEPs by the 1997 and 2004 reauthorizations of IDEA. Though its primary research base comes from studies and clinical use with individuals with severe disabilities, such as mental retardation (cognitive disability) and autism, more recent uses of FBA have focused on a broader range of individuals with problem behavior, including individuals with mild or moderate disabilities or those at risk for such disabilities.

Because FBA produces no numerical score or other measures for comparison or ranking, the major purpose of FBA is to inform practitioners regarding effective intervention options. At the individual student level, this connection between FBA and effective intervention has been well documented in both general and special education settings (e.g., Blair *et al.*, 1999; Jones *et al.*, 2000; Lee *et al.*, 1999; Meyer, 1999). FBA typically involves first defining a student’s problem behavior, followed by identifying predictable antecedent and consequence events, and, finally, developing a testable statement or hypothesis

of the function that problem behavior serves for him/her (O’Neill *et al.*, 1997).

FBA is generally considered to be a problem-solving process for addressing student problem behavior. It relies on a variety of techniques and strategies to identify the purposes of specific behavior and to help IEP teams select interventions to directly address the problem behavior. FBA is likely to be more simplified and team-based, making use of questionnaires, checklists, and team-based discussions (Conroy *et al.*, 1999). In either case, analyses focus effectively on relationships between individual student’s behavior and the environment, including the time of day, location, context, curricula, teacher, peers, and all other potentially relevant stimuli (Ryan *et al.*, 2003). FBA gathers broad and specific information in order to better understand the precise reason for a student’s problem behavior. A component of the FBA is an analysis of the information that has been gathered that results in predictions or hypotheses of what maintains the behavior. FBA looks beyond the behavior itself. The focus when conducting a FBA is on identifying significant, pupil-specific social, affective, cognitive, and/or environmental factors associated with the occurrence (and nonoccurrence) of specific behaviors. This broader perspective offers a better understanding of the function or purpose behind student behavior.

According to IDEA, a student with a disability who has an Individualized Education Program (IEP) can be disciplined in the same manner as any other student for 10 consecutive school days or less if he/she violates the school’s code of conduct. If he/she is disciplined for more than 10 consecutive school days within the same school year, school or district staff must conduct an FBA and implement a behavior intervention plan (BIP) before the 10th day, or before moving him/her to an interim alternative educational placement. In many cases, a student with an IEP will already have a BIP in place as part of his/her IEP in order to support learning. In fact, a student’s IEP must include a BIP whenever his/her behavior impedes his/her own learning or the learning of others. For students at-risk of suspension or those suspended for less than 10 days, school districts should complete an FBA and develop a behavior support plan to prevent future suspensions. An FBA provides the IEP team with critical information, including (1) interventions which have been tried and their effects, (2) possible motivation(s) underlying the student’s behavior, and (3) whether instructional and behavioral supports being provided to the student are

working. Functional assessment helps educators to understand what function the problem behavior serves for the student. This enables them to determine interventions that reduce or eliminate specific problem behavior by replacing it with acceptable behavior that serves the same purpose or function for the student (e.g., teaching a student more acceptable ways to gain peer attention). This is the broad goal of this article.

Phases of FBA

There are two phases of FBA. Phase 1 is generating hypotheses about the purposes of a child's misbehavior. To generate hypotheses (or best guesses) about what purpose a child's misbehavior serves, a teacher or consultant collects information using data collection tools. The more information collected, and the more diverse the types of information collected, the more informed the hypothesis will be. The goal is to identify the emergence of any patterns in behavior. Therefore, teachers, parents, and the student may be interviewed as well as the teacher may observe the student at various times in the school day in various classes. Phase 2 is testing those hypotheses. To test the hypotheses (or confirm our best guesses) about the purpose served by the child's misbehavior, we must make some alteration to the environment or curriculum. This requires four steps: (1) defining the misbehavior using objective words (does not finish work, rather than, lazy), (2) counting the behavior over a period of days, (3) altering some aspect of the environment or curriculum, and (4) continuing to count the behavior to see if it decreases, stays the same, or increases during alteration. If it decreases like we thought it would, then our hypothesis is confirmed. If there is no change in the behavior, then we develop another hypothesis and test it.

Focusing on Behavior

The goal of functional assessment is to deal with inappropriate behavior. Educators and service providers want to (1) rearrange events that occur before a child misbehaves (antecedents) so that they now prompt the occurrence of appropriate behavior, (2) change the consequence that comes after a behavior occurs so that the consequences are more likely to reinforce a child for performing appropriate behavior, and (3) most importantly, teach the child a replacement behavior. A replacement behavior is an appropriate behavior that the child can perform that accomplishes the same goal as the inappropriate behavior. Without teaching a child a replacement behavior, meaningful, positive changes in behavior will be difficult, if not impossible, to obtain. Students need to be taught what to do and how to behave appropriately. It is the

responsibility of the teacher (and parent) to diagnose why the problem behavior is occurring and to teach a more appropriate behavior in its place.

Problem behaviors typically fall into one or more of three general categories: (1) behavior that produces attention and other desired events (e.g., access to toys, the computer, and other desired activities), (2) behavior that allows the person to avoid or escape demands or other undesired events/activities (e.g., getting out of homework, an oral presentation, or reading out loud), and (3) behavior that occurs because of its sensory consequences (e.g., feels good or relieves pain). Students will change their behavior only when it is clear that a different response will more effectively and efficiently result in a desired outcome. Identifying the purpose of problem behaviors (what the student gains, controls, or avoids through those behaviors) can provide information that is essential to developing instructional strategies and supports to reduce or eliminate behaviors that interfere with successful classroom performance or participation. When investigating student behaviors the team will need to judge the impact of the behaviors being exhibited (see **Table 1** for questions that can be used as a way for a team to judge the significance of the behavior exhibited by the student). The team needs to decide why the behavior is occurring. For example, if a student acts out when given an assignment in math, it may not be the assignment that caused the acting-out behavior, but the fact that the student does not know what is required (a skill deficit) and thus anticipates failure or ridicule. Information of this type may be gleaned through a discussion with the student or a review of information gathered in the FBA process. This is crucial because problem behavior can have an adverse effect on learning and physical safety of students and teachers. For this reason, the actions the student displays in response to problem behavior are critical. Whether these problem behaviors disrupt instructional routines (e.g., leaving class without permission, being loud, and talking out) or pose threats to the safety of teachers and students (e.g., destroying property and physical altercation), educators are responsible for implementing interventions to reduce these behaviors (Dukes *et al.*, 2007).

Table 1 Questions to Guide team members about their behaviors

Does the student's behavior significantly differ from that of his/her classmates?
Does the behavior lessen the possibility of successful learning for the student and/or others?
Have past efforts to address the behavior using standard interventions been unsuccessful?
Does the behavior represent a skill or performance deficit, rather than a cultural difference?
Is the behavior serious, persistent, chronic, or a threat to the safety of the student or others?
If the behavior persists, is some disciplinary action likely to result?

Collecting Data

Before an FBA can be conducted, it is necessary to pinpoint the behavior causing learning or discipline problems, and to define that behavior in concrete terms that are easy to communicate and simple to measure and record. If descriptions of behaviors are vague (e.g., bad attitude), it is difficult to determine appropriate interventions. By collecting and analyzing various kinds of information about behavior that significantly disrupts the teaching and learning process, school personnel are better able to select the most appropriate interventions. It is important to obtain information on the antecedent and consequent events (i.e., events preceding or following the behavior), and past events that may influence present behavior. The information gathered in this process will be utilized to develop interventions to change and/or modify behaviors of concern and to teach new behavior patterns.

An FBA is not only for the purpose of defining and eliminating undesirable behaviors but to understand the structure and function of those behaviors in order to teach and promote effective alternatives. To a large measure, an FBA is a flexible process that is implemented when a student continues to exhibit challenging behaviors after school, and class-wide supports have been implemented. In order to complete the FBA, a clear, observable, and measureable description of the behavior of concern must be developed. The description of the behavior should include the following items: frequency (number of times), duration (how long), intensity (how often), the time between the trigger event and the behavior of concern (latency), and a description of the context in which the behavior occurs (e.g., people, setting events, activity, time, level of student participation, place, and expectations; see **Table 2** for some sample definitions).

Assessing Behaviors

It is crucial that multiple means are used to collect information about a behavior. This might include a review of student records as well as an evaluation of a sample of

the student's academic products (e.g., homework, in class assignments, and exams). In addition, the team will want to use various observation procedures, questionnaires, and interviews (e.g., teacher, parents, student, and bus driver). The team needs to decide what tools will help to better understand the causes of a specific behavior problem. Several different rating scales have been developed to try and get to the function of the behavior; however, reliability is usually poor. These scales should only be used as a starting point for systematic and direct observation of a person's behavior.

Relying strictly on interviews and rating scales should never be considered a functional assessment. A more reliable method involves directly observing the person's behavior in his/her natural environment and analyzing the behavior's antecedents (environmental events that immediately precede the problem behavior) and consequences (environmental events that immediately follow the problem behavior). Specific techniques include the record review, the scatterplot, and the ABC Observation Form. The record review is a process that can be used to gather information about a student's developmental and educational history (e.g., medical, social/emotional, communication, academic, career, and cognitive), history of the behaviors of concern, and the impact of previous interventions and supports. The purpose of a scatterplot is to identify patterns of behavior that relate to specific contextual conditions. A scatterplot is a chart or grid on which the observer records single events (e.g., number of student call outs) or a series of events (e.g., teacher requests and student responses) that occur within a given time frame (e.g., at lunch, at recess on the playground, and during teacher led reading instruction). Another way to observe student behavior is with an ABC Observation Form (Antecedent-Behavior-Consequence). This approach allows an observer to organize anecdotal or descriptive information on the student's interactions with other students and adults in such a way that patterns of behavior become clear. Possible tools to use for interviews or informant data collection are listed in **Table 3**. This is not an exhaustive list; therefore, one may have or use additional tools that would be appropriate.

Analyzing Data

Following data collection, data analysis is the next component of the FBA process. This analysis of information results in the formulation of predictions of what maintains the behavior and when and where the behavior will and will not occur (see **Table 4** for the questions the analysis should answer).

Clearly, one way to reach the conclusion about a behavior is to use a graphic tool. Using a graphic tool can help the team analyze all the compiled information.

Table 2 Example definitions of behavior

<i>Problem behavior</i>	<i>Concrete definition</i>
Doug is aggressive	Doug hits others during recess when he doesn't get his way.
Juan is disruptive	Juan makes irrelevant and inappropriate comments during class discussions.
Felipe is hyperactive	Felipe leaves his assigned area without permission, completes only parts of his independent work, and calls out answers without raising his hand.

Table 3 Data collection examples

<i>Tool</i>	<i>What it is</i>	<i>What it does</i>	<i>Uses</i>
Antecedent Behavior Consequence (ABC)	Direct observation tool. Specific event analysis. Can be analyzed from a videotape segment.	Determines what happens before a behavior occurs, what the behavior looks like during the event, and what happens after the behavior occurs.	Use when analyzing specific conditions that may be triggering or maintaining behavior.
Functional Assessment Observation Form	Direct observation tool. Multiple event recording log.	Provides information regarding predictor events, consequences, frequency, perception about how the function of the behavior is maintained, the time the behavior occurs, and patterns of behavioral occurrences.	Use when behavior occurs at a moderate to high frequency (25 times per day). Can be used with lower frequency behaviors when used as a time sampling tool.
Functional Assessment Interview	Informant interview tool.	Provides information about events that influence problem behavior.	Use when identifying settings, events, and activities.
Motivational Assessment Scale	Informant tool-analysis of specific behavior which can be used for multiple events.	Determine desired outcome or function behavior serves, interactions that are occurring, behavior patterns.	Use when developing hypotheses about behavior.
Scatterplot Analysis	Direct environment observation recording tool.	Charts baseline of information about the occurrence of the behavior within specific time increments and activities.	Use when determining when the behavior does and does not occur.
The Instructional Environmental System II	Informant/ecological observation tool multiple checklists and interview formats. Emphasis on general education classroom environment and curriculum.	Provides parent, teacher, and student perceptions about learning environment interactions and expectations. Additionally provides a direct observation format for collecting academic and behavioral data.	Use when there is a need to understand the multiple influences on a student's performance.

Table 4 Questions to answer related to the data

In which settings does the behavior occur and not occur (playground, classroom)?
What are the times when the behavior does/does not occur (during English, just prior to reading)?
Who are the individuals present when the behavior is most/least likely to occur (substitute teacher, certain students)?
What are the conditions when the behavior does/does not occur (during free play, unstructured time, in small groups)?
What activities take place prior to the behavior of concern?
What are the events or conditions that typically occur after the behavior occurs (student sent to the office)?
Who interacts with the student following a behavioral incident?
Is the student recognized when behaving appropriately?
Is there communication of expectations to the student?
Are instructions and directions for activities clear and concise?
Are the task requirements appropriate?
Does the student like or dislike the task?
Are tasks too difficult? Or too easy?
Is the physical structure of the environment appropriate?
Is an adequate level of assistance provided in order for the student to complete tasks?
Can the student communicate his/her wants and needs?
Are there medication/health concerns or needs?
Do others inadvertently reinforce the problem behavior?

This tool, called a data triangulation chart or a data triangle, provides a framework on which the team can pull together and visually compare information collected from various sources (e.g., interviews, scatterplots, and ABC charts).

Behavior Interventions

An FBA provides critical information to identify the most appropriate and relevant possible behavior interventions. This is the process of determining the cause (or function) of behavior before developing an intervention. The intervention must be based on the hypothesized cause (function) of behavior. Failure to base the intervention on the specific cause (function) very often results in ineffective and unnecessarily restrictive interventions that do not improve the problem behavior. As part of creating success, the hallmark of effective function-based behavior intervention is effective instruction (Scott *et al.*, 2001; Scott and Nelson, 1999). Effective instruction begins to identify an appropriate intervention to reduce the problem behavior. Instruction must teach the student a more appropriate way to achieve the same desired outcome.

Instruction begins with a rationale for the skill and includes clear expectations, modeling with auditory and visual examples, guided practice, independent practice, and constructive feedback (Greenwood, 2001; Lloyd *et al.*, 1997; Swanson and Hoskyn, 2001). FBA is not a simplistic event or activity. To date, questions remain about the feasibility of school-based personnel acquiring the knowledge in the FBA process and subsequently using the process to develop behavioral interventions (Scott *et al.*, 2005). Many research teams have directly compared the effects of interventions derived from FBA results to interventions selected without this information in general education settings. Results in all five studies showed little to no improvement in behavior for the non-FBA interventions and powerful effects for plans designed based on FBAs (Filter and Horner, 2006; Ingram *et al.*, 2005; Newcomer and Lewis, 2004). This research supports the use of interventions designed based on FBA results and should be developed this way.

Although the interventions teachers choose to change problem behavior are varied, they are not always effective. Ishii-Jordan (2000) found that teachers frequently select punitive interventions (e.g., threats and punishment) for students when they display behaviors that interfere with teacher routines, regardless of whether the interventions actually change the problem behavior. Unfortunately, teachers react without thinking (many times) and actions to decrease problem behaviors may actually promote or reinforce those behaviors. Critics argue that simple contingency-based interventions (rewarding desired behavior and punishing problem behavior) are unlikely to be effective with sophisticated students who engage in complex problem behavior. The state of technology for supporting students has moved away from simple consequence manipulation to more comprehensive plans that also include antecedent-based interventions designed to prevent problem behaviors (Kern *et al.*, 2002), teach functional alternative skills (O'Neill *et al.*, 1997), and promote strategies that generalize to contexts where there is no possibility of adult-delivered punishers or reinforcers (Kern and Dunlap, 1999).

Conclusion

This article began by introducing and defining FBA. Next, it discussed phases of FBA. Behavior-related data collection and analysis are discussed; and finally, interventions developed as a result of FBA are highlighted. Clearly, today's complex society calls for new ways of doing things. FBA is one critical way to discover behavior problems and intervene as needed and appropriately.

History of Special Education

L M Garrick Duhaney and S J Salend, State University of New York at New Paltz, New Paltz, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

The term special education appears to have been first used publicly by Alexander Graham Bell at a National Education Association meeting in 1884 (Winzer, 1998). However, the field of special education emerged before that event and has a long and dynamic history that has been influenced by an amalgam of international, philosophical, political, economic, legal, and sociocultural factors (Fleischer and Zames, 2001; Giordano, 2007). Although the history of special education reveals many changes (Osgood, 2007; Reynolds, 1989), it has been shaped by ongoing challenges, successes, and debates related to: (1) the purposes of special education (custodial care vs. education and segregation vs. integration); (2) the groups to be served (individuals with biologically based disabilities vs. individuals with socially constructed disabilities); (3) the identification of effective pedagogical practices and related services; and (4) the impact of special education on individuals with disabilities. While distinct from the history of people with disabilities, the history of special education also has been impacted by the ways individuals with disabilities have been treated and perceived by the larger society and culture (Smith, 1998; Winzer, 1993).

Special education today has evolved into the delivery of research-based instructional and assessment practices and related services specifically designed to promote educational, social, behavioral, and physical developments of persons with disabilities (Heward, 2006). This article outlines the main events, factors, and movements that have influenced the development of special education from its philosophical origins as a care-taking enterprise focused on deaf and blind individuals to its transformation to serving individuals with a wide range of disabilities and being an integral part of the educational system in many parts of the world.

The Origins of Special Education

Although very little record existed about persons with disabilities prior to the 1700s, by all accounts deviations from what was considered normal by society were subject to harsh and inhumane treatment, ostracism, and even death (D'Antonio, 2004; Winzer, 1993, 1998). This, however, began to change in the sixteenth and seventeenth centuries as rational philosophical beliefs about human dignity started to impact societal perceptions of individuals with disabilities and ways to educate them (Winzer, 1998). Earliest among those who tried to improve the lives of

people with disabilities were pioneer special educators and advocates who wrote about their students, their approaches, and their failures and successes (Winzer, 1993).

Philosophical Underpinnings

In the 1500s and 1600s, the education of individuals with disabilities was mainly driven by those in pursuit of philosophical knowledge (Winzer, 1993). France, where many phenomenal efforts to educate the disabled began, experienced increased philanthropic efforts related to beliefs about the essence of human nature, human reason, human rights and dignity, and self-sufficiency. This intellectual movement referred to as the Enlightenment, raised questions about conventional notions regarding sociopolitical structures and called for an egalitarian and just society that acknowledged the rights of all of its citizens (Knight, 1968; Safford and Safford, 1996; Winzer, 1993).

In England, emerging philosophical beliefs also motivated better treatment of individuals with disabilities and increased efforts to educate them (Winzer, 1993). Pioneering work on the origin and development of language led to further research by members of the Royal Society of London, a group of intellectuals and scholars (Winzer, 1998). These efforts culminated in the publication of a book by John Wallis that described the origins of language and served as an important resource guiding the education of deaf individuals (Hoolihan, 1985; Winzer, 1993).

Initial Focus on the Deaf

The earliest efforts to provide special education focused on deaf individuals (Best, 1930; Winzer, 1998). In mid-sixteenth-century Spain, Pedro Ponce de Leon, a Benedictine monk, developed oralism, which emphasized the teaching of lip-reading and speech to communicate rather than the use of signed communication, to teach wealthy deaf individuals to speak in order to obtain their inheritance (Buchanan, 1999; Burch and Sutherland, 2006; Lane, 1989; Winzer, 1998). The growth in oralism, which became the prevailing method used in deaf schools from the 1890s to the 1920s, also was supported by the original pedagogical work of Jacob Rodrigue Péreire who was considered one of the first deaf educators in France (Burch and Sutherland, 2006; Winzer, 1998). Later, the French priest Michel Charles de l'Épée who opposed Péreire's pedagogical efforts, promoted the belief that

the use of written characters and sign language was the best way to teach the deaf, which also contributed to sign language being the dominant vehicle for deaf education during the first-half of the 1800s (Winzer, 1998). Encouraged by European success in educating deaf persons, Thomas H. Gallaudet studied these methods in Europe and in 1817 established the first institution for the deaf in Hartford, Connecticut, United States of America (Osgood, 2005).

Focus on the Blind

Building on the successful efforts to educate deaf individuals, special education began to focus on the plight of the blind (Winzer, 1998). In 1784, Valentin Haüy founded the Paris Blind School and employed raised print and embossed books to teach blind students (see Winzer, 1998). In 1829, Louis Braille, who attended the Paris Blind School earlier in his life, developed his raised-dot method for reading and stylus for writing. Braille's method led to the establishment of a tactile alphabet that enabled blind individuals to read and to become more integrated members of French society (Koestler, 1976).

Effective efforts to teach blind individuals in Europe were exported to North America by advocates of the disabled (Winzer, 1993). After studying in Paris, Dr. John D. Fischer, started the New England Asylum for the Blind in 1829, which was later renamed the Perkins Institute for the Blind and is now called the Perkins School for the Blind (Fleischer and Zames, 2001; Winzer, 1993). Samuel Gridley Howe, who was appointed as the first director of the institution, worked with Laura Bridgman, a deaf-blind student. Howe successfully taught Laura Bridgman using a method that built on her ability to identify letters by distinguishing shapes, which challenged conventional beliefs that deaf-blind persons were uneducable. The successes of Howe and Bridgman also served to set the stage for the subsequent achievements of Helen Keller, a girl who was deaf and blind, and her teacher Anne Mansfield Sullivan, herself a former student at the Perkins Institute (Osgood, 2005; Smith, 1998).

The Rise of Specialized Interventions, Schools, and Institutions

There were dramatic changes in the field of special education that were related to competing beliefs about the extent to which individuals with disabilities should be feared, segregated, categorized, and educated. Whereas earlier efforts focused initially on the deaf and then the blind, the field of special education began to address issues related to individuals with cognitive disabilities. As a result, many institutions and specialized schools began to crop up and directed placement and institutional efforts.

Institutionalization

Driven by society's restrictive perceptions and fears of individuals with disabilities, particularly those persons with cognitive and emotional and behavioral difficulties, the mid-nineteenth century saw the rise of institutions and asylums for individuals with disabilities (Armstrong, 2002). Although some institutions attempted to offer educational and vocational training programs and moral and religious training (Giordano, 2007), most of these settings viewed special education as mainly having medical, vocational, and custodial purpose and serving as a means to isolate, rehabilitate, and control disabled and defective individuals who were viewed as threats to society (Armstrong, 2002; Humphries and Gordon, 1992; Winzer, 1998). In response to the humanitarian, legal, and fiscal concerns associated with institutional settings, community-based day-care and occupation centers that provided care and minimal manual and vocational training also were established (Giordano, 2007; Read and Walmsley, 2006).

Specialized Interventions, Schools, and Classes

Although institutional settings played an important role until the 1970s, the early and mid-nineteenth century and the beginning part of the twentieth century also saw the rise of specialized interventions, schools, and classes for students with disabilities in North America and Western Europe (Read and Walmsley, 2006). French physician, Jean-Marc-Gaspard Itard's work in the early 1800s with Victor, the wild boy of Aveyron, France, gained much attention. Itard described this boy as "indifferent to everything and attentive to nothing" (see Safford and Safford, 1996). This work became considered as a watershed in the development of the field of special education (Safford and Safford, 1996). Itard implemented a specialized instructional program with Victor, that fostered his cognitive and language learning and showed that individuals previously considerable uneducable could learn (Safford and Safford, 1996). Itard's successes also led other European scholars and educators (Hinshelwood, 1900; Ireland, 1877; Morgan, 1896) to publish works that presented a set of pedagogical practices for special education. The first and most influential of these publications was Édouard Seguin's *Treatise on Idiocy*, which presented unique instructional principles, strategies, and devices that served as a pedagogical model for educating individuals with disabilities (Giordano, 2007).

The writings of Itard, Seguin, and other European educators served to change society's perception of the degree to which people with disabilities could be educated and fostered, and informed efforts to provide special education via specialized schools and classes (Giordano, 2007). In addition, their work helped promote the passage of several laws related to education of students with disabilities. In the

early 1900s, France passed a law calling on local schools to institute special improvement classes for students with learning difficulties that were connected to schools serving children without disabilities (Armstrong, 2002). In 1913, Great Britain adopted the Mental Deficiency Act which established policies for defining and educating individuals with disabilities and identified the educational and governmental agencies responsible for meeting their needs (Giordano, 2007). In the long run, these laws motivated advocates of special education throughout the world and served as the forerunners of the 1970s legislation that would guarantee the educational rights of students with disabilities.

The Establishment of Advocacy Groups

The establishment of specialized schools and classes and legal initiatives in Europe, prompted families and professionals to form groups to advocate for increased educational opportunities for individuals with disabilities (Yell *et al.*, 1998). These groups included the Council for Exceptional Children, a professional organization that was founded in 1922, and the Cuyahoga County Ohio Council for the Retarded Child, one of the first coalitions of families established in 1933. Advocacy groups were successful because (1) parents got involved in the education of their children, (2) there was an increase in research on deviant behaviors, and (3) changes began to occur in teacher-preparation programs.

Intelligence Testing

The progress in educating individuals with disabilities was thwarted by the advent of intelligence testing in the early twentieth century as it led to an emphasis on more rigid notions of normality (Armstrong, 2002; Safford and Safford, 1998). Thus, intelligence testing helped promote not only the labeling of students with lower IQs as feeble minded, mentally defective, and deviant, but also the belief that these individuals were uneducable and should be segregated from others and exempted from compulsory education laws (Read and Walmsley, 2006; Yell, *et al.*, 1998). The view of intelligence as providing a genetic basis for the school success of different groups coupled with the beliefs that individuals with inferior intelligence and morality would undermine society also contributed to placement of individuals with disabilities in institutions and to the promulgation of the Eugenics movement (Bursztyn, 2007; Humphries and Gordon, 1992).

Skeels' and Dye's Research

Views of individuals with disabilities as uneducable were questioned when Skeels and Dye (1939) published landmark research that showed that children with mental retardation benefited from having a stimulating environment.

This study, coupled with related longitudinal studies, served to establish education rather than custodial care as an important purpose of special education programs. In addition, the work of Skeels and Dye demonstrated the potential of early intervention and the need to document empirically educational interventions used with students with disabilities (Morse, 2000).

The Legalization and Transformation of Special Education

The contemporary period has been marked by significant changes and growth in the field of special education (Winzer, 1993). This period has been characterized by political advocacy, which has led to the legalization of the field of special education. In turn, special education has been transformed into an integral part of the educational system and a vehicle for promoting the inclusion of the individual with disabilities into the larger society.

The Civil Rights Movement and Brown v. Topeka Board of Education

In the early 1950s, the legal precedent for much of the special education-related litigation and legislation in the United States that fueled the growth of special education was established by the civil rights movement and the 1954 case of *Brown v. Topeka Board of Education* (Blanchett *et al.*, 2005). The Supreme Court decision in this landmark civil rights case refuted the doctrine of separate but equal. The decision served as the basis for both the subsequent legal actions brought about by families to ensure that their children with disabilities received a free appropriate public education (FAPE) and the movement toward educating students with disabilities in public schools with their classmates without disabilities (Blanchett *et al.*, 2005; Morse, 2000).

Special-Education-Related Court Cases

Following the legal precedents established in *Brown v. Topeka Board of Education*, court decisions have affirmed and expanded the educational rights of individuals with disabilities. The historic outcomes in *Pennsylvania Association for Retarded Children (PARC) v. Commonwealth of Pennsylvania* 1972 established the right of individuals with disabilities to an appropriate education and gave parents of children with disabilities procedural safeguards regarding the education of their children (Hulett, 2009; Yell, 2006).

The courts also addressed issues that advanced equal educational opportunities for individuals with disabilities from culturally and linguistically diverse backgrounds in

cases such as *Diana v. California State Board of Education* (1970), *Lau v. Nichols* (1974), and *Larry P. v. Riles* (1979) (Baca and Cervantes, 2004). The consent decree in *Diana v. California State Board of Education* established that identifying Mexican-American students for placement in special education on the basis of culturally biased intelligence tests was inappropriate and should be modified to include the use of nonverbal tests, the elimination of culturally biased testing, and the administration of tests in students' primary languages. *Lau v. Nichols* extended the right to equal educational opportunity to include bilingual special education services and language programs for speakers of languages other than English and in *Larry P. v. Riles*, the court questioned the use culturally biased intelligence tests that resulted in a disproportionate number of African American students being placed in special education.

Several court cases focused on the placement of individuals with disabilities in the least-restrictive educational environment including *Daniel R. R. v. State Board of Education* (1989), *Sacramento City Unified School District Board of Education v. Rachel H.* (1994), and *Oberti v. Board of Education of the Borough of Clementon School District* (1993) (Hulett, 2009). *Daniel R. R. v. State Board of Education* established a two-prong test for determining students' placement in the general education classrooms. These are: (1) whether students can be educated in the general education classroom with supplementary aids, and (2) whether students have been included in the general education classroom to the maximum extent appropriate (Lipton, 1994). Similarly, *Oberti v. Board of Education* set forth the principle that placement in general education classrooms with instructional accommodations must be tried prior to placing students in segregated settings (Murdick *et al.*, 2007; Yell, 2006).

Advocacy and the Disability Rights Movement

In the 1960s and 1970s, the successes of the civil rights movement fostered a period of acceptance and possibilities, which led groups of individuals with disabilities, family members, and professionals to continue to form advocacy groups to overcome discrimination, segregation, and marginalization, and seek equity, opportunity, and inclusion (Giordano, 2007). Many of these groups were guided by the principle of normalization, which originated in Scandinavia, and called for the provision of educational, housing, employment, social, and leisure opportunities, for individuals with disabilities, that resemble as closely as possible the opportunities and activities enjoyed by individuals without disabilities (Wolfensberger, 1972). Advocacy efforts of these groups served as the foundation for the disability rights movement and the creation of a disability culture and disabilities studies, which affirmed and celebrated disability, and challenged society's

conventional notions of disability and the best ways to educate individuals with disabilities (Fleischer and Zames, 2001; Burch and Sutherland, 2006).

Special-Education-Related Legislation

Advocacy groups pushed for public policies that led to legislative actions intended to guide the delivery of a comprehensive set of special education services and provide individuals with disabilities with greater access to society and the public schools (Giordano, 2007; Yell, *et al.*, 1998). The enactment of the 1970 Education (handicapped children) Act in England, the *Loi d'Orientation en Faveur des Personnes Handicapées* in France in 1975, and the Education for All Handicapped Children Act in the United States in 1975 (which was renamed the Individuals with Disabilities Education Act (IDEA)) provided students with disabilities, access to public schools (Armstrong, 2002). The IDEA also mandated that students with disabilities be educated in the least-restrictive environment (LRE) and have an individualized educational plan (IEP) that guides the delivery of special education services.

International Actions

The work of advocacy groups and the passage of special education related legislation also prompted international actions that reflected a global commitment to disability rights and inclusive education (Forlin, 2008). At the World Conference on Special Needs in 1994, 92 countries and 25 international organizations endorsed the Salamanca statement, which called for the development and implementation of general education programs that educate all children and youth together. Since the adoption of the Salamanca statement, countries throughout the world have implemented various inclusive education initiatives that have been based on each country's educational philosophy and history as well as a range of social, political, cultural, and economic factors (Alur and Bach, 2008; Brown, 2005; Fletcher and Artiles, 2005; Heng and Tam, 2006; Mitchell, 2005; Mitchell and Desai, 2005). In many countries social justice and multicultural education are viewed as being inextricably linked to inclusive education, which has broadened the focus of inclusive education beyond disability to include issues of race, linguistic ability, economic status, gender, learning style, ethnicity, cultural, and religious background, family structure, and sexual orientation (Mitchell, 2005; Slee, 2005; Verma *et al.*, 2007). Building on the Salamanca statement, in 2008, the United Nations adopted a landmark pact that promotes the inclusion of individuals with disabilities throughout the world by providing them with equal access to educational, employment, and social opportunities.

Socially Constructed Disabilities and Overidentification Concerns

The passage of laws mandating the education of students with disabilities contributed to a significant increase in the numbers and noteworthy changes in the types of students served by special education. These developments were fueled by the creation of socially constructed disability categories such as emotionally disturbed and learning disabilities (Armstrong, 2002), a term that was initially used by Kirk and Bateman (1962) to describe students without sensory, physical, or severe cognitive disabilities who performed poorly in school. The creation of socially constructed disabilities and the use of unreliable tests and procedures to identify students with disabilities led to growing concerns about the overidentification of students, the disproportionate representation of students from culturally and linguistically diverse backgrounds (Artiles *et al.*, 2005; Obiakor, 2007; Ortiz, 1997), and the need for new models for identifying, assessing, categorizing, placing, and teaching individuals in need of special education (Fuchs and Fuchs, 2006; Mercer, 1973).

Inclusion in a Least Restrictive Environment

Concerns about the growth and segregated nature of special education were voiced by Lloyd Dunn (1968) in the late 1960s when he argued that special education classes for students with mild disabilities were unjustifiable because they served as a form of homogeneous grouping and tracking and limited these students' academic, social, and behavioral developments. Ongoing research questioning the efficacy of segregated special education programs beginning in the 1960s (McLeskey, 2007), legislative and judicial actions, and advocacy groups also prompted the field of special education to initially focus on mainstreaming, the regular education initiative (REI), and then the implementation of inclusion programs that educate all students together in the general education classroom (Osgood, 2005; Salend, 2008). Inclusion is a relatively recent movement and therefore, research that examines its implementation, effectiveness, and long-term impact continues to be a challenge for the field (Sindelar *et al.*, 2006). Clearly, the driving force behind inclusion is the LRE, the mandate of the law.

Distinctive and Empirical Pedagogy

Consistent with the field's legacy of searching for effective practices, this contemporary period has experienced a concerted effort to identify a distinctive and empirically based pedagogy (i.e., evidence-based method) associated with the field of special education (Giordano, 2007). The 1960s and 1970s saw controversies over effective models (e.g., the medical model vs. the behavioral model) and pedagogical practices (e.g., perceptual and modality training,

dietary changes, and motor patterning) (Mostert and Crockett, 2000; Van Acker, 2006). The inclusive education movement led special education researchers to debate the efficacy of general education placements for students with disabilities (McLeskey, 2007) and to examine culturally responsive instructional practices (Obiakor, 2007). The technological advances of the late twentieth and early twenty-first centuries also resulted in the development of a wide range of assistive and instructional technologies that have become integral parts of special education practices and transformed notions of disability (Blackhurst, 2005; Edyburn, 2003). The growing body of research on effective pedagogical practices have inevitably led to the rise of special education teacher education programs designed to increase the quantity and quality of educational personnel who work with students with disabilities (Kleinhammer-Tramill and Fiore, 2003).

Conclusion

Viewed through historical lenses in Western Europe and North America, the field of special education has an extensive and vibrant past that has been fashioned by a myriad of philosophical, sociopolitical, economic, and legal factors intricately tied to society's treatment of individuals with disabilities. Marked by ongoing debates about purposes, groups served, effective practices, and outcomes, the field of special education has experienced periods of rapid expansion and has evolved from merely care and segregation to education and inclusion. However, since much of the recorded history related to special education has focused on developments in Western Europe and North America and has been written from the perspectives of professionals, historical accounts from other parts of the world and from the viewpoints of individuals with disabilities would enrich the field of special education by broadening our collective understanding of the field's past roots, connections to present practices, and implications for future development.

Inclusion of Students with Special Needs in General Education Classrooms

M A Prater, Brigham Young University, Provo, UT, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Access to the general-education curriculum –

The meaningful interaction with instruction and curriculum used in general education by all students. It is also interpreted to include access to school activities such as lunch and recess breaks, as well as extracurricular activities.

Inclusion – In the context of schooling, a belief or philosophy that all students should be included in the general-education classroom and have access to the general-education curriculum.

Least-restrictive environment – A legal principle that students with disabilities are to be educated with students without disabilities to the maximum extent possible.

Mainstreaming – A common term for including students with disabilities in the general-education classroom to the extent possible.

In the context of schooling, inclusion is a belief or philosophy that all students should be included in the general-education classroom and have access to the general-education curriculum. Some professionals differ, however, in what is meant by all students; some add the phrase, all students to the extent possible. This allows for those with very specialized needs, such as those with chronic and significant behavioral problems, to receive services outside of the general classroom.

Some professionals distinguish between the terms inclusion and full inclusion. Full inclusion means literally all students are included with their typically developing peers regardless of services they may need; and inclusion means all students are included in general education to the extent possible. In full inclusion, services are brought to the student in the general classroom, rather than the student being removed from the classroom to receive such services. Therefore, if the student cannot meet expectations of the general classroom, these expectations are altered rather than the student removed to a different setting. Inclusive schools welcome all students and view the education of all students as the responsibility of all educators.

Historical Perspective

In the United States, prior to the passage of P.L. 94-142 in 1975 mandating education for students with disabilities, students could be denied access to public education due to their disabling condition. In 1990, the law was re-authorized as the Individuals with Disabilities Education Act or IDEA. To help compensate for previous neglect, the principle of least-restrictive environment (LRE) was included in the legislation. LRE meant that students with disabilities were to be educated with students without disabilities to the maximum extent possible. LRE is considered to be a placement issue. Removing students with disabilities from the general educational environment was to occur only when the nature or severity of the disability was so great that supplementary aids and services in general classrooms were insufficient. Putting LRE into practice implied that school districts must provide a continuum of services for students with disabilities. This continuum of services included teaching students with disabilities solely in general-education classrooms to students confined to their home or a hospital and everything in between. Students with disabilities, therefore, could be pulled out of general classrooms for portions of the day or educated in separate classrooms or special schools. The decision about where to educate a student was designed to be an individual decision based on where the needs of the student could best be met.

Although the term, mainstreaming, was never adopted in the US laws governing special education, soon after P.L. 94-142 was enacted, the term became synonymous with educating students with disabilities with their nondisabled peers whenever possible. Often such mainstreaming occurred in nonacademic classes such as art, music, and physical education while students were still segregated for academic or life-skills instruction. Even though students with disabilities were now entitled to a free, appropriate, public education, many were segregated from their typical peers all day or for a portion of the day. Many professionals and parents began to question the assumption that students who need more intensive services should be segregated to receive those services. They believed that if students' needs cannot be met in a traditional academic classroom, then the classroom should change, not the student removed from that setting. Earlier in 1986, Madeline Will, then assistant secretary of the Office of Special

Education and Rehabilitative Services in the US Department of Education, called for general and special educators to share responsibility for teaching students with disabilities. This was referred to as the regular-education initiative (REI). The REI was based on several arguments, namely: (1) students with disabilities are more alike than different from their typical peers; (2) all good teachers can teach all students, and (3) segregation is inherently inequitable and discriminatory. In all, the REI helped set the stage for the inclusion movement.

The reauthorization of IDEA in 1997 also moved inclusion forward. The reauthorization required that students with disabilities have access to the general-education curriculum. Access, as defined here, meant that students had to have meaningful interaction with the curriculum in order to learn. Clearly, access to the general curriculum required barriers be removed that may inhibit students' access, as well as additional supports provided to help them actively engage with the curriculum. The general-education curriculum was also interpreted as moving beyond instruction and materials to full school day's events including extra-curricular activities. The meaning of inclusion went beyond a placement of students with disabilities into general classroom. It was now defined as an educational outcome for students with disabilities. The most recent legislation to impact inclusion in the US was the No Child Left Behind Act of 2001 and the reauthorization of IDEA in 2004 as the Individuals with Disabilities Education Improvement Act (IDEIA). These laws mandated alignment of general-education standards with academic content for students with disabilities. This created underlying tension between being able to meet general-education standards and at the same time accommodate the individualized needs of students with disabilities. Under these laws, general education also became accountable for the academic gains made by all students, including those with disabilities.

Other education reform and social movements, such as normalization and deinstitutionalization, helped lay the foundation for the inclusion movement. The principle of normalization began in Scandinavia and was later brought to the United States. Under the normalization principle, opportunities, interactions, and experiences that parallel those of society were promoted for individuals with disabilities. This principle extended beyond educational opportunities. Individuals with disabilities were thought to be entitled to the same, for example, recreational, leisure, transportation, employment, and housing opportunities. As indicated, deinstitutionalization also impacted the inclusion movement. Reports of abusive conditions in institutions that housed individuals with disabilities resulted in their closure; and smaller, community-based living arrangements were developed. Inclusion in these contexts goes beyond education to mean inclusion of individuals with disabilities in society at large.

Pros and Cons of Inclusion

The arguments in favor of inclusive education have been based on legal, moral, educational/social, and political grounds. Proponents using the legal or civil rights' perspectives argue that segregating students is antithetical to basic human rights. All individuals, including those with disabilities, have the right to receive the same educational opportunities. Others take an ethical and moral perspective and contend that professionals serving students with disabilities, regardless of the students' needs, have a moral and ethical obligation to keep them with their typical peers. Proponents using the moral argument contend that the practice of inclusion does not require empirical support. The educational/social argument is based on the claim that those with disabilities experience developmental, educational, and social benefits. The educational/social argument also asserts that inclusion is a positive experience for teachers and typically developing peers. Teachers' professional skills improve as a result of teaching in inclusive classrooms; and peers develop more positive attitudes toward those with disabilities which increases the likelihood that those with disabilities will be accepted as equal members of society. The educational/social argument can and has been examined empirically. A summary of the results of these studies are summarized later. The last argument is political. Educating students with disabilities is expensive and costs continue to rise. Some policymakers and administrators view special education as financially draining the rest of the educational system and from their perspective one solution is to discontinue educating students with disabilities in segregated placements requiring expensive equipment and personnel. This last argument, however, goes counter to the legal mandates and experience shows that inclusion, if done properly, is not less expensive.

Opponents of inclusive education are generally concerned about the impact that inclusion has on teachers, students, and/or schooling in general. For example, they contend that general-education teachers have neither been adequately prepared nor should they be expected to work with such a wide range of student needs. Under the current wave of standards reform, teachers are increasingly accountable for the academic gains of all students for whom they are a teacher on record. Including students with disabilities in their classrooms increases general educators' teaching loads and stress levels. Many are concerned that general educators will be reprimanded if students in their classroom do not meet, for example, annual yearly progress as mandated by the No Child Left Behind Act. Concern about the role of the special educator in an inclusive model has also been raised. Traditionally, special educators were prepared to teach students with disabilities in segregated settings. With inclusion, the special educator's

role has evolved to a consultant and/or co-teacher; and, opponents argue, co-teaching often results in the special educator becoming an overly paid instructional aide to the general educator. Others argue against inclusion because they believe it will have a negative impact on students without disabilities. They believe general educators' attention to those with disabilities will leave other students' needs neglected. In addition, they believe inclusion can never meet individual needs of those who require extensive services. Opponents express concern that schools have jumped on the inclusion bandwagon before proper systemic changes have taken place; and some argue that school-wide support and systemic change required to implement inclusion are unrealistic expectations.

Implementation of Inclusion

To be considered inclusive, schools must be physically, socially, and instructionally integrating students with disabilities. That is, students with disabilities are physically placed in the same classroom as their typical peers, social relationships between students with and without disabilities are fostered, and all students are taught using the same curriculum. Students with disabilities are supported by teachers modifying instruction and how learning is measured. For students with significant disabilities, instruction is anchored in the general curriculum but expectations are appropriately adjusted (Friend and Bursuck, 2006). Typically, how schools implement inclusion varies. If full inclusion is endorsed by a school, then students with disabilities would be dispersed across all classrooms to best represent the proportion of disabilities found in the general population. Some schools, however, prefer to designate specific general-education classrooms as inclusion classrooms. In these schools, students with disabilities may be clustered within several general-education classrooms. In some inclusion models, general educators and special educators co-teach in the inclusive general-education classrooms. In other models, the special educator acts as a consultant to the general-education teacher. Regardless of the special educators' role, the following instructional strategies are generally used to implement inclusion: (1) differentiated instruction, (2) interdisciplinary curriculum, (3) technology, (4) student collaboration/peer-mediated instruction, (5) cooperative learning groups, (6) partner learning/peer tutoring, and (7) personal supports and accommodations (Villa *et al.*, 2005).

Inclusion is most prominent in preschool and early elementary grades. As children age and skill levels widen between those with disabilities and their typically developing peers, implementing inclusion becomes more difficult. Thus, the challenge of full inclusion is perhaps greatest at the high school level. In high school, academic

courses are highly academic within specialized disciplines, the number of classes in which students are enrolled increases, and the student to teacher ratios are higher. Clearly, implementing inclusion is not easy. The entire school must commit to major changes and these changes must be supported by all stakeholders, including district personnel, school boards, and family members. Some resistance is to be expected. Schools must be empowered to manage their own change and find the model that best fits their needs. No one inclusion model fits all schools, and the development of an inclusive school is never complete (McLeskey and Waldron, 2002).

Impact of Inclusion and Attitudes About Inclusion

Many studies have examined the academic and social impact of inclusion on students with and without disabilities. Researchers have also studied the perception of inclusion across various groups of stakeholders. Others have synthesized these studies into reviews of literature (e.g., Avramidis and Norwich, 2002; Duhaney and Salend, 2000; Salend and Duhaney, 1999; Schmidt *et al.*, 2002; Scott *et al.*, 1998). Findings are generally varied, complex and impacted by a multitude of variables.

Students with and Without Disabilities

The results of studies examining the impact of inclusion on students with disabilities have received mixed results. Some studies conclude that inclusion programs improve educational outcomes such as standardized test scores, grades, on-task behaviors, attitudes about school, and reading skills. Other studies indicate that certain students are not given specially designed instruction to meet their needs in the inclusive classroom, and thus, students who receive instruction in pull-out programs (e.g., resource rooms) achieve higher academic gains. Reports of social gains are also varied. Generally speaking, however, students in inclusive settings improve socially, behaviorally, and in self-concept to a greater degree than those educated in noninclusive settings. Studies examining the inclusion of students with severe disabilities found that they interacted more frequently with their nondisabled peers, but do so in a nonreciprocal manner. Those with mild disabilities, on the other hand, do develop reciprocal relationships, but some are rejected by their peers and have lower self-perceptions than those without disabilities. In the end, students with disabilities have expressed both benefits and concerns about inclusive practices. Some prefer pull-out programs because of the individualized academic help they receive. At the same time, they do not like the stigma of being pulled out of their general-education classroom which

causes them to miss general-classroom activities. At the secondary level, students report negative experiences in both general and special-education classrooms. In general education, they often feel lost and confused; and in the special education classroom, they often feel stigmatized and unchallenged.

Some studies have indicated that placing students with disabilities in inclusive classrooms does not interfere with (and to some degree may enhance) the academic progress of students without disabilities. For example, some research discovered that academic performance of typical elementary students in inclusive classrooms was equal to or better than those in noninclusive classrooms. Studies also found that general-education teachers in inclusive elementary classrooms do not significantly reduce teaching time for students without disabilities. At the secondary level, students with disabilities have been found to receive more attention from the teacher, but that attention does not have a negative impact on the academic engagement or achievement of students without disabilities. Moreover, typical peers' academic achievement was enhanced when given an opportunity to provide peer support to those with more severe disabilities. Some studies have discovered that students without disabilities generally support inclusive practices. Research has found that inclusion programs help them become more accepting and tolerant of each other. For example, fears toward those with differences were reduced and attitudes toward individuals with disabilities were improved. Typical peers view inclusion as an opportunity to gain greater appreciation for human diversity and as an opportunity to have friendships with those with disabilities.

General and Special Education Teachers/Service Providers

General-education teachers and service providers have varying attitudes about inclusion which seem to be shaped by their experiences, student characteristics, and availability of supports. Some of them support inclusion only if they are required to make minimal accommodations for students with disabilities. Others prefer pull-out programs, such as resource rooms, for students with mild disabilities. One study found, for example, that teachers were more likely to reject students with mild disabilities than those with severe disabilities. In addition, general educators who work in inclusive classrooms have been found to have more positive views of inclusion than those who have not. Elementary teachers are more likely to support inclusion than secondary teachers. Some general educators view inclusion as having helped them develop skills at meeting a wider variety of student needs including improved confidence in their teaching abilities. They also indicate more favorable attitudes toward those with disabilities. Other general educators

and service providers are concerned about whether they can truly meet the needs of students with disabilities; many of them feel they have not been adequately prepared to do so.

With the practice of full inclusion, many special educators and service providers have questioned how their job duties have and will change. Most inclusive schools create co-taught classrooms where special educators work directly with general educators in delivering instruction to all students, including those with disabilities. In this model, special educators have expressed concerns about loss of control over their own classroom environment and their role as a subordinate in the general-education classroom, particularly at the secondary level. They have also expressed concern about whether special-education students are receiving appropriate services in inclusive classrooms. Studies have indicated, however, that special educators and service providers working in inclusion classrooms report feeling more accepted by general-education teachers and students without disabilities. In general, they feel more integrated into the school community.

Family Members

Attitudes and perceptions of families of children with disabilities have been consistently explored by researchers. Results show that they have mixed, but generally positive feelings about inclusion. Family members view inclusion as a way to teach their children about needs of others and to accept human diversity. On the other hand, parents also have concerns, such as assurances that their child will receive the necessary help, and that they may emulate inappropriate behaviors of those with disabilities. In the end, researchers have concluded that the majority of parents of students with disabilities support inclusion. Some of the benefits they identify include acceptance of their children by nondisabled peers, improving their child's self-esteem, providing appropriate role models, and preparing their children for the real world. Parents also express concerns about the lack of qualified personnel and specialized services for their children being educated in inclusive classrooms and about their children being ignored, isolated, or mistreated.

International Perspective

The movement toward inclusion is a global phenomenon. Countries and regions within countries, however, are at different points along the road to implementation. Some countries have implemented inclusion more universally and for a longer period of time than the United States. Italy is one such country. In 1977, an Italian law was passed requiring that all students with disabilities be included in general-education classrooms. Unfortunately,

there exists limited research supporting positive student outcomes of inclusion in this country. Nevertheless, Italy has been identified as a model country of inclusion that others could replicate (Begeny and Martens, 2007). Denmark, Sweden, and the United Kingdom are also among the countries that have implemented some form of inclusion for a number of years. Other countries have not moved as swiftly as these countries. In 1995, for example, about 16% of students with disabilities were segregated into Australian special schools as compared to 5% in the US (Anderson *et al.*, 2007). In South Africa, students with disabilities were not guaranteed access to educational institutions until 1996 (Engelbrecht *et al.*, 2005). In the same vein, Vietnamese laws and regulations changed as late as in the 1990s allowing students with disabilities to attend either special or general-education schools (Villa *et al.*, 2003).

Inclusion is still considered a Western concept. Before it could be implemented in many places, changes in philosophical thinking and culturally embedded beliefs about those with disabilities and the role of schooling would need to change. For example, some societies still view those with disabilities as deviant or broken and that others should be protected from them. Students and their parents prefer not to be identified as having a disability given the stigma attached. Schools may have high academic standards, promote strong competition, and focus only on excellence, leaving little room for addressing individuals' needs. Additionally, individual civil rights and the idea that schools should be opportunities for improving one's quality of life are not accepted principles by all societies. Many cultures, however, are beginning to accept individuals with disabilities as potential contributing members of society. In the last few decades, such changes are reflected in grassroots movements positively impacting laws and regulations for students with disabilities across the world.

Conclusion

Inclusion is a philosophy or belief that all students are included in the general-education classroom and have access to the general-education curriculum. All students' learning is the responsibility of all educators. Full inclusion means that literally all students remain in the general-education classroom with needed services brought to them. If the student cannot meet expectations of the general classroom, then those expectations should be altered. The inclusion movement has been influenced by legal mandates, as well as social and educational reforms. Proponents of inclusion have based their arguments on legal, moral, educational/social, and political grounds. Opponents express concern about the impact of inclusion on teachers, students, and schooling in general. Empirical studies indicate that students with and without disabilities

can benefit from inclusion and that most general educators, special educators, students with and without disabilities, and family members of these students support inclusive practices. While inclusion may be found worldwide and many countries and regions have moved closer to inclusive practices in the last few decades, belief systems about disabilities continue to inhibit such practices.

Instructional Accommodations for Children with Special Needs in Inclusive Settings

A L Yurick, Cleveland State University, Cleveland, OH, USA

S Musti-Rao, The University of Cincinnati, Cincinnati, OH, USA

G Cartledge, The Ohio State University, Columbus, OH, USA

© 2010 Elsevier Ltd. All rights reserved.

Many educators can attest to the fact that classrooms in the United States are becoming increasingly diverse. In fact, some estimates indicate that up to 42% of students enrolled in public schools in 2005 reported minority status and at least 20% speak a language other than English at home (NAEP, 2008). However, the nature of diversity in the classroom extends beyond cultural and linguistic diversity; it also includes diversity in academic functioning and programming. Currently 13% of the school enrolment is being served under Individuals with Disabilities Education Act (IDEA) and up to 96% of general education teachers have reported having a student with learning disabilities in their classroom (US Department of Education, 2005). It is certainly understandable how a teacher faced with such a collage of student characteristics and needs can become overwhelmed by the task of providing appropriate instruction for all of his or her students. Now more than ever, all teachers need to be able to modify and adapt their instruction to meet their students' individual benchmarks.

Teaching within classrooms with highly diverse populations needs to be flexible both for instructional and assessment purposes. Instructional accommodations are covered in federal legislation such as Section 504 of the Rehabilitation Act of 1973 (PL 94-112) and the reauthorization of IDEA (IDEIA, 2004). Under Individuals with Disabilities Education Improvement Act (IDEIA), students with one or more of the 13 specific disability diagnoses are guaranteed reasonable accommodations necessary to ensure a free and appropriate public education. After an evaluation by a multidisciplinary team, if a student is found to have a disability, he or she should begin receiving instructional accommodations as outlined in his or her individualized education plan. However, students with other types of impairments or disabilities who are not eligible for funding under IDEIA may still secure assistance through Section 504 of the Rehabilitation Act of 1973, a civil rights law that protects individuals who have a physical or mental impairment that substantially impedes daily life activities. The definition of disability is much broader under Section 504 and may apply to students with more temporary conditions such as communicable diseases, accident injuries, short-term hospitalizations, and environmental or attention difficulties. For either law, the nature of the accommodations may function to provide both additional

services and accommodations or may be as simple as just eliminating existing barriers to optimal functioning. The nature and extent of the instructional accommodation is, and should be, individually determined according to specific needs.

The terms accommodation and adaptation are used widely in general and special education, sometimes with an element of confusion. Therefore, it is important to note the difference between an instructional accommodation and an instructional adaptation. With an instructional accommodation, the content being taught or standard performance criterion is not altered. Accommodations do not reduce learning expectations; they are intended to provide greater access to the content. All students in the classroom, regardless of disability, pursue the same curriculum and are subject to the same grading scales and evaluation procedures. Changes are made to the delivery of instruction without any change to the curricular content or conceptual difficulty. Examples of instructional accommodations might include using multiple formats to present information, using completed work samples for demonstration, providing material in large print for those with visual impairments, or enlisting an interpreter for students with hearing impairments. Unlike instructional accommodations, making an instructional adaptation includes making changes to the curricular content, physical environment, or methods while assisting children to learn in the least-restrictive environment (Bauer and Brown, 2001). Students with more significant cognitive disabilities may possess limited understanding of the general education curriculum and require modifications such as fewer assignments or material revised for lower readability level. The decision regarding whether a student requires an accommodation or an adaptation is largely an individual one and should be determined based on optimizing the outcomes for that particular student.

With the dynamics of the student populations in schools changing dramatically, there is an increased emphasis on access to the general curriculum for all students. This means that teachers need to deliver instruction with same curricular content to both students with and without special needs. In this era of multicultural classrooms and standards-based education, teachers and service providers are asking important questions about how to accommodate the individual needs of students in their

classrooms. One approach to this issue is to introduce greater flexibility through differentiating the instruction. Although the concept of differentiated instruction lies in general education and the concept of making instructional accommodations is from the field of special education, the end results are basically similar (Prater, 2007). It would be useful to view making instructional accommodations for students with special needs in the context of differentiated instruction in the inclusive classroom.

In this article, we discuss instructional accommodations in the inclusive classroom using differentiated instruction as our conceptual base. We provide a model for making accommodations plausible, and suggest some ways for using this model at various educational levels. The focus in this article is on instructional accommodations, since assessment accommodations are addressed elsewhere in the encyclopedia.

The Inclusive Classroom

The ideal inclusive classroom is one in which learners of variable readiness, learning styles, and interests can optimally benefit from the curriculum being taught. In order to achieve this goal, accommodations must be made. However, the reality is that multiple curricular areas and content must be covered. Factor this multiplicity by the number of students (and individual needs) in the classroom, and making appropriate accommodations becomes a daunting task indeed! It may be helpful to point out that not all students will require accommodations, and many will not need accommodations in multiple areas. However, for students who do need some curricular adjustments, identifying the specific aspects of instruction which can be adapted may help clarify the task.

Tomlinson (1999) makes the distinction that instructional accommodations can take at least three forms: content, process, or product. Content accommodations refer to altering the materials used in the lesson. For example, a student with a reading disability who displays off-task behavior or incomplete work samples may be able to fully participate in the lesson if the reading material is revised to reflect a more appropriate difficulty level. Likewise, students with special needs sometimes become overwhelmed by task complexity. Therefore, presenting the same content in smaller steps can make the difference between a completed product and an abandoned assignment due to frustration. In a process-type accommodation, the teacher varies instructional activities according to the learner's preferences and strengths. Rather than having students take independent notes on a chapter, the teacher might choose a more scaffolded approach such as lecturing with the assistance of guided notes. This provision ensures that the student retains a complete and accurate product without becoming lost in a lecture-style format, which is

sometimes difficult for students with learning or attention deficits. Finally, a product accommodation allows the student to illustrate his/her mastery of the lesson in a differentiated format. The culmination of most lessons is a student-generated product reflecting the student's understanding of the material. However, even if students are proficient, those who need accommodations may fail to demonstrate competencies similar to peers simply due to the nature of the assignment. Perhaps the most common example is the student who is a weak test-taker. Allowing the student more time for the exam or taking oral responses rather than written responses may ameliorate this limitation. Breaking down the classroom elements in terms of content, process, and product has its roots in the literature on differentiated instruction and therefore a clear understanding of differentiated instruction is warranted

Differentiated Instruction

In each of the aforementioned examples, the teacher is making accommodations by differentiating instruction. According to Tomlinson (2003), "differentiated instruction is responsive instruction" (p. 2). As stated, due to the increasing diversity in classrooms, teachers and service providers need approaches that are flexible enough to be responsive to their students' learning needs. In fact, in this age of accountability, it is crucial that general and special educators come to their classrooms armed with the knowledge and expertise to teach students in the most effective and efficient multidimensional manner (Meo, 2008). This means that they need to be responsive to the ever-changing dynamics of student learning and demonstrate the ability to adjust their instruction accordingly. Central to the educational reform movement is the commitment to closing the achievement gap and contributing to the overall improvement of student outcomes. These goals may be achieved by establishing the use of differentiated instructional practices as the rule, rather than the exception, for the entire school. In fact, some schools have implemented differentiated instruction at the school level and succeeded in meeting these goals (Cusumano and Mueller, 2007). However, the benefits to this type of approach are not limited to just satisfying recent educational legislation and reform. This approach is collaborative in nature and provides a real opportunity for general and special education teachers to learn from one another and streamline their teaching into a best-practice model. Differentiated instruction can serve as a platform for collaborative efforts, such as employing co-teaching approaches in the classroom (Hawkins, 2007). Most importantly, however, when teachers and service providers work collaboratively to bring their students the best instruction, student outcomes improve and students begin to feel more competent, confident, and successful in the classroom.

Choosing appropriate accommodations for individual students such that they are able to perform at their maximum potential is an important task. Unfortunately, in the past, individualized educational plan (IEP) teams have had little to no guidance on choosing accommodations. Most accommodations listed have used assessment accommodations with no emphasis on instructional accommodations. The need for a close match between instructional accommodations and assessment accommodations cannot be overstated. It is only logical that students receiving a specific type of assessment accommodation be given the same accommodation during instruction. That is, for example, if a student is given the opportunity to make oral responses during assessment, the same type of responses should have been required during instruction. By the same token, it would be inappropriate to deny students accommodations during test-taking that they used during instruction. Certain guidelines and a model can assist teachers to make decisions about designing possible accommodations for students in their classrooms.

A Model for Instructional Accommodations

Before deciding on which accommodations can facilitate students' learning, teachers and service providers must first familiarize themselves with the different types of accommodations that are possible. Viewing accommodations in terms of content, process, and product can simplify the task for teaching professionals as they begin

to plan for instruction. Although many accommodations that fall under product pertain to assessment or test accommodations, there may be some overlap with content and process accommodations, and nevertheless, will help with planning for assessment accommodations. **Table 1** lists the different accommodations under each category along with examples.

Educators can use **Table 1** to generate a list of accommodations that can be used in their classrooms. Soliciting students' input in providing accommodations may enhance its use and effectiveness. **Figure 1** shows steps that educators can use and questions to ask when making decisions on accommodations.

SM3 Model

Another way of conceptualizing instructional accommodations in the inclusive classroom is the setting, methods, motivation, and materials (SM3) model, which incorporates changes to content, process, product, and learning environment (Tomlinson, 2007).

Setting

Setting refers to the physical organization of the classroom that needs to be factored in during lesson planning. This includes the arrangement of desks and a planned seating chart based on students and their individual needs, schedule and length of activities, and other environmental elements such as lighting, noise levels, room temperature, and time of day.

Table 1 Types of instructional accommodations

Categories	Accommodations	Examples
Content	Size/quantity – vary the number of items the student is expected to learn	Reduce (or increase) number of worksheets to be completed at one time
	Difficulty – vary the level of difficulty based on students' needs	Provide partially completed class or lecture notes; list multi-step directions
	Alternative goals – vary lesson objective for students while using same materials and content	Write definition of vocabulary words vs. matching the word to its definition vs. orally defining the words
	Substitute curriculum – work on curriculum different from regular curriculum	One student with special needs works on adding with manipulatives, while rest of the class work on more complex math
Process	Input – delivery of instruction	Small group instruction vs. lecture format; motivation and reinforcement systems
	Level of support – varying the degree of assistance student receives	Provide learning aids, such as guided notes, graphic organizers, and concept maps
	Time – the actual time allotted for learning or task completion and lesson structure	Decrease (or increase) pace of instruction
	Participation – level of active involvement with the task	Active student responding (ASR), choral response, discovery learning
Product	Time – the period of time allowed to complete assignments or tests	Extended time on tests and assessments
	Output – the way a student responds to instruction	Oral responses; using word processors to write essays

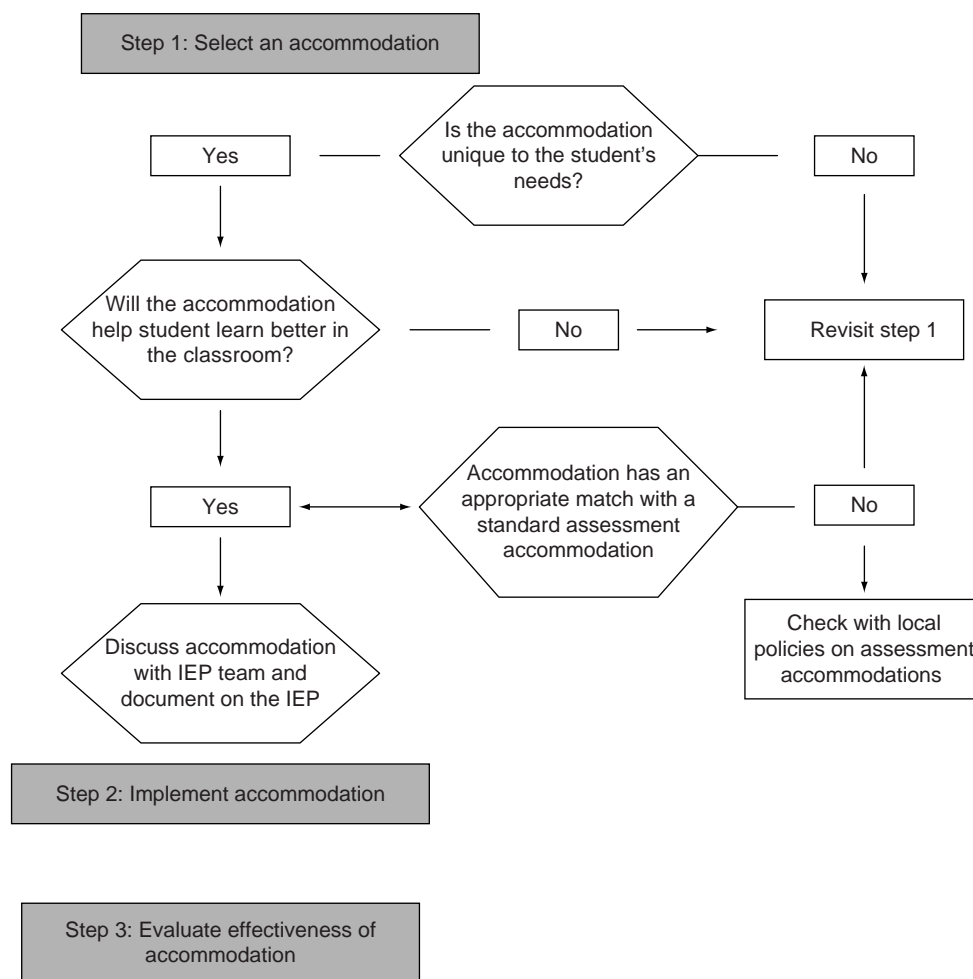

Figure 1 Accommodation selection decision tree. Adapted from Prater, M. A. (2007). *Teaching Strategies for Students with Mild to Moderate Disabilities*. Boston, MA: Pearson Education.

Methods

Methods refer to the instructional strategies that teachers employ in their classroom. Depending on the diversity in terms of ability levels, instruction can take different forms. For example, teachers can use direct instruction, cooperative learning, lecturing, or small group discussions to cover the content of the subject area. Similarly, the teachers and service providers can employ different modalities (e.g., auditory, visual, and kinesthetic) to help students with learning. Methods also refer to the type of response that students make and also the type of assessment used to evaluate their learning.

Motivation

Motivation refers to accommodations made to the social environment of the classroom to facilitate student learning. Smaller groups and peer-tutoring formats can be set up to motivate students of all ability levels. Use of various types of reinforcement systems and contingency contracts can further motivate students to learn.

Materials

Materials include tools and equipment that teachers use for instruction and assessment. Some examples of materials include desks, study carrels, guided notes, self-monitoring checklists, calculators, and computer software. Here again a close link between instructional and assessment accommodations is critical. If a student reads below grade level and receives materials at a lower reading level during assessments, then teachers and service providers will have to design the same type of accommodations during instruction. Tape-recorded materials, online resources, and simplified texts are some examples of accommodations made for students with reading problems. Any type of assistive-technology devices that are both low-tech and high-tech would fall under this category.

Assistive technology is another example of materials accommodations that enhance student learning. Assistive technology includes any device, low-tech and high-tech, that helps people with disabilities function with greater independence. Using assistive technology in the classroom

to accommodate students with disabilities can range from providing students with guided notes or partially completed notes during lectures to providing students with laptop computers with voice-recognition software to record a complete lecture. Depending on the type of disability, assistive-technology devices can be more specific. For example, students with physical disabilities often have difficulty taking notes, turning pages of a book, or taking written assessments. Alternative input devices such as alternative keyboards, joysticks, sip-and-puff systems, and touch screens assist students that have low muscle tone or functionality in their upper limbs. Students with learning disabilities may find the reading level in content area subjects (e.g., science and social studies) difficult and frustrating. Text-to-speech software programs convert printed text to auditory feedback with a scanner.

Classroom Accommodations at Elementary and Secondary Levels

It may be helpful to put this information back into context by illustrating how a classroom teacher puts content, process, or product accommodations into practice for a student with special needs in an inclusive setting. The first example describes how these accommodations can be incorporated into an elementary setting. Next, we outline the process for a student at the secondary level.

Elementary level

In Mr. Donaldson's 12 years of teaching, he learned to be flexible and responsive to the individual learning styles of each of his students. He had students with disabilities fully included in his classroom before, and learned a few techniques over the years that helped him make adjustments for these students. However, sometimes he tried several different approaches before finding one that truly suited the student's needs. Instead of making isolated and somewhat arbitrary alterations, he frequently wondered if he could streamline his approach to more effectively and efficiently make instructional accommodations that would more likely work the first time. With three students with mild disabilities fully included in his classroom this year, he would have liked to save time and energy by prescriptively matching the accommodations to the students' needs. On the other hand, Sasha was a student with a mild reading disability who sometimes became easily distracted when it was time to work independently on assignments in class. When presented with a reading or writing assignment, she made repeated trips to the pencil sharpener, asked to use the restroom, or began whispering to the student next to her. She seemed to do just about everything she could to avoid doing her work. After a discussion with the school's intervention specialist,

Mr. Donaldson hypothesized that Sasha's poor persistence to task may be exacerbated by her reading disability. That is, if parts of the assignments require reading and writing that are too overwhelming for her, she may be using her off-task behavior to avoid the assignments altogether. Mr. Donaldson reviewed the parts of his assignments that have reading or writing requirements and decided to align a content, process, and product accommodation to the assignment for Sasha in order to help her benefit more from the instruction.

For the next class assignment, a unit about the upcoming presidential election, Mr. Donaldson had his class select three or more books from the library to write a comprehensive report on each candidate. The required reading and writing for this assignment was more cumbersome for Sasha and would delay her progress through the unit. Therefore, Mr. Donaldson suggested that Sasha rely on more multimedia resources, such as television news programs, the Internet, blogs, and webcasts for the content of the unit. By making this content accommodation, Sasha was not limited in resources and she could use materials that were at her instructional level. For the research process, Sasha created a webquest related to researching for information on presidential candidates. The interactive nature of this process accommodation significantly reduced her levels of avoidance and distraction that she typically displayed when required to read independently for an extended period of time. Finally, instead of turning in a written product for the outcome measure in the unit, Mr. Donaldson suggested that Sasha's final product be an oral presentation and demonstration of her presidential candidate webquest for the class. In spite of her reading disability, she demonstrated that she gained knowledge related to the unit, while also showing her peers new resources for their further investigations. Mr. Donaldson was pleased with her overall performance and her level of understanding, and Sasha remained excited and engaged in her schoolwork.

Secondary level

Andre was a friendly, outgoing, hard-working high school sophomore. He enjoyed many sports and was an accomplished junior varsity basketball player. Unfortunately, Andre's learning disability impeded his performance in his geometry class to the degree that he risked being cut from the basketball team if his grades did not improve. Andre, his parents, the school intervention specialist, and Ms. Morgan, the geometry teacher, decided to develop a plan that would help Andre be more successful in the class. As with most geometry classes, the units were introduced in a lecture format, students practiced problems from the book independently, and then were tested on the material at the conclusion of the unit. After some discussion, it became apparent that Andre was not taking effective notes in class, and therefore, could not complete

his independent practice assignments accurately. After practicing errors on his homework, it was not surprising that his test scores suffered as well.

In order to provide more guided practice and promote better accuracy in Andre's homework, Ms. Morgan agreed upon some accommodations they could make to the assignments. First, as a content accommodation, Ms. Morgan suggested that it was not the quantity of homework problems completed that was most critical, but the accuracy of the ones he had completed. Therefore, for each assignment given, she selected a subset of problems that Andre completed as homework. To scaffold his learning further, she used this exact subset of problems for the in-class lecture and demonstration when introducing and demonstrating the material to the class. Unfortunately, Andre's poor note-taking skills did not produce an accurate model for him to refer to when doing his independent homework activities. As a process accommodation, Ms. Morgan provided Andre with a structured worksheet and guided notes, which were partially completed notes and examples that required him to write less, and therefore, focus more on the lecture being given. Additionally, Andre found it extremely helpful to audiotape the lecture and demonstration to replay while he was at home completing his assignment. Listening to the recording as he went going through his reduced assignment ensured that he performed each step correctly; and since the problems Ms. Morgan demonstrated in class were the ones Andre practiced at home, the repeated practice increased his accuracy substantially. Finally, Ms. Morgan permitted a product accommodation to be made to the final exam. Again, she reduced the length of the test and allowed Andre to take the test with her after school. In this setting, he was permitted to talk through the answers with her, just as he did during his homework assignments. An additional benefit of this accommodation was that it provided valuable insights for Ms. Morgan to understand how Andre was thinking when he made an error while solving a problem. With these relatively conspicuous accommodations, Andre's geometry performance

improved one letter grade and he was more confident in his ability to be successful in class.

Conclusion

The practice of making instructional accommodations is very consistent with the belief that students are individuals who each learn in their own unique ways (King-Shaver and Hunter, 2003). However, adapting instruction to these many individuals may be a daunting task for teachers. In this article, we have outlined a streamlined approach to incorporating these accommodations in a prescriptive fashion, rather than a haphazard application of strategies which may or may not be sufficient to assist the student. The combination of instructional flexibility and needs-based accommodations can truly result in a superior experience for both the teacher and the student. These approaches are the essence of effective individualized instruction that can make a substantial difference in the education of all students, especially those with special needs.

Interagency Agreements

L A Owens, University of Wisconsin–Milwaukee, Milwaukee, WI, USA

© 2010 Elsevier Ltd. All rights reserved.

A major barrier to postschool employment success for young adults with disabilities is the lack of access to appropriate adult services and supports. The Workforce Investment Act (WIA), Rehabilitation Act, and the Individuals with Disabilities Education Act (IDEA) mandate interagency agreements to facilitate collaborative planning and services for youth as they leave the educational system to enter the adult service system. IDEA clearly stated that providing transition services is not solely the responsibility of the school system (Cozzens *et al.*, 1999). While the reauthorization of IDEA in 2004 as the Individuals with Disabilities Education Improvement Act (IDEIA) eliminated the mandate to include a statement of interagency linkages and responsibilities, it did retain the provision that if a participating agency does not provide the transition service described in the individualized education plan (IEP), an IEP meeting must be reconvened to identify alternative strategies (i.e., Sec. 614). If possible, systematic planning for collaboration between school systems and adult service systems should begin with a state plan. This plan should include a description of roles and responsibilities between schools and adult services agencies and provide a clear alignment of goals, priorities, and resources needed to successfully collaborate. Typically, state vocational rehabilitation agencies, state departments of education, and other state agencies (i.e., State Department of Health and Social Services, and State Corrections) are involved in establishing a state plan to: (1) ensure collaboration of services, (2) expect coordinated services, (3) maximize resources, and (4) increase the effectiveness of transition efforts for students with disabilities.

Interagency agreements are a tool that can facilitate the collaborative efforts between the educational and rehabilitation systems. Interagency agreements, also known as memorandums of understanding (or MOUs), are required under the WIA and the Rehabilitation Act. Interagency agreements can be formalized written documents signed by senior administrators of all participating agencies. Agreements can also be developed at an operational or local level and be much less formal in nature. Good interagency agreements promote actions that directly or indirectly improve personal outcomes for those receiving services and promote systems change. This is the focus of the article.

Interagency Agreements and Collaboration

Schools and adult service agencies (e.g., state vocational rehabilitation, local service providers, and independent

living centers) typically operate in isolation with uncoordinated agendas. Many organizations do not have the information or experience in working with one another and this has caused difficulties in a smooth transition from school to adult life. Often, when students transition from school to adult life, there are gaps in services, duplication of services, cost ineffectiveness, and/or inaccessibility of services which can be resolved through interagency collaboration (Metzel *et al.*, 2005). Over the past 10 years, interagency agreements have been utilized to facilitate a smoother transition from one system to another. These agreements bring organizations together to focus on collective expertise and resources to improve transitioning from one system to the next. Interagency agreements promote collaborations that create systems change by outlining in a more formal way, strategies to implement services and effectively utilize resources and funding. A written interagency agreement outlines roles and responsibilities and resources to be committed to reach common goals. Interagency agreements are only as effective as the integrity with which organizations follow through on their roles and responsibilities described in the agreement.

Effective interagency agreements require collaboration between all stakeholders. These agreements are typically implemented when students move from one system to another. For example, those moving from early childhood services to the educational system or students moving from the educational system to the adult service system all benefit from interagency collaboration and the implementation of interagency agreements.

Developing a Good Interagency Agreement

Effective interagency agreements should promote actions that improve personal outcomes for individuals with disabilities and promote changes within systems providing those services. According to Butterworth *et al.* (2001), four important questions should be considered when developing interagency agreements: (1) What is the purpose of the collaboration?; (2) Who owns the interagency agreement?; (3) Who are the allies?; and (4) Will the agreement lead to action? All agencies responsible for transition planning should be engaged in a discussion revolving around these questions to ensure clarity in roles and responsibilities to enhance transition outcomes for students with disabilities.

Purpose of Collaboration

Collaboration is a mutually beneficial relationship with clear roles and responsibilities between two or more organizations to achieve a common goal. For collaboration to be most effective, there must be a commitment to the: (1) definition of mutual relationships and goals; (2) jointly developed structure and shared responsibility; (3) mutual authority and accountability; and (4d) sharing of resources and rewards (Mattessich and Monsey, 1992). When developing interagency agreements, it is important to determine the purpose of such agreements and ensure that this purpose is clear to everyone who is trying to accomplish the identified goals. Butterworth and colleagues suggest that an interagency agreement can be developed for a one-time event that is more political than service delivery focused. This type of agreement may set the stage for a large systems change initiative or bring together appropriate stakeholders to lay the groundwork for subsequent interagency collaboration. A more important purpose of an interagency agreement would be to spell out the procedures for a more mature interagency collaboration, one that has been in place over an extended period of time. This will ensure continuity of the relationship and activities involved such as planning for transition. Finally, an interagency agreement can be an effective tool that enables two or more agencies to accomplish a specific goal such as improving service delivery or implementing systems change.

Allies of Interagency Agreement

It is critical that there is a strong commitment within agencies and organizations, and other stakeholders who may be impacted by the interagency agreement. It is important to find allies internally, within organizations and systems and externally, outside the organizations or systems (e.g., advocates, political, and business).

Interagency Agreement Ownership

Interagency agreements are only effective if there are people involved who will implement the services within the agreement. According to Butterworth *et al.* (2001), owners of the interagency agreement are at the heart and soul of implementation and have a commitment to getting things done. Owners of the agreement are responsible for providing oversight and vision, leading the implementation of the agreement, and monitoring the outcomes of the agreement. In order for interagency agreements to lead to change, owners must ensure that the activities are implemented based on the goals agreed upon.

Agreement Leading to Action

Effective interagency agreements must be concrete and action oriented. To be effective, interagency agreements

must include clear goals with specific action plans for the owners to implement. While interagency agreements can be powerful tools in expanding services to improve student outcomes, it is critical that the goals and action steps are defined to increase student postschool outcomes. **Figure 1** provides a checklist to ensure that interagency agreements address each of the questions.

Strategies for Integration of Services

One impact of interagency agreements is that it provides a tool to assist professionals and individuals in crossing traditional professional boundaries. Interagency agreements must include: (1) collaboration through collective problem solving and sharing of resources; (2) cooperation where agencies interact and communicate on a regular basis with shared accountability; (3) service coordination to assist in the movement from one system to another; and (4) networking where professionals and individuals identify a range of services available in the community to support the individual in adult life (Dunst and Bruder, 2002). There are inherent challenges when students move from one system to another and it is important to consider unique approaches to collaboration. Many times, self-imposed barriers such as turf issues, competition for clients, differences in philosophies, and financial/resource constraints cause difficulties in effectively implementing interagency agreements (Woodside and McClam, 2003). An umbrella agency structure may remove some of the typical constraints involved with issues of turf (Harley, 2003) which may strengthen the impact of interagency agreements. Another alternative would be an agency broker who had knowledge of both the educational and adult service system to provide the needed services to individuals with disabilities. This broker would be part of the interagency agreement and would have a working knowledge of the services provided by each signer of the agreement.

It is critical for interagency agreements to have an impact on student outcomes and has local input and ongoing support. Service delivery and service coordination are two collaborative activities in the interagency agreements. These activities should be clearly defined to spell out exactly what services are to be delivered and exactly what constitutes coordination in order to better inform the activities and expectations that ensure accountability. Federal legislation and state policies continue to identify the expectation of interagency agreements among agencies. As a result, it is important to identify successful elements in the creation and implementation of interagency agreements that result in increasing positive postschool outcomes for individuals with disabilities. Interagency agreements provide an understanding about services provided by state agencies, school systems, and adult service agencies. An interagency agreement provides guidelines

1. The agreement has a clearly defined purpose
 - Outcomes have been defined: Outcome measures emphasize quality of post school outcomes on an based on individual needs.
In Place - Partial - Needed - Comments
 - Outcomes are being measured: A data collection system is in place, and outcome summaries are provided to key stakeholders.
In Place - Partial - Needed - Comments
2. The agreement is well supported by internal and external allies.
 - Internal allies are in place: Allies from within the partner agencies have been identified who support the agreement. Stakeholders are involved in planning and implementation.
In Place - Partial - Needed - Comments
 - External advocates are involved and committed: Support from allies outside of the partner agencies is in place to ensure support for the agreement.
In Place - Partial - Needed - Comments
 - Part of a greater whole: Partners share a common interest and mutually defined goals.
In Place - Partial - Needed - Comments
3. Ownership of the agreement is clearly defined
 - Ownership is clear: An individual is identified in each participating agency who is responsible for implementation and oversight of the agreement.
In Place - Partial - Needed - Comments
 - Linkages/relationships at an operational level: Mechanisms are in place to support ongoing communication among agency personnel who are involved in implementation.
In Place - Partial - Needed - Comments
4. The agreement is action oriented
 - Specific action plans are in place (Activities are well defined. Agreements use action-oriented terms).
In Place - Partial - Needed - Comments
 - Money or resources are committed: Funds, staff time, or other resources have been committed to the agreement by participating agencies.
In Place - Partial - Needed - Comments
5. Mechanisms for communicating values and resolving differences are included
 - Nonnegotiable organizational values have been identified and addressed (All partner agencies provide accessible and welcoming services to individuals disabilities).
In Place - Partial - Needed - Comments
 - A mechanism for resolving agency differences or disagreements during implementation of the agreement is defined.
In Place - Partial - Needed - Comments

Figure 1 Interagency agreement planning checklist.

and procedures for each agency to follow, clarifies roles and responsibilities, and identifies clear methods for communication between agencies. Developing an interagency agreement is not always easy but the benefits outweigh the time and effort involved. **Table 1** highlights essential features of effective interagency agreements (see Crane *et al.*, 2004). While state-level interagency agreements may provide a broad framework to guide transition practices, local interagency agreements allow

community organizations to clarify policies, procedures, roles, and responsibilities to be followed within and among organizations (Fowler *et al.*, 1990).

Examples of Interagency Agreements

State-level interagency agreements are important to set the stage for collaborative efforts between state and local

Table 1 Features of effective interagency agreements

<ul style="list-style-type: none"> ● Agency staff are responsible for design, revision, and implementation of the agreement. ● Agency directors have commitment to the development and implementation of the agreement. ● Input is received from direct service staff in the design, revision, and implementation of the agreement.
Opportunities are available for agency staff and directors to meet, discuss ideas, and develop relationships.
<ul style="list-style-type: none"> ● Opportunities for agency directors and direct staff to learn from each other and see how each can benefit from the mission of other organizations. ● Active involvement in strategic planning by participating agency representatives.
Collection and analysis of data are important to determine the impact and outcomes resulting from the agreement.
<ul style="list-style-type: none"> ● Utilization of data is necessary for strategic planning and continuous improvement
Dissemination of the agreement is important to all stakeholders. Training and technical assistance are needed for direct service staff regarding implementation of the agreement.

stakeholders. Generally, these agreements are developed and signed by state and local agencies that impact transition services for students with disabilities. Some interagency agreements combine birth-to-3 transition goals with the school-to-adult world transition, while others have separate agreements for each stage of transition. For instance, the Wisconsin Interagency Agreement (June 2007) was developed by the Department of Education, Division of Vocational Rehabilitation, and the Department of Health and Family Services. Included in the agreement are: (1) statement of need, (2) purpose and goals, (3) roles and responsibilities, and (4) signatures of all parties involved.

In the same vein, local-level interagency agreements are used to ensure that collaboration continues in communities. Hobbs (1993) developed an interagency agreement that can be used to define roles and responsibilities, as well as a tool for sharing information with all stakeholders. See **Figure 2** for an interagency agreement checklist (Butterworth *et al.*, 2001).

This agreement is between the center and _____ (agency name) _____.

Purpose

[Instructions: This statement must specify the principal expected outcomes of the collaborative.]

The center is an interagency collaboration program whose purpose is to: (1) develop an integrated-services approach based on a shared philosophy and a collaborative leadership structure; (2) provide services to children and families with agency staff who have increased authority to solve problems; (3) develop a cross-agency training institute to build commitment to interagency collaboration and provide technical assistance to managers and line staff; (4) develop an automated information network system that facilitates interagency personal information sharing, referrals, and collection of case characteristic and outcome data.

Much of the interagency casework will be carried out through members of a multidisciplinary team. Members of the team will continue as employees of their current agency and retain their current job classifications while taking on new caseload responsibilities for families with children who reside in the service area.

Service area

[Instructions: This section must state the geographic/jurisdictional boundaries of the program.]

The boundaries of the service area are defined as:

Responsibilities

[Instructions: This section must specify the responsibilities and roles of the parties to this agreement.]

Participating agency

Participant services

- Provide assessment, information, and referral to all children and families who live in the service area.
- Provide case-management services to eligible children and families.

Coordination

- Agree to meet with _____ (agency name) _____ staff to develop appropriate referral procedures.

Figure 2 (Continued)

- Provide regular reports and consultation to ____ (agency name) ____ staff regarding mutual clients under approved confidentiality procedures.
- Provide in-service collaboration skill-development workshops for ____ (agency name) ____ staff.

Confidentiality

- Provide training on Center confidentiality policy and procedure.

(Participating agency)

Multidisciplinary Team Members

____ (Agency name) ____ will designate a multidisciplinary team liaison/staff person to:

- Work as part of the team and help center staff coordinate services to families and children in the service area.
- Meet with center staff to develop appropriate referral and communication channels between parties.
- Attend in-service training and work shops offered at the center and elsewhere.

Confidentiality

- Agree to amend the agency's confidential procedures, as necessary, to conform with center policy; accept the center's release forms for mutually served families; and instruct and supervise members of the team on any special provisions with respect to exchange of confidential information and/or records.
- Agree to enter into any necessary memorandums of agreement to access automated confidential files.

LIFE OF AGREEMENT

This agreement shall continue to ____ (date) _____. It may be terminated earlier by a 30-day written notice from either party for cause. Cause includes, but is not limited to, a change in state, federal, or local directive. The effective date is the date this agreement is signed by both parties.

SIGNATURES

These responsibilities are agreed to by the following authorized signatories.

Participating agency:

Name (Print) _____ Title _____

Signature of center coordinator or designee _____

Date _____

Participating agency:

Name (print) _____ Title _____

Signature of director or designee _____

Date _____

Figure 2 Interagency program memorandum of agreement: linkage agreement between the center and participating agencies (see Hobbs, 1993).

Conclusion

Interagency agreements are effective tools to ensure collaboration among stakeholders to enhance outcomes for

individuals with disabilities. Interagency agreements are only as effective as the partners make them. It is critical that agreements be monitored and amended as needed to provide continual improvement in the systems that

provide the services to ensure the successful outcomes of individuals with disabilities. Interagency agreements will better affect the outcomes of individuals with disabilities if collaboration is seen as a necessary component of service delivery instead of a separate service or goal (Johnson *et al.*, 2003). Interagency collaboration strengthens professional linkages (e.g., schools and vocational rehabilitation centers) to ensure that students are provided with the supports and services needed to reach their full potential after graduating from high school.

Glossary

Collaboration – Accomplishing the work of service-delivery to young children and their families through a model of professionals working closely together across disciplines and settings. The concept involves multiple layers of the work and in practice may be actualized in various manners.

Co-teaching – A model of service delivery in which the classroom is staffed by both a general education teacher and a special education teacher who plan and implement curriculum as a team.

Direct service delivery – Services are provided by the professional directly to the child, in a classroom, pull-out room, or clinic setting.

Indirect service delivery – Services are provided by the professional who consults with the direct provider (e.g., classroom teacher), providing direction, assistance, joint problem-solving, and/or coaching to the direct service provider.

Interdisciplinary team collaboration – A model of service delivery in which team members from various disciplines work together, in their roles as direct service providers, to coordinate services and in which they have equal and shared input into decision-making.

Multi-disciplinary team collaboration – A model of service delivery in which team members from various disciplines work independently and decision-making is directed independently by each member via the pertinent discipline approach.

Trandisciplinary team collaboration – A model of service delivery in which team members from various disciplines work together in both direct and indirect service roles, thereby requiring that some individuals change roles. Services are provided in a coordinated manner with equal and shared input into decision-making from all involved team members.

The work of those who serve young children and their families has, traditionally, taken place in varied settings, including childcare centers, preschools, agencies focused on disabilities services, and public schools. These settings often exist in very different spheres, with little to no connection. Similarly, the professions involved in these services have maintained their own preservice preparation structures, professional associations, and standards.

Even in a single field – early-childhood general education – job-entry requirements for professional preparation vary greatly depending upon the work setting – childcare or public school. Finally, the professions draw variously on the historic root disciplines, such as developmental psychology, education, and social work, to mention a few. When young children with disabilities are served, the picture becomes more complicated, as professionals from the allied health and medical fields become involved. Given the complexity of these settings, collaboration is a necessary but challenging goal. This article aims to explain the nature and practice of interdisciplinary collaboration in early-childhood programs. The focus is on collaboration among professionals, although, in family-centered practice, families may indeed be considered members of interdisciplinary teams.

Models of Collaborative Work

Traditional ways of working, involving tight boundaries, disconnected service systems, and limited teaming have been slow to give way to the more comprehensive and interwoven systems needed to serve all young children well in inclusive settings. Winton (2000) told a story of her own experience in convening an interdisciplinary panel for a course presentation, noting, with regret, that most of those on the panel had not met previously, although they worked within one community and, sometimes, served the same children. Yet, she believed that there are research-based knowledge and promising initiatives that form the base for preparing personnel to work in strongly collaborative, effective ways. In her estimation, the gap between what is known about serving young children and their families and what practice actually looks like can be traced back to resources and policies.

One issue within early childhood is the lack of clear consensus on the meaning of interdisciplinary collaboration (note that the term early childhood is used to indicate both general and special education). Various forms of service delivery and practices might be described as collaborative by those involved. Even those operating within the same teams might quibble about what collaboration means and the degree to which their work is true to those terms. Ogletree *et al.* (2001) explicated three forms of teaming, each with a unique set of advantages and disadvantages. In the multidisciplinary-team model, services are delivered independently by team members, and

members do not participate equally in decision making. Rather than operating interdependently, the team members contribute input with little connection among themselves. While efficient in nature, the risks to resultant service delivery are a lack of coordination and, potentially, the buy-in that can result via joint decision making. Interdisciplinary teams provide for more direct connections and interdependence among the team members, with more equal input into decision making. In essence, advantages and disadvantages of this model are the mirror image of the multidisciplinary model. Interventions may be more coordinated, with whole-group ownership of the plans. On the other hand, time and resources are needed for this model to be effective. In addition, there is some concern that boundary issues related to the various disciplines involved may still negatively affect the work if not effectively met (see Ogletree *et al.*, 2001). Lastly, transdisciplinary teams are noted by greater release from traditional roles and disciplinary boundaries. Some members of the team act as consultants, while others deliver direct services. One advantage of this model is that the team focus can be broadened considerably. A primary disadvantage is that it is risky; its success depends upon team members valuing role change (see Ogletree *et al.*, 2001).

Each collaborative model comes with both advantages and disadvantages. Families may have varying preferences for their own team roles, as well as what they want from the various professionals involved. Professionals have their own preferences, flexibility thresholds, and resources (e.g., time). Therefore, shared commitment to the model of working together, flexibility for various situational factors, and an awareness of what is required for the teaming model to work are all important to the effectiveness of any teaming work (Ogletree *et al.*, 2001). What is clarified is that collaboration (or teaming) is not a singular concept. The complexity is increased by the multiple individual perspectives coming together, as well as the constraints and resources each individual perceives are operating.

Following Professional Standards and Recommended Practice

The major professional associations in early-childhood education are the National Association for the Education of Young Children (NAEYC), with a membership of general educators, and the Division for Early Childhood (DEC) of the Council for Exceptional Children, with a membership of special educators. The standards for initial preparation of personnel in both associations include a focus on collaboration. For example, NAEYC's standards note that at initial licensure, candidates should "demonstrate understanding of and essential skills in interdisciplinary collaboration" (NAEYC, 2001: 25). There is little

specification of what this entails, except that candidates should be able to participate in interdisciplinary teams, particularly in relation to serving children with special needs. Likewise, the standards for DEC include collaboration; the constituent parts include practices with both families and other professionals and agencies. In addition, skills for providing consultation are named, but not further delineated (DEC, 2008). Thus, it is clear that both of the major professional organizations for early-childhood educators place value on collaborative practice.

It remains up to those preparing personnel to appropriately define the skills and attitudes that lead to and allow for collaboration. West and Cannon (1988) provided early work on the essential competencies required of consultants – a role that is, often, viewed as collaborative (although expert models may be utilized as well). Based upon this work, File and Kontos (1998) conducted a needs assessment of special educators moving from a direct service role to consultation in early-childhood programs. They found that special educators' identified needs included knowledge of consultation processes (e.g., understanding stages/phases, understanding a match between consultation approaches and situational needs, implementing strategies to empower change), as well as strategies for both conflict management and collaborative problem solving. These areas overlap in large part with the heart of interdisciplinary collaborative work. Meanwhile, both the special educators and general educators believed they brought strengths in their willingness to learn and seek professional development and in the form of their enthusiastic attitudes.

Rich (2002) offered a list of benchmarks of early-childhood collaborative practices for inclusion. These benchmarked key components of File and Kontos's work (e.g., conflict-resolution processes, problem solving, continuous improvement). In addition, these indicators identified several procedural points – including communicating roles and responsibilities, developing communication strategies, and developing plans for working together. As well, Rich identified some essential stances toward collaborative work, including sharing skills, talents, and resources; and being responsive to new ideas and open to change. While it seems that the field has formed some sense of what collaboration means, implies, and requires, new aspects to collaboration continue to emerge. As Rich explained it also entails, "collaborating across disciplines and settings to plan, use, and evaluate complex or technological intervention" and "collaborating/consulting with each other to integrate specialized interventions and services into daily routines and natural settings" (p. 8). Collaborative teams are fraught with challenges, including what may be multiple perspectives on just how collaborative teams actually operate. While it is difficult to boil human interaction down to a list of skills and traits, continued work in this research area can help to specify what is essential to achieve collaboration.

Understanding Different Collaborative Practices

An illustration of the lack of clarity surrounding collaboration can be found in a case study reported by Hinojosa *et al.* (2001). This team of researchers from various disciplines (e.g., allied health, education, and psychology) commented specifically upon the challenges and the time required as they operated as an interdisciplinary research team. They collected data from an early-intervention team housed in a hospital. While referring to this team as interdisciplinary, it seemed much more aligned with Ogletree *et al.*'s (2001) definition of a multidisciplinary team. The researchers noted that roles and responsibilities of team members were individually defined and that they were confident in and comfortable with the relative autonomy of the team members' work. The research team noted that there seemed to be two programs serving the child and family – one, the therapy team, and the other, the classroom team. These two teams had different perspectives in their approach to practice, with different underlying philosophies guiding their decisions. Because therapies were provided via a pull-out model, one theme identified by the researchers was that the classroom tended to function as a “way station” (p. 212). The educational services being provided by team members were relegated to a subordinate role to the therapy services. These researchers concluded that the team – although functional, effective, and generally self-satisfied – did not operate collaboratively. While noting several constraints on the team's functioning in their particular context, Hinojosa and his colleagues concluded that “team collaboration may be hard to realize” (p. 219).

Interdisciplinary teams, as defined by Ogletree *et al.* (2001) can be found in the research literature on team teaching. In this model, teachers from both general education and special education work together in shared classrooms to meet the needs of all children. Citing the complicated relationships between co-teachers, Noonan *et al.* (2003) queried early-childhood teaching teams with regard to how similar they believed they were to each other. Factor analysis during instrument development resulted in one factor with a very high internal consistency. Interestingly, these items ranged from viewpoints toward practice (e.g., classroom arrangement, scheduling, and activity structure) to professional values (e.g., dedication to teaching, beliefs about inclusion, and confidence as an educator) to more personal characteristics (e.g., flexibility in dealing with unforeseen events, sense of humor, and ability to be supportive to colleagues and other staff). What is left to explore is the concept of threshold. In this regard, these critical questions remain pertinent. Are there areas in which team members, absolutely, must be aligned? How much interpersonal difference can be tolerated, and in what areas of belief and practice? What factors might

influence the process of negotiating similarities and differences?

A model for co-teaching collaboration in early-childhood settings was designed, implemented, and evaluated by Hunt *et al.* (2004). In addition to regular and special education staff, the professional team members included a speech–language therapist and family members. These researchers found evidence that this intervention (a well-defined structure for team meeting, planning, and assessment) was effective in producing positive child outcomes. In addition, they examined the viewpoints of team members, who generally believed the processes allowed for the sharing of individual perspectives and expertise. In addition, team members noted that their commitment was increased as they shared ownership in the planning process. In the end, the researchers noted that their grant-funded project helped to create resources needed for the group process, the lack of which could prove to be a barrier (Hunt *et al.*, 2004). Based on this study, collaborative processes require time and effort beyond teaching together in the same classroom. Collaboration is achieved through the work undertaken apart from the daily direct service to children and their families.

The change in roles – including both direct and indirect service delivery – described by Ogletree *et al.* (2001) as marking transdisciplinary collaboration is evident in early-childhood research on consultation or itinerant teacher models. Dinnebeil *et al.* (2006) conducted observations of five itinerant early-childhood special education teachers across the school year and found that teachers did not conduct their activities in classrooms in the same manner. Despite this, Dinnebeil *et al.* found that most of the time in classrooms across the sample was spent in direct service with children on teachers' caseloads. There was little conversation among adults, as well as little activity that could be viewed as consultation with early-childhood general educators. Similarly, in the activity reports, teachers were most likely to not choose tasks relative to consultation and teaming to describe their work. Some reported collaboration with other professionals – such as those from allied health – but this was still not a major job role. In sum, these special education teachers had not readily adopted role change to a more indirect service-delivery model, facilitating the work of early-childhood general educators working daily in classrooms. Instead, they periodically provided direct service on an itinerant basis and performed case-management tasks.

In another study, Wesley *et al.* (2000) explored the comfort level of special education consultants with their work. Using a profile template that was also used to indicate the severity level of children's disabilities in several areas of functioning, consultants indicated their level of comfort in consulting in specific areas. They were asked to designate how severely involved the child's disability could be before they were no longer comfortable in the

consultant role. Wesley *et al.* found that the greatest areas of discomfort were in behavioral issues, communication, and multiple disabilities. There was some indication that consultants were more comfortable serving more severely involved children in a direct service role than in a consultant role. In addition, there were differences among the consultants. Participants expressed higher comfort levels when they had more years of job experience as a consultant and when they had experienced more training in consultation processes.

Based on the literature, transdisciplinary collaboration, sometimes, provides the greatest challenges to personnel. Role change may be even more demanding than other skills that are involved in collaborative teaming processes. Wesley and Buysse (2004) found that consultants "appeared to be operating from the belief that providing consultation is parallel to providing direct early intervention services" (p. 133). Additionally, they found little discussion among the consultants they interviewed with regard to basic concepts and processes of consultation. In other words, role change at a fundamental level did not seem to have occurred.

Effectiveness of Collaborative Models

As it appears, meaningful collaboration among professionals from different disciplines is neither easy nor typical. Barriers to collaboration include time constraints, lack of commitment among team members, difficulty in establishing regular communication channels, lack of naturally occurring opportunities for frequent contact, personality differences, lack of training in roles and processes, and differences in philosophy and approach (Hinojosa *et al.*, 2001; Malone *et al.*, 2001). Wesley and Buysse (2004) noted that consultants reported they were more comfortable with their jobs when they had access to experts, technology, and training. Training in team strategies seems to be important as well for early-childhood educators operating in collaborative models (Malone *et al.*, 2001). Clearly, collaboration can be made more difficult by structural differences between the fields involved. Noonan *et al.* (2003) noted that education level varied systematically among their participants. Most of the special educators in their teaching teams held Master's degrees. Early-childhood educators were equally split between those with a bachelor's degree and those with an associate's degree or the CDA credential. They speculated that these disparities in professional development might have played a part in how team members perceived their similarities and differences with each other. These systematic differences in preservice preparation are quite common between special education and general education at the early-childhood level. In addition, the emphases of the preparation programs are dissimilar. Wesley and Buysse (2004) found that consultants were frustrated and

reported more discomfort when they believed the knowledge, skills, and attitudes of the classroom general education teachers with whom they were working differed from their own.

Malone *et al.* (2001) surveyed general education teachers who participated in teams with a variety of self-described structures, including interdisciplinary and multidisciplinary structures. They found that these early-childhood teachers held generally positive attitudes on teamwork scales. Teachers' viewpoints with regard to the performance characteristics of their teams (e.g., positive communication, role clarity, cooperation, conflict resolution, equal power) were, generally, positive. Malone *et al.* concluded that, "general education teachers are well aware of effective strategies to promote teamwork to support children with developmental concerns" (p. 588). Of course, awareness does not guarantee that collaboration will result among team members. In an interesting study, Campbell and Halbert (2002) asked service coordinators and providers in early-childhood special education to describe up to three wishes that would serve to make early-intervention systems high quality. Almost 15% of the responses related to teaming. Respondents' wishes for more communication ranged from the very concrete desire for more time to meet to changes in organizational infrastructures that would facilitate communication. Campbell and Halbert noted that wishes formed around teaming were more common among allied health professionals and among professionals with less experience. Clearly, while there exists a general literature across fields with regard to collaborative practices, there are also practice issues unique to fields. Wesley and Buysse (2004) carefully described the challenges and issues unique to early-childhood settings that may arise during each stage of the consultation process. Additionally, they proposed responses to these challenges. Expansion of this type of literature across various forms of collaborative practice in early-childhood settings would be beneficial for the field.

A key area to consider in assessing the state of the art in interdisciplinary collaboration is the experiences provided in preservice education. To what degree are professionals prepared to collaborate effectively with professionals from other fields? Research has been conducted to examine both the emphases of programs and the functioning of higher education programs. In regard to the latter, Mellin and Winton (2003) conducted surveys among faculty from higher education programs in education, medicine/nursing, allied health, and the social sciences. They found that only a small percentage of faculty activities related to preservice personnel preparation were conducted from an interdisciplinary point. Most of the variance among the participants, on this point, was predicted by work-environment variables, and these were more likely to pose barriers rather than facilitate interdisciplinary efforts. Bruder and Dunst (2005) surveyed faculty in higher education from a variety of fields. Their queries focused on course coverage

of topic areas deemed indicative of best practices. These included family-centered practice, natural environments, individualized family service plan (IFSP) processes, teaming, and service coordination. The latter two areas – both related to collaboration – were reported as receiving less coverage than the other topics. In addition, less emphasis was reported on teaming in allied health programs, compared to early-childhood special education and multidisciplinary programs. Not long ago, Kamens (2007) explored a more unique form of preservice preparation in a small study of general and special education students placed in a co-teaching student-teaching experience. She noted that there were both positive and less beneficial impacts of this experience. For instance, student teachers appeared to benefit from the peer support available through co-teaching. However, they expressed concerns with regard to being well-prepared to manage a classroom on their own. Being forced to negotiate relationships with their partner-teacher furthered students' understanding of the impact of both their own and other personalities. While student-teachers were placed with team of co-teachers, Kamens noted that their relationships as co-teachers did not necessarily mimic the relationship and style of their cooperating teacher models. In other words, the student-teacher teams developed unique interaction patterns through their work together.

Clearly, the aforementioned studies reflect that there is more work to be done within higher education and other levels to make collaboration effective. Undergraduate students are unlikely to directly experience models of collaborative practice, as faculty were less likely to report interdisciplinary teaming in teaching activities compared to research (Mellin and Winton, 2003). Furthermore, questions remain regarding course coverage. When and where should students gain competence in collaborative practices? Can this material, effectively, be embedded in a course? Should it be the focus of a stand-alone course? Can students be effectively prepared to work across multiple collaborative models, for example, interdisciplinary and transdisciplinary paradigms? In her study, Kamens (2007) noted that general education students had no specific coursework focused on collaboration, while for the special education students, this topic was covered in "some class sessions" (p. 157).

Promising Directions on Collaboration

Throughout this article, directions for future research efforts have been presented. While there is a fairly well-developed literature on training for and implementing collaborative models (see, for instance, the section titled 'Further reading'), more remains to be done.

Noonan *et al.* (2003) raised the point that there has been little examination of the role of culture in co-teaching relationships. Indeed, among the variables explored in research, this one has not been directly named. Differences

in educational preparation, personality, and style have been included in the literature, but there has been no study of how cultural background (including variations in race, ethnicity, class, language, and sexuality) may more systematically impact teaming attempts. In addition, separate systems from which professionals work could be examined from the perspective of culture. Barrera and Corso (2002) focused cross-cultural communication among professionals and families and provided a model for equalizing power differentials among groups. In addition, they stressed on accessing and integrating the strengths of different perspectives into the work of family-professional teams. Cultural differences are not restricted to only parent-professional teams but may also be found among professionals themselves. This line of scholarship can further strengthen the practice of collaborative teams while research can be conducted to help professionals better understand how these differences might play out among those involved in interdisciplinary collaboration.

The field would benefit from further development of effective ways to cross traditional disciplinary boundaries. Wesley and Buyse (2001) proposed that a communities-of-practice approach could enhance collaboration and provide great promise for the field. Through communities of practice, a group of individuals can "formalize, broaden, and deepen" the manner in which they collaborate around ideas and problem-solving (Wesley and Buyse, 2001: 121).

Conclusion

As noted earlier, the barriers operating against effective collaboration across disciplines in early-childhood programs are both many and varied. Despite this, there is much to be found in the existing literature to guide practice. Collaborative teaming requires two-pronged attention from group members, attention to issues and challenges at hand in service delivery, as well as attention to group process. Effective collaborative groups must develop a shared awareness of their expectations, roles, and strategies for operating together. While a multidisciplinary model is efficient, it no longer represents the most effective marshalling of resources toward serving young children and their families most effectively. It is necessary to draw upon the advantages of interdisciplinary and transdisciplinary models to truly achieve this goal.

Glossary

Accents – The sound differences of spoken languages. They may be derived from one's geographic region and/or the influences of foreign languages.

Articulation disorder – A common speech disorder that results when individuals are not able to produce the various sounds and sound combinations of language at the developmentally appropriate age.

Collaboration – A process whereby professionals, including parents and primary caregivers, work together for a shared purpose in a mutually beneficial, supportive relationship.

Communication – A written or spoken transmission and reception of information, which has at least three components: sender, receiver, and message.

Communicative difference/dialect – A variation of a symbol system and reflects shared regional, social, or cultural/ethnic factors.

Fluency disorder – A communication disorder that occurs when the individual has difficulty with the flow and rate of speech, which may be accompanied by struggle behavior.

Language disorder – A communication disorder that involves understanding or producing meaningful conversation.

Morphemes – The smallest linguistic unit of meaning in a language; forms a bridge between phonology and syntax.

Phonology – The system of rules that governs sounds and their combination.

Pragmatics – The actual use of language within a social context.

Semantics – The content of language.

Speech disorder – A term used when the individual's communication is unintelligible, unpleasant, or interferes with communication.

Speech-language pathologists – The professionals who treat speech and language disorders.

Syntax – The arrangement of words combined by following the rule governance and patterns of the specific language to form meaningful sentences.

Voice disorder – A communication disorder wherein there is difficulty with the quality, resonance, pitch, or intensity of one's voice.

One's language is personal, interactive, and original. It is the most human characteristic that helps to shape one's cultural and personal identity, and to a large extent, demonstrates what separates humans from other beings. It celebrates who we are and from whence we have come. It then should come as no surprise that as the nation's schools become more diverse, more challenging issues related to communication, language acquisition, language differences, and language disorders arise. To the extent possible, all students should develop language and communication skills that will aid them in being successful in both school and community settings. Learners who experience difficulty in absorbing information through listening and reading, and who are unable to express themselves in spoken words are almost certain to experience difficulties, not only in their schools, but in their communities as well. This difficulty may have an impact on the individual's ability to form satisfying relationships with others (Table 1).

The ability to effectively communicate is one of the most important aspects of an individual's development. In any setting, there may be a variety of individuals present who do not speak at all, those requiring assistive/augmentative communications, those who must learn to speech read and operate assistive listening devices, as well as those who display socially inappropriate verbal and non-verbal communication skills. An understanding of these disabilities, as well as a global understanding of language and speech development, is critical to our understanding of human beings. Children identified as special needs have many characteristics similar to those identified in typically developing children. These children may take longer to develop their speech, while others may have disabilities that are not recognized at birth but may become more apparent over time. Others may experience difficulties in school, ranging from problems with concentration, learning, language, and perception to problems with behavior. (American Academy of Child and Adolescent Psychiatry, 2008). This article provides a framework for understanding terms/concepts concerning normal speech and language development, communication, language disorders, and language differences in students with special needs. Further, it presents information on how professionals may collaborate with families/primary caregivers as a way of sharing information that should lead to expanded information for all parties involved. In addition, specific information regarding students with disabilities that may impact language development is discussed.

Table 1 Identifying children with language problems

Directions: The following behaviors may indicate that a child in your classroom has a language impairment that is in need of language intervention. Please check the appropriate items.

- ☐ Child mispronounces sounds and words.
- ☐ Child omits words, endings, such as plural-s and past tense-ed.
- ☐ Child omits small, unemphasized words, such as auxiliary verbs or prepositions.
- ☐ Child uses an immature vocabulary, overuses empty words, such as 'one' and 'thing', or seems to have difficulty recalling or finding the right word.
- ☐ Child had difficulty comprehending new words and concerns.
- ☐ Child's sentence structure seems immature or over-reliant on forms, such as subject-verb-object. It's unoriginal, dull.
- ☐ Child has difficulty with one of the following:
 - ☐ Verb tensing ☐ Articles ☐ Auxiliary verbs
 - ☐ Pronouns ☐ Irreg. verbs ☐ Prepositions
 - ☐ Word Order ☐ Irregular plurals
- ☐ Child has difficulty relating sequential events.
- ☐ Child has difficulty following directions.
- ☐ Child's questions often poorly formed.
- ☐ Child has difficulty answering questions.
- ☐ Child's comments often off topic or inappropriate for the conversation.
- ☐ There are long pauses between a remark and the child's reply or between successive remarks by the child. It's as if the child is searching for a response or is confused.
- ☐ Child appears to be attending to communication but remembers little of what is said.

Language: Definition and Attributes

It is generally agreed that a child's language skills are acquired in a predictable order. Children, however, may differ at the rate in which they acquire a given language skill. This can even occur with children in the same family group. Language, as defined by the American Speech-Language-Hearing Association (ASHA), is a "complex and dynamic system of conventional symbols that is used in various modes for thought and communication." The development of language, often hailed as the hallmark accomplishment of humans, is rule-governed with specific conventions that are learned. In humans, language is dependent upon one having a society in which to learn it, other human beings to speak to, and the intelligence to make it possible.

The development of language is a highly complex process. It begins during infancy and continues throughout one's life. Young children normally progress through several stages in developing language, and as previously highlighted, normally exhibit considerable variability in their stages of development. These differences may be due, in part, to general health, environmental influences, and heredity. Specific causes may include hearing and visual impairments, difficulty with oral-motor skills as found in children with specific syndromes, such as Down syndrome, fetal alcohol syndrome, cerebral palsy, cleft lip/palate, and Prader-Willi syndrome. Often the cause can be unknown.

It is generally agreed that today's youngsters come from more diverse cultural and linguistic backgrounds. These learners exhibit a wide range of language, learning, and behavioral characteristics that present challenges to

educators. Some are at risk of academic failure and placed in special education settings because of their limited English proficiency, behavioral characteristics, and/or socioeconomic status. Nearly 4 million of our children under the age of 18 are being reared by their grandparents or great-grandparents; many live in, or near, poverty. Factors for this occurrence include parents not being able to care for their own children because of incarceration and drug and/or alcohol abuse.

The United States is a society made up of many cultures and languages. Each person uses language differently. For one to fully appreciate or understand a language, its use, diversity, and disorders, an understanding of the broader context of language is required. Following are the attributes of language:

- language evolves within specific historical, social, and cultural contexts;
- language is rule-governed;
- language learning and use are determined by the interaction of biological, cognitive, psychological, and environmental factors; and
- effective use of language for communication requires a broad understanding of human interactions, including associated factors such as nonverbal cues, motivation, and sociocultural role.

Oftentimes, language is described along dimensions such as form (phonology, morphology, and syntax), content (semantics), and use (pragmatics). Phonology is the system of rules that governs sounds and their combination. Each language has specific sounds, or phonemes, that are characteristic of that language. A phoneme is further defined as the smallest unit of sound in a word that makes

a difference in its meaning. Morphology is the system of rules for combining sounds into meaningful units, such as words, suffixes, and prefixes. Simply stated, morphemes are the smallest linguistic unit with meaning and form a bridge between phonology and syntax. Syntax refers to the arrangement of words combined by following the rule governance and patterns of the specific language to form meaningful sentences. The content of language is referred to as the semantics of the language. The concept of semantics refers to the ability to distinguish word meaning, including multiple meanings and subtle nuances, and to understand the language. The actual use of language within a social context is referred to as pragmatics; moreover, it is the awareness of socially appropriate behaviors in communication interactions.

Developmental Milestones: Communication Skills in Young Children

Researchers such as Bernstein and Tiegerman-Farber (2002) and Owens (1988) presented detailed summaries of commonly agreed-upon communication developmental milestones in young children. They are:

- *At 12 months.* Infants recognize their own name and can follow simple motor instructions; they produce the first word and express vocabulary of one or more words.
- *At 15 months.* Infants have a vocabulary of four to six words.
- *At 16 months.* Infants develop the ability to point to toys, persons, and animals. They use jargon and words in conversation with a four-to-six-word vocabulary.
- *At 18 months.* Infants begin to use two-word utterances and have a 20-word vocabulary.
- *At 21 months.* Infants understand personal pronouns; they use 'I' and mime.
- *At 24 months.* Infants have a 200–300-word vocabulary and name common everyday objects.
- *At 36 months.* Infants have a vocabulary of 900–1000 words; create three- to four-word sentences and follow two-step commands.
- *At 48 months.* Infants have a vocabulary of 1500–1600 words and use increasingly complex sentences.
- *At 60 months.* Infants have a vocabulary of 2100–2200 words, follow three-step commands, and have 90% grammar acquisition.

Note that children's receptive vocabulary, oftentimes, exceed their expressive vocabulary. This simply means that they understand far more than they are able to verbally express. However, there are children who may not have normal developments. They may have special needs and speech/language impairment. According to the 27th Annual Report to Congress on the Implementation of the Individuals with Disabilities Education Act (IDEA)

by the US Department of Special Education, in 2003, the largest disability category was specific learning disabilities (47.4%). The next most common disability category was speech or language impairments (18.7%), followed by mental retardation (9.6%), emotional disturbance (8.0%), and other health impairments (7.5%).

Language Difference versus Language Disorder

In view of the demographic shifts in our nation's schools, it is important to understand communication in the context of students. Communication is considered to be disordered when it deviates from the standards of the community, enough to interfere with the transmission of messages and stands out as being unusually different, or it produces negative feelings within the communicator. The disorder may either be developmental or acquired through injuries or diseases that affect the brain. Conversely, speech disorders result when the individual's communication is unintelligible, unpleasant, or interferes with communication.

Communication involves languages. How then, can communication and/or language disorders be further explained? There are different kinds of communication disorders. Articulation disorders, perhaps the most common speech disorders, result when individuals are not able to produce the various sounds and sound combinations of language at the developmentally appropriate age. A fluency disorder occurs when the individual has difficulty with the flow and rate of speech. The two most common types of fluency disorders are stuttering (i.e., an interruption of the forward flow of speech) and cluttering (i.e., speech that is overly rapid, disorganized, and occasionally filled with unnecessary words and unrelated insertions). A voice disorder is one wherein there is difficulty with the quality, resonance, pitch, or intensity of one's voice. Students with language disorders may have delays in the development of comprehensive or expressive language. The question continues to be, when is a language difference misinterpreted to mean language disorder?

ASHA, the national professional, scientific, and credentialing association for speech, language, and hearing professionals, notes that English language is composed of many linguistic varieties. This may include Ebonics, Spanish-influenced English, Appalachian English, and Standard English. Accents are sound differences of spoken languages. They may be derived from one's geographic region and may be influenced by foreign languages. A communicative difference or dialect, on the other hand, can be a variation of the form and content of a language. Accents and dialects are types of language differences. A language difference, in and of itself, may not require intervention and remediation; however, those students who are found to be language disordered by a team of professionals will require

intervention and remediation. Language can be described as being disordered when it interferes with communication, calls unfavorable attention to itself, or causes its user to be maladjusted. In earlier studies, ASHA noted that an individual with a language disorder may have problems in sentence processing and in abstracting information meaningful for storage and retrieval from short- and long-term memory.

A language difference is not necessarily a language disorder. As previously explained, language contains a variety of forms, called dialects. Reiterating, dialects are a variation of a symbol system and reflect shared regional, social, or cultural/ethnic factors. Each dialect represents a functional form of English, permitting speakers to communicate adequately, while at the same time maintaining a symbolic representation of the historical, social, and cultural background of the speakers. Although some dialect speakers may have a speech or language disorder, the dialect itself is not the disorder. The presence of a dialect should not necessarily rule out the possibility that a language disorder might exist. A language disorder is a problem in understanding or producing meaningful conversation and might involve

1. a serious disruption of the language acquisition process;
2. difficulty with following rules of grammar;
3. the ability to understand or use words in correct context;
4. not choosing appropriate language for different situations; and
5. problems of written or spoken language, and/or other symbol systems.

Language disorders may vary in severity, ranging from mild to severe.

Specific Disabilities and Language Development

Some individuals may have specific disabilities that may impact language development. This may include the categories of individuals with mental disabilities, cognitive disabilities, learning disabilities, or those categorized with behavioral disorders. The existence of cognitive disabilities usually is identified early in the young child's life, due to the developmental delay evidenced by the child's overall functioning in gross and fine motor skills and usually confirmed with intellectual and behavioral assessments. Cognitive disability has been defined as intellectual functioning that is significantly below average, observed during the developmental years, and accompanied by deficits in adaptive behavior. The regulations for IDEA provide the following technical definition for cognitive disability:

Students with cognitive disability may follow the developmental sequence of language acquisition, use, and

comprehension, but they will not progress at the same rate of their intellectual functioning. Therefore, the extent and rate of acquisition of their total development of language will not be that for "typical" learners. Therefore, it is critical to clearly delineate the needed language and communication goals for the individual student considering his or her long-term life outcomes through the Individualized Education Planning (IEP) process.

Students with learning disabilities may exhibit a combination of characteristics, which may mildly, moderately, or severely impair the learning process. Learning disabilities are characterized by a significant difference in the child's achievement in some areas, as compared to the overall intelligence. Academically, students with learning disabilities may exhibit a wide range of traits, including problems with language as evidenced in reading comprehension, spoken language, written language, and reasoning abilities. Receptive and expressive language, both in the written and oral forms, can be a significant area for remediation. Difficulties will be evidenced in reading, writing, spelling, and comprehending oral and written directions across each of the academic settings. The discrepancies between expectations and achievement for students with learning disabilities increase without intense remediation in these areas.

As the exact numbers of students with learning disabilities are difficult to accurately establish, so also are the terms and defining characteristics as elusive when describing and identifying students who have been described with emotional, behavioral, or mental disorders. The federal definition of serious emotional disturbances (SEDs) includes:

A condition exhibiting one or more of the following characteristics over a long period of time and to a marked degree that adversely affects educational performance:

- An inability to learn that cannot be explained by intellectual, sensory, or health factors;
- An inability to build or maintain satisfactory interpersonal relationships with peers or teachers;
- Inappropriate types of behavior or feelings under normal circumstances;
- A general pervasive mood of unhappiness or depression; or;
- A tendency to develop physical symptoms or fears associated with personal or school problems. (Code of Federal Regulations, Title 34, 300.7(b)(9))

The causes of SED have not been adequately determined. Although various factors, such as family functioning, heredity, diet, brain trauma or disorder, and stress, have been suggested as possible causes (NICHCY, 1996), research has not shown any of these factors to be a direct cause. Given the social and emotional nature of the defining characteristics of this disability, the ramifications in the areas of speech, language, and communication are

evident, especially with communication. Social interactions, as defined by the appropriate use of pragmatics and vocabulary, are the greatest areas of needs evidenced by students with serious emotional disturbances. Because language and communication are essential components of interpersonal relationships, children with SED may experience difficulties giving and receiving information from others. Consequently, language skills seem to impact upon children's social skills.

If a professional/service provider is unsure about whether the child has a speech or language problem, he/she might refer the child for testing by a speech, language, or hearing professional. Speech-language pathologists are also specially trained to serve as consultants to teachers and other professionals on dialectal variations and modifications. Further, they are able to provide individual therapy for the child; consult with the child's teacher about the most effective ways to facilitate the child's communication in the class setting; and work closely with the family to develop goals and techniques for effective therapy in the classroom as well as at home. The use of assistive technology may help children whose physical conditions make communication difficult.

Proactive Strategies for Working with Students with Communication Disorders

To work with exceptional learners with speech and language disorders or communications disorders, it is critical to form and maintain partnerships that effectively facilitate the community of learning that occurs in the home, school, and community environments. The types of parent-teacher-community partnerships that are formed and maintained are related to an understanding of both multicultural students with exceptionalities and their diverse cultural and linguistic backgrounds. As a matter of fact, ASHA noted that:

In order to effectively meet the needs of an increasingly diverse multicultural clientele, it is very helpful for speech-language-hearing professionals to be aware of the historical, social and political factors that have contributed to the development of various speech communities throughout the United States. (American Speech-Language-Hearing Association, 2005)

Several critical factors concerning families of children with special needs and their involvement with schools are important to note. The participation of parents in an educational partnership with school staff may be affected by their comfort level. For some parents/family members of children with special needs, schools are not often seen as very user-friendly places. If parents/family members feel uncomfortable with the school's conceptualization of their parent involvement, they may choose to abstain from

any of the roles made available to them by school personnel. Many parents with limited verbal skills and little experience in negotiating the educational system may find it difficult to identify and access appropriate educational resources for their children. Dealing with any bureaucracies, including school systems, can be a frustrating and overwhelming process. These parents may rarely have the capacity to participate in educational partnerships, especially when they sense that they are dealing with a system that does not recognize that they suffer from the double-whammy of dealing with both race and disability.

For parents who have had negative experiences themselves with schools, this may present a barrier to their participation as partners in the educational process. Some of these negative experiences may be more subtle; other experiences may be more overt. For example, when parents feel that there is little or no attempt to accurately represent the historical contributions of African Americans in the school curriculum, they may be reluctant or even unwilling to form partnerships with teachers and others involved in the education of their children. Parents, including those who have children with exceptionalities, usually understand that knowledge of one's racial identity and cultural heritage are critical factors in promoting positive self-esteem in some children and in socializing them to effectively cope with racism.

Conclusion

Most would agree that the United States is a nation comprised of persons from different backgrounds, experiences, ethnic and cultural groups, and expectations. As a result, it is the responsibility of teachers and service providers to provide academic and social-emotional support that empowers both students and families with special needs. For many students with special needs, especially those that are culturally and linguistically diverse, problems of misidentification, labeling, and inappropriate schooling still remain. Specifically, educators must value community and family involvement. In addition, they must understand when students have language disorders or language differences as they explore the different types of communication disorders. Finally, they must understand that collaboration with the child's parents/primary caregivers can have a major impact on the child's communicative development and skills. This is true for all children, but especially for students whose first language is not the majority language.

Glossary

1% assessment – Another name given to alternate assessments based on alternate achievement standards; this term is used because of the Elementary and Secondary Education Act accountability system, which limits the percentage of students who may be counted as proficient on this type of assessment to 1% of the total student population.

2% assessment – Another name given to alternate assessments based on modified achievement standards; this term is used because of the Elementary and Secondary Education Act accountability system, which limits the percentage of students who may be counted as proficient on this type of assessment to 2% of the total student population.

504 plan – A plan for accommodations that is developed for students with disabilities who do not require special education services.

Accessibility – A quality of those assessments that reveal the knowledge and skills of students whose disability, limited language, or other specific characteristics create barriers to accurate measurement through large-scale assessments of the students' knowledge and skills.

Accommodations – The changes in the materials or procedures used during large-scale assessments that do not change the intended content to be measured; these changes include adjustments to the presentation of materials, responses that students make, setting of the assessments, or timing or scheduling of the assessment.

Accountability – A system for holding a person or group of people responsible for a process or product. Large-scale assessments are used to hold school systems, educators, or students responsible for the performance of the students.

Assessment – A method for collecting data; large-scale assessments are tests or other data collection procedures given to large numbers of students at the same time for the purpose of documenting student achievement.

Disability – An impairment in the sensory, intellectual, learning, or behavioral aspects of a

student's learning and performance; in the United States, specific categories of disability are identified to group students with similar characteristics.

Growth models – An approach to system accountability that looks at the performance of cohorts of students, or that looks at the performance of students longitudinally, to determine whether there is improvement, or growth, in performance over time; these models are in contrast to status models, which compare different groups of students over time.

High stakes – The consequences that are significant to either the educational system or individuals within it; assessments themselves may be designated as high stakes based on the consequences assigned to results of the assessment.

Individualized education program (IEP) –

A written document that defines the goals and directs the provision of special education services to students with disabilities who need them; identifying the way in which students participate in large-scale assessments is part of the IEP.

Modifications – The changes in the materials or procedures used during large-scale assessments that change the intended content to be measured; these changes include adjustments to the presentation of materials, responses that students make, setting of the assessments, or timing or scheduling of the assessment.

Special education – The services provided to students whose disability creates barriers to learning or demonstrating learning in assessments.

Universal design – An approach to making instruction or assessments appropriate for the widest range of students; for large-scale assessments, emphasis is given to maintaining the intended content to be measured while attending to aspects of the assessment such as item comprehensibility and readability, legibility, and similar characteristics.

Testing is an integral part of education in the United States. A significant portion of the assessment activity is devoted to administering large-scale assessments, which are given to large numbers of students at the same time for the purpose of documenting student achievement.

Other testing is conducted to diagnose student eligibility for specific programs such as gifted education or special education. In the United States, all students, including those with special education needs, participate in large-scale assessment systems. Accountability is one purpose for which large-scale assessments are used. The assessments provide all or part of the information that is used to hold schools or individuals responsible for student achievement. Accountability consequences include reporting the performance of students to the public, altering the resources directed to individuals or schools, or imposing specific sanctions for poor performance.

The inclusion of students with special needs in large-scale assessments and accountability systems is important for promoting the positive consequences that they are intended to produce, and for avoiding unintended consequences that result from exclusion. Students with disabilities, English-language learners (ELLs), and ELLs with disabilities benefit from participation because the students are held to higher expectations and provided the same educational opportunities as other students, including increased access to the curriculum, additional resources for learning, and better outcomes. Unintended consequences that are avoided include lower expectations, exclusion from instructional opportunities and resources, and poor outcomes.

Large-Scale Assessments

Large-scale assessments vary on a number of dimensions, including the purpose of the assessments, the types of items that are included in the assessment, and the consequences of their use. Decisions about these dimensions affect the inclusion of students with special needs in the assessments.

Purpose of Assessments

Large-scale assessments are used for many purposes. They provide information used to determine whether students graduate or are promoted from one grade to the next. Assessment results help determine whether students are admitted to college or have the competency to be a teacher, a dentist, or another professional or worker. They are used to make decisions about whether schools, districts, or states have produced the levels of student achievement considered necessary for them to progress through school and become successful adults.

Many large-scale assessments are used for accountability purposes. They provide information that is used to hold a student, educator, school, or district responsible for student achievement. Responsibility has consequences that may range from public reporting of assessment results

to determining that a school needs to be restructured or closed so that students have a better opportunity to achieve at higher levels.

Assessment Options for Students with Disabilities

Large-scale assessments frequently are multiple choice tests with one or more extended response items that require students to write short answers or longer essays. Occasionally, large-scale assessments may be performance events, in which the student is asked to perform a task such as a science experiment. They also may be portfolios in which the student or the student's teacher gathers evidence of learning and achievement in specific content areas.

For students with disabilities, participation in large-scale assessment systems occurs in three primary ways: in the general assessment the same way as other students take the assessment, in the general assessment with accommodations, or in an alternate assessment. Individualized education program (IEP) teams make the decision about the way in which each individual student with disabilities participates in large-scale assessments. IEP team members also determine the specific accommodations that students may need to participate in the assessment.

General assessments

Many students with disabilities take the same large-scale assessments in the same way as their peers without disabilities. Most test developers ensure that the participation of students with special needs in these assessments is appropriate by complying with accessibility principles and incorporating elements of universal design.

Accessibility and universal design include the concepts of considering all students' needs at the beginning of item and test design, clearly defining the content to be measured, ensuring that all items are comprehensible, readable, and legible, and that assessments have clear, simple, and intuitive instructions. Some universal design advocates argue that assessments must allow many ways to present items and many ways for students to respond to assessments. Both accessibility and universal design address ways to allow the students with varying characteristics and needs to show what they know and can do. The notion that accessible and universally designed assessments will help produce more valid results for students with disabilities is often not understood. Some test developers assume that an accessible or universally designed assessment is just an easier assessment.

General assessments with accommodations

The majority of students with disabilities participate in large-scale assessment systems by using accommodations when they take the assessments their peers do.

Accommodations are changes in materials or procedures that enable students with disabilities to avoid the barriers that their disabilities create. Accommodated assessment performance is a more accurate reflection of the knowledge and skills of those students needing accommodations. Accommodations do not change what the test is intended to measure; they are generally distinguished from modifications, which are changes in materials or procedures that alter what the test is intended to measure.

Accommodations and modifications frequently are categorized according to the nature of the changes that are made. A common categorization scheme for accommodations and modifications is: presentation, response, timing/scheduling, and setting. Equipment or technology accommodations are included in these categories according to the function of the equipment or technology, or may be considered as a separate category of accommodations.

There are literally hundreds of accommodations or modifications identified in state policies that determine which changes are acceptable for the state's specific content standards and the purpose of the assessment. The policies are frequently updated, with variations occurring among states and over time for the same state. States rely on existing research, logical rationales, and input from stakeholder groups to determine whether changes to standard procedures should be considered accommodations or modifications for each particular assessment content area, purpose, and grade level. Controversy over which accommodations produce valid results for students with disabilities continues despite considerable research on the effects of accommodations.

Presentation accommodations or modifications are changes in how the testing materials are presented. Examples are braille and large-print editions of the assessment, reading part or all of the assessment to the student, using a screen reader, presenting the assessment in sign language, and allowing students or teachers to highlight specific words or phrases in the assessment. For this category, the accommodations or modifications most frequently used tend to not be those that are most often allowed. For example, reading part or all of the assessment is used more often than braille editions, but braille editions are allowed by more states than reading the assessment to the student.

Response accommodations or modifications are changes in how the student responds to the assessment. Examples are using a braille or a scribe to input responses, using a calculator to help determine answers, responding in sign language, and marking in the test booklet rather than on a bubble sheet that is scanned to record students' responses.

Timing or scheduling accommodations or modifications are changes in the duration of time that a student participates in testing, or in when the student participates. Examples of timing accommodations or modifications are extended time, providing extra breaks during the assessment, and allowing

students to take the test across multiple days when other students take the test during one day. Scheduling accommodations or modifications include conducting assessments for a student only during a certain part of the day, regardless of when other students are tested, or scheduling testing for times when it is best for the individual student, regardless of the schedule for all other students.

Setting accommodations or modifications are changes in where the assessment occurs. Examples of setting accommodations or modifications include administrations to a small group or individuals, testing in the special education classroom rather than the lunchroom with other students, in a carrel to avoid distractions, or in a hospital.

IEP teams making decisions about accommodations should consider the goals of the assessment, the nature of the student's characteristics and needs, and the policies that states or districts have set to guide accommodation policies. Numerous issues surround the implementation of accommodations. IEP teams should receive training on making accommodation decisions, and states and districts should monitor the use of accommodations on assessments. Taking these steps reduces documented inconsistencies between the accommodations identified by the IEP team and the accommodations used in the classroom and during assessments.

Alternate assessments

Alternate assessments are designed for students unable to participate in typical large-scale assessments. These assessments may be designed to hold students to the same grade-level achievement standards as other students, but in a different way such as by using a portfolio assessment rather than a multiple choice assessment.

Alternate assessments may also be designed to hold students to different performance or achievement standards. The different standards may be either alternate achievement standards or modified achievement standards. The exact meaning of these alternate and modified achievement standards is not always clear.

Most assessment developers consider alternate achievement standards to reflect truly different expectations that are consistent with the significant intellectual disabilities of the students typically participating in them. Modified achievement standards, in contrast to alternate achievement standards, are directly related to the achievement standards held for all students, but represent reduced difficulty. Even though the performance or achievement standards are adjusted in these two types of alternate assessments, the assessments are still linked or aligned to the grade level of the content of the assessment. Students held to alternate or modified achievement standards have expectations for their performance that are different in some way from those for other students.

The most common type of alternate assessment is the alternate assessment based on alternate achievement

standards. Some educators refer to these as 1% assessments, due to the percentage of students in the total population who can be counted as proficient on these assessments for the accountability requirements of the Elementary and Secondary Education Act. Alternate assessments based on alternate achievement standards generally look different from traditional assessments. They tend to be portfolio assessments, performance assessments, or rating scales.

When alternate assessments based on alternate achievement standards are portfolios, or bodies of evidence as they are sometimes called, they generally involve the teacher collecting samples of student work, perhaps over a specific period of time, such as a year. These are scored against a rubric that describes performance at several levels of achievement, and may be scored by more than one person to ensure reliability of the score. Teachers select entries based on guidelines provided to them, such as a certain number of entries in each targeted content area, some entries that show the results of participating in the general education classroom, or entries that show use of technology. The criteria in the rubrics vary considerably.

Alternate assessments based on alternate achievement standards that are performance based generally involve specific tasks to which the student is to respond. The student's response to the task is judged against a rubric to produce a score. Independent observers or teachers may score each student's performance. In some cases, records of performance are developed and these are sent to a scoring center to produce scores for each student's performance.

Rating scales provide the teacher or other raters with specific criteria to judge the past performance of students. In some states or districts, raters are directed to evaluate the performance of students during a specific window of time, such as 2 weeks before other students are taking the general assessment, and in some states they are directed to rate the change in performance from the beginning to the end of the school year.

Alternate assessments based on modified achievement standards reflect a new approach to including special education students in large-scale assessment systems. Some educators refer to these assessments as 2% assessments, due to the percentage of students in the total population who can be counted as proficient on these assessments for the accountability requirements of the Elementary and Secondary Education Act. Alternate assessments based on modified achievement standards look more like general assessments than not, and are intended for students with disabilities who are unable to meet proficiency on the state assessment within the period of a student's IEP.

Accountability

Accountability refers to holding a person or group of people responsible for a process or product. When

coupled with large-scale assessment, accountability generally indicates that schools and districts, or the students and personnel within them, are held responsible for performance on assessments. Accountability systems have goals such as improved performance, ways to measure the goals such as large-scale assessments, criteria for determining when goals have been met, and consequences for meeting or not meeting the goal. When the consequences become significant, they are referred to as high stakes. High-stakes assessments can be either those where the responsibility lies with the school system, or where the responsibility lies with the individual educator or student.

The inclusion of special needs students in accountability systems creates challenges for several reasons. One reason is that there is increased concern about the potential unintended consequences that may follow when students with disabilities or ELLs are included in accountability systems. This concern exists whether the school system or educators within it are held responsible for the performance of the students, or the students themselves are held responsible through promotion or exit exams. Unintended consequences include students dropping out of school, being exposed to inappropriate instructional efforts to produce increased test scores, and losing their special education status due to the level of their performance. There are also concerns about how to best include students who may be in very different educational settings such as residential schools and how to account for students who are with some teachers for very small amounts of time or who move in and out of special education services.

System accountability

System accountability refers to holding schools, districts, and states responsible for the performance of students within them. Large-scale assessments are an integral part of most system-accountability measures, but not the only measures. Others include indicators of attendance, graduation rates, and the extent to which all students participate in large-scale assessments. In the United States, the Elementary and Secondary Education Act includes requirements for system accountability. It also requires the inclusion of all students in assessments and the accountability system.

The inclusion of students with disabilities in system accountability requires decisions to be made about how their participation in large-scale assessments will factor into accountability calculations. Students with significant cognitive disabilities often are identified as one group that does not fit the traditional assessment approach because their disabilities are intellectual and multiple in nature. If these students were to be held to the same performance standards as other students, they would always be at the bottom of the performance continuum, simply because of the nature of their disability. Determining that these

students can have their own set of performance standards based on unique assessment approaches is a solution to the challenge of how to include them.

Another challenge occurs when considering the inclusion of students who use accommodations or modifications during testing. If accommodations are considered to not change the intent of the measurement and to produce valid scores, then the use of these is not considered to inappropriately change the student's performance. Their inclusion in accountability systems then is usually considered to be appropriate without challenges, other than those logistic challenges associated with making appropriate decisions about which students need which accommodations and making sure that students who are supposed to use accommodations during testing actually do receive them.

The challenge comes from determining how to include those students who use modifications. These are changes in testing materials or procedures that alter the intent of the measurement and therefore produce invalid scores. Determining ways to represent these students in accountability systems, while not inaccurately indicating that students have valid scores, is a major challenge when including students with disabilities in accountability systems. A common approach for the inclusion of those students who use modifications is to count them as participating in the assessment, but instead of reflecting the scores that they obtained the students are assigned the lowest possible score or a zero. The Elementary and Secondary Education Act has determined, however, that for purposes of its accountability system, students using modifications cannot be counted as participants in the assessment because they do not receive valid scores. Adequate numbers of students participating in the assessment is an additional factor in the Elementary and Secondary Education Act accountability system.

Different accountability models

System accountability may take different forms depending on the model that is used. Common models are status models, cohort models, and longitudinal models. Sometimes cohort and longitudinal models are referred to as growth models. In status models, the performance of students in one grade in a year is compared to the performance of students in the same grade the next year. Status accountability measures are based on different groups of students, but the system is held accountable for showing improvement over time.

Cohort-accountability measures are based on primarily the same group of students. The performance of students in one grade in a year is compared to the performance of students in the next grade in the next year. This model results in primarily the same set of students being compared from one year to the next. Some students move out of the system, and some students move in, so there is actually some variation in the specific students included in the

comparisons. To the extent that mobility or dropout rates are higher, there is decreased consistency in the students who are included in the cohort-accountability system.

Longitudinal accountability is based on the same specific students being compared from one year to the next. This approach is highly dependent on good data management so that students can be followed across years. It is more reflective of the student population when mobility rates are small.

Growth models are a variation of these models of accountability. They use either a cohort or longitudinal approach. Sometimes they factor in the effects of students' socioeconomic, ethnic, or disability status. Value-added approaches attempt to demonstrate the added effect of the education system or teachers within it to where the student started out, including adjustments for the student's poverty status or disability status. Value-added models often are controversial when consideration is given to the inclusion of students with disabilities in them. Concerns are raised about whether these students are held to lower expectations as a result and whether they are excluded too often from these systems because of other factors in the calculations that determine value added.

Educator accountability

Educator accountability refers to holding administrators, teachers, or other school personnel responsible for the performance of students, and assigning consequences to them based on the performance of their students. Pay-for-performance systems financially reward educators for the performance of their students. Students with disabilities typically are included in calculating student performance, and special educators are also the target of the accountability systems. The inclusion of students with disabilities often causes challenges for the accountability system. Accountability system developers must determine ways to include students who may spend only part of their time or none of their time in the general education classroom. In some cases, students may receive special education services in a residential or alternative setting. All of these unique situations create challenges for the inclusion of the performance of students with disabilities in an educational accountability system. Including special educators in the accountability systems is also challenging. Unlike general education teachers, special educators may work with many more students for much shorter periods of time.

Student accountability

Student accountability refers to holding students responsible for their own performance. Promotion exams and exit or graduation exams are an integral part of most student-accountability measures. Additional measures are typically added to student-accountability decisions. For promotion exams, consideration may also be given to the amount of progress the student made during the

school year or the participation of the student in a remedial program. For exit or graduation exams, completion of course work is often another factor in determining whether the student is able to graduate.

The inclusion of students with disabilities in student-accountability measures is complicated by a history of excluding them and holding them to different standards. Regardless of whether excluded or held to different standards, the same results such as promotion to the next grade or graduation with a standard diploma often were allowed for these students. Increasingly, however, different results, such as receipt of a certificate of attendance or a special diploma rather than a standard diploma, are being imposed for those students with specific needs who do not meet the same requirements as their peers.

For students with disabilities, there may be alternative routes to the standard diploma that are not available to other students. For example, they may be allowed to demonstrate that they have met graduation performance standards by providing a portfolio of their work when they repeatedly fail the graduation exam, or they may be able to show that their classroom performance and grades are equal to those of their peers who have passed the graduation exam. A variety of approaches have been developed in some places to allow students with disabilities the opportunity to show that they have met the same student-accountability requirements as their peers. Other places have no alternative ways for students with special needs to demonstrate that they have met the requirements even though they have not been able to pass the large-scale assessment.

Summary

Large-scale assessments used for accountability purposes are a prevalent part of the educational system in states and schools in the United States. They vary in appearance and purpose. A commonality across them is that they include students with disabilities. This inclusion has required the careful consideration of how all students with special needs can participate in the assessments so that the assessment results are valid reflections of the students' knowledge and skills.

The inclusion of students with disabilities requires test developers and test users to think carefully about the nature of the assessment, its purpose, and the kinds of flexibility that can be introduced without changing what the original assessment intends to measure. When students with disabilities participate with accommodations or in an alternate assessment, careful consideration must be given to the reasons that the student is not able to participate in the general assessment in the same way as students without disabilities. When participation in the assessment other than the general assessment without

accommodations is the best option, the assessment should produce valid results for students with disabilities so that they can be combined with the performance of other students.

Literacy Instruction for Students with Special Needs

L H Mason, The Pennsylvania State University, University Park, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Children with difficulties in reading, vocabulary, and writing constitute the largest group of students identified for special education services and are most frequently included in the general education curriculum with minimal supports. A large proportion of students with special needs, perhaps over 70%, are at risk for academic failure in the general education curriculum due to a lack of foundational skills in literacy. When their achievement is compared to that of other struggling learners, students with special needs may appear similar; however, they experience reading, vocabulary, and writing problems that are more severe than those of their peers.

The National Reading Panel (NRP) report in 2000, fortunately, concluded that students' performance in reading could be improved by (1) promoting phonemic awareness that teaches students to break apart and manipulate the sounds in words; (2) promoting phonics that teaches students that sounds are represented by letters which can be blended together to make words; (3) having students practice what they have learned with guidance and feedback; and (4) teaching reading comprehension strategies (Carnine *et al.*, 2004). Correspondingly, students' vocabularies can be enhanced by directly and indirectly teaching strategies for learning word meanings. Writing performance, furthermore, can also be improved with explicit instruction in teaching students with special needs to be strategic while planning, drafting, and revising (Graham and Harris, 2003).

Instructional Approaches for Literacy

Students with special needs may have a number of problems that interfere with their learning by means of conventional general education instruction. Students with special needs, for example, often have difficulties with memory and poor language abilities. They may have interfering behaviors such as attention problems, hyperactivity, aggressive behavior, withdrawn behavior, or unusual behavior (Bos and Vaughn, 2006). Effective instruction for these students, therefore, should include careful progress monitoring; instructional planning that considers flexible groupings, adaptation, and scaffolding; and instruction that is paced well and allows for student responding and error correction. Two instructional approaches that meet this criterion, direct instruction (DI) and cognitive strategy instruction (CSI), are highlighted in this synopsis of literacy instruction. Although these approaches, often implemented to address the

diverse array of reading, vocabulary, and writing competencies, are by no means the only documented effective approaches for teaching literacy to students with special needs, both DI and CSI have been used broadly in special education and have proven effective in improving literacy outcomes for these students.

Principles for both DI and CSI are presented in **Table 1**. Although these approaches appear to be quite different, both contain congruent principles implemented in varying degrees, depending on the skill to be taught. For example, teacher-led modeling is a critical component of both DI and CSI. Instruction is criterion-based as opposed to time based. In other words, students meet a pre-established goal for learning prior to moving to the next instructional stage or lesson. Student motivation is supported in both approaches through student success as noted through demonstration and/or self-reinforcement. Although neither approach is limited in scope of skills to be taught, DI has been generally established in research as most effective for developing fluency in basic skills such as word recognition and spelling, while CSI has been established in research as most effective with higher-level skills such as reading comprehension and written expression. DI and CSI, and variations of the two approaches, will be described further in the context of specific reading, vocabulary, or writing skills to be taught. In addition to DI and CSI models, examples of other models of instruction, taken from the research literature, will be employed to illustrate the range of effective literacy practices for students with special needs.

Reading

According to the NRP (2000) report, effective reading instruction includes phonemic awareness instruction, phonics instruction, fluency instruction, vocabulary instruction, and text comprehension instruction. There is little disagreement among researchers that these components are essential for students with special needs who are struggling to learn to read (Carnine *et al.*, 2004). Although researchers and practitioners may disagree on how to teach reading, for these low-achieving students, engagement in appropriate and meaningful skill-level reading-related activities is generally deemed crucial.

Beginning reading

Although many students come to school prepared to read, students with special needs often come to school needing

Table 1 Effective instructional principles for students with special needs

<i>Direct instruction (DI)</i>	<i>Cognitive strategy instruction (CSI)</i>
<i>Unison oral responding.</i> All students in a group respond at the same time to a teacher's question or prompt.	<i>Preskill development.</i> Preskills for the task are developed. Students' prior knowledge about the task and strategy are assessed and remediation for individual students is provided as needed.
<i>Signaling.</i> Cues that are developed by the teacher to cue responses from students.	<i>Discussion.</i> The teacher and students discuss the strategy to be learned. A purpose for using the strategy is established and the benefits of using the strategy for the task, is presented.
<i>Pacing.</i> The teacher effectively paces instruction to avoid student downtime during instruction.	<i>Modeling.</i> The teacher cognitively models (models while thinking out loud) how to use and apply the strategy for the task.
<i>Monitoring.</i> Teacher systematically plans the use of elicited responses from individual students to monitor learning.	<i>Memorization.</i> Students are provided time to memorize the strategy steps until fluent in understanding any mnemonics and meanings and each strategy step.
<i>Error correction and teaching to mastery.</i> Teachers include five instructional steps: model, lead, test, firm up, and delayed test.	<i>Guided practice.</i> Instruction is scaffolded from student–teacher collaborative practice to independence based on individual student needs. Systematic feedback is given to individual students.
<i>Diagnosing.</i> Teacher works with individual students to determine areas of weaknesses.	<i>Independent practice.</i> The teacher provides independent practice across task and settings to foster generalization and maintenance.
<i>Motivation.</i> Student motivation is fostered through demonstration of student success and rewards for learning.	^a <i>Self-regulation.</i> Student takes control of learning through goal setting, self-instruction, self-evaluation, and self-reinforcement.

^aIncluded in self-regulated strategy development instruction (SRSD).

6 months to 1 year of instruction prior to beginning reading. These students will require intensive instruction in:

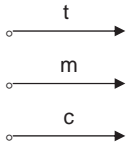

1. Phonological awareness: the identification and manipulation of spoken language (e.g., words, syllables, onsets, and rimes). This includes phonemic awareness, the identification of manipulation of sounds (phonemes) in words.
2. Letter–sound correspondence: knowledge of letters of the alphabet and the corresponding sounds they represent.
3. The alphabetic principle: the combination of phonological awareness and letter–sound correspondence.

The NRP (2000) report noted that phonological awareness is best supported by instruction that uses alphabet letters for phoneme manipulation; limits manipulation to one or two phonemes; includes phonemes in words for blending and segmenting activities; and provides explicit description about the application of phonemic skills to both reading and writing (i.e., spelling). Phonological awareness can include skills such as identification of rhyming words, listening for words with same beginning sound, identifying the number of words by clapping, and blending and segmenting words by sounds and syllables (Torgesen, 1999). Carnine *et al.* (2004) recommended DI for teaching telescoping (blending), segmenting, and rhyming skills. Telescoping and segmenting tasks teaches phonemic awareness, and provides students with practice in saying sounds and blending sounds without pausing. Rhyming assists students in understanding the relation of same-sound letter clusters and provides practice in sounding out words that begin with stop sounds (e.g., the p in pop as opposed to the r in rat). Rhyming is introduced after students have mastered telescoping and segmenting skills. **Table 2** illustrates how DI is used to teach these beginning reading skills. While a developmental model is generally accepted for teaching skills in each of these areas, it is not recommended that instruction focus on one skill at the expense of others. Simply stated, some of these students may never master a skill. Rhyming, for example, may be quite difficult for some students with special needs, whereas a higher-level skill such as syllable blending may be learned easily.

Given that phonological awareness instruction supports auditory skill development as opposed to specific skills for reading letters and words, it should be taught in conjunction with letter–sound correspondence, or instruction known as the alphabetic principle, through phonic instruction. Phonic instruction focuses on teaching students to recognize familiar words and to decode unfamiliar words. It includes teaching letter–sound associations, letter–sound correspondences, sound–spelling, written language (grapheme)–phoneme correspondences, and graphophonemic relationships. Carnine *et al.* (2004) identified six approaches to phonic instruction:

1. *Synthetic phonics.* Students convert letters into sounds, and then blend the sounds to form words.
2. *Analytic phonics.* Letter–sound relationships in learned words are analyzed; sounds are not pronounced in isolation.
3. *Analogy-based phonics.* Word families are used to identify unknown words.
4. *Phonics through spelling.* Words are segmented into phonemes; letters are written for phonemes.
5. *Embedded phonics.* Letter–sound relationships are taught during reading of connected text. (Note: this is not considered an explicit instructional approach.)
6. *Onset–rime phonics.* Common spelling patterns are used to decode words.

Table 2 Direct instruction for telescoping, segmenting, and rhyming sounds

<i>Teacher (teacher says words in quotations)</i>	<i>Unison choral responding</i>
<i>Telescoping^a</i>	
1. "Listen, we are going to play a say-the-word game. I will say the word slow. You say the word fast"(pacing).	"Go."
2. "Listen – ggggoooo-What word?" Signal (signaling).	
3. Repeat step 2 with four more words.	
4. Repeat the set of words until students can respond with no errors (error correction and teaching to mastery; motivation).	
5. Provide individual turns for students (monitoring and diagnosing).	
<i>Segmenting</i>	
1. "We are going to say words slowly."	"Ggggoooo."
2. "First word: go. I will say it slowly. Listen. Ggggoooo. You say it slowly. Get ready." Signal.	
3. Repeat procedure in step 2 with three more words.	
4. Repeat the set of words until students can respond with no errors.	
5. Provide individual turns for students.	
<i>Rhyming</i> (Write on board)	
	
1. "Listen. I am going to rhyme with – an. What am I going to rhyme with?" Signal.	
2. Model by putting finger on the dot of the first arrow and say, "My turn, rhymes with an." Pause for 1 s, move finger across arrow and say, "tan."	"An."
3. Repeat step 2 with remaining arrows.	
4. Put finger on dot of first arrow. Say, "You are going to rhyme with an. What are you going to rhyme with?" Signal. "Rhymes with an." Pause for 1 s, move finger across arrow.	"An." "Tan."
5. Repeat step 4 with remaining arrows.	
6. Provide individual turns for students.	

^aDI principles in parenthesis.

Adapted from Carmine, D. W., Silbert, J., Kame'enui, E. J., and Tarver, S. G. (2004). *Direct Instruction Reading*, 4th edn. Columbus: Merrill Prentice Hall.

Several modifications to these instructional approaches are recommended for students with special needs. First, when teaching letter–sound correspondence, a core set of frequently used consonants and short vowel sounds should be taught with consistent use of key words. Students should

learn that some letters have more than one sound, different letters can make the same sound, and more than one letter can represent some sounds. Kinesthetic (trace letters as saying sound) and visual (color-coding) approaches can be used to reinforce learning. In addition to these recommendations, explicit code instruction (instruction that is systematic and scaffolded to include modeling, guided practice, corrective feedback, and review) is recommended. Several methods have been recommended by researchers and are used widely for phonic instruction for students with special needs: (1) the linguistic approach for onset–rime and word families (e.g., *Merrill Reading Program*); (2) DI approaches (e.g., *Reading Mastery*); and (3) multisensory structured language instruction (e.g., *Wilson Reading System*) (see the section titled 'Further reading').

Fluency

Fluent readers read text quickly, accurately, with ease, and with expression. Fluency is a critical skill that is required to move the student from an over-focus on word recognition to attending to understanding what is being read. Several methods for improving reading fluency for students with special needs have been identified (Bos and Vaughn, 2006). First, fluency (e.g., number of words correctly read in 1 min minus number of errors) should be assessed and monitored. Students can plot their scores on a graph for goal setting and to support motivation. Next, teachers should model fluent reading by reading aloud to students, teaching them to preview books prior to reading, and providing practice in reading at the students' instructional to independent work-recognition level. Clearly, fluency can also be supported in the classroom by providing students opportunities for reading performance. In addition, it can be supported, for example, by asking older students to read to younger students. Teachers can model the acceptability of reading an easy book and make a difficult book more accessible by tape recording, providing partner reading, and using series books.

Repeated reading as an instructional approach for fluency has proven effective for improving reading speed, accuracy, expression, and comprehension. In repeated reading, the student reads a 50–200-word passage at their instructional level 3–5 times until a more fluent rate is achieved. The teacher provides direct support by pronouncing any unknown words while the student reads. This procedure has been modified effectively with the use of choral repeated reading, taped books, or computer-assisted instruction. Direct instruction for repeated reading should occur in a couple of short (10–15-min) sessions weekly.

Another instructional approach, peer-supported reading (i.e., classwide peer tutoring and partner reading), supports reading fluency and comprehension by providing students with special needs, multiple opportunities for reading in the general education classroom. One elementary school

Table 3 Peer-assisted learning strategies (PALSs) for reading fluency and comprehension*Features of PALS*

1. High-performing students are paired with low-performing students.
2. Students are trained in specific prompting, correction, and feedback procedures.
3. Verbal interactions are frequent to support student's opportunities to respond.
4. Student roles are reciprocal; each serves as a tutor and tutee, but the stronger reader always reads first.
5. Activities are structured.
6. Students are trained to implement activities independently.
7. Following training, PALS instruction is conducted weekly in three 35-min sessions.
8. Student pairs are assigned to teams. Points are earned by each pair by correctly responding during the activities.

PALS activities

1. Partner reading with retell
Each student reads a passage aloud for 5 min. If an error is made the tutor (the student who is listening) asks for correction. After both students have read, the weaker student states what was read in a 2-min retell. Students earn one point for each correctly read sentence, retelling earns 10 points.
2. Paragraph shrinking
During this activity students read orally, stopping at the end of each paragraph to identify the main idea. The tutor prompts the reader by asking the reader to identify who or what is most important. The reader must supply an answer in 10 words or less to earn points.
3. Prediction relay
Students complete four steps in this activity:
 - the reader predicts what will happen in next half of page
 - the remaining half of the page is read out loud
 - the reader confirms or disconfirms their prediction
 - the reader summarizes the main idea in the passage
 Students earn points for identifying the main idea in 10 words or less.

From McMaster, K. L., Fuchs, D., and Fuchs, L. S. (2006). Research on peer-assisted learning strategies: The promise and limitations of peer-mediated instruction. *Reading and Writing Quarterly*, 22, 5–25.

peer-supported method that includes a reading comprehension component, peer-assisted learning strategies (PALSs), is described in **Table 3** (McMaster *et al.*, 2006). A version of PALS, K-PALS instruction for kindergarten and first-grade students, supports young students by including more teacher support through extended coaching, and adds activities for a sound play (five games for phonological awareness) and sound and words (four activities for reading words and sentences). Additionally, PALS has been modified for high school students by changing partners more frequently than is done with younger students, by adding a system for managing and spending PALS dollars for points earned, and by focusing on reading with expository text.

Reading comprehension

Good readers maintain conscious control of their reading process by implementing strategies to support

comprehension as they deconstruct text (decode) and reconstruct meaning. Students with special needs in reading, in contrast to good readers, rely on simpler, less-efficient strategies and fail to implement what strategies they do know in a fluid, controlled fashion. Researchers, however, have clearly established that when students who struggle with reading, including students with special needs, receive explicit instruction combined with practice in comprehension strategies, reading comprehension gains are among the highest (Mastropieri and Scruggs, 1997). These strategies include reading comprehension approaches such as prior knowledge acquisition, self-questioning, main idea prompts, story grammar and text structures, summarization, and comprehension monitoring.

For students with special needs, however, successful reading comprehension is dependent on multiple elements. For these students, gains in improving reading comprehension have been more consistent and significant when multiple strategies are taught. Story grammar, for example, can be directly taught through a self-questioning strategy (Carnine *et al.*, 2004):

1. What is the story about?
2. What is she or he trying to do?
3. What happens when she or he tries to do it?
4. What happens in the end?

As students begin to read more complex expository text, as is often found in science and social studies textbooks, multifaceted approaches are best for supporting reading comprehension. Researchers (e.g., Mastropieri and Scruggs, 1997) have noted that multifaceted approaches (i.e., reciprocal teaching; collaborative strategic reading; predict, organize, search, summarize, evaluate (POSSE); and think before reading, think while reading, think after reading (TWA)) that include procedural facilitators for learning (i.e., questions, prompts, or simple outline of learning structures) with cognitive strategies to support student learning are effective in improving students' acquisition and facilitation of linking new knowledge to prior knowledge. These approaches present strategies for prior knowledge acquisition, comprehension monitoring, and summarization of information throughout reading (Baker *et al.*, 2002).

The TWA expository reading comprehension strategy, for illustration, is one approach that integrates multiple strategies to support active text engagement throughout the reading process. Individual strategies imbedded in TWA are described in **Table 4**.

In the first component of TWA, think before reading, three steps for prior knowledge acquisition are taught. Students examine text structure while completing the first step. They then develop statements and questions for what you know and think about what you want to learn. Three steps are taught in the think while reading component: reading speed, rereading parts, and linking knowledge. Students are taught to (1) monitor their

Table 4 TWA strategy

<i>TWA strategy step</i>	<i>Strategy base</i>	<i>Sources^a</i>
Think before reading: Authors' purpose	Expository text structure (description, sequential, compare/contrast, cause/effect, problem/solution)	Englert and Thomas (1984)
What I know	K-W-L What I know, what I want to learn, what I learned	Ogle (1989)
What I want to know	K-W-L	
While reading think about: Reading speed Rereading parts	Comprehension monitoring and rereading parts	Graves and Levin (1989)
Linking knowledge	Discuss students' previous experience, connect this experience with the text, and share ideas for expanding knowledge	Hansen and Pearson (1983)
After reading think about: Main idea	RAP strategy (1) read the paragraph, (2) find the sentence in the paragraph that tells the main idea of the paragraph, and (3) put the main idea into your own words	Ellis and Graves (1990)
Summarize	Five steps for summarization (delete trivial information, delete redundant information, substitute super-ordinate terms for a list of terms or actions, select a topic sentence, and invent a topic sentence)	Brown and Day (1983)
What you learned	K-W-L	

^aSee the section titled 'Further reading'.

reading speed, (2) monitor their understanding by rereading when something is not understood, and (3) make connections between their prior knowledge and the current text. Think after reading has two strategic steps developed at the paragraph level (main idea and summarizing information), followed by the final step, an oral retelling of the complete passage (what you have learned). To reinforce locating the main idea in each paragraph, students use yellow highlighters (student use of these is faded as students master the strategies) to mark sentences and phrases related to the main idea in each paragraph. Five rules are used for developing paragraph summaries; students highlight the important details in blue and trivial details in pink for

each paragraph. Once students have developed main ideas and summaries, they orally retell what had been read and learned in the passage. TWA is taught using the principles of CSI within the self-regulated strategy development (SRSD) instructional model (see Table 1). Instruction for TWA is carefully scaffolded from teacher–student collaborative practice to student–student collaborative practice to student independent practice.

Vocabulary

A student's understanding of word meanings, or their vocabulary, is often considered the glue that binds word recognition and comprehension. For students with special needs, gaps in vocabulary development cause reading delay and affect reading growth (Bos and Vaughn, 2006). There are two types of vocabulary instruction, oral vocabulary and reading vocabulary. Instruction in reading vocabulary (the words a reader recognizes in print or uses in writing) is the focus of this synopsis. Although teacher-directed instructional approaches such as oral language instruction (i.e., teaching vocabulary during reading by modeling how to use context; using synonyms and definitions) work well for average achieving students, students with special needs often require additional explicit instructional approaches.

DI for word-learning strategies, morphemic and contextual analysis, is an approach often used to support student independence in developing vocabulary. In morphemic analysis, students are taught to use word parts to interpret word meanings. For example, the teacher introduces and teaches the meaning of a morpheme (e.g., Pre usually means before, what does pre mean?). The teacher then teaches new words that include the morpheme through signaling and unison oral responding (e.g., So what does pretest mean?). Carnine *et al.* (2004) cautioned that this approach is limited by the difficulties in translating some words into functional definitions, the fact that many words have dual meanings, and the difficulty in selecting appropriate morphemes for instruction. Contextual analysis, in contrast, fosters students' independence in learning word meanings by using surrounding words in text. In contextual analysis instruction, the teacher points out the unknown word in the text, asks the students to find the words that tell what the word means, and prompts the student to restate the sentence substituting the known word for the unknown word. Students are taught to look in text for an imbedded word-definition, a synonym, a description, a contrast, or a comparison.

Mnemonics with modified CSI has been used effectively for teaching vocabulary and associated concepts to students with special needs (Hughes, 1996). The keyword picture strategy, for example, uses visualization in the following steps taught to students: (1) select a word or term; (2) state the definition; (3) select another similar

sounding word; (4) create a picture using the definition, the word to be learned, and the key word; and (5) think about and study the picture. When developing mnemonic strategies for vocabularies and concepts, Mastropieri and Scruggs (1989) recommended that the amount of elaboration required is dependent on the students' familiarity with both the word and the concept abstraction.

Writing

Good writers spend time in planning, revising, monitoring, evaluating, and regulating the writing process. Students with special needs, on the other hand, spend little time in these processes and tend to focus on low-level transcription skills (i.e., handwriting, spelling, capitalization, and punctuation). A process approach to writing (prewriting – planning and organizing, drafting, revising, editing, and publishing) combined with CSI, therefore, is generally accepted as the best instructional approach to foster students' performance in higher-level skills for written expression. For students with special needs, Graham and Harris (2003) recommended that teachers:

1. provide time for writing, a minimum of 30 min daily;
2. provide a range of writing tasks, starting with what the student knows best;
3. create a social climate that promotes writing through peer and teacher conferencing;
4. provide opportunities for writing in all academic content classes;
5. focus on the writing process;
6. focus on high-order tasks, attending to mechanics during the revision process;
7. explicitly teach the characteristics of good writing, providing examples of and modeling good writing;
8. promote higher-level composing by teaching skills for strategy use;
9. teach students to identify and set goals for their own writing; and
10. minimize grammar instruction (i.e., sentence diagramming) and overemphasis on students' errors.

Written expression

One approach for teaching written expression to students with special needs, SRSD instruction, blends explicit instruction in self-regulation procedures with CSI (see **Table 1**). Theory in students' cognitive development and learning, student behavior, and the role of affect are all utilized in SRSD (Graham and Harris, 2003).

SRSD instruction has been used effectively for teaching planning and revision strategies across narrative, persuasive, and informative genres (see **Table 5** for planning strategy examples). As illustrated in the following sample lesson sequence for teaching the 'pick my idea, organize my notes, write and say more' (POW) + 'topic sentence, reasons, explain reasons, ending' (TREE) persuasive writing

Table 5 Strategies for written expression

Narrative writing	POW + W-W-W, What = 2, How = 2 Pick my idea. Organize my notes – use W-W-W, What = 2, How = 2! Write and say more. + Who is the main character? Where does the story take place? When does the story take place? What does the main character do or want to do? What happens next? How does the story end? How do the characters feel?
Persuasive writing	POW + TREE Pick my idea. Organize my notes – use TREE! Write and say more. + Topic sentence Tell what you believe! Reasons – 3 or more Why do I believe this? Will my readers believe this? Explain reasons Say more about each reason. Ending Wrap it up right!
Informative writing	Plan and write ^a P = Pay attention to the prompt L = List main ideas to develop your essay A = Add supporting ideas (details, examples, etc.) N = Number major points in the order you will use them and W = Work from your plan to develop a thesis statement R = Remember your goals I = Include transition words for each paragraph T = Try to use different kinds of sentences E = Exciting, interesting, \$1 000 000 words

^aDeveloped by S. De La Paz. See Harris *et al.* (2008) for complete lesson plans and materials.

strategy, instruction is recursive rather than linear. In other words, lessons and instructional stages and principles are repeated and revisited based on individual student needs:

1. *Lesson one.* The purpose of the first lesson is to introduce POW + TREE and to discuss the steps for each strategy. The teacher leads a discussion of what good writers do when writing an essay. The strategic parts are introduced and each step is described. The teacher then guides students in locating essay parts in an essay example. The students and the teacher both sign a learning contract: the student setting a goal to learn and use POW + TREE, the instructor committing to

do his/her best in teaching the strategy. In this first lesson and all subsequent lessons, each student is provided time to practice memorizing the POW and TREE steps; then students are told that they will be asked to share the steps from memory in the next session.

2. *Lesson two.* This lesson begins with the initial activity of all lessons: asking students to write out the POW + TREE and state the steps orally. If needed, the teacher asks students to locate essay parts in another persuasive essay. Students are asked to locate essay parts in one of their previously written essays. To reduce the possibility of an inappropriate reaction from the student, the teacher stresses, "Of course, the essay does not have all the parts; you did not know the POW + TREE strategy!" Students mark a graphing sheet to correspond with their essay parts. The teacher and students then discuss what could have been done to make their essay better.
3. *Lesson three.* Following memorization practice, the teacher cognitively models using the strategy by demonstrating how and when to use any support materials (e.g., graphic organizer). Following the teacher's modeling, students develop and record personal self-statements to be used while thinking of good ideas (relax, ask for help), while working (use POW or use TREE, I can do this), and to check work (examine, "perfect").
4. *Lesson four.* The teacher and students collaboratively write a persuasive essay, students provide ideas for the essay while the teacher writes the notes and essay. Support materials are used, self-instructions are reinforced, and the number of essay parts are examined and recorded on the graphing sheet.
5. *Lesson five.* Students write their own notes and essay with teacher guidance and supporting materials. If a student is having difficulty with any of the strategy processes, the teacher can return to modeling or collaborative practice.
6. *Guided practice.* The focus of all remaining lessons is to scaffold instruction until each student can independently implement all strategic steps without teacher or material support. Instructional materials, for example, are gradually replaced with student-written products (i.e., students write their planning outline on blank paper).
7. *Independent practice.* Once students can independently write a persuasive essay with all essay parts, the teacher can provide opportunities to support generalization and maintenance. The prompt can be revised to a different format, or the teacher can ask the student to write in a different academic class with a different teacher.

Transcription skills

Students with special needs generally have difficulty with both spelling and handwriting and these difficulties can interrupt composition processes, limit writing development, and mark a student as a poor writer (Graham, 1999). Students with special needs should be taught how to spell

words they use frequently in writing; generate reasonable spellings for unknown words; check and correct spelling errors; and develop a desire to spell correctly. A modified DI approach, using phonemic awareness and phonic rules, is often best for teaching spelling to students with special needs. DI for spelling includes mastery of daily words (no more than three a day or 12 a week), individualized instruction, and continual review. In addition, word-study approaches have proven effective for students with special needs. For example, the five-step word-study strategy (say the word; write and say the word, check the word; trace and say the word; write the word from memory and check; repeat the five steps) can be effectively used within a test-study-test (test; provide word study for misspelled words; and retest) spelling approach (Graham, 1999). Maintenance and generalization should be supported by continual review of previously learned words and integration of spelling words with students' reading and writing.

The goal of handwriting instruction is to teach students an efficient way to write letters and words legibly and fluently. DI is recommended for teaching handwriting to students with disabilities. Effective handwriting instruction includes (1) individualization to meet a student's needs; (2) frequently taught short lessons; (3) explicit modeling; (4) comparing and contrasting letter features; (5) facilitative supports such as marks for paper placement on student desks and tripod grip molds for pencils; (6) teaching students independence for evaluating and improving their handwriting; (7) handwriting fluency; and (8) mastery practice in isolation followed by application in context. In the end, spelling and handwriting instruction should be explicit and systematic. Graham (1999) suggested that teachers include less-formal methods of instruction (i.e., using teachable moments to model) to cultivate correct spelling and handwriting development.

Conclusion

Literacy instruction is best supported when reading, vocabulary, and writing are integrated. For example, students with special needs should be taught to read and spell words simultaneously. Word meanings should be taught throughout both the reading and writing processes. Written expression should be applied as a method for extending and fostering reading comprehension. By integrating these processes, students with special needs have multiple opportunities to practice and improve skills in literacy.

Glossary

Anchored instruction – Portrays or anchors problems in realistic contexts from which students identify embedded data that leads to a plausible solution.

Cognitive strategy instruction – Teaches students to monitor their own learning activities with methods such as with modeling, verbal rehearsal, and feedback.

Concrete-to-representational-to-abstract (CRA) sequence – Teaches students math concepts by representing them with concrete materials followed by pictures and drawings and finally by math numbers and operations.

Curriculum-based measurement – Is an example of formative assessment that measures student academic progress with frequent tests for the purpose of managing instruction.

Direct instruction – Refers to teaching number facts, operations, and problem solving in explicit and systematic ways.

Enhanced anchored instruction – Is a form of anchored instruction specifically designed for developing the problem-solving skills of adolescents with learning disabilities.

Graphic organizers – Use visual displays and graphic diagrams to help students develop meaningful representations of problem types.

Learning disability in math (MD) – Refers to an array of difficulties some students experience in computing and problem solving in math.

Metacognition – Refers to the ability to monitor and self-regulate one's own thinking.

Peer-mediated instruction – Includes a variety of interventions in which students without MD provide students with MD additional learning and practice opportunities.

Schema-based instruction – Helps to teach students the underlying structure of problems thereby helping them identify procedures for solving specific kinds of problems.

Self-regulated learning – Refers to helping students monitor and record their own activities related to academic and behavior.

Introduction

By most accounts, up to 8% of the school-age population has a disability in learning math. The difficulties experienced by students with math disabilities (denoted MD) center on two main areas: computation and problem solving. Within each area, many of these students exhibit other characteristics, such as confusion over sign operations and difficulty aligning numbers. To develop their computation skills, school instruction focuses primarily on number sense, automaticity with number combinations, and procedural fluency (i.e., adding, subtracting, multiplying, and dividing). Instruction on developing students' problem-solving skills is aimed primarily at comprehending the meaning of problems and helping students devise appropriate strategies for solving them. National assessments and research reports have highlighted the seriousness of the problem in both areas. For example, results from the large-scale testing efforts such as the National Assessment of Educational Progress revealed that approximately two-thirds of eighth-grade students with MD scored below the basic level, far below what is necessary for success in secondary education and job settings. Students scoring at the basic level should complete problems correctly using diagrams, charts, and graphs as well as understand informal algebraic and geometric concepts in problem solving. Thus, what is now called basic skills, as defined by contemporary standards, extend far beyond procedural competency and reflect the high levels of proficiency advocated by many math organizations such as the National Council of Teachers of Mathematics (NCTM).

In addition to point-in-time assessments, longitudinal studies have shown that students with MD fall even further behind their peers as they progress through high school. The National Longitudinal Transition Study-2, for example, reported that 14–27% of secondary youth with MD scored more than two standard deviations below the mean of average-achieving students across math subtests. These academic difficulties often lead to other problems such as inappropriate school behaviors. It is common knowledge that difficulties in math begin at an early age. At the elementary level, research indicates students with MD gain only 1 year of achievement on procedural skills for every 2 years they are in school. In particular, students lag far behind their classmates in whole-number operations, fractions and decimals computation, and problem solving.

One of the most obvious characteristics of students with MD is their inability to (1) develop conceptual understanding of number, (2) use this knowledge to help them retrieve basic math facts from memory, and (3) achieve fluency with math facts. Clearly, in solving problems, students with MD face challenges identifying relevant information from text due in part to reading and comprehension difficulties. These students often experience problems such as focusing attention on key task variables, self-monitoring during problem solving, and self-management. At the secondary level, students with MD experience both long-term and short-term memory deficits, have difficulty organizing information, and make more procedural errors than students without MD. The purpose of this article is to describe strategies that have been developed for remediating the aforementioned learning difficulties in math.

Historical Backdrop

In the late 1980s and early 1990s, there emerged a growing concern in the general mathematics community that students were not developing sufficient understanding of math concepts to be successful problem solvers. The publication of the NCTM standards in 1989 recommended teachers place more emphasis on helping students develop sophisticated understanding of math concepts and less importance on rote memorization. Not only the ability to compute accurately remained a legitimate goal, but it was also recognized that postsecondary settings (i.e., job and education) wanted students and workers who could compute and use math as a tool for solving important problems. In an effort to improve the math achievement of all students, including students with MD, the US Department of Education set six strategic goals. They were most likely fueled by:

1. a series of reports urging educators to help all students acquire essential skills for successful employment in the twenty-first century;
2. the low skills demonstrated by large numbers of students on national tests; and
3. the lackluster showing of students in international comparisons.

Coinciding with these recommendations, the No Child Left Behind Act of 2001 imposed an increased level of external accountability on schools and states to demonstrate higher student achievement in reading and math. The Individuals with Disabilities Education Act required students with special needs to participate in assessments with accommodations as needed.

Most recently, the National Mathematics Advisory Panel, commissioned by the US Department of Education, emphasized the need to provide all children with a sound education in math. Among its recommendations, the panel emphasized the need to teach students to proficiency, which

means developing automaticity in number facts, accurate and automatic execution of algorithms, and the use of these competencies to solve important problems. The report also suggested that curriculum should simultaneously develop students' conceptual understanding, computation fluency, and problem-solving skills. Of particular interest to teachers of students with MD is their finding that educators should not be too quick in making assumptions about the ability of children to learn math based solely on their age or presumed readiness to learn. When provided with appropriate teaching strategies, based on frequent formative assessments, all students can learn math. Researchers and teachers over the past several decades have developed these strategies, which range from explicit instruction on basic facts to constructivist approaches aimed at developing students' ability to solve problems.

Math Instruction for Students with MD

Early pioneers in math education made important contributions to the development of teaching strategies and curricular materials for students with MD. Much of this work was characterized by teacher-led explicit instruction on well-defined skills. Based primarily on behavioral orientations, teachers used direct instruction that incorporated tightly controlled and scripted lessons to teach small chunks of math skills in sequential steps. As new concepts were introduced, teachers used prompts to scaffold understanding, which were gradually phased out when students showed they no longer needed them. Frequent assessments, called mastery checks, were used to monitor student progress. When mastery was not achieved, teachers followed prescribed procedures to remediate their students' skills. As instruction for students with MD at that time typically took place in resource rooms, teachers taught students in small groups, which the teachers were encouraged to reshuffle based on student performance. Direct instruction approaches were shown to be effective for improving certain kinds of math skills of particular students with MD. However, as students with MD were more fully included in general-education classrooms, their math instruction became more aligned with that of their classmates. Both the math content and the instructional strategies used to teach the content had to be modified and adapted to enable students with MD to use the general-education curriculum. Although it remained important for all students to develop basic skills, students with MD faced the additional challenge of solving problems, promoting higher levels of conceptual understanding.

Following are some strategies developed by researchers and teachers to improve both the computation and problem-solving skills of students with MD. In most other reviews of this kind, instruction has been grouped according to instructional orientation (e.g., behavioral or cognitive);

however, these distinctions are not useful because they do not adequately account the instructional goals or the subtleties of intervention procedures. For that reason, a representative sample of methods is described, which has improved the math performance of students with MD without trying to categorize them according to orientation. It is important to note that not all worthy instructional strategies could be included in this article because of space limitations.

Schema-Based Instruction and Graphic Organizers

The most common way of teaching students problem-solving skills is with text-based problems. Test developers also use word problems to assess student performance. Unfortunately for many students with MD, they experience difficulty in math and reading, which further limits their comprehension of the problems presented in text. For students to access these representations, they must first understand the structure of the problem and then match it to knowledge networks stored in memory. These knowledge networks help students choose the strategies and mathematical operations that most likely will lead to a successful solution of the problem. Apparently, schema-based instruction helps to reduce the reading comprehension difficulties by using graphic organizers, or schemas, in the form of visual displays and graphic diagrams to help students develop meaningful representations of problem types. First, teachers explicitly teach students the structure of several problem types and how to distinguish between them. Then, teachers supply students with graphic representations of different problem types. Once students are able to identify key features of problem types, they are taught to find the solution to the problem by matching the graphic to the problem type.

The primary difference between schema-based instruction and other forms of strategy instruction is the depth at which the mathematical relations are taught in the diagrams. General strategy instruction leads students through a series of steps in solving word problems (e.g., reading the problem, drawing a picture, solving the problem, and checking the work). Often, the underlying structures of problems are not explicitly taught and problem schemata are not categorized. During schema-based instruction, however, students are taught deep structures of problems and how math procedures can be used to solve each type of problem.

Example

Yesterday, John earned \$27.50 for mowing the lawn. John spent \$5.50 for lunch. Now John has \$22.00 (Figure 1).

Graduated Guidance Sequence

Sequencing math instruction has traditionally attracted much attention and for good reason. As with many students, the abstractions posed in math problems are especially difficult for students with MD to comprehend. Often,

Figure 1 Graphic representation of the word problem.

students need to relate the abstract to something tangible that they already know. The sequence recommended for students with and without MD generally follows a concrete-to-representational-to-abstract (CRA) sequence. At the concrete level, the abstraction is modeled with materials (e.g., unifix cubes, blocks, and beans). At this stage, students are actively engaged in manipulating materials that show the concept they will eventually learn as an abstraction. When they are able to demonstrate their knowledge with manipulatives, teachers transfer the concepts to semiconcrete representations in the form of pictures or drawings. As they move to the abstract stage, the pictures are replaced with math symbols such as numbers and operations. At all three stages, students are afforded many opportunities to practice and demonstrate their understanding.

One way of showing the CRA sequence among middle school students with MD is with fraction strips, which are useful for demonstrating equivalence of fractions. For example, students can be given four long strips of paper and asked to imagine the first strip is a long candy bar shared by two people. Students decide to share the candy bar by folding the paper in half. The teacher then directs them to label the fold to indicate the relative size of the candy bar to that point ($1/2$). The students repeat the process with three more strips – representing candy bars that needed to be shared among 4, 8, and 16 people – using repeated folding. Each fold is labeled with its appropriate fraction. Once all four fraction strips are labeled, students are asked to offer any observations. The teachers' questions encourage students to focus on fraction equivalence and the relationship between a fraction's size and its numerator and denominator. For example, a teacher asks students to answer the following questions as they compare fractions indicated on their fraction strips:

- What is the relationship between the size of the denominator and the number of pieces into which the fraction strip is divided?
- What fractions on your strips are equivalent to $1/4$?
- What is another name for $2/8$?
- What is another name for $1/2$?
- On our fraction strips, the numerator is always smaller than or equal to the denominator. Does it always have to be this way? Could you have a fraction like $5/4$? How would you represent it?

On subsequent days, students can use their fraction strips to solve problems such as “If you have $\frac{3}{4}$ of a candy bar and your partner has $\frac{1}{2}$ of a candy bar, who has more? How much more? How much do you have together?” Teachers can ask students to show how they could use their fraction strips to solve addition and subtraction problems such as $\frac{3}{8} + \frac{1}{8}$ and $\frac{1}{4} + \frac{5}{16}$. At the beginning of this sequence, teachers encourage students to focus on their understanding of fraction equivalency rather than on highly procedural sequences or memorized rules to find common denominators. As students demonstrate their understanding of fractions and equivalence, teachers can move to instruction that emphasizes more procedural knowledge. It should be noted that the CRA strategy is recommended for use with all students in the primary grades. However, teachers may need to continue teaching older students with MD with this sequence because they lack the ability to form mental models of abstract concepts without concrete and representational scaffolds.

Peer-Mediated Instruction

Peer-mediated instruction encompasses a variety of interventions in which a student without MD assists a student with MD in learning and practicing math tasks. The most popular version of this practice is called Peer-Assisted Learning Strategies (PALS). With PALS, every student in the class is paired. Each student in the pair takes turns as a tutor and tutee while working on classroom activities provided by the teacher. Typically, PALS is implemented in elementary classrooms for several 35-min sessions per week. The underlying theory to this approach is that peer interaction, if carefully planned, can have powerful effects on academic motivation and achievement. Some of this motivation can be attributed to the increased socialization experiences that peer-mediated instruction affords both the tutor and tutee. Students tend to stay on the task longer and engage in productive practice on math facts, computational skills, and problem solving. In addition to increasing student motivation and academic progress, peer-mediated instruction enables teachers to accommodate students with a wide range of abilities. Teachers monitor the discussions of student pairs and provide additional help as needed.

To implement peer-mediated instruction effectively, teachers must first teach students how to be effective tutors and receptive tutees. Students have to learn both roles because they switch roles during each tutoring session. As a tutee, students are taught appropriate methods for seeking help when they do not understand a concept. In some instances, the pair develops a signal to indicate when the tutee needs help. These may include taps on the desk or pointing to the tutor. Tutors need to pay close

attention to tutees so they know when to offer help. They also need to describe ways of finding the answer rather than simply giving the answer. Teachers are responsible for providing tutors with objectives for the lessons and prompts that can be used strategically to reinforce skills.

Cognitive Strategy Instruction and Self-Regulation

Students with MD display difficulty with memory, attention, and self-regulation. These characteristics are due, in part, to their immature problem-solving strategies and their failure to monitor their own performance. Cognitive strategy instruction attempts to explicitly teach students to monitor their own learning activities with methods such as modeling, verbal rehearsal, and feedback. To help students solve problems, teachers provide students with strategies such as paraphrasing, visualization, and planning. Self-regulation teaches students to take control of their own learning and move to independence. Training in self-monitoring often includes ways that may help students engage in self-assessment, self-recording, and self-instruction. Students are taught to monitor their own activities related to academic and behavior. For example, students can be taught to monitor and record the number of problems they have completed or computed correctly during study time. They can record their data in a concrete way, such as on a card in their folder or attached to their desktop. When students first use the self-monitoring system, an external source may cue them to record the data. As they become more accustomed to the procedures, they eventually monitor their own activities.

One of the important features of self-regulation is that teachers can develop self-monitoring checklists and procedures based on individual needs of their students. For example, when given problems that require finding equivalent fractions, a checklist could be written this way:

1. I looked at denominators of the fractions.
2. I saw that the denominators were not the same.
3. I asked myself if the smaller denominator could be multiplied by a number to make it the same as the larger denominator.
4. If the answer to #3 is yes, I multiply the numerator and the denominator by that number.
5. If the answer to #4 is no, I need to find the least common multiple for both denominators.

As students go through their mental checklist, they talk themselves through the problem-solving routine. They may also ask themselves additional questions such as the function of denominators compared to numerators in the example provided above. To buttress self-regulation, teachers may teach students acronyms to help them remember the sequence of more generic problem-solving steps. For example, students are taught to remember

RPV-HECC (read, paraphrase, visualize, hypothesize, estimate, compute, and check) for solving word problems. Students are explicitly taught how to use each procedure in the sequence. Montague (2006) suggested the following instructional methods:

- Teachers model self-regulation strategies during math instruction.
- Students practice these strategies before applying them.
- Teachers provide students with cue cards or prompt sheets to remind them of the instruction they should follow when completing the task.
- Teachers provide students with a record of progress either in chart or graph format.
- Teachers fade cues and prompts as students become more skilled and independent, applying appropriate strategies.

It should be emphasized that students with MD may not use the strategies unless they have had ample opportunities to practice using the strategy. Ways of getting them to use these strategies independently is through explicit practice that includes (1) verbal practice designed to help students talk through the intent of the strategy; (2) controlled practice and feedback on materials written at their own instructional level; (3) advanced practice on materials with grade level materials; and (4) generalization on new but related materials.

Formative Assessment

Formative assessment is a way of monitoring the effects of instruction on the math performance of students with MD. It differs from summative assessment in the frequency of administration, the relative length of the tests, and instructional purpose. Formative tests are usually made up of small number of items that measure specifically what students were expected to have learned over a period of days or weeks. Curriculum-based measurement (CBM) is one kind of formative assessment that indexes student achievement and provides teachers with important information about how to manage instruction. From these frequent measures, growth rates (or slopes) are graphed for each student. These slopes are then compared to typical growth rates of students to assess how well students are progressing.

The use of frequent, ongoing assessment is included in this article because appropriate instruction depends on the validity and reliability of student evaluation. CBM strategies are the best known of these types of assessment strategies, but teachers can also develop their own monitoring strategies. What is most important is that they identify the math difficulties that students have and then devise methods for remediating them in a timely manner. Frequent and ongoing assessment of student skills is also a critical element of Response to Intervention (RTI), a way

of identifying patterns of achievement among students who may be at risk of developing serious problems in math. The RTI approach may help teachers make more informed decisions about how to align instruction with individual learning needs of children.

Enhanced Anchored Instruction

Enhanced Anchored Instruction (EAI) is a method specially designed for developing problem-solving skills of adolescents with MD. EAI is based on the concept of anchored instruction, popularized by the Cognition and Technology Group at Vanderbilt. In anchored instruction classrooms, learning activities are designed around an anchor, usually presented in an 8–12-min video. The video portrays actors who are attempting to solve a realistic problem. All the information for solving the problem, and its subproblems, are presented in motivating contexts in the video. To solve the problem, students have to identify what information is relevant and then formulate a plan that will eventually lead to a successful solution. A primary objective of anchored lessons is to help eliminate the inert knowledge problem that exists when typical school-based learning materials do not tap what many low-achieving students know. Students may have relevant knowledge but do not know when and under what conditions to apply it.

EAI extends anchored instruction by affording students additional opportunities to practice their skills as they solve analogous problems in applied contexts. In studies involving students with MD, students first solve a problem in a multimedia format and then apply what they learn in related hands-on problems. One important finding in these studies is the ability of EAI to directly immerse students in problem contexts, thus helping to eliminate the comprehension difficulties those with low skills in math and reading often experience with complex text-based problems. An example of a multimedia-based anchor is called *Fraction of the Cost*, which stars three middle school students. The video opens in a skateboard store and rink where students are shown discussing how they can afford to buy materials for building a skateboard ramp. To figure out the most economical use of 2×4 s ($2'' \times 4''$) lumber in *Fraction of the Cost*, students first need to identify the lengths of boards shown in the plan. Then they convert these dimensions from feet and inches to inches and try out several combinations of lengths to maximize their use of available wood. Once they compute what additional wood is needed, they consult the store advertisement to decide what to buy. Their final task is to show (1) how much money they had to spend, (2) construct a materials list, and (3) calculate sales tax and the total cost.

After students solve the problems posed in *Fraction of the Cost*, they work on solving a related problem called the *Hovercraft Challenge*, in which students plan and construct a rollover cage for a hovercraft out of polyvinyl

chloride (PVC) pipe. Small groups of students plan how they can make the cage in the most economical way. When the cages are complete, students lift them onto a 4 × 4-ft plywood platform (i.e., hovercraft). A leaf blower inserted into a hole in the plywood powers the hovercraft, which inflates the plastic attached to its underside and elevates it slightly above the floor. On the last day of the project, students ride on their hovercrafts in relay races up and down the halls of the school. Clearly, each anchor requires a mix of math skills. In the example above, to solve the problem, students need to:

1. calculate percent of money in a savings account and sales tax,
2. read a tape measure,
3. convert feet to inches,
3. visualize building plans,
4. build a table of materials,
5. compute whole numbers and mixed fractions,
6. estimate and compute combinations, and
7. compute total cost.

Conclusion

Over the past two decades, considerable progress has been made in developing and testing strategies and curricula to enhance the computation and problem-solving skills of children with MD. As more students with MD were included in general-education classrooms, instruction for these students had to be crafted in ways that could be used alongside their peers without MD. Some of these methods are summarized in this article. It is important to note that explicit instruction still benefits a large number of students with MD and should be continued. However, math instruction should take a balanced approach that includes both student-centered and teacher-directed practices.

Overrepresentation of Culturally and Linguistically Diverse Students in Special Education

S C Trent, University of Virginia, Charlottesville, VA, USA

© 2010 Elsevier Ltd. All rights reserved.

Overrepresentation of Culturally and Linguistically Diverse Students in Special Education

The overrepresentation of historically underserved students (historically underserved students are students from diverse racial/ethnic, linguistic, and socioeconomically disadvantaged backgrounds who have traditionally experienced significant school failure; this term is used instead of minority students or culturally and linguistically diverse learners (CLD) to illuminate the responsibility of educational agencies and school districts to address historical, political, and systemic constraints that impede learning rather than adopting a traditional deficit view which places the blame for school failure primarily on students and their families) in special education in the high incidence categories of learning disabilities (LD), intellectual or developmental disabilities (IDD) (IDD has replaced the label formally referred to as mild mental retardation), and emotional and/or behavioral disorders (E/BD) has been a controversial issue in education for several decades. Overrepresentation is defined “as the representation of a group in a category that exceeds our expectations for that group, or differs substantially from the representation of others in that category” (Skiba *et al.*, 2008: 266).

Generally, two methods are used to determine if students are overrepresented in special education: the composition index and the risk index or risk ratio method. The composition index determines “the extent to which a group is over- or underrepresented in a category compared to its proportion in the broader population” (Skiba *et al.*, 2008: 266). The risk index and risk ratio determines “the extent to which a group is found eligible for service at a rate differing from that of other groups” (see Skiba *et al.*, 2008: 266). Widespread use of these measures over three decades reveals that overrepresentation does indeed exist (Artiles and Trent, 1994; Chinn and Hughes, 1987; Donovan and Cross, 2002; Heller *et al.*, 1982; Parrish, 2002). For example, over time, researchers have determined that African-American students continue to be overrepresented in programs for students with IDD and E/BD (Donovan and Cross, 2002). Researchers have also found that proportionally, some historically underserved students with disabilities, particularly African-American students, are placed in more restrictive settings than their White counterparts.

Moreover, parallels exist between poor school performance, high-incidence disabilities, and time served in the juvenile justice system (Drakeford and Staples, 2006). To a lesser degree, Native American, Latina/o, and some Asian or Pacific Islanders subgroups continue to be overrepresented in some of the high-incidence categories (Osher *et al.*, 2004; Parrish, 2002).

Some scholars purport that overrepresentation is unfortunate yet often necessary because many historically underserved students come from economically disadvantaged backgrounds (MacMillan and Reschly, 1998). Risk factors used to support this argument include, but are not limited to, (1) improper prenatal care, (2) teenage parenthood, (3) single parent households, (4) low birth weight, (5) poor nutrition, and (6) limited opportunities to engage in school readiness activities in the home and community prior to school enrolment. While there is ample evidence that documents the adverse effects of risk factors on student performance, results from large-scale studies reveal that only about 33% of the racial gap in education is explained by socioeconomic status (Hedges and Nowell, 1999; Mickelson, 2003). In addition, Skiba *et al.* (2005) found in their research that, “poverty makes a weak and inconsistent contribution to the prediction of disproportionality across a number of disability categories” (p. 130). These findings raise the questions: Can overrepresentation of these students in special education be attributed predominantly to deficits that reside within them? Are there school factors that contribute to overrepresentation and underachievement?

Of course, it is known that significant numbers of historically underserved students attend poorly funded schools with inadequate human and material resources (Children’s Defense Fund, 2004). Obviously, these school factors adversely affect outcomes for these learners. But, the question remains, are there other school factors that contribute to dismal outcomes that have been reported for decades? Emerging research supports the hypothesis that there are, and that throughout our nation’s history, we have placed preeminent focus on identifying deficits that reside within children, their families, and their communities. In addition, we have placed far too little emphasis on understanding how schools can create and sustain environments that provide culturally responsive, evidence-based practices that engage all students affectively, educationally, and developmentally (Cartledge and Kourea, 2008; Deschenes

et al., 2001; Dorn, 2007). One can hypothesize further that the overrepresentation of these students in high-incidence special education programs and their subsequent low academic achievement may be attributed to a preeminent focus on deficit thinking. The under-acknowledgement of these truths has had a profound adverse affect on attempts to meet the needs of historically underserved students more effectively, even when reform initiatives emanate from genuine concern and good intentions (Anderson, 1998; Spencer 2008a, 2008b).

In order to chart a more successful course for the present and the future, it is necessary to understand more completely how deficit thinking has influenced past educational practices for historically underserved students. This effort might lead to a better understanding of the patterns in behavior and thinking that have contributed and continue to contribute to the sustainment of overrepresentation, poor academic outcomes, and limited postsecondary opportunities for these learners (Obiakor and Ford, 2002; Trent and Artiles, 2007). Understanding of this history, if acknowledged, valued, and incorporated into current and future educational reforms, can also contribute to the creation of more effective school environments for these students. Hence, in the remainder of this article, the author summarizes the traditional deficit thinking that still guides educational policy and practices, presents under-acknowledged theories and research that challenge this thinking, and elucidates how these theories can be used to create and sustain school environments where more students experience success. Note that the content herein is not an indictment of special education for historically underserved students. Instead, it is a call for equitable educational opportunities for all children, especially those who historically have not experienced sustained access to effective and equitable educational opportunities in general and/or special education (Edgar *et al.*, 2002; Lee, 2008).

Traditional Explanations for School Failure among Historically Underserved Students

For many years, researchers have developed explanations for the sustained school failure and overrepresentation in special education in the high-incidence categories among historically underserved students. Causes include legal and administrative requirements, characteristics of students, quality of the instruction received, possible biases in the assessment process, characteristics of the home and family environment, and broader historical and cultural contexts (i.e., overemphasis on a deficit perspective and conflicts between minority and dominant cultures) (Chinn and Hughes, 1987; Heller *et al.*, 2002). Other factors identified by Donovan and Cross (2002)

include “education personnel, class size, and school funding” (p. 172). Categorization of these factors reveals positions that explain school failure for these students – cultural deficits (deficit thinking) and cultural differences.

Cultural Deficits: It's Something Within

Deficit thinking posits that, “the student who fails in school does so because of internal deficits or deficiencies. Such deficits manifest, it is alleged, in limited intellectual abilities, linguistic shortcomings, lack of motivation to learn and immoral behavior” (Valencia, 1997: 2). These beliefs have resulted in the emergence of explanations for school failure that include (1) the genetic pathology model, (2) the cultural disadvantage model, and (3) the cultural and accumulated environmental deficit model.

Genetic pathology. Proponents of the genetic pathology model argued that genetic make-up played a more substantial role in determining cognitive ability than did the environment. Moreover, proponents of this model insisted that the racial achievement gap was mainly the result of inherent racial differences in intellectual capabilities (McCray *et al.*, 2003; Menchaca, 1997).

Cultural disadvantage. The liberal orientation embraced by this country during the 1960s diminished the popularity of the genetic pathology model and ushered in ideals of equality and social justice for all US citizens. Foley (1997) and Pearl (1997) asserted that during this period, even though a desire to elevate the status of historically underserved citizens was the stated intent of participants of this movement, one form of pathology was replaced by another to explain the school failure of students from these backgrounds. More specifically, Pearl argued:

“[t]he *cultural deprivation model* singled out the family unit (rather than genes) as the transmitter of deficiencies. Although culture (or the alleged lack of it, as indicated by the notion of deprivation) was central to the cultural deprivation model, the family was key to this deficit framework. The family unit – mother, father, home environment – was pegged as the carrier of the pathology.” (p. 133)

Cultural and accumulated environmental deficits. Supporters of the cultural and accumulated environmental deficit model argued that deficiencies within the family unit that are sustained over time will lead to cognitive deficits that are irreversible. Due to the inadequate socialization of parents and communities, historically underserved children did not receive the adequate stimulation needed to prepare them to be successful in school. These enduring environmental deficits made it virtually impossible to break the cycle of poverty and limited the intellectual capacity of these children; it was highly unlikely that the cycle could be broken (Foley, 1997).

In sum, this deficit focus contributed to school failure for many historically underserved children; and they, their parents, and their communities were blamed primarily for this failure. These beliefs were sustained in part because educators rarely entertained the notion that poor school performance might also be linked to other factors such as their beliefs, poorly funded schools, and inappropriate instruction. These factors, coupled with Darwinian theory, the introduction of Jim Crow legislation, and immigration laws made it morally and legally justifiable to segregate these students from mainstream students (Deschenes *et al.*, 2000; Span, 2003; Valencia and Suzuki, 2001). Also, standardized intelligence tests administered in English became very popular in the US during the first three decades of the twentieth century and provided scientific justification for segregated schooling practices. Many historians lauded the work of those who developed special education programs largely based on results from IQ tests (e.g., Kode, 2002). Armed with this new technology, educators believed that they would be able to sort students into programs that were more aligned with their abilities and provide them with the tools they needed to be successful in life. However, those who have studied this era through a sociocultural lens contend that the use of IQ tests resulted in segregated classrooms and schools for recent immigrants, African-Americans, and Native Americans. The primary goal was to separate these children from the true Americans, those of Western European descent, who had been fully assimilated into the majority culture (Dorn, 2007; Valencia and Suzuki, 2001). Furthermore, the curriculum was standard and focused largely on remediation and vocational skills (Safford and Safford, 1998). Despite evidence to the contrary, these beliefs have persisted over time and remain with us today (Herrstein and Murray, 1994; Heubert, 2002; Spencer, 2008b).

Alternative Explanations for School Failure: Beyond Blaming the Victim

Several researchers and theorists disagree with models derived from deficit thinking. Banks (2008) provided a reason for the rejection of this argument, *to wit*:

Unlike cultural deprivation theorists, cultural difference theorists reject the idea that low-income students and students of color have cultural deficits. They believe that ethnic groups such as African-Americans, Mexican Americans, Asian Americans, and Native Americans have strong, rich, and diverse cultures (Gay, 2000; Alim and Baugh, 2007). These cultures consist of languages, values, behavioral styles, and the perspectives that can enrich the lives of all Americans The school must change in ways that will allow it to respect and reflect the culture of low-income students and students of color and at the

same time use teaching strategies that are consistent with their cultural characteristics. (p. 54)

Models derived from cultural difference theory include: (1) cultural incongruity, (2) the oppositional cultural framework, and (3) stereotype threat.

Cultural Incongruity Model

Those who embrace this model purport that historically underserved students experience persistent school failure not because of deficits that reside within them, but because aspects of their cultures are incompatible with the thinking, behaviors, and values of mainstream culture (Ladson-Billings, 1994). These incompatibilities result in lowered expectations, intolerance, and inequitable decision-making processes. For example, research conducted during the school desegregation era as well as current research reveals that historically underserved students are suspended from school at significantly higher rates than White students (Yudof, 1975). In addition, researchers have found that justifications for suspensions for the former group are based more on subjective (e.g., overlapping speech seen as disrespectful) versus objective criteria (e.g., physical altercations) and are influenced by factors in and outside of school. These factors include criminalization of African-Americans by the media, race and class privilege emanating from cultural norms that dictate what is considered normal and abnormal, and zero tolerance policies (Monroe, 2005).

Oppositional Cultural Framework

The underlying thesis of this model is that involuntary immigrants (e.g. African-American students), due to stereotypical beliefs and sustained discrimination on the part of the majority culture, take on reactionary thinking and behaviors (e.g., variant dialects, unpreparedness, brash or disrespectful interactions with authority figures) that are oppositional to school success. In part, these behaviors are attributed to students' fears of being labeled as a wannabe or as acting White if they overtly engage in teacher pleasing behaviors and experience school success. These behaviors threaten their designation as valued members of their peer groups (Mickelson, 2003; Ogbu, 2003).

Stereotype Threat

Proponents of this model argue that long-standing stereotypes about people from historically underserved groups can have an adverse effect on the academic performance of students from these groups. Steele (1977) demonstrated empirically the existence of this model. As Mickelson (2003) summarized, Steele found that if, "academically able black students are cued about race before engaging in

an intellectual task, their performance will be lower than that of comparable blacks who did not receive such a cue” (p. 1069). This anxiety suppresses motivation to engage in intellectually challenging activities because if students fail, they are validating the stereotypes (Artiles *et al.*, 2009).

Models based on cultural difference theory afford schools and educators the opportunity to consider factors beyond within-group deficits to explain school failure. By viewing teaching and learning through this lens, one can see that there are multiple factors that contribute to school failure including the role of history in shaping beliefs about people and their children and how these beliefs influence the identity, development, and performance of these children. Furthermore, these models elucidate the importance of instructional relevance and responsiveness. Also, this theory reinforces the belief that all students come to school with funds of knowledge that can be used to inform instruction (Gonzalez and Moll, 2002). In this vein, educators need to examine more closely their frames of reference about others’ children, develop ways to access information that might mitigate biases and stereotypes, and from this inquiry develop instructional practices that are more culturally responsive, evidence-based, and effective (Berry and McClain, 2009).

Still, just as deficit theory alone is inadequate to explain school failure, cultural difference theory, if not operationalized contextually, will not bring about the changes in education that teacher educators and practitioners seek to achieve. Instead, an ecological/contextual conceptualization that accounts for the interplay between deficits and differences, risk and protective factors, and the political nature of schooling must be used to frame current problems and create more far-reaching and efficacious solutions. An example of how this framework can be used to address overrepresentation is provided below.

Toward an Ecological and Contextual View of Overrepresentation

Within an ecological/contextual view of overrepresentation, the unit of analysis is not students from historically underrepresented groups and the deficits that reside within them, but these students within the context of an extremely complex and interactive activity system charged to meet their educational needs. The interconnected, interactive layers of the activity system include the experiences of these children within multiple contexts such as the larger society (outer layer), their families and communities, and their school districts, schools, and classrooms (inner layer). In other words, learning does not occur in a vacuum, but within situated contexts; and these contexts shape how students view themselves and how others view them. If others’ acknowledged or unacknowledged beliefs about students are adversely influenced by culturally based

constructs grounded in pathology, their experiences in school may lead to less than desired results. In fact, results may be injurious.

Spencer (2008b) provided an example of how the interplay between the layers of the activity system might result in such undesirable outcomes. While acknowledging that special education has resulted in many benefits for many children, she explained that practices that lead to special education placement may put many historically underserved students at risk. Using an ecological/contextual framework, she argued that the study of overrepresentation not only requires more than acknowledgement of deficits or cultural mismatches, but requires a deeper understanding of how societal factors (e.g., prevailing social norms) may influence educators’ views about historically underserved students. Furthermore, these norms will subsequently mediate these educators’ thinking and actions in schools and classrooms. For example, educators who adopt prevailing social norms about low-income African-American males may categorize these students as would-be criminals who, due to their disrespect for norms and rule-governed behaviors set forth by the larger society, will likely end up in the juvenile justice system (Monroe, 2005). Internalization of these beliefs adversely affects teacher efficacy and consequently, the performance of students who have been marginalized. This marginalization is exacerbated when these same educators do not acknowledge that many children from historically underserved backgrounds are expected to make the same gains as more privileged children despite the obvious inequities faced by the former. Failure to acknowledge that protective factors are provided in more abundance for privileged students leads to the false assumption that the contexts for both groups of students are virtually the same. This assumption may result in feelings of superiority and entitlement on the part of privileged students and detract from the identity development and motivation of historically underserved students (e.g., stereotype threat).

Because failure is attributed to pathology, members of the educational enterprise tend to conclude that some students need instruction that must be delivered by trained special education teachers. This pathological status does not acknowledge contexts that influence cognitive and emotional development and how risk factors in schools such as teacher beliefs and quality of instruction may affect students’ social and academic performance. In this situation, significant numbers of students from historically underserved backgrounds will be placed in special education and many of them will be served in more restrictive settings than White students. Consistent with the progressive education movement of the early twentieth century, there is a high likelihood that instruction in these settings will be inadequate and unresponsive to the needs of students.

Implications and Conclusions

Given the ecological/contextual theory outlined above, stakeholders who are truly committed to equitable educational practices for all children must ask questions such as: What are the political, sociocultural, and economic factors that have cumulatively contributed to the overrepresentation of historically underserved students in special education? What theories and models have been used to frame the discourse on overrepresentation? Whose theories and models have been ignored? What contextual factors must change if heretofore unacknowledged voices are to be heard, valued, and incorporated? How might power, racism, and/or classism contribute to overrepresentation? What processes and rules are needed to sustain authentic participation among all stakeholders including parents? Finally, the most important question we need to ask is: How do we create and sustain safe educational environments where the desired collective outcome is not higher scores on state-wide assessments but, "more equal levels of student achievement and improved social outcomes for all students" (Anderson, 1998: 575)? Otherwise, we will continue to implement policies and practices that historically have not addressed the root of the problem, and the persistent failure and overrepresentation in special education of significant numbers of students from historically underserved groups will be unabated.

Paraprofessionals in Special Education

B Y Ashbaker and S C Dunn, Brigham Young University, Provo, UT, USA

J Morgan, Swansea Metropolitan University, Wales, UK

© 2010 Elsevier Ltd. All rights reserved.

Prior to 1975, the US Congress found that the educational needs of children with disabilities were not being fully met. In fact, Congress found that more than 50% of children with disabilities in the United States were not receiving appropriate educational services, and one million children with disabilities were entirely excluded from the public school system and from being educated with their peers. Further, there were many children with disabilities in regular school programs who were prevented from having successful educational experiences because their disabilities remained undiagnosed PL 94-142. Congress enacted the Education for All Handicapped Children Act (EAHCA) of 1975 to ensure that all children with disabilities have available to them a free appropriate public education that emphasizes special education and related services designed to meet their unique needs and prepare them for further education, employment, and independent living. The EAHCA was reauthorized as the Individuals with Disabilities Education Act (IDEA) and again as the Individuals with Disabilities Education Improvement Act (IDEIA) of 2004. This later law tried to set standards for school districts in educating students with disabilities and in providing federal funding to support appropriate services for these students.

In 2001 the No Child Left Behind (NCLB) Act added new emphasis to the legislation as it required paraprofessionals working in Title I programs to have training beyond the high school requirement that most schools held. Likewise, the changes in the IDEIA requirement were intended to more closely match the NCLB requirements for instructional paraprofessionals, but continue to remain essentially unchanged.

What did change, however, were training requirements for paraprofessionals. By incorporating principles of NCLB, the IDEIA included a requirement that the personnel who were needed to carry out the services (including paraprofessionals) must be appropriately and adequately trained, and supervised. But, with increased costs and shrinking budgets, school administration had become more creative in utilizing the services of paraprofessionals in place of higher-paid professional staff. Federal regulations require states and districts to ensure that paraprofessionals are only assigned appropriate duties and that they are properly trained and supervised (Ashbaker and Morgan, 2006). Assigning paraprofessionals to duties that should be performed by teachers or other more highly qualified credentialed staff violated the

law. Moreover, failing to provide them with proper training appears to compromise the student's right to a free and appropriate public education. This article focuses on the changing roles of paraprofessionals in the field of special education.

Paraprofessionals have become increasingly important in the US public education system. Indeed, in the 2003–04 school year, 91% of public schools reported employing at least one paraprofessional (Hampden-Thompson *et al.*, 2007); yet, there has been confusion on what to call the personnel who provide student support through tutoring, assisting, or working as a student and teacher aide in the instructional process (Morgan and Ashbaker, 2001). A national change began when the NCLB Act specifically defined paraprofessionals and specified their responsibilities and limitations with regard to their employment by the local educational agency (LEA). A portion of IDEIA federal money is spent each year to provide services of paraprofessionals to assist children with disabilities; and today, most public schools have instructional paraprofessionals employed as support staff responsible for assisting in the delivery of instruction (Hoffman and Sable, 2006).

When paraprofessionals were first introduced into classrooms, their main role was one of support to the teacher in the form of clerical work. Typically, their duties consisted of taking attendance, checking papers, preparing materials and bulletin boards, organizing paperwork, collecting money, and other clerical or housekeeping duties (Blalock, 1991; French, 1999). Over time, this workforce of people has come to be utilized for many other important tasks within classrooms. Paraprofessionals are often found in self-contained classes, resource rooms, and bridging inclusion activities in general-education classrooms. Assigned classrooms will determine the types of roles performed by paraprofessional. Broer *et al.* (2005) found that students with intellectual disabilities viewed paraprofessionals as having various roles such as mother, friend, protector, and primary teacher. Chopra *et al.* (2004) suggested that paraprofessionals also play the role of connector, especially since they connect parents to teachers, parents to community services, students to teachers, students to parents, students to peers, and students to the curriculum. In many instances, paraprofessionals work one-on-one with students or conduct small group activities that have been prepared by the classroom teacher (Daniels and McBride, 2001; Minondo *et al.*, 2001). Rueda and Monzo (2002) identified the major

roles of the paraprofessional to include (1) instruction, (2) school support, (3) liaison, (4) personal support, and (5) one-to-one class support. With each of these roles, come specific responsibilities. Oftentimes, children with disabilities need additional supports or related services in order to receive a free and appropriate public education. Paraprofessionals may also serve under the direction of speech–language pathologists, physical therapists, and occupational therapist (often called para-therapists) as they deliver related services while being trained and supervised by professionals (IDEA Public Law, Section 26(a)). Their services have been found to be important and needed.

Paraprofessionals in the United Kingdom

In the United Kingdom, the term used for paraprofessionals in government documentation is teaching assistants (TAs). In 2000, the Department for Education and Science (DfES) published *Supporting the TA: A Good Practice Guide*, which suggested that TAs provide four different types of support noted below:

1. For pupils – all pupils they encounter during their working day, not just those they have responsibility for.
2. For teachers – by carrying out routine tasks and more specialist teaching roles.
3. For the curriculum – particularly literacy and numeracy.
4. For the whole school – as part of a team which promotes the well-being of pupils.

According to the UK's Department for Education and Science (DfES, 2000), there were over 146 000 TAs in schools in England in 2005. **Table 1** shows the proportion of TAs working in elementary, secondary, and special schools, and also provides a comparison with the numbers and proportions of teachers working in those settings. The number of TAs has been steadily increasing since 1997, when there were only about 61 000 in England, with the largest increase around 2004–05 with the UK government's workforce-remodeling initiative. Apparently, this initiative gave teachers a half-day each week for

preparation and planning, and allowed TAs (who were appropriately qualified and experienced) to cover for them (Morgan, 2007). In addition to these figures for English schools, there were more than 13 000 TAs working in schools in Wales, and in Scotland (where the title is Classroom Assistants) more than 7500 TAs working in primary schools alone.

The Training and Development Agency for Schools (TDA) – the UK government department responsible for standards in teaching – in 2002, produced the National Occupational Standards (NOS) for teaching/classroom assistants. These standards contain competencies not only considered necessary for effectiveness, but also appropriate for developing job descriptions, recruiting new staff, and conducting staff appraisals. **Table 2** lists the basic concepts underpinning the standards.

Additionally, there are professional standards for higher-level teaching assistants (HLTAs) – a relatively new qualification represented as level 4 on **Table 5**. The HLTA program was conceived in response to concerns over teacher workloads and over who could provide classroom support at a level to help teachers with their responsibilities while preserving teachers' status. In 2004, the government document: *The Education (Specified Work and Registration) Regulations* provided guidance on who could appropriately undertake tasks such as preparing, planning, and delivering lessons and assessing pupil performance, tasks formerly considered appropriate only for teachers. The document authorized schools to use TAs for this type of work, but preferably only those with higher-level status. Standards for HLTAs are listed in **Table 3**.

As it appears, the standards cover a very broad range of activities relating closely to a teacher's role. However, there is a clear indication that HLTAs are still required to work under the direction of a teacher.

Paraprofessionals and Training Programs

An in-depth review of the literature on the use of paraprofessionals in special education concludes that there is insufficient evidence – which is minimal, at best – to support the practice of relying on paraprofessionals in

Table 1 Numbers of teaching assistants (TAs) and teachers in England in 2005

Stage	Number (and %)	
	TAs	Teachers
Primary schools	95 460 (65%)	204 840 (47%)
Secondary schools	29 980 (21%)	220 760 (50%)
Special schools	18 540 (13%)	14 900 (3%)
Pupil referral units (PRUs)	2 070 (1%)	6 520 (1%)
Total	146 050	447 020

Table 2 National occupational standards (NOS) for TAs: Basic concepts

- Working in partnership with the teacher
- Working within statutory and organizational frameworks
- Supporting inclusion
- Equal opportunities
- Anti-discrimination
- Celebrating diversity
- Promoting pupils' independence
- Confidentiality
- Continuous professional development

Table 3 Professional standards for higher-level teaching assistants (HLTAs)

1. <i>Professional values and practice</i>	
•	Have high expectations of all pupils; respect social, cultural, linguistic, religious, and ethnic backgrounds; commit to raising educational achievement
•	Build and maintain successful relationships with pupils; treat them consistently, with respect and consideration, with concern for their development as learners
•	Demonstrate and promote the positive values, attitudes, and behavior they expect from pupils
•	Work collaboratively with colleagues, knowing when to seek help and advice
•	Liaise sensitively and effectively with parents and carers
•	Improve their own practice, through observation, evaluation, and discussion with colleagues
2. <i>Knowledge and understanding</i>	
•	Have sufficient understanding of their specialist area to support pupils' learning; acquire further knowledge to contribute effectively and with confidence
•	Be familiar with the school curriculum, age-related expectations of pupils, and the relevant teaching methods and testing/examination frameworks
•	Understand the aims, content, teaching strategies, and intended outcomes for lessons, and understand the place of these in the overall teaching program
•	Know how to use information and communication technology (ICT) to advance pupils' learning
•	Know the key factors that affect the way pupils learn
•	Have a qualification in English/literacy and mathematics/numeracy equivalent to at least level 2 of the National Qualifications Framework.
•	Be aware of the statutory frameworks relevant to their role
•	Know the legal definition of special-educational needs (SEN), familiar with the SEN Code of Practice, and know key factors that affect the way SEN pupils learn
•	Know a range of strategies to promote good behavior and establish a purposeful and disciplined learning environment

the delivery of instruction (Giangreco *et al.*, 2001). The 2004 IDEIA and its alignment with the NCLB of 2002 compelled states and school districts to look at personnel-development programs to support their paraprofessionals. They could not use lack of funds as an excuse to avoid offering training. The NCLB Act stipulated that a "local educational agency receiving funds under this part may use such funds to support ongoing training and professional development to assist teachers and paraprofessionals in satisfying the requirements of this section." It directed that "each local educational agency receiving assistance under this part shall ensure that a paraprofessional working in a program supported with funds under this part is not assigned a duty inconsistent with this subsection." These NCLB regulations have given school districts specific obligations to provide paraprofessionals with adequate training and supervision. When an

accident, improper disclosure, or other adverse incident involving a paraprofessional leads to a lawsuit, the district may significantly reduce its potential liability if it can prove that its paraprofessionals received adequate training and supervision (Ashbaker and Minney, 2007).

There is no nationally accepted training program for newly hired paraprofessionals, leaving school districts responsible to properly train and orient their paraprofessionals. Effective instruction is the key to the use of paraprofessionals in schools. Hofmeister *et al.* (1996) suggested that the increased training and use of paraprofessionals could offset limited resources in rural schools. Morgan and Ashbaker (2001) recommended specific supervision for paraprofessionals, where they are given guided practice under the direction of an educator.

Further, Ashbaker and Wilder (2007) encouraged rural-school administrators to tap into the pool of potential teachers from among the paraprofessionals. Citing research, they argued that paraprofessionals would be good candidates for teacher training programs because they usually live in the community – suggesting staying power – they are native speakers of students' languages, and they provide a sorely needed language resource. They bring with them a great deal of classroom experience and a sense of how children learn based on how they themselves learn (Ashbaker and Wilder, 2007). Moreover, as the number of immigrant children in United States classrooms continues to grow each year, paraprofessionals expand the pool of potential teachers from underrepresented groups because they represent minority populations in greater percentages than do teachers (Haselkorn and Fidelier, 1996). Paraprofessional-to-teacher programs save school districts funds associated with lower attrition rates in teacher-education programs and among newly hired teachers (Hentschke, 1995).

Training for TAs in the United Kingdom is the responsibility of the School Workforce Development Board (SWDB). The support staff's link on the TDA website provides details of the various qualifications now available to TAs. These include national vocational qualifications (NVQs), modern apprenticeships, HLTA status, and the foundation degree. In addition, although this does not lead to a formal qualification, the United Kingdom requires (and provides materials for) induction training for TAs. **Table 4** provides a brief overview of each of these programs.

Required Skills for Paraprofessionals

For paraprofessionals to work effectively with special populations, they need the necessary skills. Due to the changing roles within the profession, the skill set needed to work effectively is also changing. In the past, skills

Table 4 Training and qualifications for TAs in the United Kingdom

All new TAs should undergo basic induction/orientation training carried out by someone in the school. In addition, the UK government now requires local education authorities (LEAs) to administer a set induction program for new TAs – ideally 4 days of training, with a strong emphasis on supporting the national literacy and numeracy strategies from reception to year 6 (K–6). The government has provided materials for the training, which is considered appropriate for both elementary and secondary levels, and all subject areas, as materials provided can be adapted to local needs, and expanded as necessary. The four modules cover the (1) TA's role in supporting teaching and learning; (2) national literacy strategy; (3) national numeracy strategy; and (4) how TAs can promote high standards of child behavior. TAs should be assigned a school-based mentor who should supervise activities undertaken during and after the induction training.

National vocational qualifications (NVQs)

NVQs (in England and Wales, Scottish vocational qualifications (SVQs) in Scotland) were developed in response to the national occupational skills, and are available at levels 2 and 3, with mandatory and optional items at each level.

For level 2, four units of competence from the NOS are mandatory (help with classroom resources and records, help with care and support of pupils, provide support for learning activities, and provide effective support for your colleagues) and three more units must be chosen from the remaining five (literacy/numeracy, management of behavior, pupil safety and security, pupil health and well-being, and ICT).

At level 3, TAs must pass ten units of competence from the NOS, four mandatory courses (management of behavior, establishing and maintaining relationships with individuals and groups, supporting pupils during learning activities, and reviewing and developing your own professional practice) and six electives.

NVQs are a work-based qualification – a TA must be in employment so that assignments and assessments can be based on current responsibilities and performance.

Modern apprenticeships

This is a qualification that has been available to TAs only since 2004. The modern apprenticeship differs from traditional apprenticeships in that there is no age limit. Apprenticeships are also a form of work-based learning, and provide training through a combination of college courses and work experience, with government funding often available to cover tuition fees and a small weekly wage paid to the apprentice by the employer. Many apprenticeships can be completed within 2 years. This combination of college and practical application on the job is intended to provide a high-level technical qualification so that new knowledge can immediately be applied to a work situation.

Modern apprenticeships use the traditional model of a partnership between a training organization and industry, with college instruction supplemented by on-the-job training. However, the modern apprenticeship is not a set course of study or specific qualification, but rather a package of qualifications appropriate to the skills needed for the chosen career. Qualifications can be gained singly and independently and through a variety of routes.

Table 4 Continued

Modern apprenticeships are available at either foundation or advanced level—foundation for TAs with limited responsibilities working under the close supervision of a teacher; advanced for TAs working under the direction of a teacher, but contributing to planning, implementing, and evaluating learning activities. The Scottish modern apprenticeship has some differences in the components because of the differences in the Scottish education system. There is no fixed time period for the apprenticeship. Typically, a foundation modern apprenticeship takes 12–15 months, an advanced modern apprenticeship about 2 years.

The higher-level teaching assistant (HLTA)

The high-level teaching assistant program came out of the National Agreement, Raising Standards and Tackling Workload of January 2003. The purpose of the program was to recognize the high level of work that many TAs were already undertaking, and to provide opportunities for TAs to take on additional roles and responsibilities to reduce teacher workloads. A TA must already be in employment to gain HLTA status; however the training component is minimal – a matter of hours only. The program has two major components:

- A portfolio of written evidence that the TA meets the standards established for HLTA status, and
- An assessment (through interview and observation) by an outside moderator or examiner.

The foundation degree (FdA)

The FdA is also a work-based training option of recent date. Most often offered on a part-time basis, with some daytime sessions but mostly twilight sessions held in the evenings or after school hours, courses are usually modular and cover such topics as learning theory, effective teaching strategies, and behavior management. Course assignments are related directly to students' current classroom situation. A part-time FdA program typically takes 3 years to complete. A major advantage of the FdA is that it can usually be counted toward a full teaching qualification. The Foundation Forward website provides further information.

associated with clerical work were needed but now skills associated with working one-on-one with children and collaboration skills are more the focus. Killoran *et al.* (2001) identified competencies that must be exhibited by paraprofessionals, namely:

- knowledge and range of child development and the impact of disabilities on children and their families;
- assessment-related confidentiality issues;
- working in partnerships;
- respect of families' culture and diversity;
- sharing information with families and assisting them to embed goals and activities;
- effective communication skills;
- ability to create an appropriate environment;
- positive social interactions;

Continued

- ability to implement and evaluate progress, to make program-data-based changes, and to use adaptive equipment/techniques;
- ability to manage/schedule daily operations and maintain safe environments;
- responsive leadership skills, collaborative teaming, ability to facilitate interpersonal and social skills, and to problem solve;
- develop and implement effective transition plans;
- use of self-evaluation for professional growth and ability to receive professional feedback; and
- adhere to identified codes of ethics.

Paraprofessionals and Instructional Process

The NCLB Act specified that a paraprofessional may be assigned to:

- provide one-on-one tutoring if such tutoring is scheduled at a time when a student would not otherwise receive instruction from a teacher;
- assist with classroom management, such as organizing instructional and other materials;
- provide assistance in a computer laboratory;
- conduct parental involvement activities;
- provide support in a library or media center;
- act as a translator; or
- provide instructional support services to students under the direct supervision of a highly qualified teacher (NCLB, Section 1119(g)(2)).

Furthermore, the NCLB Act specified the limitations of a paraprofessional's duties, stating a paraprofessional may not provide any instructional service to a student unless the paraprofessional is working under the direct supervision of a teacher consistent with Section 1119; but they are allowed to:

Assume limited duties that are assigned to similar personnel who are not working in a program supported with funds under this part, including duties beyond classroom instruction or that do not benefit participating children, so long as the amount of time spent on such duties is the same proportion of total work time as prevails with respect to similar personnel at the same school. (NCLB, 2002)

In the United Kingdom, job assignments and responsibilities are distinguished based on training. In the 2003 document, *School Support Staff: The Way Forward*, the United Kingdom distinguished four levels of TAs, according to qualifications, knowledge and skills, and the responsibilities they would therefore undertake. At levels 1 and 2, the requirements are designated as general. At levels 3 and 4, a distinction is made between those working to support and deliver learning, and those providing

behavior guidance or support. (See Table 5 for a comparison of roles, qualifications, and knowledge/skills at each of the four levels for TAs working to support and deliver learning.) As Table 5 shows, the gradual increase in knowledge/skills corresponding to increased levels of responsibility is accompanied by a decrease in intensity of supervision from a professional. At level 4, TAs not only take considerable responsibility for teaching, but also work quite independently, even supervising other TAs.

Although IDEIA stated that paraprofessionals who are providing special-education services must be adequately supervised and the NCLB Act requires that Title I paraprofessionals must work under the supervision of a teacher, there is as yet, no federal standard for what constitutes adequate supervision. Moreover, the NCLB Act and IDEIA required paraprofessionals to be appropriately trained and supervised. These are new roles for both the teacher as the supervisor and the paraprofessional as a support instructor. Oftentimes, the paraprofessional has not received prior training for instructional support and thus needs additional supervision and assistance in order to feel adequate to the task (Rueda and Monzo, 2002). This is especially important because many paraprofessionals may not know that they are supervised. Likewise, teachers may feel that they do not know how to formally supervise their paraprofessionals (Salzberg and Morgan, 1995).

The consequence of not providing supervised preparation could be disastrous; children with disabilities failing to receive a free appropriate public education (FAPE), paraprofessionals overstepping the limits of their training and authority, and teachers delegating curricular and instructional decisions – all of these actions can give ground to abounding lawsuits. By formalizing and documenting individual supervisory routines and procedures, school personnel and the district can meet its legal obligation to ensure that all personnel are adequately supervised and that properly trained staff support the educational services provided to special-education students. However, adequate supervision requires a large investment of time and energy devoted to this process. Schedules must be adjusted and resources allocated as teachers and paraprofessionals often do not have the allotted time to sit down together due to their other roles and responsibilities (Ashbaker and Morgan, 2001). Leblanc *et al.* (2005) suggested that verbal review, videotaped demonstration, performance feedback, rehearsal, and modeling can be used as methods for the teacher to provide instructional supervision and help paraprofessionals to improve their instructional skills. Some school districts and undergraduate institutions have begun to incorporate courses for teachers to learn how to manage and supervise their paraprofessionals (Trautman, 2004); and much of the supervision can be done on the job as teachers and paraprofessionals work together to support student learning (Ashbaker and Morgan, 1999).

Table 5 Four levels of roles, qualifications, knowledge, and skills required of TAs in the United Kingdom

Level 1	Level 2	Level 3	Level 4
<p>Basic role</p> <p>Work under the direct instruction of teaching/senior staff, usually in the classroom with the teacher, to support access to learning for pupils and provide general support to the teacher in the management of pupils and the classroom</p>	<p>Work under the instruction/ guidance of teaching/senior staff to undertake work/care/ support programs, to enable access to learning for pupils and to assist the teacher in the management of pupils and the classroom. Work may be carried out in the classroom or outside the main teaching area</p>	<p>Work under the guidance of teaching/senior staff and within an agreed system of supervision, to implement agreed work programs with individuals/groups, in or out of the classroom</p> <p>This could include those requiring detailed and specialist knowledge in particular areas and will involve assisting the teacher in the whole planning cycle and the management/ preparation of resources</p> <p>May also occasionally supervise whole classes during short-term absence of teacher. The primary focus will be to maintain good order and keep pupils on task. Will need to respond to questions and generally assist pupils to undertake set activities</p>	<p>Complement the professional work of teachers by taking responsibility for agreed learning activities under an agreed system of supervision</p> <p>This may involve planning, preparing, and delivering learning activities for individuals/groups or short term for whole classes, and monitoring pupils and assessing, recording, and reporting on pupils achievement, progress and development</p> <p>Responsible for the management and development of a specialist area within the school and/or management of other teaching assistants including allocation and monitoring of work, appraisal, and training</p>
<p>Qualifications</p> <p>-Good numeracy/literacy skills</p>	<p>-Good numeracy/literacy skills</p>	<p>-Very good numeracy/literacy skills</p>	<p>-Excellent numeracy/literacy skills (maths and English equivalent to NVQ Level 2)</p>
<p>-Completion of TA induction program</p>	<p>-Completion of TA induction program</p>	<p>-NVQ 3 for TAs or equivalent qualification or experience</p>	<p>-Meet HLTA standards or equivalent qualification or experience</p>
<p>-Participate in development and training opportunities</p>	<p>-NVQ 2 for TAs or equivalent qualifications/experience</p> <p>-Training in the relevant learning strategies e.g., literacy</p> <p>-First aid as appropriate</p>	<p>-Training in relevant strategies e.g., literacy, and/or in particular curriculum or learning area e.g., bilingual, sign language, dyslexia, ICT, math, English, CACHE</p> <p>-Appropriate first aid training</p>	<p>-Training in relevant learning strategies e.g., literacy</p> <p>-Specialist skills/training in curriculum or learning area e.g., bilingual, sign language, ICT</p>
<p>Knowledge and skills</p> <p>-Appropriate knowledge of first aid</p>	<p>-Effective use of ICT to support learning. Use of other equipment technology – video, photocopier</p>	<p>-Use ICT effectively to support learning. Use of other equipment technology – video, photocopier</p>	<p>-Use ICT effectively to support learning</p>
<p>-Use basic technology – computer, video, photocopier</p>	<p>-Understanding of relevant policies/codes of practice and awareness of relevant legislation</p>	<p>-Full working knowledge of relevant policies/codes of practice and awareness of relevant legislation</p>	<p>-Full working knowledge of relevant policies/codes of practice/legislation</p>
<p>-Ability to relate well to children and adults</p>	<p>-General understanding of national/foundation stage curriculum and other basic learning programs/strategies</p>	<p>-Working knowledge of national/foundation stage curriculum and other relevant learning programs/strategies</p>	<p>-Working knowledge and experience of implementing national/foundation stage curriculum and other relevant learning programs/ strategies. Understanding of statutory frameworks relating to teaching</p>

Conclusion

Paraprofessional-to-teacher programs save school districts funds associated with lower attrition rates in teacher-education programs and among newly hired teachers (Hentschke, 1995). Paraprofessional training programs must be research-based programs that produce a highly skilled paraprofessional workforce. Articulation agreements must be forged at the local and state levels, as well as reciprocal agreements across states that recognize the quality of the training and the skills gained. Pickett *et al.* (2006) at the National Resource Center for Paraprofessionals (NRCPP) noted that although there has been some progress in developing policies and standards, in far too many situations, these efforts have been piecemeal and have not led to infrastructures and policies that are integral parts of statewide systems of personnel development. Similar conditions are visible in the United Kingdom where there are now moves to standardize pay and training for paraprofessionals. It is when good initiatives are developed along with a strong infrastructure that paraprofessionals will receive the recognition and value that they deserve. This must happen with the overarching goal of improving the quality of educational services for students with special needs and their families.

Parent and Family Involvement in the Education of Children with Special Needs

L P Prater, Southeast Missouri State University, Cape Girardeau, MO, USA

© 2010 Elsevier Ltd. All rights reserved.

The education of any child is a very complex issue, comprising interconnected internal and external relationships (Garrett and Morgan, 2002). This is especially true when the child has been identified as one with special needs, primarily because of the wide variance of those needs and abilities. Educating these children is much more than molding a piece of clay, or drawing on a blank canvas, as some would describe child socialization. There are so many variables that impact how knowledge is imparted from one human to another, even if there are no special needs identified. In fact, the phenomenon called education is rather mysterious. When does learning begin? How is knowledge gained? By definition, who is an educated person? Who is responsible for educating children? Can all children learn? These are merely a few of the questions one might ask. In attempting to respond to these questions, it must be recognized that all children are unique. There are some children who are more different than others and have been identified as having special needs, constituting a wide array of behaviors, ability, and performance levels, as well as challenges.

In an effort to match the special needs of children with appropriate services, labels have been devised to facilitate this process. There are advantages and disadvantages to this strategy, especially if children are labeled inaccurately or if there are political motivations involved. For example, there are instances in which children with special needs are labeled differently depending on where they live. In more affluent areas, more children are labeled as learning disabled, rather than mentally retarded. These labels matter because they are connected to specified services, sometimes including fiscal support. For instance, there is currently much attention and grant opportunities focused on autism. The critical question could be asked, "Are there more students with autism or are more students, who would have received other labels a few years earlier, being labeled as autistic?" This is why teachers, service providers, and parents should be knowledgeable about the values of parent and family involvement. Children, and especially those with special needs, are educated within a societal system and not in isolation. This is a three-prong system composed of family, educators, and, collectively, other societal constituents such as social service agencies and policymakers. As with any three-legged unit, all pieces are necessary for the structure to stand. The family, in concert with educators and

others who impact this process, is a significant factor in educating children with special needs.

The late social scientist Urie Bronfenbrenner (1977) developed a classic systems model that aligns with internal and external variables which impact family functioning. In that model, the family ecosystem is divided into subsystems of micro-, meso-, exo-, and macro-levels. The family unit and school are at the micro- and meso-levels, respectively, and have regular interaction with each other. Social service agencies and policymakers are at the exo-level and attitudes, beliefs, and culture operate at the macro-level. This family systems approach should be used in educating students with exceptionalities, because these children and their families are very much interconnected with other groups. In this article, the focus is on the significant micro- and meso-subsystems as the systems components within which the family and school interact to accomplish the goal of educating children with special needs.

Identity of Family Members

In contemporary times, many forms of relationships are recognized as representative of a family. Traditionally, in some cultures, a family unit consisted of a legal union between a man and a woman and their biological children. That definition has been greatly expanded. Persons may identify themselves as family members if they are related by blood, marriage, or self-imposed affiliation. They may cooperate economically and may or may not share a common household, such as extended family members, and may not have children. If children are in the household, they may be their biological children, step-children, foster children, or adopted. In fact, the least common family structure today mirrors the traditional model. For example, in America, the fastest growing family structure is single females with children. When children with special needs are part of a single-parent household, parenting responsibilities can become overwhelming. Family structure may, in part, explain the educational outcomes of these children. There may not be time and energy for one person to work, care for the household, assist with educational programming at home, and actively participate in school functions. In addition, many of these single parents, who are mostly mothers, have parenting responsibilities with other children as well.

The list of ways that families of children with special needs differ is unlimited. To name a few, families differ in family size, socioeconomic status, number and educational level of parents as primary caregivers, ethnicity, and in the primary language spoken in the household. All of these factors influence the likelihood of family involvement with schools. Increasingly, schools are asked to serve these diverse families and accomplish parity of educational outcomes, regardless of the frame of reference with which the child enters.

Unique Circumstances Impacting Parental Participation in Schooling

It is assumed that all potential parents want the perfect child, the one who is perfectly formed, perfectly behaved, and perfectly functioning in every way. In reality, some children are born with mild, moderate, and severe congenital disabilities. Circumstances may cause children born, without these differences, to acquire physical or mentally limiting conditions. Illness or accidents are most likely the culprits in those cases. Parents may experience chronic sorrow, grief, and mourning for the loss of their ideal child (Winkler *et al.*, 1981). These feelings can recur at transitional periods such as the child's entrance into school or onset of puberty. Parents may become engulfed with bitterness or anger and wonder why this happened to them. Although unintentional, they may become consumed with jealousy of families with children identified as normal. Does society prepare families to parent a special needs child? No, there is no proactive socialization process to prepare parents for this situation. Possibly, this is one reason that the divorce rate is high for couples with a special-needs child. The caregiving demands are high and stressful, and can lead to increased feelings of depression, helplessness, guilt and blame, and decreased feelings of parental competence.

Parenting is a tough and important role, maybe the most challenging in all of society. When this responsibility is coupled with parenting a child with special needs, involvement in discretionary school activities may be less of a priority. Other than the legislated involvement and meetings, or school contact initiated as a result of reported problems, these parents tend to be uninvolved. The time within their 24 h in a day, 7 days in a week, and 12 months in a year are occupied with the daily challenges of financing the needs of their child; managing a myriad of unpredictable and atypical circumstances; navigating the related legal and social systems; and handling the resulting family-relationship issues. Families experience stressful situations unknown to other families. The anticipated daily family functioning of their dreams remains a fantasy. It is amazing that they function as well as they do. For

example, some families, who parent one of the children diagnosed with autism, have experienced financial ruin in trying to secure and finance services for their child. If it is a two-parent household, one parent may have to remain outside of the labor force to care for the child's needs. This further reduces the family income! The possible genetic influence may cause some families to have more than one child with autism, especially if the siblings are twins. Government assistance is very specified and limited, if it exists at all for children with autism in some communities. In countries with socialized medicine programs, this may not be a problem. In the United States, there is no entitlement for universal healthcare. For some families, there may be government-subsidized care; in other situations, care is dependent upon the family's ability to fiscally support the health needs of the child. It must also be recognized that many of these families have typically developing children to support as well. Rather than criticize these families for the low participation in school activities, educators, social agency representatives, and policymakers should be more sensitive to the inadequacy of support that is needed for these families, and contribute to advocacy initiatives to provide more assistance.

The typical school day conflicts with the work schedule of many parents, including parents of special needs children. This fact is significantly a barrier for families of low income and those with inflexible positions that prohibit leave time to visit school settings. For these parents, this is a double disadvantage. They cannot afford absence from work to participate in many of the school functions and they are judged as being apathetic, uncaring, or uninterested with regard to their child's schooling. There are fewer high-income families and, therefore, as compared to others, many of these families are within the range of poverty, which presents a multitude of circumstances which serves as a barrier to their participation in school activities.

Children with special needs are members of families from all social classes. Parents at all economic levels should perceive that they have the opportunity for participation in some form of school activity, but social class is an issue. The social stratification results in many of the parents of the same income having children clustered in the same school. In schools where a large majority of the children are from families with low income, there is low parental participation. Conversely, children from families with high income, tend to attend the same schools. As their parents are more likely to have professional careers with flexibility of schedules, their participation in school events is higher. The attention that these parents give to the child and school interaction is not a signal that they love their child any more than parents with inflexible work schedules. It does signify that there is more of an opportunity for them to be involved. Being concerned about a child's education is not a function of income level.

Family members of children with special needs, like everyone else, are impacted by past experiences. Memories of the school experiences of family members influence their attitudes and perceptions about school. Those with positive experiences tend to be more open to school interaction, than family members with memories of negative events during their own school years. Similar to any other situation, persons tend to avoid unpleasant situations and embrace positive ones. There are parents, especially those with less education than school officials, who feel intimidated by school personnel. Insecurity, inferiority, and embarrassment are emotions they feel when in the presence of teachers or school administrators. Their response to avoiding these feelings is merely to limit school visits to mandated appearances. Overall, parental involvement is a result of the family's perceived skills and abilities, their employment and other obligations, and opportunities provided by the school.

Family Participation in Schooling Children with Special Needs

A primary responsibility of schools is to educate students, but students are connected to some part of a family unit, in which most of their time is spent. Family members are actually the first teachers. Collectively, considering the child's total being of time and influence, school is dwarfed by home and family impacts. There is a role in educating students that is occupied only by family members and cannot be replaced by school faculty, administrators and staff, school board members, or legislators. School personnel and others making important decisions about schooling may have degrees from the best colleges and universities, but lack crucial information known only to family members.

The school needs to take the lead on whether the parent will be afforded only a passive role, or encouraged to assume an active role. The participation has to go beyond the traditional model of parent-teacher association (PTA), established in 1924, and the school climate must be welcoming and encouraging of parental involvement. To accommodate this involvement, schools can structure opportunities for parents to participate in schooling (Epstein, 1986). There are some situations in magnet schools in which family members are required to volunteer a specified number of hours at the school. As mentioned earlier, some level of involvement is mandated for parents of children with special needs. In the United States, the Individuals with Disabilities Education Act (IDEA) of 1990, Public Law 101-476 provided the opportunity for the parents of children with special needs to influence the education of their children. Parents of children in special-education programs are legally required to

participate in the child's individualized educational plan. Public Law 101-476 and its 1997 amended version, especially addressed parents and educational resources for minority children (Prater and Ivarie, 1999).

For many parents, they are invited to the school to assist the teacher in the classroom, raise funds, chaperone field trips, or possibly help coach a ball team. For parents of special-needs children, the involvement tends to be more focused. The educational process can be a 7-days-a-week, 24-hours-a-day process, depending on the nature of the birth or acquired differences. The parent and teacher partnership is much more significant than baking cookies for a class party. Of course, parents often help with homework, but parental assistance with homework for a special-needs child is more intense, more focused, and more than likely, more time consuming.

Parents who can navigate the political and educational system are empowered to get the best services for their children. Schools that seek to empower parents assume that parents are capable of influencing the outcome of their child's educational process.

However, sometimes there is a disconnect between families and school personnel. Society is becoming more diverse, not less diverse. Considering that families reside within a global society, this diversity includes racial, ethnic, language, and cultural differences, but must also include differences in cognitive, emotional, and physical functioning. When there were more homogeneous school populations and neighborhood schools, empowerment of parents did not seem to be a concern. The incidence of children in need of special education was not much of an issue, because children with special needs were not sent to school. They were mostly kept at home and shielded from public view.

Family involvement is a certainty for parents of children in special-education programs, if only indicated by parents signing a consent form, rather than actively participating in policymaking. This formal, one-way communication, from school to home is limiting and does not empower parents. When families are empowered, they feel that their views have value. When families are not empowered, there is a feeling of powerlessness, followed by intimidation that prohibits them from asking important questions on their child's behalf. To empower parents, parental involvement should include roles such as advocates and policymakers.

School personnel must view each child and family within a framework that encompasses the entire political, social, economic, cultural, and spiritual experiences that shape the identity and behavior of the families and children with special needs. For more than any other population of school-age children, the one-size-fits-all approach is inappropriate, which is exactly why the individualized educational program emerged. For these children and families, there are endless variances.

Teachers, like everyone else, may tend to avoid situations in which they perceive rejection as the outcome. Sensing negative reactions from parents, there could be instances in which teachers are more passive in seeking parental involvement because they fear an unsuccessful result. Some of this fear could be based on biased pre-judgments, myths, or stereotypes couched within Urie Bronfenbrenner's macro-level inclusive of attitudes, beliefs, and cultures. In these circumstances, parents can sense the feelings of teachers and reciprocate with feelings of isolation, alienation, and disengagement.

In establishing a support system for parent involvement, school personnel should become familiar with the child's uniqueness, the family, and the school's community to determine those activities that are more likely to solicit the desired outcome of parental involvement. As parents are afforded a greater role in defining involvement, they will gain greater confidence leading to increased participation in educational decision making focused on their child with special needs. Aside from meetings to discuss the individualized educational plan, family members have few avenues by which they can challenge curriculum choices, instructional strategies, or additional educational resources for their child.

In too many situations, educators continue to exclude families, devalue their suggestions, primarily use the ideas of experts, and value more the opinions of those who have possibly never even met the students. Prater and Tanner (1995) completed a case study report that detailed the tragedy of such practices, and the subsequent result of sabotaging parental aspirations and curtailing educational opportunities for youth in special-education programs. It is a mistake to rely solely on the ideas of experts and ignore the real people most knowledgeable about the child, the families. It is vital that parents are empowered and parental involvement is integrated into the instructional plans for students in special education, beginning with early childhood special education and continuing throughout the educational process.

Creating a School Environment to Empower Families

There is a mistaken notion that involvement and empowerment are synonymous terms. Involvement may merely imply some form of contact, but empowerment is more of a reciprocal partnership that includes decision making and influences outcomes. In order for parents to be empowered in special-education programs, they must assume roles as assessors, presenters of reports, policy-makers, advocates, and peer supporters. Educators will not be a vehicle for empowering parents unless they respect the fact that parents are themselves empowered

with an understanding of the system within which families of children with special needs exist and function. Coupled with educators' need to understand, is the need to avoid stereotyping families based on a presumption of uniformity of experience, culture, and knowledge. Often, there is cultural and educational dissonance between school governance professionals and the families they serve. If there are no deliberate attempts to eliminate, or at least bridge these poles, a barrier develops that will cause families to avoid school participation. This cultural divide is very evident in America, where school-governing bodies tend to be male, White, and middle class. By contrast, minorities comprise the majority of children enrolled in special-education programs.

The school environment can facilitate or impede successful relationships between the school and families. Perceptions based on gender, sexism, and social stratification can reinforce dissonance between parents and teachers, causing some educators to view parents as the cause of problems with schooling their children. These perceptions marginalize parents and inhibit parental empowerment, and discourage involvement. There must be trust between families and school personnel. Without trust, little will be accomplished. To benefit the educational goals for the child, this trust must be mutual and must be earned to be acquired.

One might ask, How can educators earn this trust? For parents to trust school personnel, there must be a consistent pattern of positive experiences, resulting in a strong foundation of credibility rooted in honesty and practices targeted to the sincere well-being of the child. For whatever the reason, this does not always occur. If a child is misdiagnosed, misplaced, mislabeled, or miseducated, trust is compromised. If there are unanswered questions as to why certain groups are overrepresented in remedial programs and rarely in gifted programs, it may be difficult to accomplish a comfortable level of trust. One might assume that because a child is assigned to a special-education classroom that he or she is appropriately placed. This might not necessarily be the situation. As described previously in Bronfenbrenner's systems model, the macro-level comprises attitudes and beliefs. Despite their academic credentials, educators have personal biases which serve to influence behavior in their professional activities.

Benefits of Family and School Partnerships

Regardless of the challenges, schools must seek to engage parents. There are positive outcomes involved in reaching out to parents. By any measure, students in special-education programs benefit from the partnership. The academic outcome is more positive and the availability of the joint resources provides additional assistance. Time and

energy lost in disruptions between the family and school are costly, with the child being the biggest loser. With the help of school personnel, parents who can navigate the political, educational, and social systems are empowered to get the best services for their children. Unfortunately, some parents do not even know their rights. When parents know the laws and have political expertise, they can create happenings. For example, in one mid-Western town in the United States, parents lobbied state legislators to get millions of state money allocated to serve children with autism in their district. This occurrence would not have happened without parental collaboration and intervention.

Summary

An effective relationship between family and school impacts school adjustment and progress. As there are so many variables in the education of children with special needs, all opportunities must be explored to create and sustain effective partnerships between families and the schools, even those options that have never been used before, or may seem atypical. To address the fact that families are different, there should be more development of projects targeted to specific groups, such as grandparents raising grandchildren, single fathers, foster parents, and other groups of identifiable populations parenting children with special needs.

Institutions preparing teachers must include sensitivity to the role of parents in their teacher-training curriculum, because current and future educators must empower parents. This sensitivity must include knowledge of multicultural factors. Otherwise, it may be assumed that a culture different from the educator implies a lower status of cognitive functioning and educational deficits for the children and families. Currently, school professionals are not prepared for these diverse families.

If parents are not empowered, they cannot and will not advocate for the child. Intimidation may prohibit them from asking important questions or seeking social service support. More importantly, a systemic network of negative attitudes will serve to victimize parents and retard the likelihood of parents establishing a partnership in the education of their children. Empowered parents ask questions and insist on accountability.

The model used by schools for involving parents is outdated. It has not changed, but the family structures and lifestyles have changed. Rather than expecting parents and the child to modify their behavior, it is imperative that educators modify their behavior and attitudes toward students in special education and their families. The complexity of family functioning must be considered in order for families to be repositioned as active, equal partners in schooling. Educational systems nurturing special-education programs must establish a web of support

for its students. Students, parents, educators, employers, lawmakers, and other community entities must be totally focused on an integrated goal of educating all of the students with special needs.

Peer Relations and Socialization of Children and Adolescents with Special Needs

L M Bullock, University of North Texas, Denton, TX, USA

M Wong-Lo, University of North Texas, Denton, TX, USA

R A Gable, Old Dominion University, Norfolk, VA, USA

According to the literature, children who are socially competent, experience positive social interpersonal relationships, peer acceptance, satisfactory school adjustment, and cope with and adapt to the demands of various social settings (Gresham *et al.*, 2003). In the absence of these prosocial skills, students suffer – both socially and academically (Bullock and Gable, 2001; Kerr and Nelson, 2006; Schoenfield *et al.*, in press). Indeed, a defining characteristic of children with emotional/behavioral disorders is the inability to build or maintain satisfactory interpersonal relationships (Kauffman, 2003; Kerr and Nelson, 2006). Between 35% and 75% of children with learning disabilities exhibit problems establishing and maintaining friendships (Kavale and Forness, 1996). In addition, a significant number of individuals with cognitive impairments show social skill deficits (Strain and Kerr, 1981). With the disillusionment of a two-box system of public education – one box for general education and the other for special education students, there has been mounting attention given to peer relations and social development of students with special needs.

We have long recognized the critical role that peer relationships play in children's overall socialization. To better understand that developmental process and how that knowledge can improve prevention/intervention efforts, researchers have examined the role peer relationships play in the development of both adaptive and maladaptive patterns of behavior (e.g., Deater-Deckard, 2001; Santos and Winegar, 1999). This growing body of research has increased substantially our understanding of the complex nature of social interpersonal relationships among children and adolescents – with and without special needs. Notwithstanding the contributions of these investigations, a myriad of questions remain regarding the nuances of children's interpersonal relationships (Ellis and Zbaratany, 2007) and the socialization process as it relates to individuals with special needs (Larrivee and Horne, 1991).

In this article, we examine peer relations and socialization of children/adolescents with special needs. To accomplish our goal, we conducted a review of the accumulated literature by means of the search engine ERIC and Academic Search Premier using the keywords: peer relations, socialization, and special education. Furthermore, we used the Internet search engine Google and the same keywords to obtain additional information.

In addition, we conducted a manual search of textbooks and professional journals. Finally, we made use of various reference lists to complete our literature review on peer relations and socialization of students with disabilities.

Past-to-Present Perspectives on Peer Socialization

Beginning in the 1920s, child development specialists were among the first to focus attention on social development and the role of peers in the socialization process (Haynie and Osgood, 2005). For example, Piaget (1932) posed that peer experiences contribute uniquely to children's social development and what they might reasonably expect from peer relationships. Hartup (1977, 1979) asserted that children who did not experience positive encounters with peers are developmentally at risk. Similarly, Piaget (1978) maintained that children who fail to learn from early social interactions must either learn to alter their behavior or risk peer rejection. Subsequently, a series of longitudinal studies confirmed these assumptions and documented the fact that social interpersonal problems from childhood to late adolescence are inextricably linked to early manifestations of peer-group problems and to later social maladjustment (McCord *et al.*, 1963; Roff *et al.*, 1972). In one such study, Roff *et al.* found that poor relations in the primary grades were highly predictive of adolescent delinquency and mental health problems in adulthood. Others also have documented the long-term deleterious effects of isolation and social withdrawal during childhood (e.g., Kauffman 2003; Kerr and Nelson, 2006; Strain and Kerr, 1981).

Although the underpinning for peer relationships starts with parents and other caregivers, the task of adjusting to the peer group begins in preschool (Read, 1960; Ross *et al.*, 1990). Not surprisingly, early-childhood educators attach major significance to social development and the socialization experiences that occur in these early peer-group interactions (Forness *et al.*, 1981). For instance, Read looked closely at nursery school education and its contributions to understanding the basics of human behavior and the socialization process. Read noted that early-childhood education is a place where adults learn much from their observations of children, as they interact with them and, most importantly, provide them with a setting that nurtures

interpersonal relationships. Fortunately, the majority of preschoolers thrive in such an environment and make gains in such disparate areas as critical thinking, expressive and receptive language, problem solving, and prosocialization. However, from the beginning, some children struggle in one or more of these areas, to the degree that they stand apart from their normally developing classmates.

Cook and Wollersheim (1976) explored individual differences among children to the degree to which some are labeled as disabled. They highlighted the potential negative consequences of labeling students, but noted the fact that positive social contacts can engender more positive attitudes and increase the level of peer acceptance. Earlier in their seminal work, Hartup *et al.* (1967) demonstrated that positive social interactions could ameliorate many emergent social interpersonal problems. In the same dimension, Morrison and Borthwick (1983) investigated the relationship between patterns of classroom behavior and the relative social status of children with special needs. They found that classmate's perspectives on cognitive and behavioral performance contribute differentially to social acceptance versus peer rejection. Across time, researchers have examined numerous factors that relate to the overall social adjustment of children and adolescents. Among the more significant findings is the fact that the development of peer relationships and academic achievement are interrelated and of equal importance to peer acceptance (Quicke, 1986). In addition, Quicke asserted that peer interactions were a critical part of the learning process for all students – with or without disabilities. Adults influence not only academics, but also socialization. Studies on the relationship between teachers' perception and socially appropriate behavior indicate that students who fail to meet teacher expectations are at increased risk for poor social interactions with teachers and peers, diminished academic performance, and a disproportionately higher number of disciplinary problems (Bereiter and Engelmann, 1967; Driscoll and Carter, 2004; Stainback and Stainback, 1992). The net result is that students who do not perform well academically risk disapproval of both classmates and adults and, if those problems go untreated, they increase the prospect of future school-related problems.

Chronological Age and the Socialization Process

There is ample evidence that peer interactions represent an important context within which children reach various social-interpersonal milestones (Hartup, 1979; Hartup and Stevens, 1997; Hodges *et al.*, 1999; Kao, 2000; Parker and Asher, 1987). From the beginning, peer attitudes play a pivotal role in the overall socialization of children and youth with and without special needs (McDougall

et al., 2004). At the elementary-school level, children engage in a wide range of social exchanges in various settings, such as the classroom, cafeteria, and the playground. Research suggests that children's peer interactions occur on several different levels: (1) general interactions, (2) interpersonal relationships, and (3) peer groups (Rubin *et al.*, 1998). Research on children's general interactions and relationships with peers suggest that children place a great deal of emphasis on social competence (Diamond and Carpenter, 2000; Ellis and Zarbatany, 2007; Hodges *et al.*, 1999) and popularity (Parker and Asher, 1987; Rubin *et al.*, 1998). In both respects, children at risk or with disabilities are more likely to be marginalized than their classmates.

By early adolescence, the majority of social interactions occur within a group context (Crockett *et al.*, 1984). In a study of 1872, high schoolers, McDougall *et al.* (2004) found that 61% of the participants held attitudes toward peers with special needs that ranged from slightly above neutral to very positive. However, 21% of the students held slightly below neutral to very negative attitudes toward peers with special needs. The researchers also found that when school personnel put emphasis on understanding and acceptance of students with individual differences, students had a more positive attitude toward classmates with special needs (McDougall *et al.*, 2004). In a related investigation, Hartup and Stevens (1997) looked at the influence of children's dyadic friendships on friends' behavior and found that attitudes generally become more alike over time. One conclusion is that, although adults have a powerful influence on children, routine exchanges with other children appear to play a critical role in overall social development (Musser and Graziano, 1991). Peer-peer interactions afford children experiences that are not endemic to child-adult interactions and have a profound impact on the social development of students with and without special needs (Hartup, 1983; Parker and Asher, 1987). At the same time, research on adolescent peer relationships indicates that popularity in this age group represents a defining characteristic of adaptive social development (e.g., Musser and Graziano, 1991). Interestingly, adolescence popularity within their peer group does not immunize them from succumbing to anti-social, delinquent behavior, and substance abuse (Allen *et al.*, 2005). Furthermore, Allen and his colleagues found that, in early adolescence, peer popularity plays a dual role. That is, adolescents who are popular within their wider peer group also are likely to be viewed as being more competent within their closest friendships.

Gender-Related Differences and Socialization

Our review revealed substantial gender-related differences, peer relationships, and the socialization process

(Rose and Rudolph, 2006). Studies on the frequency of group interactions among young children have resulted in conflicting outcomes (e.g., Benenson, 1993; Fabes *et al.*, 2003; Martin and Fabes, 2001). Studies conducted on playgroups revealed larger playgroup sizes for boys than girls, and that there were gender-related differences in the organization of children's playtime activities (Lever, 1976; 1978). Specifically, Lever (1976) found six differences of peer socialization between boys and girls including the fact that boys play outdoors far more than girls. Rather than participate in outdoor activities, girls preferred to play board games or with dolls. Even though boys and girls spent essentially the same amount of time playing alone, boys more often played in larger and more age-heterogeneous groups. Boys engaged in more competitive games than girls, with boys' games lasting longer than girls' games. In addition, researchers who assessed the frequency of dyadic interaction among young children found that boys interact in dyads as frequently, or more frequently, than do girls (Benenson, 1993; Benenson *et al.*, 1997; Martin and Fabes, 2001). Although it is difficult to draw any definitive conclusions, it is reasonable to conclude that the disparate nature of female/male play behavior results in different cognitive, emotional, and behavioral lessons learned.

Rose and Rudolph (2006) argued that girls have a greater tendency than boys to experience stress within the context of a dyadic friendship and to experience vicariously the emotional stress experienced by friends who are part of their social network. Purportedly, girls experience higher levels of stress than boys, particularly during adolescence. The only kind of peer stress that boys experience more than girls was physical and direct verbal victimization. One possible conclusion is that these gender-related differences may make girls more vulnerable to problems of emotional adjustment (Rose and Rudolph, 2006). Repeated exposure to peer stress may lead to diminished perceptions of social competence, concern about friends' welfare, and a sense of hopelessness, all of which can put youth at risk for emotional difficulties such as anxiety and depression (Rudolph, 2002). Further, girls tend to be exposed more to peer stress than boys – especially during adolescence (Rudolph and Hammen, 1999) which may explain the differences in age of onset and intensification of internalizing versus externalizing problems of adolescence (Rose and Rudolph, 2006). Males are diagnosed earlier and manifest more externalizing problems, such as verbal and physical aggression and antisocial acts; whereas, females are guilty of engaging in the so-called status offenses – behavior that is chronically unacceptable, such as running away and sexual activity. In sum, the differing social and emotional nature of male-versus female-dominated peer groups underscore the significance of individual cognitive, emotional, and behavioral coping skills and the influence

peers exert over one another's behavior. Finally, it seems logical to consider age- and gender-related differences in the socialization process, for both students with and without special needs.

Research on behavioral adjustment between boys and girls suggests that boys are more often exposed to overt or physical victimization and that exposure may contribute to their propensity for developing more externalizing behavioral problems such as aggression and antisocial behavior (Rose and Rudolph, 2006). In addition, boys are more likely to be targets of overt victimization which is highly predictive of an increase in externalizing problems over time (Hodges *et al.*, 1999; Hodges and Perry, 1999). There have been relatively few studies on peer stressors; those that have been conducted have produced inconsistent outcomes. Some indicate that the effects of peer stressors on adjustment are similar for boys and girls; while, others suggest that the effects may vary by sex (Rose and Rudolph, 2006). Peer-related stress among girls can pose a serious threat to their emotional well-being (Rose and Rudolph, 2006). Specifically, girls find that interpersonal stress (Rudolph, 2002) and relational or social victimization more emotionally challenging than their male counterparts (Crick *et al.*, 1996). Girls also report experiencing more negative emotions within the context of peer-peer interactions (Larson and Asmussen, 1991). The significance of these investigations is that interpersonal and peer stress are highly correlated with emotional difficulties for both female and male students, but the impact of that stress may manifest itself in different gender-specific ways (Rudolph, 2002).

Rose and Rudolph (2006) maintained that in responding to behavioral problems, girls tend to be more active in seeking support, whereas, boys are less likely to seek outside support and instead try to internalize negative feelings. Unresolved interpersonal conflict among peers may lead to future misunderstandings and hard feelings which, in turn, may precipitate bouts of physical aggression calculated to satisfy a desire for revenge (Rose and Rudolph, 2006). Additionally, Pollack (1998) suggested that because boys have fewer outlets for expressing emotions, such as disappointment or hurt feelings, it is more likely that they will express their emotions through anger and/or overt aggression.

As Rose and Rudolph (2006) pointed out, the social exchanges that occur within a relationship among children/adolescents are inextricably linked to positive emotional adjustment. Oldenburg and Kerns (1997) found that the perception of friendship as validation of an individual's self-worth can translate into lower levels of depression. In addition, positive interpersonal peer relationships appear to decrease the risk of school-related behavior problems (see Rose and Rudolph). In contrast, a negative emotional adjustment can have broad implications with regard to an individual's assessment of self and feelings of

low self-worth, emotional depression, and/or physical anxiety. In sum, gender-related differences appear to account for at least some of variance in children's emotional and behavioral adjustment versus nonadjustment (see Rose and Rudolph).

Culture and Socialization

Some researchers believe that culturally related factors play a key role in how society responds to the behavior of males versus females (e.g., Cartledge and Loe, 2001). However, Hastings *et al.* (2007) noted that gender differences in prosocial behavior may be more attributable to perception than to reality. They believe adults may be more likely to notice and to remember the prosocial behavior of girls because they conform to a cultural stereotype of appropriate feminine behavior. However, Cartledge and Loe (2001) discussed ways in which culture plays a role in shaping the school environment and how it impacts differently among diverse ethnic groups. Cartledge and Loe further explained that collectivistic and individualist orientations were the major distinctions between the dominant group in this society and those of other culturally diverse groups. Earlier, Kao (2000) summarized the stigma attached to diverse groups where students' self-images are shaped on the basis of what defines success among ethnic youth; particularly, some students from culturally diverse backgrounds speak of academic goals in terms of avoiding failure while Asian students focus on keeping up with high expectations on their academic pursuits. Additionally, Kao explored the effects of group image in relation to racial and ethnic stereotypes and expectations and further found that (1) groups defined their goals primarily in terms of the stereotypical images attached to their ethnic group, (2) minority youth focused on avoiding failure defined by prevalent group stereotypes, and these images maintain racially and ethnically segregated extracurricular activities that reinforced segregated peer groups, and (3) socialization with same-race peers promotes comparable conceptions of success within racial groups.

Aside from cultural influences on peer relations, researchers have examined economics and its effect on the development of interpersonal relationships. For example, Garner *et al.* (1994) investigated social competence among low-income populations and its effect on emotional development and socialization. They found that there is a positive correlation between emotional socialization practices and emotional knowledge in the development of low-income children's interpersonal skills. Garner (1996) found that the affective or moral attributions of low-income school-age children were similar to those of middle-income children. Middle- and low-income children reported more empathy, altruism, and

more aggression than guilt or denial, in response to a hypothetical emotion-eliciting situation (see Garner, 1996). Garner *et al.* (1994) stressed that family socialization practices are linked to the social competence of the child, the child's social and cognitive knowledge, and that the child's social and cognitive knowledge contributed to the child's overall social competence. Notwithstanding the obvious influence of families, there is compelling evidence that situational or contextual factors influence the socialization among peers with or without special needs as well (Favazza and Odom, 1997; Hampson, 1984; Haynie and Osgood, 2005).

Program Integration and Social Development

The long-standing practice of serving young children with special needs in settings that include normally developing peers is predicated on moral, legal, and educational grounds (Bailey *et al.*, 1998; Strain and Kerr, 1981). Various authors have offered a moral rationale to support of inclusive practices, namely, that children with special needs have a right to a life that is as normal as possible (Stainback and Stainback, 1992). Some (e.g., Diamond and Carpenter, 2000) have interpreted this perspective to include participation in the same high-quality programs afforded to children without special needs, along with participation in class activities and in positive relationships with individual class members. An educational justification for inclusion typically has focused on the developmental benefits of inclusion for children with special needs, including providing a more challenging and socially responsive learning environment in which they have an opportunity to learn from more competent peers.

Recent federal legislation, specifically the Individual with Disabilities Education Improvement Act (IDEIA) (IDEIA, 2004) and the Americans with Disabilities Act (ADA) (1990), lend legislative and legal support for inclusion (US Department of Education, 2007). IDEIA requires that children with special needs receive education services in the least-restrictive environment and, to the maximum extent appropriate, are educated with children who are not disabled (Buysse and Bailey, 1993). Research on social influences that stem from the integration of children with and without special needs has focused on various approaches and has yielded support for a mix of program options (Buysse and Bailey). Advocates of early integration offer a three-fold argument: (1) children have not yet formed impressions or biases about groups of individuals; therefore, it is important to minimize the probability of overt teasing or rejection, (2) early interactions with persons who have special needs should increase the future probability of acceptance by normally developing peers, and (3) early placement of children in real-world settings creates an expectation on the part of professionals and

parents that integration is the norm that more adequately prepares children with special needs to succeed – academically and socially – in a mainstream environment. In a closely related study, Wentzel (1993) explored the relationship between academic outcomes, measured against grades and standardized achievement test scores and students' social and academic behavior. Teacher ratings of students' prosocial behavior were a significant predictor of standardized achievement test scores. Finally, prosocial, antisocial, and academic behavior was highly predictive of students' grade-point averages. As others before, Gresham *et al.* (2001) claimed that the ability to interact successfully with peers and significant adults is one of the most important aspects of students' development. Other researchers (e.g., Parker and Asher, 1987) have emphasized that maintaining social competence and social adjustments depends on the extent to which students are able to (1) establish and maintain satisfactory interpersonal relationships, (2) gain peer acceptance, (3) establish and maintain friendships, and (4) terminate negative or pernicious interpersonal relationships.

Promoting Peer Relations and Socialization through Programs and Interventions

There is significant overlap between specific programs and the actual interventions conducted within those environments designed to promote peer relations and socialization in schools for students with special needs (Brown *et al.*, 2001; King-Sears, 2001; Mathur and Rutherford, 1991). Although the original concept of head start stressed the social and emotional aspects of a child's development (Zigler and Trickett, 1978), more prominent early-childhood programs emphasized curricular activities that would facilitate cognitive and language developments (Gray *et al.*, 1966; Weikart *et al.*, 1971), as well as reading and math (Bereiter and Engelmann, 1967). Social development was addressed in global, unspecified terms that related to a child's self-concept and sense of personal achievement (Brown *et al.*, 2001).

Diamond (2001) postulated that if children's experiences in inclusive programs are positive, these experiences will support the development of positive attitudes toward people with special needs, both during the early and in later years. In contrast, negative experiences in inclusive programs may lead to the development of prejudices toward people with special needs (Stoneman, 1993). In addition, research with preschool children has shown that peer-mediated intervention can be successful in facilitating children's successful participation in preschool activities (e.g., Robertson *et al.*, 2003). Research conducted on mid-childhood and adolescents indicated enduring positive

outcomes of participation in programs with peers with special needs (Mervis, 1998; Ryan, 2000).

Other researchers (e.g., Moroz and Jones, 2002) have examined the effectiveness of positive peer reporting on children's social involvement. Positive peer reporting is a technique that consisted of rewarding peers for publicly praising the social behavior of their peers. Moroz and Jones' findings supported the use of peers as sources of positive reinforcement for the prosocial behavior of at-risk children. In addition, Ang and Hughes (2001) conducted a meta-analytic investigation that explored the potential benefits of skills training with antisocial youth based on group settings. They found that in 38 studies of social skills training interventions and treatment with anti-social youth, skills-training interventions delivered in the context of groups consisting of only anti-social peers produced smaller benefits than did skills-training interventions that avoided aggregating antisocial peers. In their follow-up, 18 studies reported that treatments provided in the context of either mixed or individual treatment produced larger effect sizes than did deviant-only group interventions. Further, their findings suggested an implication for the recruitment of prosocial peers for inclusion in skills training interventions for aggressive and antisocial youth.

Conclusion

Both researchers and practitioners have long shown interest in peer relations and the socialization process. Despite a growing body of research, gaps between research and practice have become increasingly problematic and pose a major obstacle to optimizing positive student outcomes (Cook *et al.*, 2003). In reflecting on the progress within special education, Kauffman (2003) offered the following observations: (1) the scientific basis for special education is not yet universally accepted; (2) too many in the field discount science as a way of finding things out and believe that special education is fundamentally flawed, second rate, and ineffective as it relates to prevention, (3) we have yet to attach enough importance to academic instruction, (4) we have done too little to address the needs families who suffer the vicissitudes of poverty or the needs of children who have a variety of undesirable life outcomes, and (5) we must strive to achieve the elusive goal of greater harmony, mutual understanding, and equality of opportunity regardless of ethnicity or gender. In the past several decades, we have made real progress in promoting the prosocialization and peer acceptance of students with special needs, but much is yet to be accomplished. Given the life-altering significance of that challenge, now is not the time for modest ambitions.

Introduction

Researchers, policymakers, and teachers currently focus on identifying educational practices that are research based. Effective educational practices must (1) have evidence that is supported by rigorous and scientific data, and (2) have a body of studies that demonstrate positive outcomes. The No Child Left Behind Act (NCLB) of (2001) (Public Law 107-110), and the Individuals with Disabilities Education Improvement Act (IDEIA) of 2004 (Public Law 108-446) have directed teachers – in the United States – to use scientifically based research to drive their decisions with regard to educational interventions.

This type of research is objective, empirical, and replicable. It has valid and reliable data, employs particular research designs, and undergoes rigorous data analysis (see *Identifying and Implementing Educational Practices Supported by Rigorous Evidence: A User-Friendly Guide*, 2007 (US Department of Education, 2007)). Increasing exposure to scientifically based practices using proven instructional methods, materials, technologies, and supports will help students with disabilities to engage in acquiring and generalizing functional content from the general education curriculum. One such program that has a strong scientific basis – and has a body of studies that demonstrate positive outcomes – is peer tutoring (Baker *et al.*, 2004; Calhoun and Fuchs, 2003).

Due partly to NCLB and IDEIA 2004 mandates, teachers and service providers must hold their students with disabilities to the same instructional standards as normally developing peers. This push toward increased inclusion and standards in general education classes creates many obstacles. To cope with varied instructional and social demands on the increased inclusion, teachers often rely on peer tutoring to help diverse students survive and succeed. This article defines peer tutoring and discusses its importance to students with special needs.

Peer Tutoring: Definition and Rationale

A component under the direct-instruction practice of teaching to master is the practice of peer tutoring. Peer tutoring allows students to receive a substantial amount of practice in a specific skill without demanding a great deal of individual teacher attention, while still receiving immediate feedback to determine mastery of the skill

(Maheady *et al.*, 1994; O'Shea *et al.*, 1998). It has been in vogue for a number of years because of the scientific rigor it has undergone to support its effectiveness and efficacy. It has been at the center of scientifically based studies concerning students with and without disabilities – centering on students serving as powerful instructional resources to themselves, while providing positive social interactions to others (Maheady *et al.*, 2001; Mastropieri *et al.*, 2001, 2007). In fact, it is built on one major premise: students helping students to learn. Peer-tutoring programs contain components for active student response, opportunity to respond, feedback, and reinforcement. Important to the successful implementation of peer tutoring is the belief that teachers have confidence in students to instruct and support other students through practice. Other teacher beliefs that are critical to the successful use of peer tutoring include (1) peer tutoring is one means that allows students to receive a substantial amount of practice of a specific skill, (2) peer tutoring – as a teaching approach to assessment and intervention – is effective, convenient to classroom practice, and replete with instructional value to all students involved in the practice, and (3) through instruction in peer tutoring that reinforces the practice of appropriate instructional or behavioral responses, students can gain the ability to control their own actions covertly and maintain more control over situations.

Designing Peer Tutoring

The actual design of peer tutoring is simple: once the teacher determines the specific skill that needs to be mastered, the peer tutor provides the stimulus and the tutee (i.e., the receiver of the tutoring services) responds appropriately to that stimulus. The stimulus provided by the peer tutor can be from almost any subject area, but it must be a discreet variable that cues the tutee to respond appropriately. In addition, the peer-tutoring session that the teacher designs can be across students' ability and achievement levels if the teacher has clearly delineated the stimulus-response chain (O'Shea *et al.*, 1998). Researchers have examined types of peer-tutoring groups. The traditional tutor group involves two students; one student less skilled in a particular area tutored by a more capable student. However, tutoring can also involve a team of three members: one tutor and two tutees. A grouping of as many as six students of heterogeneous ability, also, may

compose the structure. It is imperative that teachers design and arrange groups heterogeneously – by skill ability – to ensure that each tutoring group has a student within the group whose ability for the particular skill being studied can assist the less capable student(s) when necessary (Maheady *et al.*, 1988, 1994). Teachers focusing on peer tutoring underscore the use of pairing appropriate student combinations. Teachers can assign dyads, small groups, or class-wide group based on their knowledge of student achievements, ability levels, social skills, interests, and preferences for selected topics. Their implementation of peer tutoring through the use of dyads or groups has allowed students to practice previously taught skills that include a wide range from academic concepts to specific rule differentiation. Academic and social benefits of peer tutoring have been clearly demonstrated in various settings and with a myriad of academic concepts. Research has clearly demonstrated the effectiveness of peer tutoring (Carlson *et al.*, 1985; Scruggs and Richter, 1985; King, 1982; Maher, 1984; Mathes *et al.*, 1994) as a method for teaching specific skills. To a large group peer tutoring also has resulted in increased academic performance by both the tutor and the tutee (Greer and Polirstok, 1982; Mathes *et al.*, 1994).

Peer-tutoring groups may involve a student with a disability in the role of tutee and the general education student as the tutor. In one study, results indicated that students with disabilities involved in peer-tutoring experiences scored significantly higher on posttesting in social studies than those students studying independently for the same test. The peer-tutoring session for students with disabilities and nondisabled peers resulted in all students reaching mastery (Campbell *et al.*, 1991). Other studies have viewed the role of students with disabilities as the tutor as well as the tutee, also reporting on positive academic gains made by students with and without disabilities (Dineen *et al.*, 1977). Peer tutoring resulting in increased academic performance – both by the tutor and the tutee – was the focus of studies that confirmed positive results for both members of the dyad (Greer and Polirstok, 1982; Mathes *et al.*, 1994). As it appears, peer tutoring has a built-in means for structuring interactions among and across students who normally do not socialize (Valcante and Stoddard, 1990). For example, it can be a valid means for increasing the socialization of isolated students and has proven to be beneficial for improving social skills of the tutor as well as the tutee (Cohen *et al.*, 1982; Maher, 1984). Jenkins and Jenkins (1985) confirmed that peer tutoring also allows students to practice appropriate social skills, while improving students' social standing within the class. Clearly, peer-tutoring programs can be used to promote and increase confidence in students because – through practicing content-area skills – many students report that they become the experts in the area and, in return, have greater confidence in content knowledge. Peer tutoring can be used effectively in diverse populations, especially inclusive classrooms

(Medcalf *et al.*, 2004; Nixon, *et al.*, 2001; Wright and Cleary, 2006).

Processes and Procedures Involved in Peer Tutoring

The success of a peer-tutoring program relies on a clear understanding of expectations and procedures for the tutoring session. It is critical that teachers, or other knowledgeable adults, provide training in skills of tutoring to peer tutors. Niedermeyer (1970) found increased mastery of content when tutors received structured training that included:

- Teaching the tutor a structured plan for each session.
- Teaching the tutor appropriate academic responses.
- Providing practice in giving appropriate corrective feedback.
- Providing practice in giving appropriate social reinforcements for correct responses.
- Developing a practical means for evaluating the tutor and tutees' progress in each session.

It is imperative that the tutor be knowledgeable of the content knowledge and skill being taught in the tutoring session. This may require that teachers hold a pretutoring session addressing the content and attributes of information to the tutor, as well as holding ongoing training sessions as warranted throughout the year (Brown *et al.*, 1971).

The Process of Structuring Specific Tasks

In order to ensure classroom success when implementing peer-tutoring opportunities, the tutor must demonstrate commitment to the tutoring session – approaching each session with the same enthusiasm a classroom teacher needs to approach each lesson. For this reason, teachers work to ensure that tutoring sessions provide structure to each student dyad with specific tasks to complete. Those class-wide programs designing and implementing a contingency plan for the positive learning and interaction of the tutor–tutee grouping also reported higher success rates when specific, structured tasks are apparent prior to the tutoring-session implementation (Delquardi *et al.*, 1986; Greenwood *et al.*, 1991).

Teachers can design and implement a point system for those tutoring groups who complete the daily assignments or reach mastery of material. To determine mastery of materials, evaluative tools – such as curriculum-based assessment (Deno and Fuchs, 1987; Fuchs and Deno, 1991; King-Sears, 1994) or precision teaching (Lindsley, 1972, 1990) – that detect daily progress are most effective for providing quick reinforcement for the students' efforts. Teachers can target ongoing data collection using a daily check of progress and on-task behavior(s). As teachers

or students use graphing charts to display data, students visually see progress and can receive opportunities to realize that hard work pays off. In addition, teachers can plan and implement an intermittent bonus point system every time positive phrases emanate from a student dyad or a tutoring group.

Initial training may impede the start of tutoring sessions, but it is imperative that the tutor is cognizant of his/her responsibilities and is capable of completing the task. The teacher needs to model appropriate behaviors throughout the teaching day – such that, in large-group formats, the teacher continues to model explicitly and directly – and guide the use of important teacher behaviors of structuring, demonstration, prompt, practice, and reinforcement for the tutor (Stoddard and Valcante, 1991).

The Process of Preparing for Peer Tutoring

Teachers can facilitate student success through the use of structured peer-tutoring sessions when they offer to students structured sessions and opportunities to practice (O'Shea *et al.*, 1998). The critical aspect of peer tutoring through dyads, small groups, or class-wide peer tutoring is that teachers control instruction, but use peer tutoring to support students' practice. Teachers must determine what and how subject-matter content will be presented (i.e., they observe and evaluate students, and demonstrate target responses, and lead students in making responses prior to having students practice in peer opportunities). As teachers gradually fade cues, students, increasingly, are able to work with peers. They are expected to give extensive practice so that students have sufficient opportunities to make responses and, thus, master the target skills. Practice activities are done in a fast-paced mode so that there is a high density of responses during instructional periods.

Teachers employing peer tutoring must monitor the accuracy of student responses, ensuring that dyads, groups, or the entire class engage in academic tasks. When tutors err, teachers must respond to provide corrective feedback. There are critical teacher behaviors that correlate positively with student academic gains. Teachers using direct observation and instruction include not only specific tutoring procedures, but, often, use highly structured peer-tutoring materials. The purpose of these materials is to help teachers systematically direct tutors–tutees in making accurate responses. Precise communication must occur between the tutor and tutee. During instruction but prior to tutoring sessions, teachers model target responses, lead students in making responses, and periodically test students' skills to respond without teacher cues.

Students with disabilities profit from classroom experiences in which teachers execute observation, assessment, and instructional behaviors in a standard, systematic manner. If teachers use predictable steps in peer-tutoring opportunities, such students are able to participate in dyads,

small groups, or class-wide opportunities, and perform responses in a more consistent manner. For example, when teachers execute the demonstration step of concept development, they model target responses for tutor and tutees. These responses relate to the performance of an academic rule (e.g., sets of procedures for performing academic tasks such as solving computations with regrouping) or the formation of concepts (e.g., well-defined categories of information used for classification – such as names of state capitals). Teachers are, then, in a better position to observe and assess what is being practiced when peer-tutoring opportunities are initiated. Teachers need to offer guided practice that is supervised prior to (and during) peer-tutoring sessions, as warranted. Guided practice entails teachers using cues and prompts to emit target responses. Teachers lead groups of students in making the desired response (i.e., the teacher and students perform the response simultaneously) prior to dyad implementation. As students demonstrate accurate responses, the teacher gradually fades his/her degree of leading. Instead of making the response with the dyads, the teacher allows the tutor to present the stimulus and has the tutee or group of tutees respond. Using unison responding, class-wide tutees respond – making responses simultaneously, allowing more opportunities for responding during a period of time. Teachers must monitor the response of individual dyads to determine whether all are responding accurately. As students become more accurate in their responding, they shift the performance criterion to fast and accurate responding and concentrate on asking for as many responses as possible during a guided-practice session. This increases opportunities to respond and help to ensure skill mastery. Effective teachers ensure that responses are demonstrated and that students have numerous opportunities to practice responses while the teacher leads.

Finally, once students have performed responses accurately without cues or prompts, teachers using peer-tutoring assign dyads in class-wide grouping and provide dyads the opportunity to practice response accuracy and speed. Independent practice, therefore, is minimally supervised practice in which dyads respond in class-wide opportunities without the teachers' presence. Two important and closely related features of independent practice assist in skill development and efficient management of class-wide activities. First, teachers can work with other groups of students while dyads practice independently; and second, dyads must be making accurate responses so they can truly work independently of the teacher (i.e., without a constant parade of dyads moving over to the teacher to ask questions about their seatwork). When students engage in class-wide peer-tutoring activities, the teacher should prepare them and monitor their progress in completing the assignment. As a sequence typically, the teacher should: (1) give directions to complete the peer-tutoring tasks, (2) lead class-wide activities in completing example tasks, (3) indicate

Table 1 Skills facilitating active presentation–response of both the tutor and tutee

<i>Tutor presentation</i>	<i>Tutee response</i>
1. Orally states spelling word	Writes spelling word orally states spelling word
2. Card with vocabulary word from core academic domains: science, reading, mathematics, social studies, geography, computers, health, world history, economics	Orally defines word
3. Card with math fact on front	Mentally computes and orally states the answer
4. Orally states a numeral	Writes the numeral stated
5. Presentation of a color on a card	Orally states the color

deadline for completing activity, (4) circulate and assist dyads, if warranted, and (5) review class-wide responses to activity tasks during – and at the culmination of – peer tutoring. Clearly, ongoing observation better ensures that dyads will not proceed through an extended series of tutoring sessions with high-error rates before instruction is modified to improve response accuracy. Monitoring can take the form of simply tallying the number of correct and error responses dyads make during an oral practice session or on a paper-and-pencil tutoring assignment. These frequencies can be kept in a daily log or a bulletin-board chart, or can be plotted on a graph. Teachers continue to collect instructional data based on educational decisions and by linking their evaluations and instruction.

Procedures to Ensure Appropriate Peer-Tutoring Content

Teachers must ensure that the content of material to be mastered within the tutor session is appropriate for members of a particular dyad. They can work actively to adapt the presentation of content to fit a tutoring session. For example, Heron *et al.* (1983) reported that most successful dyads are those in which there is active participation by both members of the group in a tutor–tutee interaction mode. In addition, those practice areas that allow student dyads to use a predeveloped correct answer key enable students of equal abilities to pair. The key to correct responding can prevent arguments by overzealous partners who are certain that their incorrect answer is correct. The skills identified by O'Shea, *et al.* (1998) lend themselves to an active presentation–response of both the tutor and tutee (see **Table 1**).

Greenwood *et al.* (1991) reported on the benefits and practice effects of continually introducing new material to class-wide groups once the previous information has been mastered. If the expectation of the peer-tutoring experience is to increase interaction between two students, the dyad must meet for a consistent period of time. Those peer-tutoring sessions resulting in quick mastery of content information ending the tutoring session may be successful for teaching content mastery, but the limited social interactions of the tutor and tutee may not promote long-term reciprocal

benefits in partner relationships. Teachers' monitoring of social interactions, task completion, and student engagement become critical antecedents to material introduction and future class-wide assignments.

What are the Benefits of Peer-Tutoring Opportunities?

It has become increasingly evident that peer tutoring has a sound theoretical basis. It has a consensus with existing literature and produces desired outcomes (Heron *et al.*, 2006; Wright and Cleary, 2006). Peer tutoring offers a practical solution to meet the demands of inclusive learning milieus with diverse learners of varying abilities and levels (Copeland *et al.*, 2004; Maheady *et al.*, 2001; Mastropieri *et al.*, 2007). It has been shown to increase students' confidence and achievement through practice in core subject areas – such as mathematics, reading, and written expression. In addition, it holds justification beyond the purpose of increasing students' opportunities for practice and academic achievement. Class-wide programs can support teachers' inclusion opportunities as they work in different instructional groupings of students with varying needs.

One of the most recognized and heavily researched peer-tutoring programs is entitled, Peer-Assisted Learning Strategies (PALS) (Baker *et al.*, 2004; Calhoun and Fuchs, 2003; Fuchs *et al.*, 2000). This program is typically used for mathematics and starts with the teacher designing appropriate student dyads to practice mathematical problems. In this program, the teacher must instruct students to tutor each other through specific guidelines. Typically, a student with low achievement or ability can be paired with a peer without disabilities. PALS has been found to promote and improve computational as well as comprehension skills for students with disabilities. Teachers favor PALS over other programs because teachers consistently use it to assist with the task of class-wide progress monitoring. Students report that they actually favor the program over receiving tangible rewards and report that seeing their progress helps to motivate them (either as tutors or tutees), irrespective of ability level (Baker *et al.*, 2004; Fuchs *et al.*, 2000).

Strategies can be taught and learned from the use of peer-tutoring programs. For example, Calhoun and Fuchs (2003) reported that the use of *PALS* can be an extremely viable instructional technique to use in mathematic classes at the high school level. Baker *et al.* (2004) confirmed the use of *PALS*—finding that students can improve cognitively and socially from working with their peers, as students can explain and clarify issues for one another, while developing solid strategies and skills for solving problems. Reading and writing skills can also be improved in inclusive classrooms through the use of peer-tutoring programs. Through various studies, it was found that both tutors and tutees improved their writing skills and benefited overall from participating in the peer-tutoring sessions. Both groups were found to be on task a majority of the time and also expressed enjoyment about working in dyads with their peers (Medcalf *et al.*, 2004; Nixon *et al.*, 2001; Wright and Cleary, 2006). Clearly, peer-tutoring programs can be optimized throughout inclusive education and can yield many possible benefits for all students. McDonnell *et al.* (2001) reported that a class-wide peer-tutoring program—combined with curriculum and accommodations—can improve levels of academic responding and decrease levels of competitive behaviors for students with disabilities. They also concluded that peer-tutoring programs can increase meaningful participation among all diverse, classroom learners. In addition, adult benefits derived from the use of peer-tutoring programs have been confirmed associated with cost, accommodation, and duration. Peer tutoring is highly cost effective to schools and is user friendly. Teachers can use these programs effectively and correctly while helping to produce significant gains in academic achievement for students, while not costing school entities much, if any, money. Classroom teachers can easily establish peer tutoring to accommodate students' social needs, in accordance with student demographics and classroom composition. Simply put, peer tutoring is durable across districts (Nugent, 2001).

Conclusion

Peer tutoring is a very successful and effective practice methodology to help students increase their academic and social skills. Peer-tutoring programs are important in today's classrooms. They have proven to be objective, empirical, and replicable; in addition, they have been substantiated by valid and reliable data, across research designs and undergoing rigorous data analysis. Many teachers working with students with disabilities use teacher-guided instruction in class-wide programs directed toward the mastery of specific skills. By using peer tutoring, they can include all students in inclusion programs with high rates of engagement. These authors believe peer-tutoring programs can be successfully utilized and maximized. Teachers have the

burden of trying to meet the needs of all students and the task of creating a positive working environment where all students can collaborate and share in learning. With the use of a peer-tutoring program, competency levels of both students with and without disabilities can benefit. A class-wide peer-tutoring program can improve levels of academic responding and decrease levels of competing behaviors. Peer-tutoring programs are effective to use across all ages and abilities. They help students to make marked improvements throughout various disciplines while increasing their socialization skills and accelerating their confidence and motivation. Programs are positive and effective to use with diverse populations, across all age levels, and for different types of subject matter. Additionally, peer tutoring enables teachers to teach strategies and give students time to practice these strategies through tutoring sessions (Copeland *et al.*, 2004; Davenport *et al.*, 2004; Mastropieri *et al.*, 2001; McDonnell *et al.*, 2001). Finally, peer tutoring makes so much sense in this age of inclusion. It has been research proven and its pedagogical benefits are impressive.

Postsecondary Participation of Students with Special Needs

R A Stodden and K D Roberts, University of Hawaii at Manoa, Honolulu, HI, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Education is the key factor in achieving meaningful employment and an enhanced quality of life for persons with special needs. As the US strives to compete in the global economy, leaders in the nation's business, information, and commerce sectors have indicated the need for highly educated workers who are competent in higher-order thinking and possess specialized technical skills. This need, coupled with gradual changes in the US labor market, functionally mandates a post-secondary education for those seeking professional success and financial stability. Completion of post-secondary education, including vocational-technical training, significantly improves the chances of those with and without special needs to secure gainful and satisfying employment and achieve financial independence. With this reality, it is encouraging to see that students with disabilities who earn bachelor of arts degrees attain subsequent employment nearly on par with students without disabilities (National Council on Disability, 2000; Office of Special Education and Rehabilitative Services, 2000).

Policy and curricular changes supported by the Individuals with Disabilities Education Act (IDEA) and Title II of the Higher Education Act (HEA) under the No Child Left Behind Act (NCLB) have focused on improving academic achievement and post-high school expectations for students with special needs, with the aim of facilitating access to higher education. Although they have support in secondary education under IDEA, students with special needs who successfully complete secondary education are too often inadequately prepared to accept responsibility for their own life decisions during the post-high school years (Brinckerhoff, 1994; Izzo *et al.*, 2001). In post-secondary settings, students who may have previously received a prescriptive web of support in secondary school, often find themselves unprepared to face the necessities of making complex financial decisions, learning about their legal rights, and self-advocating for their support needs. Quite suddenly, the provision of assistance is no longer automatic or standardized under one federal rubric. The Rehabilitation Act and the Americans with Disabilities Act (ADA) do not mandate specific accommodations. Individual institutions have considerable discretion to interpret the parameters of the reasonable accommodations required by law. Resources are often inadequate and disconnected. The type, range, and availability of services as well as the terms related to these services are often widely discrepant

and poorly integrated while access to mentors or technological training is either limited or nonexistent (Stodden *et al.*, 2002). This article provides an overview of issues currently faced by individuals with special needs in terms of access to, retention in, and completion of post-secondary education programs. Possible solutions and suggestions are also provided.

Gaining Access to Post-Secondary Education

Youth with special needs seeking the right of access to post-secondary education may encounter formidable obstacles in their pursuit. Two of the biggest challenges students will face are the preparation for, and the transition to, these programs.

K-12 Preparation for and Transition to Post-Secondary Education

For individuals with special needs transition to post-secondary education is generally smoother if, during their secondary education, they are engaged in rigorous learning through curricula focused on post-secondary-education goals. However, often during secondary school, emphasis is instead placed on providing youth with special needs with prescriptive, specialized services and supports focused specifically upon remediating learning or behavior deficits experienced by them. Often the determination of these supports is made without the student's involvement in the decision-making process (Abery and Stancliffe, 1996). This process, in which professionals and parents often make the decisions, limits the opportunities for students with special needs to develop and practice their self-determination and self-advocacy skills (Izzo and Lamb, 2002). Not surprisingly, these students often leave secondary school with neither these skills, nor the knowledge of the impact that their special need has upon their learning or of the related modes of assistance which can help mitigate this impact. Furthermore, they may lack the understanding of how to negotiate post-secondary settings, where the provision of reasonable accommodations rather than detailed services designed to meet individual needs is the focus (National Center for the Study of Postsecondary Education Supports, 2002; Stodden *et al.*, 2003a). Without the essential skills of access to higher education namely self-determination and

self-advocacy, students with special needs face an uphill task in transitioning to post-secondary education.

Efforts have been made over the past 20 years to teach youth with special needs the skills of self-determination and self-advocacy (i.e., decision making, problem solving, goal setting and attainment, and leadership) based on teacher interpretations of self-determination. However, the literature suggests that these efforts would be more effective if they were based instead on providing real opportunities for students to make their own decisions and accept their consequences (Brinckerhoff, 1994; Izzo *et al.*, 2001). Building the skills of self-advocacy and self-determination is essential for empowering students with special needs seeking post-secondary education, as they have to face the transition from services provided under IDEA to the self-advocacy required in post-secondary education under the ADA and the Rehabilitation Act.

Another barrier faced by students with special needs is the difficulty of achieving high academic standards, which is often exacerbated by the failure of secondary institutions to provide adequate or appropriate curricula (Berliner and Biddle, 1996; Fuchs and Fuchs, 1998; Hatch, 1998). According to Stodden *et al.* (2003), there is an all too common tendency for secondary schools to place students with special needs in separate classrooms where they may receive substandard secondary curricular content (Stodden *et al.*, 2003a, 2003b). This problem is magnified by other institutional factors including problems with disability identification in secondary institutions (Thurlow, 2001), poor use and application of promising technology (Burgstahler, 2002), poor coordination and management of supports and services (Whelley *et al.*, 2002), and lack of clarity among professionals and families about the necessary supports and accommodations to be provided (Stodden *et al.*, 2003a).

Other issues affecting academic performance include state-standard-based curricula and assessment measures designed without input from special educators, which needlessly increase the challenges for students with special needs and their teachers (Stodden *et al.*, 2003b); teacher concerns such as inadequate professional development, excessive paperwork, and attrition specifically resulting from these problems (American Youth Policy Forum and Center on Education Policy, 2002); academic and career counselors who lack the necessary skills to provide guidance to students with special needs; and inadequate direction and counsel due to a lack of coordination among teachers and counseling staff. Perhaps the most troubling barrier to academic achievement for students with special needs is the one constructed by teachers, career counselors, administrators, family members, and the students themselves. Shackling students with special needs with low expectations and a limited sense of opportunity makes them develop a sense of failure before they have even begun to explore their interests and aspirations (Stodden *et al.*, 2002).

In May 2000, The National Council on Disability stated that endeavors to promote a smooth transition from secondary to post-secondary education have not met the goals of federal laws and initiatives, such as IDEA and Section 504 of the Rehabilitation Act. The Council attributed this to a number of factors including the methods of transition planning, which do not involve the students themselves, and the inadequate allocation of resources (NCD, 2000). Adding to the difficulty of the task, state and local education agencies across the United States are experiencing a chronic shortage of qualified personnel to serve children and youth with special needs (American Youth Policy Forum and Center on Education Policy, 2002). When supports and services are available, too often they are primarily focused on the students achieving a single academic outcome rather than on a holistic approach focused upon a continuum of outcomes leading to a successful transition (Izzo and Lamb, 2002; Stodden *et al.*, 2003). Part of the problem is the lack of consensus on the definition of a successful outcomes. For example, if obtaining a general educational development (GED) or high school diploma is viewed as a successful outcome, then the preparation process may be viewed as finished with the completion of high school. This premature and short-sighted view of outcome may provide justification that special-education services, offered in secondary school, are no longer necessary and therefore, be retracted in post-secondary education institutions. Hence, the selective process of developing certain skills or goals is unlikely to ameliorate the ability of students with special needs to face upcoming challenges in their transition and participation in post-secondary education.

Complicating current secondary-school transition efforts further is the lack of awareness among educators and parents regarding the policy contrasts between IDEA at the secondary level and ADA and Section 504 at the post-secondary level. Many secondary schools lack a formal structure to assist students in adjusting to the highly discrepant laws governing secondary and post-secondary education (Stodden *et al.*, 2003b). As a result, they do not tailor the delivery of services and instruction toward strengthening the links between secondary and post-secondary education. The result is that the students themselves, parents, and other natural supports are often caught unaware when the level of service provision drops and/or is not automatically extended following high school (Stodden *et al.*, 2003a). The lack of knowledge about differences in their rights, services, and funding has the effect of discouraging or possibly even barring students with special needs from higher education.

As students with special needs endeavor to access post-secondary education, they may find that circumstances vary significantly from college to college, and from state to state. Each college provides a different level and type of support. Some institutions employ a single counselor to

take responsibility for disability issues. In such institutions, staff members provide advice and letters to professors verifying that a student request for accommodations is justified. Little else may be provided. At other schools, multiple staff members coordinate services and accommodations for students with special needs so that the educational environment provides supplementary support, and additional staff is prepared to teach the students about self-advocacy (Youth Advisory Committee to the National Council on Disability, 2003).

Clearly, the challenge to locate and advocate for services and accommodations can be quite frustrating. The various systems feature limited resources, inconsistent terminology, disconnected agencies, inconsistent laws, and conflicting eligibility requirements. This is difficult to manage, even for the most self-determined student (Whelley *et al.*, 2002). Ultimately, without a functioning, successful transition program from secondary to post-secondary education, youth with special needs find themselves burdened with additional disadvantages.

Recommendations: Preparation for and Transition to Post-Secondary Education

Reform efforts that work for all students will also work for students with special needs. The same strategies that recent research has found to improve the outcomes for many students with special needs can easily be employed to better serve all at-risk youth. Five effective research-based recommendations are presented here:

- *Facilitate a personalized atmosphere and closer relationships between students and high school staff.* As this is best accomplished through smaller schools, provide incentives for schools to dramatically restructure schedules, create schools within a school, or build new facilities. Use evidence-based strategies to improve one-on-one relationships with youth at risk. Encourage families to develop collaborative and mutually beneficial relationships with high school staff, employers, and college personnel who can assist students to transition. Provide incentives to role models, those successful individuals with special needs who can mentor youth facing similar challenges. Fund follow-up studies on students who are educated through these reforms, 1 year and 3 years after leaving school, to record their outcomes and refine future efforts. Continue to call for improvements until adult outcomes for youth with disabilities match those of their peers without disabilities.
- *Provide opportunities for students to apply their knowledge in realistic settings.* Give employers incentives to offer students a variety of work experiences (i.e., job shadow and job tryout, or internships) that are closely linked to the academic studies and future career goals of youth at risk. Enable more effective collaboration among employers,

career guidance staff, and students. Increase vocational rehabilitation agency involvement by increasing the number of students (ages 16–22) they serve and promoting their use of post-secondary education services. Make individualized education plans (IEPs) to identify career prep opportunities for students with special needs, and use these IEPs to regularly record students' progress as they explore careers. Promote self-determination education to encourage students to actively participate in, and take responsibility for, their career preparation and/or transition to college.

- *Prepare teacher and school personnel to have the highest quality and capacity.* Ensure that all educators are highly qualified to teach students at risk through licensure requirements, mentoring of new teachers, and incentives. Absorb teachers in training and in the field to hone and update their knowledge and document this with individual professional-development plans. It is vital to encourage stakeholder involvement to design and implement proven professional development activities. This can be done economically if districts are given targeted finances to fund long-term support and incentives to master teachers and other professionals.
- *Incorporate multiple uses of technology as a tool to raise student achievement.* Provide up-to-date computer technology to reform efforts that link technology use to career preparation and the future goals of youth with special needs. Improve and support competency in the use of technology by all students, and staff who serve them. Provide personal assistive technology (AT) such as computer software and hardware for audio/visual/learning impairments, and mobility devices for physical impairments, to students with special needs. Enable students with special needs to improve functions of daily living that present barriers to their pursuit of a challenging education and career.
- *Align educational standards at all levels and across districts and colleges.* Ensure that state policy aligns with national reform efforts that include evidence-based strategies. Preparing youth at risk to succeed in any state college requires the creation of common and multiple measures of readiness, and not just single high-stakes academic tests, for advancement to higher education and/or professional careers. Insist on the participation and accountability of stakeholders at all levels, from students and families, to teachers, to all administrators. Encourage stakeholder commitment to the design, implementation, and outcome evaluation of all standards alignment efforts.

Having the aforementioned elements in place and implemented in the K-12 educational system would greatly increase the entry of youth with special needs into post-secondary education. However, after post-secondary entrance, the provision of services and support possible in

K-12 schools is not matched in the new educational landscape. In order for individuals to access services in post-secondary settings, they must (1) disclose their disability, (2) provide documentation of their disability, and (3) request specific support, services, and accommodations necessary to succeed in their classes. Accomplishing these steps requires a skill set that many individuals with special needs do not have. Thus, the necessity of requesting for services becomes another barrier that may impede post-secondary education success. The issues around these steps arise during secondary education due to inadequate transition preparation. In addition to the difficulty of requesting for these services, primary gaps exist in the fragmented and inconsistent support services that are available in post-secondary-education settings. Suddenly, students with special needs may find themselves burdened with the necessity of essentially becoming their own case managers, a responsibility that may, for them, be insurmountable.

Participation, Retention, and Persistence in Post-Secondary Education

For most students, participation in post-secondary education goes beyond merely being physically present in a lecture hall. It is the opportunity to ask questions, to discuss ideas with classmates, to have a critical conversation with professors, to reflect upon readings, to explore the library, to have access to information, to work on research projects, to have coffee with friends, and be able to participate at campus social and cultural events that really completes the college experience. A quality education is about coming away from each campus experience with knowledge gained about, and insight into, a wide variety of human experiences and disciplines. Most critically for students with special needs, it is about being able to do these things without hardship that exceeds that of the typical student during the post-secondary educational years. For many of these students, however, issues surrounding self-advocacy and determination, social life needs, availability of educational assistance, differences in academic requirements, and limited preparation for post-secondary education become a primary preoccupation, and a distraction that affects academic performance (Burgstahler *et al.*, 2001). These problems are amplified in the presence of institutional inadequacies in providing services that would accommodate persons with special needs. Additional factors that come into play such as finances, availability of supports, socioeconomic status, culture, parental background, and school-commute distances often compound these challenges.

One factor affecting participation of persons in post-secondary education is the limited availability of educational and related supports within academic institutions. Once a student enters higher education, the lack of

student input and selective emphasis in servicing students may leave students with special needs at a disadvantage when it comes to exercising self-advocacy skills. Most supports are not directly individualized for the specific needs of individual students in post-secondary education. For example, teacher-centered, instead of student-centered, curricula and instructional methods have been the dominant approaches at the post-secondary level for a very long time. In this situation, the entrenched educational method reduces opportunities for students with special needs or less-traditional learning styles to thrive. Implementation of approaches that work for all learners becomes a critical issue in imparting knowledge that students need to thrive in the post-secondary setting and later in life.

For students who disclose their special needs and present appropriate documentation to support service offices, Section 504 of the Rehabilitation of 1973 mandates that post-secondary institutions provide reasonable accommodations to ensure full access to program offerings (Frank and Wade, 1993; West *et al.*, 1993). Post-secondary schools have no legal obligation to help students transition into their institution. Educators and institutions typically define their role with students more clearly in preparing them to succeed in future education and employment settings (Siegel and Sleeter, 1991). Furthermore, disability service staff members are often caught between the need to protect the rights of students and the needs of the post-secondary institution. Post-secondary administrations require consultation by staff members who also must adhere to particular state and federal guidelines. The lack of consensus on the nature of the supports to be provided can be difficult for staff as well as for students seeking accurate and complete information to determine which institutions and organizations are best prepared to meet their needs.

Another factor affecting participation in post-secondary education is the absence of any minimum standards of disability support provision. Many of the challenges students with special needs face are connected to necessary services and accommodations related to their specific needs. The lack of standardization of support services among academic institutions tends to result in differing levels and types of services and supports, and students are often left to manage complicated and unguided procedures on their own. Some institutions have single academic or counseling service staff members who take on disability issues as a small portion of their job description, and basically provide advice and a letter to professors verifying that a student's request for accommodation is justified. In contrast, in other schools, multiple staff persons, coordinated services, and accommodations are in place for students with special needs (Youth Advisory Committee to the National Council on Disability, 2003).

The lack of, or limited access to, support and its availability is a major factor that eventually discourages or excludes many students with special needs from continuing

their schooling. For instance, a national survey developed and distributed to post-secondary students with disabilities by the National Center for the Study of Postsecondary Educational Supports (2000) found that while supports such as testing accommodations, note-takers, personal counseling, and advocacy assistance were requested and extended with some regularity, disability specific scholarships, assessments and evaluations, real-time captioning, AT, and study-abroad opportunities were rarely offered to students with special needs (Stodden *et al.*, 2001). Furthermore, this study found that 50% of the respondents indicated that their institutions did not offer accessible transportation on campus for students with disabilities and many campuses still featured architectural barriers (Stodden *et al.*, 2001). The survey revealed that equal access and reasonable accommodations are still an issue for individuals with special needs attempting to continue in higher education, and often the most basic needs pertaining to their activities of daily living, including physical access, are unmet.

Several studies have confirmed these findings of institutional inadequacies and found that most post-secondary institutions are not at par in assisting youth with special needs (Stodden *et al.*, 2003a; Whelley *et al.*, 2002). A major problem encountered is the insufficient number of staff members handling huge caseloads to accommodate students. According to Gajar (1998), there are insufficient resources they are to serve the large numbers of youth with special needs who require case-management assistance and related support needs. Post-secondary educational institutions often do not provide per capita funding for disability support services, so as increased numbers of youth with special needs enter the various institutions, budgetary and faculty resources for support become thin and impact decisions.

Another factor affecting persistence and retention is that faculty members and other academic personnel in post-secondary education settings are often unaware of disability needs and supports. Limited awareness about their students' special needs prevents staff members and other academic personnel from providing the most suitable approach to enhancing the access and ability of students to learn. Moreover, the lack of proper background in managing students with special needs may invite further misunderstanding and conflict, and eventually lead these students to drop out. Finally, when accommodations and services are not provided by universities or colleges, students with special needs pursue post-secondary education at a higher risk for failure. Consequently, their grades and scholarship access are reduced, or they may have to pay for services themselves, thus increasing their cost of attendance in post-secondary education (the sum of which is the starting point for calculating student need for financial aid) (Youth Advisory Committee to the National Council on Disability, 2003).

Recommendations: Participation, Retention, and Persistence in Post-Secondary Education

The following are steps to achieve the important objectives of increasing participation, retention and persistence of students with special needs.

1. *Personnel development.* Improved faculty and staff (e.g., instructional faculty, financial-aid personnel, student-service personnel, and disability-support personnel) knowledge, and skills on a range of disability related topics such as:

- rights and responsibilities
- range of special needs (e.g., learning disability (LD), other hidden disabilities, and medical conditions)
- AT
- accommodations
- types of appropriate accommodation
- accommodations intended to level the playing field and not provide an unfair advantage; and
- universally designed instruction focused on content accessible for all students.

It is necessary for faculty and individuals who interact with individuals with special needs at the post-secondary education level to become knowledgeable in the areas mentioned above as relevant to each faculty and staff member's role and responsibilities.

2. *Increased connectedness with peers and other supportive individuals.* Feeling and being connected to others is an important consideration for everyone. Research has shown that a sense of belonging is a primary indicator of success in post-secondary education. Some strategies to improve post-secondary education institutions in this area include:

- Smaller learning communities that provide for cohorts of students to, at a minimum, take their prerequisite courses together. Results include increased retention and grade-point averages (GPAs) and higher levels of completion. Smaller learning communities are also shown to make the transition from secondary to post-secondary education easier.
- Disability support groups that may assist in helping individuals better understand their unique needs and provide peer support.
- Mentoring programs including reciprocal mentoring where students with special needs serve as mentors for post-secondary education faculty and staff and vice versa. In addition, peer-mentoring programs are also valuable in providing support for students as they maneuver through their post-secondary education.

3. *Increased access to technology.* The range of technology, including AT, on the market today has the potential to

increase access to and success in post-secondary education. However, individuals with special needs do not always have access to these tools. Many technologies that could specifically benefit individuals with special needs, such as electronic augmentative communication devices and voice-recognition software, are quite costly. Sometimes individuals or institutions invest in technology but these tools go unused because of a lack of adequate training. Finally, individuals with special needs can gain increased access if an effort is made to link them with agencies that provide financial support for AT purchase and training.

4. *Increased access to appropriate accommodations.* There is a substantial need to provide appropriate accommodations to students with special needs in post-secondary education and increase faculty and support staff knowledge and awareness regarding these accommodations. The most widely used accommodations include: extended time on tests, quiet rooms for testing, note takers in class, access to a computer to take exams, multi-modality instruction, flexible assignments, flexible deadlines, accessible classrooms, approval to turn in assignments late as appropriate to the disability and situation, sign-language interpreters, and materials available electronically for greater access.

Conclusion

Although gains have been made to support individuals with special needs in attending and complete post-secondary education, there are still numerous challenges to address. Positive changes will sustain only through concerted efforts by students, families, educators, administrators, and support staffers. First, we must address the realization that our expectations for students with special needs are too low and serve to artificially limit these students' horizons. In an increasingly competitive global economy, these limited horizons come at a great cost. Second, students need to be challenged and encouraged to view their education as continuing beyond secondary education. Third, special effort must be made to prepare students for transition from high school to postsecondary settings, and institutional capacity must be increased to support this. Specifically, students must be given training and opportunities to develop their self-determination and self-advocacy skills at the secondary level. Fourth, increased knowledge and awareness is necessary for students, faculty, and support staff regarding the provision of appropriate accommodations and a supportive and connected learning environment. By working toward these objectives and building on previous successes, we can re-envision post-secondary education as a realistic and productive option for persons with special needs,

and recreate our campuses as true models for inclusion and democracy.

Glossary

Alternative intervention – The strategies different from what are already being implemented to help student functioning in the general education classroom.

Accommodations – These provide access for students with disabilities to participate in a course, standard, or test. They do not fundamentally lower or alter the standard or expectation of the course or test.

Behavior interventionist – A specialist who develops interventions to help students with behavioral issues.

Instructional strategies – The attempts to remedy the identified educational concerns prior to the evaluation of a student for special education services.

Intervention – A teaching technique aimed at improving an academic or behavioral concern.

Intervention assistance teams – The teams made up of professionals with different areas of expertise who help analyze student data and suggest possible interventions to be implemented by the classroom teacher.

Modifications – The changes made to standards, test location, timing, courses, scheduling, expectations, and/or other attributes that provide access for a student with a disability to participate in a standard, course, or test, which does fundamentally alter or lower the standard or expectation of the test, course, or standard.

Pre-referral – A process that happens prior to the referral of a student to special education.

Referral – A process, to evaluate a student for special education services, which happens when pre-referral strategies are ineffective.

Strategies – Synonymous with interventions, these teaching techniques are aimed at improving an academic or behavioral concern.

are afforded the necessary accommodations and modifications in the general education setting prior to determining eligibility for special education services. Accommodations provide access for students with disabilities to participate in a course, standard, or test. They do not fundamentally lower or alter the standard or expectation of the course or test. Some accommodations include:

1. varying of activities, frequent breaks, and extended time;
2. preferential seating, physical arrangement of the room, and change in classroom setup;
3. shortening test length, and test format options (matching vs. fill in the blank); and
4. highlighting material, notes provided by the teacher, computer, calculator, and books on tape.

Modifications are changes made to standards, test location, timing, courses, scheduling, expectations, and/or other attributes that provide access for a student with a disability to participate in a standard, course, or test, which does fundamentally alter or lower the standard or expectation of the test, course, or standard. Some modifications include:

1. lowering the reading level of the test;
2. simplifying reading level and vocabulary on worksheets and assignments;
3. grading based on individualized education plan (IEP) goals; and
4. curriculum modified to meet user needs.

As it appears, accommodations level the playing field, whereas modifications change the playing field. Such accommodations/modifications are typically referred to as pre-referral intervention or instructional strategies and are recommended by the pre-referral assistance team (referred to as a pre-referral team, student assistant team, teacher assistance team, school-based intervention team, or child study team). This team is comprised of individuals with the knowledge and expertise to provide guidance and assistance to teachers. Members of the team might include classroom teachers, the special education teacher, school psychologist, student counselor, behavior interventionist, and principal. Regardless of the specific name given to the team, the purpose is to derive pre-intervention strategies or alternative intervention strategies. In research settings, pre-referral intervention teams have proven effective and worthwhile. Specifically, they have “(a) reduced special education referrals, (b) reduced unnecessary special

According to Truscott *et al.* (2005), “Contemporary special education programming and classification proposals place effective prereferral intervention at the center of special education delivery and diagnosis” (p. 130). The use of a pre-referral intervention process ensures that students

education testing, (c) resulted in more appropriate special education referral referrals, (d) resulted in improved student performance, and (e) resulted in improved teachers attitudes and handling difficult-to-teach students” (Truscott *et al.*, 2005: 131). Hammond and Ingalls (1999) summarized several critical factors obtained from various research projects that assure the effectiveness of such teams. These pre-referral intervention team’s success factors are listed below:

- administrative support for actions and activities;
- defined purpose exists which team members are aware;
- adequate training is provided in the implementation of the interventions;
- team members learn effective team skills;
- support from professional colleagues;
- effective communication among members;
- efficient system of operations; and
- efficacy of teacher time.

“Preintervention strategies are attempts to remedy the identified educational concerns prior to the evaluation of a student for special education services. Any intervention or combination of preintervention strategies should be used for a significant length of time; and objective, measureable data should be collected continuously in order to adequately assess the results” (Murdock and Petch-Hogan, 1996: 173). Pre-referral interventions are planned and systematic efforts to resolve apparent learning or behavioral problems initiated by the problem-solving team, and the design and outcomes of these interventions must be documented. The concept of the pre-referral assistance team is not a new one; however, “the intervention assistance reform effort was designed to be proactive and focus on providing more effective instruction to meet students needs in the general education classrooms” (Rock and Zigmond, 2001: 1). Clearly, the use of pre-referral assistance teams within a school can dramatically reduce the numbers of referrals into special education. In addition, “the teams have been extremely effective in helping to maintain a student, who is encountering academic or behavioral problems, within the general education setting” (Hammond and Ingalls, 1999: 2). The use of pre-referral teams has recently been given a greater emphasis in the referral process with the recent legislation of the Individuals with Disabilities Education Act (IDEA) 2004 in regard to response to intervention (RTI) in the identification of children with learning disabilities. RTI is an approach for sorting out whether a struggling student really is a student with a disability as defined by IDEA or just needs more intensive regular education strategies to succeed in school. It usually consists of three levels of assistance and may be used to see how students respond to research-based interventions and other direct supports.

Pre-referral intervention, as a critical instructional practice, can be implemented to reduce the overidentification

of students with disabilities (Kovaleski *et al.*, 1999). The use of a pre-referral intervention model “is an indirect delivery model of services that focuses on interventions occurring at the point of teacher referral” (Murdock and Petch-Hogan, 1996: 172). Clearly, “such a model allows not only for the prevention of inappropriate placements, but also for the provision of assistance to the general education teacher to enhance his/her interactions with students with disabilities” (Murdock and Petch-Hogan, 1996: 172). Research has indicated that everyone makes progress when best practices are followed by practitioners. When investigating the effectiveness of pre-referral interventions, the implications are very clear. First, assistance is provided to students in their home classrooms before special education is considered. Second, through the work of the pre-referral team, collaborative relationships are developed to enhance the effectiveness of programs. Third, effective pre-referral interventions will decrease the numbers of referrals to special education and can save money by having fewer inappropriate placements. Finally, educational programs can be enhanced to create a more inclusive school environment for all students (Buck *et al.*, 2003).

As previously mentioned, the pre-referral team focuses on the reasons a child may be experiencing difficulty related to behavioral or academic skills. Pre-referral interventions or strategies are derived from a brainstorming session in which the identified concerns lay the foundation. During this session, previous interventions employed within the classroom setting are analyzed along with student success using the strategies. Pre-referral strategies are then developed along with a specific plan as to how the strategies will be carried out. This plan would also involve timelines in which interventions should take place and how the success of the strategy will be monitored. The use of the pre-referral instructional strategies or interventions in the general education setting to target the needs of students with specific learning needs or behavioral problems are mandated by Part 200 Regulations. Section 200.2 (b) (7) and Part 200.4 (d) of the Commissioner of Education specifically state, “General education support services, instructional modifications, alternative instructional approaches, or alternative program options have been attempted to address the students performance prior to a referral to the committee on Special Education.” Therefore, not only do the pre-intervention strategies need to be developed and implemented, but the process must also be documented along with the impact the recommended strategies had on student learning.

The use of an intervention assistance team will assist the classroom teacher in developing instructional strategies that focus on the specific needs of the student. Well-developed intervention teams recognize the need for strong interventional strategies. “Research based practices must be incorporated into the teams’ recommendations to

increase the likelihood of intervention effectiveness” (Papalia-Berardi and Hall, 2007: 107). Questions that the teams should consider are listed below:

- When considering data collected on the student issue, what intervention should be tried to improve the situation?
- What interventions are most natural, least intrusive, and most effective?
- What training is required for the person who needs to implement the intervention?
- How might other students be impacted by the intervention?
- How will the proposed intervention improve the current situation?
- How will the team know if the intervention is effective?
- What resources are needed and how easily can this intervention be implemented?

Clearly, answering these questions will aid the team with action plan development, which is vital for the successful execution of intervention strategies. The action plan should describe, in detail, who is responsible for each intervention step, the best setting for implementation, dates for initiation of the intervention, and methods for assessing progress toward intervention goals. Data should be collected frequently and consistently to document progress or lack of it. These data will help the team to decide whether the intervention (1) was working, (2) should be continued, and, ultimately, (3) was successful.

Effective Pre-Intervention Strategies

Several studies have been conducted to determine the most effective and most frequently used intervention strategies. However, each of the suggested strategies should be viewed with caution as strategies should not be recommended based on the success rate of their use with other students as a sole reason of selection. Suggested strategies should only be employed after careful analyses of the student’s needs and strengths. Individualizing strategies to meet the needs of students will increase the success of the strategy. It is also imperative that strategies are based on the premise that “extra help for struggling learners must be more than additional practice” (Burns, 2007: 17). Whitten and Dieker (1995) surveyed 312 elementary schools in Illinois and found that only 178 schools had intervention assistance teams. Questionnaires completed by 83 schools identified the eight most frequently implemented strategies. These strategies respectively include behavior management, curricular modification, individualized instruction, small-group instruction, peer tutoring, consultation with professionals, teacher observations, and cooperative learning. Although these eight strategies were the most frequently occurring strategies, the order of

effectiveness of the strategies did not align to those strategies most frequently used. In order, the most successful strategies reported were behavioral management, peer tutoring, individualized instruction, small-group instruction, consultation with professionals, teacher/student conferences, teacher observations, and cooperative learning. Below are brief descriptions of these strategies:

- *Behavior management.* This entails implementing interventions to manage behavior. Examples include a behavior contract, token economy, reinforcement schedule, and choice menus.
- *Peer tutoring.* This involves having students who know strategies and content and they teach other students how to complete an assignment or task implementing the strategy. (Note: this does not replace classroom instruction by the teacher; it is intended to reinforce and supplement classroom instruction.) Students must also be trained (tutor and tutee) for this intervention to be effective.
- *Individualized instruction.* This type of instruction meets students’ needs by considering student’s knowledge and skill base before designing instruction. Each student gets what he/she needs to be successful in the classroom.
- *Small-group instruction.* This involves teaching three to four students together in a small group. Reinforcement of previously learned skills or new skill development can be emphasized. This decreases the teacher–student ratio and can better meet student academic and behavioral needs.
- *Consultation with professionals.* In this case, the teacher works with other professionals to capitalize on their expertise to help them teach content and skills and improve student behavior.
- *Teacher/student conferences.* These conferences entail frequently meeting with students to discuss progress, strengths, and areas in need of improvement; they can also be used to assess how instruction/learning is progressing in the classroom. It is important to remember that students have valuable information and insight in the instructional process.
- *Teacher observations.* These observations are conducted to see how progress is resulting and whether the intervention is effective. One must remember that when conducting observations it is important to operationally define the behavior to be observed as well as choose an accurate recording procedure (i.e., frequency, duration, time sampling, and interval) to collect data on the behavior.
- *Cooperative learning.* These learning groups consist of three to four students working toward a common goal or outcome. Typically, students are placed in groups by the teacher; and they are commonly assigned roles and responsibilities commensurate with their skills and

abilities. (Note: this does not replace classroom instruction, but is intended to reinforce and supplement classroom instruction.) Students must also be trained on the roles and responsibilities of each member and how to work collaboratively with each other.

Implications for Effective Pre-Referral Implementation

The above information is particularly interesting, considering the data that Lane *et al.* (2004) obtained in their investigation. In their study, they obtained 354 elementary teachers' views of the interventions generated by the pre-referral teams. Of the 799 interventions reported, 485 or 61.79% focused on academic issues, 102 or 12.77% dealt exclusively with behavior concerns, and others were a combination of academic and behavior issues. It is clearly evidenced that a majority of interventions are currently focusing on both academic and behavioral issues. Despite the types of interventions that are implemented, "there is little question that everyone gains when professionals follow best practices in their work. In the case of prereferral interventions, the implications for effective implementation are clear" (Buck *et al.*, 2003: 358). Below are implications for effective implementation of strategies:

- First, students receive assistance in their own classrooms prior to considering a special education placement as an option. For example, a teacher may give copies of PowerPoint presentations to the students so that they can follow along during the lecture.
- Administrators carefully and purposefully plan times when teachers can work together to develop a collaborative relationship which hopefully allows them to develop effective programs beyond concerns for pre-referral strategies. For example, teachers are given planning times simultaneously so they can actually meet and discuss student issues and plan for success.
- If teachers have time to plan and develop appropriate pre-referral strategies that are effective, the result should be a reduction of the number of inappropriate referrals to special education which will help schools and districts save money due to fewer inappropriate placements. For example, having pre-referral teams in place can help teachers to not refer students for special education, thus saving the district money if the student's needs are met in the general education classroom.
- A more inclusive school environment can be created by having an effective pre-referral strategy program in place because it can enhance educational programs for all students. For example, if the pre-referral strategy program is in place and effective, it can result in providing acceptable strategies for students to stay in the general

education classroom which can result in more effective programs for all students.

To a large measure, effectively implementing a pre-referral intervention process will allow the following factors, which may result in misidentification of students as needing special education services, to be more closely examined: lack of cultural background experiences, low socioeconomic levels, limited English-proficient, bilingual, students lacking educational experiences, and those students whose educational foundation or experiences were experienced with a teacher who may have a teaching style that did not match the students learning style.

Conclusion

Current research in the field reports that implementation of the pre-referral model has directly impacted assessment and referral processes. Specifically, pre-referral implementation has reduced special education referrals, decreased unnecessary special education referrals, provided more appropriate special education referrals, increased overall student performance, and improved specific teachers' attitudes and skills in handling difficult-to-teach students. However, without clear federal mandates regulating state guidelines in reference to the pre-referral process, a clear consensus will not be met. Pugach and Johnson (1989) stated that "the outcome of special education's current involvement with prereferral will likely be a good indicator of the path the field chooses to pursue." (p. 224). It is apparent that this outcome is still under investigation. Although the use of pre-referral interventions is common practice, the act or process of the implementation of such a model is still varied in nature. A systematic approach is necessary to measure the effectiveness of pre-referral interventions with regard to quality, accountability, and equity.

Preventing Antisocial Behavior and Delinquency: A Comprehensive School-wide Approach

P R Hallam, K R Young, P Caldarella, D G Wall, and L Christensen, Brigham Young University, Provo, UT, USA

© 2010 Elsevier Ltd. All rights reserved.

Antisocial behavior can be conceptualized as any conduct that is hostile to the well-being of an individual, group, system, or society (Walker *et al.*, 2004). When the antisocial behavior of youth leads to illegal or criminal acts, it is labeled as juvenile delinquency (Kauffman, 2005). To specifically define the problems regarding juvenile delinquency, we refer to the key findings of a report released by the United States Office of Juvenile Justice and Delinquency Prevention (Loeber *et al.*, 2003). The number of child delinquents (between the ages of 7 and 12) handled in the nation's juvenile courts has increased by 33% over the last decade (Synder, 2001; as cited in Loeber *et al.*, 2003: 1). Delinquent youth have a specific offense profile. They make up one-third of all juvenile arrests for arson, one-fifth of juvenile arrests for vandalism and sex offenses, one-eighth of juvenile arrests for forcible rape and burglary, and one-twelfth of juvenile arrests for violent crime. This report concluded that pre-teen youth with juvenile court records are "far more likely to become chronic juvenile offenders than youth whose initial contact occurs at a later age, [thus] there is reason for concern about the growing number of child delinquents" (Loeber *et al.*, 2003: 1).

Intervening with delinquent youth is one of the most difficult challenges for families, schools, and communities, primarily because there are no guaranteed solutions for preventing and treating delinquency, especially for youth with violent behaviors (Kauffman *et al.*, 2004). Historically, schools have struggled with educating pre-delinquent and delinquent youth. For example, incarcerated youth often have histories of school failure (Center on Crime, Communities, and Culture, 1997) and struggle with severe behavioral and learning difficulties not sufficiently identified or treated in schools (Nelson, 2000). Research also suggests that the earlier a child receives effective interventions, the greater the probability of success (Walker *et al.*, 2004). The goal should be to keep youth off the pathway to delinquency or reverse the direction as early as possible. Educational researchers strongly suggest a need for both prevention and intervention strategies that have been empirically demonstrated to be effective, as many current practices lack such validation (Nelson *et al.*, 2004). No single practice or approach has been proven to be highly effective in either preventing or intervening in juvenile delinquency. Therefore, a comprehensive school-wide approach is the preferred model. A comprehensive approach includes multiple components and requires the involvement and commitment of many individuals.

To be successful in addressing the needs of at-risk youth, schools must invest more than ever in implementing systems to properly intervene with students who are on the pathway to juvenile delinquency. We agree with Walker *et al.* (2004) who stated,

The problem is not one of not knowing what to do, but rather one of forging a marriage between research-based intervention programs and practices that are known to work, and also reforming school structures and systems in ways that support their effective use and sustainability over the long term (p. 33).

This article describes a prevention approach designed to produce system improvement by training school-based teams to gather and respond to data to prevent antisocial behavior and delinquency. This comprehensive approach includes the following components: (1) ensuring that the school has supportive administrative leadership, along with commitment and buy-in from faculty and staff; (2) providing high-quality needs-based professional development; (3) using academic and behavioral screening to identify at-risk youth; (4) using data systems and data-based decision-making practices; (5) using evidence-based strategies such as response to intervention or PBS; (6) integrating programs and planning into regular school operations through PLCs; and (8) implementing continuous program evaluation and modification. This approach combines research on best practices in delinquency prevention with the goal of increasing the capacity of school personnel to provide sustainable benefits to the organization and its students. Before further describing this approach, the needs and the challenges facing schools in implementing such a program are discussed.

Needs and Challenges Facing Schools

The United States has experienced a dramatic change in its demographics over the last 5 years. Educational leaders are required to prioritize decisions to emphasize helping students who are failing to meet rising academic standards. Increases in student populations and in the number of students who are at risk of failure, occurring in an environment of dwindling resources, are also challenging schools. The results include a growing trend for school failure and other issues that often accompany juvenile delinquency. Disaggregated student-achievement data

have revealed large gaps in achievement scores for students of poverty and minority ethnic groups (Ray-Taylor, 2003). For low-performing students, school failure often includes or evolves into emotional or behavioral problems, including antisocial behaviors, the precursors of delinquency (Office of Juvenile Justice and Delinquency Prevention, 2008).

School Failure, Juvenile Delinquency, and Antisocial Behavior

There is a strong association between school failure and juvenile delinquency. In 2003, there were over 96 000 youth in the United States incarcerated in juvenile correctional facilities (Office of Juvenile Justice and Delinquency Prevention, 2008). Large numbers of these youth struggle with literacy and have experienced academic failure in school (Nelson *et al.*, 2004). They are often male, socioeconomically disadvantaged, and members of minority groups (Quinn *et al.*, 2005). Many wrestle with significant behavioral and learning difficulties which may not have been adequately identified or treated in schools, leading some to call juvenile justice, the default system for students (1) who cannot read or write, (2) have mental health problems, and (3) drop out or are expelled from school (Nelson, 2000). In fact, 3 years after leaving school, 70% of antisocial youth are arrested (Walker *et al.*, 2004). The reality is that youth who struggle, grow up to be adults who struggle. People who drop out of school commit 82% of all crimes in the United States (American Psychological Association Commission on Violence and Youth, 1993). Walker *et al.* (1995) explained that the pathway to delinquency, criminality, and eventually prison begins very early in a child's life, often with early antisocial behavior.

Antisocial behavior is disruptive to the perpetrators, peers, families, schools, and communities; and it can take numerous forms – from noncompliance in early childhood to fighting in middle childhood and vandalism in adolescence. Although the typography varies, all forms of antisocial behavior share some common characteristics; they are unpleasant, destructive, or aversive to those victimized (Dishion and Patterson, 2006). Once established, antisocial behavior has proven to be highly resistant to intervention efforts in home, school, and community settings. According to Walker *et al.* (2004),

Kazdin (1987) has argued that, after about age 8, antisocial behavior and conduct disorder should be viewed as a chronic disorder (like diabetes) that has no cure but that can be controlled and managed. . . . Having said this, it is important to note that it is never too late to intervene with behaviorally at-risk children and youth (p. 10).

Therefore, early student identification and intervention are essential to the success of an effective prevention program. Antisocial behavior can thus be conceptualized

as the primary pathway to delinquency; and understanding this pathway is a requisite step in explaining delinquency.

From an abundance of research, four key factors contributing to antisocial behavior and delinquency have been identified (Jimerson *et al.*, 2006). First are individual factors, including problem-solving abilities, language development, cognitive processing, self-regulation skills, and mental-health symptomology. Second are peer factors, such as normative group behavior and affiliation with youth involved in antisocial conduct. Third are family factors, including the nature of social and disciplinary transactions, as well as communication patterns. Finally, there are school factors, such as the prevalence and nature of social supports and disciplinary programs. Considering the number and complexity of these factors, as well as their idiosyncratic interplay in the lives of youth, it is improbable that a single developmental pathway will ever be identified. Nevertheless, enough is currently known to organize and employ effective prevention and intervention efforts targeting antisocial behavior and delinquency in schools.

Schools are the most salient context for prevention and early-intervention efforts because they provide more access to more youth than any other setting. Although these targeted efforts could be implemented in various settings (e.g., home, clinic, hospital, or juvenile justice system), they are most commonly found within the school context (Sprague and Walker, 2000). Numerous school-based programs have been developed to reduce students' antisocial and delinquent behaviors by helping students gain prosocial skills. For example, a recent meta-analysis examining 83 school-based studies revealed that if such programs were comprehensive, they significantly reduced students' antisocial behavior, hostile attribution bias, hostile interpersonal-negotiation strategies, and aggressive fantasies (Derzon, 2006). Early intervention in the home, school, and community is the single best way of diverting children from the path of antisocial behavior (Walker *et al.*, 2004). Effective school-based prevention programs train faculty to identify and respond to student needs earlier than they presently do.

Prior Fragmented Efforts

For years, schools have been challenged with the question of how best to serve students who struggle academically and behaviorally. Unfortunately, fragmented initiatives have been implemented to resolve problems without examining the culture of schools and fully understanding their mission and priorities (Sarason, 1996). Greenberg *et al.* (2003) argued that these programs are unsuccessful for several reasons. First, programs promoting worthy prevention and lifestyle goals (e.g., drug and alcohol prevention, conflict resolution, and violence prevention) are often shortlived

because they are disconnected from the overall academic mission of the school. Second, these programs typically do not have strong administrative support; and personnel responsible for implementation are not professionally trained. In addition, these programs are rarely efficiently monitored and assessed for their effectiveness.

As it appears, schools have begun to prioritize needs and implement research-based programs that are designed to use data in making decisions on academic and behavioral matters. While schools have prioritized their resources to support such programs, many are either in the early stages of implementation or do not have an efficient system for tying these practices together in a comprehensive and coordinated approach. Comprehensive prevention programs are designed to enable organizers to prioritize and tie these services together through pooling community, higher education, and public-school resources to improve school success for at-risk students.

A Comprehensive School-Wide Approach

Greenberg *et al.* (2003) lamented that, “rather than integrating these segments and seeing the contributions of prevention programming to academic as well as social and emotional development, educators often make the false choice to emphasize academics only” (p. 472). In addition, they suggested designing and evaluating new programs that improve health and social–emotional skills as well as academic achievement of students. An effective prevention program includes seven critical components that help school-based teams screen students in both academic and behavioral dimensions and then use data

to make decisions that help prevent juvenile delinquency. The seven goals and objectives of successful school-wide comprehensive prevention programs are highlighted in **Table 1**.

Administrative Leadership and Faculty Buy-In

Administrative leadership (e.g., principal or district-level leadership) is essential for the success of any school-wide prevention effort (Kam *et al.*, 2003). Researchers at the Mid-Continent Research for Education and Learning (McREL) Institute (2005) conducted a meta-analysis of school-level leadership and its impact on student achievement. They found that school leadership has an indirect but significant impact on schools and on student learning (Marzano *et al.*, 2005). This and other evidence lead Killion (2000) to state that improving school leadership is important in resolving problems facing schools today.

Administrative leadership ensures that schools have access to resources and ongoing professional development necessary to implement programs with fidelity. Effective administrators communicate the vision and need for the program, inform their faculty what is required of them, discuss how the program will benefit the school, and then monitor progress by holding people accountable. Without such administrative leadership, any attempts at school-wide prevention will likely fail. Faculty and staff must also support school-wide prevention efforts. Faculty buy-in should be formally assessed via informational meetings and commitment from the majority of the faculty before implementing any school-wide prevention

Table 1 The seven goals and objectives of a comprehensive school-wide prevention program

Goals	Objectives
1. Ensure administrative support and faculty buy-in	1. Conduct informational meetings and obtain signed agreements from a majority of the faculty
2. Ensure high-quality professional development	2. Conduct an assessment to determine faculty readiness and professional-development needs
3. Enhance early identification of students who are academically and/or behaviorally at risk for school failure and juvenile delinquency	3. Ensure that faculty are trained in and implement academic and behavioral screening procedures, including a procedure that classifies students into low, medium, or high risk
4. Improve faculty access to students' academic and behavioral information via the district data systems	4. Ensure that faculty in schools are trained how to input and access students' academic and behavioral information via the district data systems
a. Improve faculty data-based decision-making (DBDM) skills to choose evidence-based interventions	a. Provide faculty training in academic and behavioral DBDM
	b. Enable weekly meeting of faculty-grade-level teams to apply DBDM practices
5. Implement evidence-based strategies	5. Provide faculty training in evidence-based strategies including response to intervention (RTI) and positive-behavior support (PBS)
6. Integrate program and planning into the regular school operations	6. Structure regular and consistent collaborative-grade-level professional learning communities (PLCs)
7. Provide continuous program evaluation	7. Conduct ongoing evaluation and modify practices accordingly

effort. Otherwise, the lack of a critical mass of faculty will make implementation weak and potentially ineffective (Fashola and Slavin, 1996).

Needs-Based Professional Development

Professional development is critical to the success of any prevention effort because advances in student learning cannot be expected without proportionate improvements in the quality of teaching (Guskey, 2002). Professional development offerings are most successful when they have (1) sufficient funding for implementation, (2) buy-in from participants, (3) recognition of beliefs and practices of participating faculty, (4) outside resources, and (5) common goals among participants (Richardson, 2003). Consideration of the school context is essential in designing training that meets the goals of creating teacher change and improving student outcomes (Guskey, 2003). An ongoing needs assessment based on both student data and faculty input should be conducted to ascertain what types of professional development activities are needed throughout the year.

When determining which types of professional-development programs are needed, some preliminary steps must be followed. First, data should be available to determine the needs of the school. The following might be considered:

- juvenile crime index of the school attendance area;
- student mobility rate;
- percentage of students who apply for free school lunch at each school;
- percentage of ethnic minority students at each school;
- percentage of limited-English-proficiency students at each school;
- percentage of students at each school from a single-parent family;
- percentage of faculty turnover;
- percentage of students with disabilities;
- daily attendance rate;
- proficiency levels of students in language, arts, math, and science;
- adequate yearly progress of students;
- achievement gap; and
- parental involvement.

The second step is to determine the school's strengths and needs by assessing the following variables:

- student-achievement data known and readily available;
- behavioral problems (who, when, and where) tracked and consequences followed;
- whether academically and behaviorally at-risk youths have been identified;
- whether school leadership values the need to use data to make decisions;

- whether school staff values the use of data in making decisions;
- collaboration teams that are in place and time available for collaboration and data-based decision making;
- whether a majority of the faculty are committed to the project; and
- the amount of support for the program that exists at the district level.

The results of these two steps help determine the types of professional development that schools need as a starting point.

A train-the-trainer model (Anderson *et al.*, 1996), ideally supported by district trainers who in turn train school trainers, is recommended in order to build sustainability and expansion to other schools within the district. This model is based on adult learning theory, which states that people who train others remember 90% of the material they teach, and diffusion of innovation theory, which states that people adopt new information through their trusted social networks (UCLA Center for Health Policy Research, 2008). For schools, it is suggested that the process begin by developing a cadre of skilled school-based trainers, who in turn train others in their school on how to plan and conduct the varied components of the prevention program. For example, we have found that school administrators, grade-level team leaders, and staff developers are ideal trainers who can provide onsite, ongoing support and follow-up. School-based trainers will also enhance the capacity of schools to use their existing database, screen for the early identification of students at risk for juvenile delinquency, and effectively use data to make intervention decisions.

Academic and Behavioral Screening

Screening is intended to alleviate the wait-to-fail approach often inherent in the educational process (Glover and Albers, 2007). Through systematic screening procedures, it is possible to assess, remediate, or prevent many of the factors that contribute to the development of antisocial behavior and delinquency (Sprague and Walker, 2000). With the most recent reauthorization of IDEA, there is a targeted emphasis on prevention and early intervention through the RTI and PBS models (US Department of Education, 2004). Early screening and identification are essential components of a successful prevention program, as they avoid waiting for students to fail before addressing their needs (Albers *et al.*, 2007).

Academic and behavioral screening make use of the data found in schools' data systems, including grades, criterion-referenced test scores, curriculum-based assessment results, office discipline referrals, suspensions, expulsions, safe school violations, and attendance data. Other screening criteria may be added to the data systems

as appropriate. For example, the dynamic indicators of basic early literacy skills (DIBELS), an academic screening instrument for reading performance originally developed by researchers at the University of Oregon, uses curriculum-based measurement procedures and functions as a general outcome measure (Deno and Mirkin, 1977; Fuchs and Deno, 1994). The tool is designed to assess and monitor the acquisition of early-literacy skills from kindergarten through sixth grade (Kaminski *et al.*, 2008). Research-based benchmark goals are used as part of DIBELS to provide educators and service providers with standards for assessing the progress of all students, including those at risk. Teachers administer the first assessment at the beginning of the year and use the results as a screening tool. The DIBELS assessments are then given two additional times during the school year, allowing educators to determine each student's progress on benchmark goals and make instructional changes as appropriate. Students' scores are assigned a category of progress that aids in planning appropriate evidence-based strategies to help them meet early-literacy goals.

Schools can use the systematic screening for behavior disorders (SSBD) (Walker and Severson, 1992) to help identify students who are behaviorally or emotionally at risk. The SSBD is a multistage process whereby teachers nominate, rank order, and then rate students from their classes who display internalizing or externalizing behavior problems. The SSBD has been shown to be useful to both elementary and secondary schools when attempting to identify students and behaviors that need attention from school personnel (Caldarella *et al.*, 2008; Marchant *et al.*, in press).

School administrators and program coordinators should collect both academic and behavioral screening data and monitor the percentage of students who are classified into high, medium, or low risk. Screening should at a minimum be conducted once in the beginning of the school year to identify students in need of extra supports. However, some types of screening data could be analyzed quarterly (e.g., grades and results of curriculum-based assessments) or even daily (attendance and office discipline referrals). The essence of effective screening is to use data as they become available to help identify at-risk students and make data-based decisions to prevent further decline in academic and behavioral performance.

Data Systems and Data-Based Decision Making

Schools need to have a feasible way to track student academic and behavioral data, as well as aggregate and disaggregate them easily. These functions can be accomplished through using an effective data collection and reporting system. Technology and data are among the most important supports needed for collaborative school-based teams.

In the absence of proper technological support, even the best-trained team will encounter barriers that continually impact the improvement of students' educational outcomes (Wayman *et al.*, 2006). It is suggested that schools use their existing database management system, assuming it is reliable and of high quality (e.g., efficient, accessible, and comprehensive). Doing so increases buy-in and reduces the perception that the school is always adding something new. Such systems must provide student data directly to classroom teachers to inform their daily instructional decisions.

However, the use of data at the school level is incredibly difficult because school personnel often lack proper systemic supports for data use (Stringfield *et al.*, 2001). For example, many teachers do not understand how to access, interpret, and use data to design appropriate interventions. Typically, each district has a data system, but the skill and understanding teachers have on how to access and use the system is often deficient. In fact, Holcomb (2004) identified the lack of proper training as one of the major reasons why data are not widely used by teachers and administrators. Thus, an important component of an effective prevention program is training on the collaborative use and analysis of data to determine and address individual student academic and behavioral needs.

School stakeholders need to share the belief that data are essential to instructional and behavioral decision making for students. An increasing amount of evidence supports the impact of access and use of academic and behavioral data on student outcomes (Stringfield *et al.*, 2001). When teachers and principals track student data systematically, they can make adjustments in educational practice that result in measurable improvements in student success. "Good data are as much a resource as staff, books, and computers" (National Forum on Education Statistics, 2004: 3). Through collection, analysis, and response to data, needs are recognized and addressed. When this information is incorporated into an improvement plan, impact on student outcomes is not only possible but likely (Jones and Mulvenon, 2003). Increasing the skill and capacity of teachers and administrators to understand and use data cannot be accomplished through the traditional one-time workshop because, as Holcomb (2004) suggested, "Understanding how to use data to guide decision making is far more complex than individual knowledge and skill acquisition, and it must be embedded in the ongoing work of groups of professionals" (p. 30). Thus, an important component of an effective prevention program is training on the collaborative analysis and use of data from which individual student needs can be determined. Such a program incorporates training in data-based decision making, based on a problem-solving model consisting of a set of sequential and repeatable steps: for example, (1) define and analyze the problem within context, (2) develop a hypothesis and determine possible interventions, (3) monitor progress and evaluate the effectiveness of

interventions, and (4) repeat the cycle as needed (Lau *et al.*, 2006). Utilizing a problem-solving model such as this has been demonstrated to effectively facilitate students' academic achievement and behavioral improvement (Shinn, 2007).

Evidence-Based Strategies

In order to facilitate the most efficient and effective prevention or intervention effort possible, schools should be taught and encouraged to use evidence-based strategies and ongoing progress monitoring (Ikeda *et al.*, 1996). When school faculty find that evidence-based strategies benefit their students, they are more likely to implement these practices (Biglan *et al.*, 2003). Two evidence-based strategies that schools should consider using to aid in prevention and intervention efforts are RTI and PBS.

RTI is an integrated approach that encompasses general, remedial, and special education through a multi-level service-delivery model. It utilizes a problem-solving framework to identify and address academic and behavioral difficulties for all students via evidence-based interventions. RTI is the practice of (1) providing high-quality instruction and intervention that is matched to each students' needs, and (2) using both learning rate over time and student-performance level to make essential educational decisions that guide classroom instruction (Batsche *et al.*, 2005). RTI practices are proactive, incorporating both prevention and intervention. As it stands, RTI is intended to reduce the number of instructional casualties by providing high-quality instruction and interventions matched to student needs (Pieranelo and Giuliani, 2008: 60). Instructional interventions are monitored frequently to make decisions about changes in instruction (National Association of State Directors of Special Education, 2006). By using RTI, districts and school teams can provide interventions to students as soon as a need is identified, in contrast to the traditional approach associated with the

aptitude-achievement discrepancy models used for identifying specific learning disabilities – sometimes criticized as a wait-to-fail approach (Glover and Albers, 2007).

PBS is another comprehensive multilevel school-wide approach. The primary level of PBS, also called universal support, consists of a wide range of strategies designed to achieve positive social and learning outcomes and to prevent problem behavior (Lewis and Sugai, 1999). These strategies include clearly articulated rules, opportunities for teaching and rehearsing expected behaviors and procedures, pre-correction reminders to alert students to expectations, and high rates of positive recognition – all of which are procedures for preventing problem behavior (Sugai and Horner, 2002). The secondary level comprises selected interventions designed to address the needs of students identified as emotionally or behaviorally at risk. These interventions may include small group instruction or individualized support such as anger management, social and emotional learning, or mentoring. For students identified as highly at risk, a tertiary level of PBS is designed to provide more intensive interventions such as individualized function-based assessment and intervention or wrap-around services (e.g., family and community resources).

As described in the previous section, the three-tiered model on which RTI and PBS are based uses preventative approaches to create positive school environments (Sugai *et al.*, 2002) (see **Figure 1**). This model is based on research indicating that approximately 80% of students respond to universal interventions. Targeted interventions can provide specific services and support to an estimated 10–15% of students who may have been labeled as at risk and projected to benefit from services such as small group instruction. The more intensive individual interventions target approximately 1–5% of students who require highly focused assessment and intervention services, including those with educational disabilities (Horner and Sugai, 2002; Sugai and Horner, 2002). RTI has typically focused on academics, while PBS has

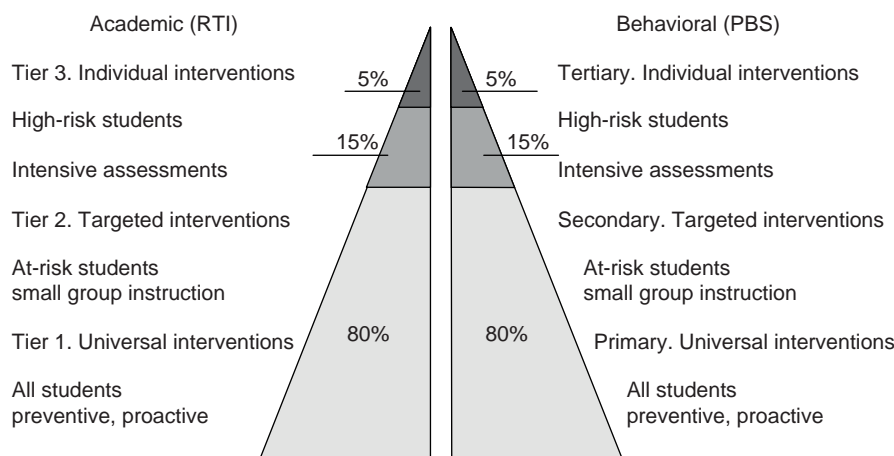

Figure 1 The three-tiered model on which response to intervention (RTI) and positive-behavior support (PBS) are based.

focused on behavior. However, in any prevention or intervention program targeting juvenile delinquency, both should be addressed. For example, at-risk students often struggle behaviorally and academically; thus grade-level teams may realize they need additional expertise for choosing, implementing, and evaluating evidenced-based interventions to address both needs. This could prompt the administrator or program coordinator to arrange for the use of additional school or district resources such as PBS or RTI.

Integration with Regular School Operations

For any prevention model to be successful, the critical components must be integrated into the regular operations of the school. Such integration requires teachers and administrators to continually focus on students they have identified as at risk and then monitor and adjust their prevention strategies as necessary. This process is very different from the one-shot workshop-driven approach common in schools. The National Staff Development Council (2009) suggested that the most powerful forms of staff development occur in regularly scheduled collaborative teams that meet to learn, plan, and problem solve together for the purpose of improving student learning. Collaboration is supported by many researchers as an efficient way to improve education and recommended as an effective method of placing a student-centered focus on school data (Schmoker, 2004). Earlier, DuFour (2002) reported that in the Chicago Public School system, at-risk schools with strong PLCs were four times more likely to improve academic outcomes than were schools with weaker faculty collaboration. As Schmoker (2004) noted, "Though such terms as 'learning communities' and 'lesson study' are heard more than ever, we hardly acknowledge their central importance in actual practice . . . [as a] time for teachers to create, test, and refine their lessons and strategies together" (p. 431).

PLCs provide embedded professional development for teachers and administrators involved in school-improvement efforts such as delinquency prevention. PLCs are composed of collaborative teams of teachers and other school professionals who meet regularly (ideally weekly) to examine the academic and behavioral progress of their students (DuFour and Eaker, 1998). They concentrate on the needs of students by seeking out and implementing effective practices with the goal of increasing student achievement. Teachers and administrators work together toward common objectives creating a results orientation by which learning for all students is expected and their progress is celebrated. Schools working as PLCs have a shared vision, engage in collective inquiry, are action oriented, and expect continuous improvement and results. While successful PLCs focus on achieving these characteristics, DuFour (2004) suggested they also

continually ask these three crucial questions: (1) What do we want each student to learn? (2) How will we know when each student has learned it? and (3) How will we respond when a student experiences difficulty in learning?

DuFour (2004) summarized how to create a PLC by advising participants to "focus on learning rather than on teaching, work collaboratively, and hold yourself accountable for results" (p. 1). Proponents believe PLCs offer the most hope for sustained substantive school improvement (DuFour, 2007; McLaughlin, 1995). Fragmentation and incoherence are cited by the National Staff Development Council (2009) as the most common threats to effective staff-development approaches. Thus, PLC teams that have a clear vision of student learning and are focused on continuous improvement and experimentation eliminate these threats; and school improvement can move forward at a quicker pace.

Program Evaluation and Modification

The continuous evaluation of student outcomes is critical to the success of any delinquency-prevention program. Both formative and summative assessments are important in program evaluation, as illustrated in the following examples. Formative assessment could be accomplished as a part of weekly PLCs where team members track academic and behavioral changes in students classified in each of the three at-risk categories and make instructional changes based on this feedback. Summative assessment could be accomplished by comparing data from the beginning of the year with data from the end of the year (pre/post comparison) to determine whether the program is meeting the goals of decreasing risk (antisocial behaviors and office discipline referrals) and increasing resiliency (academics and social skills). If the program is not achieving its goals, an important issue to assess as part of the evaluation is treatment integrity, or whether the intervention is implemented as intended (Lane and Beebe-Frankenberger, 2004). Interventions which are not implemented properly are less likely to achieve the desired outcomes. In addition, social validity – the social significance, acceptability, and importance of the intervention – must also be assessed, as interventions with low social validity also tend to have low treatment fidelity (Lane and Beebe-Frankenberger). This is especially critical for students who come from socioeconomically disadvantaged or culturally and linguistically diverse backgrounds.

Conclusion

This article has explored problems associated with juvenile delinquency and challenges facing schools as they attempt to implement early-intervention strategies for students identified as at risk. Research regarding the

prevention of antisocial behavior and delinquency has been reviewed to synthesize best practices to develop a comprehensive school-wide approach. We have laid out goals and objectives of such a program and described each of its seven components in detail. Surely, we agree with other experts who have concluded that prevention is a better approach than remediation for addressing juvenile delinquency, and the earlier the better (Kauffman, 2005; Loeber *et al.*, 2003; Walker *et al.*, 2004). The prevention program outlined in the article seeks to target the antecedents of delinquency by implementing a comprehensive school-wide approach that includes (1) ensuring that the school has supportive administrative leadership, with commitment and buy-in from faculty and staff; (2) providing high-quality needs-based professional development; (3) using academic and behavioral screening for the identification of at-risk youth; (4) using data systems and data-based decision-making practices; (5) using evidence-based strategies such as RTI and PBS; (6) integrating programs and planning into regular school operations through PLCs; and (7) implementing continuous program evaluation and modification. As at-risk students are identified early, evidence-based strategies implemented, and student responses monitored and tracked regularly, incidents of juvenile delinquency may be dramatically reduced.

Glossary

Accelerated cognitive and intuitive abilities –

The ability to easily and efficiently acquire, retain, conceptualize, synthesize, and learn new information; as well as process and manipulate large amounts of information at an accelerated pace.

Accelerated instruction – Students with above average academic and intellectual aptitude receive modified/adapted instruction that provides them the opportunity to advance more rapidly through their schooling or to finish schooling at an earlier age than their peers. The curriculum is clearly adapted to the higher aptitude level of students in these programs.

Augmented curriculum – A wide-ranging scope of resources (including out of grade level print and non-print materials) is made available to enhance the curriculum and supplement independent learning opportunities for students with gifts and talents.

Curriculum models – A set of planned cognitive, social, cultural, and emotional experiences that meet the needs of students who are gifted and talented.

Compacted curriculum – Learning experiences that are accelerated in a developmentally appropriate (not redundant) method to meet the needs, interests, and abilities of students who are gifted and talented students.

Differentiated instruction – Differentiated instruction provides for the accelerated development of critical, creative, problem solving and research skills, advanced content, and authentic and appropriate products for gifted students.

Gifted education – Special practices, procedures and theories used to teach children who are gifted and talented.

Gifted and talented – Children and youth with outstanding talent or intellectual ability who perform or show the potential for performing at remarkably high levels of accomplishment or achievement.

Individuals with exceptional abilities have been celebrated throughout history. Our understanding and description of giftedness, however, has changed over time (Smith *et al.*, 2004; VanTassel-Baska and Brown, 2009). Early twentieth-century giftedness studies emanated from research on

the inheritance of mental incompetence, below normal academic achievement among children, development of assessment instruments to measure both the below- and above-average intelligence, and the realization that public schools could not adequately meet the needs of all children (Coleman and Cross, 2005). Terman and Hollingworth, two of the earliest pioneers in the area of gifted research, conducted some of the earliest and most widely published analyses on gifted children. The discipline of gifted education has evolved in relation to the emerging scientific and technological needs of the country, particularly those emanating after the Soviet Union's launch of Sputnik in the late 1950s (Turnbull *et al.*, 2004).

National interests in the education of students with gifts and talents led to the commission of several highly publicized reports, namely the Marland (1972) Report, *A Nation at Risk* (1983), *National Excellence* (1993), and *A Nation Deceived* (2004). The highly acclaimed Marland (1972) Report, defined giftedness as capacity for high performance, demonstrated achievement, and/or potential ability in any of the areas of general intellectual ability, specific academic aptitude, creative or productive thinking, leadership, visual and performing arts, and psychomotor abilities. The report also provided assessments of the needs of students with gifts and resulted in direct assistance to gifted education and the establishment of the US Office of the Gifted and Talented. This definition of giftedness continues to be the foundation of many gifted programs in most districts and states (Karnes and Beane, 2009). Earlier in 1983, *A Nation At Risk* presented startling data that indicated that students in the United States were no longer receiving a superior education, and could not compete globally (Coleman and Cross, 2005). Several of the many report recommendations included but were not limited to: (1) standards for identification and servicing of students with gifts, (2) increasing services to gifted-education programs, (3) improving curriculum enrichment, and (4) creating accelerated instructional approaches (VanTassel-Baska, 1998; VanTassel-Baska and Brown, 2009).

Consequently, in 1988, Congress passed the Jacob K. Javits Gifted and Talented Student Education Act. This Act provided financial support and resources for the Office of Gifted and Talented Education, a national research center focusing on children with gifts, and demonstration projects in gifted education. In 1990, a National Center on Gifted and Talented was established (Turnbull

et al., 2004). The No Child Left Behind Act of 2001 (NCLB, P. L. 107-110), formerly known as the Elementary and Secondary Education Act (ESEA), was enacted to eliminate the achievement gap that exists among students in US schools and ensure that children of all abilities and racial, ethnic, cultural, and socioeconomic backgrounds have a fair, equal, and significant opportunity to obtain a high-quality education, and be taught by highly qualified teachers. In *A Nation Deceived* (2004), Colangelo, Assouline, and Gross described the advantages of accelerated programs for students with gifts and talents and further highlighted America's inability to effectively address the academic, psychosocial, and emotional needs of its most able students in spite of the overwhelming research supporting accelerated programming and differentiated instructional practice. The twenty-first century provides an opportunity of limitless possibilities and hopefully a national focus on the education of children who are gifted and talented.

Characteristics of Gifted and Talented

The study of giftedness encompasses both children and adults and it involves the investigation of cognitive, affective, intuitive, and psychomotor attributes. Much of the research on giftedness (e.g., Clark, 2008; Hallahan and Kauffman, 2003; Smith *et al.*, 2004) describes children with gifts and talents as manifesting a wide range of abilities, including accelerated cognitive and intuitive abilities, a phenomenal memory, excellent recall, visual and performing abilities, and psychomotor intelligence. These children also have the ability to quickly acquire, retain, conceptualize, synthesize, and learn new information as well as the ability to easily process and manipulate large amounts of information at an accelerated pace.

These children are also highly inquisitive. Not only do they enjoy learning, they also have a strong desire to learn and an intense need for mental stimulation. They have the innate ability to learn faster and are more intent and focused on pursuing their interests, a capacity for seeing unusual and diverse relationships, as well as an unusual ability to think abstractly. To a large measure, these children possess superior problem-solving skills, can easily apply and transfer knowledge to new situations, and show an interest in a wide range of topics and disciplines (Smith *et al.*, 2004).

Other characteristics manifested by children with gifts and talents include (1) the ability to expand their understanding of concepts in a number of ways, including their ability to connect with other ideas (e.g., see the relationship between concepts or through their understanding of the perspectives of others); (2) the willingness to be persistent and goal directed and show the capacity to learn at a much earlier age; (3) the ability to learn to speak early

and talk in sentences using complex sentence structure before the age of 2 or 3; and (4) the ability to have highly receptive vocabularies and come to school reading significantly beyond their chronological age-mates. Many of these children possess advanced verbal abilities, extensive vocabularies, and vivid imaginations. Due to their unique abilities, they often require accelerated instruction and sophisticated instructional materials. They are highly motivated and extremely independent. Many are recognized by their teachers for their superior achievement in one or more academic domains (e.g., reading, math, and science). These children like to take risks, and have a high tolerance for ambiguity. They have a strong dislike for skill and drill activities; and find conventional instructional practices less motivating, less challenging, and less rewarding. Like students with disabilities, there exist both inter- and intra-individual differences in their performance. In addition to their high levels of intelligence, some possess high levels of creativity particularly in the visual and performing arts, while others demonstrate outstanding intuitive, leadership, and psychomotor abilities. No doubt, these children display unique social and emotional characteristics (Clark, 2008). They hold high expectations of themselves, possess a keen (sometimes subtle) sense of humor, and have a strong sense of self-awareness. They strive for perfection, are highly focused, and experience enormous stress from failure. They possess high morals, have a strong sense of justice, and are sensitive to the feelings and needs of others. Many of these children display high energy levels in their work and play which can sometimes be misinterpreted and misdiagnosed by psychologists and other health professionals as a form of hyperactivity or an emotional or behavioral disorder. The most common misconception about these children is that they lack social and emotional competence (Clark, 2008). While there are some of them who feel different, have low self-esteem, are misunderstood or socially isolated, most are well adjusted, sensitive, healthy, emotionally independent, and stable individuals who are well liked by their peers (Clark, 2008) and who possess emotional traits that are well balanced. Clearly, the aforementioned characteristics are only examples of attributes of children with gifts and talents and should not be considered as exhaustive. Not every child identified as gifted or talented will display all of these traits.

Beliefs About Intelligence and Gifted Education

Given what we know about the nature versus nurture argument as related to human development and intelligence, it is not surprising that giftedness is considered to result from both genetic and environmental influences (Friend, 2005; Daniels, 2003). The correlation between

intelligence and gifted education continues to impact our decision making regarding curriculum models implemented in the school district. Traditionally, intelligence theories have affected the way in which we identify and assess students, our attitudes toward giftedness and gifted students, the curriculum models upon which we base our programs and interventions, and many other aspects of gifted education.

Research in the areas of gifted and talented has been closely linked with intelligence studies (Plucker, 2001). Many scholars concerned with matters of intelligence also focused on manifestations of talent and genius: Terman (1925) initiated long-term studies in giftedness; and Hollingworth (1942) pioneered work with exceptional children and women; Renzulli (1979) concentrated on distinguishing between real world and academic giftedness; Feldman (1980) looked at developmental trajectories unique to each intellectual domain; Gardner (1983) implemented multiple intelligences as a model; Gagne (1985) focused on the differences between giftedness as potential and talent as fulfillment of potential; and Sternberg (1985) examined the types of gifted abilities, as well as the strengths and weaknesses of intelligence, to name just a few. Many of these theories dominate and bridge the chasm between intelligence and gifted education.

Curricular and Programmatic Models

Connecting intelligence theories to curricular models requires a juxtapositioning of the theories with specific curricular models. VanTassel-Baska and Brown (2009) defined curricular models as a curriculum design and development framework that provides a systematic approach to developing an appropriate curriculum for the target population. These curricular models must include in their frameworks the ability to identify curriculum-product elements. In order for a model to be effective, it must possess differentiation, flexibility, transferability, and usability across content areas, age/grade span, and flexible grouping models. Additionally, it must delineate ways in which it responds to the particular needs of the individual with gifts. The models are descriptive and do not validate the most effective method for maximizing student development in a specific time or space. Each of the curricular models has more than 10 years of supportive research, development, and implementation undergirding its use, endurance, and attention (Coleman and Cross, 2005; VanTassel-Baska and Brown, 2009). The following are subsections that discuss these models.

The Stanley Model of Talent Identification

The Stanley model focuses on lifelong education for the individual. Model principles include: (1) utilization of assessment instruments that encourage high-level verbal and mathematical reasoning; (2) diagnostic instructional

methodologies; (3) accelerated and fast-paced core content; and (4) flexible curriculum across the school environment. This content-based model is aligned with national standards, is highly sustainable, and demonstrates the benefits of acceleration for advancement.

The Renzulli Schoolwide Enrichment Triad Model

The major principles of the Schoolwide Enrichment Triad Model (SEM) model are supported by the (1) use of interest and learning style inventories to assess inter and extracurricular abilities; (2) provision of compacting curriculum (i.e., the regular curriculum is modified by eliminating mastered content, and substituting alternative work); and (3) access to the appropriate triad level based on students' abilities, interest, and task commitment. Enrichment level 1 consists of general exploratory experiences (e.g., guest speakers, field trips, and interest centers); enrichment level 2 includes instructional strategies designed to promote thinking; and enrichment level 3 utilizes analytical activities and creative productions that support primary inquiry and thinking.

Gardner's Multiple Intelligences (MI)

The Gardner model is a core-curricula approach that employs the multidimensional concept of intelligence (Gardner, 1983). The eight types of intelligence are defined as (1) verbal/linguistic, (2) logical/mathematical, (3) visual/spatial, (4) musical/rhythmic, (5) bodily/kinesthetic, (6) interpersonal, (7) intrapersonal, and (8) naturalistic. The multiple-intelligences curricula model has been used as the base curriculum for the identification of individual differences and multidimensional evaluation.

The Schlichter Model for Talents Unlimited Inc. (TU)

Talents Unlimited was based upon Guilford's (1967) inquiry into the nature of intelligence and it features four major components which include (1) a demonstration of talents, productive thinking, decision making, and academic abilities; (2) instructional materials; (3) in-service professional development for teachers; and (4) assessment of students' thinking-skills development (Schlichter, 1981). The model has been noted for developing student's creative and critical thinking.

Sternberg's Triarchic Componential Model

The Sternberg's Triarchic Componential Model (STTCM) is based upon information-processing intelligence theory

(Sternberg, 1985). The model incorporates components of the mental processes used in thinking. These components include (1) the executive process component is involved in planning, decision making, and monitoring performance; (2) the performance component processes facilitate executive problem-solving strategies; and (3) the knowledge-acquisition component facilitates the acquisition, retention, and transference of new information. This model supports the concept that interaction and feedback between the individual and his/her environment within any given context allows cognitive development to occur.

VanTassel-Baska's Integrated Curriculum Model

The Van-Tassel-Baska Integrated Curriculum model (ICM) was developed for high-ability learners. It is based upon three dimensions: (1) advanced content; (2) high-level process and product work; and (3) divergent and convergent thought development and understanding. The use of advanced curricula and accelerated rates of instruction in core subject areas is supported by an extensive body of research. Over 30 years of research supports the implementation of more enrichment-oriented models for students with gifts and talents (VanTassel-Baska and Brown, 2009).

On the whole, decisions as to which curricular model to implement should be consistent with general premises of general school policy. It is important that the model supports students' understanding of reality; recognize curriculum alternatives based on various gifts and talents; and be responsive to the effect of student choices (Coleman and Cross, 2005).

Differentiated Instruction for Students with Gifts and Talents

The most powerful models of instruction are accelerated, interactive, and differentiated. Differentiation is defined by the (1) individualized learning needs of children with gifts and talents; (2) specific content and skill sets of the curriculum; (3) pedagogy used to convey the content; and (4) flexible settings needed to effectively implement the curriculum (Kaplan, 2005; VanTassel-Baska and Brown, 2009). Differentiated instruction encourages the learner to construct and produce knowledge in meaningful ways. Within the construct of differentiated instruction, students engage in generating original products, collaborative construction of knowledge, and problem-based learning. Differentiated strategies include (1) individual and group summarizing; (2) investigation of divergent perspectives, higher-order critical thinking; (3) brainstorming; (4) Socratic dialog; (5) problem-solving processes; and (6) team teaching.

Differentiated curriculum for students with gifts is based on the strengths of the students and the inability of the core curriculum to meet the needs of this population. The analysis of the skill sets of these students with respect to the traditional core-curriculum content, processes, and product components justifies the rationale for a differentiated curriculum.

Differentiated core-curriculum programs should stimulate the development of students' actual and potential abilities as well as their skills, creativity, and talents. Instructional strategies for students with gifts and talents utilize several curriculum modifications to meet the challenges faced by inadequacy of the core curriculum. These modifications include (1) higher levels of thinking, (2) open-discovery learning, (3) evidence of reasoning, (4) freedom of choice, (5) group interaction, (6) pacing/acceleration, and (7) variety of processes. Implementing these elements to modify the core curriculum helps teachers to (1) present content related to comprehensive; (2) broad-based issues; (3) integrate multiple disciplines; (4) allow for in-depth self-selected learning; (5) develop independent study skills; (6) focus on open-ended tasks; (7) develop research methods; (8) encourage the development of new products and techniques; (9) self-understanding; and (10) self-directedness.

Conclusion

While there are a number of strategies and approaches that can be used to deliver instructional services to students with gifts and talents, this article shares information on some of the strategies and approaches commonly used by school districts. It is important to keep in mind that all programs, regardless of grade level or curriculum model used, must enhance (1) flexible teaching strategies, (2) multiple venues for students to reach their learning and creative potentials, (3) continuous measures to assess progress, (4) collaborative construction of knowledge through peer and teacher interactions, and (5) continuity. From our perspective, our goal is to have highly qualified teachers with specialized training to teach students with gifts and talents using creative multidimensional techniques.

Related Services for Children with Special Needs

S O Obi, Kentucky State University, Frankfort, KY, USA

© 2010 Elsevier Ltd. All rights reserved.

Special education means specially designed instruction, provided at no cost to parents, to meet the unusual needs of a student with exceptionalities. These include special materials, teaching techniques, equipment, and/or facilities. The regular classroom or special education teacher who is aware of the individual needs of students and skilled at meeting them may need consultation with special education, transportation, audiology, psychological services, physical therapy, occupational therapy, recreation, early identification, medical services, school health services, counseling, social work services, and parent counseling and training. This article focuses on how students' needs can be met with these related services.

Children with disabilities have sometimes been prevented from attending their neighborhood schools or benefiting from educational activities by circumstances that impeded their access or participation: a child who uses a wheelchair, for example, may require a specially equipped school bus; one with special health needs may require medication several times a day; and a child with an orthopedic impairment may need physical therapy to maintain sufficient strength and flexibility in his/her arms and legs. Individuals with Disabilities Education Improvement Act (IDEIA) requires that schools provide any related services that a child with a disability may need to access and benefit from special education (Heward, 2009). More specifically, if special education is to be effective, related services will be necessary. A child who is between the ages of 3 and 21 years with a verified disability and also demonstrates the need of a related service, may be eligible to receive them. The receipt of a related service is based on the documented and assessed needs of the child. In determining whether or not assessed educational needs should be met by a specific related service, the following should be apparent. In other words, related services are required for a student with disabilities when:

- the services are necessary for a student to gain access to a special education program or the services outlined in an individual education plan (IEP);
- the services are necessary for a student to remain physically in an educational program;
- a student cannot make meaningful progress toward the goals and objectives of an IEP without the services;
- a student's various needs are so intertwined that an integrated program of a special education and related services is needed; and

- progress toward the goals and objectives of the IEP is dependent on the resolution of other needs.

The IEP team is necessary to accomplish the need for related services. However, it should consider terminating a specific service if the IEP goals have been met and no additional services are necessary to meet the child's educational needs. Termination should also be considered when the potential for further change appears unlikely based on previous documented intervention attempts (Schafer, 1998).

Service delivery, the intensity of the service, and the frequency of service are determined by the IEP team based on the child's educationally related needs. The critical determinants are the individual, unique educational needs of the child, and the most appropriate manner in which the special education needs can be supported by the related services in question. In developing goals and objectives for related services, IEP team members should consider the following factors:

- the least-restrictive environment needed to accomplish the goals and objectives for the related service;
- the type of skills to be learned and the methods and strategies of intervention anticipated;
- the level of expertise required to provide the service; and
- the need for and availability of others to carry out the child's IEP.

In general, service delivery will vary in frequency depending on the needs of the child. The need for sharing of information among IEP team members and joint program planning and evaluation must be done throughout the program plan. Monitoring of student performance is necessary to determine if the amount of service is appropriate to promote progress toward attainment of the child's special education goals and objectives (Nebraska Department of Education, 2000).

Related Service Professionals

Many types of professionals are needed to provide multidisciplinary services required by individuals with disabilities. A special educator might be a paraprofessional (teacher's aide), a resource teacher, a consultant, an itinerant teacher, a special education classroom teacher, a job coach, an assistive technology specialist, a home or

hospital teacher, a diagnostician, or an administrator. Furthermore, a teacher may assume several of these professional roles during his/her career. In addition, a special education professional might work in a related service as a school psychologist, a speech/language pathologist, an audiologist, an occupational therapist, a physical therapist, a counselor, a nurse or physician, a transportation specialist, a recreational therapist, a supported living worker, a personal-care attendant, a vocational rehabilitation worker, or a lawyer (Smith, 1998).

Special education teachers and others who work with individuals with disabilities must be able to collaborate and cooperate with professionals from a variety of disciplines. They work together in multidisciplinary teams (MDTs) comprised of those professionals each individual student needs. It is through collaboration and working together as a team that is ultimately the key to successful integration for individual students, given that they require various combinations of services over their school careers (Smith, 1998). Special education teachers collaborate in many areas that touch a child's life. They use collaborative skills when working with parents and families, performing multidisciplinary assessments, working with a team to develop individualized program plans, coordinating the components of students' individualized plans, and helping them make transitions through the school years and from school to work. For instance, the Nebraska Department of Education (2000) categorized services into three types, which are detailed below.

Direct Service

In direct service, the related service provider works with a child individually or in a small group on a regularly scheduled basis to assist the child to develop skills relevant to the child's educational performance. The emphasis of direct service is performance and skill acquisition to benefit from instruction. Direct service may also be indicated to maintain newly acquired skills or to slow down the rate of regression. Collaboration with parents, teachers, and paraeducators is necessary to achieve goals and carry-over activities into regular routine. Consultation is needed to maximize the educational benefit of the intervention.

Integrated Service

Integrated service combines direct, hands-on child contact and consultation with others directly involved with the child. There is an emphasis placed on the need for practice of skills in the child's daily routine. The process of goal achievement is shared among those involved with the education of the child. Those involved may include the related service provider, teachers, parents, and classroom paraeducators. Intervention typically includes adapting activities occurring in the child's routine and creating opportunities

for him/her to practice new skills with others. The related service is provided within his/her daily environment, and should always include others involved with him/her to carry out the delegated activities or services.

Consultative Service

The related service provider in consultative services focuses on providing input to teacher, staff, and parents regarding the child's specific needs rather than providing direct services. This does not preclude the need for the related service provider to work directly with the child to identify needs or solve problems. The related service provider supports the educational program, but is not the primary provider of services. The child's needs may not be rapidly changing or only minimal input is needed from the related service provider. Consequently, only periodic direct contact is needed. The related service provider's involvement includes providing suggestion to the teacher, staff, and parents for modifications of educational materials and the environment as well as infrequent monitoring of the child's progress and any adaptive devices that may be used.

Types and Definitions of Related Services

The IDEIA requires school boards to provide related, or supportive, services to students with disabilities, when children need such services to assist them in benefiting from their special education programs. Other services may be deemed related services if they assist students with disabilities in benefiting from special education. For example, services such as artistic and cultural programs or art, music, and dance therapy could be related services under the appropriate circumstances. Persons of varying professional backgrounds who have a variety of occupational titles may provide related services. The detailed types, definitions, and professionals of related services as indicated in IDEIA (2004) are discussed below.

Audiology

Audiology is provided by audiologists and speech/language pathologists to children with known or suspected hearing or listening disorders, and/or those with speech or language delays. It is the scope of practice for speech/language pathology (SLP) to provide the communication assessment and rehabilitation services to children who are deaf or hearing impaired, as described in the American Speech-Language-Hearing Association (ASHA, 1996) Scope of Practice in Speech-Language Pathology. Deconde *et al.* (1997) suggested that children with central auditory processing disorders (CAPDs) may be eligible for special education or 504 services, depending on the severity

and implications of the problem – usually students with significant CAPD qualify for eligibility consideration with either a hearing, speech/language, or learning disability. The audiologist is the only professional who is qualified to perform an audiological evaluation for verification purposes. For purposes of the MDT evaluation, the audiologist provides a written report that documents the hearing loss.

Counseling

Counseling means assisting parents in understanding the special needs of their children and providing them with information about child development. Services include social skills, peer relationships, crisis intervention, and classroom guidance, including topics such as self-concept, decision making, problem solving, and system support. System support includes referring children and families to community agencies or providers, support groups, and law enforcement. These services are provided by qualified social workers, psychologists, guidance counselors, rehabilitation counselors, or other qualified personnel defined by the professional scope of practices.

Early Identification and Assessment Services

These services mean the implementation of a formal plan for identifying a disability as early as possible in a child's life. As stated by the American Academy of Pediatrics Committee on Children with Disabilities (1994), early identification of children leads to effective therapy of conditions for which a definitive treatment is available. In conditions that cannot be fully reversed, early intervention improves the child's outcomes and enables families to develop strategies and obtain resources for successful family function. In order to engage in the practice of medicine, a physician, surgeon, or obstetrician, must be duly licensed by the state in which he/she practices. Specifically, the varieties of providers that are involved in screening young children include pediatricians, family practitioners, physician assistants and nurse practitioners in pediatrics and family practice, and public health nurses. Any medical provider may make a referral to the local school district.

Medical Service

These services are provided by a licensed physician to determine a child's medically related disability that results in his/her need for special education and related services. In order to receive services, the school-age child must have a verified disability that has the potential to interfere with his/her educational process and school performance. An accurate medical diagnosis provides the family and school personnel information about the child's condition as well as particular precautions that

may pertain to him/her and impact the educational program. The attending physician can also be of assistance in the development of expected goals and provide opinion about the provision of related services for the child's special education program. It is also appropriate for the treating physician to assist the evaluation team, including the parent, in determining whether the child's disability would be eligible for services under Section 504 of the Rehabilitation Act of 1973. It is the responsibility of the school district's MDT to evaluate his/her eligibility for special education and related services.

Occupational Therapy

This kind of therapy is provided by qualified occupational therapists. It includes:

- improving, developing, or restoring functions impaired or lost through illness, injury, or deprivation;
- improving ability to perform tasks for independent functioning if functions are impaired or lost; and
- preventing, through early intervention, initial or further impairment or loss of function.

Occupational therapy is intended to serve children from 3 to 21 years of age, who have a verified disability. This therapy may include feeding and self-help skills, fine and visual motor skills, visual processing skills, sensory processing, and positioning and adaptive services or equipment. Those who are qualified to provide this therapy include registered and licensed occupational therapists, certified occupational therapy assistants, and occupational therapy aides.

Orientation and Mobility Service

These services are provided to students with visual impairments and blindness by qualified personnel to enable them to attain systematic orientation and safe movement within their environments in school, home, and community. They include teaching students the following:

- spatial and environmental concepts and use of information received by the senses (such as sound, temperature, and vibrations) to establish, maintain, or regain orientation and line of travel (e.g., using sound at a traffic light to cross the street);
- the use of long cane to supplement visual travel skills or as a tool for safely negotiating the environment for students with no available travel vision;
- understand and use remaining vision and distance low vision aids, as appropriate; and
- other concepts, techniques, and tools as determined appropriate.

Hazekamp and Huebner (1989) noted that the ability to understand, interact with, and move within one's physical

and spatial environment is a fundamental developmental skill. This ability is one of the milestones indicative of maturation for students with sights or visually impairments. The development of orientation and mobility skills is essential for students to travel independently in various community settings. Services in this area are provided by Certified Orientation and Mobility Specialists (COMS) and Certified Orientation and Mobility Assistants (COMA).

Parent Counseling Services

These services assist parents in understanding the special needs of their child and in providing them with information about child development. They also help parents to acquire the necessary skills that will allow them to support the implementation of their child's IEP (Wright and Wright, 2007). Parent counseling as a related service may be provided by school guidance counselors, social workers, psychologists, or other qualified personnel.

Physical Therapy

This kind of therapy is provided by a qualified physical therapist. Physical therapy serves children aged 3–21 with a verified disability; and it involves gross motor skills, orthopedic concerns, impaired mobility, and adaptive equipment/positioning needs that interfere with the student's educational performance. The focus of educational services is to allow the student to benefit from his/her special education program by promoting functional independence or participation within the educational environment (Wright and Wright, 2007).

Psychological Services

These services include administering and interpreting assessments, consulting with other staff members, planning psychological services and counseling, assessing behaviors, and developing positive behavioral intervention strategies. School psychologists are required to have valid certification in education and psychology to serve children from birth to age 21 and families within school districts. As a related service, school psychologists work closely with classroom teachers and paraprofessional providers on such issues as behavior management and instructional practices. In providing the full range of psychological services, they also work closely with school counselors and, when available, with school social workers. The decision as to who specifically provides a particular service is usually made by the MDT or during the IEP meeting. A variety of factors can be considered when making this decision. These include availability, expertise in the specific need area, and previous experience with the individual student and/or the family. (Stuberg and Schafer, 2000).

Recreational Therapy

This kind of therapy provides assistance, instruction, and strategies to facilitate the short-term objectives of special education. This therapy is also important to the long-range life goals of the student with disabilities. It facilitates social involvement and friendships and encourages and provides skills associated with opportunities for community integration. As an educational tool, recreational therapy can be used to achieve cognitive, social, emotional, and physical objectives identified as learning needs. Recreation includes:

- assessment of leisure function;
- therapeutic recreation services;
- recreation programs in schools and community agencies; and
- leisure education.

The recreational therapist is not a teacher, but rather is a supportive trained certified therapeutic recreational specialist (CTRS), who works and consults with other education personnel to extend and enhance the students' total education.

Rehabilitation Counseling

This means services provided by qualified personnel in individual or group session that focus specifically on:

- career development;
- employment preparation;
- achieving independence; and
- integration in the workplace and community of a student with a disability.

The term also includes vocational rehabilitation services provided to a student with disabilities by vocational rehabilitation programs funded under the Rehabilitation Act of 1973, as amended.

Rehabilitation counseling is intended to serve students aged 14–21 with a verified disability and a current IEP with transition plan in place as mandated by Individuals with Disabilities Education Act (IDEA). Rehabilitation counseling can be provided by any special education endorsement, guidance and counseling, vocational special needs, or diversified occupations endorsement, or special services certificate for school rehabilitation counselor.

School Health and School Nurse Services

These health services are designed to enable a child with a disability to receive free appropriate public education as described in the child's IEP. School nurse services are provided by a qualified school nurse. School health services may be provided by either a qualified school nurse or other qualified person. Health services provided by a

registered nurse include services designed to help a student protect, improve, and maintain physical, emotional, and social well-being. Students with special health conditions may require the provision of a safe and healthy environment, emergency health care procedures, communicable disease prevention and control, administration of medication, administration of invasive nursing procedures, individualized health assessment and care planning, and health care record keeping.

Social Work

Social work services in schools include:

- preparing a social developmental history on a child with a disability;
- group and individual counseling with the child and family;
- working with problems in a child's living situation (e.g., home, school, and community) that affect the child's adjustment in school;
- mobilizing school and community resources to enable the child to learn as effectively as possible in his/her educational program; and
- assisting in developing positive behavior intervention strategies.

Social work services in the school are provided by an individual with a baccalaureate or master's degree in social work from an approved educational program. School social workers develop skills for effective service to children, families, personnel of the local education agency, and the community (NASW, 1992).

Speech/Language Pathology

This means providing services that include:

- identification of children with speech or language impairments;
- diagnosis and appraisal of specific speech or language impairments as well as referral for medication or other professional attention necessary for the habilitation of speech or language impairments;
- provision of speech and language services for habilitation or prevention of communicative impairments;
- counseling and guidance of parents, children, and teacher regarding speech and language impairments; and
- referral for medical or other professional attention necessary for the habilitation of speech or language impairments.

Speech/language pathologists serve children with speech, voice, language, communication, swallowing, and related disabilities. It is provided by a person who holds a valid and current credential as a speech or hearing specialist from an academic program approved by the board. In

order for a student to receive SLP as a related service from his/her resident public school district, he/she must have a verified disability as determined by a multidisciplinary evaluation team.

Transportation

This includes:

- travel to and from school and between schools;
- travel in and around school buildings;
- specialized equipment (such as special or adapted buses, lifts, and ramps), if required to provide special transportation for child with a disability.

A student cannot benefit from an educational program if he/she cannot get to the program. For this reason, transportation is probably the most common related service that school boards provide. The transportation personnel will, with training provided by the district, be responsible for taking appropriate safety precautions and care of children with a wide range of ages and disabilities.

Recommendations for Practice

Clearly, school boards must provide students with disabilities with related services when such services are necessary for them to benefit from their special education programs. The only limitation that has been placed on what may be considered a related service is that medical services are exempted unless they are for diagnostic or evaluative purposes. Much litigation has ensued from the IDEA's related services provision. This litigation has given school officials considerable guidance. The following recommendations have been developed on that litigation. Schools officials should:

- Provide related services to students who are receiving special education if they are necessary for the student to receive educational benefit.
- Consider whether a student with a disability who is not receiving special education may be entitled to related services under Section 504.
- Provide services of a life-support nature, if necessary, during the school day.
- Provide medical services, if needed, for diagnostic or evaluative purposes.
- Provide all necessary school health services that can be performed by a school nurse, health aide, or other trained layperson.
- Provide a full-time nurse to help guarantee that students with significant medical needs are integrated into public schools.
- Check to see if students who require extensive health-related services are eligible for Medicaid benefits that

could offset the costs of many expensive health-related services.

- Investigate the option of using parents' health insurance, particularly for a diagnostic and evaluative services (however, parents may not be required to use their health insurance if it will incur a cost to them in the form of a reduction in benefits, a cap on benefits, or an increased premium).
- Provide psychotherapy, social work services, or counseling when the resolution of emotional concern is a prerequisite to a student's successful progress toward the goals of the IEP.
- Be diligent in ascertaining exactly what is the primary reason for a residential placement, as placements that are required for reason that are not education may not be the responsibility of the school board.
- Provide special transportation when a student is unable to access a standard mode of transportation.
- Avoid excessively long bus or van rides to school. All transportation arrangements must be reasonable.
- Make provisions for any child whose disability prevents him/her from getting to and from the transportation vehicle.
- Provide transportation to and from a residential facility.
- Establish natural policies regarding transportation of all students to day care centers or after-school caretakers.
- Ensure that students with disabilities are given the same considerations as students who are disabled regarding transportation outside of the school's attendance boundaries.
- Provide an aide on the transportation vehicle, if necessary, to ensure safe passage for medically fragile students.
- Make alteration to the physical plant to allow a student with a disability to participate fully in and benefit from an education program (however, another option may be to bus the student to a nearby school that is accessible if the required alterations would be excessively costly).
- Provide parents with training so that there is consistency between the techniques used in school and at home (this option may be a viable alternative to residential placement).
- Pay a student's room and board expenses if the only facility that can provide an appropriate education is not within commuting distance from the child's home.
- Provide full access to sports or other extracurricular activities whenever a student qualifies for participation.
- Include participation in sports or other extracurricular activities in a student's IEP if these activities may assist

him/her in benefiting from his or her educational programming.

- Provide assistive technology to students with disabilities when needed (however, school boards are not required to provide personal devices that a student would require regardless of whether the child attended school).
- Consider instruction in daily living skills when developing transition services for students who are close to exiting the educational system.

Conclusion

Students with disabilities need related services to maximize their fullest potential. However, these services must be provided by qualified personnel to effectively help students to benefit from special education programs. This article has addressed related services, related professionals, and basic issues surrounding related services. Basic qualifications of the related professionals are necessary to prevent litigations on schools. The overall goal is for professionals and related professionals to collaborate, consult, and cooperate to facilitate services for students who need them.

Risk and Resilience Frameworks in Understanding Special Education

W-Y Hsieh and M L Donahue, University of Illinois at Chicago, Chicago, IL, USA

Glossary

Culturally responsive pedagogy – Culturally responsive pedagogy comprises three dimensions: (1) institutional (the administration and its policies and values), (2) personal (the cognitive and emotional processes teachers must engage in to become culturally responsive), and (3) instructional (materials, strategies, and activities that form the basis of instruction). Teaching and learning occur in a culturally supported, learner-centered context, whereby the strengths students bring to school are identified, nurtured, and utilized to promote student achievement in a culturally responsive classroom (The National Center for Culturally Responsive Educational Systems).

High-incidence disabilities – Learning disabilities, emotional/behavioral disorders, mild intellectual disabilities or speech/language disabilities.

Inclusive settings – Inclusion as a value supports the right of all children regardless of their diverse abilities to participate actively in natural settings within their communities. A natural setting is one in which the child would spend time if he or she had not had a disability (The Division for Early Childhood of the Council for Exceptional Children).

Protective factors – Positive factors that help to mitigate adversity in development.

Risk factors – Adverse factors and stressors that tend to result in negative outcomes in development.

Special education – Individualized education programs for students with special needs that address the students' individual differences and respond to their needs.

The ecological model – A model proposed by Urie Bronfenbrenner, proposing that a child's development must be understood at the center of a nested system of interactive influences. These consist of a microsystem (a child's immediate surroundings, e.g., family), a mesosystem (the relationship between the structures of the child's microsystem, e.g., interaction between the child's teacher and his parents), an exosystem (the larger social system that does not impact the child directly, e.g., parent workplace schedule), and a macrosystem (the outermost layer in the child's

environment, e.g., cultural values). This model illustrates how a child's development is affected by the relationships and interactions of the four systems.

The risk-resilience model – Children raised with multiple adverse influences, including disabilities, may still achieve positive outcomes, given the right combination and timing of protective factors.

Historically, the field of special education has focused on identifying hallmarks or common characteristics of particular disabilities, in a search for the definition and refinement of various disability categories (e.g., learning disabilities, autism, and hearing impairment). However, the foundation of special education lies in the recognition of individual differences in human development (Osgood, 2008). Researchers and practitioners in special education have long been aware that assessment and intervention policies for students with disabilities depend on the understanding of the developmental trajectory of a variety of individual, family, and community factors and their interactions. These professionals affirm that individual differences in physical, cognitive, and emotional outcomes are not simply noise or measurement error in the data, but must be taken into account by some viable theory and intervention model.

It is no surprise then that the first conceptualization of the risk and resilience framework was derived from research by Werner and Smith (1982) on students with developmental disabilities. As one of the first comprehensive and longitudinal developmental studies with a large sample, Werner *et al.* (1971) studied the entire cohort of infants born on the island of Kauai in 1955. The influence of a wide range of biological and environmental factors on the cognitive and emotional outcomes of these individuals was then investigated periodically for the next 40 years (Werner and Smith, 1982, 1992, 2001). This rich source of data helped identify the power of adverse factors and stressors in explaining negative outcomes (risk factors), as well as the positive factors that helped to mitigate this adversity (protective factors). One compelling finding was a subset of children who beat the odds (i.e., children exposed to significant biological risk, poverty, and poor parenting who still managed to achieve positive life

experiences and achievements). This group of invincible or resilient children triggered a dramatic search for risk and protective factors and their transactions that could explain positive developmental outcomes in the face of adversity (e.g., Reiff *et al.*, 1997). Since then researchers who study disability have been eager to invoke risk/resilience models (e.g., King *et al.*, 2003; Murray, 2003; Spekman *et al.*, 1993; Werner and Smith, 2001; Williamson, 2007; Wong, 2003). In fact, the principles of this framework affirm the most strongly held beliefs of special educators. The risk–resilience model recruits the metaphor that children raised with multiple adverse influences, including disabilities, may still achieve positive outcomes, given the right combination and timing of protective factors. This success-story perspective laid the groundwork for the special education field.

Another reason for the appeal of the risk/resilience model in explaining the unpredictable outcomes of children with special needs is its developmental and transactional focus. What constitutes a risk or protective factor may differ in different contexts, and at different ages. Further, factors that appear to have no influence at one point may have a sleeper effect later. For example, Werner (1993) found that positive temperament did not buffer negative outcomes in a group of 18-year-olds with learning disabilities, but by the time these individuals reached the age of 32, early measures of temperament did predict positive adjustment, including marital and vocational satisfaction. Further, risk and protective factors are not likely to have equal impact, and so determining their relative importance is desirable. For example, for some outcomes, the particular risks to which a child is subjected are less important than the sheer quantity of them (e.g., Sameroff *et al.*, 1993). Most importantly, risk and protective factors can work together in different ways to produce outcomes. Protective factors embedded in a child's family and educational contexts may lead naturally to intervention efforts. Identifying the transaction of these factors can also guide intervention efforts, in that some risk factors may be more amenable to intervention at some points than at others. Another question is whether there is more of a payoff if efforts are directed to lowering risks or to adding or supporting protective factors. In this article, we describe and illustrate the use of the risk and resilience frameworks in guiding research and policy in special education. Risk and protective factors that arise from the interaction of individual, family, and community characteristics are illustrated; and implications for assessment, intervention, and teacher preparation are highlighted.

Risk and Protective Factors

Research on resilience in individuals without special needs has revealed that children who are exposed to adverse

conditions or multiple risks do not necessarily experience negative outcomes (Rutter, 2000). Of course, the dynamics of individual characteristics and environmental factors make it sometimes difficult to define resilience (Kraemer *et al.*, 2001) as risk and protective factors that mediate an individual's vulnerability to negative life outcomes may be biological, psychological, cognitive, or environmental. The ecological model by Bronfenbrenner (1986) illustrates how a child's development is affected by the transactions of individual, family, and community factors.

Individual Factors

Of course, disability itself is a risk factor that makes individuals more vulnerable to adverse conditions; these effects can persist across the lifespan. Research on risk/resilience on different types of disabilities shows similar pathways. For example, individuals with learning disabilities (LDs) typically show discrepancies between intellectual abilities and academic performance. This gap can lead to social and emotional problems in addition to academic difficulties (e.g., Wong and Donahue, 2002). Higher school dropout rates, unemployment, job difficulties, and lower rates of postsecondary school attendance are more likely to occur in individuals with LDs (Blackorby and Wagner, 1996; Goldstein *et al.*, 1998; Murray *et al.*, 2000; Spekman *et al.*, 1993). Students with emotional and behavioral disorders (EBDs) experience similar negative outcomes, as well as higher incarceration rates (e.g., Frank *et al.*, 1995; Malmgren *et al.*, 1998; Wagner, 1995). While students with mild cognitive disabilities have many similar problems following high school, these youth are even more likely to experience a constellation of poor outcomes compared to youth with LDs and EBDs (Affleck *et al.*, 1990; Blackorby and Wagner, 1996).

For many students, however, individual characteristics may lessen the impact of their disabilities. The identification of a disability itself may become a protective factor for some students and their families. For example, a student with LD stated that placement in special education helped him succeed in college (Miller, 1997). Cosden *et al.* (2002) confirmed that even factors such as physical attractiveness, athletic abilities, and social skills can be protective factors for individuals with LD. Regarding social acceptance, individual variables such as race, gender, severity of disability, and oral language ability have all been found to influence positive peer relationships (Pearl and Donahue, 2004). Other mediating factors include the individual's temperament and self-understanding. Even within samples of people with special needs, temperament has been found to be an important mediator of later development, as it elicits different responses from a variety of caring people around the individual (e.g., parents, teachers, and friends) (Cosden *et al.*, 2002; Garmezy, 1991; Werner and Smith, 2001). Chess and Thomas (1991) classified behaviors

that demonstrate temperamental characteristics in young children into three clusters: easy, difficult, and slow to warm-up temperaments. They found infants with a constellation of difficult temperamental traits were prone to behavioral problems in early and middle childhood. Negative traits of these temperament types increase the likelihood of developing behavioral problems or reduced social and academic competence (e.g., Bates and Pettit, 2007; Guerin *et al.*, 2003). Another factor that mitigates the effects of disability and enhances an individual's resilience is self-understanding. Adolescents and adults with LDs who understood and accepted their disability were more likely to have values and skills to assess their cognitive strengths and weaknesses, set up realistic goals, and strive to attain their goals. As children and adolescents, they were found to have regular responsibilities, and later established realistic education and vocational plans (Cosden *et al.*, 2002; Spekman *et al.*, 1993; Werner and Smith, 2001). Other strengths related to beliefs about one's self (e.g., self-esteem, self-efficacy, problem-solving skills, positive identity, and social competence) have also been found to be resources that help children thrive under adverse environments (Daniel and Wassell, 2002; Hagborg, 1996).

Family Factors

Perhaps the most compelling research evidence for the interactive effects of risk and protective factors on child development comes from studies of the family environment. In particular, a family's efforts and adaptability in supporting a child with special needs may be a lifetime challenge (Spekman *et al.*, 1993). In searching for resources, the family may have more contact with different professionals, which can itself be stressful (Waggoner and Wilgosh, 1990). Murray (2003) summarized a list of risk and protective factors at the family level. Risk factors include low socioeconomic status, inconsistent, harsh, and disorganized parenting style, family history of mental illness, and history of child maltreatment. In fact, growing up in an abusive home environment is a risk factor for emotional and behavioral problems across one's life span (Cicchetti and Carlson, 1989). Protective factors include secure child-caregiver attachment relationship, warm but demanding parenting style, family composition, parent level of education, and stable parent employment. For example, in one study of health-compromising behaviors among youth with LDs, EBDs, mobility impairments, and youth without disabilities, protective factors that reduced students' use of health-compromising behaviors included family connectedness, parental presence, parental expectations, and activities with parents (Blum *et al.*, 2001). Other researchers also highlight the personal characteristics of parents and child, including the fit between the child's temperament and the parenting style, and the external support available to

the family, such as a caring and supportive extended family member (Morrison and Cosden, 1997).

In addition to the aforementioned tangible factors, how parents perceive their child's academic and behavioral disabilities and strengths may lessen the stress created by the disability (Murray, 2003). Those who adjust well to having a child with special needs have been termed 'resilient families', who can appreciate the positive contributions of disability to their family life and well-being (Hastings *et al.*, 2005). These families not only understand the nature of the child's disability, but also recognize the importance of not generalizing that disability to the whole child (Switzer, 1985). For example, families of children with autism reported that family members became more connected as they pulled resources together to support their child with autism (Bayat, 2007). Additionally, parenting style mediates children's beliefs about their abilities and their own goals. For example, children's self-esteem is promoted when raised in a structured, supportive, and emotionally stable home context (Cosden *et al.*, 2002; Werner and Smith, 2001) with at least one caring parent. Resilient children had mothers who provided good role models, with education beyond high school, and good jobs (Werner and Smith, 2001). In contrast, findings of research on the nature of parental expectations for children's academic performance vary. Some studies suggest that lower parental expectations result in lower anxiety and higher overall student achievement in their children (Tollison *et al.*, 1987). In contrast, other evidence suggests that parents' high expectations facilitated resilience in their children with disabilities (Reynolds, 1999).

School and Community Factors

As schools are often the settings in which disabilities are first identified and in which special education services are first provided, characteristics of school and classroom structure, teacher beliefs and skills, and peer relationships are critical to fostering resilience (Pianta and Walsh, 1998; Werner and Smith, 2001). For example, even in schools with few resources, values and practices of teachers have been shown to be important factors in the successful inclusion of students with special needs in general education classrooms, resulting in growth in both social domains (Hutchinson *et al.*, 2002) and academic domains (Scruggs and Mastropieri, 1994).

Frustration experienced in school environments can make school itself a risk factor for individuals with special needs (Pianta and Walsh, 1998). In a study of self-perception and achievement (Lackaye *et al.*, 2006), adolescents with LDs reported more negative moods, lower self-efficacy in academic and social areas, lower levels of hope, and less investment of effort in their academic work. Importantly, a subgroup of students with LDs who were successful in their studies reported low levels of hope even though they

had similar academic performance as their peers without LDs. In addition, placement in special education impacts individuals with LDs, but results vary. One successful student with LD appreciated special education placement (Miller, 1997). Conversely, in another case study, the participant reported a dislike of special education classes and felt he missed out on many academic opportunities due to the teacher's low expectations (Miller and Fritz, 1998). The acute shortage of qualified special education teachers in urban schools may exacerbate students' feelings of frustration and experiences of ineffective teaching strategies.

The role of community factors in creating resilience in students with disabilities is still not well understood. However, some evidence suggests that supportive adults outside of family and school contexts (e.g., youth leaders and members of church groups) also serve as protective factors, through providing sustained emotional support or serving as role models (Cosden *et al.*, 2002; Garnezy, 1991). Other environmental factors such as having access to opportunities at crucial life transition points were instrumental in successful adult adaptation (Werner and Smith, 2001). For example, opportunities to take college preparation courses, to have a job, and to make a career choice created avenues to transition to adulthood. Community factors such as exposure to violence (Vig, 1996), access to playgrounds and park districts, and availability of medical care are also likely to interact with family and school efforts.

Conclusion

Risk and resilience models for explaining the developmental trajectories of individuals with disabilities hold great promise for improving special education, especially for broadening and enhancing assessment practices. First, this framework moves the field away from the prevailing deficit model that emphasizes the narrow developmental milestones that the child has not achieved. For example, evidence that social competence and positive self-perceptions explain long-term outcomes at least as well as cognitive and academic abilities suggests that more emphasis is needed on the assessment of individuals' personal-social characteristics. Similarly, professionals using a risk/resilience lens are reminded to assess a child within a constellation of individual, family, and school/community characteristics. The identification of protective factors in each of these domains and contexts is at least as important as uncovering the risk factors.

A corollary to this notion is that professionals should avoid unexamined assumptions about what personal or family factors in fact promote risk or resilience. For example, a child with a disability from a low-income environment may be a member of a close extended family whose support counteracts the effects of limited financial

resources. Similarly, the recognition that each student is embedded in multiple contexts opens up the possibility that risk factors in one context may emerge as protective factors in another setting. For example, reticence in a classroom where oral contributions are valued may look like a risk factor, but may emerge as a protective factor in family or community cultural contexts where being quiet is considered a sign of respect to elders.

Reframing the assessment of risk and protective factors surrounding a child with a special need broadens the intervention process. Examining curricula goals through the lens of family and community resources and expectations is likely to help the teacher design more culturally and contextually appropriate tasks and strategies. Similarly, recruiting intervention agents from outside the school opens up other positive human resources, recognizing the multiple contexts that support a student. For example, if there is stress in the parent-child relationship, a supportive neighbor or sibling or coach may be a better choice for helping the child with homework. Importantly, revising teacher preparation programs within risk resilience frameworks will resonate with efforts to enhance culturally responsive pedagogy in today's increasingly diverse society.

School Dropout Prevention

F E Obiakor, University of Wisconsin-Milwaukee, Milwaukee, WI, USA

© 2010 Elsevier Ltd. All rights reserved.

In an ideal world, people would always benefit from a difficult situation and turn it to some personal gain. However, to categorically assume that a person will emerge renewed from a crisis is naïve and ignores the reality of what life crises can do to a person. I do not believe that every life crisis offers a challenge or an opportunity for positive growth experience, a chance to emerge a better and stronger person. In the real world, an event may leave a person changed in ways that could only be construed as adverse. A person's failure to gain strength from such an event reflects the reality of personal experience, not some problem in the attitude or perspective of the person. (Holmes, 1994, p. ix)

Holmes' (1994) statement reflects intriguing realities that human beings endure. Understandably, bad stuff happens to good or bad people – that is the reality of personal experience. Since personal experience is a part of life's reality, blaming the victim can have far-reaching negative psychological and educational consequences (Obiakor *et al.*, 1997). One such consequence is learned helplessness that results in the self-fulfilling prophecy that eats deeper at the resiliency quotient or the inner power of people with and without special needs (Rosenthal and Jacobson, 1968).

Holmes (1994) explained that real-life problems can be temporal or lasting. He indicated:

To efficiently address a temporal real-life problem, the person experiencing the problem and those who are trying to help must deal with the reality of what the person is experiencing. Neither the person nor the helper should approach efforts to resolve distress as if the origin of the problem were psychopathological. It is not. Moreover, life situations outside the person's control may change, the person may learn new ways to cope, or the person may learn ways to change the situation itself. Thus, the possibility of change offers hope of eventual resolution of the problem. Nonetheless, the distress must be endured, and the person's efforts to cope with that distress require support. (p. 4)

He added:

One must keep in mind when considering lasting real-life problems that the psychological and emotional damage of the event has been done; there is no possibility of resolution through any action that might be taken by the person or the helper. However, to say that resolution is not

possible is not the same as saying that there is nothing one can do to help the person deal with conflict and distress. (p. 5)

Clearly, real-life problems affect real people, whether they are young, youthful, or old. However, how we deal with these problems has continued to matter in our families, schools, communities, and nation (Holmes, 1994; Obiakor *et al.*, 1997). Just as grown-ups quit their jobs, divorce their husbands or wives, or engage in strange actions when they feel overwhelmed by life's crises, our children and youth drop out of school and fail to complete their education when confronted with their own life's crises. Rather than make negative judgments and draw illusory conclusions that are based on biological determinism and pathological interpretations (Gould, 1981), general and special educators can creatively help our youth to stay in school, dream big dreams, graduate from school, and become productive citizens. In this article, commonsense approaches to preventing dropout and increasing school completion are discussed.

School Dropout in Context

School dropout and school completion have been burning issues confronting general and special educators and school leaders for a long time. Schools and government agencies have made some efforts to deal with these issues. Consider the following recent examples. The promulgation of the 2001 No Child Left Behind Act (Public Law 107-110) presented an excellent rationale for leaving no child behind and dealing with all educational problems confronting our children and youth. It was supposed to reduce and eliminate the existing achievement gaps between disadvantaged students and, to a large extent, increase institutional accountability for adequate yearly student progress. In 2004, the Individuals with Disabilities Education Improvement Act (2004; Public Law 108-446) was passed to deal with educational problems confronting learners with special needs. While these legislative efforts have created some form of accountability in educational programming, they appear to have "scotched the snake, but not killed it." The goal of educating all learners is still far from reach (Obiakor *et al.*, 2002b).

At present, dropout rates among students with special needs are still high and pervasive. According to

Williams Bost and Riccomini (2006), dropout rates “vary by characteristics such as ethnicity, socioeconomic status, geographical location, and type of disability” (p. 301). Earlier, the US Department of Education (2003) noted that students with emotional and behavioral disorders and students with learning disabilities drop out more than others with disabilities. The intriguing question continues to be, what actually causes school drop-out? In her study, Williams Bost (2007) found some factors that cause school dropout. As she pointed out:

- Problem behaviors coupled with academic difficulties or prior academic failures are key risk factors that are predictive of school dropout.
- The repeated use of exclusionary discipline practices, such as suspension, has been identified as one of the major factors contributing to dropout. Exclusion from class due to disciplinary action also leads to lost instructional time and increased academic difficulties.
- Academic progress and school completion are not equally distributed across disability, income, or ethnicity. Almost half of youth with emotional disturbances drop out. Youth with disabilities from low-income households continue to experience high dropout rates, and Hispanic youth have experienced the smallest improvement in school completion over time.
- High absenteeism and being held back a grade are serious risk factors for dropping out that can be monitored by schools.
- Feelings of isolation and alienation often lead to social and psychological disengagement that result in school dropout. (p. 1)

In addition to the above points, many disenfranchised students (e.g., culturally and linguistically diverse (CLD) students), with and without exceptionalities, drop out of school because of endemic school-related and teacher-related factors such as (1) misidentification, (2) misassessment, (3) miscategorization/mislabeling, (4) misplacement, and (5) misinstruction/misintervention (Obiakor, 2001, 2007, 2008; Obiakor and Beachum, 2005a, 2005b; Obiakor *et al.*, 2002a). There is nothing more frustrating than to be educated in an environment where one is expected to be ‘invisible’ and see himself/herself as a ‘silenced voice’. When CLD students feel unwanted, they perform less and fail to maximize their fullest potential. When expectations are low, inaccurate, or prejudicial, the potential of students is not maximized, and productivity suffers (Obiakor, 1999; Obiakor *et al.*, 2002a). Additionally, when assumptions are negative and based on biological determinism (i.e., genetic superiority or inferiority), underlying pathological deficit-oriented technique is prescribed; and students suffer (see Gould, 1981). It is in the interest of the society to deal with issues of school dropout and school completion.

Consider the following negative consequences of school dropout:

- Dropouts have fewer options for postsecondary education than do students who remain in school. Additionally, only a few dropouts complete a general educational development (GED) within 2 years of leaving high school.
- Dropouts are more likely to be unemployed or employed in low-skilled, lower-paying positions. While initial earning may be comparable between dropouts and graduates, dropouts tend to work more jobs and earn less per hour than graduates.
- Dropouts also experience a ceiling effect in earning power much sooner than graduates.
- Dropouts are more likely to commit crimes as compared to students who complete school. Three to 5 years after dropping out, the cumulative arrest rate for youth with serious emotional disturbance (SED) is 73%.
- Dropouts are more likely than high school graduates to need the support of living with parents in early adulthood, experience health problems, engage in criminal activities, and become dependent on welfare and other government programs. (Williams Bost, 2007, p. 2)

Dropout Prevention to Increase School Completion

It is imperative that school completion be the goal of students, families, schools, communities, and government. To reduce student dropout and increase school completion, all stakeholders must collaborate, consult, and cooperate with each other. In other words, the whole village must work together to enhance school completion. As a result, the CSM is prescribed to connect all stake-holding entities in helping students to complete school (Obiakor, 2001; Obiakor *et al.*, 2002b). The CSM has mutually inclusive elements that are operational when:

- The development and use of identification, assessment, and instructional strategies function within multidimensional and cultural contexts.
- The creation of a collaborative system of community support for families has its guiding principle in the eradication of social stereotyping based on race, ethnicity, national origin, gender, and socioeconomic status.
- The development of an awareness and appreciation for the many family forms values individual differences and strengths.
- The thwarting of conditions leading to violence in the home or the community cultivates a sense of safety for children and families.
- The advocacy for economic policies and human services attests to being pro-family by virtue of proven outcomes.
- The promotion of culturally competent practices in schools and in the larger society respects differences in worldviews and learning styles among individuals.

- The advocacy for expanded services provides for affordable quality childcare to meet the varied needs of all families and children (e.g., infant and adolescent 24-h care and weekend care).
- The development of collaborative community approaches to problem solving involves students, parents, schools, community leaders, and government agencies.
- The recognition that the problem in at-risk situations is not only in the individual but also in institutional barriers in the environment.
- The reconfiguration of curricula eliminates the hidden curriculum and other culturally insensitive curricula variables.
- The reinstitution of rites of passage and service opportunities cultivates a sense of belonging and resiliency in youth.
- The broadening of visions in educational reform includes economic reform and the investment in human capital.

These aforementioned elements must be functional in nature and lead to goal-directed decisions of stakeholders (i.e., students, families, schools, communities, and government agencies). Surely, these stakeholders have to play specific and interrelated roles to maximize the potential for school completion in this age of change.

The Student's Role in Preventing School Dropout

Based on the CSM, the student has roles to play in increasing his/her school completion. This is not the traditional blame-the-victim idea; it is the individual's power and ability to be involved in his/her destiny (Obiakor and Weaver, 1995). There are success stories of persons who have pulled themselves up by their own boot straps, even though some had boots without straps and straps without boots. Since the self is so important in reducing school dropout, students must be taught to be resilient and believe in themselves (Obiakor and Beachum, 2005a). Specifically, they can be taught to:

- develop self-talks and individual plans;
- relax and not jump to conclusions;
- learn to work collaboratively and consultatively with others;
- engage in positive thinking;
- talk with counselors about personal and school problems;
- be a part of school conflict-resolution teams;
- inform adults and parents when situations are not going right;
- manage their time properly;
- respect school regulations and society's laws; and
- utilize mentors from the school and community.

The Family's Role in Preventing School Dropout

Family functioning and parent-child relationships have greater influence in career development than family structure or parents' educational and occupational status (Kerka, 2000). Parents must be proactive, involved, and supportive. Negative home circumstances can affect school performance; and when parents are discouraged in the education of their children, they become unaware of how their children perform. Kerka concluded that proactive families:

- are well-organized, cohesive, and expressive;
- are extroverted and manage conflict positively;
- seek out ways to grow;
- make decisions through the democratic process;
- are sociable;
- encourage individual development;
- are emotionally engaged; and
- are willing to work with their child, school authorities, and community and government agencies.

The School's Role in Preventing School Dropout

Schools have the power to uplift humanity when teachers and service providers are well prepared. Poorly prepared, ill-prepared, or unprepared professionals negatively impact their students. Renschler (1992) agreed that schools can increase students' motivation by implementing policies that promote:

- goal-setting and self-regulation;
- student choices;
- student achievements;
- teamwork and cooperative learning; and
- self-assessment models rather than social comparisons.

Apparently, schools can reduce the failure syndrome (Brophy, 1998) if they are to increase school-completion strategies for students. The failure syndrome can be reversed when schools value their students, collaborate with families, work with community members, and consult with government agencies (King, 2003; Obiakor *et al.*, 2002a; 2002b). For instance, King concluded that teachers and service providers must arrange and modify their classrooms and programs to:

- facilitate on-task behaviors;
- facilitate listening and attending skills;
- facilitate academic performance;
- make implementation of a behavior management system easy;
- allow for large, small, and cooperative grouping and one-on-one instruction;
- have a place for students to relax; and
- provide students with private space. (p. 12)

In addition to the above points, schools must have prudent professionals who can use common sense approaches to solve problems (Algozzine, 1995). These professionals must engage all students with realistic expectations and avoid the myth of socioeconomic dissonance (i.e., when poverty is viewed as the ultimate cause of all students' malaise). Poverty does not mean that students and their parents have poor intelligence, poor self-concept, and poor zest for success (Obiakor, 1999, 2001, 2007, 2008; Obiakor and Beachum, 2005a, 2005b; Utley and Obiakor, 2001). To avoid all forms of prejudicial, xenophobic, and racist actions that force some students to hate school or drop out of school, general and special educators and school leaders must:

- know who they are;
- learn the facts when they are in doubt;
- change their thinking;
- use resource persons;
- build self-concepts;
- teach with divergent techniques;
- make the right choices; and
- continue to learn.

The Community's Role in Preventing School Dropout

The community traditionally houses a wealth of resources that students can access for academic and social development (Ford, 2002). Additionally, students can take advantage of the many learning opportunities that are available within the community (e.g., libraries, museums, schools, jobs, and entrepreneurial offers). Some communities are more forward-looking than others, and some are extremely destructive to their children and youth. Dooley and Toscano-Nixon (2002) concluded that some communities are:

- Dysfunctional and struggling – in such communities, “the problem can be traced back to either the role that community members are playing or the direction that community members are following” (p. 103).
- Borderline – in such communities, “there is universal community participation and the citizens rely heavily on the government to impose changes” (p. 104).
- Conscientious – in such communities, “all members assume their social and moral responsibilities to their community's social and economic growth” (p. 106).

To reduce dropout rates and increase school-completion rates, the goal is to have conscientious communities that:

- develop cutting-edge programs that build capacity for change for students at risk;
- help to build responsible citizens through churches, mosques, synagogues, and community agencies (e.g., YMCA,

YWCA, Boy Scouts, Girl Scouts, Boys and Girls Club, Urban League, to name a few);

- discover softer ways to manage behavior problems and not build jails/prisons to replace schools; and
- have as their slogan, “Together we can make a difference,” and as their principle, “It takes a whole village to raise a child.”

The Government's Role in Preventing School Dropout

Government initiatives (e.g., No Child Left Behind Act and the Individuals with Disabilities Education Improvement Act) have been instrumental in buttressing some levels of accountability in schools and communities. In many cases, they have provided funding to various institutions, school districts, and community organizations to create innovative school-completion programs such as charter, voucher, and choice schools. However, to effectively increase school completion of students, the government must support programs by:

- establishing policies that buttress positive changes and advancements;
- instituting laws that protect its citizens; for instance, due process of students, parents, and teachers must be maintained;
- imposing penalties on institutions that violate the civil rights of students;
- funding research to discover new ways of doing things;
- coordinating conferences that bring professionals and agencies together;
- making programs accountable to their consumers/students;
- assisting institutions in shifting their paradigms and powers; and
- rewarding visionary leaders and programs that do what they are supposed to do.

Conclusion

In this article, it has been argued that everyone goes through some form of crisis. There are apparent and underlying stressors that impinge upon all human activities. While grown-ups lose it and quit their jobs or divorce their husbands/wives, students drop out of school and become societal problems. It is imperative that general and special education teachers, service providers, and leaders build proactive programs that can reduce dropout and increase school completion. Students, parents, teachers, community members, and policymakers must work together for the common good. It is in this spirit that the CSM is prescribed to take advantage of the energies of all stakeholders.

We must avoid unwarranted labels, derogatory categories, and illusory generalizations that disempower students. We strongly believe that disempowered students drop out of school, do not graduate, and get involved in anti-social behaviors. Finally, we must practicalize the Native American proverb, "all the flowers of all the tomorrows are in the seeds of today." In the words of Brooks (1991):

While all students deserve to have their islands of competence displayed and built upon, there is a more urgent need to do so for those students who lack confidence in their ability to learn. If we can reinforce the areas of strength these students possess, my experience has been that we can open the way for a 'ripple effect', where students may be willing to venture forth and confront tasks that have been problematic for them. (p. 32)

School-Based Services for Children with Special Needs

S O Obi, Kentucky State University, Frankfort, KY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Assistive technology – Devices or services to help compensate for an individual's disability.

Cascade of educational services – A range of placement and instructional options for children with disabilities with placement ranging from the general education classroom to special school, residential, home bound, or hospital placement.

Collaboration – Professionals working in partnerships to provide educational services.

Coteaching – General and special education teachers' team teaching.

Due process – Noncourt proceeding before an impartial hearing officer, used when parents and school personnel disagree on a special education issue.

Inclusion – Educating students with disabilities in general education classrooms.

Individualized education program – Management tool to identify and organize needed services.

Individualized family service plan – Identifies and organizes services and resources for infants and toddlers (birth to age three) and their families.

Related services – Special education services from a wide range of disciplines and professions.

Special education – Individualized education and services for students with disabilities sometimes including gifted and talented students.

The Education of All Handicapped Children's Act of 1975 and its reauthorizations and amendments guarantee a free and appropriate public education (FAPE) for all youngsters with disabilities through age 21. Although, some of these laws (e.g., PL 99-457 and PL 101-476) include incentives and mandates for states to implement services for infants, toddlers, and their families, they provide guidelines for assisting high-school students make the transition from school to postschool activities (Smith and Luckasson, 1995). It is common knowledge that special education is based on the individual needs of the student; and it is also clear that individualized instruction is delivered in a wide range of settings, ranging from itinerant teachers, who travel from school to school, to center schools. To a large measure, school-based services are necessary to help students with special needs to maximize their potential. This is the thrust of this article.

School-Based Educational Options

The laws require that students with special needs be educated in the least restrictive environment (LRE). These environments may be:

- *Regular class*. Student remains in the regular class. The teacher and/or student receive assistance from a specialist – itinerant or consultative.
- *Resource class*. Student attends a regular class most of the day but goes to a special education class several hours per day or for blocks of time each week.
- *Special education class (partially self-contained)*. Student attends a special class but is integrated into regular education classes for a considerable amount of time each day.
- *Special education class (self-contained)*. Student attends a special class most of the school day and is inducted into regular education activities minimally.
- *Special education schools (center schools)*. Some private separate school facility, public residential facility serve only students with a specific category of disability. Some offer residential services; others do not.

Apparently, special education services should be flexible and responsive to the needs of the student. Students with special needs should have access to a variety of services, varying by type, intensity, location, personnel, and length of time. For example, in some cases, the regular education classroom can meet the needs of the student with some support from a consulting teacher or specialist (e.g., a speech/language pathologist). At other times, more intense services are required. As long as an array of services is available, students should not be forced to prove themselves at every step of the ladder before finally entering a regular classroom program (see **Table 1**).

Special education is meant for infants, preschoolers, and elementary through high-school students with disabilities, and (in some cases) individuals with disabilities up through the age of 21. In other words, the laws (see the Individuals with Disabilities Education Improvement Act of 2004; IDEIA 2004) require that individualized education plan be provided to all students who are receiving special education services. Clearly, at the heart of individualized programs are individualized education plans (IEPs) for school children ages 3–21 and individualized family service plans (IFSPs) for infants and toddlers (birth through age 2) with disabilities and their families. In some states, the guarantee of an individualized education is

Table 1 Cascade of educational services for students with special needs

Homebound or hospital
Eligible student receives services at home or in a hospital program for a minimum of four consecutive weeks as documented by a physician.
Separate classroom
Student receives special education and related services for most of the day under the direction of a special education teacher.
Student is integrated for some specials on an individual basis.
Separate school
Student receives special education and related services under a specially trained staff in a nonintegrated setting. Student is transported every day.
Residential school
Student receives special education and related services under a specially trained staff. The student actually lives at the school and receives care or services 24 h a day.
Resource room
Student is in a general education setting for the majority of the school day but goes to the special education resource room for specialized instruction for part of each school day.
Regular classroom with supplementary instruction and services
Student receives a prescribed program under the direction of the regular classroom teacher and also receives instruction and related services within the regular classroom from the special educator and/or a parent educator.
Regular classroom with consultation
Student receives a prescribed program under the direction of the regular classroom teacher, who is supported by ongoing consultation from the special educator(s).
Regular classroom
Student receives a prescribed program under the direction of the regular classroom teacher.

extended to gifted students as well, but because gifted students' education is not addressed by federal law, this is not a requirement. IEPs and IFSPs are cornerstones that guarantee appropriate education to each student with a disability. An appropriate education is tailor-made, individually designed, and complete with supportive (related) services. In addition, parents of students with disabilities have important roles to play. For example, they are expected to participate in the development of their children's IEPs. One idea behind the IEP is for parents to become partners with teachers and schools – as a result, many parents and families participate actively in decision making about their child's education. All parents of children with disabilities enjoy the right to due process, procedures to follow when they do not agree with schools about the education planned for or being delivered to their children. Moreover, they are entitled to services not usually offered to parents of typical learners. For example, for infants and toddlers with disabilities (ages birth to 2), parents and their children receive intensive instruction through special education (Smith, 2007).

An important difference between special education and general education is the array of services offered to

students and their families. Special education provides additional services to help students with disabilities profit from instruction. It includes direct services from special education teachers, as well as instruction and therapy from related services professionals – experts from a broad array of disciplines other than education. These multidisciplinary services, in many cases, are what make inclusion possible for many students with special needs, because they provide individualized assistance to them for extended periods of the school day. Three commonly used related services are speech therapy, physical therapy, and assistive technology (AT). Therefore, special education is a comprehensive set of services designed to support the education of students with disabilities. Specifically, special education involves many different professions and specialty areas. When some or all of these related services are enlisted, the result is multidisciplinary teams (i.e., groups of professionals with different areas of expertise who work together to meet the educational needs of each student with a disability) (Smith, 2007).

The overarching purpose of special education is to make it possible for all children with special needs to achieve to their fullest potential so that as adults, they can attain full community presence by holding meaningful jobs and living independently. Inclusive education – that is, participating exclusively in the general education classroom using the general education curriculum – is not necessarily a goal of special education (Kavale and Mostert, 2003). However, too few students with disabilities leave school with a standard diploma; and parents, policymakers, and advocates insist that these students should participate in the general education curriculum and be a part of accountability measures (e.g., state- and district-wide tests) that monitor all students' progress (US Department of Education, 2002). Increased participation in the general education is expected to lead to increased graduation rates. Therefore, beginning with Individuals with Disabilities Education Act (IDEA) '97, extended through No Child Left Behind Act (NCLB) of 2001, and reinforced in Individuals with Disabilities Education Improvement Act (IDEIA) 2004, IEPs must address students' access and participation in the general education curriculum and justify any limitations (Wehmeyer *et al.*, 2003). If a student is removed from the typical general education curriculum, the IEP must specifically explain why the student cannot participate at this particular time (US Department of Education, 2005). As indicated in IDEIA 2004, general education curriculum is not appropriate for all students with disabilities. Some require an alternative curriculum, intensive treatment, or supplemental instruction on topics not available or suitable for instruction in the general education classroom. For example, students with blindness and visual impairments need to master orientation and mobility training and learn job skills in community placements; students with cognitive

disabilities need to learn how to use public skills training students with cerebral palsy might need physical therapy; student with stuttering problem might need speech therapy; students with learning disabilities might need phonics instruction, and so on (Smith, 2007).

School-Based Service Professionals

Many different types of professionals are needed to provide services required by children with special needs. A special education professional might be a paraprofessional (teacher's aide), a resource teacher, a consultant, an itinerant teacher, a special education classroom teacher, a job coach, an AT specialist, a diagnostician, or an administrator. Furthermore, a teacher may assume several of these professional roles during his/her career. In addition, a special education professional might work in a related service as a school psychologist, a speech/language pathologist, an audiologist, an occupational therapist, a physical therapist, a counselor, a nurse or physician, a transportation specialist, or a recreational therapist. The detailed roles of the professionals as indicated in IDEIA 2004 are as follows:

- *Special educator*: One who might be a resource specialist, a consultant, an itinerant teacher, a special education classroom teacher, a job coach, a home or hospital teacher, or an administrator. The skills needed by special educators are many. They must have in-depth knowledge about making accommodations, differentiating instruction, implementing practices validated through rigorous research, monitoring students' progress, and ensuring that every student with a disability receives an appropriate education. Because of the requirements that teachers be highly qualified, co-teaching is gaining in popularity, particularly at the middle- and high-school levels, where meeting the requirements of every core subject area that special educators teach is not possible. Blending the expertise of general education professionals (e.g., math, science, history, and English) and special educators through co-teaching arrangements can make services received truly special (Magiera *et al.*, 2005). Special educators (1) assist with data collection, (2) test effectiveness of educational modifications and accommodations, (3) individualize instruction, (4) apply instruction to small groups, (5) adapt material and instruction, (6) consult with and provide assistance to other educators, monitor progress frequently, (7) determine appropriate adaptations and accommodations, (8) foster parent partnerships, (9) communicate with school personnel about needed accommodations, (10) train and supervise paraprofessionals, (11) advocate for each student with a disability, (12) coordinate students' related services, (13) conduct in-service training sessions about access to the general education curriculum, (14) develop the IEP, and (15) maintain records of accommodations and IEP progress.
- *Assistive technologist*. One who offers high-tech equipment, low-tech aids, and other devices that help compensate for the needs of children with special needs (e.g., speech-to-text translators, holders to keep books open, and wheelchairs).
- *Audiologist*. One who examines hearing losses and auditory problems.
- *Social workers, psychologists, and guidance counselors*. School counselors are related professionals who provide individual counseling, group counseling, guidance, and consultation.
- *Interpreters*. They translate auditory communications into sign language for deaf students.
- *School nurses*. They provide and assist with special health care needs.
- *Occupational therapists (OTs)*. They direct activities that help improve muscular control and develop self-help skills.
- *Orientation mobility specialists*. They teach blind students and students with low vision how to move through environments, and travel safely and efficiently from place to place.
- *Social counselors, parent counselors, and psychologists*. These are service providers who assist parents in preparation for IEP meetings and in becoming more involved in their child's special education programs.
- *Physical therapists (PTs)*. They treat physical disabilities and motor problems through many nonmedical means.
- *School psychologists, clinical psychologist, educational diagnosticians, and psychometricians*. They are service providers who administer psychological and educational tests and interpret results.
- *Speech/language pathologists (SLPs)*. They diagnose and treat problems to the area of speech and language development.
- *Therapeutic physical therapists and recreation specialists*. They assess and provide instruction in leisure skills and recreational activities.
- *Transportation specialists*. They provide travel to and from school, as well as in and around school.
- *School principal*. A key person in the collaborative effort at every school (Praisner, 2003). As principals often coordinate management efforts at their site, they can be most helpful in developing and ensuring the delivery of accommodations and modifications, in monitoring the array of services indicated on every student's IEP, and in ensuring the coordination of services throughout the school and across the district.
- *General educators*. They conduct prereferral assessments, instruction using tactics of varying intensity, instruction

under different conditions, apply instruction to whole class and small groups, ensure maximal access to the general education curriculum by implementing adaptations and accommodations, train and supervise peer tutors, develop and maintain portfolios, implement adaptations and accommodations for testing situations, communicate with parents and families, work in partnership with special education personnel, work with paraprofessionals, participate in IEP meetings, facilitate the scheduling and delivery of related services, maintain anecdotal records, and keep records of accommodations use and effectiveness.

- *Special needs students.* When these students are of age they are involved in the development of their own IEPs. They contribute to their IEP meetings by (1) describing their strengths, weaknesses, and needs; (2) evaluating their progress toward accomplishing their goals; (3) bringing a list of accommodations, and explaining how each is helpful; (4) communicating their preferences and interests; and (5) articulating their long-term goals and desires for life, work, and post-secondary schooling.

As it stands, special education teachers and other professionals and service providers, who work with students with special needs, must collaborate and work cooperatively with professionals from a variety of disciplines, since students with special needs require various combinations of services over their school careers. These teachers, professionals, and service providers collaborate in many areas that touch a child's life. They use collaboration skills when working with parents and families, performing multidisciplinary assessments, working with a team to develop individualized plans, and helping them make the transitions through the school years and from school to work or work to school (Smith and Luckasson, 1995).

Special Education Categories

Through IDEIA 2004 the federal government describes 13 disability categories that can be used to qualify infants, toddlers, preschoolers, and students eligible to receive special education services. Within these categories are many conditions, such as stuttering, included as a speech impairment; or attention-deficit hyperactivity disorder (ADHD), included under the other health impairment category; and Tourette's syndrome, in the government's emotional disturbance category. Moreover, in an attempt to avoid either incorrectly labeling young children as having a disability when they do not or identifying them with the wrong disability, the federal government provides the option of using a general category (non-disability-specific group) for children under the age of

8 (Muller and Markowitz, 2004). Each area of disability, included in the federal regulations governing programs and services for children with special needs, is defined in the following sections.

Mental Retardation (Cognitive Disability)

This is a disability that involves school-age children who are clearly and consistently behind their peers in all areas, including academic, social, language, and self-care skills that it is obvious to anyone who interacts with them that they require special education and related services. Mental retardation (cognitive disability) ranges from mild to severe, but often overlaps with low-incidence disabilities. This condition is manifested during the developmental period. An interdisciplinary team develops a profile of the types and intensity of needed supports.

Specific Learning Disabilities

This is a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written. Academic deficits are the defining feature of learning disabilities. The academic area that poses the most difficulty for most children with learning disabilities is reading. Children with learning disabilities may also have problems with written or spoken language and with math. Some may exhibit visual and/or auditory perceptual disabilities in that they are unable to organize and interpret visual and/or auditory stimuli. Children with learning disabilities are typically inactive learners who lack strategies for attacking academic problems. Two major approaches to the academic problems of students with learning disabilities are cognitive training and direct instruction. For these students who have ADHD, educational approaches should focus on structure and stimulus reduction, behavior modification, cognitive training, and modification.

Emotional and Behavioral Disorders

Emotional/behavioral disorders (E/BD) is a disability characterized by behavioral or emotional responses in school programs so different from age, cultural, or ethnic norms that they adversely affect educational performance. The inappropriate behaviors must be long-standing patterns that occur regularly and often enough as to interfere consistently with the student's own learning process. The two conceptual models that guide most educational programs are the psycho-educational model and the behavioral model. Regardless of the model that guides education, successful strategies must include (1) systematic data-based interventions, (2) continuous assessment and monitoring of progress, (3) prevision for practice

of new skills, (4) treatment matched to the problem, (5) multicomponent treatment, (6) programming for transfer and maintenance, and (7) commitment to sustained intervention.

Autism

Autism is a developmental disorder characterized by significant and pervasive impairment in several areas of development. Autism spectrum disorders (ASD) include five developmental disabilities of childhood: autistic disorder, Asperger syndrome, childhood disintegrative disorder, pervasive developmental disorder, and Rett's syndrome. Children with autism require carefully planned, meticulously delivered, and continually evaluated and analyzed instruction. Successful educational approach must include (1) applied behavior analysis, (2) discrete trial planning (DTT), an important part of applied behavior analysis, (3) picture exchange communication system (PECS), (4) social stories that explain social situations and expected behaviors, and (5) picture activity schedules – a series of images, photos, icons, or video clips depicting activities a child can perform.

Communication Disorders (Speech and Language Impairments)

Speech and language are tools used for communication; speech is the behavior of forming and sequencing the sounds of oral language and language is the communication of ideas. Communication disorders may involve speech or language or both. A speech disorder is an impairment of voice, articulation or speech sounds, and/or fluency. A language disorder is the impairment of comprehension and/or use of a spoken, written, and/or other symbol system and may involve the form, content, and/or function of language. SLPs employ a wide range of techniques for identifying, evaluating, and providing therapeutic services to children. These include (1) structured exercises and drills as well as individual and group therapy sessions, (2) helping children speak as clearly as possible, (3) treating voice disorders medically if the cause is organic, (4) encouraging precommunication activities explore expressive language, and (5) aided or unaided augmentative and alternative communication.

Deafness and Hearing Loss

Children who cannot hear sounds at or above a certain intensity level, 90 db, are classified as deaf and others are classified as hard of hearing. They may require various instructional modifications and related services in order to make full use of their learning opportunities. The three major approaches to teaching deaf and hard-of-hearing students are oral/aural approach, total communication, and

bilingual–bicultural approach. Regardless of instructional approach, the primary objective of all teachers and service providers of students with hearing loss is the development and use of language and communication skills (Heward, 2006).

Blindness and Low Vision

Students, who must learn to read Braille or use aural methods, are classified as blind and those who can read print, even though they may need magnification, have low vision. Many students who are legally blind are not educationally blind because they can read print. Numerous specialized teaching methods and curriculum materials have been developed in an effort to overcome the obstacles to learning presented by blindness and low vision. Advances in instructional methodology and, in particular, technology have greatly increased access to the general education curriculum and academic success among students with visual impairments. Educational approaches must include (1) Braille, (2) standard print prerecorded materials, (3) visual efficiency, (4) approach magnification, (5) optical devices, (6) large print, (7) instruction in orientation and mobility, (8) development of listening skills, and (9) instruction in functional living skills.

Physical Disabilities, Health Impairment, and ADHD

Children and youth with physical disabilities are those whose physical limitations or health problems interfere with school attendance or learning to such an extent that special services, training, equipment, materials, or facilities are required. Some children with ADHD are served under the other health impairments category of IDEA, with the reasoning that their condition results in a heightened alertness that adversely affects their educational performance. However, many children with ADHD are served under other learning disabilities or emotional disturbance. For children whose disability is only physical, curriculum and educational goals should be the same as for their nondisabled peers. The intensive health and learning needs of students require a complex and coordinated array of specialized instruction, therapy, and related services. Many students with physical and health impairments need (1) intensive instruction in a parallel curriculum (Bowe, 2000: 75); and (2) adoptive methods and ATs for mobility, communication, and daily-living tasks.

Developmentally Delayed

Children identified as preschool delayed are those who are ages 3 and 4 or those 5-year-olds who are ineligible for kindergarten and whose development and/or behavior is so significantly delayed or atypical that special education and related services are required.

Low-Incidence Disabilities (Severe/Multiple Disabilities, Deaf-Blindness, and Traumatic Brain Injury)

Multiple disabilities make up concomitant impairments (mental retardation–blindness, mental retardation–orthopedic impairment, etc.), the combination of which causes such severe educational problems that they cannot be accommodated in special education programs solely for one of the impairments. The term does not include deaf–blindness. Most students with severe disabilities exhibit extreme deficits in intellectual functioning. Many need special services and supports because of motor impediments; communication, visual, and auditory impairments; and medical conditions such as seizure disorders. Contemporary curriculum content for students with several disabilities is characterized by its focus on functional skills that can be used in immediate and future domestic, vocational, community, and recreational/leisure environments (Heward, 2006). Some students with severe disabilities use augmentative and alternative systems of communication (AAC), such as gestures, pictorial communication boards, and electronic communication aids.

Transitioning Students to Adulthood: Beyond Narrow Confines

Transition from school to life in the community has become the most challenging issue in special education today. Models for school-to-adult-life transition stress the importance of a functional secondary school curriculum that provides work experience in (1) integrated community job sites, (2) systematic coordination between school and adult service agencies, (3) parental involvement and support, and (4) a written individualized transition plan (ITP) to guide the entire process. Secondary school programs can enhance the competitive employment prospects for young adults with disabilities by (1) stressing functional, vocational skills; (2) conducting school-based instruction in integrated settings as much as possible; and (3) beginning community-based instruction as early as age 12 for students with severe disabilities.

AT places an important part in the transition of students with special needs. AT is any item, piece of equipment, or product that is used to increase, maintain, or improve the functional capabilities of children with special needs. It is common knowledge that many students need AT to transition from school to work, and vice versa.

Conclusion

Special education comes into consideration when a student is suspected of or has been identified as having

behavioral, emotional, sensory, or other disability that requires school-based services. This article has addressed the cornerstone for appropriate school-based services and school-based professional for children with special needs.

Self-Determination

Glossary

Autonomous functioning – Autonomy means, literally, self (*auto*) rule or law (*nomos*). A behavior is autonomous if the person acts (1) according to his or her own preferences, interests, and/or abilities and (2) independently, free from undue external influence or interference.

Decision making – The process of making a judgment about which of several options is the best option given one's circumstances.

Problem solving – The act of identifying and explicating a problem (e.g., a situation or event for which one does not know a solution), and selecting alternatives that address the event or circumstance.

Psychological empowerment – The multiple dimensions of perceived control, including cognitive, personality, and motivational domains of perceived control. People acting in a psychologically empowered manner do so on the basis of a belief that (1) they have control over circumstances that are important to them (i.e., internal locus of control); (2) they possess the requisite skills to achieve desired outcomes (i.e., self-efficacy); and (3) if they choose to apply those skills, the identified outcomes will result (i.e., outcome expectations).

Self-determination – The volitional actions that enable one to act as the primary causal agent in one's life and to maintain or improve one's quality of life.

Self-realization – A process whereby people use a comprehensive, and reasonably accurate, knowledge of themselves and their strengths and limitations to act in such a manner as to capitalize on this self-knowledge and self-awareness.

Self-regulation – The process of setting goals, developing action plans to achieve those goals, implementing and following action plans, evaluating outcomes of action plans, and changing action plans, if the goal is not achieved.

The international literature in special-needs education documents that an effective education for students with disabilities must include instruction to promote student self-determination. Research has linked higher self-determination to positive adult outcomes, including employment and independent living, for youth with special

educational needs (Emerson *et al.*, 2001; Wehmeyer and Palmer, 2003; Wehmeyer and Schwartz, 1997), as well as to a higher quality of life (Lachapelle *et al.*, 2005; Nota *et al.*, 2007; Wehmeyer and Schwartz, 1998). Further, most school standards for all students include a focus on skills leading to enhanced self-determination (e.g., goal setting, problem solving, decision making, self-advocacy, self-management, and others) and when instruction is available school-wide to address these component elements, all students benefit (Wehmeyer *et al.*, 2004). Finally, there is evidence that students with special educational needs can acquire the knowledge and skills to become more self-determined if provided such instruction (Algozzine *et al.*, 2001). The purpose of this article is to introduce the self-determination construct to educators working with students with special educational needs and to identify instructional and assessment strategies that enable teachers to promote self-determination.

What is Self-Determination?

There are now numerous frameworks that serve as a basis for instructional design to promote self-determination (Wehmeyer *et al.*, 2003), as well as specially designed instructional methods, materials, strategies, and assessments to promote and measure self-determination (Wehmeyer *et al.*, 2007; Wehmeyer and Field, 2007). The framework that guides the presentation of relevant interventions in this article is based on a model of self-determination (Wehmeyer *et al.*, 2003) in which self-determined behavior refers to "volitional actions that enable one to act as the primary causal agent in one's life and to maintain or improve one's quality of life" (Wehmeyer, 2005: 117). An act or event is self-determined if the individual's action reflects four essential characteristics: (1) the individual acted autonomously, (2) the behaviors were self-regulated, (3) the person initiated and responded to event(s) in a psychologically empowered manner, and (4) the person acted in a self-realizing manner. Self-determination refers to self- (vs. other) caused action to people acting volitionally, based upon their own will. The word volitional is defined as the act or instance of making a conscious choice or decision. Conscious means intentionally conceived or done – deliberate. Volitional behavior, then, implies that one acts consciously – with intent. Self-determined behavior is volitional and intentional, not simply random and nonpurposeful.

The concept of causal agency is central to this perspective. Broadly defined, causal agency implies that it is the person who makes or causes things to happen in his or her life. One frequent misinterpretation of self-determination is that it means 'doing it yourself'. When self-determination is interpreted this way, however, there is an obvious problem for most students with special educational needs, who frequently have limits to the number and types of activities they can perform independently. However, the capacity to perform specific behaviors is secondary in importance to whether one is the causal agent (e.g., caused in some way to happen) over outcomes those specific behaviors are implemented to achieve. Thus, students who may not be able to independently make a complex decision or solve a difficult problem may be able, with support, to participate in the decision-making process, and thus have the opportunity to be the causal agents in the decision-making process, and consequently, act in a self-determined manner.

Wehmeyer *et al.* (2003) have argued that self-determination emerges across the life span as children and adolescents learn skills and develop attitudes and beliefs that enable them to be causal agents in their lives. These skills and attitudes are referred to in this model as component elements of self-determined behavior, and include choice making, problem solving, decision making, goal setting and attainment, self-advocacy, and self-management skills.

Factors That Contribute to Self-Determination

Self-determination can be impacted by environmental and intra-individual factors. The following section discusses these factors.

Environmental Factors Related to Self-Determination

Research internationally has consistently and repeatedly shown that environments in which adults and youth with disabilities live, learn, work, and play affect opportunities for them to become self-determined. This research has shown that adults with disabilities who live or work in more congregate or restrictive settings have fewer opportunities to make choices and decisions, to self-advocate, and to set goals (Duvdevany *et al.*, 2002; Emerson *et al.*, 2001; Tossebro, 1995; Stancliffe *et al.*, 2000; Wehmeyer and Bolding, 1999).

Intra-Individual Factors Contributing to Self-Determination

There are some data pertaining to the contribution of individual characteristics, including intelligence level,

age, gender, and adaptive behavior, on self-determination. Stancliffe *et al.* (2000) found that self-determination competencies (skills) and levels of adaptive or challenging behaviors were significant predictors of the expression of self-determination, with the former predicting higher self-determination and the latter (challenging behavior) lower self-determination. Like other factors discussed in this section, the relationship between self-determination and adaptive or challenging behaviors seemed to be mediated by the degree to which these factors related to variables such as where one lives or works and/or the choice opportunities one has. For example, in a UK sample, Perry and Felce (2005) found that objective measures of choice were positively correlated with adaptive-behavior scores. In addition, data pertaining to differences in self-determination by gender are found to be limited and mixed. Soresi *et al.* (2004) found, in an Italian sample, that adolescent males tended to have higher self-determination scores than females. Alternatively, Wehmeyer (1996) and Wehmeyer and Garner (2003) examined the self-determination of large samples of adolescents with cognitive disabilities, and found no significant differences between males and females on overall self-determination scores, although females scored slightly higher than their male counterparts. The relationship between gender and self-determination is, almost certainly, a function of societal norms and gender roles and expectations and not a function of any true intra-individual factor. As to the impact of age on self-determination, Wehmeyer and Garner found that age did not predict the membership of adults with developmental disabilities in a high or low self-determination group. In a sample of students aged 15–18 years, though, Wehmeyer (1996) found a consistent trend for higher self-determination scores as a function of increased age. In general, as children age and have increased opportunities to assume responsibility for their lives, they will have increased opportunity to become more self-determined. Although people continue to become more self-determined as they grow older, at some point that steady growth in self-determination levels off.

Research has consistently documented a statistically significant relationship between self-determination and intelligence level, as measured by intelligence quotient (IQ) scores (Wehmeyer *et al.*, 2003), with that relationship between measured self-determination and IQ scores ranging between $r = 0.15$ and 0.20 . It stands to reason that if one has greater capacity to solve complex problems, make decisions, and figure out the means to achieve goals, one will have greater capacity to act in a self-determined manner. What is surprising is that the relationship between IQ and self-determination, while statistically significant in large sample studies, remains practically insignificant. Once again, though, the relationship between self-determination and intelligence is complex. Wehmeyer and Garner (2003) conducted a series of

analyses to determine predictors of self-determination, autonomy, work setting (competitive vs. congregate), and living arrangement (independent vs. congregate) for individuals with intellectual disability. Only choice opportunity (from among four variables, including IQ score) predicted self-determination, while everything except IQ scores predicted autonomy level, with higher perceptions of choice opportunity being the most powerful predictor. Level of IQ was, however, the most significant contributor to employment and living outcomes, with IQ the only significant predictor for the former (work) and self-determination and autonomy also significant predictors of more positive living outcomes. In other words, IQ level predicted where people would live or work, but was not a predictor of whether they would be self-determined. Only choice opportunities predicted the latter, a finding consistent with the previously reviewed literature on the relationship between choice and environment.

Finally, self-determination has been linked by research to a more positive individual quality of life. Wehmeyer and Schwartz (1998) found that self-determination status predicted membership in a high quality of life group for adults with developmental disabilities. Lachapelle *et al.* (2005) examined the relationship between self-determination and quality of life for a larger sample of adults with disabilities in Canada, United States, Belgium, and France, and found that self-determination predicted membership in the high self-determination group, and overall, self-determination and quality of life were significantly correlated ($r = 0.49$). Similarly, Neely-Barnes *et al.* (2008) found that community-based living arrangements and greater opportunities to make choices were associated in a sample of adults with developmental disabilities, and these were, in turn, associated with greater quality of life.

Importance of Self-Determination to Students with Special Educational Needs

Self-determination is important to students with special needs because instruction to promote self-determination is a means to greater access to the general education curriculum and because students who are more self-determined achieve more positive adult outcomes. These points are discussed in the following section.

Improving Access to General Education

An important benefit of promoting self-determination is that it provides a means to ensure that students receiving special educational services in general education classroom settings can become involved with the general education curriculum. Wehmeyer *et al.* (2004) identified two ways that this occurs. First, by identifying where in the general education curriculum all students are expected to

learn skills and knowledge related to the component elements of self-determined behavior, teachers can promote self-determination and promote access to the general education curriculum. Second, teaching students with disabilities the skills they need to become more self-determined – problem solving, goal setting, decision making, and self-directed learning skills – provides students with valuable skills to enhance their academic performance. Students who are more self-determined – who learn to effectively set learning goals and objectives to reach those goals and then use problem-solving and self-regulation skills to tackle the activities to achieve those goals – will ultimately be able to perform, academically, more successfully.

There are now multiple studies confirming that student-directed learning strategies can be taught to enable students with special educational needs to self-direct learning in the general education classroom (Agran *et al.*, 2003; Wehmeyer *et al.*, 2007). Studies have also tested the impact of interventions to promote self-determination on student progress on goals derived from the general education curriculum. For example, Palmer *et al.* (2004) examined the attainment of goals linked to science, social studies, or language arts standards for middle school students with intellectual disability. Students were taught to self-direct learning to address a goal derived from the state standard in each content area that emphasized a self-determination focus. Students were able to achieve educationally relevant goals tied to district-level standards at expected or greater than expected levels, thus supporting the suggestion that instruction in self-determination can serve as an entry point to the general curriculum for students with disabilities.

Increasing Positive Adult Outcomes

The impact of student self-determination on more positive adult outcomes, including employment, independent living, and community inclusion, has been a principal factor in the growing emphasis within special needs education on promoting self-determination. There are a number of studies that provide evidence of the relationship between self-determination and more positive student outcomes. Wehmeyer and Schwartz (1997) and Wehmeyer and Palmer (2003) measured the self-determination of students with cognitive disabilities and then examined adult outcomes both at 1 year and 3 years after high school. Students in the high self-determination group were twice as likely as youth in the low self-determination group to be employed 1 year out of school and earned, on average, more than students in the low self-determination group who were employed. One year after high school, students in the high self-determination group were disproportionately likely to have moved from where they were living during high school, and by the third year they were still disproportionately likely to live somewhere other than their high school

home and were significantly more likely to live independently. For employed students, by the third year, those scoring higher in self-determination made statistically significant advances in obtaining job benefits, including vacation, sick leave, and health insurance, an outcome not shared by their peers in the low self-determination group. Earlier, Sowers and Powers (1995) showed that students with disabilities involved in instruction to promote self-determination increased their participation and independence in performing community activities. In summary, there is an expanding base of evidence suggesting that higher self-determination and increased capacity in the component elements of self-determined behavior results in better educational and adult outcomes for youth and young adults with special educational needs.

Strategies for Promoting Self-Determination

As noted previously, Algozzine *et al.* (2001) revealed that there are a number of empirically validated methods and strategies that enable students with special educational needs to acquire skills and knowledge pertaining to component elements of self-determined behavior. These behaviors help these students to self-regulate learning and improve overall self-determination. Following are sections that discuss these strategies.

Goal Setting

Having the skills to set and attain goals is central to one's self-determination. The process of promoting goal-setting skills involves working with students to help them learn to: (1) identify and define a goal clearly and concretely, (2) develop a series of objectives or tasks to achieve the goal, and (3) specify the actions necessary to achieve the desired outcome. At each step, students must make choices and decisions about what goals they wish to pursue and what actions they wish to take to achieve their goals. Goal-setting activities can be easily incorporated into a variety of educational activities and instructional domains, as well as in educational planning, as discussed subsequently. Research has suggested some strategies to make goals both meaningful and attainable for students with disabilities. First, goals should be challenging. If they are too easy, there is no motivation to do the work to attain them, nor is there a feeling of accomplishment after achieving them. Second, while it is preferable for students to set their own goals, if this is not possible and goals need to be set by teachers, then the students' preferences and interests should be incorporated into the goal to increase the students' motivation to pursue the goal. In the end, goals with personal meaning are more likely to be attained.

Choice Making

Choice making is simply the expression of a preference between two or more options. Opportunities to make choices should be infused throughout a student's day, as experiences with making choices teach students that they can exert control over their environment. Students can be provided opportunities to choose within or between instructional activities, choose with whom they engage in a task, where they engage in an activity, and if they complete an activity at all. Some students may need to learn how to make choices, particularly if the students' previous opportunities to do so have been restricted. Further, choices can be made more meaningful for students by involving them in decisions about what, how, and why they learn. Research has found that when students with disabilities are provided opportunities to make choices, reductions in problem behaviors and increases in adaptive behaviors are observed (Shogren *et al.*, 2004).

Problem Solving

A problem is an activity or task for which a solution is not known or readily apparent. The process of solving a problem involves: (1) identifying and defining the problem, (2) listing possible solutions, (3) identifying the impact of each solution, (4) making a judgment about a preferred solution, and (5) evaluating the efficacy of the judgment. Research not only shows that students with disabilities generate fewer potential solutions to problems and have greater difficulty solving more complex problems (Gumpel *et al.*, 2000), but also that students benefit from instructional efforts to promote this outcome (Crites and Dunn, 2004). Developing skills associated with social problem solving may be particularly important for students with disabilities. Research suggests that students with autism, for example, may have difficulty understanding social and emotional cues, which limit their ability to interact with others, but, again, interventions have been shown to be effective in improving problem-solving skills for this population (Bauminger, 2002).

Decision Making

Decision making involves coming to a judgment about which of a number of potential options is best at a given time. Making effective decisions involves: (1) identifying alternative courses of action, (2) identifying possible consequences of each action, (3) assessing the probability of each consequence occurring, (4) choosing the best alternative, and (5) implementing the decision. Working to promote systematic decision-making skills is best addressed at the secondary level, while at the elementary level a focus on choice making and problem solving can support the development of effective decision-making

skills later in life. When teaching decision-making skills, opportunities to make decisions should be embedded in the curriculum. By supporting students to make decisions in real-world situations, they will better develop their ability to conceptualize and generalize the decision-making process. The process of evaluating alternatives is an area in which direct instruction should occur; students can be provided support to (1) develop lists of decision options, (2) evaluate the risk and benefit associated with a given alternative, and (3) evaluate biases in their decision making. Students often evaluate risk somewhat differently than adults, perhaps because they see the excitement of risk as positive, rather than negative. However, by teaching students how to evaluate and conceptualize risk, both in terms of short-term and long-term consequences, these biases can be reduced.

Self-Regulation

Self-regulation involves student-directed learning. It is the process of setting goals, developing action plans to achieve those goals, implementing and following action plans, evaluating outcomes of action plans, and changing actions plans, if the goal was not achieved (Mithaug, 1993). Since self-regulation involves the use of student-directed learning strategies, students can be taught to self-regulate, self-direct, or self-manage their behaviors through external operants, such as visual or audio/verbal prompts or self-recording devices, or through internal operants, such as self-instruction, self-monitoring, self-evaluation, or self-reinforcement (Agran *et al.*, 2003). When students are taught and provided opportunities to use self-directed strategies, it gives them more control over initiating tasks, moving through task sequences, evaluating their success on the task and then reinforcing themselves for task completion. These strategies can be applied to academic, vocational, community participation, and functional curriculum goals and objectives.

One of the first steps in teaching a student a new skill or behavior is to have a clear plan of the steps and sequence of the task, as well as the cues and stimuli that occur naturally within the task or learning situation. Built within the context of a task analysis, this plan should map out the “instructional cues or directions, setting, teaching and task materials, opportunities for choice making and prompts and procedures for fading prompts, and consequences” (Snell and Brown, 2000: 151). Such strategies are called antecedent cue-regulation strategies. These are frequently combined with self-instruction strategies, in which the goal is to move toward self-instruction where the student is taught to verbalize cues that direct or maintain his or her own behavior (Agran *et al.*, 2003). Another strategy, self-monitoring, involves teaching a student to track his or her progress toward a goal, followed by a self-evaluation of that progress. Typically, a student uses

a checklist of steps or set of criteria that have been provided in advance to observe and monitor progress. For example, Sands and Doll (2005) recommended the use of self-monitoring as a support to goal setting and attainment and described several methods where students can track their progress through the use of rubrics, graphs or charts, a series of audio prompts, and checklists. These same tools can be used to teach students to self-record progress. When a desired behavior or skill involves a series of steps, each step may serve as a natural cue, which then serves as a catalyst for the student to take the subsequent step. Finally, self-evaluation is a summative process whereby students judge the progress toward their goal and the quality of their work. If they determine they have achieved their goal, they can use self-reinforcement strategies. With self-reinforcement, they are involved in identifying and administering their own consequences for having successfully completed a target skill or behavior. In other words, a student is taught how to reward herself for a job well done or to recognize errors that need to be addressed and corrected.

Self-Advocacy

Students with disabilities need to learn to advocate on their own behalf. To be an effective self-advocate, students have to learn both how to advocate and what to advocate for. There are ample opportunities for students to practice and learn self-advocacy skills within the context of the educational planning process. Too often, students’ perspectives have been lost, because students have not had opportunities or skills to express their perspectives within educational planning and decision-making meetings. A first step to enabling them to express their wants and needs during these meetings is educating them about their rights and responsibilities in these areas. Instructional strategies have been developed for teaching such knowledge to students with disabilities (Wehmeyer and Field, 2007). When teaching students how to advocate for themselves, the focus should be on teaching them how to be assertive, how to effectively communicate their perspective (either verbally or in written or pictorial form), how to negotiate, how to compromise, and how to deal with systems and bureaucracies. Students need to be provided real-world opportunities to practice these skills. This can be done by embedding opportunities for self-advocacy within the school day, by allowing students to set up a class schedule, work out their supports with a resource room teacher or other support provider, or participate in individual education plan (IEP) and transition meetings.

Self-Awareness and Self-Knowledge

The final component elements of self-determined behavior focus on the attitudes, beliefs, and perceptions that

enable people to act in a self-determined manner. Students need to develop perceptions of efficacy, along with self-awareness and self-knowledge, to give them the motivation and confidence to practice the skills discussed above. Research has shown that students with developmental disabilities tend to have less-adaptive perceptions of efficacy and outcome expectations than do students without disabilities (Wehmeyer *et al.*, 2003). For students to become more self-determined, they must possess a reasonably accurate understanding of their strengths, abilities, unique learning and support needs, and limitations. Further, they must know how to utilize this understanding to maximize success and progress.

Instructional Models, Curricular Materials, and Assessments to Promote Self-Determination

The Self-Determined Learning Model of Instruction (SDLMI) (Wehmeyer *et al.*, 2003) is an instructional model that has been shown to be effective in promoting self-determination and student-directed learning. The SDLMI is a model of teaching based on the component elements of self-determination, the process of self-regulated problem solving, and research on student-directed learning. Implementation of the model consists of a three-phase instructional process. Each instructional phase presents a problem to be solved by the student. The student solves each problem by posing and answering a series of four student questions per phase that students learn, modify to make their own, and apply to reach self-selected goals. Each question is linked to a set of teacher objectives. Each instructional phase includes a list of educational supports that teachers can use to enable students to self-direct learning. In each instructional phase, the student is the primary agent for choices, decisions, and actions, even when eventual actions are teacher directed. The student questions in the model are constructed to direct the student through a problem-solving sequence in each instructional phase. To answer questions in this sequence, students must regulate their own problem solving by (1) setting goals to meet needs, (2) constructing plans to meet goals, and (3) adjusting actions to complete plans. As noted, each instructional phase poses a problem the student must solve (What is my goal? What is my plan? What have I learned?), by solving a series of problems posed by questions in each phase. The four questions differ in each phase, but represent identical steps in the problem-solving sequence: (1) identify the problem, (2) identify potential solutions to the problem, (3) identify barriers to solving the problem, and (4) identify consequences of each solution. The solutions to the problems in each phase lead to the problem-solving sequence in the next phase.

The teacher objectives within the model are objectives that teachers intend to accomplish by implementing the model. In each instructional phase, the objectives are linked directly to the student questions. These objectives can be met by utilizing strategies provided in the educational supports section of the model. The emphasis in the model on the use of educational supports that are student directed provides another means of teaching students to teach themselves. As important as this is, however, not every instructional strategy implemented will be student directed. There are circumstances in which the most effective instructional method or strategy to achieve a particular educational outcome will be a teacher-directed strategy. Students who are considering what plan of action to implement to achieve a self-selected goal can recognize that teachers have expertise in instructional strategies and take full advantage of that expertise.

As indicated, the aforementioned strategies are to be infused into instruction across the curriculum. There are, however, several curricular materials and assessments available that provide direction for teachers seeking to promote student self-determination. A comprehensive examination of these curricular materials is beyond the scope of this article. Test *et al.* (2000), however, conducted an extensive review of existing curricular materials to promote self-determination and located 60 such products. Reviews and information about most of these procedures are available online and, as such, readers are referred to that resource for greater detail on the array of materials available. Further, a number of assessments exist to enable teachers to assess student needs with regard to instruction in self-determination. Most of these are available online through the Zarrow Center at the University of Oklahoma.

Another instructional focus that has emerged as important to promoting self-determination entails encouraging student involvement in educational planning and decision making, as discussed previously. Involvement in education planning, decision making, and instruction can take many forms, from students generating their own educational goals and objectives, to tracking their progress on self-selected goals or objectives, to running their own educational planning meeting. It is important to emphasize that it is not what the student does in the meeting that is critical, but, instead, the degree to which the student is an equal partner in and, to the greatest extent possible, in control of his or her planning. Students with severe disabilities can be involved in their educational program every bit as much as students with less-severe disabilities. Student involvement may look very different in these cases, and students with more severe disabilities may not be able to make independent decisions or solve problems, but that is not the criteria by which we should judge student involvement. It is, instead, the degree to which the student is actively engaged and empowered in his or her planning and education program. Clearly, there are

multiple advantages to student involvement. Test *et al.* (2004) reviewed studies examining efforts to promote student involvement, and concluded that there was clear evidence that such efforts enhanced student involvement in educational planning. In addition, student involvement in the educational process is a good way to teach and allow students to practice skills important to self-determination (i.e., goal setting, decision making, and/or negotiation), self-advocacy, leadership, and teamwork. There are several programs designed to promote student involvement, and information about them can be found in the section titled 'Relevant websites'.

Conclusion

Promoting self-determination has become best practice in the education of students with disabilities. Those students who leave school as self-determined young people achieve more positive adult outcomes. Moreover, promoting student self-determination provides, as it were, a gateway to the general education for students with disabilities, and can result in enhanced learning skills. This article overviewed the methods, materials, and strategies to achieve the outcome that enables students with and without disabilities to become more self-determined. If educators are to achieve the outcomes most envisioned for their students, they will need to ensure that students with disabilities are provided sufficient opportunities to learn these skills and strategies, and to use them to play a meaningful role in their educational programs, from planning to implementation.

Social Competence

Social competence is a topic of increasing importance to many professionals in the field of education and rehabilitation. Social competence refers to the social, emotional, and cognitive skills and behaviors that young adults need for successful social adjustment in school and beyond. Over the years, research has suggested that an individual's social and emotional adjustment, academic and cognitive development, and sense of citizenship are enhanced by opportunities to strengthen social competence during his/her youth (Hartup and Moore, 1990; Kinsey, 2000; Ladd and Profilet, 1996; McClellan and Kinsey, 1999; Parker and Asher, 1987; Rogoff, 1990). The ability to successfully engage socially with peers and significant others (i.e., parents, teachers, and counselors) is an essential part of a student's development (Gresham *et al.*, 2001). Further, school success and academic success have been related to levels of social competence. Simply stated, social competence plays a critical role in a student's ability to flourish and navigate the complexities of the school, family, and work (Brown and Heath, 1998). This is the focus of this article.

For many students, particularly those with high-incidence disabilities, the area of social development presents ongoing challenges (Gresham *et al.*, 1997). It has been suggested that children with mild disabilities experience lower levels of social skills, adaptive behavior, and peer connections. As noted by Elliott and Gresham (1991), young persons lacking social skills have fewer interactions with their typical peers resulting in negative relationships. Elksnin and Elksnin (1998) asserted that students who are unsuccessful in learning suitable social skills have a lower probability of finishing their education, obtaining employment, and attaining stable adulthood. Social problems have also been cited as key factors in job loss for persons with disabilities (Hagner *et al.*, 1992).

While the issue of social competence is indeed a crucial one, there is no single factor that can sufficiently describe a person's social competence (Brown and Heath, 1998). Social competence involves the ability to apply social aptitudes and behaviors across a variety of settings and involves social skills, adaptive behavior, motivation, and interpretation of the social situation (Elksnin and Elksnin, 1998). The socially competent student possesses a range of skills that enables him/her to interpret his/her social setting, react to social cues and contexts, and achieve positive outcomes in situations. Elksnin and Elksnin noted social competence entails more than social skills; the interpretation of the social context and recognition of the expectations

and norms of the situation are integral and critical components of social competence.

Social Competence versus Social Skills

In the past, the distinctions between the constructs of social skills and social competence have been blurred, as they have been used interchangeably. While both social skills and social competence are interrelated, they are not indistinguishable (McFall, 1982). The term social competence, in contrast to social skills, refers to a broad construct that includes both adaptive behaviors (social skills) and an evaluative component that judges those specific behaviors in a given context (Gresham, 1982). Evaluation of social competence, as recommended by Gresham (1986), should involve:

1. pertinent judgment of a student's social actions by significant persons (e.g., peers, teachers, and family);
2. assessment of social behaviors according to a defined set of conditions; and
3. social actions compared to specific norms (e.g., social skills rating scale).

While social competence is connected to the concept of social skills, the distinctions are significant. Social skills refer to specific behaviors utilized within a specific social activity or interaction (e.g., greeting another person and taking turns). Social skills are behaviors that can be acquired through instruction and then performed in completing a task. In contrast, social competency centers on the evaluation of social outcomes, and based on a judgment of how well the individual has performed the social behavior in a specific situation (McFall, 1982). Thus, the success of social performance depends on not only the behavioral aspect (what the person did) and the environmental aspect (when, where, and with whom did it occur) but includes the evaluation by others. Thus, the success of social interaction results not only from knowledge of specific social skills but also from the understanding of the norms, roles, demands, and expectations of a given context. Social competence encompasses a person's ability to (1) possess specific social skills in his/her repertoire, (2) evaluate a given situation as to the social criterion and expectations, and (3) know when and how to use those social skills within a given context. In sum, social competence reflects the ability to use social skills based on a person's perceptions and understanding of the social environment (Smith *et al.*, 2006).

Perspectives on Social Competence

Historically, numerous conceptualizations of social competence have been described throughout the literature. Greenspan's (1981) characterization of personal competence asserts that the construct of personal competence is characterized by three domains:

1. academic competence,
2. social competence, and
3. physical competence.

For children with mild disabilities, issues related to academic and social abilities have the most salience, while students with more significant disabilities (e.g., severe and profound mental retardation) or health-related impairments (e.g., cerebral palsy and traumatic brain injury) experience more challenges in physical competence (Gresham *et al.*, 1997). Earlier, McFall (1982) noted that social competence, while closely related to social skills, has distinguishable differences. Social skills are discrete behaviors employed by an individual in completing social tasks, whereas social competence derives from the evaluation of an individual's performance based on a social agent's judgments. These judgments may be based on opinions of significant others (e.g., teacher, parents, and peers), as to whether the social task was performed adequately in comparison to explicit criteria (e.g., number of social interactions initiated based on an expected criterion). McFall's view of social competence considers social skills to be specific behaviors which result in judgments of social competence. Thus, social skills are behaviors, and social competence represents a judgment about those behaviors.

Social competence has been viewed from the perspective of social validity. A person can be seen as socially competent if exhibiting socially acceptable skills that achieve the desired, valid social outcomes in a given context (Gresham, 1982). Within the framework of social validity, social competency can be characterized as socially significant behaviors exhibited in specific situations which predict important social outcomes for children and youth (Gresham, 1983; Gresham and Elliott, 1990). Socially significant behaviors signify behaviors that significant persons in the situation (e.g., parents, teachers, and peers) consider valuable and desirable and which predict socially important outcomes – these outcomes represent outcomes that others consider valuable, adaptive, and useful. They are also outcomes which improve a person's ability to function in social settings. Outcomes considered socially important may include peer acceptance (McConnell and Odom, 1986; Parker and Asher, 1987) and teacher and parental acceptance (Gresham and Elliott, 1990). Gresham and Reschly (1988) conceptualized social competence as a multidimensional construct that includes adaptive behavior, social skills, and peer-relationship variables (e.g., peer acceptance, friendship, and peer rejection). This conceptualization is similar to

Gresham's earlier (Gresham, 1983) social validity definition of social skills. According to this definition, social skills are those behaviors which, within certain situations, predict important social outcomes for children and youth. In school settings, important social outcomes might include:

1. peer acceptance,
2. significant others' positive judgments of social competence,
3. academic achievement,
4. adequate self-concept,
5. positive attitudes toward school, and
6. freedom from loneliness.

This definition has the advantage of specifying behaviors in which children and youth may be deficient and relating these deficiencies to socially important outcomes in school settings. Vaughn and Hogan (1990) proffered an additional model of social competence. While similar to previous interpretations, they consider the role of higher-order thinking within the concept of social competence. Within their model, social competence is a complexity of four factors: (1) pro-social interactions with peers, (2) correct social awareness/perceptions; (3) lack of maladaptive behavior, and (4) successful social skills. Under this model, socially competent individuals would experience peer status, friendships, and positive family interactions. Individuals would demonstrate age-appropriate levels of interpersonal problem solving, self-monitoring, and self appraisal of their social capacity. Social competence results from the interaction and correlation between the four components, thus no one element by itself can accurately describe a student's social competency (see Vaughn and Hogan, 1990).

The Role of Social Competence in Disability Classification

As stated earlier, making distinctions between social competence and social skills is vital as the two constructs play a pivotal role in defining specific disabilities, such as serious emotional disabilities (SEDs) or learning disabilities. Increasingly, the classification of students with high-incidence disabilities has relied on the construct of social competence as a decisive factor in the determination of disability. Current criteria used in classifying mental retardation (cognitive disability) consider the significance of both cognitive and social competence as having similar influence (Gresham *et al.*, 1995). Deficits in social competence are viewed by some as key determinants in classifying students with emotional disorders (Forness and Knitzer, 1992) as well as students with specific learning disabilities (ICLD, 1987) and attention-deficit hyperactivity disorder (ADHD; Barkley, 1990). According to criteria listed in the Individuals with Disabilities Act (IDEIA), students with SED lack the ability to develop or sustain acceptable social connections with

their peers or adults and in typical situations experience uncharacteristic emotions. Recently, the position among many professionals, government groups (e.g., Interagency Committee on Learning Disabilities), and professional organizations (e.g., NJCLD), is that deficits in social competence and social skills constitute a specific learning disability (Gresham *et al.*, 1997).

Students with mild disabilities have frequently been recommended for evaluation for special education services due to the teacher's perceptions that they do not meet acceptable expectations or standards for social behavior (Gresham *et al.*, 1997). Teachers typically expect and tolerate a level of behavior that conforms to their notions of teachability (Hersh and Walker, 1983). A teachability profile signifies those patterns of social behavior that include absence of disruptive behavior, compliance, as well as academic related (e.g., attention to task and listening). In addition, schools may view such students as resistant to intervention in the course of determining their eligibility for special education (Gresham, 1991). Since the goal of any intervention is to create a positive change in a target behavior, resistance to intervention would indicate that a given intervention has failed to produce such change.

Socially Competent Behavior

In reviewing the literature on social-behavioral competence in school settings, students with disabilities are characterized as facing challenges as they attempt to navigate social behavior expectations in two domains: adult/teacher relation and student/peer relation. Regarding adult/teacher interactions, students with disabilities must understand and meet the social standards of the school and classroom environment. In terms of peer relationships, students with disabilities must adjust their social behavior so that it meets the standards for peer acceptance and results in friendship (Walker *et al.*, 2004). Social competence includes pro-social behaviors that promote the student's ability to interact and develop positive relationships with others. Pro-social behaviors include flexibility, empathy, caring, communication, and humor (Bernard, 1991). Earlier, Hazel *et al.* (1981) assert that prosocial competencies demand that a person possess prosocial skills and in a given situation, understand what behavior is required.

There is a difference between being popular and having friendships. According to Welsch and Bierman (1998), while some individuals are outgoing and have many friends, others may be shy and are happy with one or two good friends. They suggest that three characteristics be considered when assessing social competence:

1. the nature of the individual's social behavior (e.g., are they aggressive, bossy, disruptive, or impulsive);
2. the way in which students are perceived by peers (e.g., are they disliked, teased, ostracized, or ignored); and

3. the stability and duration of peer problems (e.g., are the problems with peer relationships short term).

Assessment of Social Competence

The value of any assessment process lies in its validity. In turn, valid assessment should generate accurate decisions about a student's behavior, and in turn produce beneficial results (Walker *et al.*, 2004). A principle purpose of assessment is to assist in developing appropriate intervention strategies that will improve social behavior. According to Gresham (1982), assessment of social competence examines three primary factors: (1) assessment of person's social actions based on views of significant others, (2) appraisal of social behavior according to set standards, and (3) actual performance of social behaviors. Underlying every valid assessment process are key assumptions that serve as the basis for the process. Depending upon the context of the situation, expectations, and a student's acculturation, students will frequently differ from their peers in terms of their behavior. In addition, assessments represent samples of a student's behavior and no singular assessment can provide adequate information about the student's status (Witt *et al.*, 1998). Decisions should be based on a collection of information from multiple sources about behavior patterns, and include environmental information. As Walker *et al.* (2004) noted, assessment information should be "multimethod, multi-agent, and multisetting in nature" (p. 85).

Different assessment methods have been used to identify and classify social skill deficits. Gresham and Lambros (1998) described assessment approaches as either direct or indirect. Direct assessment techniques evaluate behavior in real time in the actual, natural setting. Structured observation of a student's behavior in his/her natural surroundings at school or home would be a typical type of direct assessment. Indirect approaches examine behavior out of context and away from the actual time of occurrence. These approaches include the use of behavioral rating scales or interviews by teachers or parents. Social skills assessment should be approached in a systematic, thoughtful manner. While different sources have suggested a range of stages and goals for social skills assessment, three major goals emerge as a guide for the process:

1. problem identification – this examines strengths, competing problems, deficit acquisition, performance, and fluency;
2. problem analysis includes functional behavioral analysis, targeting behaviors, and determining social validity; and
3. treatment evaluation involves assessment of outcome measures and generalization and maintenance of intervention outcomes (Gresham, 2001; Walker *et al.*, 2004).

Techniques for evaluating social behaviors may involve a range of commonly used approaches that vary according

to the purpose and desired outcomes of the assessment. Major categories of assessment procedures include (1) behavior rating scales, (2) social skills rating scales, and (3) functional behavioral assessment (FBA). Behavior rating scales are one common method frequently used by parents and teachers to evaluate a student's behavior. They are considered by some as more cost effective, reliable, and objective when compared with other forms of assessment (Gresham and Elliott, 1990). Social skills rating scales (SSRSs) examine specific social skills behavior that measure the rater's perceptions of the student's skills across various social domains. While a number of rating scales are available, some are considered more user friendly and based on standardized samples (Walker *et al.*, 2004). Two frequently used tools include the SSRS (Gresham and Elliott, 1990); and the Walker–McConnell Scales of Social Competence and School Adjustment (SSCSA) (Walker and McConnell, 1995). The central purpose of an FBA is to identify the function or cause of a student's target behavior and to subsequently teach him/her an acceptable replacement behavior that will meet the student's needs. The primary goal is to determine the specific communicative intent of a behavior for a student through observation, interviews, and review of relevant information (O'Neill *et al.*, 1997). FBA emphasizes examination of the environmental factors that may elicit unacceptable behavior (target behaviors) and may reveal what outcomes student receives as a result of exhibiting those behaviors. FBA would then provide support by teaching positive alternatives that would achieve the same results.

While a variety of assessment methods are utilized to evaluate social competency in terms of social skills and social literacy, Strichter *et al.* (2007), in their review of recommended practices, noted that an array of formal and informal tools should be used.

Employing multiple measures of social functioning can provide the types of information needed to make both data-based decisions as well as provide a complete description of intervention efficacy (Bryan, 1997).

Interventions to Increase Social Competence

Before interventions can be identified, it is important to conduct a social autopsy where an adult assists an individual to improve social skills by jointly analyzing social errors he/she makes and designs alternative strategies (Lavoie, 2005). Once the skill of social competence has been identified, strategies for remediation can be identified. These strategies for increasing social competence differ depending upon the age of the individual. One strategy involves social skill training (SST) to teach individuals verbal and nonverbal ways of interacting in social

situations. This training can be done either with a small group of students or using video modeling. Clearly, it helps the individual to learn to interpret the subtle cues involved in social interaction. Finding a good social niche for the individual is critical in SST. Often large, unstructured settings (e.g., recess, study hall, and lunch) are particularly difficult situations for students who have difficulty with social skills. More structured, smaller peer-interaction setting where adults can support and guide positive peer interaction generally work best.

SST is considered an effective approach to increasing social competence for students who are socially at risk (Bullis *et al.*, 2001). SST, if implemented in a structured, systematic, and ongoing manner, can assist students who demonstrate social skills acquisition and/or performance deficits. It is important to remember that not all children demonstrate social competence or incompetence in all settings. This is why it is essential to complete an accurate social skills assessment that will identify specific social problems. SST may be conducted at a universal level (all students in a group, classroom, or school) or at an individual level. Universal SST strategies may include class-wide social skills programs or school-wide positive discipline approaches where all students are taught the same skills in the same manner. Such methods strive to promote positive behaviors, minimize unacceptable behaviors from developing, and create positive school climates.

Conclusion

It is important to note that social skills vary as do the strategies depending upon the age of the student. Developmental changes occur in the structure and quality of peer interactions which affect the complexity of skills contributing to social competence. The ways in which children spend their time changes with age. As children grow, their preferences for play change, as well as the thinking and language skills that provide a foundation for social competence also change (Welsch and Bierman, 1998). As teachers and service providers, we need to understand each child and what he/she needs to interact socially and competently in our changing society.

Societal interest in individuals with high aptitudes, gifts, talents, and extraordinary abilities dates back thousands of years – perhaps, as early as 3000 BC. In Western cultures, interest in superior abilities of individuals was stimulated by the works of Charles Darwin and Sir Francis Galton in the 1800s. Lewis M. Terman – a noted psychologist and influential pioneer in the field of gifted education – conducted a comprehensive research study of gifted individuals, in the 1920s, that drew attention to the identification, education, and nurturing of students with gifts and talents. Leta Stetter Hollingworth – another influential pioneer – taught the first course for gifted students and published the first textbook in the field of gifted education.

Concepts such as gifted and talented have been closely linked with intelligence. This thinking went into high gear, during the early 1900s, when French Psychologists Alfred Binet and Theodore Simon were commissioned to construct a test that provides a means for schools to determine the educability of students on the basis of intellectual ability. While the terms gifted and talented are, often, used interchangeably throughout the literature, there are some conceptual differences between these two. Gagné (1985; 1991) differentiated the concepts by defining giftedness as above-average competence in natural, untrained, spontaneous, and human ability (aptitude, intellectual, or creative abilities) and talent as above-average competence in an area or field of human activity (e.g., mathematics or music) which manifests itself when the individual engages in systematic learning, training, and practicing.

It was the 1957 launch of the space capsule Sputnik by the Soviet Union that stimulated momentum in the gifted-education movement in the United States. This historical event was viewed as a risk to national security. It not only provoked the United States to rethink the quality of American schooling, but also led to the passage of the National Defense Education Act in 1958, the appropriation of federal funding for the establishment of programs for gifted students, the development of ways to identify students with superior abilities and high academic achievements (particularly in math and science), and research to identify effective methods for providing quality educational experiences to gifted students.

During the late 1960s, emphasis on the education of gifted students shifted and took a back seat to civil rights and antipoverty movement concerns on educational equity and the improvement of schools for at-risk students. In 1970, the United States Congress commissioned

a study to examine the needs of gifted students – which resulted in the highly acclaimed 1972 Marland Report. This report provided impetus for the first direct assistance to gifted education and the establishment of the US Office of the Gifted and Talented. National interests in the education of students with gifts and talents led to the establishment of the World Council for Gifted Children, which was formed in 1975. In 1981, the US Department of Education created a National Commission on Excellence in Education to examine the quality of education in American Schools. In its 1983 report, national concerns for the problems afflicting American education were once again renewed. This groundbreaking study recommended the development of a set of standards for the identification and provision of enriched and accelerated programs for students who are gifted and talented. Consequently, in 1988, Congress passed the Jacob K. Javits Gifted and Talented Student Education Act, which provided financial support and resources for the Office of Gifted and Talented Education – a national research center focusing on gifted children, and demonstration projects in gifted education. In addition, in 1990, a National Center on Gifted and Talented was established. This center – comprised of a consortium of universities – addresses research needs in the field.

In 1993, the second national report on the status of educating gifted and talented students was issued by the US Department of Education, Office of Educational Research and Improvement. This report described the state of gifted education as being a quite crisis and identified a number of indicators that pointed to the need of America to change the way it educates gifted and talented youth and those with the potential for high abilities. In addition, the report found that gifted education still suffered from (1) a lack of highly qualified teachers, (2) questionable methods for identifying gifted students, (3) weak curriculum standards, (4) limited learning opportunities for disadvantaged and minority children, and (5) a failure of the educational system to challenge gifted and talented youngsters to work to their full potential. In 1994, the Jacob K. Javits Act was reauthorized, but the funding appropriated was significantly reduced as a result of Congressional party changes and differing political and philosophical views of its constituents. In 2001, the Javits Act was again reauthorized. This reauthorization was contained in the No Child Left Behind Act of 2001 (NCLB, P. L. 107–110) – formerly known as the Elementary and Secondary Education Act

(ESEA) – and signed into law by President George Bush on 8 January 2002. NCLB is a historic law that was enacted to eliminate the achievement gap that exists among students in US schools and ensure that children of all racial, ethnic, cultural, and socioeconomic backgrounds, and children with exceptional learning needs (e.g., children with disabilities and those with gifts and talents) have a fair, equal, and significant opportunity to obtain a high-quality education, and be taught by highly qualified teachers.

Definitions of Gifted and Talented

Over the years, many theorists, psychologists, researchers, and practitioners not only grappled with the concept of giftedness but also proposed numerous definitions of giftedness, yet, none has been universally accepted as a standard definitional criterion to describe the extraordinary gifts, remarkable talents, outstandingly high level of abilities and potentialities of children and youth. Problems associated with the definition of giftedness stem from multiple sources, including (1) differing theoretical views on giftedness; (2) the wide range of characteristics associated with children having extraordinary skills, abilities, aptitudes, and talents; (3) the varying definitions of giftedness (e.g., psychometric definitions, trait definitions, educationally oriented definitions); (4) the variance across cultures as to what is considered giftedness; (5) the various terminologies used; and (6) ongoing research in the field (Daniels, 2003).

The first federal definition of giftedness was introduced in the Marland Report. This report, commissioned by Congress in 1972, identified six categories of giftedness, encouraged schools to define giftedness broadly (i.e., to extend beyond intellectual ability), and provided the catalyst for the development of a US Office of Gifted and Talented. The report also served as the foundation upon which gifted educational programs are built. According to the Marland Report

Gifted and talented children are defined as those identified by professionally qualified persons who by virtue of outstanding abilities, are capable of high performance. These are children who require differentiated educational programs and/or services beyond those normally provided by the regular school program in order to realize their contribution to self and society. (p. 2)

The report added

Children capable of high performance are those who demonstrate any of the following abilities or aptitudes, singly or in combination in any of the following areas: (1) general intellectual ability, (2) specific academic aptitude, (3) creative or productive thinking, (4) leadership ability, (5) visual and performing arts aptitude, and (6) psychomotor ability. (p. 2)

The most current federal definition of giftedness can be found in the NCLB Act. Under this law,

The term “gifted and talented”, when used with respect to students, children, or youth, means students, children, or youth who give evidence of high achievement capability in areas such as intellectual, creative, artistic, or leadership capacity, or in specific academic fields, and who need services or activities not ordinarily provided by the school in order to fully develop those capabilities (Title IX, Part A, Section 9101(22), p. 1959).

While federal definitions of giftedness have been criticized over the years (e.g., not providing school districts with the specificity necessary to guide professionals in the identification of students with gifts and talents; emphasizing performance as the defining characteristic of giftedness; not placing an emphasis on observable behaviors), many school districts still base their definition of giftedness on federal definitions (Daniels, 2003). Perhaps, the most influential contemporary definition of gifted is that proposed by the National Center for Gifted Children (NCGC) – an organization composed of parents, teachers, educators, other professionals, and community leaders. As the NCGC pointed out

A gifted person is someone who shows, or has the potential for showing, an exceptional level of performance in one or more areas of expression. . . . Some of these abilities are very general and can affect a broad spectrum of the person's life, such as leadership skills or the ability to think creatively. Some are very specific talents and are only evident in particular circumstances, such as a special aptitude in mathematics, science, or music. The term *giftedness* provides a general reference to this spectrum of abilities without being specific or dependent on a single measure or index

The NCGC further stated

A person's giftedness should not be confused with the means by which giftedness is observed or assessed. Parent, teacher, or student recommendations, a high mark on an examination, or a high IQ score are not giftedness; they may be a signal that giftedness exists. Some of these indices of giftedness are more sensitive than others to differences in the person's environment.

Thus, definitions of giftedness can reflect a broad array of purposes. They may be used to (1) identify and count children to establish prevalence estimates; (2) diagnose, label, and place students in specially designed accelerated or enrichment programs; (3) enable professionals, parents, and others to communicate effectively with regard to students who have high abilities or talents; (4) serve as a medium to establish priorities for funding educational or support programs; and (5) facilitate legislative efforts on behalf of gifted and talented individuals (Daniels, 2003).

Prevalence, Characteristics, and Etiology of Giftedness

Determination of prevalence estimates for children with gifts and talents can be quite challenging. The complexity is due, in part, to variations among state definitions of giftedness in terms of the children to whom they apply, state laws and local policies governing the identification of students for gifted and talented programs, and the availability of funding for such programs. Problems with determining prevalence are, further, exacerbated by the forms of giftedness and talents being considered, the traits of giftedness being assessed, the minimum threshold for intellectual quotient (IQ), and the political, educational, and societal landscape of the times. Although prevalence estimates for children with gifts and talents are highly variable, the NCGTC estimated that approximately 5% of the student population (or 3 million children) in the United States are gifted.

The study of giftedness encompasses both children and adults and it involves the investigation of both cognitive and affective attributes. Much of the research on giftedness (e.g., Clark, 2008; Daniels, 2003; Friend, 2005; Glass, 2004; Hallahan and Kauffman, 2003; Smith, 2004) describes gifted and talented children as manifesting a wide range of abilities – including accelerated cognitive abilities, a phenomenal memory, and excellent recall. These children also have the ability to quickly acquire, retain, conceptualize, synthesize, learn new information, and easily process and manipulate large amounts of information. In addition, children with gifts and talents are very curious and highly inquisitive. Not only do they enjoy learning, but they also have a strong desire to learn and an intense need for mental stimulation. They have a strong need to pursue their own interests, a capacity for seeing unusual and diverse relationships, and an unusual ability to think abstractly. Clearly, they possess superior problem-solving skills, can easily apply and transfer knowledge to new situations, and show an interest in a wide range of topics and disciplines. They are able to expand their understanding of concepts in a number of ways, including their ability to connect with other ideas (e.g., see the relationship between concepts or through their understanding of the perspectives of others). They are also persistent and goal directed. They are capable of learning more rapidly than their peers and are knowledgeable concerning things at a much earlier age. They learn to speak early and can talk in sentences using complex sentence structures before the age of 2 or 3.

Apparently, children with gifts and talents have highly receptive vocabularies and come to school reading significantly beyond their chronological age-mates. Many possess advance verbal abilities, extensive vocabularies, and vivid imaginations. Because of their unique abilities, they often require accelerated instruction and sophisticated instructional materials. In addition, they are highly motivated and

extremely independent. Many are recognized by their teachers for their superior achievement in one or more academic domains (e.g., reading, math, science). These children like to take risks and have a high tolerance for ambiguity. They have a strong dislike for drill-and-practice activities and are easily bored and impatient with routine tasks. In addition, they find conventional instructional practices less motivating, less challenging, and less rewarding. Similar to students with disabilities, there exist both inter- and intraindividual differences in their performance. Despite their high levels of intelligence, some possess high levels of creativity – particularly in the visual and performing arts – while others demonstrate outstanding leadership and psychomotor abilities.

Children who are gifted and talented display unique social and emotional characteristics (Clark, 2008; Daniels, 2003; Friend, 2005). They hold high expectations of themselves, possess a keen (sometimes subtle) sense of humor, and have a strong sense of self-awareness. These children strive for perfection, are highly focused, and experience enormous stress from failure. They possess high morals, have a strong sense of justice, and are sensitive to the feelings and needs of others. Additionally, they display high energy levels in their work and play which can, sometimes, be misinterpreted and misdiagnosed by psychologists and other health professionals as a form of hyperactivity or an emotional or behavioral disorder. The most common misconception with regard to gifted children is that they lack social and emotional competence (Clark, 2008). While there are some gifted and talented children who feel different, have low self-esteem, or are misunderstood or socially isolated, most are well-adjusted, sensitive, healthy, emotionally independent, and stable individuals who are well liked by their peers (Clark, 2008) and who possess emotional traits that are well balanced.

It should be noted that the characteristics presented, in this article, are only examples of attributes of children with gifts and talents and should not be considered as exhaustive. Not every child identified as gifted or talented will display all of these traits. Given what is known about human development and the role of the environment, it is not surprising that giftedness is considered to result from genetic and environmental influences (Daniels, 2003; Friend, 2005). While it is, generally, believed that genetic makeup plays a more important role than the environment in the development of gifts and talents, the effects of environmental influences (e.g., family, school, home, community) on the development of one's potential should not be underestimated.

Identifying Gifts and Talents

Students with gifts and talents can be found across all racial, ethnic, cultural, linguistic, socioeconomic, and

even disability groups (Clark, 2008; Daniels, 2002). What remains a salient and prominent concern is how to accurately identify these students, particularly those from underrepresented populations (i.e., at risk students, racial and ethnic minority students, students from economically depressed or low-socioeconomic backgrounds, students with limited English proficiency; Callahan, 2005; Daniels, 2002; Ford, 1998; Ford *et al.*, 2008). Although there are procedures required by federal law for identifying students with disabilities, such procedures are nonexistent for students who are gifted and talented (Friend, 2005).

Despite the fact that culturally, linguistically, and ethnically diverse students make up a substantial percentage of the school-age population in US schools, they still constitute a small proportion of the students in gifted and talented programs. Data by the National Academy of Sciences (Donovan and Cross, 2002) on the representation of minority students in gifted and special education report that, while there is considerable variation among states in how they identify and classify students for giftedness, students that comprise some of the racial/ethnic groups still continue to be less likely to be in gifted programs compared to their white counterparts. Possible causes of racial/ethnic disparities among students in gifted programs include (1) lack of incentives or opportunities, (2) lack of teacher recruitment and referrals, (3) poor IQ-test performance by students from cultural and linguistically diverse backgrounds, and (4) deficit thinking orientations (Ford *et al.*, 2008). In addition, disparities occur because of (1) inadequate opportunities for talent development, (2) inadequate or one-shot paper-and-pencil assessments, and (3) policies and procedures that interfere with the funding of gifted programs and the identification of students from underserved populations (Callahan, 2005). To a larger degree, disparities occur because of (1) inadequate screening procedures and identification tools, (2) the lack of authentic and multidimensional assessments, and (3) the lack of a universally accepted definition of giftedness (Daniels, 2002). They also occur because of (1) differences in states criteria for giftedness, (2) limited language development, (3) learning-style differences, and (4) teacher quality (Donovan and Cross, 2002). Gender is another area in which disparities occur in gifted and talented programs. Girls – compared to boys – are less likely to be recognized or identified as gifted. While there has been a gradual increase in the number of girls identified as gifted in recent years, they are still underrepresented in gifted and talented programs. Factors that contribute to the under identification of girls in gifted and talented programs can be attributed to a number of variables, including societal and cultural stereotyping of the roles of girls, biases related to sex roles, and teacher biases about the areas of academic achievement for boys (e.g., math, science, technology) versus that of girls (e.g., English, reading, writing, the arts; Friend, 2005; Smith, 2004).

Because of wide-ranging attributes of giftedness and biases inherent in the identification process, the assessment of children for gifts and talents should be conducted by a group of professionals representing different areas of expertise, and be comprised of multiple criteria, multiple assessments, multiple approaches, and multiple sources of information derived from both quantitative and qualitative sources. In addition, they should include carefully selected formal and informal measures that do not discriminate against students who differ from the mainstream (i.e., students from economically disadvantaged backgrounds, at-risk students, and students with disabilities and gifts). Procedures for identifying children for gifted and talented programs, generally, comprise five basic steps – screening, referral, assessment, classification, and placement. Among assessment tools commonly used to identify gifted children (or children with potential gifts and talents) are intelligence tests; achievement tests; divergent thinking and creativity tests; aptitude tests; nonverbal ability tests; personality inventories; scales on leadership; alternative or performance-based assessments; teacher, self, parent, peer, and community nominations; students' grades, portfolios, work samples, and products; in-school and outside-of-school observations; checklists and rating scales; and recommendations of professional artists (Clark, 2008; Daniels, 2003; Friend, 2005).

A number of factors can inhibit or impede the identification of gifted children and children with the potential for giftedness (e.g., Callahan, 2005; Clark, 2008; Daniels, 2003). Among school-related factors are boredom, poor teaching, poor educational experiences, limited learning opportunities, the teacher's inability to recognize gifted behaviors of students, inappropriate curricula, teacher quality, lack of use of culturally responsiveness practices in teaching, limited use of positive reinforcement, and lack of consideration of students' learning styles. Among the environmentally related factors are unfavorable environmental conditions, poverty, limited-to-no access to community resources, and substance abuse. Family-related factors that can adversely affect the identification of gifted children include poor healthcare, family disorganization, single-parent families, insufficient infant stimulation, lack of exposure to books and other educational experiences, abuse, neglect, and drugs.

Educational Considerations for Students with Gifts and Talents

Educational placement alternatives for students with gifts and talents – and those with the potential for giftedness – can range from very restrictive (e.g., special schools, self-contained classrooms, home schooling), partially restricted (e.g., resource rooms and pull-out programs), to very inclusive settings (e.g., traditional schools and general education

classrooms). The types of placement alternatives for the delivery of educational services can vary from state to state as well as within individual school districts. Educational programs should stimulate the development of students' actual and potential abilities as well as their skills, creativity, and talents. The two approaches most widely used to deliver instruction to these students are enrichment and acceleration. Enriching the content of instruction (enrichment) incorporates many creative and innovative strategies. It includes additional topics and activities, expanding the study of a specific topic in more depth than is typically pursued in the traditional curriculum, using new curriculum strategies and techniques, having the student engage in independent study, providing the student with access to a mentor who shares similar interests, and participating in internship programs that allow for firsthand experiences in the profession or area of interest. Acceleration enables students to learn and progress at a rate commensurate with their abilities. This approach can take on a variety of forms. It includes early entrance to kindergarten and early entrance to college, grade-level advancement (i.e., grade-skipping), taking high school classes while in middle school, taking honors and advanced placement (AP) classes while in high school, taking advanced courses by correspondence or via the Internet, enrolling in extra courses for early graduation, using technology resources, and enrolling in intensive summer programs or summer institutes.

Ability grouping – another approach to teaching students with gifts and talents – has been used in schools for over a decade. This approach involves the placement of two or more students with comparable abilities (who can keep pace with each other) into small informal groups for subject-matter instruction. Curriculum compacting is another way in which teachers can meet the needs of these students. It involves streamlining lessons by eliminating the coverage of content, concepts, or topics the student already knows, has mastered, or is capable of mastering in a fraction of the time that is required by peers, and the reallocation of that time to other enrichment activities. It is important to keep in mind that all programs for students with gifts and talents, irrespective of grade level or how they are structured, must provide what Clark (2008) described as differentiated instruction to allow for (1) flexibility in teaching, (2) multiple venues for students to reach their learning potential, (3) continuous measures to assess progress, (4) activities that lead to intellectually stimulating peer interactions, (5) continuity, and (6) teachers with specialized training on gifted learners.

Conclusion

Societal interest in persons with gifts and talents – including those with extraordinary abilities or aptitudes – dates back thousands of years, and it is unlikely that

interest among this population will change anytime soon. Although children with gifts and talents exist across all racial, ethnic, cultural, linguistic, socioeconomic, and disability groups, what remains a salient concern is how to accurately identify them – particularly those from at-risk and underrepresented populations. Despite the fact that children with gifts and talents share many characteristics (e.g., cognitive, academic, social/emotional characteristics) commonly cited throughout the literature, much discussion still exists with regard to definitions of giftedness and the representation of minority students in gifted education programs. While there are a number of factors that underscore minority student representation, researchers are still grappling with factors that are known to influence their identification and visibility within the schools. Factors that appear most prevalent are test bias, gender bias, teacher quality, the lack of culturally responsive teaching practices, a lack of use of instructional practices directed toward students' learning styles, and limited learning opportunities or opportunities to demonstrate giftedness. Although educational placement alternatives and enrichment programs for children with gifts and talents vary widely, discussions about these types of programs tend to be relatively well received and less controversial in nature.

Transition from School to Adult Life

M J McCollin, Slippery Rock University of Pennsylvania, Slippery Rock, PA, USA

F E Obiakor, University of Wisconsin–Milwaukee, Milwaukee, WI, USA

© 2010 Elsevier Ltd. All rights reserved.

The transition from birth to childhood, through adolescence, and then to adulthood is a turbulent and sometimes unconventional evolution all people experience with varying degrees of achievements and challenges. This transition involves several interrelated events, role changes, and behavioral adjustments linked with many person-centered life occurrences (e.g., beginning school, puberty, search for independence, search for autonomy, graduating from secondary school, employment, family, social relationships, and growing older) that occur throughout adult life. Transition to the complexities of adulthood can be challenging for most young adults.

Many students with disabilities have difficulty in successfully making the transition from adolescence to adulthood and then from school to work. Sometimes these students (1) do not graduate; (2) encounter great difficulty in finding and maintaining suited employment; (3) exhibit high levels of unemployment or underemployment; (4) are socioeconomically unstable; (5) have limited access to community resources; (6) are involved with the justice system; (7) do not receive postsecondary training; and (8) become dependent on their families or government programs (Hallahan and Kauffman, 2003; Halpern, 1994; Rusch and Chadsey, 1998; Sands and Wehmeyer, 1996; Wehman, 2001). Overall postschool outcomes for students with disabilities are substandard. Research has found that students with severe and multiple disabilities and those with emotional behavioral disorders typically have poorer outcomes compared to those with specific learning disabilities or speech and language impairments (Rampey *et al.*, 2009). Therefore, in preparing students with disabilities for continued education, adult responsibilities, independence, and employment, transition planning must also include strategies (e.g., self-determination and self-advocacy), for successfully negotiating the challenges, concerns, and uncertainties of adulthood. To ensure successful functioning in adulthood, these strategies should be acknowledged, considered, and addressed within the context of the transition plan so that students with disabilities are able to competently deal with the challenges of life (Patton and Dunn, 1998; Smith *et al.*, 2004; Wehmeyer *et al.*, 1998). This is the focus of this article.

Historical Overview of Federal Transition Services Legislation

In 1976, the Vocational Education Amendments (P.L. 94-482) established the need for collaboration among

vocational education and other job-training programs as well as increased funding for vocational-education programs and youth with disabilities. During the mid-1980s, the Carl D. Perkins Vocational and Technical Education Act (P.L. 98-524) further provided resources for young people with disabilities to successfully prepare for transition from secondary education to the world of adulthood. The act was passed to

assure that individuals who are inadequately served under vocational education programs are assured access to quality vocational educational programs, especially individuals who are disadvantaged, who are handicapped, men and women who are entering non-traditional occupations, adults who are in need of training and retraining, individuals who are single parents or homemakers, individuals with limited English proficiency, and individuals who are incarcerated in correctional institutions.

Since 1983, there has been a legislative prioritization regarding transition services for students with disabilities. P.L. 94-142 was amended with a new Section 626, entitled Secondary Education and Transition Services for Handicapped Youth to authorize federal grants to support the coordination of educational and adult transitional service programs for youth with disabilities. The 1990 amendments of IDEA, continued federal support for transition-related activities, refined transition services, and mandated that student interests, preferences, and needs be considered when developing transition plans. Moreover, IDEA required that the Individualized Education Program (IEP) for students ages 16 and older take into consideration specific transition components (i.e., transition services and inter-agency collaborations). The 1997 amendment of IDEA produced the most significant mandates related to special education legislation: (1) the expansion of the transition requirements regarding age at which services were to be introduced on the IEP, and more importantly (2) the significance of postschool outcomes for students with IEPs. The most recent reauthorized IDEA 2004 further defines transition services as a coordinated set of activities for a student with disability that:

- is designed to be within an outcome-oriented process, which promotes both academic and functional achievement in an effort to facilitate the movement from school to postschool activities, including postsecondary education, vocational education, integrated employment (including supported employment), continuing

and adult education, adult services, independent living, or community participation;

- is based on the individual student's needs, taking into account the student's capacity, access to support and resources, preferences, and interests; and
- includes instruction, related services, community experiences, the development of employment and other postschool adult living objectives, and when appropriate, acquisition of daily living skills and functional vocational evaluation. (H.R. 1350, Sec 602[34]).

As a result of the significant prioritization of transition services for students with IEPs, there has been considerable improvement of postschool outcomes and student skill development (Wehmeyer, 1998).

Transition Planning

The skill sets needed to successfully navigate adulthood in the twenty-first century is much more complex and comprehensive than those required by previous generations. Today's young adults must not only contend with challenges of employment, family life, leisure, and recreation, health and quality of life, but also with access to technology and community resources, interagency collaboration, and self-determination. Adulthood means being an active, contributing, and independent member of the community and greater society. Independence for an adult includes the ability to participate in society, work, have a home, autonomy, self-respect, raise a family, and share the joys and responsibilities of community life (Neubert, 2003). Adults with disabilities face numerous obstacles within the context of their daily living that affects not only their ability to access and use community resources but also limits the opportunities they have for social interaction and self-fulfillment (Heward, 2008). Therefore, transition planning is a critical aspect for successful navigation of adult life. Paramount to transition planning are the concepts of collaboration and interagency communication. These concepts are important and comparatively new to special-education service providers (Heward, 2008). Transition planning is conceptualized as the coordination, delivery, and transfer of services from the secondary school program to receiving agencies (e.g., employers, postsecondary education and vocational training programs, and residential service providers).

Effective transition planning must have a student focus, involve parents and families, and foster interagency and interdisciplinary collaboration. Within the context of student-focused planning, students have an opportunity to strengthen and develop self-determination and self-advocacy skills through practice and implementation. Paramount to student-focused planning is the development of a student's self-awareness which directly impacts

educational decisions. A self-aware person is able to take into consideration his/her own goals, vision, and interests when making educational decisions (Kohler and Field, 2003). An important strategy to help students identify their interests and preferences is to provide them with interdisciplinary curricular experiences so that they are able to (1) reflect on their experiences, (2) derive meaning particular to their context, and (3) use that information for future decision making (Kohler and Field, 2003).

Parental and Family Involvement

Parental or family involvement is a critical aspect of successful transition planning. It involves the development of participation and role, empowerment, and training of family members; hence allowing families the ability to actively participate in the decision-making processes for their family members is critical. Family involvement has been shown to (1) improve school attendance, (2) improve student's self-esteem and confidence, (3) reduce dropout rates, and (4) improve student autonomy – a critical aspect of self-determination (Sands and Wehmeyer, 1996). Student-focused planning is extended and supported through parent or family involvement.

Collaboration and Consultation

Collaboration and communication between and among professionals and families are key to effective transition planning. In special education, collaboration and consultation are important in the planning and delivery of transition services to secondary students with disabilities. Although interagency cooperation is critical to the success of transition, the amendments to IDEA made it clear that the initial and most significant transition responsibilities lie with schools (Heward, 2008). As it appears, every state has a history of federally maintained work-study and vocational training programs; however, the systematic coordination of and communication between schools and community-based adult services have not regularly occurred (Sands and Wehmeyer, 1996). As a result of the limited collaboration, many young adults in transition are not able to access the necessary community supports and resources.

Collaborative interagency and interdisciplinary collaboration are fostered by agreements that clearly articulate goals, roles, communication strategies, and other collaborative actions that enhance the curriculum and service delivery. Interagency collaboration includes activities between family, special educators, and adult service providers such as working as a team, sharing information, attending transition planning meetings, accessing community resources, and establishing and utilizing effective lines of communication to benefit students with disabilities as they transition from high school to the adult world.

The purpose of these collaborative activities is to implement an integrated system that addresses lifelong learning and supports the needs of a community member. Addressing barriers to effective collaboration such as ineffective use of transition meetings, intimidating language, and complex agency procedures may be an important goal of the interagency collaboration, thereby affording students with disabilities the opportunity to have successful entry into adult life (Oertle and Trach, 2007). To be successful in adult life, young people urgently need an interdisciplinary high school curriculum that has a strong focus on their transitional needs (Dowdy *et al.*, 1990).

Significance of Self-Determination and Self-Advocacy

Self-determination is a set of skills or competencies that assist students in (1) determining their wants and needs, (2) deciding on the best actions to take, (3) taking the action, (4) evaluating, and (5) improving on the outcome (Repetto, 2003). Self-determination is a highly critical skill necessary for successful navigation of adult life; without this skill, others will be responsible for making decisions in the lives of individuals with disabilities. Specific skills in self-determination include decision making, coping with failure, self-assessment, action planning, and option exploration (Carter *et al.*, 2008; Repetto, 2003; Wehmeyer and Palmer, 2003). Engaging in self-determination strategies during the formal transition planning process and throughout adult life requires students to complete tasks they may find challenging. These strategies may include the ability to actively participate in transition meetings, self-disclose strengths and weaknesses, and request services and accommodations (Repetto, 2003).

Conclusion

Often, students with disabilities experience even greater challenges when transitioning from school to the adult world. For the purposes of this article, the developmental imperative of transitioning from school to adulthood (e.g., choosing a career; moving out of one's parents' home; establishing social networks, transportation, and recreational activities independent of one's parents) is a challenge for most adolescents. For students with disabilities, transition may be considerably more difficult if adequate planning, support, and training are not provided. Successful participation in adulthood requires active long-range planning by students, their parents or families, school staff, and adult service providers. It is essential that students have a thorough understanding of the consequences and options for their transition plans. The attainment of positive postschool outcomes for adolescents and adults with disabilities is dependent upon professionals becoming more knowledgeable about

the changing demands of education. Creative solutions are essential to helping this population gain access to tools and information so that they can add to the world knowledge and economy, thereby increasing their own potential worth.

Visual Impairment

W Sapp, Visual Impairment Education Services, Cohutta, GA, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Blindness – It technically refers to a total absence of vision, although the term is often used to refer to severe visual impairments that result in a need for primarily using nonvisual sensory information.

Low vision – It refers to visual impairments that are less severe than blindness but still impact a person's ability to complete daily activities to some degree.

Visual impairments – These include low vision and blindness and refer to any degree of impairment to a person's ability to see, which affects his or her daily life.

Visual impairments, including low vision and blindness, occur in a small percentage of children in all countries around the globe. The percentage of children with visual impairments and the causes of visual impairment vary greatly between developing countries and wealthier nations; and access to clean water and medical care are major influences on the rates and types of visual impairments. Regardless, all children with visual impairments deserve an appropriate education that gives them “the opportunity to be equal and the right to be different” (Hatlen, 1996: 25). In this article, the author advances this premise.

Legislative and Policy Support for Students with Visual Impairments

According to the United Nations' Universal Declaration of Human Rights, article 26, all people have the right to a free and compulsory primary education and parents have the right to choose the kind of education that will be given to their children. The United Nations' International Covenant on Economic, Social, and Cultural Rights, which has been ratified by 155 nations, further expounds upon the right to a free education stating that education shall encourage the development of dignity and “shall enable all persons to participate effectively in a free society.” The basic human right to receive an education applies to all children and youth, including those with visual impairments.

Many countries have passed federal legislation to codify the aforementioned educational rights for people with visual impairments. For example, in the US, the 1990 Individuals with Disabilities Education Act outlines the

educational rights for all students with disabilities and makes specific reference to some of the unique needs of students who are blind. This law requires that materials be provided in appropriate formats for students who are blind and that Braille instruction be provided for students who are blind unless their educational team determines that another media (e.g., print with optical devices) is more appropriate for the student. In Great Britain, the Disability Discrimination Act protects the rights of children and adults to receive a basic and higher education without discrimination due to their disabilities, including visual impairments. In Canada, the Charter of Rights and Freedoms and the Education Act guarantee appropriate access and educational services for people with visual impairments and other disabilities. Even with these worldwide efforts, people with visual impairments still fail to receive appropriate educational programming to maximize their full potential.

Etiologies of Visual Impairments and Their Impact

Before discussing the implications of visual impairments, it is important to understand several key concepts: definitions of key terms related to visual impairments, the most prevalent etiologies of visual impairments, and the functional implications of different types of visual impairments.

Definitions

Visual impairments include low vision and blindness and refer to any degree of impairment to a person's ability to see that affects his or her daily life. Blindness technically refers to a total absence of vision, although the term is often used to refer to severe visual impairments that result in a need for primarily using nonvisual sensory information. Low vision refers to visual impairments that are less severe than blindness but still impact a person's ability to complete daily activities to some degree. People with low vision may need to use tools and techniques to enhance their ability to use their limited vision, or they may need to use nonvisual means for completing tasks.

Etiologies and Prevalence

The rate of visual impairments in children in wealthy nations is approximately 1–2 per 1000 children with

only approximately 1 in 10 000 having a severe visual impairment or total blindness. In developing countries, the rates of severe visual impairments are estimated to be ten times higher than in wealthier nations, occurring at a rate of one in 1000 children (Gilbert *et al.*, 1999).

The most prevalent types of visual impairments vary depending on age and geographic location. For children in developing countries, the most prevalent forms of visual impairments are vitamin A deficiency, corneal scarring, trachoma (an eye infection), inherited conditions, and onchocerciasis (river blindness caused by a parasitic worm that lives in contaminated waterways) (Gilbert *et al.*, 1999; Roodhooft, 2002). With the exception of inherited conditions, all of these causes of visual impairments are preventable through proper nutrition, hygiene, and medical care. Unfortunately, many children in developing countries do not have access to these basic needs that would prevent their visual impairments.

In wealthier nations where basic nutrition, sanitation, and healthcare are more readily available, different causes result in most childhood visual impairments. In the US, the most common causes of visual impairments in children are cortical vision impairment, optic nerve hypoplasia, retinopathy of prematurity, albinism, and abnormalities in the structures of the eye (Hatton and Model Registry of Early Childhood Visual Impairment Collaboration Group, 2001). Some of these causes of visual impairment are often associated with the presence of additional disabilities (e.g., cortical visual impairment) and the rates of these etiologies have increased as medical care allows children with more severe disabilities and children born with extremely low birth weights to survive.

Functional Implications

Visual impairments impact many aspects of seeing. Most visual impairments are the result of damage to one or more structures in the eye. When the eye is damaged, there can be reduced acuity (clarity of what is seen), reduced visual fields (e.g., tunnel vision or blind spots), reduced ability to see color or contrast, or difficulty with lighting and glare, or some combination of these problems. Visual impairments, such as cortical vision impairment and optic nerve hypoplasia, are the result of a poorly developed or damaged optic nerve or visual cortex. These conditions can have any or all of the problems associated with damage to the eye; and additionally, there is difficulty in the brain receiving and processing visual information.

Coupled with the causes of visual impairments and the differing impacts on vision that can occur, a major factor in the needs of a person with visual impairments is based on when the visual impairment first occurred. Adventitious visual impairments occur after a child or teen has lived with typical vision for many years, benefiting from

visual information to understand and interact with his or her world. Children who experience an adventitious visual impairment have to adjust psychologically to the vision loss and learn new ways to do things they already knew how to do (e.g., dressing, reading, and eating). Congenital visual impairments occur at birth or when a child is very young. Children with congenital visual impairments develop their concepts about the world with limited or no visual input. Vision typically helps children unify the information they receive through their other senses and helps them gather vast amounts of information more quickly than they can do with other senses. When vision is absent or impaired in the early years, children need intentional interactions with their world to develop logical and accurate concepts.

Educational Needs of Students with Visual Impairments

When parents and teachers learn that a child has a visual impairment, they are often at a loss as to what that student needs. Each student has unique needs but there are some general guidelines that apply to all children with visual impairments. When selecting adaptations for a child, it is important that only the adaptations that are appropriate for him/her are used. Using adaptations that are not appropriate for a child may result in no benefit for him/her, may be harmful for the child's education, and may promote unhealthy attitudes about functioning with a visual impairment for the child, the family, and the community.

Due to the vast range of visual etiologies, visual functioning, and visual experiences, it is impossible to predict the educational needs of students just by knowing that they have a visual impairment. It is critical to know how they functionally use their vision and other senses in their usual daily routines. It is also important to know if their visual conditions are stable or fluctuating and if they are expected to improve or worsen. Additionally, if other disabilities are present, their impact on learning must also be considered. Due to the complexity of these factors, it is best if a teacher knowledgeable about educating students with visual impairments takes an active role in planning and implementing an educational plan for students with visual impairments. Most countries have teachers who specialize in teaching these students and their expertise should be relied upon when working with them. General information on medical care, expectations for achievement, and typical adaptations must be provided; this information is applicable to many, but not all, children with visual impairments.

Medical care is obviously essential in monitoring the eye health of children with visual impairments. Proper medical care can prevent many of the visual impairments

and minimize the severity of others. Even when people are totally blind, they should still receive regular eye examinations to ensure that there are no additional problems with the eyes and optic nerve such as infections or tumors. The frequency of such examinations should be determined by the child's ophthalmologist. When working with children with visual impairments, adults must maintain high standards and high expectations for them. They should be (1) expected to learn the same skills and knowledge that other children the same age are learning, (2) held to the same standard in completing work and chores at home and at school, and (3) expected to interact appropriately with adults and peers demonstrating positive social skills. To a large measure, when providing instruction to children with visual impairments, there are some general guidelines that may be useful. Teachers and service providers must always introduce themselves when approaching a child who is blind; they must not ask the child to guess who they are from their voice. They must describe information that other students are receiving visually. In addition, they must use precise language rather than general terms such as "over there" that cannot be understood without accompanying gestures. Finally, they must realize that children will have different levels of comfort with their visual impairment and, therefore, they must be discreet in discussing their visual impairments and offering adaptations.

For children with low vision, there are five adaptations to the environment that can enhance their ability to use their vision (Corn, 1989). Depending on the type of visual impairment, increasing or decreasing lighting can improve visual performance. For almost all children with low vision, positioning the child so that there is minimal glare from lights is beneficial. Allowing the child to position himself/herself at the best distance for viewing is helpful. While most children with visual impairments see better the closer they are to material, some children see best from a distance. Adjusting the color and contrast of an object can also allow a child to see the object better. Some children will see certain colors more easily than others and most children will benefit if there is high contrast between the color of the object or print and the color of the background. The final adaptation is to allow the child more time to process the information received visually or to take breaks to prevent visual fatigue. Each child's visual needs are different and, therefore, it is important to provide the appropriate adaptations and only adaptations that are needed. Many children with visual impairments can be taught in their local schools with support from specialists who can direct adaptations, share modified materials and resources, and provide specialized instruction as needed. Other children may require more extensive support from specialized classrooms or schools for children with visual impairments.

Accessing Materials

To receive an appropriate education, students with visual impairments must be able to access the same learning materials (books, pictures, maps, and graphs) as other students. Lack of access to written material is one of the greatest challenges faced by people with visual impairments. A variety of ways of accessing written materials are available to people with visual impairments; these ways are referred to as learning media. Determining the appropriate media requires knowledge and understanding of visual impairments, their impact on learning, and the individual needs of the student. There is no hierarchy of preference in which media is used, rather the best media for a student is the one that allows the student to gain knowledge and information as independently and efficiently as possible (Lusk and Corn, 2006). Most frequently, students use a combination of media to read different materials depending on the time, location, and purpose of reading. Some students find that using a combination of Braille, print, and taped materials allows them to learn most effectively. For instance, when students with visual impairments read print, there are several options available to them: regular print, regular print with optical devices, large print, and electronic magnification. Students with low vision often experience eye fatigue when reading and writing, resulting in headaches, blurred vision (beyond the child's typical visual impairment), and slow reading speeds. The goal of using adapted reading materials is to allow students access to visual materials that cannot be easily seen so that they can read more quickly and with more comfort. With all types of visual learning, adjusting lighting can be extremely helpful. Some students will benefit from having brighter light, while others will function better with dimmer lighting. All students benefit from light that produces minimal glare.

Some students with mild low vision are able to access some standard print (e.g., text in elementary level textbooks). To read standard size texts, students may hold the text very close to their eyes; this will not harm their eyes. Other students may use optical devices to access print (Lussenhop and Corn, 2002). Optical devices use lenses to enlarge the size of the image received by the eye (Zimmerman, 1996). Optical devices for near vision, known as magnifiers (hand-held, stand, or spectacle-mounted), enlarge the size of print or other material that is viewed at close range, within a few inches. These devices allow students to access print that is too small for them to comfortably read without magnification and allows students to view other learning materials such as maps, diagrams, charts, and pictures. Optical devices known as monoculars or telescopes allow students to view print and other visual information at a distance such as material printed on a chalkboard, teacher demonstrations, and

audiovisual materials. Optical devices come in many configurations and must be individually prescribed for each student with low vision. Giving a student a device with too much or too little magnification will not be beneficial. Instruction in using the devices greatly increases the ability of students to use the devices for learning and recreational purposes. Clearly, optical devices are not appropriate for all students with low vision who read print, and in these instances, large-print books and materials can be purchased. Large-print materials are simply enlarged versions of standard print books. The font size of texts is increased and usually accompanying graphics are enlarged as well. Some students find large-print textbooks helpful, but for others, the amount of enlargement is not sufficient to allow them to read for extended periods of time. For students who require more magnification than can be achieved with optical devices or large print, electronic magnification systems such as closed circuit televisions (CCTVs) can be used. CCTVs use a camera to capture an image and display the enlarged image on the screen. They can be adjusted from low levels of magnification to extremely high levels. Some CCTVs are able to use a movable camera to capture both near images, such as a textbook, and distance images, such as the chalkboard. However, CCTVs are bulky, require electricity to run, and are expensive, but for some students, they allow access to materials that would otherwise be unavailable.

Many students with visual impairments find Braille to be the most efficient reading media. Braille is a system of embossed dots arranged in a six-dot cell used for reading and writing. Although other embossed systems of reading have been used, Braille is the most frequently used system. Braille, originally developed in the 1700s in France, has been adopted by most countries as the system for tactual reading and writing. It employs different combinations of dots to represent letters, punctuation marks, and accents that are applicable to any language. Standard Braille can be used with any language using the Latin alphabet; and many other written systems, including but not limited to Hebrew, Japanese, and Chinese, also have Braille versions. In English, there are additional Braille symbols to represent certain words and combinations of letters; and there are additional codes and symbols to handle specialized writing such as math, computer code, and music. Official rules for Braille usage in the US and Canada are determined by the Braille Authority of North America. The International Council of English Braille promotes the unified English Braille code that provides a single code for literature, math, and computers. This code has been adopted by Australia, New Zealand, Nigeria, and South Africa.

Regardless of which code is used, students must have a means for writing using Braille so that they can read their own work. The slate and stylus is the original and least expensive tool for writing Braille. The slate is a metal or

plastic hinged frame in which paper is inserted. The stylus is an instrument with a metal point used to press each dot into the paper from the back. Manual Braille writers, such as the Perkins Braille writer, are similar to manual typewriters, but rather than having standard letters on the keyboard, they have six keys for the six dots in the Braille code. When one or more keys are pressed, the corresponding dots are embossed onto the paper. Electronic Braille writers are similar to manual Braille writers but they require less finger strength to use and provide options for more easily correcting errors. Electronic Braille note takers are small computers employing a six-eight button key pad for input. These devices typically have word processing programs, calculators, calendars, address books, and other common computing programs. They allow users to read back their material using voice output, refreshable Braille (a series of metal pins that raise and lower to form Braille cells), printing in Braille when connected to a Braille embosser, and printing in print when connected to a printer. Computers with specialized software can also be used to write in Braille either using the standard keyboard or using part of the home row as a standard six-key Braille keyboard.

Though students need a written form of communication, many students find auditory materials to be good supplements to print and/or Braille. Occasionally, a student will have a visual impairment that does not allow print reading and a physical impairment that prevents Braille reading; this student will, by necessity, be an auditory reader. Auditory materials are available in four-track tapes that are coded with sections and pages so students can more easily find specific material. Auditory materials are also available in digital formats that allow even greater flexibility in use. One of the benefits of taped and digitized material is that it can be played at faster-than-average speeds, thus decreasing the amount of time necessary to listen to the material. The use of live readers (a person who reads the material aloud) is also an effective tool for students to access materials that are not available in any other format.

Unique Instructional Needs

Students with visual impairments are limited in the visual information they receive and, therefore, they often require instruction in areas that go beyond standard school curricula. One formulation of the instruction needed by students with visual impairments is the expanded core curriculum (Hatlen, 1996), a curriculum that proposes nine areas in which students with visual impairments should be assessed. For any area in which deficits are noted, instruction should be provided enabling the student to learn skills commensurate with their typically sighted peers and to fully participate in society. When a student

has a visual impairment and additional disabilities, they may require more assistance in the following areas and may never reach full independence, but they should still receive instruction in these areas appropriate to their potential:

1. *Academic and compensatory skills.* These refer to the standard academic skills and adapted skills that allow students to participate in standard academics. Compensatory skills could include instruction in Braille reading and writing or the use of an abacus to compute mathematical problems.
2. *Career skills.* These are the skills necessary to participate in the work force and include everything from knowledge of possible jobs to an ability to work independently and complete tasks. It includes more advanced skills such as completing a job application, knowing how to act in an interview, and gaining the skills needed for a specific job.
3. *Independent living skills.* These are the basic tasks that people complete each day to care for themselves. Independent living skills include skills necessary for hygiene, grooming, dressing, eating, shopping for necessities, etc.
4. *Orientation and mobility.* These refer to the systematic skills and concepts necessary for people with visual impairments to know their location in space and to travel safely, independently, gracefully, and efficiently in all environments (Blasch *et al.*, 1997). Instruction may involve learning to use all senses to gather information about one's environment, developing skills using a long cane to detect obstacles, and determining when to request assistance from others. In many countries, instructors specialize in orientation and mobility so that instruction can be provided to maximize independent travel while minimizing the dangers inherent in traveling independently with limited or no sight.
5. *Recreation and leisure skills.* These are skills for spending one's free time in enjoyable and healthy ways. These are important skills for maintaining one's physical and emotional health.
6. *Self-advocacy skills.* These are skills that allow a student to request assistance when needed and reject assistance when not required. Learned helplessness frequently occurs in children with visual impairments when well-meaning adults and peers do everything for the child. Self-advocacy skills allow children to learn to be independent and feel confident in their own abilities.
7. *Social skills.* These are the skills necessary to interact with family, friends, and community members. Skills as basic as knowing how to position yourself when talking with someone can be difficult for a child with a severe visual impairment who cannot observe others. Social skills are important for the person with the visual impairment to develop friendships, find a mate,

interact with people in their communities, and maintain employment.

8. *Technology skills.* These are critical for allowing access to the wider world of knowledge and information. Advances in technology have changed the world for everyone and adapted software and hardware allows people with visual impairments to also benefit from the new technology. Knowing what technology is appropriate and how to use that technology requires instruction and practice.
9. *Visual and sensory skills.* These refer to learning how to best use one's remaining vision and other senses to gain information about the world.

Not all students will need instruction in every area of the expanded core curriculum, but most will have deficits in at least one area. Recognizing that these are potential areas of need and addressing concerns that are identified can greatly enhance the educational outcomes for students with visual impairments.

Conclusion

Students with visual impairments are found in every country in the world. Their degree of visual impairment ranges from very mild to total blindness, meaning that there is not a single set of adaptations or skills that will be appropriate for all children. A teacher knowledgeable about educating children with visual impairments should evaluate each child to determine the best way to meet his/her educational needs. Based on this assessment, instructional adaptations, specialized materials, and instruction in unique skills must be provided. When adequate instruction is provided and a child is expected to meet high standards, there are no limits to what the child can accomplish.

Workforce Issues in Special Education

E Carlson, Westat, Rockville, MD, USA

B Billingsley, Virginia Tech, Blackburg, VA, USA

Maintaining an adequate supply of qualified personnel to educate children with special needs is an ongoing challenge that is embedded within a cultural, political, and economic context. This context helps to shape the workforce through its influence on personnel shortages/surpluses; expectations for educators, in terms of professional knowledge and skills; and the conditions of service that educators encounter in their work. There is no consensus on what constitutes personnel quality in general or special education. As such, it may be more appropriate to discuss a qualified workforce as opposed to a high-quality workforce, since qualifications can be observed, measured, or documented more easily than quality, recognizing that the one is an imperfect substitute for the other. Credentialing agencies set minimal standards for entry into the profession, and as such, define workforce qualifications. However, it is important to note that those standards differ considerably across jurisdictions.

In any field, members of a qualified workforce are expected to possess the requisite professional knowledge and skills. Over time and across locales, those may differ. Educators typically acquire their professional knowledge and skills through initial preparation, induction, and continuing professional development, including work experience. As such, institutions that provide education and training to teachers and other service providers help shape the knowledge and skills they possess. In addition, conditions of service constitute the third factor promoting or impeding development of a qualified workforce. These include work contexts, such as school climate, roles and responsibilities, and levels of support, as well as overall compensation (e.g., salary, benefits, and rewards of teaching). Conditions of service play a critical role, not only affecting the performance of the workforce directly but also affecting it indirectly through its influence on supply/demand and turnover/retention.

It is important to note that in some countries, a qualified and committed special education workforce includes not only special education teachers but also high-quality general education teachers and related service personnel, for example, speech-language pathologists, physical therapists, occupational therapists, and paraprofessionals. In other countries, related services are provided through healthcare systems. While the myriad of professionals involved in providing services to children with special needs makes workforce issues complex (see **Figure 1**), the underlying constructs driving workforce quality are

similar for each type of service provider. Thus, it is critical to understand workforce issues in special education, the focus of this article.

Personnel Shortage/Surplus

In traditional microeconomic models, shortages of goods or services exist when demand exceeds supply. Many geographic regions have experienced long-standing shortages of personnel to meet the educational needs of children with disabilities. During 1997 to 2003, between 7 and 13% of special education teachers in the US were not fully certified for their positions (Boe, 2006). In education, workforce shortages can be quantified in two primary ways: the number of unfilled vacancies and the number of individuals employed who do not meet minimum job qualifications (e.g., certification requirements). Counts of unfilled vacancies are typically much lower than counts of unqualified staff, as education agencies assume that even an unqualified educator is better than none. To properly discuss personnel shortage or surplus, it is critical to define workforce supply, demand, and retention.

Workforce Supply

Understanding long-term shortages of personnel in special education requires familiarity with workforce supply as well as workforce demand. On the supply side, qualified special education personnel are available from a variety of sources:

- current workforce of qualified and unqualified personnel;
- new, traditionally prepared personnel;
- new, alternatively prepared personnel;
- reserve pool (i.e., personnel who are fully qualified but not currently working in the field); and
- underqualified individuals already working in the field who may complete the necessary preparation to become fully qualified (McLeskey *et al.*, 2004).

Graduates of traditional teacher education programs account for a sizable portion of new special education teachers, and in the US, the production of teachers from these traditional programs increased by over 20% from 1993 to 1998 and now exceeds 20 000 graduates per year (US Department of Education, National Center for Education Statistics (NCES), 2001; McLeskey *et al.*, 2004). Of course,

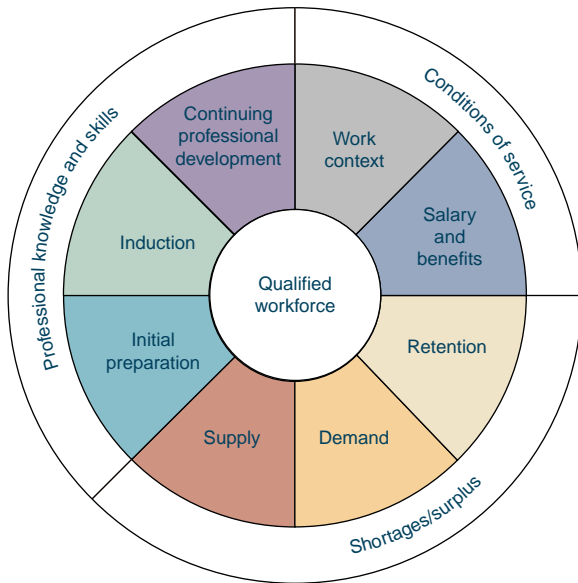

Figure 1 Factors in securing a qualified workforce.

not everyone completing a teacher-preparation program will take up a teaching position. In the US, the percentage of graduates taking up teaching positions in the year after graduation may be as low as 40% (Boe *et al.*, 1999).

Newly prepared special educators and related service providers who do not immediately take a special education position enter the reserve pool of those qualified but not employed in the field. The reserve pool can be a significant source of qualified personnel, since many members of the reserve pool eventually enter or return to teaching.

In reaction to chronic shortages of education professionals, alternative routes to certification have rapidly expanded. These preparation programs provide access to teaching credentials that circumvent conventional college and university preparation programs. They vary considerably in length and structure, delivery mode, and candidate population. Alternative routes to certification now represent a small but growing source of new special education professionals (Feistritzer, 2001). Another group of special educators are those teaching but not yet fully qualified for their positions. Very little is known about this group of teachers, except that research suggests they are likely to become a turnover liability (Miller *et al.*, 1999).

Workforce Demand

Two primary factors drive the demand for special education teachers and related services personnel. The first is the increasing student enrolment in special education. Rapid enrolment growth in special education has had a dramatic effect on demand, particularly in light of the numbers of

teachers prepared yearly for this field. For example, between 1992 and 1999, the population of school-age children in the US grew 7% nationally. In comparison, the special education enrolment increased 20% over the same period, fueling the demand for special educators and related services personnel (McLeskey *et al.*, 2004).

Caseloads for special educators and related service personnel are the second factor driving demand. If jurisdictions have no caseload limits, educators may serve larger and larger numbers of children, undoubtedly affecting the quality of services, but without increasing the number of vacancies or positions filled by uncertified personnel. However, because of concerns about the quality of services, many jurisdictions have limits on the number of children that can be served by any one individual or in one class. Increases in special education caseloads and waivers to bypass caseload limits may be a byproduct of personnel shortages and, in fact, may mask shortages in some locales.

Workforce Retention

Retention or its inverse, turnover, is a mediating variable in the supply–demand equation. How long special education teachers stay in teaching or in a district influences the demand for new personnel. Turnover is a broad term that refers to teacher attrition and teacher migration to other districts and positions. For example, turnover may refer to leaving the profession, transferring to other districts or states, or changing fields within education. Depending on the definition of leaving, rates will vary widely from 7% for those leaving the teaching profession to roughly 22% for all types of turnover combined (Boe *et al.*, 2007). Although turnover is sometimes positive, because recently hired teachers are a source of new ideas and enthusiasm, high levels of attrition are expensive. Turnover requires that limited resources be spent on recruitment, hiring, and induction, and can interfere with the development of coherent programs. In periods of teacher shortage, high levels of turnover are particularly problematic, since it is often difficult to find qualified replacements for those who leave. Ingersoll (2001) used the image of a revolving door to illustrate the difficulty of building a qualified workforce when many leave after only a few years in the classroom. Some school systems have a more difficult time both attracting and retaining teachers. For example, urban and rural systems have higher turnover than suburban systems. Not surprisingly, high-poverty school systems also tend to have more turnover than wealthier ones (Guarino *et al.*, 2006). When turnover is high, students are more likely to be taught by less-qualified and less-experienced teachers.

Retention and turnover are influenced by a wide range of complex variables: economic conditions, the age distribution of staff, and the attractiveness and compensation of teaching compared with other occupations. Efforts to

reduce turnover need to be based on an understanding of factors that contribute to leaving, such as teacher characteristics, teacher ability and preparation, and working conditions. Although several researchers have investigated the relationship of teacher characteristics, such as age, gender, and race, few conclusions can be drawn. Age is the only demographic variable that is consistently linked to turnover in the special education literature. Early career leaving is often presented as part of a U-shaped curve, where teachers are more likely to leave early in their careers, less likely during mid-career, and then more likely as they get closer to retirement. Reasons for higher levels of leaving among early career teachers have been attributed to fewer accrued investments (e.g., home and retirement system) (Grissmer and Kirby, 1987) as well as difficulties some new teachers have adjusting to teaching (Ingersoll, 2001). The relationship between gender and attrition has been included in only a few special education studies, and the findings are mixed (Billingsley, 2004). Race as a factor in special education-leaving studies has also been inconclusive (Singer, 1992).

Teacher qualifications have received less attention in the turnover literature than any other set of variables. Researchers have demonstrated higher levels of attrition among uncertified teachers than certified teachers (Boe *et al.*, 1999). Only a few researchers have considered the association between special educators' academic abilities and their decisions to stay or leave, and one large-scale study has shown that teachers with higher tested ability are more likely to leave the field (Singer, 1992). The most researched area is the influence of working conditions on teacher turnover. Special educators leave teaching for two types of reasons: personal (e.g., staying home with children or relocating) and professional. Overall, special education teachers are more likely to leave because of dissatisfaction with their work than general educators. The reasons special education teachers give for leaving include problematic work circumstances, such as school climate, isolation, high caseloads, lack of administrative support, and excessive bureaucratic responsibilities (Billingsley, 2004).

Professional Knowledge and Skills

Teacher educators, policymakers, and researchers agree that expert teachers are knowledgeable about their subject. For example, teacher knowledge of language has been correlated with observed classroom practices, and teachers with subject-matter preparation are able to secure better gains in student achievement than their counterparts without such preparation. However, in addition to subject-matter knowledge, expert teachers may have knowledge that is unique to teaching content, and this knowledge enables them to represent subject matter for the novice learner. This is the knowledge that teachers use for instructional purposes,

including the decisions made during planning and instruction. For example, research suggests that teachers with both subject-matter expertise and education coursework in methods for teaching a particular subject secure larger student-achievement gains than teachers with subject-matter expertise alone (Monk, 1994).

It is important to recognize that the knowledge and skills required for a specific teaching assignment may differ over time and across locations. The curriculum is driven by the culture in which children are being educated, and so are expectations for achievement. For example, as children with less-severe disabilities are identified, the special education curriculum may focus increasingly on academic content and away from a life-skills orientation. Additionally, it is important to note that special educators' responsibilities extend beyond instruction. The Council for Exceptional Children (2003), an international professional organization, developed standards for professional practice for special educators. These include instructional responsibilities as well as management of behavior, support procedures (such as delivering therapies or administering medications), and parent relationships.

Initial Preparation

Initial preparation is designed to equip educators with the basic knowledge and skills necessary to assist children in achieving learning standards established by their education agencies. Fully certified teachers produce higher achievement scores in mathematics and reading than less-than-fully-certified teachers; teachers with subject-matter preparation in mathematics and science accompanied by related pedagogical courses influence student achievement more than teachers with only subject-matter preparation; and teachers with pedagogical and content preparation are better able to engage students in the learning process. However, research on teacher-preparation programs lacks empirical evidence linking program features with classroom practices and student performance (Wilson *et al.*, 2001). There are a number of reasons for this research deficit: teacher preparation is a long and complex process; the direct outcome (i.e., teacher quality) is ill-defined; and working conditions present a strong moderating effect on teaching performance, which makes measures of the ultimate outcome of interest (i.e., child outcomes) difficult to attribute to teacher preparation.

Expert opinion has been used to identify some features considered exemplary in initial preparation of teachers. These features include:

- coherent program vision;
- conscious blending of theory, disciplinary knowledge, and subject-specific pedagogical knowledge and practice;
- carefully crafted field experiences;
- standards for ensuring quality graduates;

- active faculty pedagogy that employs modeling, connects theory and practice, and promotes reflection;
- focus on meeting the needs of a diverse student population; and
- collaboration as a vehicle for building professional community (Brownell *et al.*, 2003).

Graduates of less-intensive special education training programs, particularly brief alternative routes, feel less well-prepared and are less likely to stay in the field (Boe *et al.*, 2006). However, no consistent differences have been documented in traditionally and alternatively certified teachers in terms of teacher efficacy or teacher competence as measured by classroom observations or principal or supervisor ratings of teacher competence (Hawley, 1992; Rosenberg and Sindelar, 2005).

Induction

New special educators often enter the workforce with unrealistic expectations and report that their first years in the classroom are difficult and stressful. These new teachers struggle to apply what they have learned in their teacher-preparation programs at the same time that they must establish routines, collaborate with general education teachers, and manage a range of varied tasks in limited time. New teachers with difficult assignments and little support often leave teaching prematurely, making it difficult to build a qualified workforce. To support teachers through these intense early years, researchers and policymakers have called for responsive induction programs. Induction programs are built around the belief that regardless of the quality of initial preparation, new teachers need support and guidance as they learn to apply their knowledge and skills in complex school settings. Although there is some evidence that induction makes a difference in teacher retention and quality, many new special education teachers receive minimal support and assistance (Billingsley *et al.*, 2004).

Induction programs need to be tailored to the qualifications of the individual teacher and the context in which they work. Mentoring is frequently recommended as a component of induction. New teachers benefit from experienced special education mentors who are available to help them with the problems they confront, to observe and provide feedback, and to help them navigate their complex roles in schools. Induction programs may also include orientation seminars, peer meetings, professional development activities, and ongoing opportunities to reflect about teaching practice. Clearly, responsive induction programs require substantial commitments. Some countries and states commit significant resources to prepare and reward mentors, schedule release time for mentors to work with new teachers, and provide ongoing professional development. Others create university-school partnerships

and professional development schools to support induction. Although these model programs are expensive, the investment in induction may be offset by improved teacher quality, increased retention, and reduced attrition costs (e.g., for recruiting and hiring replacements).

Continuing Professional Development

Continuing professional development, including on-the-job training can make an important contribution to educators' professional knowledge and skills, and ultimately to improved outcomes for students with disabilities. The content of staff development needs to focus on research-based practices shown to be effective with students with disabilities. Unfortunately, there is evidence that many of these practices are often not used (Cook and Schirmer, 2003; Gersten and Dimino, 2001). Another area of need is the development of collaborative knowledge and skills, so that special and general education teachers, paraprofessionals, and related service personnel can work together to address the diverse needs of students with disabilities (Friend and Cook, 2003). Surely, professional development plans require attention to not only the content, but also how the content is delivered and supported. Professional development is most likely to be successful in school environments where teacher learning is part of the daily culture. In learning communities, teachers are partners in their own professional development — they plan and work together around instructional challenges, use student data to make modifications in their practices, and discuss what is working and what needs improvement.

It has been suggested that teachers need to have a conceptual understanding of new practices so they can better use and adapt these practices in their classrooms. Teachers are more likely to be successful with new instructional processes when they are given clear and specific guidelines for implementation and when the practices can be used within the structure of their classrooms. As a result, professional development is also encouraged through a range of opportunities, such as learning to be a mentor or teacher leader, participating in an external teacher network or professional organization, or earning advanced credentials, such as a graduate degree or national board certification.

Conditions of Service

Conditions of service refer to compensation and work context as they influence teacher quality. Teacher quality is influenced by the ability to attract and retain the best special educators and to structure the work environment in ways that encourage continuous development of

teacher expertise and promote productive use of teachers' knowledge and skills. Following are subsections that discuss two conditions of service: compensation and work context.

Compensation

The labor economic theory of supply and demand suggests that teachers will enter and stay in teaching (or a particular position) if it is the most attractive activity available based on overall compensation (Guarino *et al.*, 2006). Compensation in this context is not limited to salary and benefits; rather, it includes any aspect of work that influences one's desire to enter, stay or leave, such as location, work schedule, or the intrinsic rewards that one derives from teaching. Conditions of service are important in that they have an influence on the desirability of teaching as a career and, once employed, whether teaching remains an attractive alternative among all of those available.

Work Context

All teachers need certain conditions to do their work well, including strong leadership; a positive school climate; teaching resources; and the time, schedule, and supports needed to carry out their varied responsibilities. Teachers who participate in a learning culture have opportunities to continue to acquire knowledge and skills and to refine their teaching practices, thus improving teacher quality. Knowledgeable teachers in supportive work environments are more likely to be successful and find teaching rewarding. Although many special education teachers are satisfied with their work, not all of them find their work contexts supportive. The turnover literature links a broad range of work problems to teacher dissatisfaction and turnover, such as inadequate or uncompetitive salaries, poor school climates, lack of administrative support, problems with collaboration and inclusion, role overload and paperwork, high caseloads, and isolation. New teachers are particularly vulnerable to these working conditions. Many of these problems prevent teachers from functioning effectively in their roles as teachers. Over time, problematic working conditions lead to stress, dissatisfaction, and reduced commitment. Roughly, one-third of teacher attrition in special education is to general education positions, and teachers' dissatisfaction with special education teaching is a contributor to this loss.

District and school leaders are in a powerful position to shape the work context and the ways in which students with disabilities are served in schools. Leaders who help facilitate shared understanding about these students can do much to reduce the chronic problems reported by special education teachers and other service providers.

Leadership is also needed for the development of induction programs and the creation of reasonable teacher roles. These actions should help not only to alleviate some of the major contributors to turnover, but also to provide teachers with greater opportunities to meet the needs of their students (Littrell *et al.*, 1994).

Conclusions

In summary, although it is widely acknowledged that a knowledgeable and skilled workforce is essential to enhance student achievement, the chronic and persistent shortage of qualified special education teachers and related service personnel threatens the education that students with disabilities receive. Comprehensive efforts by policymakers and administrators are needed to attract and prepare promising personnel, support them in their early years through responsive induction programs, and provide them with ongoing professional development opportunities throughout their careers. At the same time, conditions of service, including salary, benefits, and the work context have an impact on teacher quality. Teachers are more likely to thrive in environments that are supportive, collegial, and include well-designed work assignments. Conditions of work influence not only the extent to which teachers are successful with their students, but also their job satisfaction and career decisions as well.

PREFACE

A preface usually provides a brief introduction to a work, intended to set the stage, provide some background insight, and whet the appetite of the reader. In our case, however, this preface has to address a fundamental question, one that was in our minds at the time we were recruited as Editors-in-Chief for the International Encyclopedia of Education. The question was “Why do we need an Encyclopedia? Its subtext was inspired by the ever-growing, ever-popular Internet. We believe that *this* Encyclopedia is desperately needed and will become a valued resource in education and associated social sciences and arts. The reasons are intellectual and procedural. Anyone with a modicum of knowledge knows that finding and trusting information gleaned from the Internet are two separate actions. The reliance on browsers to help discover references and comments result in resources based on popularity not quality. Pithy titles catch the eye and references rise in the ranks of browser searchers. Related to this is the “editing” in the Internet realm of populist efforts at encyclopedia, references, and other compilations. Once again, after removing offensive material, the accuracy, completeness, lack of bias, and other provenance for entries simply do not exist. Experienced researchers in education can sort through and make intelligent choices. Novices and many journeyman, or practitioners, parents, and policy makers cannot. Contrast how this Encyclopedia was built. Key domains of educational research were identified, and a tentative list of sub-domains or useful applied areas was posited. Then the Editors-in-Chief (apologies for the awkwardness of the term) identified the leading researcher in a particular domain, and with surprisingly little effort, recruited them to participate. They in turn identified the two best researchers in a sub-domain, such as formative assessment or the training of pre-school teachers. The authors of the sections of the Encyclopedia do not represent a collective group of friends and acquaintances, although friendships have been made. Rather they embody a deep and broad scholarly community. The difference from compiled Internet resources is the built-expertise and intellectual engagement of the authors. The summary of the developments and futures in their personal areas of scholarship have been filtered through their years of experience, both as scholars and communicators. Quality, then, is endemic to each piece, developed through this top-down identification of expertise, and made indelible by the bottom-up application of high standards from people leading the sub-domains – the authors, and the domains themselves, the section editors.

On a procedural level, the publishers early committed to the notion that this Encyclopedia would also be an online resource, and access would be available through print, for those with strong bookcases and the persisting love of turning real pages. The Internet version will allow multiple prisms through which the reader may access articles and provide, as it were, an emulation of the Internet in our field, albeit bounded by expertise and high quality.

What must be underscored in the assessment of this effort are the Editors-in-Chief and the publishers’ commitment to find excellence worldwide. We tried very hard to persuade notable scholars from all parts of the world to make contributions. Less than to fulfill the title of “International,” we were on the hunt for perspectives that would enrich the scope and depth of the sections. Our section editors put in enormous time attempting to find the best in the field, wherever they resided. Yet, not everyone is in the volume. Some were overcommitted. Many were not fully confident of their English, and the automated translation software has not yet met standards for technical writing. We believe that such writing and editing tools will make the outreach to an even broader International group of scholars possible in future revisions, or online updates. Furthermore, the birth of the World Educational Research Association (in 2009) will provide a better set of interlocking networks to find and evaluate scholarship from any place on the globe.

Finally, the scope of the effort must be acknowledged: 28 section editors, 926 articles were commissioned, drafted, reviewed, redrafted, edited, and put together in the space of four years. The publishers underwent some internal changes, and alterations in management. We as Editors-in-Chief, changed roles, moved, and also had to keep our own research and development enterprises afloat. Deadlines wobbled; authors dropped from view and had to be replaced.

Yet, at times frustrating as all development is, we find the final product exhilarating. We are enthusiastic not simply because it came into being at all, but because the collective light of the minds that wrote have left a bright resource for the future, one that will impact the way our colleagues understand and experience the educational knowledge, improvement, and impact in the future.

HOW TO USE THE ENCYCLOPEDIA

The International Encyclopedia of Education is intended for use by students, research professionals, and interested others. Articles have been chosen to reflect major disciplines in the study of education and common topics of research by academics in this domain. Each article serves as a comprehensive overview of a given area, providing both breadth of coverage for students, and depth of coverage for research professionals. We have designed the encyclopedia with the following features for maximum accessibility for all readers.

The contents of the encyclopedia are arranged alphabetically by section, and within sections, alphabetically by article. The Subject Index is located in Volume 8. Some topics are covered in a multitude of articles from differing perspectives, while other topics may have only one entry. We encourage use of the index for access to a subject area, rather than use of the Contents list alone, so that a reader has a full notion of the coverage of that topic.

The articles include cross-references to other related encyclopedia articles, suggested further readings where applicable, and many contain relevant websites for additional information. We encourage readers to use the cross-references to locate other encyclopedia articles that will provide more detailed information about a subject.

The Further Reading sections include recent secondary sources to aid the reader in locating more detailed or technical information. Review articles and research articles that are considered of primary importance to the understanding of a given subject area are also listed. These suggested further readings are not intended to provide a full reference listing of all material covered in the context of a given article, but are provided as next steps for a reader looking for additional information.

VOLUME 1

A

Adult Education

Adult Education Overview	<i>K Rubenson</i>	1
--------------------------	-------------------	---

Adult Education – Adult Learning, Instruction and Program Planning

Adult Learning	<i>S B Merriam</i>	12
Adult Learning and Instruction: Transformative Learning Perspectives	<i>P Cranton</i>	18
Adult Learning in a Biographic Perspective	<i>L West</i>	25
Adult Learning, Instruction and Programme Planning: Insights from Freire	<i>P Mayo</i>	31
Characteristics of Adult Learning	<i>K Illeris</i>	36
Informal Learning: A Contested Concept	<i>P Hodgkinson</i>	42
Organizational Learning	<i>P-E Ellström</i>	47
Program Planning	<i>A L Wilson and R M Cervero</i>	53
Workplace Learning Frameworks	<i>S Billett</i>	58

Adult Education – as a Field of Study

Class Analysis in Adult Education	<i>T Nesbit</i>	64
Gender Analysis	<i>J Stalker</i>	70
Race and Ethnicity in the Field of Adult Education	<i>J Johnson-Bailey and D Drake-Clark</i>	77
Trends in Workplace Learning Research	<i>T Fenwick</i>	83

Adult Education – Concepts

Lifelong Learning	<i>J Field</i>	89
Rewriting the History of Adult Education: The Search for Narrative Structures	<i>B J Hake</i>	96

Adult Education – Domains and Provision

Adult Basic Education: A Challenge for Vocational Based Learning	<i>R Höghelm</i>	102
Adult Literacy Education	<i>L Tett and R St.Clair</i>	107
Citizenship and Immigrant Education	<i>D Schugurensky</i>	113
Community Based Adult Education	<i>B Connolly</i>	120
Continuing Professional Education: Multiple Stakeholders and Agendas	<i>R M Cervero and B J Daley</i>	127
Financing of Adult and Lifelong Learning	<i>Å Sohlman</i>	133
Labor Education	<i>K Forrester</i>	139
Learning Cities and Regions	<i>C Duke</i>	144
Museums as Sites of Adult Learning	<i>R S Grenier</i>	150
Overview of Lifelong Learning Policies and Systems	<i>D-B Kwon and C H O Daeyeon</i>	156
Popular Adult Education	<i>S Tøsse</i>	162
Provision of Prior Learning Assessment	<i>P Andersson</i>	169
The Age of Learning: Seniors Learning	<i>P Jarvis</i>	175
University Adult Continuing Education: The Extra-Mural Tradition Revisited	<i>M Slowey</i>	183

Adult Education – Economy and Society

Adult Education and Civil Society	<i>J Crowther and I Martin</i>	191
Adult Education and Nation-Building	<i>S Walters</i>	198
Economic Outcomes of Adult Education and Training	<i>A Ferrer and W C Riddell</i>	204
Health and Adult Learning	<i>P Bélanger and M Robitaille</i>	211
Modernization Processes and the Changing Function of Adult Learning	<i>H S Olesen</i>	217
The Political Economy of Adult Education	<i>G Rees</i>	223
Wider Benefits of Adult Education	<i>R Desjardins and T Schuller</i>	229

Adult Education – Participation

Barriers to Participation in Adult Education	<i>K Rubenson</i>	234
Participation in Adult Learning	<i>R Desjardins</i>	240

C**Comparative Education**

Comparative and International Education: English-Language Scholarly Publications	<i>D Post and M Fedri</i>	251
Comparative Education: Philosophical Issues and Concepts	<i>M Mason and C W Evers</i>	257
Comparative Education: Societies and Associations	<i>M Bray</i>	266

Curriculum Development

Curriculum and Religion	<i>C Kapitzke and P Graham</i>	272
Gender and Curriculum	<i>J Marsh</i>	277
Local Teacher-Based Curriculum Development	<i>M D Osborne and H B Barker</i>	283

Curriculum Development – Contexts

Curriculum and Human Rights	<i>C Lohrenscheit</i>	287
Curriculum and the Education of Cultural and Linguistic Minorities	<i>S May</i>	293
Curriculum in Postcolonial Contexts	<i>A Hickling-Hudson</i>	299
Curriculum, Economic and Cultural Development	<i>A Rampal</i>	307
Globalization and Curriculum	<i>R Dale</i>	312
Popular Culture	<i>K Schultz and R Throop</i>	318

Curriculum Development – Evaluation and Research

An Overview of Research in Curriculum Inquiry	<i>F M Connelly and S J Xu</i>	324
Curriculum Evaluation: Approaches and Methodologies	<i>V Klenowski</i>	335
Curriculum Studies, Discourse Analysis, and the Construction of Historical Time	<i>J Laspina</i>	342
Curriculum Use in the Classroom	<i>M Ben-Peretz and B Eilam</i>	348
The Roots and Routes of Teacher-Based Action Research and Curriculum Inquiry: An Historical Perspective	<i>L G Putney and J L Green</i>	355

Curriculum Development – Planning and Development

Curriculum and Syllabus Design	<i>A Woods, A Luke, and K Weir</i>	362
Curriculum and the Publishing Industry	<i>J Larson, A-R Allen, and D Osborn</i>	368
Curriculum and Teacher Change	<i>J G Ladwig</i>	374
Curriculum Governance and Planning	<i>B Levin</i>	379
Curriculum Planning and Systems Change	<i>Z Deng</i>	384
Curriculum, Digital Resources and Delivery	<i>Y Zhao, G Zhang, and C Lai</i>	390
Textbook Development and Selection	<i>P Shannon</i>	397

Curriculum Development – Subject Matter

Curriculum and Globalization: Higher Education	<i>K H Mok</i>	403
Curriculum Development as Subject Matter: Social Studies	<i>J Brophy and J Alleman</i>	411
Curriculum Development in the Area of Reading	<i>C L Madda and T E Raphael</i>	415
Curriculum in the Arts	<i>C M Thompson, L Bresler, and T E Costantino</i>	423
Curriculum: Foreign Language Learning	<i>Angel M Y Lin</i>	428
First Language Learning	<i>T Rogers and L Moffatt</i>	435
Learning a Second Language in First Language Environments	<i>E Bernhardt and D J Tedick</i>	441
Literature	<i>S Hynds</i>	447
Mathematics	<i>B Kaur and C P Vistro-Yu</i>	453
Physical Education and Sports	<i>D Kirk</i>	459
Primary and Elementary/Middle Grades Reading	<i>D E Alvermann and C A Mallozzi</i>	464
Science	<i>Y Kali and M Linn</i>	468

Curriculum Development – Theory

Bilingual Learning (Learning L1 and L2 in an L1 and L2 Environment)	<i>D Schwinge</i>	475
Curriculum and Complex Systems Theory	<i>W-M Roth and J Thom</i>	481

Curriculum and Constructivism	<i>B Davis and D Sumara</i>	488
Curriculum and Critical Theory	<i>L Yates</i>	494
Curriculum and Poststructuralist Theory	<i>J L Miller</i>	499
Curriculum and Structuralist Sociology: The Theory of Codes and Knowledge Structures	<i>J Muller and J Gamble</i>	505
Curriculum Reform	<i>R Gilbert</i>	510
Early Childhood Curriculum and Developmental Theory	<i>S M-Y Lim and C Genishi</i>	514

D

Demography and Social Change

An Evaluation Framework for E-Learning Effectiveness in the Arab World	<i>W AbuSneineh and M Zairi</i>	521
Globalization and Social Justice in Higher Education	<i>E Kimura-Walsh</i>	536
Racial Inequality and the Economic Payoffs of Higher Education	<i>S A Lachtman</i>	542
School Health Education	<i>J S Yang</i>	547

Demography and Social Change – Demography

A Paradigm of Contradictions: Racism and Science Education	<i>B A Brown and J W Mutegi</i>	554
Africana Studies: Past, Present And Future	<i>B R Hare, A Young, J B Stewart, and D P Aldridge</i>	565
Beyond Black Nationalism to Black Internationalism: The Compelling Case for Examining Black Educational Challenges Globally	<i>K Freeman</i>	573
Beyond Racial, Ethnic, and Gender Bias in Education Statistics	<i>J T Lott and C Bennett</i>	581
Caste and Education in India	<i>G G Wankhede</i>	589
Demography, Community, and the Education of Asian American and Pacific Islander Students	<i>R T Teranishi</i>	595
Educational Attainment and Mortality Differentials	<i>H D Horton, L Hixson, and S M Monnat</i>	602
Educational Opportunity and Latino/Chicano College Choice: New Findings, and Theoretical Perspectives	<i>M A Ceja and P A Pérez</i>	610
Ethnic Minority Identity and Educational Outcomes in a Rising China	<i>G A Postiglione</i>	616
Ethnic Studies and Women's Studies: From the Past to the Present, Providing a Space in the Academy for Scholarship Focused on the Histories and Experiences of Marginalized People	<i>C A Brown</i>	623
Gender Equity in Higher Education: Challenges and Celebrations	<i>L Morley</i>	629
Locating Space and Place in the College Access Debate: New Tools for Mapping and Understanding Educational Inequity and Stratification	<i>B Cantwell and J F Milem</i>	636
Public Policy and Inequality in Postsecondary Opportunity: Educational Statistics and the Failure of Education Reform	<i>E P St. John, K Williams, and K Moronski</i>	649
The Education of Indigenous Students	<i>J W Tippeconnic and S C Faircloth</i>	661
The Health Advantages of Educational Attainment	<i>G Y Dinwiddie</i>	667
To Go or Not to Go: Access and Barriers to Ethnic Minority Participation in Higher Education within the United Kingdom	<i>P Brug and T L Oliver</i>	673
Universal Secondary Education and the Two-Tiered School System in the English-Speaking Caribbean	<i>P Anderson and J Devonish</i>	679
Women of Color in Science, Technology, Engineering and Mathematics (STEM): Refining the Concepts, Reframing the Issues	<i>C B Leggon</i>	686

Demography and Social Change – Social Change

Educational Diversity in U.S. Law Schools	<i>C E Daye, A T Panter, W R Allen, M E Deo, and L F Wightman</i>	691
Educational Reform	<i>F Lopez-Segrera</i>	698
Emergence of For-profit Higher Education	<i>X Li</i>	705
Engaged Education: Experiential Learning, Intensive Field Experiences, and Social Change	<i>T R Rone</i>	711
Higher Education and Social Change in Mexico	<i>A Mungaray, G Estrella, P Moctezuma, and M Ramírez-Urquidy</i>	719
The Changing Role of the State in Higher Education	<i>K Gürüz</i>	728
The Role of the State in School Reform: Responding to Increasing Ethnic Diversity in Britain	<i>P Ratcliffe</i>	737
Transforming Mindsets Through Education for Sustainable Development	<i>V M Segovia</i>	746

Demography and Social Change – Sociology

Achievement Motivation in Ethnic Minority Youth	<i>S Graham and E Bryant</i>	753
Affirmative Action and Higher Education in Brazil	<i>J T dos Santos and D M Queiroz</i>	760
Black in White: Black Students at White and Black Colleges	<i>L Evans and J R Feagin</i>	767
Bologna Process: On the way to a Common European Higher Education Area	<i>A V Rezaev</i>	772
Critical Race Theory in Education Research	<i>R Vue and C B Newman</i>	779
Cultural Diversification and Japanese Education: Social Constructions of the New Diversity	<i>R Tsuneyoshi</i>	787
Education in War Countries: A Disempowerment of Society	<i>J L Nkata</i>	793
Educational Attainments of U.S. Black Males and Females: 1971 to 2003	<i>F B Bonner, M-C Jipguep-Akhtar, and R J Harrison</i>	799
Educational Preparation: Fostering the Self-Efficacy and Resilience of Urban Adolescent Youth	<i>M B Spencer and B Tinsley</i>	806
HIV Education for Low-Literate People: Transforming Students and Communities through Paulo Freire's Praxis and the Pedagogy of Action	<i>N Z Haniff</i>	814
How Are Discussions of Interdisciplinary Studies Linked to Diversity Discourse?	<i>C N Spence</i>	823
Identifying Patterns of Doctoral Attrition Across Academic Fields	<i>A James, K J Fosnacht, E B Stolzenberg, and D Thirumalai</i>	827
Male Underachievement in Education Across the Globe: A Shift in Paradigm for Gender Disparities Regarding Academic Achievement	<i>J F L Jackson, J L Moore III, and R A Leon</i>	838
Noncognitive Measures for Higher Education Admissions	<i>W E Sedlacek</i>	845
Peace Education	<i>J Page</i>	850
Remote Control: Africa's Development and Outflow to Developed Nations of Technical Talent	<i>F Haniff</i>	855
Scholar-Baller®: Student Athlete Socialization, Motivation and Academic Performance in American Society	<i>C K Harrison, S Bukstein, J Mottley, E Comeaux, J Boyd, C Parks, and D Heikkinen</i>	860
Service-Learning and Diversity as Mediums to Foster Civic and Community Engagement in Undergraduates	<i>L Oseguera</i>	866
Success and Failure in Education and Criminal Justice: Identifying Common Mechanisms	<i>S Ramirez and A Harris</i>	874
The History of Education: Race and Education	<i>J O Jewell</i>	881

VOLUME 2**E****Early Childhood Care and Education Theory**

- Early Childhood Care and Education: The Family, The Market, and The State *S B Kamerman and M J Neuman* 1
- Gender Issues in Early Childhood Education and Care *B Pocock* 11

Early Childhood Education and Care Governance

- Early Childhood Risk, Protection and Abuse Prevention *E Khoo* 17
- Evaluating Early Childhood Education and Care Programs *M Janus and S Brinkman* 25

Early Childhood Education and Care Investment

- Investing in Early Childhood Education and Care: The Health and Wellbeing Case *T Moore and F Oberklaid* 32
- Cost-effective Early Childhood Programs from Preschool to Third Grade *A J Reynolds, J A Temple, and B White* 38
- Early Childhood in Post-Modern Cultures: Thoughts and Some Concerns *P Gammage* 49
- Investing in Early Childhood Education and Care: Some Policy Implications *J Bennett* 55
- Investing in Early Childhood Education and Care: The Economic Case *G Cleveland and M Krashinsky* 63

Early Childhood Education and Care Programs

- Early Care and Education Programs for Infants and Toddlers *B Nyland* 69
- Literacies in Early Childhood: The Preschool Period *M Flear and B Raban* 75
- Participation in Early Childhood Education and Care Programs: Equity, Diversity and Educational Disadvantage *M Vandenbroeck* 81
- Teaching in Early Childhood Centers Instructional Methods and Child Outcomes *I Siraj-Blatchford* 86

Early Childhood Education and Care Provision

- Early Childhood Education and Care in the People's Republic of China *Zeng Xiaodong* 93
- Home-Based and Institutional Early-Childhood Education and Care Services *R Fukkink and H Blok* 98
- Integrated Early Childhood Education and Care Services – Care, Upbringing, Education and Health *S Colley* 104
- Issues of Access and Program Quality *J T Hustedt and W S Barnett* 110
- Kindergarten Transitions and Linkages to Primary School – Readiness Re-conceptualized *A Petriwskyj* 120
- Parent Support in Early Childhood – Approaches and Outcomes *K S Howard, K A Beckmann, and J Brooks-Gunn* 126

Early Childhood Education and Care Research

- Development and Implementation of Early Learning Standards in the United States *C Scott-Little* 132
- Global Status of Early Learning and Development Standards *P R Britto and S L Kagan* 138
- Rethinking Early Childhood Education and Care: Implications for Research and Evaluation *K Thorpe, D Cloney, and C Tayler* 144

Early Childhood Education and Care Theory

- Child Rearing and Early Education: Parents and Professionals: Theoretical and Historical Influences *H Penn* 151

Early Childhood Education and Care Workforce

- Early Childhood Education and Care Professional Profiles in the United Kingdom: Multiagency Teamwork and Transdisciplinary Challenges *A Anning and P Calder* 157
- Early Childhood Education and Care Staff Support: Mentoring and Professional Development in Finland *P Lindberg* 162

Economics of Education

- Education and Health *P Muennig* 169
- Data *M Perez and M Socias* 178
- Empirical Research Methods in the Economics of Education *P J McEwan* 187
- Theoretical Concepts in the Economics of Education *D J Brewer, G C Hentschke, and E R Eide* 193

Economics of Education – Costs and Financing of Schooling

- Cost–Benefit Analysis and Cost–Effectiveness Analysis *C Belfield and H M Levin* 199
- Economic Approaches to Adequacy *J Imazeki* 204
- Economic Approaches to School Efficiency *L L Taylor* 210
- School Finance Reform *T Downes* 216
- School Finance: An Overview *J K Rice, D H Monk, and J Zhang* 222
- The Economics of Tuition and Fees in Higher Education *R G Ehrenberg* 229

Economics of Education – External Benefits of Schooling

- Education and Civic Engagement *T S Dee* 235
- Education and Crime *L Lochner* 239
- Education and Economic Growth *E A Hanushek and L Wößmann* 245
- Parental Socioeconomic Status, Child Health, and Human Capital *J Currie and J Goodman* 253
- The External Benefits of Education *W W McMahon* 260

Economics of Education – Labor Markets, Education and Earnings

- Education and Inequality *J Blanden and S Machin* 272
- Human Capital *E R Eide and M H Showalter* 282
- Race Earnings Differentials *M Carnoy* 288
- Returns to Education in Developed Countries *M Gunderson and P Oreopoulos* 298
- Returns to Education in Developing Countries *H A Patrinos and G Psacharopoulos* 305
- School Quality and Earnings *J R Betts* 313
- Signaling in the Labor Market *M E Page* 321
- The Economics of High School Dropouts *R W Rumberger* 325

Economics of Education – Markets, Incentives and School Choice

- Competition and Student Performance *A A Payne* 331
- Educational Privatization *C Belfield and H M Levin* 337

Student Incentives	<i>E R Eide and M H Showalter</i>	342
The Economic Role of the State in Education	<i>D N Plank and T E Davis</i>	347
The Economics of Catholic Schools	<i>W Sander and D Cohen-Zada</i>	354
The Economics of Charter Schools	<i>R Zimmer and R Buddin</i>	360
The Economics of Parental Choice	<i>R Chakrabarti and J Roy</i>	367
The Economics of School Accountability	<i>D N Figlio and H F Ladd</i>	374
The Efficacy of Educational Vouchers	<i>R Zimmer and E P Bettinger</i>	380
Tiebout Sorting and Competition	<i>T J Nechyba</i>	388

Economics of Education – Production of Schooling

Desegregation, Academic Achievement and Earnings	<i>S Rivkin</i>	394
Education Production Functions: Concepts	<i>D N Harris</i>	402
Education Production Functions: Developed Country Evidence	<i>E A Hanushek</i>	407
Education Production Functions: Evidence from Developing Countries	<i>P Glewwe and S Lambert</i>	412
Family Environment in the Production of Schooling	<i>R Rothstein</i>	423
Neighborhoods and Peers in the Production of Schooling	<i>J Vigdor and J Ludwig</i>	431
Teacher Quality in Education Production	<i>I Pelayo and D J Brewer</i>	438
The Economics of Class Size	<i>D W Schanzenbach</i>	443
The Economics of Early Childhood Interventions	<i>M Nores</i>	450

Economics of Education – Teaching Labor Markets

An Overview of Teacher Labor Markets	<i>H Lankford and J Wyckoff</i>	456
Compensating Differentials in Teacher Labor Markets	<i>J Chambers</i>	465
Economic Approaches to Teacher Recruitment and Retention	<i>S Loeb and J Myung</i>	473
Teacher Incentives	<i>L Santibañez</i>	481
Teacher Supply	<i>P Dolton</i>	489
Teacher Training and Preparation in the United States	<i>M Podgursky, M G Springer, and R Hutton</i>	498
Teachers in Developing Countries	<i>F H Rogers and E Vegas</i>	504
The Economics of Teachers' Unions in the United States	<i>K Strunk</i>	512

Education of Children with Special Needs

Adapted Physical Activity for Students with Special Needs	<i>S R Hodge</i>	519
Assessment Accommodations for Children with Special Needs	<i>R J Kettler and S N Elliott</i>	530
Assistive Technology and Educational Practice	<i>H P Parette and G R Peterson-Karlan</i>	537
Augmentative–Alternative Communication	<i>C Mason and K M Chinn</i>	544
Community Integration and Employment of Youth with Special Needs	<i>B A Ford and A W Daviso III</i>	550
Cooperative Learning for Children with Special Needs	<i>E A Dooley and K R Kossar</i>	555
Co-Teaching	<i>E D Cramer</i>	560
Cultural and Linguistic Diversity and Children with Special Needs	<i>J M Patton, N Day-Vines, and A McSwain</i>	565
Curriculum-Based Assessment and Students with Special Needs	<i>D J O'Shea and J D Katsafanas</i>	571

Diagnosis and Classification	<i>M Sapp</i>	577
Direct Instruction and the Education of Children with Special Needs	<i>T Mehring</i>	584
Disabilities and Gifted Education	<i>V I Daniels and M J McCollin</i>	588
Early Childhood Special Education: Birth to Eight Years Old	<i>T S Lovelace, R Gardner III, J B Axe, and D M Sainato</i>	594
Early Intervention for Students with Special Needs	<i>P A Grant</i>	608
Early Transition of Children with Special Needs	<i>S A Fowler</i>	613
Educating Children Who are Deaf-Blind	<i>J Wood and K M Chinn</i>	621
Educating Children with Deafness and Hearing Impairments	<i>G M Mukuria and C J Eleweke</i>	628
Educating Children with Other Health Impairments (ADHD)	<i>G M Mukuria and F E Obiakor</i>	634
Educating Children with Physical Disabilities	<i>Z P Nkabinde, F E Obiakor, M T Ofor, and D J Smith</i>	640
Educating Children with Specific Learning Disabilities	<i>P A Grant and P B Grant</i>	646
Educating Children with Speech and Language Disorders	<i>S L Green and C D Qualls</i>	654
Educating Students with Autism and Related Disorders	<i>T T Dyches</i>	661
Educating Students with Cognitive Disabilities	<i>J P Bakken</i>	669
Educating Students with Emotional and Behavioral Disorders	<i>S W Smith and G G Taylor</i>	678
Educating Students with Special Needs: An Overview	<i>F E Obiakor, M K Harris, P Harris-Obiakor, and G M Mukuria</i>	688
Educating Students with Traumatic Brain Injury	<i>S Burkhardt and A Rotatori</i>	695
English Language Learners with Special Needs	<i>R Rueda and G Ragusa</i>	701
Functional Behavioral Assessment	<i>J P Bakken</i>	708
History of Special Education	<i>L M Garrick Duhaney and S J Salend</i>	714
Inclusion of Students with Special Needs in General Education Classrooms	<i>M A Prater</i>	721
Instructional Accommodations for Children with Special Needs in Inclusive Settings	<i>A L Yurick, S Musti-Rao, and G Cartledge</i>	727
Interagency Agreements	<i>L A Owens</i>	733
Interdisciplinary Collaboration in Early Childhood	<i>N File</i>	739
Language Development in Children with Special Needs	<i>M S L Stewart</i>	745
Large Scale Assessment and Accountability and Students with Special Needs	<i>M L Thurlow</i>	752
Literacy Instruction for Students with Special Needs	<i>L H Mason</i>	759
Math Instruction for Children with Special Needs	<i>B A Bottge</i>	767
Overrepresentation of Culturally and Linguistically Diverse Students in Special Education	<i>S C Trent</i>	774
Paraprofessionals in Special Education	<i>B Y Ashbaker, S C Dunn, and J Morgan</i>	780
Parent and Family Involvement in the Education of Children with Special Needs	<i>L P Prater</i>	788
Peer Relations and Socialization of Children and Adolescents with Special Needs	<i>L M Bullock, M Wong-Lo, and R A Gable</i>	794
Peer-Tutoring	<i>L J O'Shea and D J O'Shea</i>	802
Postsecondary Participation of Students with Special Needs	<i>R A Stodden and K D Roberts</i>	808
Prereferral Strategies	<i>C G Simpson and J P Bakken</i>	815

Preventing Antisocial Behavior and Delinquency: A Comprehensive School-wide Approach <i>P R Hallam, K R Young, P Caldarella, D G Wall, and L Christensen</i>	820
Programs and Instructional Strategies for Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	829
Related Services for Children with Special Needs <i>S O Obi</i>	834
Risk and Resilience Frameworks in Understanding Special Education <i>W-Y Hsieh and M L Donahue</i>	840
School Dropout Prevention <i>F E Obiakor</i>	845
School-Based Services for Children with Special Needs <i>S O Obi</i>	850
Self-Determination <i>M L Wehmeyer</i>	857
Social Competence <i>L A Owens and S Johnston-Rodriguez</i>	865
The Identification of Students with Gifts and Talents <i>V I Daniels and M J McCollin</i>	870
Transition from School to Adult Life <i>M J McCollin and F E Obiakor</i>	876
Visual Impairment <i>W Sapp</i>	880
Workforce Issues in Special Education <i>E Carlson and B Billingsley</i>	886

VOLUME 3

Education of Professionals

An Overview of Accreditation, Certification, and Licensure Processes <i>J J Norcini and M van Zanten</i>	1
Educating America's Military Officers <i>M H Adamshick</i>	7
Education for Architecture in the United States and Canada <i>S Schreiber</i>	13
Education for Medicine <i>M B Anderson</i>	19
Education for the Legal Profession <i>J W Wegner</i>	25
Education of Clergy <i>D O Aleshire</i>	31
Framing Professions Education <i>P S O'Sullivan</i>	37
Issues in Accounting/Business Education <i>W H Gijsselaers and R G Milter</i>	39
Professions – Engineering <i>J Heywood</i>	45
Professions – Health-Related <i>G M Jensen and C B Royeen</i>	51
Professions – Pharmacy <i>D E Beck</i>	58
Teaching for the Complex Practice of Nursing <i>P Benner and M Sutphen</i>	65
Veterinary Education <i>K M Edmondson</i>	71

Education Research Methodology: Quantitative Methods and Research

Abductive Research Methods <i>B D Haig</i>	77
Field Experimentation in Education <i>M A Constanas</i>	83
Internal Validity <i>M H Clark and S C Middleton</i>	90
Methods for Approximating Random Assignment <i>B Schneider and S-K McDonald</i>	97
Methods for Approximating Random Assignment: Regression Discontinuity and Propensity Scores <i>L M Scheier</i>	104

Multitrait–Multimethod Designs	<i>M Bong and S Hong</i>	111
Multivariate Longitudinal Data Analysis	<i>H Liu and L Chang</i>	120
Quasi-Experimentation: Two Group Design	<i>E Hong</i>	128
Regression Discontinuity Designs	<i>A Kelava, S Rohrmann, and V Hodapp</i>	134
Sampling	<i>R S Brown</i>	142
Statistical Conclusion Validity	<i>P L Busk</i>	147
Survey Research Methods	<i>A Fink</i>	152

Educational Assessment

An Overview of Educational Assessment	<i>M James</i>	161
Assessment and the Evaluation of Institutional Effectiveness	<i>S M Thomas</i>	172
Assessment in Schools – Dispositions	<i>R D Crick</i>	181
Assessment in Schools Related To Literacy: Reading	<i>K J Topping</i>	189
Impact of Assessment on Students' Learning Strategies and Implications for Judging Assessment Quality	<i>M Segers, F Dochy, and D Gijbels</i>	196

Educational Assessment – Assessment Activities

Alternative Assessment	<i>G Stobart and C Gipps</i>	202
Classroom Assessment Tasks and Tests	<i>J Phelan and J Phelan</i>	209
Dynamic Assessment	<i>J G Elliott, E L Grigorenko, and W C M Resing</i>	220
Instructional System Provided Feedback	<i>H F O'Neil, S Chuang, and T Huang</i>	226
Peer and Self-assessment	<i>C Harrison</i>	231
Portfolio Assessment	<i>V Klenowski</i>	236
Records of Achievement: Beyond Traditional Tests	<i>P Broadfoot</i>	243

Educational Assessment – Assessment in Domains

Assessment in Higher Education	<i>D R Sadler</i>	249
Assessment in Schools – Affective Domain	<i>M Ventura, R D Roberts, and M Zeidner</i>	256
Assessment in Schools – Creative Subjects	<i>T E Costantino and L Bresler</i>	262
Assessment in Schools – Learning to Learn	<i>A Hautamäki, J Hautamäki, and S Kupiainen</i>	268
Assessment in Schools – Literacy Writing (Extended)	<i>J M Parr and L Earl</i>	273
Assessment in Schools – Mathematics	<i>M Brown and J Hodgen</i>	279
Assessment in Schools – Oracy	<i>A L Bailey</i>	285
Assessment in Schools – Primary Science	<i>W Harlen</i>	293
Assessment in Schools – Secondary Science	<i>J Shemwell, A Fu, M Figueroa, R Davis, and R Shavelson</i>	300
Assessment in Schools – Technology Education and ICT	<i>A Jones, B Cowie, and J Moreland</i>	311
Assessment in the Early Years	<i>M J Drummond</i>	316
Assessment in the History, Civics and Social Studies Domains	<i>P G Avery</i>	323
Assessment in the Workplace of Performance, Developing Expertise and Competence	<i>A J Brown</i>	330
Assessment in Vocational Education	<i>K Ecclestone</i>	337

Educational Assessment – Concepts and Issues

Assessing Group Work	<i>M Galton</i>	342
Assessment and the Regulation of Learning	<i>L Allal</i>	348
Challenges of Developing and Implementing Formative Assessment Practices in Schools	<i>R Sutton</i>	353
Formative Assessment	<i>P Black</i>	359
Formative Assessment and Instructional Planning	<i>B Marshall</i>	365
Progression and Assessment: Developmental Assessment	<i>M Forster and G Masters</i>	369
Students' Rights in Assessment and Evaluation	<i>J Gardner and B Holmes</i>	378
Summative Assessment by Teachers	<i>R Daugherty</i>	384
The Multiple Purposes of Assessment	<i>P E Newton</i>	392
The Relationship between Assessment and the Organization and Practice of Teaching	<i>L B Resnick, D William, R Apodaca, and E S Rangel</i>	397

Educational Assessment – Enhancing Quality and Use

Assessment Conversations: Reading and Writing Conferences with Students and with Parents	<i>M Barrs</i>	403
Assessment: Pre-service and In-service Teacher Education	<i>A Davies</i>	410
Classroom Assessment in Policy Context (Australia)	<i>J J Cumming</i>	417
Classroom Assessment in Policy Context (England and France)	<i>M Osborn and M Raveaud</i>	425
Classroom Assessment in Policy Context (French Sources)	<i>D Laveault</i>	432
Classroom Assessment in Policy Context (Hong Kong)	<i>D Carless</i>	438
Classroom Assessment in Policy Context (New Zealand)	<i>T J Crooks</i>	443
Classroom Assessment in Policy Context (Sub-Saharan Africa)	<i>S J Howie, L Zimmerman, and K Draper</i>	449
Moderation of Student Work by Teachers	<i>G S Maxwell</i>	457
School Policies and Practices to Support Effective Classroom Assessment for Learning	<i>D Pedder</i>	464
Student Assessment: Policy and Practice in Eastern Europe	<i>G Bethell</i>	472

Educational Assessment – Key Relationships

Assessment Practice in Policy Context: Latin American Countries	<i>F M Rizo</i>	479
Impact of Assessment on Learner Groups (Boys/Girls)	<i>J Elwood</i>	486
Impact of Assessment on Learner Groups (Disabilities)	<i>M Rouse</i>	492
Impact of Assessment on Students' Test Anxiety	<i>P Buchwald and C Schwarzer</i>	498
Impact of Assessments on Classroom Practice	<i>J L Herman</i>	506
Social Practices in School Assessment and their Impact on Learner Identities	<i>A Pollard and A Filer</i>	512

Educational Evaluation – Concepts, Practice, and Future Directions

Educational Evaluation: Concepts, Practice, and Future Directions	<i>Y J Ni</i>	518
---	---------------	-----

Educational Evaluation – Contemporary Themes in Evaluation

Evaluating E-Learning	<i>D D Williams and C R Graham</i>	530
Evaluating Schools as Learning Communities	<i>S M Thomas</i>	539
Evaluation of Adult Education and Training Programs	<i>G McNamara, P Joyce, and J O'Hara</i>	548
Evaluation of Integrated Health Programs in School	<i>T M Franke</i>	555

Formative Assessment in Teacher Education and Teacher Professional Development	<i>H Tillema</i>	563
Informal Education and Evaluation	<i>T Jeffs</i>	572
Methods to Evaluate Technology	<i>W L Bewley</i>	578

Educational Evaluation – Contexts of Educational Evaluation

Cost Analysis in Evaluation Studies	<i>J D Fletcher</i>	585
Cultural Issues that Can Affect the Validity of Educational Evaluations	<i>R P Durán</i>	592
Evaluation and Accountability	<i>E Sato and S N Rabinowitz</i>	600
Evaluation Governance and Planning	<i>R Picciotto</i>	607
Evaluation Use	<i>V G Thomas</i>	614
Moral and Ethical Issues in Evaluation	<i>M Morris</i>	622
The Role of Stakeholders in Educational Evaluation	<i>S Taut and M C Alkin</i>	629

Educational Evaluation – Evaluation Domains

Curriculum Evaluation	<i>T Levin</i>	636
Evaluating Education in Three Policy Eras	<i>M A Peters, R Britez, and S M Weber</i>	645
Evaluation of Mathematics Education Programs	<i>J Cai</i>	653
Evaluation of Science Education Programs	<i>G Berberoğlu</i>	660
Evaluation of Social Studies and Civic Education Programs	<i>S G Grant</i>	667
Evaluation of Teacher Quality and Practice	<i>W Robinson and J Campbell</i>	674
International Evaluations	<i>A Schleicher</i>	681
National Assessment Programs: The Example of the U.S. National Assessment of Educational Progress	<i>M Schneider</i>	690
Principal Evaluation: Concepts, Needs and Realities	<i>N S Glasman and L D Glasman</i>	698
Program Evaluation	<i>C A Christie and L A Fierro</i>	706
School Based Evaluation: Purposes, Protocols and Processes	<i>J MacBeath</i>	713
School Inspection/External School Evaluation	<i>C Chapman and P Earley</i>	719
The International System for Teacher Observation and Feedback: A Theoretical Framework for Developing International Instruments	<i>L Kyriakides, B P M Creemers, C Teddlie, and D Muijs</i>	726

Educational Evaluation – Evaluation Methods

Evaluation Methodology	<i>M Chatterji</i>	735
Evaluation Reporting and Communicating	<i>R T Torres</i>	746
Longitudinal Evaluation Designs	<i>X Ma</i>	757
Meta-evaluation: Purpose, Prescription, and Practice	<i>L A Wingate</i>	765

Educational Evaluation – Purposes and Models of Educational Evaluation

Defining Quality in Evaluation	<i>P Dahler-Larsen</i>	775
Internal and External Evaluation	<i>D Nevo</i>	781
Needs Assessment in Education	<i>J W Altschuld and T L Lepicki</i>	786
The Purpose of Educational Evaluation	<i>S Mathison</i>	792
Understanding Approaches to Evaluation	<i>A J Love</i>	798

VOLUME 4**Educational Measurement**

Ability Testing	<i>P B Tymms</i>	1
Admissions Testing	<i>R Zwick</i>	7
Appropriateness Measurement: Person Fit	<i>R R Meijer and A M Weekers</i>	15
Automated Essay Scoring: Writing Assessment and Instruction	<i>M D Shermis, J Burstein, D Higgins, and K Zechner</i>	20
Classical Test Theory Reliability	<i>M D Miller</i>	27
Criterion-Referenced Measurement	<i>S A Shrock and W C Coscarelli</i>	31
Differential Item Functioning	<i>M D Hidalgo and J Gómez-Benito</i>	36
Educational Measurement: Overview	<i>R L Linn</i>	45
Equating and Scaling	<i>A A von Davier</i>	50
Fairness	<i>C Gipps and G Stobart</i>	56
Generalizability Theory	<i>R L Brennan</i>	61
Impact of Assessment on Classroom Practice	<i>J L Herman</i>	69
Intelligent Systems	<i>V J Shute and D Zapata-Rivera</i>	75
Item Response Theory	<i>W J van der Linden</i>	81
National Assessments	<i>T J Crooks</i>	89
Norm-Referenced Measurement	<i>H D Hoover</i>	95
Progress Monitoring	<i>L S Fuchs and D Fuchs</i>	102
Rasch Models	<i>D Andrich</i>	111
Scoring Rubrics	<i>J A Arter</i>	123
Second Language Assessment	<i>L F Bachman</i>	140
Self Adaptive Testing	<i>J Revuelta</i>	148
Student Test Results in School Accountability	<i>L S Hamilton</i>	153
Test Development	<i>S M Downing</i>	159
Test Translation and Adaptation	<i>A Allalouf and P Hanani</i>	166
Testing Creativity	<i>M A Runco</i>	170
Testing in History	<i>S Wineburg and B Fogo</i>	175
Validity	<i>R L Linn</i>	181
Validity of Achievement Gains on High-Stakes Tests	<i>D Koretz</i>	186
Validity of Educational Indicators	<i>B P M Creemers and L Kyriakides</i>	193

G**Globalization of Universities and Institutions**

Globalization, Universities and Medium of Instruction	<i>J Lo Bianco</i>	201
The Washington Accord on Engineering Curriculum	<i>E Ko</i>	209

H

Higher Education

Higher Education: An Overview	<i>P Scott</i>	217
-------------------------------	----------------	-----

Higher Education – Management, Leadership and Governance

Academic Managers – Heads of Departments/Schools	<i>S Marshall</i>	229
Leading and Managing the University – Presidents and their Senior Management Team	<i>R Middlehurst, T Kennie, and S Woodfield</i>	238
Management of and in Higher Education Institutions	<i>B Sporn</i>	245
Managerialism and Collegialism in Higher Education Institutions	<i>M Shattock</i>	251
Strategic Planning in Higher Education	<i>L Zechlin</i>	256
The Changing Role of University Presidents, Vice-Chancellors and Rectors	<i>M F Green and P D Eckel</i>	264
The Changing Roles of University Governing Boards and Councils	<i>J Fielden</i>	273

Higher Education – Research and Scholarship

Funding of University Research	<i>G Harman</i>	279
Mobility of PhD Students and Scientists	<i>S Avveduto</i>	286
National Science Policy and Universities	<i>M Henkel and U Kogan</i>	294
Research Commercialization	<i>S Slaughter</i>	300
Research Quality Assessment	<i>I McNay</i>	307
The Management of University Research	<i>J Kirkland</i>	316
The Training of New Scientists	<i>R Neumann</i>	322

Higher Education – Society

Academic Freedom	<i>S F Macintyre</i>	328
Access and Equity in Higher Education	<i>G Baldwin and R James</i>	334
Boundaries of Institutional Autonomy and their Impact on Higher Education	<i>V L Meek</i>	341
Diversity of Higher Education	<i>U Teichler</i>	347
Employability of University Graduates and Graduate Outcomes	<i>J Brennan</i>	354
Higher Education and the Knowledge Society	<i>J Välimaa</i>	360
Higher Education and the Labor Market	<i>J Enders</i>	365
Higher Education and the Transformation of Society	<i>P Scott</i>	370
Quality Assurance in Higher Education – Practices and Issues	<i>D Dill</i>	377
The Role of Accreditation of Higher Education Institutions	<i>J S Eaton</i>	384
Universities and Regional Development	<i>J Goddard and J Puukka</i>	390
Universities' Engagement with Society	<i>D Watson</i>	398

Higher Education – Teaching and Learning in Higher Education

Distance Education and Open Universities	<i>A Kanwar and J Daniel</i>	404
Education Development in Higher Education	<i>Y Ryan and K Fraser</i>	411
Effective Use of Technology in Teaching and Learning in HE	<i>D Laurillard</i>	419

Facilitating Students' Success – Student Support and Learning Resources in Universities	<i>E Woodberry and C Barnes</i>	427
Faculty Values and Expectations and Their Implications for Teaching, Learning and the Organization of Higher Education Institutions	<i>K Harman</i>	433
Flexible Learning in Higher Education	<i>S Alexander</i>	441
Innovation in Teaching and Curriculum Design	<i>J M Dearn</i>	448
Productivity of University Faculty Staff	<i>S Kyvik</i>	455
Promoting Effective Student Learning in Higher Education	<i>K Trigwell</i>	461
Student Attrition from Higher Education Institutions	<i>M Hayden</i>	467
University Students' Experiences of Higher Education	<i>C McInnis</i>	473
What Do University Students Learn?	<i>G D Kuh and B K Bridges</i>	479

Higher Education – Tertiary Education in a Globalized World

Associations of Universities	<i>G F Moodie</i>	485
Collective Bargaining in Higher Education	<i>C Allport, K McAlpine, and S Roberts</i>	491
Financing of Higher Education	<i>B Chapman and P Tulip</i>	499
Higher Education Crossing Borders	<i>J Knight</i>	507
Higher Education in Post-Conflict Societies	<i>M Daxner</i>	514
Higher Education in the New Economies	<i>J Fielden</i>	520
Human Resource Issues in Higher Education	<i>E El-Khawas</i>	527
International Accreditation in Higher Education	<i>A Stella and D Woodhouse</i>	533
Internationalization of Higher Education	<i>M van der Wende</i>	540
National and International Rankings of Higher Education	<i>S Marginson</i>	546
Steering of Higher Education Systems – The Role of the State	<i>K Yokoyama and V L Meek</i>	554
Student and Faculty Transnational Mobility in Higher Education	<i>U Lanzendorf and B M Kehm</i>	559
The Bologna Process in European Higher Education	<i>D Rich</i>	566
The Economics and Finance of Higher Education	<i>A Wolf</i>	573
The Role of the OECD in the Development of Higher Education in a Globalized World	<i>R Yelland</i>	584
Transforming Higher Education in Developing Countries: The Role of the World Bank	<i>J Salmi and R M Bassett</i>	590
UNESCO's Role in the Development of Higher Education in a Globalized World	<i>S Uvalić-Trumbić</i>	597

Higher Education – The Organization and Financing of Higher Education

Higher Education in Federal Systems	<i>M A M Cortés and U Teichler</i>	603
Pathways and Articulation into Higher Education	<i>G F Moodie</i>	609
Unitary, Binary and other National Systems of Higher Education	<i>L Goedegebuure</i>	616
Viewing Private Higher Education: How Much, Where, Why, and What?	<i>D C Levy</i>	622

I

Immigration

Children of Migrant Populations	<i>M M Suárez-Orozco and C Suárez-Orozco</i>	629
Third Culture Kids	<i>R E Van Reken</i>	636

International Comparisons

IEA Studies in ICT	<i>N Law</i>	644
IEA Studies in Mathematics and Science	<i>F K S Leung</i>	650
IEA Study in Civic Education	<i>J Torney-Purta, J-A Amadeo, and J Schwillie</i>	656
IEA: Globalization and Assessment	<i>H Wagemaker</i>	663

International Organizations in Education

Education and the European Union	<i>S Hegarty</i>	669
National University on Educational Planning and Administration, New Delhi	<i>J B G Tilak</i>	676
On School Management – International Council on School Effectiveness and Improvement, Commonwealth Council on Educational Administration and Management	<i>A Walker and T Townsend</i>	681
UNESCO's International Institute for Educational Planning	<i>S J Hite and M Bray</i>	688

L**Leadership and Management**

Leadership and Management Overview	<i>B Mulford</i>	695
------------------------------------	------------------	-----

Leadership and Management – as a Field of Study

Contexts for Leadership at the Beginning of the 21st Century	<i>M Bottery</i>	704
Educational Leadership: Philosophical Issues	<i>C W Evers</i>	710
Ethical/Moral Issues in Educational Leadership	<i>R J Starratt, L Langlois, and P Duignan</i>	717
History of Educational Leadership/Management	<i>R Bates</i>	724
Educational Leadership as a Field of Study: Professional Journals 1994–2006	<i>A R Thomas</i>	731
Research on Educational Leadership – Approaches/Promising Directions	<i>W A Firestone and V M J Robinson</i>	740

Leadership and Management – Leader Preparation

Leaders for Productive Schools	<i>J Murphy, S N Elliott, E B Goldring, and A C Porter</i>	746
New Approaches in Preparing School Leaders	<i>S G Huber</i>	752
Research for Leaders: The National College for School Leadership	<i>G Southworth</i>	762
School Leadership Standards	<i>L Ingvarson</i>	768

Leadership and Management – Leadership Issues

Effective Leadership in Challenging Schools	<i>A Harris</i>	777
Esthetics, Educational Leadership and Management	<i>R Bates</i>	783
Leader Mistreatment of Teachers	<i>J Blase and J Blase</i>	790
Leadership and Gender	<i>J Blackmore</i>	797
Leadership and Student Voice	<i>C Lanskey and J Rudduck</i>	803
Leadership and Urban Education	<i>K A Riley</i>	809
Leadership for Learning	<i>J MacBeath</i>	817
Leadership in Diverse Cultures	<i>A Walker and P K Yu-kwong</i>	824

Leading Diverse Schools	<i>J Ryan</i>	832
Supervision and Personnel Administration	<i>P D Tucker and D G Pounder</i>	839
The Big Challenge: Leadership for Inclusion	<i>M Ainscow and A Sandill</i>	846
The Educational Leader's New Work	<i>P Gronn</i>	852

VOLUME 5

Leadership and Management – Leadership Types

A Distributed Perspective on School Leadership and Management	<i>J P Spillane</i>	1
Leadership: Authentic	<i>P T Begley</i>	7
Leadership: Democratic	<i>J Møller</i>	12
Leadership: Instructional	<i>P Hallinger, K Leithwood, and R H Heck</i>	18
Leadership: Transformative	<i>C M Shields</i>	26
Strategic Leadership	<i>B Davies and B J Davies</i>	34
Teacher Leadership and Organizational Development	<i>A Harris</i>	40
Understanding How Leadership Influences Student Learning	<i>K Leithwood and B Levin</i>	45

Leadership and Management – Politics and Governance

Equity and Educational Effectiveness	<i>P Sammons</i>	51
Leading/Managing Schools in Communities Made Poor	<i>P Thomson</i>	58
Principals Role in Restructuring Schools	<i>G M Crow and K D Peterson</i>	66
School Reform and Restructuring: Self Managing School	<i>B J Caldwell</i>	72
System Leadership	<i>D Hopkins and R Higham</i>	78

Leadership and Management – School and Community

Educational Leadership and Social Capital	<i>J West-Burnham</i>	85
Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy	<i>D Jackson</i>	92
Networks and Communities of Knowledge	<i>T Schuller and H Theisens</i>	100
School Community Relations	<i>R L Crowson and E B Goldring</i>	106
Social Capital, Educational Institutions and Leadership	<i>S Kilpatrick, S Johns, and B Mulford</i>	113

Leadership and Management – School Effectiveness and Improvement

Leadership and Technology	<i>C F Webber</i>	120
Leadership in the Implementation of Innovations	<i>I E Bogotch, T Townsend, and M Acker-Hocevar</i>	128
Leadership: School Improvement	<i>R H Heck and P Hallinger</i>	135
Organizational Learning in Schools	<i>B Mulford and H Silins</i>	143
Professional Learning Community	<i>L Stoll</i>	151
Transformational School Leadership	<i>K Leithwood</i>	158

Learning and Cognition – Issues and Concepts

Attention in Cognition and Early Learning	<i>M Heimann, T Tjus, and K Strid</i>	165
Concept Learning	<i>S J Unsworth and D L Medin</i>	172
Cooperative Learning	<i>R E Slavin</i>	177
Intelligence	<i>R J Sternberg</i>	184
Learning from Multiple Information Sources	<i>H I Strømsø and I Bråten</i>	191
Memory	<i>S Magnussen and T Brennen</i>	197
Metacognition	<i>L Baker</i>	204
Personal Epistemology in Education: Concepts, Issues, and Implications	<i>I Bråten</i>	211
Piaget: Recent Work	<i>L Smith</i>	218
The Adult Development of Cognition and Learning	<i>E A L Stine-Morrow and J M Parisi</i>	225
Vygotsky and Recent Developments	<i>J V Wertsch</i>	231

Learning and Cognition – Issues and Concepts – Focus on Cognition

Cognition and Emotion	<i>F Pons, M de Rosnay, and F Cuisinier</i>	237
Cognition: Overview and Recent Trends	<i>J Wiley and B D Jee</i>	245
Development of Creativity	<i>M A Runco</i>	251
Knowledge Domains and Domain Learning	<i>L Maggioni and P A Alexander</i>	255
Problem Solving and Human Expertise	<i>T J Nokes, C D Schunn, and M T H Chi</i>	265
Problem Solving and Reasoning	<i>R E Mayer</i>	273
Reasoning, Moral and Social	<i>N S Jampol, C B Richardson, and M Killen</i>	279
Remembering as Social Activity	<i>D Middleton</i>	285

Learning and Cognition – Issues, Concepts, Types

Computer-Supported Collaborative Learning: Basic Concepts, Multiple Perspectives, and Emerging Trends	<i>S R Ludvigsen and A I Mørch</i>	290
Learning as Inquiry	<i>S R Goldman, J Radinsky, S Tozer, and D Wink</i>	297
Learning Through Narrative Socialization	<i>A Fasulo</i>	303
Neuroscience Bases of Learning	<i>M H Immordino-Yang and K W Fischer</i>	310
The Neuroscience of Reading	<i>U Goswami</i>	317

Learning and Cognition – Issues, Concepts, Types – Focus on Learning

Learning Strategies	<i>C E Weinstein, J Jung, and T W Acee</i>	323
Learning Through Play	<i>K Aronsson</i>	330
Situated View of Learning	<i>A Collins and J G Greeno</i>	335
The Neuroscience of Aging and Cognition	<i>W J Hoyer and B Bessette-Symons</i>	340

Learning and Cognition – Language, Literacy and Subject-Related

An Overview of Language and Literacy in Educational Settings	<i>V G Aukrust</i>	345
Bilingualism and Learning	<i>L S Verplaetse and E Schmitt</i>	355
Classroom Discourse and Student Learning	<i>L Hemphill</i>	361
Early Writing	<i>B E Hagtvet</i>	367

First Language Acquisition	<i>N B Ratner</i>	375
Foreign Language Learning	<i>C Kinginger</i>	382
Learning Science	<i>J Leach and P Scott</i>	387
Learning to Read	<i>M S Burns and J K Kidd</i>	394
Mathematics Learning	<i>L Verschaffel, B Greer, and E De Corte</i>	401
Music Learning	<i>S Hallam</i>	407
Reading Comprehension: Reading for Learning	<i>C E Snow</i>	413
Second Language Learning	<i>J S Arnfast, J N Jørgensen, and A Holmen</i>	419
Writing: Advanced	<i>R Andrews</i>	426

Learning and Cognition – Other Issues

Gender and Learning	<i>L Yates and J McLeod</i>	432
Parent–Child Relationships in Early Learning	<i>C P Edwards, S M Sheridan, and L L Knoche</i>	438
Peer Interaction and Learning	<i>S Blum-Kulka and S Dvir-Gvirsman</i>	444

Learning and Cognition – Places of Learning

Learning in a Cross-Cultural Perspective	<i>L-F Zhang and R J Sternberg</i>	450
Learning Outside of School	<i>T Nunes</i>	457
Reasoning and Explanatory Talk: Learning in Everyday Settings	<i>D E Beals</i>	464

Learning and Cognition – Theoretical Perspectives – Learning

Apprenticeship Approach to Learning	<i>K Nielsen</i>	469
Connectionism and Learning	<i>T R Shultz</i>	476
Constructivism and Learning	<i>S Sjøberg</i>	485
Cultural–Historical Activity Theory	<i>A Havnes</i>	491
Learning in a Sociocultural Perspective	<i>R Säljö</i>	498
Self-Regulated Learning and Socio-Cognitive Theory	<i>P H Winne and A F Hadwin</i>	503

N

National Systems of Education

Australia	<i>C N Power</i>	510
Austria	<i>M J Gaertner</i>	517
Bangladesh	<i>R Z Dewan</i>	524
Barbados	<i>R Rudder</i>	534
Bulgaria	<i>A Chavdarova and D Vesselinov</i>	540
England	<i>C Whatford</i>	550
Estonia	<i>M Keränen and J Kõrgesaar</i>	555
Fiji	<i>I Senibulu</i>	563
Finland	<i>J E Tuovinen</i>	569
France	<i>M Sellier</i>	576

Germany	<i>A Hüfner and K Hüfner</i>	582
Ghana	<i>R Palmer</i>	590
Greece	<i>K Toura and A Karagiannis</i>	599
Iceland	<i>M Hardardottir and M Gunnlaugsdóttir</i>	605
Indonesia	<i>A C Alwasilah and Furqon</i>	611
Israel	<i>A Volansky</i>	618
Jamaica	<i>E Hannam</i>	627
Latvia	<i>A Joma</i>	630
Lebanon	<i>N A Mneimneh</i>	636
Lithuania	<i>J Navickaitė, L Paurienė, R Zablackė, A Tijūnelytė, and V Kožemiakina</i>	656
Malawi	<i>F R Mkandawire and D Mulera</i>	666
Malta	<i>C Farrugia</i>	673

Sri Lanka	<i>B M J Balasooriya, M M Wehella, and S U Wijeratne</i>	813
Suriname	<i>H R Ori</i>	826
Taiwan	<i>C-M Lee</i>	834
Tanzania	<i>R Wedgwood</i>	841
Thailand	<i>C Rukspollmuang</i>	847
The Gambia	<i>Y A-M Jobe</i>	858
The Philippines	<i>E A P Valenzuela</i>	865
Uruguay	<i>B Guinovart and C Troncoso</i>	873
USA	<i>B Pusser and M E R Lloyd</i>	888
Zanzibar	<i>I M Hija</i>	896

VOLUME 6**P****Philosophy of Education**

Philosophy of Education: Overview	<i>P Enslin</i>	1
-----------------------------------	-----------------	---

Philosophy of Education – Contemporary Issues

Neoliberalism, the Market and Performativity	<i>M A Peters</i>	11
Parents and Children's Rights	<i>M Clayton</i>	17
Peace Education	<i>I Gur-Ze'ev</i>	22
Philosophy and Educational Research	<i>D Bridges</i>	29
Race, Critical Race Theory and Whiteness	<i>B Applebaum</i>	36
School Choice and the Common School	<i>G Haydon</i>	44

Philosophy of Education – Philosophical Perspective

African Philosophy of Education	<i>K Horsthemke</i>	50
Feminism	<i>L Stone</i>	56
Hermeneutics	<i>C Bingham</i>	63
Islamic Education	<i>Y Waghid</i>	69
Liberalism and Education	<i>W Feinberg</i>	74
Phenomenology and Existentialism	<i>B Levering</i>	80
Pragmatism	<i>B Thayer-Bacon</i>	86
Psychoanalysis and Education	<i>P Smeyers</i>	92
Social and Cultural Capital in Education	<i>M Print</i>	97
The Aims of Education	<i>R Marples</i>	103
The Analytical Tradition	<i>D Carr</i>	108

Philosophy of Education – Philosophical Themes

Adult Learning: Philosophical Issues	<i>D Beckett</i>	114
Autonomy	<i>C A Wringe</i>	121
Bildung	<i>J Masschelein and N Ricken</i>	127
Critical Theory and Pedagogy	<i>M Mason</i>	133
Critical Thinking	<i>H Siegel</i>	141
Environmental Education	<i>M Bonnett</i>	146
Identity	<i>M S Merry</i>	152
Inclusion	<i>R Cigman</i>	158
Justice and Care	<i>M Tjiattas</i>	164
Lifelong Learning	<i>J Halliday</i>	170
Post-Structuralism and Education	<i>M Mason and M Clarke</i>	175
Reason and Rationality	<i>P Hogan</i>	183

Religious and Spiritual Education	<i>J C Conroy and S J McKinney</i>	189
The Capabilities Approach	<i>L Terzi</i>	194

Primary and Secondary Education – Learning and Teaching in School Age Education

Class Size – Arguments and Evidence	<i>P Blatchford and K C Lai</i>	200
Continuing Professional Development of Teachers	<i>P Earley</i>	207
Homeschooling	<i>P Farenga</i>	214
Innovations and Early Intervention in the Teaching of Literacy	<i>R E Slavin</i>	221
Personalized Learning in School Age Education	<i>D Hopkins</i>	227
Perspectives on Schooling in the Middle Years	<i>V J Russell</i>	233
Reform of the School Workforce	<i>H M Gunter and G Forrester</i>	242
Secondary Education in Developing Countries	<i>P Hughes and A Walker</i>	249

Primary and Secondary Education – Social Justice Issues in School Age Education

Community Focused Schools	<i>A Dyson</i>	255
---------------------------	----------------	-----

Primary and Secondary Education – The Effectiveness of School Systems

Reforming the American School System	<i>M Barber</i>	261
School Effectiveness in Developed Societies	<i>D Reynolds</i>	269
School to School Collaboration: Innovation and Improvement	<i>R Higham</i>	274
Studies of School Improvement in Developing Countries	<i>S E Anderson</i>	281
Sustainable Educational Reform	<i>A Hargreaves</i>	289
The Role of the District in Tri Level Reform	<i>M Fullan</i>	295
Whole School Designs for Enhancing Student Achievement	<i>S Stringfield and J Nunnery</i>	303

Q

Qualitative Research

Action Research in Education	<i>E Stringer</i>	311
Classroom Ethnography	<i>F Erickson</i>	320
Computer Assisted Qualitative Data Analysis	<i>C Silver and A Lewins</i>	326
Conversational Analysis	<i>H G Levine</i>	335
Critical Ethnography	<i>D Foley</i>	337
Critical Race Theory	<i>D Gillborn and G Ladson-Billings</i>	341
Critical Theory	<i>J J Ryoo and P McLaren</i>	348
Cultural Studies	<i>R Gaztambide-Fernández and K Cairns</i>	354
Cultural–Historical Activity Theory	<i>Laboratory for Comparative Human Cognition</i>	360
Design Experiments	<i>A Collins</i>	367
Discourse Analysis	<i>P Nikander and S Vehviläinen</i>	373
Document Analysis	<i>T Rapley and K N Jenkins</i>	380
Ethnography	<i>M Hammersley</i>	386

Ethnomethodology in Education Research	<i>D Macbeth</i>	392
Focus Groups	<i>D L Morgan and K Hoffman</i>	401
Grounded Theory	<i>K Charmaz and A Bryant</i>	406
Hermeneutics	<i>J Dyer</i>	413
Interpretive Research	<i>E Rauscher and M E Graue</i>	419
Interviews and Interviewing	<i>A Marvasti</i>	424
Life History	<i>J A Hatch and S K Newsom</i>	430
Narrative Inquiry	<i>D J Clandinin and J Huber</i>	436
Participant Observation	<i>J Schostak</i>	442
Phenomenology	<i>M van Manen and C A Adams</i>	449
Qualitative Case Studies	<i>S B Merriam</i>	456
Qualitative Data Management	<i>C Grbich</i>	463
Semiotics	<i>M Danesi</i>	475
Symbolic Interactionism, Naturalistic Inquiry, and Education	<i>J A Forte</i>	481
The Quality of Evidence in Qualitative Research	<i>S K Biklen</i>	488
Visual Data in Education Research	<i>J Wagner</i>	498

Qualitative Research – Standards of Proof

Validity: Mapping Diverse Perspectives	<i>G B Rossman, S F Rallis, and A M Kuntz</i>	505
--	---	-----

Quantitative and Qualitative Approaches to Research – Integration

Mixed Methods	<i>A Tashakkori and I Newman</i>	514
---------------	----------------------------------	-----

Quantitative Methods and Research Design

External Validity	<i>G E Matt, A Brewer, and M Sklar</i>	521
-------------------	--	-----

R

Role of NGOs in Globalization

NGOs and Globalization of Education	<i>M Ahmed</i>	529
-------------------------------------	----------------	-----

S

Social and Emotional Aspects of Learning

Achievement Goal Theory: Definitions, Correlates, and Unresolved Questions	<i>T Urdan</i>	537
Affect, Mood and Emotions	<i>S Schnall</i>	544
Anxiety	<i>M Zeidner</i>	549
Attribution Theory	<i>B Weiner</i>	558
Children's Friendship	<i>S R Asher and K L McDonald</i>	564
Coping with Stressful Situations: An Important Aspect of Self-Regulation	<i>M Boekaerts</i>	570
Culture in Motivation Research: A Challenging and Enriching Contribution	<i>K Kimmel and S Volet</i>	576
Early Social Development and Schooling	<i>G M van der Aalsvoort</i>	585

Emotion in Educational Contexts	<i>P A Schutz, P D Quijada, S de Vries, and M Lynde</i>	591
Empathy	<i>R Arnold</i>	597
Flow in Education	<i>J A Schmidt</i>	605
Interest	<i>M Ainley</i>	612
Intrinsic and Extrinsic Motivation	<i>C Levesque, K J Copeland, M D Pattie, and E L Deci</i>	618
Motivating Students in Classrooms	<i>J Brophy</i>	624
Motivation Regulation	<i>C A Wolters and S A Mueller</i>	631
Peer Learning in the Classroom	<i>N M Webb</i>	636
Poverty, Effects of on Social and Emotional Development	<i>N Philipsen Hetzner, A D Johnson, and J Brooks-Gunn</i>	643
Seeking Help as an Adaptive Response to Learning Difficulties: Person, Situation, and Developmental Influences	<i>S A Karabenick and R S Newman</i>	653
Self-Concept in Learning: Reciprocal effects model between academic self-concept and academic achievement	<i>H W Marsh and L F Scalas</i>	660
Self-Efficacy Beliefs	<i>D H Schunk and F Pajares</i>	668
Social and Emotional Outcomes of Learning	<i>J Vorhaus</i>	673
Social Aspects of Collaborative Learning	<i>M Arvaja and P Häkkinen</i>	685
Social Development and Schooling	<i>G W Ladd</i>	691
Social Interaction and Learning	<i>K Littleton</i>	698
Social Networks and the Education of Children and Youth	<i>B Schneider, T G Ford, and L Perez-Felkner</i>	705
Sociocultural Issues in Motivation	<i>R A Walker</i>	712
Socioemotional Aspects of Technology-Supported Learning	<i>S Järvelä</i>	718
Volitional Control of Learning	<i>J Husman and L Corno</i>	724
Wellbeing	<i>T Hascher</i>	732

VOLUME 7

Statistics

An Overview of Statistics in Education	<i>S Sinharay</i>	2
Analysis and Interpretation of Multivariate Data	<i>D J Bartholomew</i>	12
Analysis of Covariance	<i>N T Longford</i>	18
Analysis of Extreme Values in Education	<i>J Beirlant, G Dierckx, K Luwel, and P Onghena</i>	25
Analysis of Variance	<i>B M King</i>	32
Bayesian Statistical Analysis	<i>G Kokolakis</i>	37
Bootstrap Method	<i>K Singh and M Xie</i>	46
Canonical Correlation	<i>A Basu and A Mandal</i>	52
Categorical Data Analysis	<i>S E Fienberg and B W Junker</i>	58
Causal Inference	<i>D B Rubin</i>	66
Cluster Analysis: Overview	<i>S Landau and I Chis Ster</i>	72

Cognitive Psychology and Educational Statistics	<i>H S Kim and S Embretson</i>	84
Computational Statistics	<i>J E Gentle</i>	93
Continuous Probability Distributions	<i>S Sinharay</i>	98
Correspondence Analysis	<i>M Greenacre</i>	103
Data Mining	<i>R S J d Baker</i>	112
Decision Theory	<i>M Mendoza and E Gutiérrez-Peña</i>	119
Design of Experiments	<i>C A Albers and T R Kratochwill</i>	125
Discrete Probability Distributions	<i>S Sinharay</i>	132
Discrimination and Classification	<i>R C Neath and M S Johnson</i>	135
Empirical Bayes Methods	<i>E Ip and G Molenberghs</i>	142
Evaluation Research	<i>T Kellaghan</i>	150
Exploratory Data Analysis	<i>A Unwin</i>	156
Factor Analysis: An Overview and Some Contemporary Advances	<i>F A N Alhija</i>	162
Generalized Linear Mixed Models	<i>S Rabe-Hesketh and A Skrondal</i>	171
Generalized Linear Models	<i>J J Faraway</i>	178
Generating Random Numbers	<i>P J Pashley and A Amodeo</i>	184
Goodness-of-Fit Testing	<i>A Maydeu-Olivares and C García-Forero</i>	190
Graphical Models	<i>R G Almond</i>	197
Growth Modeling	<i>I Plewis</i>	203
Hierarchical Linear Models	<i>D Rindskopf</i>	210
Hypothesis Testing and Confidence Intervals	<i>T R Konold and X Fan</i>	216
Instrumental Variables	<i>E P Bettinger</i>	223
Jackknife Methods	<i>S Sinharay</i>	229
Large-sample Statistical Methods	<i>J M Singer and D F Andrade</i>	232
Latent Class Models	<i>J K Vermunt</i>	238
Markov Chain Monte Carlo	<i>A M Johansen</i>	245
Matrix Algebra	<i>H Yanai and H Ishii</i>	253
Measure of Association	<i>G-H Huang</i>	260
Measures of Central Tendency	<i>D Clark-Carter</i>	264
Measures of Dispersion, Skewness and Kurtosis	<i>D Rindskopf and M Shiyko</i>	267
Meta Analysis	<i>J Sánchez-Meca and F Marín-Martínez</i>	274
Missing Data	<i>C A W Glas</i>	283
Model Selection	<i>S J Haberman</i>	289
Monte Carlo Methods	<i>A M Johansen</i>	296
Multidimensional Scaling	<i>Z Zhang and Y Takane</i>	304
Multiple Comparisons	<i>C Lewis</i>	312
Multivariate Analysis of Variance	<i>N T Longford</i>	319
Multivariate Linear Regression	<i>S Ganesh</i>	324
Multivariate Normal Distribution	<i>J Tacq</i>	332

Nonlinear Regression Analysis	<i>H-H Huang, C K Hsiao, and S-Y Huang</i>	339
Nonparametric Statistical Methods	<i>K Sijtsma and W H M Emons</i>	347
Observational Studies	<i>P R Rosenbaum</i>	354
Order Statistics	<i>I Bairamov</i>	360
Point Estimation Methods with Applications to Item Response Theory Models	<i>F Bartolucci and L Scrucca</i>	366
Principal Components Analysis	<i>D J Bartholomew</i>	374
Probability Theory	<i>T Rudas</i>	378
Recursive Partitioning	<i>S Landau and S Barthel</i>	383
Sampling	<i>J Qian</i>	390
Sequential Probability Ratio Test	<i>T J H M Eggen</i>	396
Sequential Testing	<i>H J Vos</i>	401
Signal Detection Theory	<i>H Abdi</i>	407
Small Area Estimation	<i>A Noble</i>	411
Statistical Analysis of Functional Data	<i>F Ferraty, P Sarda, and P Vieu</i>	417
Statistical Inequalities	<i>H M Mahmoud and J L Gastwirth</i>	426
Statistical Paradoxes	<i>Y-K Tu</i>	429
Statistical Power Analysis	<i>L V Hedges and C Rhoads</i>	436
Statistical Significance Versus Effect Size	<i>X Fan and T R Konold</i>	444
Stochastic Processes	<i>F Baudoin</i>	451
Structural Equation Models	<i>S-Y Lee and X-Y Song</i>	453
Survival Data Analysis	<i>A F De Champlain</i>	459
The Normal Distribution and its Applications	<i>J Tacq</i>	467
Time Series Analysis	<i>P J Brockwell</i>	474
Univariate Linear Regression	<i>M L Hazelton</i>	482
Value-Added Models	<i>D F McCaffrey</i>	489

An Overview of Accreditation, Certification, and Licensure Processes

J J Norcini and M van Zanten, Foundation for Advancement of International Medical Education and Research (FAIMER), Philadelphia, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The qualities or stages of development of a profession are: (1) the activity becomes a full-time job, (2) formal training is available, (3) the job becomes the subject of university study, (4) professional associations are established, (5) practitioners are licensed, and (6) a code of ethical practice is adopted. In describing the characteristics of a profession, some authors have included both a formal training mechanism and a means for testing the competence of practitioners. Although the definition of a profession has evolved steadily from these early efforts, some form of recognition, both of education and the individual professional, remains central. Accreditation, licensure, and certification are the most common forms of these recognitions.

The Centre for Educational Research and Innovation of the Organization for Economic Cooperation and Development (OECD) has recently reviewed the status of quality assurance and professional recognition around the world. The Centre's research demonstrates that most of the OECD member nations have these types of quality-assurance mechanisms in place and that many non-OECD members do as well, or are in the process of developing such systems. However, there is great diversity in the

nature and rigor of the processes employed and of the scope and governance of the regulatory bodies that oversee the recognition.

Given the diversity across countries, the purpose of this article is to broadly describe accreditation, licensure, and certification. Specifically, we define the terms, explain the benefits to a variety of different stakeholders, provide descriptions of some of the models currently in use, and review the evidence in favor of their effectiveness.

Accreditation

In the field of education in the professions, accreditation can be defined as a process by which a designated authority reviews and evaluates an educational institution or specific program using a set of clearly defined criteria and procedures. Accreditation of educational programs can be mandatory or voluntary, depending on the scope and authority of the organization. While there is diversity in the methods of implementation, most accreditation processes share the following approach:

1. a guided self-study is conducted by the institution;
2. an external review and site visit is conducted by a peer committee;

3. based on the self-review data and information gathered on site, an accreditation decision is made by the organization, or a recommendation is given to a governmental ministry for final approval;
4. decisions and reports are published and disseminated; and
5. the process is repeated at specified intervals, usually every 4–8 years.

Benefits of Accreditation

Independent third-party certifiers, such as an accreditation authority that reviews educational institutions, provide market signals to the public concerning the value of the product under review. Through a system of accreditation, educational institutions and programs can demonstrate objective evidence of quality. Within the professions, sometimes a certain degree of uniformity of study programs is required by governmental or guild-specific organizations. In settings where accreditation is mandatory, the public is ensured that all educational institutions are meeting a minimal level of required quality. Where accreditation is voluntary, benefits to an educational institution could include increased student applications, higher profits, better retention of current students, ease of student mobility, and an enhanced reputation. Individual students, especially those entering specialized professions, often carry a stronger legitimacy in the workforce if they are graduates of programs that have been successfully assessed against rigorous standards of quality.

In addition to promoting educational quality within a specific country, accreditation processes can allow for the direct comparison of professional training experiences and the mutual acceptance of degrees. A standardized process or recognition of transparent systems of education evaluation is increasingly useful as cross-border movement of professionals continues to rise worldwide. For example, the Washington Accord of 1989 set generic criteria, policies, and procedures for accrediting engineering academic programs. Countries that sign the Washington Accord formally agree to accept each other's engineering program accreditation decisions. In the field of medical education, regional cooperation of accreditation activities in various areas in the world, including the Caribbean, Central and South America, and the Gulf region, is evidence of a growing need to pool resources and facilitate the evaluation of foreign degrees. Some international accreditation systems have no legal standing, either nationally or internationally, but are used for comparison and benchmarking of similar professional education programs. An example of such international cooperation is the European Quality Improvement System (EQUIS), which has evolved to become a global system of quality assessment, improvement, and accreditation of higher education institutions in the field of management and business administration.

Models of Accreditation

Accreditation organizations can accredit educational institutions as a whole, or accredit specific programs, that is, law, business, nursing, etc. Some countries use both models, such as in the United States (US), where 19 institutional accrediting organizations accredited approximately 6300 institutions as a whole, and more than 60 programmatic accrediting organizations accredit approximately 17 500 programs. Some countries have chosen to adopt only one of these models. For example, in the Philippines, a voluntary accreditation system utilizes four separate accrediting organizations recognized by the Philippine Department of Education to evaluate only higher education programs, not institutions. Some countries use one organization employing a hybrid system, such as The Norwegian Agency of Quality Assurance in Education (NOKUT), which accredits both educational institutions and/or study programs.

Accreditation systems can vary in scope and nature of the authority charged with the quality review. In many countries around the world, the government is directly responsible for designing and implementing a process of educational institution quality assurance. For example, most accrediting bodies in Central and South America, such as those in Argentina, Colombia, and Ecuador, are governmental entities. In contrast, in other countries, autonomous, independently run organizations are accountable for ensuring education quality. The Japanese government requires all universities to undergo accreditation by a certified body, and the government accepts the accreditation decision granted by various independent agencies. The Japan University Accreditation Association (JUAA) and the National Institute for Academic Degrees and University Evaluation (NIAD-UE) both accredit Japanese educational institutions. In other instances, an independent agency is responsible for designing and implementing a quality-assurance process and making recommendations to a ministry to grant the official accreditation status. In the Czech Republic, the Czech Republic Accreditation Commission (CRAC) is an advisory body that evaluates higher education institutions and programs, and the Ministry of Education, Youth and Sports makes the final accreditation decisions. In the case of medical education programs, the country's Ministry of Health must also approve of the recommendation of the CRAC as a prerequisite to the final decision by the Ministry of Education. In India, the National Assessment and Accreditation Council (NAAC) voluntarily assesses institutions of higher education. While the NAAC process uses generic criteria and is voluntary, many professions in India require a review of educational programs by specific organizations. For example, the National Board of Accreditation (NBA) was created by the All India Council for Technical Education (AICTE) to evaluate technical programs, such as engineering and technology, architecture, and town and country planning.

Accreditation systems can also focus on either the process of the education, or on outcomes, or a combination. A process-focused approach measures an educational program's potential to effectively train students by determining compliance with accreditation standards. For example, an accreditation system utilizing a process model considers if the educational program has established a mission and objectives, employees suitably qualified instructors, uses an approved curriculum, and complies with resource requirements. In contrast, rather than focusing on a program's potential to educate professionals, an accreditation approach based on outcomes focuses on the students' or graduates' actual accomplishments. An outcomes-based accreditation system strives to measure the students' level of achievement of the learning objectives established by the program.

Development of Accreditation Systems

Accreditation systems are developed for various reasons and can be the result of influences from a variety of sources. In many countries, the development of accreditation systems has been the result of government laws aimed at ensuring quality in domestic educational institutions. In other instances, the government was not directly responsible for the evolution of accreditation systems. For example, in the US, at the end of the nineteenth century there was virtually no oversight of higher education, and quality and curriculum content varied significantly between institutions. Among the professions, knowledge and learning were becoming more specialized and numerous educational institutions were operating with wide variation in quality. In addition, the population was becoming more mobile and institutions needed a mechanism for evaluating the education of transfer students. This situation led to accreditation activities beginning simultaneously from professional organizations outside of the educational arena, and from within the educational institutions themselves. The advancement of applicable national or international standards has also been a key factor influencing the development of an accreditation system for various professions. Standards authorities provide sampling and testing protocols that can be used by accreditation authorities in their review process, and supply structure and guidance on appropriate benchmarks.

Evidence of Effectiveness

The general purpose of accreditation systems in professions education is to ensure that a minimum level of standards has been met, and frequently also to promote quality improvement activities within the educational institutions or programs. Despite the recent trends toward establishment and enhancement of these systems in the

global realm, much of the support for these activities tends to be limited to numerous positive anecdotal accounts regarding improvement. Traditionally, accreditation has been based on qualitative rather than quantitative assessments of educational program criteria, and therefore isolating the linkage between accreditation variables and appropriate outcomes can be difficult. As a result, it appears that few rigorous investigations have been conducted and published evaluating the effectiveness of accreditation processes. One study measuring the impact of a change in accreditation standards on engineering programs noted significantly higher levels in students' learning outcomes as a result of the new system. Evaluations of various criteria to determine the effectiveness of an accreditation system on postgraduate medical training programs in the field of cardiology have demonstrated positive findings, and also some inconclusive results. A recent systematic review of health-sector accreditation, which included some studies of educational programs, also noted both positive and inconsistent findings.

Recently, there has been an increased call for extended research in a variety of fields to link educational institution accreditation to quality indicators, and a request that standards be based on data which clearly demonstrates that schools which adhere to these benchmarks produce students who are more knowledgeable and skilled than their peers from nonaccredited institutions. In addition, within established evaluation systems, it is often not known which specific aspects of the accreditation protocols and procedures can be linked to improved quality. Therefore, while accreditation systems continue to become more numerous, and have well-established and publicly accepted face validity as a means of ensuring a minimum standard of quality, further research is necessary to specifically describe the value of these systems in terms of improved workplace skills of the graduates. For example, as is the case within many specialized healthcare fields, little research has been done to evaluate if accreditation processes improve the quality of nursing education, and most importantly, ultimately the longer-term outcome of improvement in the quality of patient care delivered by the nurse graduates.

Licensure and Certification

A license is formal permission from a government for an individual to engage in a particular occupation. Certification is the same, except that the recognition is usually granted by a nongovernmental entity. Registration, a term used extensively outside of the US, is comparable in function to both of these in that individuals must register with an organization for a particular occupation. For purposes of this article, we will use the terms recognition or professional recognition to refer to all of these concepts.

According to the Centre for Educational Research and Innovation, the nature of the institutions that grant professional recognition varies considerably from country to country. In some, they are governmental, in some they are independent, and in some both governmental and independent agencies (sometimes professional associations) operate, with the latter often holding higher standards. In addition to variation in the nature of the regulatory institutions, there is also diversity in both the definitions of particular professions and the standards held for them. This wide range of practice and concepts limits the degree to which generalizations can be drawn about professional recognition, thereby limiting the mobility of the professionals themselves.

Although there are exceptions, the regulatory institutions typically require that an individual completes an accredited or recognized educational process and passes an examination before acquiring a license or certificate. In some instances, a period of professional practice is also required. Historically, the license/certificate was granted in perpetuity, but in recent years a system of maintenance of certification is becoming increasingly common across a variety of professions.

Benefits of Licensure and Certification

The four chief stakeholders in professional recognition are clients (or patients), the professionals themselves, employers, and the profession as a whole. With a recognized professional, individual clients should experience improved quality of services, reduced risks of adverse events, and increased satisfaction. For the individual professionals, licensure and certification establish their credentials, improve their career opportunities, often increase their earnings, offer peer recognition, and reflect achievement and commitment.

Licensure and certification also have benefits for institutions. For employers, hiring recognized professionals serves as recruitment tool, demonstrates staff credibility, and anchors the hiring decision in an objective marker of competence. Moreover, it improves the quality and efficiency of the services provided to clients and enhances their satisfaction. For the profession itself, recognition defines the scope of competence and practice, acts as a barrier to entry, ensures high standards, and promotes professionalism.

Models of Licensure and Certification

There are several models of licensure and certification ranging from general recognition in a broad area to recognition in more focused aspects of practice. Often, licensure and registration convey privilege in a general field of activity and the institutions conferring it have

wide-ranging power over the profession. For example, the Institute of Chartered Accountants of India (ICAI) was created by statute and it (1) regulates the profession in India, (2) is responsible for professional development, and (3) acts in an advisory capacity to government and other institutions. The ICAI has multiple functions including setting the curriculum, providing the examination, taking disciplinary action against individuals when warranted, creating accounting standards, generating ethical standards, peer review, and post-qualification course development.

In contrast, US institutions that grant licenses or registrations often have a much more focused set of activities. This more restrictive role is intended to eliminate the potential conflicts of interest inherent in having multiple responsibilities (i.e., being involved in education, regulation, and professional advocacy all at the same time). For example, the National Council of Architectural Registration Boards (NCARB) is composed of the 50 jurisdictions in the US that grant licenses in the field. For certification, it requires a degree from an accredited institution, successful completion of an intern development program, and successful performance on a registration examination. It does not regulate the profession nor does it represent either the educational process or concerns of practicing architects.

Within broad disciplines, there is frequently a need to recognize focused areas of practice. For example, in teaching, the National Board for Professional Teaching Standards (NBPTS) in the US offers certification in 25 different areas, such as mathematics in early adolescence, mathematics in adolescence and young adulthood, and reading in early and middle childhood. Similarly, in the UK, the different medical specialties are recognized through separate royal colleges (e.g., the Royal College of Physicians and the Royal College of Surgeons).

Recognition at the level of specialties within broad disciplines is more frequently, although not exclusively, voluntary and carries with it no legal restrictions on the scope of practice. For example, NBPTS teacher certification was created as a voluntary process aimed at raising standards in the field. Likewise, certification in the medical specialties in the US is voluntary. Neither acts as a barrier to entry to practice for those who do not hold the certificate, although diplomates of these boards have advantage by virtue of the fact that they have demonstrated their expertise. In some instances, such as the UK Royal College of Physicians, membership is required to progress in training.

As fields mature and are driven by advances in science and practice, it is not unusual for subspecialties to develop. For instance, in the US, cardiovascular diseases constitute a subspecialty of internal medicine. To become certified in this field, physicians must first train and acquire certification in internal medicine before undergoing training and certification in cardiovascular diseases.

It is also not unusual for these fields to spawn their own subspecialties. Therefore, for example, cardiovascular diseases in the US now have their own subspecialties, including interventional cardiology and clinical cardiac electrophysiology. Further, different specialties sometime share the same subspecialty. In the US, sleep medicine is a subspecialty of family medicine, internal medicine, psychiatry and neurology, pediatrics, and otolaryngology.

Within a broad discipline, the development of specialties and subspecialties is influenced by a variety of scientific, social, political, and cultural factors. Consequently, the final results may vary across country and may not even be consistent within the same country. For instance, in the US, the medical specialties have tended to remain integrated within internal medicine, while the surgical specialties have tended to separate. This makes international comparisons difficult and it also has implications for the portability of these credentials.

Requirements

Although a variety of different requirements are used for professional recognition, most regulatory entities often require two or more of the following: (1) an approved educational experience, (2) a practice experience, and (3) successful examination performance. For example, NCARB requires the applicant to have earned a professional degree from an accredited program, satisfy intern training requirements, pass all parts of the examination, acquire licenses from a jurisdiction in the US, and then apply for certification. Similarly, the National Council of Examiners for Engineers and Surveyors (NCEES) has four requirements that must be satisfied to obtain a state license: (1) graduation from an accredited engineering program, (2) successful performance on a test of fundamentals, (3) a period of approved work experience, and (4) successful performance on a discipline-specific examination.

Evidence of Effectiveness

The development of evidence for the effectiveness of licensure and certification programs is a relatively recent event. Moreover, most of it focuses on the examination since it is typically the most discriminating step in the process. The evidence most often seeks to establish the relationship of certification test scores to the quality of the educational process, scores on other tests, and practice performance.

One example of this type of work is the research on examination scores used as part of certification in internal medicine and its subspecialties. These scores have positive relationships with the quality of undergraduate medical education. More importantly, they are sensitive to the presence and amount of formal training in a discipline and how well trainees perform during that training. They are

also responsive to the educational characteristics of the training experience, such as faculty–trainee ratio.

There are correlations between the certifying examination in internal medicine, which is composed of multiple-choice questions, and other methods of assessment including other written examination formats, oral examinations, essay examinations, video simulations, written simulations, computer-based simulations, and faculty ratings of competence. Naturally, these correlations are greater when the two measures focus on the same aspects of competence.

It is well established in medicine that larger practice volume is associated with better patient outcomes. There is evidence that scores on the certifying examinations in critical care medicine are correlated with practice volume as well. Most importantly, certification status and examination scores have reasonable relationships with actual outcomes in practice, such as mortality following acute myocardial infarction.

This relationship with practice performance has been found with other professions as well. Students of teachers certified by the NBPTS had higher test scores, greater learning gains, and they demonstrated deeper learning. Of note, these effects were of particular benefit to special needs and minority children.

Summary

This article has provided an overview of a number of issues pertaining to accreditation of educational programs and licensure and certification of individual professionals. Examples of current practices, various models, development of systems, evidence of effectiveness, and the need for further research have been described.

The report by OECD highlights the fact that most quality-assurance mechanisms in accreditation, licensure, and certification focus on national concerns and public institutions and practices. As a consequence, there is frequently no framework for formally coordinating efforts across borders. The effect of this lack of legally sanctioned regional or global cooperation frequently leaves the burgeoning e-learning offerings and the rapidly increasing numbers of for-profit schools unregulated, which are also often not under the jurisdiction of the currently operating national accreditation systems. In addition, it limits the mobility of professionals whose credentials neither have common meaning nor reflect comparable standards across borders.

While the creation of an international framework may have positive effects on the quality of education in the developed countries, it may also have unintended consequences for less-developed countries. For example, the issue of brain drain among numerous professions, such as physicians, nurses, and other health care providers, is of significance in those countries with the highest burden of

disease. Anything that enhances the mobility of professionals is likely to exacerbate this problem. It is important that the creation of regional or international frameworks of educational quality assurance and/or foreign-degree recognition also be accompanied by policies that ensure equitable access critical professional services.

Educating America's Military Officers

M H Adamshick, US Naval Academy, Annapolis, MD, USA

The Professional Military Officer

From as early as the seventeenth century, the formal education of a professional corps of military officers in Western society can be attributed to two significant factors. One was the transformation of military leadership from members of the noble class to those non-noble people selected because of their specialized education and training. The other was the rise of the nation-state and the subsequent formation of large armies requiring military leaders with specialized education and training to accommodate the parallel advance in military technology and tactics. The professionalization of the military officer necessitated the creation of formal institutions of higher learning to equip military leaders to accommodate this technical and doctrinal transformation. This gave rise to the military schools and academies from the eighteenth century until the beginning of the nineteenth century in most important Western countries. The Russian Military Academy was founded in St. Petersburg in 1723; the Royal Military Academy of the United Kingdom was founded in 1741; the *Ecole Royale Militaire* was founded in France in 1751; and the Prussian *Kriegs-Akademie* in Potsdam was established in 1765. The nineteenth century saw the establishment of Sandhurst in Great Britain and West Point in the United States in 1802; Saint-Cyr in France in 1808; and the *Kriegs-Akademie* in Königsberg (Prussia) in 1810. Initially dedicated to professional indoctrination and training of military commanders, the education of military officers evolved in concert with the technological and scientific pace of the nineteenth century. The focus on leadership and military strategy gave way to an educational curriculum focused on scientific and engineering matters and eventually aligned with the traditional format of the university. In twentieth century Europe and in the United States, the education of military officers took on a very standardized pattern, even though there were some differences from country to country. The pattern exhibited the following:

1. The basic educational program was conducted in typically 2–4 years and primarily focused on doctrinal study and professional training.
2. The location for educating military professionals was segregated from similar educational places for nonmilitary students and was generally a stand-alone institution.
3. Admission to the institution was generally restricted to young males who had already earned a secondary

education in a civilian school. Most students were in their late teens or early 20s.

4. Selection criteria were highly formalized, based upon an assessment of a variety of factors, and were intended to preserve the quality and nature of the military professional.
5. Entrance to the institution gave members a military status granting the institution some social control over their new members.

Today, all US military officers begin their service by receiving a common commission from the president by swearing their allegiance to support and defend the constitution of the United States. The commission, which is similar for all military branches (the Army, Navy, Air Force, and Marine Corps), is both a letter of instruction and a grant of authority that commands the officer to “carefully and diligently discharge the duties of the office to which appointed . . .” The commission delineates that all commissioned officers, like all officials of the executive branch of government, serve at the pleasure of the president.

The profession of the military officer displays particular characteristics some of which, as suggested by Huntington, are expertise, responsibility, and corporateness, while for others, such as Janowitz, they are a core of skills that is difficult to master and of considerable social importance, autonomy or self-rule, an ethical code, and a system of compulsion. These two authors, considered the fathers of contemporary sociology of the military, believe that the military officer corps most closely represent the ideal type of profession. The professionalization of the US military officer corps begins at the candidate's commissioning source.

The US military commissions about 20 000 officers each year. Almost all officers are college graduates. About 40% of officers received their commissions through participation in Reserve Officer Training (ROTC) programs at civilian colleges and universities, about 22% through officer candidate schools (OCSs) or officer training schools (OTSs), and about 11% – primarily people with medical or legal training or the clergy – receive direct commissions. A significant minority (about 15%) are commissioned through three federal military academies: the US Military Academy at West Point, NY; the US Air Force Academy at Colorado Springs, CO; and the US Naval Academy at Annapolis, MD. Some Naval Academy graduates are commissioned to serve in the Marine Corps rather than the Navy.

Military Officer Development (Leader Education)

The traditional higher education academic experience for the officer candidate student is similar to their civilian counterparts in most aspects. Candidates choose their academic course of study and select a major within the guidelines of the ROTC scholarship program funding their enrollment. All must comply with the academic guidelines enforced by the institution as directed by accreditation standards. From an educational standpoint, what remains unique is the military leader development model students experience in each commissioning program. For example, the US military academies invest a considerable amount of their cadets' and midshipmen's years in education for leadership. Each academy endeavors to synthesize the entire experience of student activity into a leadership component that prepares the young adult for their subsequent military service. The experience of officer formation is different for each cadet and midshipman, although each institution endeavors to control this variation through standardized training and adherence to strict performance requirements. Variance occurs due to differences in student background, culture, trait personalities, intelligence, motivation, interests, activities, and a whole host of other variables that cannot be controlled for in the officer development model. Simply, students have different traits and experiences that may profoundly effect how they ultimately lead. What does remain constant for each cohort group, however, is a core academic program aligned with the broad leader development model. Core leadership instruction at the federal military service academies forms the academic bedrock of the leadership development continuum for each school. Generally, each program acknowledges that certain individual characteristics, attributes, or skills are associated with effective leader's performance under various conditions, and that these military institutions develop or cultivate these characteristics in future leaders. While the officer development experience is uniquely different at each commissioning source, the military services have a standard set of officer attributes that must be met by every candidate upon the completion of their educational program.

The Professional Military Educational Continuum

Pre-Commissioning

Military education received at institutions and through programs producing commissioned officers upon graduation is referred to as pre-commissioning, which focuses on preparing officer candidates to become commissioned officers within the Military Department that administers the pre-commissioning program. The curricula are

oriented toward providing candidates with a basic grounding in the US defense establishment and their chosen military service, as well as a foundation in leadership, management, ethics, and other subjects necessary in preparing them to serve as commissioned officers.

Primary

Education typically received at grades (officer) O-1 through O-3 subsequent to commissioning is considered as primary education, which focuses on preparing junior officers to serve in their assigned branch or warfare or staff specialty. The curricula are predominantly service oriented, primarily addressing the tactical level of war. Service schools that have programs centered on pay grade O-3 officers will foster an understanding of joint war-fighting necessary for success at this level. Joint learning areas are embedded in service professional military education (PME) instruction.

Intermediate

Education typically received at grade O-4 approximately 9–11 years after commissioning is referred to as intermediate education, which focuses on war-fighting within the context of operational art. Officers expand their understanding of joint force deployment and employment at the operational and tactical levels of war. They gain a better understanding of joint and service perspectives. Inherent in this level is the development of an officer's analytic capabilities and creative thought processes. In addition to continuing development of their joint war-fighting expertise, they are introduced to theater strategy and plans, national military strategy, and national security strategy and policy.

Senior

Senior education is typically received at grades O-5 or O-6, approximately 15–17 years after commissioning. Here, the focus is to prepare officers for positions of strategic leadership. Senior education focuses on strategy, theater campaign planning, the art and science of developing, and integrating and applying the instruments of national power (diplomatic, informational, military, and economic) during peace and war. Studies at these colleges should emphasize analysis, foster critical examination, encourage creativity, and provide a progressively broader educational experience.

General/Flag Officer

This constitutes the education received as a general/flag officer (G/FO). The number of commissioned officers

eligible to serve at this rank is determined by federal law and is a small percentage of the total force strength. The percentage of commissioned officers on active duty serving at the G/FO rank is approximately 4.3% of the total commissioned officer force (875 G/FOs out of approximately 203 000 commissioned officers). The promotion rate from O-6 to G/FO is about 2% across each military service. Courses within the G/FO level of the Joint Professional Military Education (JPME) continuum prepare senior officers of the US Armed Forces for high-level joint, interagency, and multinational responsibilities. These courses may address grand strategy, national security strategy, national military strategy, theater strategy, and the conduct of campaigns and military operations in a joint, interagency, and multinational environment to achieve US national interests and objectives. G/FO JPME is tiered to ensure the progressive and continuous development of executive-level officers.

Officer/Leader Development at the United States Military Service Academies

Broadly defined, the approach to studying leadership/officership at all three military service academies is based upon an experiential learning model comprised of conceptualization, experimentation, reinforcement, and reflection over a period of 4 years in residence. This is accomplished through a fairly common process of personal learning, classroom instruction, and interaction, complemented by the unique professional experiences and opportunities for reflection during the academic year and through summer training. The leadership education program consists of formal instruction by military and civilian professionals in leadership, management, philosophy and ethics, human behavior, and law; complemented by the practical knowledge and real-time experiences with operational service components. This relevant and effective combination of academic and professional expertise profoundly enhances the learning environment. This approach intends to transform the learning environment from an abstract study into a more pertinent and timely application of knowledge.

Core Officer/Leader Development Curriculum

All three military service academies enrol students in core academic courses throughout their 4 years of study in addition to the courses specific to their chosen academic major. While the academic core curriculum at each institution varies, the officer/leader development curriculum remains consistently aligned with academic courses in psychology, leadership, management, ethics, philosophy, and law. As major requirements and specializations allow, many students are afforded the opportunity to take

specialized electives in addition to the core requirements. The core provides a consistent 4-year program that allows officer candidates to study leadership, human behavior, ethics, law, and character, as well as individual, group, and organizational behavior. All will gain an understanding and appreciation of the values, culture, identity, and specialized knowledge encompassed by the military profession.

Leadership education

West Point requires all cadets to take general or advanced psychology in their freshman year and military leadership in their junior year. The focus of the introductory psychology course is the development of an awareness and understanding of one's own behavior and the behavior of others. Emphasis is placed on applying the behavioral principles learned to the cadets' current lives and their functioning as future officers. Military leadership is a multidisciplinary study of leadership in an organizational context which focuses on the integration of theory and practice. The cadet studies the leader's direct influence on individual motivation and group processes through the application of leadership theories, skills, and attributes. In addition, the cadet learns how to influence subordinates indirectly through organizational systems and procedures, organizational culture, and ethical climate.

Midshipmen at Annapolis are required to take principles of self-leadership and organizational dynamics in their freshmen year and theory and applications of leadership in their junior year. They begin the study of leadership in the context of theories and principles of individual and group behavior. The introductory course emphasizes the development and understanding of personal strengths, values, and opportunities for growth. The theory and applications course builds on the concepts introduced in the first year by examining the theory and research of the contingent and dynamic process of leadership. The course combines literature from the fields of social psychology, organizational behavior, and group dynamics to help students understand the factors that influence leadership in a military context.

At the US Air Force Academy, all cadets are required to take introduction to behavioral sciences in their freshman year, foundations for leadership development in their junior year, and management and command in their final year before graduation. The introductory course provides an introduction to the scientific study of behavior and mental processes across diverse levels of analyses. The leadership development course explores leadership development as a scientific study. Specifically, the course examines principles that will set students on a lifelong path of becoming a leader of character who treats others with respect and dignity. Management focuses on the successful techniques that allow people to understand and influence their environment.

Philosophy and ethics education

Sophomore cadets at the US Military Academy take a core course in philosophy designed to develop capacities to think clearly and critically. Sophomore Naval Academy Midshipmen take ethics and moral reasoning for the military leaders. This course is structured around classical and contemporary writings in moral philosophy. At the Air Force Academy, cadets take ethics in their junior year. Students study several major moral theories and their application to contemporary problems with special emphasis on the moral problems of the profession of arms.

All three schools use classical writings and contemporary case studies to illuminate the moral and philosophical complexities of the modern military professional. The students enjoy a faculty comprised of military officers and civilian philosophers and the curriculum differs on matters of emphasis regarding philosophical theory over moral reasoning and applied ethics.

Law education

West Point seniors enrol in constitutional/military law, a course that studies the US Constitution and the military justice system. Cadets acquire information and skills in order to recognize and resolve constitutional and legal problems. The course provides analytical models for dealing with problems regarding societal and military order. Midshipmen take law for the junior officer in their senior year. This course provides a survey of relevant legal topics applicable to the role of the future junior officer as a leader, manager, and decision maker. Students examine operational law concepts, including the law of armed conflict, rules of engagement, and the law of the sea. They also study the various types of military investigations, as well as the different types of disciplinary venues, such as nonjudicial punishment and courts-martial. Students are provided with an exposure to the various crimes enumerated in the Uniform Code of Military Justice, and the administrative discharge process. Cadets at the Air Force Academy are required to take law for Air Force officers in their sophomore year. This course introduces cadets to the legal knowledge and skills they will need as Air Force officers and educated citizens. The course examines the nature of law and its role in American society and the military and introduces substantive areas of the law that military officers likely will encounter in their personal and official capacities.

Professional Military Education

PME is the critical element in officer development and is the foundation of a joint learning continuum that ensures that the US Armed Forces are intrinsically

learning organizations. The PME vision understands that young officers join their particular service, receive training and education in a joint (interservice) context, gain experience, pursue self-development, and, over the breadth of their careers, become the senior leaders of the joint force. Performance and potential are the alchemy of this growth, but nothing ensures that they are properly prepared leaders more than the care given to the content of their training, education, experience, and self-development opportunities. Modern PME guidelines entail ensuring that military officers are properly prepared for their leadership roles at every level of activity and employment, thus also ensuring that the US armed forces remain capable of defeating present-day and future threats.

PME intends to build an officer who understands the strategic implications of tactical actions and the consequences that strategic actions have on the tactical environment. Service delivery of PME, taught in a joint context, instills basic service core competencies; joint PME instills joint core competencies. JPME should position an officer to recognize and operate in tactical, operational, and strategic levels of national security.

The Ronald W. Reagan National Defense Authorization Act of 2005 expanded the opportunities to receive JPME and established a link between joint officer development and JPME. The future joint force requires knowledgeable, empowered, innovative, and decisive leaders capable of succeeding in fluid and perhaps chaotic operating environments with more comprehensive knowledge of interagency and multinational cultures and capabilities. Officer Professional Military Education Policy (OPMEP) is at the heart of building those officers. This policy intends to maintain a force of dedicated, highly educated, and well-trained men and women capable of leveraging new ideas that will succeed in the complex and fast-paced environment of future military operations.

The military officer education continuum reflects the dynamic system of officer career education. It identifies areas of emphasis at each educational level and provides joint curriculum guidance for PME institutions. It is a comprehensive frame of reference depicting the progressive nature of PME and JPME, guiding an officer's individual development over time. The continuum structures the development of service and joint officers by organizing the PME continuum into five military educational levels: pre-commissioning, primary, intermediate, senior, and G/FO. It defines the focus of each educational level in terms of the major levels of war (tactical, operational, and strategic) and links the educational levels such that each builds upon the knowledge and values gained in previous levels. The continuum also recognizes both the distinctiveness and interdependence of joint and service schools in officer education. Service schools, in keeping with their role of developing service specialists, place emphasis on

education primarily from a service perspective in accordance with joint learning areas and objectives. Joint schools emphasize joint education from a joint perspective.

International Military Education and Training

The International Military Education and Training (IMET) program is a component of US security assistance that provides training on a grant basis to students from allied and friendly nations. Funding is appropriated from the International Affairs Budget of the Department of State. It is a key component of US security assistance that provides US training on a grant basis to students from allied and friendly nations. Students are exposed to US military procedures and the manner in which the US military functions under civilian control. They may receive as examples of types of training: PME as well as technical training. Overall objectives of the IMET program are:

1. to further the goal of regional stability through effective, mutually beneficial military-to-military relations, which culminate in increased understanding and defense cooperation between the United States and foreign countries; and
2. to increase the ability of foreign national military and civilian personnel to absorb and maintain basic democratic values and protect internationally recognized human rights.

The IMET objectives are achieved through a variety of military education and training activities conducted by the US Department of Defense for foreign military and civilian officials. These include: formal instruction involving over 2000 courses taught at approximately 150 military schools and installations; on-the-job training; orientation tours for key senior military and civilian officials; and mobile education teams which take the curriculum to the host country.

Education for Architecture in the United States and Canada

S Schreiber, University of Massachusetts, Amherst, MA, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Architecture is one of the key professions involved in shaping the built environment and urban space. Architectural education has the primary purposes of producing competent, creative, critically minded, and ethical professional designers/builders who contribute to the social, economic, and cultural development of society – both nationally and globally. To achieve those purposes, it is an interdisciplinary field that comprises several major components: humanities, social and physical sciences, technology, and the creative arts.

Institutionalized architecture education developed in the second-half of the nineteenth century in response to broadening objectives for higher education, increasingly complex building systems requiring the expertise of specialized professionals, and new knowledge from related fields. Since then, architecture programs have flourished in a wide range of academic settings.

Regulation of the profession of architecture, including the licensing of practitioners, is a function of each US state/territory or Canadian province/territory exercising its power to protect the health, safety, and welfare of the people. Each jurisdiction registers architects by its own set of requirements. The requirements are generally consistent from jurisdiction to jurisdiction, but there are variations. The requirements to become an architect are often described as a three-legged stool, which includes:

- education (usually an accredited degree),
- experience (structured internship), and
- examination (the architect registration exam).

These requirements can often be completed concurrently. For example, some of the internship can be completed during school, and in many jurisdictions, some of the examinations can be completed during the internship.

All jurisdictions have an education requirement which may be satisfied by earning a professional degree in architecture accredited by the National Architectural Accrediting Board (NAAB) in the United States or the Canadian Architectural Certification Board (CACB) in Canada. Many registration boards requiring a professional degree in architecture from an NAAB/CACB-accredited program also accept other education assessed as equivalent (e.g., a professional degree in architecture from a foreign institution). Not all boards require a professional degree from an accredited program to satisfy their education requirements. Some boards require a pre-professional

degree in architecture, while others require a bachelor's degree in any subject.

The entire path to licensure typically requires 8–10 years – 5–7 years in school plus a 3-year internship. The internship years are spent as a salaried employee in an architectural or related practice working under the supervision of registered professionals.

The National Council of Architectural Registration Boards (NCARB) in the United States and the Committee of Canadian Architectural Councils (CCAC) have established standards and criteria that most licensing boards have adopted as their standard for admission to licensing examinations. Satisfaction of these requirements facilitates initial and subsequent reciprocal licensure.

The three-step path to architecture licensure – education, experience, and examination – is similar in many countries. However, in some countries, including many in Latin America and Europe, the completion of the professional architecture degree is equivalent to earning an architecture license. In this system, passing the capstone project is the same as passing a licensing exam.

Discussions regarding reciprocity between countries with similar licensing systems (such as the one that exists between the United States and Canada) have been promising and may lead to an easy transfer between countries in the near future. In 2008, accreditation and validation agencies from Australia, Canada, China, Korea, Mexico, the United States, and the Commonwealth Association of Architects announced the ratification of an agreement (the Canberra Accord) declaring substantial equivalency of professional degrees in architecture covered by their accreditation/validation systems. It is anticipated that the Canberra Accord will facilitate international mobility of graduates in architecture and contribute to improving the quality of architectural education through benchmarking.

Education

Architecture is recognized as a broadly based academic subject studied in its own right and as a professional discipline that leads to licensure. In most schools of architecture, these two concepts are richly interwoven and are reflected in the degree options for students.

Architecture programs fit into one of the four following categories:

1. *Pre-professional architecture degree.* This term refers to architecturally focused 4-year degrees that are not

professional degrees (and thus cannot be accredited). These degrees have titles such as BS in architecture, BS in architectural studies, BA in architecture, bachelor of environmental design, bachelor of architectural studies, etc. The amount of architecture work in the program varies and will determine the length of time required to complete further professional architecture studies.

2. *Professional (accredited) architecture degree.* A professional architecture degree is one that is accredited by NAAB or CACB. Accredited degrees are required by most jurisdictions for licensure as an architect. In the United States, these degrees are either the bachelor of architecture (BArch) degree or the master of architecture (MArch) degree, or the doctor of architecture (DArch). In Canada, the only accredited degree is the master of architecture.

The bachelor of architecture normally requires at least 5 years. The master of architecture requires from 1 to 5 years depending on the individual student's previous education. When the master's degree follows a 4-year, pre-professional architecture degree, it represents the two in the term four-plus-two program, and is the final portion of the professional phase of the study program. The doctor of architecture may require 7 years to complete.

3. *Post-professional architecture degree.* This is a graduate degree offered to students who already have a professional degree in architecture. Such degree programs are not accredited by NAAB and CACB. The degrees may be in highly specialized areas of study such as design theory, healthcare facilities, preservation, interior design, solar design, etc. This type of degree can be either a master's degree or, in a few cases, a PhD or other doctorate.
4. *Nonprofessional graduate architecture degree.* This title refers to graduate degrees in architecture offered to students who do not have a professional degree and wish to pursue nonprofessional graduate work in architecture. These programs vary widely in duration and degree title.

Professional (Accredited) Architecture Degrees

The NAAB and the CACB are the national architecture accrediting bodies in the United States and Canada, respectively. The board of directors of the NAAB and the CACB include representatives from architecture schools, professional societies, licensing authorities, and students. The NAAB and CACB operating under similar procedures determine whether architecture programs meet certain minimum education criteria including faculty qualifications, physical facilities, budget, curricula, course content, and program goals.

Only specific professional degree programs, not architectural schools, are accredited. A professional degree program is accredited by the same standards whether it leads to a bachelor of architecture, a master of architecture degree, or a doctor of architecture. Most schools offer only one or two accredited architectural degrees, but may have other related degree programs. For example, a school of architecture may offer a program in historic preservation or architectural engineering as well as the accredited professional architecture degree program. There are about 130 schools offering professional architecture degree programs in the United States and Canada.

Every architecture program has its special features and unique philosophy. Some schools offer many options while others have a more defined program. A single school may offer several accredited professional degree programs – for example, it may offer both a 5-year undergraduate degree for high school graduates, and a 3.5-year graduate degree intended for people who already have a degree in another field.

There are several usual paths to obtaining the professional degree in architecture:

- *Bachelor of architecture.* The 5-year bachelor of architecture degree requires a minimum of 5 years of study (equivalent to 150 credit hours minimum) and a 3-year internship (some of which can be completed in the fourth and fifth years of the program).

A 5-year program provides the quickest route to satisfy the academic requirements for licensure. Many bachelor of architecture programs begin with a concentration of architecture courses in a fairly prescribed manner, although some schools begin with a general course of instruction. Electives tend to be few and exposure to other fields limited.

Many bachelor of architecture programs, however, have devised curriculum structures which allow for considerable flexibility. These programs are broken into yearly components of 2 + 3, 1 + 4, 3 + 2, and 4 + 1, with entry and exit points from the various phases of the full 5-year program. In most schools, the student's work is carefully reviewed before advancement to the next phase. Such points provide a relatively easy means of transfer into an architecture program; transfer to another institution, particularly between degrees; or transfer to another academic discipline. The logical break points may also be used by the faculty to transfer out students who have demonstrated little progress. The early segments of the curriculum mix pre-professional design courses with general education and often serve as a common base for several different environmental design disciplines such as architecture, landscape architecture, industrial design, graphic design, etc.

Most professional degree programs also accept transfer students at the designated break points, but transfer

credit is usually evaluated on an individual course-by-course and case-by-case basis. While the structure of some programs makes it relatively easy for a professional school to accept transfer students from both junior colleges and other colleges, many feeder programs cannot match the academic depth, library and faculty resources, and extracurricular activities of the professional schools.

The CACB does not recognize the bachelor of architecture.

- *Master of architecture (5.5 years).* The 5.5-year master of architecture degree path may be entered directly from high school requiring about 168 credits and following a curriculum that is similar to that of a bachelor of architecture program. Students must be expressly accepted into the university's graduate school in order to pursue the final phase of this degree. Those who do not qualify for graduate study have the option of completing a nonprofessional undergraduate degree, with the possibility of pursuing the master's degree in one of the more traditional paths at another institution. Several schools are planning to convert their BArch programs over the coming years to MArch programs.
- *Pre-professional degree plus master of architecture.* The pre-professional degree plus master of architecture degree normally requires 6 years to complete and a 3-year internship (some of which can be completed during the fourth of the undergraduate program and during the graduate program). The flexibility in the program is readily apparent. At the end of 4 years, the student has a college degree and may decide to continue in architecture and get the professional master's degree, spend 1 or 2 years working for an architect, or change disciplines and pursue study in other design-related fields. Or the graduate may decide at this point to shift careers completely and/or seek an advanced degree outside the design field.

Pre-professional programs are not professionally accredited and vary widely with respect to title, emphasis, electives, requirements, and specific architecture offerings. They are, however, preparatory for advanced architectural or other environmental design fields. The 4-year pre-professional program may be subdivided into two phases, such as 2 + 2, or 1 + 4. The pre-professional programs provide time for experiencing a wider range of subjects, allowing the maturing student a better opportunity to make career choices. Ideally, the extra courses in the humanities and social sciences will give students a broader background from which to start their professional education.

For those who ultimately receive advanced degrees in design areas other than architecture or in nonarchitecture subjects, the 4-year degree may be preferable to the 5-year professional program in minimizing coursework and time. One other advantage of a four-plus-two program is the potential for earning the professional degree

at an institution other than where the undergraduate work was completed.

The graduate degree component of the four-plus-two path is the professional NAAB- or CACB-accredited degree. This degree is most appropriate for students who have a 4-year, pre-professional undergraduate degree in architecture. The course of study generally takes 2 years; however, at some schools, up to 3 years is required. These programs are designed to provide the professional education of the student as well as provide an opportunity for independent and creative exploration.

- *Nonarchitecture degree plus master of architecture.* The non-architecture degree plus master of architecture degree requires 7–8 years of study (a 4-year undergraduate degree plus a 3.5-year master of architecture degree), and a 3-year internship (some of which can be completed during the graduate program). The immersion into architecture is quick and very intense in this program. Some schools provide all of the education at the graduate level, while others will admit degree holders into their professional master's program with deficiencies. This means that preparatory undergraduate coursework must first be successfully completed before formal admittance to the graduate program. However, like the 2-year master of architecture degree, the 3.5-year MArch may be a fully NAAB- or CACB-accredited professional degree program, and successful graduates have professional education credentials equal to those with a BArch or other MArch.
- *Doctor of architecture.* The doctor of architecture was recently recognized by NAAB as a professional degree. It requires either an undergraduate baccalaureate degree or a minimum of 120 undergraduate semester credit hours, or the equivalent, and a minimum of 90 graduate-level semester credit hours, or the equivalent, in academic coursework in professional studies and electives.

Characteristics of Professional (Accredited) Architecture Programs

Students and faculty

In 2007, approximately 30 000 students were enrolled in NAAB- and CACB-accredited programs. That year, about 2600 students earned NAAB-accredited bachelor of architecture degrees, 2640 earned NAAB-accredited master of architecture degrees, 330 earned CACB-accredited master of architecture degrees, and 11 earned NAAB-accredited doctor of architecture degrees.

There are approximately 2200 full-time architecture faculty in the United States and Canada, and about 3300 part-time faculty. About 73% of the faculty members are women and 79% are white. About 22% of faculty members have PhDs with most holding the master of architecture (or equivalent) which is considered the terminal degree in the discipline.

Admissions

Admissions standards for undergraduate architecture programs vary widely. At many universities, students must be admitted to both the university and the architecture program. Some programs will admit students only as sophomores or juniors. Many programs, particularly bachelor of architecture programs, require a portfolio for admission. Most master of architecture programs require the Graduate Record Exam, a portfolio, completion of undergraduate calculus and physics, and architecture history.

Coursework

The structure and content of curricula of architecture programs in the United States and Canada are reasonably consistent. As accreditation does not distinguish between undergraduate and graduate degrees, bachelors programs can appear to be similar to masters and doctoral programs. The curriculum of NAAB- and CACB-accredited degree programs includes professional studies, general studies, and electives. To gain and retain accreditation of its degree program, each institution must both develop a program specific to its mission and also educate students to be knowledgeable and capable of producing work that can be measured by, and satisfy, specific performance criteria. The content of the professional studies can be divided into five main areas: design and graphics, technology, history and theory, and practice.

Design and graphics

The core of professional architecture programs, in both credit hours and time, is design which is almost always taught as a studio course. In most programs, design is a required course every semester, with an emphasis on actual or hypothetical architectural problems. Professional programs generally endeavor to educate students in the contextual, technical, and pragmatic aspects of architectural design.

Students work individually or collaboratively with a faculty critic. Design solutions are graphically (and often verbally) presented to juries of faculty and professionals who discuss and evaluate the student solutions. Ideally, knowledge from other courses is applied in the design studio.

Typically, there are 12–18 students for each design-studio critic. The studio critic may operate independently, doing his or her own projects and following his or her own schedule. The studio may be part of a coordinated effort involving several sections, an entire level, or even the entire school. The assignment typically includes a building type; a list of requirements that the building must satisfy; a description of the site on which the building will be located; and a statement and/or reading list that either explicitly describes or implicitly suggests the pedagogic motives and goals of the critic.

Studio courses have the greatest amount of student–teacher contact in the curriculum, and more than most other courses in any university. They are ordinarily four to nine credit courses and meet 3 or 4 days each week for 2–4 h per day. Part of this time is spent working independently, part is spent getting critiques of work at the desk, and part is spent evaluating work in group reviews or pinups. Conversation, not lecture, is the prevailing pedagogical mode, and the students must make decisions about what kinds of information they will use to address the problem.

In the first year of design (foundation), projects are usually abstract and conceptual. Students are introduced to visual composition in two and three dimensions, concepts of spatial and functional organization, circulation, and structural behavior. Beginning studios often focus on nonbuilding spatial context; beginning-user consciousness with a familiarity of spatial analysis, design-process methodology, and development of communication skills; and design literacy. The foundation sequence continues with greater emphasis on the environment, user-space study, and further skill development; introduction of qualitative technical materials; a minimum proficiency in the design and communication of simple buildings with an introductory understanding of construction and structural systems; and data analysis, programming, site analysis, and design.

Students then advance into higher-level design studios, where they explore design projects with more complicated site and program requirements and opportunities for more sophisticated investigations. Intermediate studios might focus on simple and complex building case studies with qualitative technical input and a general proficiency in the complete design of simple buildings with a minimum ability to deal with complex buildings and multi-building complexes, site analysis, and design. Advanced studios might focus on the synthesis of complex building and multi-building complexes within the urban context; integration of technical information; general proficiency in the total synthesis of complex buildings and related systems; and transportation, communication, life-safety systems, and social ramifications of planning and architecture.

The last semester of design frequently involves an independent capstone project. This may require research and preparation in the preceding semester, during which the student selects a topic or project and gathers the data needed to undertake the design. Most capstone work is done independently, unlike the preceding design studios. These projects often emphasize complex building design, planning, and urban design, involving mastery of data collection, analysis, programming, planning, building design, structures, building systems, landscape design, and other related knowledge. Students in the capstone year normally have an adviser or advisory committee of faculty who may review the student's progress.

Almost all architectural schools have adopted minimum standards of competency and performance that students must meet before advancing to the next level of design studio or before graduation. Since the design studio sequence is continuous throughout most programs, it is not unusual to find studio sections with students who did not all begin architectural school at the same time.

Typically, several nonarchitectural disciplines play key roles in determining architectural solutions – the behavioral sciences, engineering (structural and mechanical), and economics, to name a few of the more obvious. While some schools have made concerted efforts to teach these and other disciplines in an integrated studio situation, in many programs the actual instruction is still provided in discrete courses – sometimes in the architecture department, sometimes in other colleges.

A typical architecture program will recognize the importance of graphic and communication skills – instruction is given in freehand drawing, digital media, and graphic delineation.

Technology

Architecture students must have an understanding of building science and the accumulated experience of construction. Courses typically focus on structural systems, environmental control systems (building elements that pertain to the modification of the microclimate for purposes of human use and comfort), construction materials, and assemblies (the characteristics of building materials and how they are used, made, and applied in a building project).

History/theory

All architecture programs require the study of the history of architecture to, including Western and non-Western, national and regional traditions. Topics include historical movements in architecture, history of architecture, history of art and architecture, history of building technology, and theory of architecture. Architecture students must learn to see how buildings function, and how the future is built on the basis of the current understanding of the past. Analyzing architectural precedents, coupled with reading the many texts on architecture theory written by historians and architects, helps situate architectural design in an historical context.

Practice

Practice courses are concerned with the protocols of the profession including project process (the entire range of activities involved in a typical architectural design project as it moves from inception through completion of construction), project economics (the financial aspects of building, including the economics of development), business management (the concepts, ethics, and procedures

related to different forms of organization for architectural practice, including private and corporate offices as well as public-sector organizations and agencies), and laws and regulations (the body of common law, legislation, and regulation, including rules of professional conduct, that affect architectural practice).

General education and electives

Interspersed with architectural or technical support courses are general education and elective courses. A program may require the student to select a directed sequence of courses in one field as well as attempt to provide a diverse exposure to some of the many studies important to architecture, such as psychology, philosophy, history, geography, economics, urban studies, literature, sociology, and political science.

Assessment

Since 1984, the NAAB began requiring student-outcome assessments for all programs of architecture degrees. Accredited programs in the United States and Canada must now demonstrate student proficiencies in a wide range of areas. The most significant is comprehensive design, in which each student must demonstrate an ability to produce a comprehensive architectural project based on a building program and site that includes development of programmed spaces demonstrating an understanding of technical systems, life-safety provisions, and the principles of sustainability.

Experience

One must complete training requirements in structured internship programs to become licensed architects in the United States and Canada. Comprehensive internship programs are designed reinforce the knowledge, integrity, judgment, skills, discipline, and quest for learning that must serve the architect for a lifetime. Interns can gain experience from working in small architecture firms, large firms, engineers, contractors, and other professionals in firms across the country and around the world. The programs are designed to take about 3 years and can begin prior to graduation when the appropriate requirements are fulfilled.

In most US states, this training requirement is fulfilled by completing the intern development program (IDP). The IDP is offered by the NCARB. In Canada, the internship in architecture program (IAP) is a comprehensive program administered by the ten provincial associations of architects. Many schools have integrated internships into their curricula, while others require some work experience to graduate.

Examination

The Architect Registration Examination (ARE) is designed to determine whether applicants for architectural licensure possess sufficient knowledge, skills, and abilities to provide professional services while protecting the health, safety, and welfare of the general public. Each of the divisions of the ARE is designed to test for minimum competency in a specific area important to the protection of the public. NCARB develops the ARE specifications through extensive practice analyses. The process is further refined by cut-score studies and regular monitoring. Pass rates on the exam are regularly posted. The ARE, which is offered in French and English, and in metric and feet/inches, is accepted by all United States and Canadian licensing jurisdictions.

Continuing Education

Most states and provinces require continuing education for architects to maintain licenses. A typical requirement is 12 contact hours per year in subjects beyond the basic knowledge of the discipline, and particularly in areas focusing on the health, safety, and welfare of the public.

Education for Medicine

M B Anderson, Association of American Medical Colleges, Washington, DC, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

The goal of medical education is to produce physicians who are prepared to serve the fundamental purposes of medicine and who have a profound sense of service and commitment to their patients. Physicians must possess the attributes that are necessary to meet their individual and collective responsibilities to society, to their patients, their patients' families, and to the profession. The goal of medical education is universal and the issues faced by medical educators throughout the world are the same. While the goals are the same, there are many differences in the approaches taken to achieve those goals. Medical education is inextricably intertwined with the culture of the country, the expectations of physicians in each country, the economy, the health care system, and the structure of the educational programs in each country. In addition to differences in curriculum and pedagogy, governmental regulations for certification and licensure of physicians as well as the accreditation of educational programs are different in every country.

Medical schools teach medical students, of course. But they do much more. Medical schools and teaching hospitals also train medical residents during the 3–7-year period following the MD degree (postgraduate education), which leads to eligibility for licensure and board certification in many countries. They are involved in continuing medical-education programs, too, which allow physicians to stay current with the fast-moving advances in diagnostic capability and therapeutic techniques and with the expanding knowledge on medical-intervention outcomes. Medical schools also are committed to the education of biomedical scientists through PhD training programs.

Medical education is undergoing significant changes worldwide, particularly in the United States. These changes are a response to increased scientific knowledge, differences in the way that students learn, increasing regulatory and governmental pressures, and changing expectations of society and the patients cared for by physicians.

Each of these elements is considered in the following pages, with the recognition that the goal of medical education is the same, while the mechanisms to educate and license physicians to practice differs according to the country and the system in which the education occurs. The changes underway in US medical education are both reflected in changes underway in other countries as well as informed by a network of international medical educators.

Admission to Medical School

Admission to medical school in the United States and Canada is a selective process, which contrasts with the open enrolment policies of many other countries. Selective admission allows medical schools to admit women and men who, in the faculty's opinion, have the academic abilities and personal qualities requisite for a profession based on high standards of competence and service to others. By retaining the prerogative to select their students, medical school faculty also can ensure that the number of enrolling students matches available resources. In countries with an open enrolment, the class size is reduced gradually during the first and second years of medical school through attrition and knowledge examinations.

With the exception of one US medical school, (University of Missouri-Kansas City) all students entering medical school are required to have a baccalaureate degree, while most countries outside of the United States and Canada admit students directly from secondary school (US high school) and follow a 6–8-year program of medical education. There are several BA–MD programs where students enter the program from high school and earn their bachelor's degree and MD in 6–8 years.

In the United States, most schools require that entering students have taken and successfully passed certain science courses. The faculty at each medical school use broad-based selection criteria in their admission process, including prior academic achievement, assessments of the candidate's academic abilities and personal qualities by college faculty and advisors, and evidence of values and attitudes commensurate with a career of service. All medical schools conduct interviews to assess the personal qualities, values, and attitudes of applicants, a practice less common in business, law, and other professional schools. The final responsibility for selecting students to an MD-granting educational program rests with the faculty admissions committee at each medical school. Most US medical schools use the Association of American Medical Colleges-sponsored Medical College Admission Test (MCAT) to assist admission committees evaluate students' academic abilities. This is a standardized examination that includes questions in the biological sciences, physical sciences, and verbal reasoning, and composition of a writing sample. A few countries (e.g., Japan and Korea) have begun to experiment with the application of the MCAT to their admissions process.

The Medical School Curriculum

Medical school curricula, although quite varied, have as their goal the preparation of students to enter a period of graduate medical education. The 4 years of medical school in the United States and Canada include preclinical (basic science) education and clinical education. Medical schools outside of the US and Canada incorporate basic science and clinical education as well though it is structured differently due to the longer medical-school experience.

Each medical school's faculty is responsible for determining the curriculum of the medical school and for establishing the criteria for assessing student performance, promotion, and graduation from that medical school.

The US medical-education system, while undergoing significant change currently, was based on the German medical-education system, promoted by Abraham Flexner in his report to the Carnegie Foundation in 1910. In this model, the medical school was based in the university with its attendant access to research and a solid grounding in science. The traditional curriculum in US medical schools has been a highly compressed, 2-year block of didactic, discipline-oriented basic sciences followed by 2 years of largely hospital-based clinical activity. Most US and Canadian medical students spend their first 2 years in the study of anatomy and cell biology, biochemistry and molecular biology, genetics, physiology, pharmacology, microbiology, neuroscience, and pathology, with a transitional course on physical diagnosis, medical interviewing, and an introduction to the practice of clinical medicine. These core courses are often enriched by other specific medical-science courses or topics such as medical ethics, biostatistics, humanities in medicine, and medical sociology.

These first 2 years of basic-science preparation are generally followed by a year of required clerkships in clinical disciplines that include internal medicine, pediatrics, psychiatry, obstetrics and gynecology, surgery, and family medicine. Increasingly, clinical clerkships in ambulatory-based medicine are part of the required experience. The length of these clerkships may vary from 5–12 or even 16 weeks. Individual schools may also have other required clinical experiences of a shorter duration than major clerkships. The clerkship is a period where the student works either on the hospital wards or in a physician's clinic, in supervised direct contact with patients.

The fourth year of medical school provides additional clinical experiences, generally by means of a mixture of elective and required course work, in disciplines such as radiology, anesthesiology, and the medical and surgical subspecialties.

Change

While this has been the dominant method of instruction and structure of the educational program, there are

significant changes underway in medical schools in the United States and Canada, as well as globally. The changes being implemented stem from medical educators' consensus that education and training must be closely aligned with society's needs and expectations; parallel developments in a healthcare system that is growing increasingly more complex; prepare students for a lifetime of continuous learning and self-improvement; and provide a training ground for future leaders.

The objective of most of the change is to develop the medical student as an adult learner, one who is a self-starter, a problem solver, and a critical thinker, and to link more closely the content of the coursework with the treatment of patients. There are numerous and complex reasons for the changes, but among the key issues are the following:

- There has been an exponential growth in biomedical knowledge. In particular, advances in molecular and cell biology have refined the understanding of mechanisms governing health and disease.
- Recent discoveries in biochemistry, immunology, and genetics that explain fundamental biological processes mandate a closer integration of the study of the basic sciences with clinical medicine. Such integration can only be achieved through a more interdisciplinary approach to medical education.
- A number of recent studies of medical education emphasize the desirability of making education more student and learning oriented, rather than faculty and teaching oriented. This requires that medical faculties offer educational experiences in which students are active, independent learners and problem solvers, rather than passive recipients of information.
- Greater attention is being given to the patient–physician relationship and on providing students with the skills and attitudes to make this relationship more meaningful. There is also increased emphasis on a physician's responsibility to work with individual patients and their communities to promote health and prevent disease.
- Heretofore, most clinical education has taken place in the teaching hospital. However, in recent years, medical educators have come to recognize that the teaching hospital has significant deficiencies as an educational setting.

Clinical Education

Perhaps the most significant changes have occurred in the ways in which medical students learn to interact with, diagnose, and treat patients. Experience in clinical settings occurs early in students' medical education. Some first-year medical students begin to see patients immediately; others are assigned a patient or family in their first year and follow those patients throughout their 4 years.

Traditionally, the inpatient services of the teaching hospitals provided an ideal educational setting for the clinical education of medical students. Medical students were able to observe, discuss, and participate in diagnostic and therapeutic activities in the company of and supervised by residents and faculty physicians. As patients were hospitalized for many common ailments for sufficient lengths of stay, students witnessed the whole course of admission, workup, diagnosis, treatment, and follow-up care.

While medical schools continue to use hospital inpatient services, these sites have developed some limitations as clinical-training settings. Technological advances and the financial incentives inherent in modern healthcare systems in the United States mean patients are hospitalized less frequently. Patients admitted to teaching hospitals today have very complex, highly specialized, acute illnesses that represent a skewed distribution of the medical conditions students will confront later in the office or clinic setting. Those who do receive care in a teaching hospital tend to stay for a shorter period, with much of the initial diagnostic workup and posttreatment care occurring in the ambulatory setting. As a result, medical students have little time to get to know hospitalized patients, to study their medical conditions, and to follow the course of treatment. They also see little of the early stages of illness and disease.

Although major teaching hospitals remain an important component of clinical education, other sites have gained prominence in medical student training. US medical students interact with patients in ambulatory clinics, physician offices, nursing homes, hospices, community clinics, and even prisons.

US medical schools rely on more than 1000 community hospitals as inpatient sites for one or more required clerkships. About 30 medical schools operate clinical campuses at great distances from the main medical school campus where a portion of the third- and fourth-year class receives clinical training.

The focus on communities is new for medical schools in the United States, though more a part of the curriculum in other countries. In the United States, public health and medicine have been taught separately, in different disciplines and different schools since the beginning of the twentieth century. There is now far more attention to the health of populations. The outpatient and clinic settings provide more representative patient populations and enable a strong educational focus on patient- and family-centered care; communication skills; health literacy; understanding the social, psychological, and cultural aspects of disease and disability and their implications for care; and public health and population-based medicine.

Responding to demographic, cultural and social changes, and the explosion of new medical knowledge, medical schools have dramatically expanded their curricula to include and integrate new topics such as: pain management,

and palliative care; emerging public health threats such as biological and chemical terrorism; epidemiology, preventive health, personalized health and population-based care; domestic violence and other sociobehavioral issues; and chemo-preventive methods, and medical genetics.

How Medical Students Learn

Simulations

One outcome of the changing demographics and location of the patient population has been to include the use of simulations, both human and mechanical (including computers, mannequins, and virtual reality) to introduce students to patient care. In addition to the changes to hospital-based care, the technology for simulations has improved to the extent that a good simulation can be created that is virtually indistinguishable from a real patient encounter. Second, patient care has moved more to the outpatient, ambulatory setting in the United States due to payment regulations, and innovations such as laparoscopic surgeries that can be done without a hospital admission. The typical hospital-ward-teaching environment has become more challenging for medical-student education because, in the United States, patients who are in the hospital are there because they are too ill to be cared for in an outpatient setting and therefore it is more difficult for the student to conduct routine histories and physicals on the patient; the patients who are in the hospital are there for a shorter duration, which means that it is more difficult for the student to participate in a longitudinal experience from admission, through work up, through care and treatment plan, to follow-up care. Medical students often are assigned a family or a group of patients who they follow through the course of their medical-school experience, in lieu of the hospital-based patient. Medical educators have expressed long-standing concern that the medical school experience does not adequately prepare physicians to attend to the personal/psychological needs of patients or to the healthcare needs of communities. The longitudinal experience allows the student to participate in the healthcare of an individual over an extended period of time.

The changes in the demographics of the patient population and the need to increase clinical encounters has led to the use of human simulations, called standardized patients, a pedagogy in use throughout the world. The idea of the standardized patient in Canada and the United States is attributed to Drs. Howard Barrows and Paula Stillman. The standardized patient is someone who presents with either a chronic condition or is trained to simulate a medical condition (e.g., one can be trained to simulate a collapsed lung, or the symptoms of multiple sclerosis) and the person presents with the same medical history and medical situation each time for each student, hence the term standardized patients. Standardized

patients are used for both teaching and assessment and are a component of the physician licensure examination in the United States.

Problem-based learning

Another prevalent pedagogy in medical schools throughout the world is a concept adapted from the case-based learning originated in law schools that is usually called problem-based learning (PBL). This pedagogy was created by Dr. Howard Barrows when he was at McMaster University in Canada. PBL involves a small group of students engaged in self-directed learning aimed at gaining an understanding of the ways that biological science and clinical disciplines can elucidate a specific scientific or clinical problem. Research examining the effectiveness of PBL as a pedagogy has shown that students possess increased lifelong learning skills, work better in teams, and enjoy their education more than learning from a strictly lecture-based curricula.

Competency-based education

Competency-based education and learning is increasing in United States medical schools, stimulated by reports such as, Objectives for Medical Student Education and the Accreditation Council for Graduate Medical Education (ACGME) Core Competencies. Competency-based education allows students to learn at their own pace, to focus on mastering a competency rather than focusing on passing a course, and promotes lifelong learning. A competency is a complex set of behaviors built on the components of knowledge, attitudes, skills, and competence as personal ability and it must be demonstrated. The ACGME competencies are domains in which a physician must ultimately demonstrate competence.

The principles of clinical research are another important component in modern medical education. In 1910, Abraham Flexner stated that “research can no more be divorced from medical education than can medical education be divorced from research.” That sentiment is vital in today’s world of tremendous breakthroughs in the knowledge and understanding of the biologic basis of human health. Therefore, medical schools introduce students to the basic principles of clinical and translational research, including how such research is conducted, evaluated, explained to patients, and applied to patient care.

These changes in educational venue and objectives have been essential for medical students to prepare properly for practice in the twenty-first century, but have not been without challenges. Modern-day health care, for example, places a premium on doctors’ efficiency and productivity in patient care. Teaching in ambulatory settings may incur other costs, such as capital and infrastructure required to accommodate students in clinics, transportation, and living expenses when the site is distant from the medical school, and the effort and

expense of recruiting and training community physicians who are not full-time faculty. Geographically dispersed sites that use large cadres of community physicians also challenge medical schools to ensure that students have a comparable educational experience and are assessed with similar standards.

Residency Education

Following the award of the MD degree, in the United States and Canada, young physicians begin an intensive period of hospital-based clinical training, the residency, which is designed to prepare them for the practice of a particular medical specialty. This period is called graduate or postgraduate medical education and is characterized in the United States by the internship and residency. Residency as a component of medical education began at Johns Hopkins Hospital in the 1890s, modeled on the assistantships prevalent at the time in Germany. Residents were called house officers because they literally lived in the hospital. Even today, residents are sometimes referred to as house officers or house staff.

All medical-school graduates who seek full medical licensure and board certification in a medical specialty or subspecialty in the United States must complete a period of residency training. Residency programs vary in length depending upon specialty but generally last 3–5 years for initial board certification and subspecialty training may extend the period of education to as long as 11 years following the award of the MD degree.

Graduate medical education is a period of education in which the physician is still a student in training even though they perform procedures, make diagnoses, and are involved in all aspects of patient care. The difference between the attending physician and the physician in graduate training is that the resident still lacks the experience to practice independently in their specialty. In fact, in the US system, residents are both graduates in training and often the primary teachers of students on hospital wards. Residents assume responsibility for patients under supervision of physician faculty. Their clinical experiences are organized as a series of rotations that may include assignments to inpatient services, hospital-outpatient clinics, and sites in the community such as community health centers and physician offices. Each rotation has a set of defined educational objectives for which the resident is evaluated. Residents also participate in conferences, seminars, and other nonpatient learning experiences as well as independent, self-directed learning, and scholarly activities.

The accreditation process for residency programs emphasizes the actual outcomes of what residents learn rather than just the program’s potential to educate. Residents are expected to demonstrate competence in

six domains of knowledge, skills, and attitudes deemed necessary to be effective and compassionate physicians (the ACGME competencies).

Licensure and Certification

Licensure and certification of physicians is approached individually by each country. The United States and Canada have different licensing bodies; in the United Kingdom, physicians are certified by the General Medical Council and in some countries there is no national licensing and certifying process for physicians in practice.

The external examination required of all candidates for licensure that will permit them to practice medicine in the United States, whether they are graduates of accredited US schools or of foreign medical schools, is the three-part United States Medical Licensing Examination (USMLE), co-sponsored by the National Board of Medical Examiners (NBME) and the Federation of State Medical Boards (FSMB), which represents the various state and jurisdictional licensing authorities. The three steps of the examination include:

- step 1, which focuses on knowledge of the basic sciences and is often taken at the conclusion of the second year of medical school;
- step 2 focuses on the knowledge and understanding necessary to give clinical care under supervision and includes both a written and a clinical-skills examination and is usually taken before graduation from medical school; and
- step 3, which focuses on the knowledge and understanding necessary for the unsupervised practice of medicine and is usually taken during or after the first year of residency training.

International medical graduates seeking entry to accredited residency programs must first obtain a certificate awarded by the Educational Commission for Foreign Medical Graduates (ECFMG). This certificate is based upon satisfactory passing scores of the USMLE basic science and clinical science components (including a clinical-skills exam that requires spoken-English-language proficiency) and on documentation of a completed education program for, and receipt of, a medical diploma.

The USMLE examination is constructed by committees comprised of faculty of US medical schools, expert in the subjects being examined. The USMLE is a high-stakes examination because the majority of US medical schools uses passage of the USMLE step 1 and step 2 examinations as one criterion for graduation from medical school. As such, the examination has a significant impact on medical-school curricula.

There are efforts underway in several countries to develop national certifying examinations. The United

Kingdom has created the Foundation Programme, a 2-year training program required of all graduates in order to practice medicine in the UK. The program is conducted by 14 medical schools and deaneries in the UK. Competencies have been identified and foundation doctors must complete all competencies to be certified.

Accreditation

Medical schools in the United States and Canada have a unified accreditation process, conducted by the Liaison Committee on Medical Education (LCME) for US schools and the LCME and the Association of Faculties of Medicine of Canada (AFMC) for Canadian schools. Many countries do not have any sort of nationally sanctioned accreditation process though the standards set forth by the World Federation for Medical Education (WFME) and the Bologna Declaration are being instituted throughout the world. In 2005, the Association for Medical Education in Europe (AMEE) and the WFME issued a joint statement on the Bologna Process and medical education that endorsed the Bologna Process and urged governmental bodies to implement the elements outlined in the Bologna document. The WFME has established standards for medical-student education that are being implemented in many countries and they are promoting accreditation standards.

Summary

The goals of medical education are universal – to educate physicians who are caring professionals, who will bring a humanistic, patient-centered approach to care, who are lifelong learners, and who recognize the importance of research to the advancement of medicine as well as the fundamental importance of the basic sciences to medicine. These goals are met using different pedagogical approaches and different curricula, but the outcome is the same.

There are many questions facing medical education as it advances in the twenty-first century. These include how the educational program can keep up with the rapid increase in scientific knowledge; what impact the new technologies will have on patient care; what the understanding of the human genome will mean for patient-centered care; and how to balance the increases in technology with the importance of the patient's story.

Education for the Legal Profession

Introduction and Comparative Context

Lawyers and Their Roles

Legal education occurs within a professional, educational, and regulatory context that is best considered at the outset. Different societies cast lawyers in a variety of roles, and professional employment patterns differ. For example, many common law countries, including the United States, have a unitary bar (meaning that there is not a distinction in licensure for lawyers who advise clients in office settings and those who appear as advocates in the courts. England and Canada, among others, are common law countries but distinguish in licensure between solicitors (who advise clients outside the courtroom and draft documents) and barristers (who appear before the courts). Civil law jurisdictions (drawing upon Roman traditions and emphasizing legal principles embodied in codes) typically employ a preponderance of lawyers in government roles including those of notary (responsible for verifying facts, drafting documents, and managing land registries) and judge (who are involved in the inquisitorial system for investigating, finding facts, charging, and adjudicating criminal conduct). Lawyers in such systems often specialize in one or another role rather than being free to shift from position to position and role to role as in many common law jurisdictions. In many common law jurisdictions, lawyers are more significantly employed in the private sector, increasingly in larger firms. Although many American jurisdictions provide opportunities for certification of lawyer specialists in substantive areas, most rely on requirements for experience and special licensure examinations to determine eligibility for such recognition, rather than concentrations of academic courses during law school.

Student Preparation

Significant differences among legal-education systems also result from the prior educational experiences of students, and differences in the background and maturity of law students play an important role in the goals and design of legal education around the world. For example, many countries allow students to study law as part of their undergraduate educations. Within the European Union (and other interested countries), the Bologna process and related initiatives have driven important changes in higher-educational processes. These initiatives are designed to distinguish between bachelors', masters', and doctoral levels

of education; recognize the work of students who have studied in other countries; promote mobility; develop quality-assurance standards; and foster common curricular standards. It is expected that 3-year undergraduate degrees will become common in Europe, and curricula will be modified to reflect a European (rather than only national) focus. Nonetheless, students may be required to complete an additional year of articling or intensive practical training before licensure, offered either by the established bar or by intensive programs affiliated with certain law schools.

In contrast, American legal education requires postgraduate preparation rather than concentration during undergraduate programs. Such education is open to those with prior experience in any number of undergraduate fields. No articling is required prior to licensure, and graduates need only pass a bar examination in specific jurisdictions to receive a general license to practice law. Japan, among others, has moved toward a similar system of postgraduate education for lawyers in recent years.

Accreditation and Licensure

Countries differ in their approaches to accreditation and licensure. Some, such as Japan and Korea, have historically used very stringent licensing examinations to limit significantly the number of lawyers and judges compared to those who are educated in the law in the nation as a whole.

American legal education, on the other hand, operates within a more balkanized regulatory system through which each state regulates candidates seeking licensure to practice law. State supreme courts derive power from state constitutions that afford them ultimate authority to determine who is to be admitted to practice and how a license to practice is to be maintained, while state legislation generally establishes a state-specific state bar entity charged with disciplinary oversight of licensed lawyers. Most states have a board of bar examiners charged with reviewing candidates for admission. Candidates must generally attend an accredited law school, take requisite courses, satisfy requirements for character and fitness (such as those relating to honesty, criminal conduct, and financial propriety), and perform satisfactorily on mandatory licensing examinations. The American Bar Association (ABA), through its section on legal education and admission to the Bar (ABA), serves as the principal accrediting body for American legal education. State high courts regard the ABA as an appropriate entity to

develop minimum standards for assessing law-school programs. Once a school has received ABA accreditation, the schools' graduates are allowed to sit for the bar in a state other than the one in which they attended law school. The ABA's accreditation power also derives from the United States Department of Education, which certifies accrediting agencies before students enrolled in those programs are eligible for federal financial aid.

Educational Institutions and Their Communities

The number of educational institutions offering law programs varies from country to country. The International Association of Law Schools publishes information on the number of law programs in many countries and the differences in legal systems that shape educational programs. In the United States, approximately 200 law schools offer programs approved by the ABA and designed to permit graduates to sit for bar examinations within the United States, generally after receiving a Juris Doctor (JD) degree. The number of law students receiving JD degrees has increased from 35 604 in 1980–81 to 42 518 in 2006–07, and now face significantly increased tuition (in 2007 private schools charged US\$32 367 on average, while public schools charged US\$26 691 to nonresidents and US\$15 455 to state residents). American law students typically fund their education through substantial educational loans, resulting in significant debt upon graduation. Admission to American law schools depends on students' performance on the law school admissions test (LSAT), undergraduate performance, and other indicators. The Law School Admissions Council (LSAC) and the ABA have cautioned against excessive reliance on the LSAT in admission decisions, but law schools' increasing sensitivity to rankings by US News and World Report have led many to increase reliance on this measure reaching admissions decisions. The United States Supreme Court's decision in *Grutter v. Bollinger* has permitted law schools to continue efforts to diversify the legal profession by weighing students' diverse backgrounds and experiences, at least for now.

Pedagogy, Curriculum, and Delivery of Instruction

Signature Pedagogy: The Case-Dialog Method and the Cognitive Apprenticeship

In many countries where students study law as undergraduates, traditional strategies such as lectures are often employed. American legal education on the other hand has adopted the case-dialog method as its signature

pedagogy since that approach pioneered at Harvard Law School beginning in the 1870s. This approach focuses on cases drawn from appellate court decisions, and collected in case book anthologies. Sometimes referred to as the Socratic method, this approach does involve dialog, but does not reflect the disinterested inquiry after the good employed by the Greek sage. Instead, the method involves faculty–student interchanges focused on questions implicit in the subject matter (the dialectical quality of legal disputes and the dynamic character of analogical reasoning across jurisdictions and time) and is driven by the instructional goal of developing students' capacity for independent professional thought. The case-dialog method provides a platform for instruction in legal reasoning (developing higher-order thinking skills and an epistemology suitable to the legal context). It helps beginning students understand the law by developing legal literacy, depicting the legal landscape, and introduces Anglo-American common law jurisprudence. It is especially useful in teaching students to navigate the zone of uncertainty that is central to the exercise of professional judgment in a rapidly changing world. Students are called upon to recite the facts, holdings, and reasoning of cases, requiring them to develop content knowledge, comprehend the sometimes arcane cases they must read, tease apart key analytical elements, synthesize cases, apply key principles to novel fact patterns, evaluate judicial reasoning, and compare judicial and legislative approaches to significant problems. This work is not undertaken in the abstract, since students must simultaneously master a new vocabulary of legal language, become more adept critical readers, and imagine themselves in the roles of lawyers serving as attorneys for varying parties, counselors, judges, or legislators.

The case-dialog method is particularly powerful in helping students face the necessity of wading into unknown waters. It forces them to grapple with carefully posed questions, treat questions as a routine part of professional inquiry, reconstruct knowledge in working with cases, and tame uncertainty by asking and answering questions. The case-dialog method fits well with principles of situated learning and cognitive apprenticeships, and provides instructors with a ready means to draw out students by modeling, coaching, scaffolding, and fading while insisting that novices articulate, reflect, and explore their insights through dialog.

Despite its power, the case-dialog method has important drawbacks. It is especially effective in dealing with the cognitive apprenticeship, but its shadow side tends to limit attention to the apprenticeship of skills and practice and the apprenticeship of identity and values unless instructors deliberately compensate for its narrow focus on appellate cases and emphasis on lawyers in litigation roles. The case-dialog method emphasizes only particular kinds of doctrinally oriented principles that

function as doctrinal baselines, ingrains caution about overgeneralization, and introduces legislative, transactional, and cross-cultural perspectives only if instructors go out of their way to do so. The method tends to discourage critiques of legal principles except as to procedural justice, clarity, and efficiency, and provides no ready platform for conversations about substantive justice in the classroom.

In contrast to some other fields, American legal education's signature pedagogy is employed full force during the first year of a 3-year program of professional education, rather than as a capstone that positions students to move into the profession as is true in fields such as medicine and nursing. It tends to limit the extent to which students can be introduced to the broader range of skills and characteristics of professional expertise, particularly if their instructors have had little actual professional experience.

Skills and Practice

Evolving Expectations

The development of clinical educational initiatives has drawn considerable attention from around the world. Even as the case-dialog method and attention to the cognitive apprenticeship dominated American legal education, some American faculty members and students began efforts to deliver needed legal services to the poor through programs associated with scattered law schools. The Ford Foundation fostered these developments through the Council on Legal Education for Professional Responsibility (CLEPR) and clinical offerings in American law schools expanded substantially as a result. The ABA subsequently undertook a number of initiatives designed to encourage American law schools to integrate professional skills programs in their educational programs. ABA president Robert MacCrate chaired the Task Force on Law Schools and the Profession – Narrowing the Gap, working with practitioners, judges, and legal educators to map professional skills and values deserving of considered attention during law school and beyond.

In the years following the MacCrate report, the ABA adopted more rigorous accreditation standards mandating that schools provide substantial instruction designed to provide graduates with basic competence in legal analysis and reasoning, legal research, problem solving, and oral and written communication, at least one rigorous writing experience, adequate instruction in professional skills, and live-client or other real-life practice experiences for credit . . . through clinics or externships. Law schools were required to offer substantial opportunities for live-client or other real-life practice experiences, appropriately supervised and designed to encourage reflection by students on their experiences and on the values

and responsibilities of the legal profession, and the development of one's ability to assess his or her performance and level of competence.

Common Models

Four principal models for providing instruction designed to develop practice-oriented professional skills have emerged in American law schools and have served as models elsewhere.

Clinical programs generally involve live clients, that is, those who seek legal assistance in connection with matters that licensed lawyers would otherwise handle. In many states, third-year practice rules limit clients who may be assisted to those of limited means, and may require that only carefully supervised students who have completed two full years of law school can provide representation. Most clinical programs have a specific focus, for example, representation of indigent clients in civil matters, juvenile or appellate defense, assistance economic development or small businesses, domestic violence, representation of immigrants, or policy development in specified areas. While individual programs differ, most involve students in specific matters that allow them to learn how to interview and counsel clients, comply with ethical obligations, gather facts, develop case theories, prepare documents, make oral presentations, and collaborate with others.

Several pedagogical strategies quite unlike the case-dialog method are commonly employed in clinical settings. Faculty supervisors engage in one-on-one coaching to assist students in developing and demonstrating pertinent professional skills. Students are also encouraged to reflect on their work in order to gain deeper insights. Students in clinical programs are often exposed to distinctive pedagogical strategies involving case rounds. Many clinical programs also require classroom components that introduce theory or basic skills instruction either concurrently or as a prerequisite of clinical enrolment.

Externships (postings in which law students are assigned to work under practitioners or judges in field settings) are also common in American law schools. The types of placements vary by location, but often encompass an array of settings including the chambers of trial and appellate judges, public defenders' or prosecutors' offices, government agencies, legal services, nonprofit organizations, and corporate counsel offices. Under ABA accreditation requirements, externships are required to have clearly stated objectives and evaluation strategies, well-trained field supervisors, close oversight and periodic site visits by law school faculty supervisors, and integrated opportunities for students to reflect on the work undertaken in the field. Students receiving academic credit for externships may not receive compensation.

Simulation courses have also become quite popular in law schools. Simulation courses often involve extensive

case files or similar materials designed to present specific lawyering tasks (such as cross-examination or interviewing). Students are provided with overviews of key content in lecture settings, and then asked to engage in role plays in which they have the opportunity to practice key professional skills. Practitioners are often involved in critiques of student performance. While many courses in specific areas (such as trial advocacy, pretrial practice, interviewing, counseling, and negotiation) have been established to develop specific types of practice skills, there has been a growing interest by some faculty members in creating more complex problems and instructional modules. Few of these courses approach the sophistication of the Simulated Professional Learning Environment (SIMPLE) developed by Prof. Paul Mahrag of Glasgow Graduate School of Law, University of Strathclyde, Scotland, and his colleagues as a means of preparing students with advanced professional skills for entry into the practicing legal profession in the United Kingdom.

Practicum courses are gradually emerging as a distinctive approach to providing education in professional skills. Such offerings often involve team teaching by law faculty members with colleagues from the practicing bar, or efforts by nonclinical faculty members to develop courses focused on engaging law students in projects with real-world application.

Legal writing offerings in the first year of law school also incorporate distinctive pedagogical strategies. Increasingly, such offerings situate beginning law students in professional contexts and call upon them to prepare legal memoranda, opinion letters, briefs, and oral arguments focused on legal problems that might arise in practice. Many schools employ practicing lawyers and judges as adjunct faculty members responsible for providing such instruction. A number of law schools have also begun to expand their legal writing courses to address a broader array of professional skills, including counseling, interviewing, fact-finding, problem solving and negotiation, and have stretched such courses into the second year of law school.

The Clinical Legal Education Association (CLEA), under the leadership of Prof. Roy Stuckey, has initiated a best-practices project designed to emphasize the importance of setting goals, organizing and delivering varied types of instruction, assessing students learning, and evaluating the success of the program of instruction. The best-practices project seeks to improve all facets of legal education by bringing to bear important insights about pedagogy and instructional priorities that are relevant not only to clinical legal education but also to legal education more generally.

Professional Identity and Values

Intensified attention was devoted to the role of American law schools in developing students' sense of professional

identity and values in the aftermath of the Watergate scandal in the early 1970s when lawyers serving as presidential advisers were widely viewed as having failed to abide by professional obligations. The ABA subsequently incorporated an accreditation requirement requiring students to receive instruction in the legal profession, including the history, goals, structure, and responsibilities of the legal profession and its members. This requirement was subsequently revised to refer explicitly to the values and rules of the legal profession. States have reinforced this requirement by incorporating requirements that law graduates take a special licensing examination on professional responsibility before they may be admitted to the bar.

Two major approaches to instruction in professional responsibility and ethics have emerged to address this requirement. American law schools typically offer free-standing courses on professional responsibility using instructional strategies focused on cases and rules in order to meet this requirement. More recently, instructional strategies have put greater emphasis on contextualized problems and case studies. Typically, free-standing courses cover the role of lawyers as advocates and counselors, regulatory powers relating to discipline and bar admission, the attorney–client relationship, confidentiality, conflicts of interest, and special requirements applicable in criminal and civil settings.

Leading scholars in the field have urged that law schools incorporate a pervasive approach, so that students receive instruction not only in a stand-alone course, but also in contexts across the full range of substantive fields. Clinical legal educators generally give special consideration to issues of professional responsibility in connection with students' work with clients. Efforts by other faculty members to incorporate ethics and professional responsibility into substantive courses have tended to be sporadic at best.

Increasingly, American law schools have used the informal curriculum to address concerns about a decline in professionalism (standards of civility, mutual respect, service, and integrity that exceed the minimums set by disciplinary standards). Professionalism initiatives often focus on orientation programs, acceptance of professionalism codes, speakers, mentoring programs, and specialized courses (e.g., in law office management). Some schools have also encouraged students develop work/life balance in keeping with growing interest in humanizing legal education. Many law schools have developed affiliations with local Inns of Court (local groups including law students, young and more senior lawyers, judges and law professors) who meet on a recurring basis for educational programs and informal networking.

American law schools have also worked closely with the bar in developing robust *pro bono* programs that invite or require students to offer legal services at no cost to those of individuals and organizations serving those of limited means. The ABA's accreditation standards state

that law schools “should encourage (their) students to participate in *pro bono* activities and provide opportunities for them to do so.”

Curriculum

Legal education in the United States is a 3-year postgraduate program open to students who have already completed undergraduate programs and have majored in a variety of fields. Apart from the accreditation requirement that instruction in professional responsibility be provided, American law schools are generally not required to provide instruction in particular substantive areas. Nonetheless, clear patterns are widely evident across most American law schools. Curricular offerings in other countries vary depending on undergraduate or graduate emphasis.

American first-year curricula typically include common law subjects that provide substantive grounding, facilitate development of analytical abilities through use of the case-dialog method, and cover subjects generally tested by bar examinations. Most law schools include criminal law, torts, contracts, property, civil procedure, and constitutional law as part of the first-year curriculum. Legal research and writing is also a staple of the first year. Some schools incorporate a broader range of professional skills (e.g., negotiation and counseling) within the scope of core offerings, but many extend such instruction into the second year. In recent years, some elite law schools have moved to include courses in legislation or the regulatory state as part of the first-year curriculum in order to provide more balanced coverage. Others have included coverage of international or comparative law, at times through intensive intersession programs.

American law schools typically offer a cafeteria array of options for students in the second and third year of their programs. Generally, students are advised about the coverage of bar examinations in jurisdictions in which they may seek licensure. The upper division curriculum typically includes coverage in the areas of litigation, business and tax law; employment law; family law; constitutional and civil rights law; international and comparative law; environmental law; property and intellectual property; litigation; and perspectives on the law. Some law schools have developed concentrations of courses in substantive areas as an option for students who wish to devote focused attention to particular fields, while others offer joint degrees in fields such as business, planning, public administration, health, and social work. A substantial number offer LLM degrees targeted to international students or those seeking advanced preparation in specialized fields such as tax or international law.

Delivery Strategies

American law schools have been relatively slow in exploring educational strategies using advanced technology.

The computer-assisted legal instruction (CALI) initiative provides several hundred web-based tutorials authored by law faculty members, sponsors conferences, facilitates use of pod-casting, explores other means of developing electronic instructional materials, and hosts a consortium fostering development of online courses. Pioneering professors have developed specialized courses and online LLM degrees, while Concord Law School has developed a comprehensive degree program that offers all courses online.

The ABA regulates distance education and programs reliant upon technological transmission through its accreditation standards. Offerings must be carefully planned and separately authorized as a part of the curriculum. Students must be supervised, involved in ample interaction with instructors, and carefully monitored and assessed. Distance-education courses may not be offered to students until they have completed their first year, and are limited to four units per semester and 12 units toward a standard law degree.

Assessment

American law schools are quite weak when it comes to assessment, according to a recent Carnegie Foundation study. ABA accreditation requirements require schools to adhere to sound academic standards and monitor students' academic achievement. Schools must also periodically review their mission and curricula, but most lack the will or expertise to link educational programs to outcome measures or specific goals. As large student/faculty ratios characterize many core courses, formative assessments are used infrequently. Traditional examinations typically include problems based on complex hypothetical fact patterns requiring students to analyze and apply legal principles. Many instructors also use multiple-choice questions to assess the breadth of student knowledge and provide students with practice in responding to the types of questions included in multi-state bar examinations. Most courses in American law schools are graded on a curve so that grades in larger courses reflect a standard distribution.

Recent developments reflect growing attention to assessment as a formative tool. Most American law schools have developed academic-support programs designed to assist students who may be at risk of performing below their potential (e.g., those who are first-generation college graduates), participants in admission-by-performance programs, and students who fare poorly at the outset of their law school careers. The LSAC has provided important support for academic support professionals. Those serving in these capacities have enriched educational programs by virtue of their backgrounds in educational theory as well as law. Academic-support programs have extended

their reach beyond the first year, particularly since the ABA has adopted a requirement that law schools demonstrate that the bulk of their students pass state bar examinations (or that they have programs in place to assist them to do so). Bar preparation courses designed to strengthen the ability of low-performing law students to succeed on bar examinations may now be offered for credit, and many schools have begun to make them available on an optional or required basis.

Other countries have adopted much more sophisticated assessment practices, for example, as part of the Bologna process discussed above.

Education of Clergy

D O Aleshire, The Association of Theological Schools in the United States and Canada, Pittsburgh, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

The education of clergy varies by religious tradition (i.e., Christianity or Judaism); by subgroups or denominations within the same tradition (i.e., Lutheran, Baptist, Presbyterian within Christianity or Orthodox, Conservative, and Reformed within Judaism); and across continents. Education varies by tradition and denomination because each authorizes clergy for ministry in different ways. Clerical education varies by continent because theological education typically follows the dominant educational pattern of the continent, and those patterns vary. In the context of these many variations, however, educational goals tend to be similar because clerical work has common aspects. Across traditions, denominations, and continents, clergy (1) preside at worship and liturgical celebrations, (2) teach, preach, and otherwise seek to communicate religious understanding; (3) provide guidance and leadership to congregations or parishes where the faithful gather for worship, instruction, mission, and fellowship; (4) provide spiritual care in the context of major life events such as birth, marriage, illness, and death; and (5) lead religious communities to address human need and moral vision. This article explores influences on the education of clergy and describes characteristics of the normative pattern of theological education in North America.

Influences on Clergy Education

The education of clergy is influenced by patterns of identifying qualifications for ministerial work and systems for providing authorization to do that work. Three patterns are particularly instructive because of their implications for contemporary aspects of the education of clergy.

Three Patterns of Clerical Qualification and Authorization

For ancient Israelites, the members of the tribe of Levi were responsible for overseeing religious practices. Priesthood was the tribal community's family business. Little is known about the education of these early priests, but they must have learned first from a parent, then from the structures that the tribe maintained to pass on its unique work. No contemporary religious community identifies clergy by family of origin; however, some contemporary patterns of clerical education may be similar to those ancient practices. They were evident in early America,

where a person reads with an experienced clergyman as preparation for ministry. While this model was not a unique form of professional education in the nineteenth century, it is unique in that it continues as a form of clergy education for some religious groups. In some religious communities, an experienced pastor or religious leader takes under his or her tutelage younger persons who learn from the senior clergy and serve as assistants in the senior minister's congregation until they have one of their own.

History is full of the emergence of new religious movements. Some became world religions, others lingered as sectarian groups on the margin, but all of them had clergy. In a new religious movement, how do the clergy attain clerical authority? It cannot be bestowed by an external source or be based on the leader's mastery of traditional religious teaching. It emerges from the leader's ability to articulate new religious teaching or convey a unique relationship with the divine. While this kind of religious authority is historically evident in new religious movements, it also functions in many established religious communities. In either, education tends to take a back seat. The fastest growing segment of global Christianity in the twentieth century was Pentecostalism, and as a new pattern of religious expression within Christianity, it was inclined toward this pattern of ministerial qualification and authorization. For some, authenticity in religious leadership is determined by gifts and abilities that are God-given rather than human-learned.

The early Puritans in North America (and others in many branches of Christianity throughout its history) vested a central qualification for ministry in theological knowledge. They advocated a learned ministry and, as a result, founded Harvard, Yale, and other institutions for the education of ministers. A learned ministry involved religious fidelity and conviction, to be sure, but also valued knowing religious texts and tradition and being able to communicate them. Advanced education for ministry in colonial America often resulted in ministers being among the most-educated members of the community. This pattern of ministerial qualification continues, and most established Christian churches or denominations in North America and elsewhere in the world have institutions for the advanced education of their respective clergy. The hundreds of theological schools in North America, with their curricula, disciplinary specializations, and qualities characteristic of higher education institutions, are the legacy of the learned ministry model.

Implications for Contemporary Education of Clergy

These patterns of clerical qualification and educational practice have a palpable influence on contemporary education of clergy. All three of them are present, both as unique models and in various combinations. No other profession in the developed West is subject to the variations inherent in clerical education. One can be considered a qualified clergy person, and duly authorized for ministry, on the basis of a graduate professional degree or no formal education at all. Few other professions have this kind of free-market form and flexibility. In the midst of these all but endless variations, a normative pattern has emerged in North America. It is graduate professional education, and while bent in many ways, it is the dominant model and the focus of this article.

Characteristics of Education of Clergy

The education of clergy in North America has several salient characteristics, including differing levels of education, a common curricular design, a perceptible educational culture, signature pedagogies, accreditation of degree-granting institutions, and the unique pattern of licensure following graduation.

Levels of Clerical Education

During the twentieth century, postbaccalaureate degree education emerged as the normative pattern of clergy education in the United States and Canada for Protestants, Roman Catholics, and most Orthodox Christians, as well as for the education of rabbis. Alongside this dominant model, two other models have continued with a sizable number of educational providers and students enrolled: baccalaureate degree education with a concentration in theological studies and nondegree certificate education.

Graduate professional theological education

Graduate professional theological education involves the equivalent of either 3 or 4 years of full-time study that results in the master of divinity degree (MDiv). Schools offering the master of divinity are either free-standing theological schools (most often called seminaries) or divinity schools related to a larger educational institution, such as a university. In general, these degree programs include classroom-based education, context-based education, and often some form of clinical-based education in hospitals or other institutions. Four-year MDiv programs typically require the equivalent of an entire academic year in congregational or parish-based work – either during 1 academic year or in the three summers between 4 academic years. Faculty in schools offering the MDiv typically hold research doctorates or, in pastoral arts disciplines,

either a research or professional doctorate. In the United States and Canada, the median enrolment of the more than 250 schools that are members of the Association of Theological Schools (ATS) is about 200, and the typical faculty numbers are 12–15, with disciplinary expertise in a variety of fields of study. Rabbinic programs of study for several Jewish denominations require 5 years of postbaccalaureate study, and most institutions require at least some residential study in Israel. Successful completion of the 5-year program results in the master of arts in Hebrew letters and/or ordination to the rabbinate, which in Judaism is an action of the rabbinic faculty. Buddhist institutions offer a master of Buddhist studies as preparation for ministry or chaplaincy, and Islamic schools offer a master of arts in Islamic studies, although this degree may or may not lead to the recipient becoming an imam.

Baccalaureate and certificate education

Another model for the education of Christian clergy in North America uses baccalaureate and nondegree programs of study. Some baccalaureate programs are offered by church-related or Christian colleges, and others are offered by Bible colleges. The Bible college movement began in the late nineteenth century among conservative Protestants who thought that ministry addressed so many urgent issues that training should be focused and limited to essential skills needed for the work. Bible colleges continue to offer 4-year programs of study that include the equivalent of 3 years of courses in Bible, theological disciplines, and ministry studies, and 1 year of courses in general education. Successful completion of the program of study results in degrees such as a bachelor of ministry, bachelor of theology, or bachelor of arts in biblical studies. Compared to liberal arts colleges, Bible colleges typically have much smaller enrolments and fewer degree programs. Nondegree programs are abundant, but because of their small size and local focus, statistics about them are difficult to obtain. These programs are typically offered by individual congregations or local denominational agencies for persons who are serving in ministry but do not have a baccalaureate degree. In North America, these programs have often been the means of education for bivocational clergy (persons who work in a church but have a job in an unrelated area as primary means of income) or persons who belong to immigrant communities or communities that have limited access to post-secondary educational opportunities.

Educational levels outside North America

These three levels of theological education – graduate professional, baccalaureate professional, and nondegree certificate programs – are characteristic of Christian theological education worldwide. In countries with advanced educational systems, such as many Asian countries, the graduate professional model is dominant. In countries with modest educational infrastructure, certificate training

programs are most typical, as they are for certain groups throughout the world. Europe and the United Kingdom continue an older sophisticated pattern of 5-year professional baccalaureate programs or university degrees from a faculty of theology followed by church-related nondegree programs for pastoral formation.

Theological Curriculum

Across these educational models, and perhaps most dominant in the graduate professional model of clergy education, the central curricular goal is “the development of theological understanding, that is, aptitude for theological reflection and wisdom pertaining to responsible life in faith” (in the language the Association of Theological Schools (ATS) accrediting standards). Within this overarching goal, clergy education typically addresses four major areas of study:

1. the text and tradition of the religious community served by the school;
2. issues related to the community and context in which ministry is undertaken;
3. skills and abilities needed for ministerial leadership; and
4. spiritual and personal development.

Schools vary in the ways they approach these four areas and the amount of attention they give to each; however, most programs of ministerial education include some educational attention to all four.

Theological understanding

The overarching goal of education for religious leadership is not specialized knowledge or technical professional skill. Ministerial work certainly requires this knowledge and these skills, but they are not the ultimate educational goal of the theological curriculum. The ultimate goal is a theological wisdom that provides an undergirding and overarching frame for religious life and work. A religious leader is, first and foremost, a religious person, and religious leadership emerges from religious identity. Ministry begins with a pervasive religious vision, however defined, that orders perspective on life. Excellence begins with theological wisdom pertaining to responsible life in faith – however that may be understood or construed. A curriculum for clergy education begins with this affirmation and continues with the more typical professional school emphasis on areas of study.

Text and tradition

Religious vocation requires an intellectual knowledge of the texts and tradition of a faith community. The theological curriculum includes: study of sacred texts and how to interpret them, theology and how doctrine has emerged historically, and the history of the long tradition in which

religious visions are located. Excellent ministerial leadership requires an intellectual grasp of the tradition of the faith community. Ministers should know something, and they should know it not as information that can be recalled but as constructs that can be argued, analogies that can be sustained, and images that have intellectual credibility.

Ministry contexts and broader culture

Religious leadership entails attending to the public voice and work of the religious tradition. The curriculum typically requires some classroom study and contextual experiences that help students understand the social dimensions of religious communities and the role of religion in broader social contexts. This may involve ministries of mercy as congregations mount programs to the poor, homeless, hungry, and others in need; or, it may involve public witness as the religious community brings its commitments to public debate and policy.

Abilities requisite to ministry

Religious vocation also requires a number of professional skills and abilities. These abilities include preaching, liturgical arts, teaching, counseling, administration, and other aspects of ministerial practice. Religious leadership involves the exercise of a wide range of activities, and the theological curriculum seeks to maximize the quality with which these practices are performed. These activities are not the applied version of what is learned more theoretically in theological or philosophical studies. Activities of professional practice, while theologically grounded, have their antecedent theoretical constructions in areas such as communications theory, educational theory and practice, organizational development, and counseling psychology.

Spiritual awareness and moral sensibility

Ministerial leadership involves spiritual awareness and moral sensibility and character. Somehow, the pervasive religious vision must take root in the way the minister orders his or her life. The minister is not spiritual or moral on behalf of parishioners or congregants, but pursues this kind of integrity because he or she has a theological understanding pertaining to responsible life in faith. The presence of spiritual awareness and moral responsibility in ministerial lives contributes to the congregation's confidence in the priest's or minister's capacity to lead. Seminary students do not graduate spiritually or morally mature – these are lifelong tasks for people of faith. They are not easily learned from formal educational strategies; they form over time as people deal with texts, human beings, ministry contexts, and the struggles of human existence.

The Educational Culture of Theological Schools

Theological schools tend to be educationally intense environments because students are grappling with what they believe and hold to be true. Their subject matter extends to perceptions of ultimate meaning and truth. Theological education invites students to discern a religious vision of right human relationships as much as it instructs them in how to interpret texts and traditions. The result of this intensity is the ability of theological schools to form a particularly powerful form of educational culture. An educational culture is not the result of structured educational processes; the faculty never votes to decide what the school's culture will be. Rather, the culture exists alongside formal curricular structures as a powerful educational force with observable impact on both professional socialization and personal formation.

One study of the culture in two theological schools explored the process by which culture functions as an educational agent. It begins with a dominant cultural message that identifies a vision of right and wrong, truth and untruth, as well as of acceptable and unacceptable patterns of human relating. In a variety of ways, from a variety of voices, this message is presented and represented. Theological schools, however, are not single-idea environments, and there are alternative cultural messages that compete with the dominant cultural message. In one study of students in two very different theological schools, students could articulate the central cultural message as well as the alternative messages that compete with it. In addition, students bring religious convictions and perceptions with them to seminary, and these perceptions are often at odds with the central and alternative cultural messages. The result is a struggle between competing and compelling visions. The struggle often leads to assimilation of the dominant cultural message, but it does not end there. The struggle continues as students find themselves in ministry contexts where the theological school's more rarified message is tested against the muddled realities of ministerial practice. In the end, students appear to come to a resolution in which they affirm some, but not all, of the religious perceptions that they brought with them to the seminary; affirm much, but not all, of the central message the seminary conveyed; and come to a resolution by the end of their seminary study that differs both from what they brought to theological study and from the central message of the school.

Signature Pedagogies

The Carnegie Foundation for the Advancement of Teaching included clergy education in its study of education for the professions, and that study, more than any other, has identified the signature pedagogy that is present in theological education. Theological education, the study noted,

focuses pedagogically on four activities: interpretation, formation, contextualization, and performance. Together, these four pedagogical intentions constitute a signature pedagogy in theological education – an educational strategy that signals the most central elements of ministerial practice. The signature pedagogy in theological education is ubiquitous. It is evident in the work of the faculty as a whole, in course after course, in different ways, and in different combinations, as they teach with a focus on interpretation, formation, contextualization, and performance. Students do not experience one of these pedagogical strategies in their study of one discipline and another strategy in another discipline. They experience many of them, in different combinations, in most of their classes.

Interpretation

Theological faculty members spend a great deal of time on the interpretation of texts. Most theological learning is textually based, and interpretation is crucial to theological learning and pastoral practice. Interpretation is a complex activity. Professors use different processes, but most of them guide students in learning how to interpret a text. Interpreting religious texts involves close reading and analysis, but that is not all. Interpretation is never only about a text; it is a process of using a text in the context of situations and relationships. These characteristics of interpretation are closely associated with how theological educators understand critical thinking.

Formation

Formational pedagogy aims at students learning the “dispositions, habits, knowledge, and skills that cohere in professional identity and practice, commitments and integrity.” Formational learning is critical to theological studies, and it is central to the deepest intentions in professional service that are present in other professions as well. It seeks to cultivate personal character, intellectual capacity, and professional abilities into a human whole. The result is a habit, a disposition, which undergirds the life and work of the religious leader. Formational pedagogy is more than religious language for professional formation. Ministry is a profession that depends on the religious leader affirming for himself or herself what religion holds true for all others; it is a form of professional practice in which the personhood and religious commitments of the minister are as crucial to effective practice as the knowledge and skills these leaders employ in their work.

Contextualizing

The third pedagogy, contextualization, is a function of the way in which all religious knowledge is situated in social, historical, relational, or other contexts. To function faithfully in ministry, students need to learn the contexts of

texts, historical events, religious practices, and ministerial work. Contexts are not just backgrounds that serve as settings for texts or religious practices; they involve patterns of relationship, in the Carnegie study, that range from social structures to personal dispositions and habits. Contextualization involves the pedagogical efforts by which religion's long and ancient traditions are brought into in dialog with current realities.

Performance

A final pedagogical focus is on performance. Ministry has its public leadership dimensions, and students need to learn the performance skills involved in preaching, liturgy, public leadership, and other ministerial tasks. Competence in the performance of these public dimensions of ministry is crucial to the leadership of communities of faith, but in ministry, performance has a unique character. The minister or priest performs as a person of faith, and this performance guides the community into its own shared and corporate faith. When a minister preaches a sermon, the goal is not applause for the performance but a deepened or more-informed faith in the listener. Ministerial performance is not like an actor who takes on the role of a character. Rather, it is an outward, public representation of an inward disposition.

Accreditation

In the United States, institutions that provide education for clergy are accredited in one of four ways, depending on tradition and level of theological education that they provide.

Graduate professional theological education

Graduate professional schools of theology are accredited by the Commission on Accrediting of the Association of Theological Schools in the United States and Canada (ATS). ATS accredits about 235 seminaries, divinity schools, and schools of theology, all of which have as one of their educational tasks the education of clergy. The ATS Commission on Accrediting accredits institutions according to institutional standards and approves each degree program offered by the school on the basis of degree program standards. ATS member schools currently reflect the broad range of Christian churches and denominations in North America. Jewish institutions that provide postbaccalaureate programs of study are accredited by one of the six regional accrediting associations in the United States and are also eligible to pursue accreditation with ATS. The regional agencies accredit a wide range of schools in one geographical area. Because regional agencies do not specialize in one kind of educational institution, their standards are broadly institutional and can be applied to colleges, universities, and special-purpose institutions such as seminaries. In addition

to their accreditation by ATS, about 80% of free-standing Christian seminaries are also accredited by a regional accrediting body.

Baccalaureate and certificate theological education

Bible colleges are the primary providers of baccalaureate-level theological education for conservative Christians, and they are accredited by the Association for Biblical Higher Education (ABHE), which has about 120 accredited institutions. While some of these schools are also accredited by a regional agency, ABHE serves as their primary agency for accreditation, affiliation, and articulating the aims and purposes of baccalaureate theological education. Several of these schools also have graduate professional seminaries, most of which are accredited by ATS. Bible colleges with seminaries provide both baccalaureate and graduate, professional forms of education for clergy. The Rabbinic and Talmudic schools that train Orthodox rabbis are accredited by the Association of Advanced Rabbinic and Talmudic Schools. Their degree programs are generally 4 or 5 years in duration and involve concentrated study of Hebrew texts and the Talmud. While no agencies accredit the nondegree institute and certificate programs of theological education, some denominations approve certificate or nondegree programs for clerical certification.

Licensure and Continuing Education

Unlike most professions in North America, clergy are not certified or licensed by a governmental entity. They are certified – ordained – by a bishop in some church bodies, by an individual denomination in other church bodies, and by individual congregations in still others. Each of these religious bodies determines the criteria for ordination or other forms of licensing, and each one of them may have a dominant educational qualification; however, alternative sets of qualifications also lead to authorization for ministry. Because of these multiple variations, ministerial credentials have limited public usefulness other than that the clergy person has been duly authorized or certified by the procedures of that person's religious community. When clergy participate in certain government-related functions, such as presiding at a marriage ceremony, a governmental authority may request demonstration that they are credentialed clergy, but the governmental authority typically does not certify clergy to perform their religious duties. This varies significantly on the basis of whether a country has an established state religion or not. In a similar way, the criteria for continued certification, including requirements for continuing professional education, are determined by the religious community authorizing the clergyperson, and these range from regular annual requirements to none at all.

Framing Professions Education

P S O'Sullivan, UCSF School of Medicine, San Francisco, CA, USA

© 2010 Elsevier Ltd. All rights reserved.

A profession is generally defined as requiring advanced knowledge. This definition of a profession does not tell us much about professionals nor about how to educate them. Here we introduce a number of professions and the specific approach to their education, including curriculum, pedagogy, accreditation, and licensure. The list of professions is not exhaustive, but these articles provide insights into the many issues, changes, and challenges that the professions are facing and how these influences are addressed in education. A number of our authors have provided context for this overview. We have drawn on their writings to frame the introduction, including the development of a profession (Heywood) and the work of the Carnegie Foundation for the Advancement of Teaching (Benner, Sutphen, and Wegner).

Historically, professions have developed because of a certain mystique that surrounds their knowledge which is needed and valued by diverse people. These practitioners develop formal associations and devise ways to control entry to the profession. The profession establishes a system of education and defines standards for acceptance of a professional into the practice. Importantly, the profession adopts codes of professional ethic that provides assurance to the public that their interests are protected. Education is the primary means by which entry into the profession is controlled. This process can lead to a scarcity of members of the profession, thus enhancing its prestige. Moreover, since professions have distinct practices, the education is a balance of the tension between practical and theoretical knowledge.

The education of a professional has been studied primarily by sociologists. In a series of studies on education for the professions, the Carnegie Foundation for the Advancement of Teaching proposed a threefold framework of metaphorical apprenticeships useful in conceptualizing the dimensions of professional education and comparison of professional education across disciplinary fields. The first, cognitive, apprenticeship focuses on developing students' thinking skills in the specific context and content related to the profession. The second apprenticeship, of skill and practice, focuses on developing students' abilities to understand and intervene in particular contexts and to perform as expert professionals responsible for the well-being of others. The third apprenticeship, of identity and purpose, concerns the development of students' appreciation for professional roles, possible conflicting dimensions of those roles, ethical obligations, and individual meaning derived by professionals from the

work they do. Taken together, these dimensions result in professional formation that brings together epistemology, knowledge, skill in action, and professional responsibilities and beliefs.

The Carnegie Foundation studies also highlight much about domain-specific educational practices and pedagogies. Each professional discipline needs to design curricula and pedagogies in relation to integrative teaching of the three professional apprenticeships specific to their particular discipline. Discipline-specific teaching and learning are based upon a deep understanding of the practice and structure of the discipline. While much can be learned from the general body of research on teaching and learning, each discipline, particularly practice disciplines, needs to teach in ways that give students the best access to the practice so that they understand the notions of good and practical goals and boundaries of the discipline.

The framework from the Carnegie Foundation for the Advancement of Teaching emphasizes the power of signature pedagogies, that is, characteristic approaches to teaching that are widely adopted by instructors and programs across a field of professional education, generally reflecting an alignment of theory and practice in the given field, and possessing unusual power to shape understanding of the nature of knowledge and professional roles. Shulman has argued that signature pedagogies have three dimensions: a surface structure (the action of teaching and learning), a deep structure (based on assumptions about how best to teach), and an implicit structure (reflecting judgments about attitudes, values, and dispositions in the field). In addition, signature pedagogies tend to have a shadow side, reflecting what it leaves out. Shulman has attributed the power of signature pedagogies to several factors. Typically, they involve pervasive repetition and routine, resulting in habits of mind that can be employed, almost automatically, when engaging in complex problem solving. They generally require students to perform in a role, necessitating activity, interaction, and visibility within a public setting before others that fosters accountability. They require students to grapple with uncertainty in order to develop professional judgment. Often, the emotional stakes are high (coupling excitement with anxiety), resulting in experiences that shape students in profound ways affecting their values and dispositions as members of a particular profession.

Research by scholars such as Dunne, Eraut, Grossman, McDonald, Shulman, and Sullivan has expanded the line of inquiry on teaching and learning in the professions.

All professional disciplines share the need for teaching and learning in practice situations, where students learn to use practical reasoning across time, as situations unfold. All must use practical reasoning in addition to the formal analytical thinking that they are taught in their practice discipline, whether it be diagnostic 'rule in' and 'rule out' thinking or standard guidelines for public practices. They also learn the appropriate use of different types of critical and creative, imaginative thinking. As all practice disciplines use practical reasoning, practitioners typically must learn to recognize and characterize the nature of the practical situation as it presents itself. The logic of practical reasoning lies in recognizing the nature of the practical situation, staying open to feedback about one's practical grasp and moving from there. Practical reasoning occurs through engagement in the situation rather than standing outside the situation in an abstract, completely detached style.

The entries in this section will describe these issues as they apply to a number of traditional and emerging professions. There are several descriptions that merit highlighting as a preview. The description of the professions emerging from the allied health sciences captures the various struggles of control and recognition to obtain the stature as a profession. A number of professions describe the development of competencies that provide challenges to the curriculum, pedagogy, and assessment that goes well beyond the traditional emphasis on knowledge. Assessment, particularly of skills beyond knowledge, is increasing prevalent in every profession. Performance assessments are particularly important since learners are expected to perform in a context similar to the practice arena. This is a higher fidelity of assessment and an indication as to how someone may practice than was available from traditional paper-and-pencil examinations and, perhaps, observations. Technology has highly influenced the

nature of both the educational and assessment processes. In general, licensure and accreditation characterize most professions and what is notable in the context of these topics is the degree to which these efforts are tending to expand globally, facilitating the ability to practice the profession in other than the jurisdiction where one was educated.

Issues in Accounting/Business Education

W H Gijsselaers, Maastricht University, Maastricht, The Netherlands

R G Milter, Johns Hopkins University, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Attestation – The evidence by which something is affirmed to be correct, true, or genuine.

Certification programs – Require some amount of business education at higher levels as a baseline to earn designation as business professional.

Content-based curriculum notions – Puts focus on questions of What should we teach, and not on pedagogy (how should we teach?).

Criticasters – A petty or inferior critic.

Functional silos business school curricula – Business taught around key disciplines (accounting, finance, strategic management, and marketing) with strong foundations in scientific approaches to problems as they occur in business practice.

Handelshoyskole and Handelshochschule – Business Schools founded in the European tradition to prepare business professionals for the trade profession with a strong orientation on bookkeeping, commerce, and economics. Courses are typically taught with a strong orientation toward business practice.

International accreditation bodies – International organizations that accredit business schools to promote and improve higher education in business education.

MBA degree – Master of Business Administration degree pursued for career enhancement for business professionals with at least 2 years of work experience in various backgrounds (engineering, law, healthcare, etc.).

MSc degree in business – Master of Science degree for students without initial work experience.

National accreditation bodies – Deal with keeping standards for academic education.

a program was developed that included courses in accounting, mercantile law, economics, finance, and statistics. Such courses are still considered as cornerstones of any modern business-education program. Over the past century, business education has held a unique position with business schools serving as knowledge-creation institutions through research and by delivering substantial amounts of bachelor and master graduates.

Accounting education went through a similar development as business education. Students who wanted more practical business training went to commercial schools. These schools frequently evolved into separate schools for business training only. Again, it was the Wharton School leading the way by introducing an accounting course in 1883. It can be easily understood that in those days, academics considered the newly developing programs in business and accounting as too practical or too much aligned to the needs of business practice. Yet, accounting became very quickly the strongest specialization within business education in terms of student numbers and disciplinary development. Today, accounting is considered to be indispensable for our complex modern society, because accountants judge whether companies' annual reports are in accordance to US generally accepted accounting principles (GAAP) or, for businesses located in other countries, to their accounting standards. As such, accountants play a major role in society, and can be considered as true professionals when it comes to licensure to practice, registration requirements for professional association, and professional courts of appeal. In many Western business schools, accounting is a required portion of their basic-degree programs. A few institutions of higher education offer stand-alone accounting programs (without offering other business degrees).

Available figures about undergraduate enrolments and degrees granted demonstrate that the market share of business degrees fluctuates around 20% in the United States, and 10% in the United Kingdom. During the second-half of the 1990s, business education worldwide saw an erosion of its enrolment. Despite these fluctuations, it was demonstrated that market share of business degrees fluctuated between 15% in the 1970s in the US and reached a high of 24% in the late 1980s.

Graduate business education shows similar developments. Western-style business education in Europe and North America deliver professional degrees – the master of business administration (MBA) degree and the master of science degree in business (MSc) for students without initial

Definition of a Profession

Overview

Business education has demonstrated unprecedented growth since the first bachelors program in 1881 was offered at the University of Pennsylvania in 1881. It is said that through the efforts of businessman Joseph Wharton,

work experience. The MBA degree is pursued for career enhancement for business professionals with at least 2 years of work experience in various backgrounds (engineering, law, healthcare, etc.). MBA education has become a big industry. In the 1990s, about 75,000 MBAs graduated each year in the US. The numbers of MBA programs and students has continued to grow since that time and growth is prominent across the US, Europe, and Asia.

The fields and industries served by business education providers are very diverse. There is no standard model for business-education programs, nor is there a standard higher education platform compared to other professions. Providers range from traditional university-based business schools, for-profit institutions, and independent business colleges sponsored or governed by chambers of commerce. Next, hybrid faculties or institutions can be found offering business degrees within a setting of business and economics-degree programs, or colleges for business and engineering within technical universities. Finally, business itself provides programs through in-company training, or within the framework of corporate universities, which can also result in business degrees in cooperation with universities or other accredited institutions.

Typical business school curricula hold a strong functional orientation. Business schools have become highly specialized places that teach business around key disciplines (accounting, finance, strategic management, and marketing) with strong foundations in scientific approaches to problems as they occur in business practice. While on one hand business research has developed strongly along these disciplinary lines, passionate calls have been voiced to organize teaching and research around themes, projects, or problem situations as they occur in business practice. The arguments in favor of this call are similar to those pronounced in many other professions (e.g., medicine and healthcare): people in real jobs do not encounter carefully formulated disciplinary problems or neat stylized prepackaged cases, but they work within places with messy data, in environments of calculated chaos, or in situations where the impending problems are not even recognized. The evident answer to these criticisms is that business scholars work in academic institutions that seek generalizable theories by using analytic tools to examine data – data that are preferably quantitative.

One of the key concerns – and debates among business scholars – is the currency and relevance of business curricula. While core courses and electives follow the organization of business schools in functional silos, the issue is whether boundary-spanning courses or cross-disciplinary courses might better address the problem of keeping business curricula up to date. Another concern is whether the educational methods of many business programs provide true understanding of business practice. This debate goes further than the traditional questions as to whether lectures are a place of learning, and whether they inspire

and help students gain an understanding of course contents. The issue is whether one can understand business practice without having the experience of business practice. Again, this issue resembles previous debates in other professions such as medicine or healthcare.

Historical Perspective

Mintzberg provides an excellent brief history of business education in his book about MBA education in the US. He describes how the first master degree in business was offered in 1900 by Dartmouth College. Harvard (1908) and Stanford (1925) followed with master degrees, while bachelor programs in business became more and more *en vogue*. The major input for these master programs came not from business but from the established academic disciplines, for example, economics, sociology, psychology, and political science.

The establishment of bachelor and master degree programs in business was a response to the increasing need for trained managers due to progressive industrial developments. Through research and education, business schools sought to introduce scientific methods in the analysis of business processes. However, pretty much from the outset, doubt was raised about the academic credibility of business education. In the early 1950s, concerns were expressed about the academic standards at both undergraduate and postgraduate levels. Reports (Carnegie Report and Ford Report) were commissioned by the US government to recommend changes in business-education programs. In the 1960s, similar developments took place in Europe.

Schools in Europe had already developed a strong tradition in vocational education focused on training commercial and management skills such as bookkeeping. For example, several European countries established vocational high schools with an explicit focus on education in trade. Norway had the tradition of *Handelsbøyskole*, and Germany its *Handelshochschule*. During the 1960s and 1970s, universities and independent schools emerged out of these schools dedicated to academic research and training in business. Another typical European progression is that many business-education degrees developed out of economics programs. Universities in several West European countries offered economics programs with specializations or electives in business economics and accounting. Around the 1980s, these programs attracted more and more students and turned into business-administration programs at the (under)graduate level.

With respect to MBA education in Europe, tremendous growth can be observed. It is said that in 1988, only 1200 students graduated with an MBA degree in the UK. In 2000, more than 200 MBA programs were offered by 100 universities and business schools delivering about 10,000 MBA graduates. Substantial increases in market demands for MBA graduates also caused another development. More

and more MBA students do not fit within the traditional college populations (18–24-year-olds). Data about student enrolment in MBA programs can be found at the Association to Advance Collegiate Schools of Business (AACSB)'s website. This site shows that substantial shifts can be noted in the demographic characteristics of the business degree student populations with respect to the demand for part-time education, the amount of work experience before they enter the program, and the increased average age of students.

Specialized Technical Knowledge, Habits of Mind (Academic Training)

Criticisms on the nature of business education seem to be fueled by two leading arguments. First, the question is raised whether business school curricula overemphasize that management is a science and not a profession based on best-evidence practices. One of the critical issues is whether business education is overly scientific and out of touch with business realities, and whether business schools concentrate on research which has little to do with the needs of the business world. Second, it has been argued that business graduates do not have a realistic understanding of the business world. The issue is whether graduates are sufficiently prepared to appropriately respond to current work situations. Attention is needed to insure that graduates in management possess adequate problem-solving abilities, decision-making skills, and leadership skills.

Clearly, these issues are not exclusive to business education. Other domains in professional education deal with similar concerns. In medical education, calls for change have been expressed since the publication of the early Flexner Report in 1910. As medicine took on professional status in the early twentieth century, there was a definite need to establish clinical education in the basic laboratory sciences. Due to a lack of scientific foundations, medical training was in need of educational reform. Flexner was one of the first to recognize that, due to the advancement of medicine, clinical practice should be connected to theoretical laboratory sciences.

Tacit Body of Skills Shared by Competent Practitioners (Apprenticeships)

Before cognitive-science approaches became fashionable to analyze managerial practice, data collection was based on interviews or survey data from human-resource executives, management practitioners, members of executive advisory boards, program directors, and graduates. A consistent research finding is that about four required competencies may be identified that are needed to function adequately in managerial practice. Graduates are expected to possess (1) functional competencies (discipline specific), (2) systemic competencies (cross-disciplinary knowledge

and skills), (3) personal competencies (self-management), and (4) organizational competencies (managing others). It has been found that employers put a growing emphasis on interpersonal skills such as interpersonal communication, team-building, and cognitive skills such as problem solving.

Current cognitive research on expertise development in business, management, and accounting suggest that students, graduates, and experienced business professionals go through similar stages in expertise development as has been implemented in medicine. For example, it has been demonstrated that graduates and students possess significant amounts of factual knowledge, but are not yet able to transform their school knowledge into dynamic knowledge. This finding suggests that the significance of acquiring formal knowledge and formal learning is commonly over-emphasized. Graduates typically possess large amounts of formal knowledge but this is not enough for solving practical problems. This finding confirms claims from critics that formal business education produces only limited conditions for the development of managerial expertise. The absence of developing practical know-how within business schools is a point of concern for educational reform, because it seems to be an extremely powerful learning tool for development of managerial expertise.

Values and Attitudes Shared by Professional Community (Ethical and Moral Dimension)

The values and attitudes shared by the professional business community across industry boundaries are perhaps best formulated by the Ethics and Compliance Officers Association in their standards of conduct for business ethics and compliance professionals as displayed below:

1. Responsibilities to my employing organization:
 - be a role model in adhering to my employer's code of conduct;
 - proactively advocate the integration of ethical business practices and a commitment to compliance into all aspects of my employer's business;
 - ensure to the best of my abilities that my employer upholds all relevant laws and regulations wherever business is conducted;
 - be a leader in the formation of ethical business practices in support of evolving business strategies and opportunities, taking into consideration legal requirements, customs, and best practices;
 - raise and escalate, as necessary, significant business ethics and compliance issues;
 - protect confidential information obtained in the course of my professional activities unless disclosure of such information is required by law, applicable regulation, or company policy, or if maintaining the confidentiality of such information would create an appreciable health or safety risk; and

- avoid any actual, potential, or perceived conflicts between my personal and business responsibilities, and promptly disclose and resolve any issues that may arise.
2. Responsibilities to the profession:
- maintain exemplary standards of personal and professional integrity;
 - strive to continually advance my knowledge of business ethics and compliance;
 - work both individually and collectively with other members of the business ethics and compliance profession to advance the development of business ethics and compliance; and
 - take advantage of opportunities to improve public understanding of business ethics and compliance and their importance to sound business management.

Cross-Cutting Issues

Accreditation of Programs

Next to national accreditation bodies that deal with keeping standards for academic education, business education faces the rather unique situation of international accreditation bodies in the US and Europe. In the US, the AACSB has developed from a national organization (a not-for-profit corporation of educational institutions) that accredits US business schools to an international organization to promote and improve higher education in business education. It was founded in 1916, and established the first set of accreditation standards for business schools in 1919. To date, AACSB has accredited about 560 member institutions of which about 30% have additional specialized accreditation for their accounting programs. About 100 accreditation council members are at colleges and universities outside the United States. It is important to note that accreditation by AACSB is for schools not programs with the exception of accreditation for accounting programs.

In Europe, there are two leading accreditation organizations: the European Foundation for Management Development (EFMD) and the Association of MBAs (AMBA). EFMD is a global organization devoted to the continuous improvement of management development. It has accredited more than 100 business schools across 33 countries. The brand name for its accreditation activities is European Quality Improvement System (EQUIS). EQUIS is not primarily focused on the MBA or any other specific program. Its scope covers all programs offered by an institution from the first degree to the PhD. The institution gets accredited, not an individual degree program. In addition to EQUIS, EFMD has developed other accreditation services for individual programs within institutions. While EFMD mainly focuses on accreditation of institutions,

AMBA's accreditation service is dedicated to all MBA, doctor of business administration (DBA), and master of brand management (MBM) programs. AMBA, established in 1967, is considered to be the international impartial authority on postgraduate business education. AMBA is a global organization and has accredited MBA, DBA, or MBM programs at more than 150 business schools.

Of the approximate 3000 business schools worldwide, about 1% of these schools hold the so-called triple-crown accreditation. This connotes that the business school or its programs is accredited by AACSB, EFMD, and AMBA. Within the community of business schools, receiving the triple crown holds an element of prestige.

Licensure and Certification of Individual

Degrees, licenses, and certifications are many when we look at business professionals. Most of the licensures and certification programs require some amount of education at higher levels as a baseline to earning their designation. Many business-school programs provide instruction specifically geared to equip an individual with the necessary knowledge and skills needed to perform the requirements for earning licenses and certifications. All of the programs that provide instruction and certification provide a code of ethics or some form of professional standards for those professionals who hold their designation. To follow is an overview of some of the most widely supported license and certificate programs.

Certified public accountant

One certification that is also tied to state/federal regulations in the United States is the certified public accountant (CPA). The CPA is a license that is required to serve in public accounting as an independent auditor. State laws govern the specific authority and responsibilities of the CPA. Although specific requirements may vary by state, most require an undergraduate degree with 120 semester hours. There is also a requirement for 24–30 semester hours of specific coursework in accounting that could be earned via an undergraduate or graduate degree program. Many states also mandate an experience criterion that includes a minimum of 1–2 years experience in audit or accounting work. As the CPA license typically takes 18 months to complete beyond the requirements listed above, many students opt to pursue a master's degree that fulfills these additional requirements. Beyond the classroom and experience requirements, individuals must sit for a 14-h computerized exam administered by the American Institute of Certified Public Accountants, which serves as the governing body for CPAs in the US. The exam consists of four key sections: (1) auditing and attestation, (2) financial accounting and reporting, (3) regulation, and (4) business environment and concepts. For more on this license, see the AICPA website.

Chartered financial analyst

Another popular designation among students at business schools is the chartered financial analyst (CFA). The CFA designation requires a broad understanding of finance implications across a number of other disciplines including accounting, economics, statistical analysis, and portfolio management. Unlike the CPA, the CFA is not regulated by state or federal governments and there is no legal requirement to hold the designation in order to serve as a financial analyst. Being a CFA charterholder provides recognition of financial expertise that is often accepted as parallel to holding an MBA with a concentration in finance. The CFA designation is granted by the CFA Institute that provides a rather extensive routine in which to earn the charter. For more, see the website of the CFA institute.

Certificate in investment performance measurement

The certificate in investment performance measurement (CIPM) targets ethical excellence and technical expertise in the application of investment performance evaluation and presentation, analytical techniques, and standards. In order to earn the CIPM designation, one must have 2 years professional experience with calculating, analyzing, evaluating, or presenting investment results; providing consulting services related to such activities; verifying global investment performance standards (GIPS) compliance; supervising persons who perform such activities; or teaching such activities. Alternatively, one can substitute 4 years experience in the investment industry. Candidates must agree to comply with the CIPM Association code of ethics and standards of professional conduct and pass both a principles and expert exam. For more, see website of the CFA institute.

Financial risk management

A widely accepted professional certification for senior risk managers is the financial risk management (FRM) that benchmarks knowledge regarding strategic areas of FRM including: credit, market, operational, and investment-management risks. Certification requires a passing score on the FRM exam, active fellow membership in the Global Association of Risk Professionals (GARP), and a minimum of 2 years experience in the area of financial risk management or another related field. For more on FRM, see the website of GARP.

Earning licenses and certifications are more and more required for business professionals who provide advice about financial investments, or work as personal financial advisor. Depending on their activities, different certificates and licenses are required.

Professional Code of Conduct (Ethics)

As mentioned earlier, all the university, licensure, and certification programs contain some statement of purpose

that includes a code of conduct, ethics code, or other statements of expected professional behavior. An increasing number of corporations and businesses are joining the Ethics and Compliance Officer Association (ECOA), formerly called the Ethics Officer Association. Membership in that organization has grown significantly since its inception in 1991 (current membership is over 1300 ethics and compliance professionals around the globe). The association provides a platform for knowledge expansion and thought leadership across all industries for business leaders holding compliance and/or ethics positions. The association's vision is to be the recognized authority on business ethics, compliance, and corporate integrity. More information is available at ECOA's site.

Globalization and Diversity: Progressive Responsibilities of the Professional

There is an absolute resounding call around the globe for greater accountability by business professionals. More than that, business organizations are reaching out to demonstrate value to customers, shareholders, employees, and society. Narrow focus on short-term profits has been demonstrated as a path to destruction as businesses, both large and small, have been dissolved over the past decade. Today, business models offering sustainability must include much larger vision statements and much larger landscapes that hold all stakeholders, not just shareholders. Since the turn of this century, we have experienced a shrinking, flatter world where technology has made it possible to collaborate and share information instantaneously across time and space. The ease at which consumers can access information adds to the urgency and importance of accurate and legitimate information dissemination by business leaders. Business futurists like Peter Drucker and Charles Handy have been providing accurate, albeit provocative, forecasts on the look and feel of the future of organizational life for sometime now. The future of management and leadership has been proclaimed by such thinkers as Warren Bennis, Gary Hamel, and Peter Senge. Although taking different paths, each of these scholars has highlighted an urgency for business leaders to begin to think and act as professionals. It is clearly time to accept the fact that future organizational life will be very different from how things worked in the past. This difference must be accepted and promoted by a new breed of leaders: A breed that must take on increasing progressive responsibilities.

Signature Pedagogy

In order to respond to these progressive responsibilities of business leaders, business education must accept the challenge to help in the development of requisite capabilities to lead the organizations of the future. Business professions have consistently called for more dynamic and

responsive learning platforms to prepare the next generation of leaders, yet universities have been unresponsive to such calls. Some valiant models have been provided that target a more vibrant, responsive, and integrated approach to developing business leaders and industry leaders have also weighed in on the importance of upgrading the educational platforms to better address current and future business needs.

Business schools have sought many ways to bridge the gap between theory and practice by incorporating business practice into their curricula through cases (Harvard case method) and projects, or through learning methods that heavily rely on understanding practice (e.g., action learning, project-based learning, and problem-based learning). However, curricular-reform visions seem to be driven by content-based notions (what should we teach?), and less by pedagogy (how should we teach?). In this way, business education is lagging behind by developments in other professions (especially medicine and healthcare) that went through profound instructional changes based on educational-research findings and input from professional practice. On the other hand, business education is beginning to close the gap with other domains in professional education as is reflected in its emphasis on accreditation, and its strong links with business practice and societal needs.

Professions – Engineering

J Heywood, Trinity College Dublin, Dublin, Republic of Ireland

© 2010 Elsevier Ltd. All rights reserved.

Introduction

A striking feature of social change in the nineteenth and twentieth centuries was the rise of the number of occupations into the ranks of the professions. Engineering was among the earliest to seek this status. This has not been without controversy, for what are the characteristics of a profession?

The occupations that concern us here are ones based on extensive academic and practical knowledge and/or social skills and, in time, they generate a special mystique of their own. The clients of these occupations constitute a varied and heterogeneous population that offers considerable potential for exploitation by members of the occupation. As a result, the moral practitioners establish associations to create and protect a monopoly and to control entry. Education and training have been and are used as the prime means of selection. This discriminatory role would seem to be as important as their role in the provision and improvement of knowledge for it seems that sometimes an education is provided that is not suited to the work task. They practice self-regulation and, if possible, seek to have it placed on a statutory footing. In the UK, in order to become a profession an occupation builds up a system of education and training and defines methods and regulations for acceptance; and in order to establish a position of responsible guarantors of the public interest they adopt a code of practice or professional ethic. Taken together, all these serve to provide the professional person with status and British society clearly acquiesces in the hierarchy that has evolved. As there is a potential for conflict between public and professional interest, public support for these restrictive practices will depend on the perception that it has of the effectiveness with which a professional organization deals with malpractice. In this respect, there has been some criticism of regulatory bodies, for example, law and medicine.

It is against this general context that the engineering profession is considered but primarily in respect of education and training, codes of practice, and professional autonomy with a focus on identity and status. Developments in Europe, North America, and the UK are considered within their historical context. While there are many similarities, there are also considerable differences.

Learned Societies and the Development of the Professional Associations

When the Royal Society was founded in 1660, its members met on a weekly basis to discuss experiments and other topics of scientific interest. Its purpose is expressed in its title in the Royal Charter it received in 1663, namely, *The Royal Society for Improving Natural Knowledge*. It was a society of amateurs and persons actively engaged in scientific work. It was a learned society and it published proceedings, and great importance was attached to the development of a library. In 1847, it imposed membership requirements and Fellows (FRS) now had to be elected on the basis of their scientific work. A very small number of Fellows are elected each year. Fellowship is a scarce commodity that is highly prized by the scientific community and generally valued by society. It is an élite. A Royal Charter provides it with a legal framework of governance and carries with it considerable prestige.

Engineers in Britain have long wanted to emulate the Royal Society and in so doing substantially improve the status of the profession. In 1976, the Royal Academy Engineering was founded. It is representative of every branch of engineering. In that sense it provides engineering with an identity. Sixty Fellows are elected each year and that makes fellowship a scarce commodity. Its equivalent in the USA is the National Academy of Engineering (NAE) which has had a more positive role in policymaking. The NAE was founded in 1964, 101 years after the National Science Foundation (NSF), by the same act of incorporation as the NSF. Its advisory role to government is spelt out in its charter thus “whenever called upon by any department or agency of government to investigate, examine, experiment and report upon any subject of science or art.” Like the Academy in the UK, whose brief does not extend that far, it is an independent, nonprofit institution and proclaims to “provide engineering leadership in service to the nation.” Nevertheless, distinguished American engineers continue to decry the lack of engineers in prominent positions as they do in the UK, and hence the ability to influence policy. However, it is the professional associations in the UK and USA that are of interest here rather than the academies.

James Smeaton, an FRS who coined the term civil engineer to distinguish between his kind of work

(e.g., constructing lighthouses) and that of military engineer, founded the Society of Civil Engineers in 1771. It was a learned society. Later in 1818, the Institution of Civil Engineers was founded to become both a learned society and the first professional association of engineers. It obtained a Royal Charter in 1828 with the purpose of fostering and promoting the art of civil engineering that was seen at that time to embrace all engineering. However, The Institutions of Mechanical and Electrical Engineers were founded in 1847 and 1871, respectively. These institutions greatly valued their learned function and in particular their libraries. Numerous other institutions were created in the twentieth century representing various specializations in engineering.

In 1887, irrespective of the fact that there were university departments of engineering, the Institution of Civil Engineers set its own qualifying examinations. By 1889, they had raised the standards to correspond with that of a general university degree. The other institutions were to follow suit. In 1921, the government initiated a system of national certificates for work done by technical college students on part-time courses. Assessors of the higher stages of these courses were appointed by a joint committee that was representative of the professional institutions and the Ministry of Education. The assessors reviewed the examination papers and marking. The complete course to degree level took about 7 years. Until the 1970s this was a major route for training electrical and mechanical engineers. By that time it had been agreed that all engineers should be educated in full-time degree programs.

The Chartered Engineer and Professional Engineer Qualifications

By the 1960s a need was felt to bring some coherence to the educational activities of these numerous institutions. To meet this need they formed a Council of Engineering Institutions (CEI) and this became their examining body for the award of the chartered engineer (C. Eng) qualification. Subsequently, it was replaced by an Engineering Council UK. Its Royal Charter empowered it to regulate the engineering profession in the UK. It functions through 36 institutions that are licensed by the Council to place members on its register in one of three grades – chartered engineer, incorporated engineer (previously technician engineer), and engineering technician. Placement on these registers requires skill in a range of competencies and practical experience.

Membership of the American professional societies does not entitle a person to practice engineering in the sense that they can take legal responsibility for the documents they sign. This is particularly important in civil and mechanical engineering. Each state requires such persons to be licensed and they are recognized by the letters PE

(professional engineer) after their names. Each state has its own requirements for licensure but there is also an examination set by a National Council of Examiners for Engineering and Surveying (NCEES). There is a three-stage process after graduation that begins with a ‘Fundamentals of engineering’ examination: this is followed by work experience and completed by an examination in the ‘Principles and practice of engineering’ (PE). After 2015, candidates for the PE will require a master’s degree in engineering which would seem to align it with the Bologna process (see below). A distinction is made between graduate engineers and professional engineers. A university teacher is not required to be a PE. Engineers employed in interstate commerce are not regulated and some industrial exemptions are given. In some states the title engineer is protected.

An Innovative Merger

The most recent development in the UK is the merger of the Institution of Electrical Engineers (IEE) with the Institution of Incorporated Engineers (IIE) to become the Institution of Engineering and Technology. The use of the term technology clearly responds to popular usage and may help resolve the identity issue. The IEE was a society that granted chartered status to electrical engineers. The IIE granted incorporated status to a group that had been called engineering technicians. They are broadly equivalent academically to holders of technology degrees in the USA. The IIE embraced technicians in mechanical and general engineering and had merged with other technician institutions in the electrical and radio fields to become the IIE. The new institution thus embraces both professional and technician engineers as do the American Societies.

The Origins of Validation (Accreditation) in the UK

In the UK, these developments were paralleled between 1956 and 1992 with a search for status and identity by those educational institutions in the public sector allowed to do degree-level work; in short, they sought university status. The overt intention was to improve the quality of technological education. In 1956, a National Council for Technological Awards (NCTA) created a system of validation of diplomas awarded by ten of these colleges, and that is, arguably, the origin of current systems of accreditation in the UK. The professional engineering institutions participated in that practice. These colleges became universities in 1967. NCTA was replaced by the Council for National Academic Awards (CNAA) which was created for all other colleges in the public sector with degree programs irrespective of subject, and by 1992 all those institutions had become universities.

France and the Origins of the US System of Engineering Education

No problems of identity and status were experienced in France. From the beginning there was a deliberate attempt to create *corps d'élite* of military engineers through the development of a college – the *École Polytechnique* that would provide a high-level education with emphasis on science together with studies in practical subjects and the humanities. A similar *Grands École* to provide a similar kind of élite for industry was created in 1829. Their mission is the same today. Engineering acquired status from the beginning and in continental Europe engineers are held in much higher esteem, particularly in Germany than in Britain and North America.

In the USA, Rensselaer Polytechnic was founded in 1823 and its curriculum was subsequently remodeled so that by 1850 it mirrored that of the *École Centrale des Arts and Manufactures* in Paris. That model of parallel studies in the physical sciences, mathematics, technical subjects, and the humanities remains the basis of engineering curricular in North America to this day.

The American Societies and the American Society for Engineering Education

In 1852, the American Society of Civil Engineers was founded for all engineers. Had it remained for all (and likewise the Institution of Civil Engineers) the profession may have had a stronger identity. However, as in England, societies were soon formed for mechanical and electrical engineers. They never provided a qualifications route that was left to the universities. One outcome was that in 1893 some teachers in the US organized the Society for the Promotion of Engineering Education that made some influential recommendations. It later became the American Society for Engineering Education (ASEE) and again in that guise it was responsible for a number of very influential reports. It is represented in the accreditation process that began in 1932 as the Engineers Council for Professional Development (ECPD) now Accreditation Board for Engineering and Technology (ABET). ASEE has enabled a continuing discussion to take place about matters concerning engineering education in a way that the professional institutions in Europe and the UK have not. During the last 2 or 3 years academics have begun to talk of engineering education coming of age. Thus, it is possible to conceive of an engineering education profession. Given precedents from school teaching it is possible to distinguish between restricted and extended professionalism among engineering educators. For example, restricted professionalism regards teaching as an intuitive activity, whereas extended professionalism regards it as a rational activity supported by research and evaluation. Thus, extended

professionals will not only be conversant with research and development (R&D) in their own fields of engineering, but also in that of engineering education. They will keep abreast of both subject areas. The perspective of restricted professional is limited to the immediate time and place, whereas that of extended professional embraces the broader social context of both engineering and engineering education. Whereas a restricted professional believes skills are derived from experience, the extended professional believes that skills are derived from a mediation between experience and theory, etc. The Centre for Scholarship in Engineering Education (CASEE) of National Academy of Engineering (NAE) which is encouraging research and best practice in engineering education is encouraging extended professionalism among engineering educators in the USA.

The Washington Accord and Developments in Europe

In 1989 an international agreement called the Washington Accord was signed. Its purpose was to develop an instrument that would enable the mutual recognition of professional degree programs across the world. At the heart of this task is the mutual recognition of systems of accreditation. Support for this move came from a pan-European organization representative of the engineering institutions: *Fédération Européenne d'Associations Nationales d'Ingénieurs* (FEANI). This would require agreement on approaches to program accreditation. In Britain, modern principles of accreditation were established in 1956 by the NCTA. Procedures were established in France in 2007, Germany in 2002, Portugal in 2008, and in Russia much earlier in 1992. Within Europe, FEANI brought together a group who proposed a European accredited engineer. There followed a European Union (EU)-funded project to establish an agency for accreditation (the European Network for Accreditation of Engineering Education, ENAEE) that was incorporated in 2006. It has established accreditation for bachelor and masters degrees. This work relates to the Bologna Declaration signed in 1999 by 45 countries with the intention of creating a European system of higher education that facilitated student mobility. The pattern of education that has been agreed follows two cycles. The first cycle is of 3 years duration for a basic degree and a second cycle of 2 years for a master's degree. A broad interpretation of the Declaration enables universities to apply it to engineering programs. There is a debate about whether graduates from the engineering science program are employable after 3 years, although there is a 3-year program that leads to an engineering technology qualification. Whereas in some universities in Germany the master degree programs are designed to allow engineering technology graduates to enter

these programs directly, this is not generally the case. Normally, they would be expected to pursue an additional program of study prior to entry to the master's program.

Education, Occupation, and Professionalization

The foregoing remarks illustrate the importance attached to educational qualifications by organizations seeking to become professions and professions seeking to enhance their status. However, the content also contributes to perceptions of identity and content is very much a product of history. There is little doubt that when such persons as James Smeaton set up these fledgling societies they were trying to escape from the image of engineering as something done by craftsmen. They wanted to promote its scientific dimension (theory) and this has had consequences that may or may not have been beneficial. Therefore, it was that universities on both sides of the Atlantic have tended to emphasize the scientific dimension at the expense of design and the academic at the expense of the practical. Promotion depends on research in some aspect of engineering science and design can count for little. Not only do university departments of engineering have to provide courses and assessments that meet these requirements, their selection criteria have to ensure that students are capable of success in the courses they offer. In Britain, this affects the choice of subjects (A levels) that pupils make in high school, and in the highly specialized curriculum of the high school this means physics, mathematics, and generally another science. First, this puts them in competition with physics as a subject of study at university because physics departments want the same qualifications and in the past physics has had higher status. Second, it prevents them from taking other subjects that might be valuable. Cambridge University has refused to accept a diploma in engineering developed with the support of the Engineering Council UK unless the candidate has physics at A level. For example, very few universities regard metal work as suitable, yet it is an ideal subject for developing the spatial ability that is essential not only for design but also for mathematics. Third, like physics, engineering gives the perception of it being an extremely difficult subject. In both subjects, there has been a decline in the number of applicants and this has been a matter of considerable concern.

There has been particular concern in the English-speaking world to increase the number of women entering engineering, and the number obtaining high positions in engineering and engineering education. Some have argued that the curriculum is insufficiently humane to attract women. Programs that might, such as service (engineering in the community) courses, have low status as does the low-tech approach required when the community in which students work is in a developing nation. High

status is attached to work in high tech. Yet, according to an American report from the Carnegie Foundation "the widespread emphasis of theory over practice . . . discourages many potential students while leaving graduates with too little exposure to real-world problems and ethical dilemmas."

Codes of Conduct and Professionalization

As important as education is to occupations, seeking to become a profession is the code of conduct. Unlike the other professions that have a unitary code of conduct, various associations (e.g., ABET, the National Society of Professional Engineers (NSPE) and the Institute of Electrical and Electronic Engineers (IEEE)) in the USA have developed codes of conduct all of which differ. The same is true of the UK. However, most recently, the Royal Academy has published a code. Michael Davis in his critique of engineering ethics makes the point that in the USA an engineer could be subject to different codes and this could make it difficult for him/her to know what to do. It is not far fetched to equate the code with identity and having to choose between codes his/her identity might become confused. Davis supports the explanation that codes of conduct are important because they are a contract between individuals that protects them from certain consequences of competition. "They provide a guide to what engineers might reasonably expect of each other. [...] it should also provide a guide to what we may expect other members of our profession to help us to do." Inherent in that view is the responsibility for the development of new members of the profession. The more important points are that (1) the code provides unifying framework of values and (2) if all engineers adhere to the same code, then an engineer is in a position to explain to other engineers why a particular course of action is unjustified and not be in the position of putting his/her job at risk. Davis who uses the story of the *Challenger* disaster to make his point concludes that "in practice the ethics of engineers is as important to the success of engineering as good design or testing is." That suitably translated could apply to any human endeavor. The implications for the teaching of ethics are profound because it makes it much more than a discussion of codes of conduct. It would also seem that a unitary code goes some way to providing an underlying bond to the fragmentation that is perceived by some to have lost engineering its professional identity, provided that there is common skill (competency – ability base).

Professional Autonomy

One of the complaints that this approach overcomes is the view that engineers are employees and, have therefore, to

do what their employers tell them. The problems of whistle blowing are much discussed. Without detailing Davis's discussion of these matters he does raise an issue that is common to professions that are made up mainly of employees and that is the question of autonomy. This applies in particular to teachers where micromanagement has been a feature of some governments' attempts to improve schooling. It has been argued that these strictures have led to the deprofessionalization of teaching. The question has been how in a situation of serious constraints on teaching, teachers' professional autonomy can be made consistent with employer requirements? In respect of teaching, it has been argued that the way in which teachers are socialized into teaching coupled with limitations in their training leads it to a form of restricted professionalism. Moreover, it is argued that extending teacher professionalism would enhance rather than limit the possibility of providing the better education that employers seek. Bowen argues that caring, which is an important characteristic of the teaching and medical professions, should also be fundamental to an engineering ethic: "The special capabilities for promoting wellbeing that engineers possess bring special responsibilities." Davis suggests that research needs to be implemented on professional autonomy. One approach might be to examine the attitudes of professionals at work to restricted and extended professionalism and how organizational structure and the values associated with it influence professional behavior.

Emerging Issues

The academies in China, the UK, the USA, and similar organizations have become interested in philosophy and engineering. Much of what is being argued in workshops and seminars in recent years relates to the identity of engineering. Is there a philosophy of engineering that is distinct from a philosophy of science? The question arises from the fact that the emphasis in engineering courses is on science subjects and their application and the consequent view that engineering is but applied science. Very often, industry will employ physicists to do what engineers do, which suggests that some industrialists see little difference between engineering and physics. An important subquestion about which there has been much discussion is: In what ways do the thought patterns (processes, ways of thinking) of engineers differ from those of scientists? Questions such as these raise important epistemological issues and have a bearing on the curriculum. They are directly concerned with the questions: What is engineering? Also, what is an engineer? Questions are also being asked about content and approach to the teaching of ethics, its relation to and provision in the curriculum for moral development. One of the potential challenges that

might arise is that should the answers come up with an alternative to the present curriculum, a substantial paradigm shift in attitudes and values would be required. As indicated in many reports, design has very little prestige in spite of the fact that it is central to engineering. Liberal studies have little or no place in the hierarchy. If Rosalind Williams' thesis that the fragmentation of engineering has caused engineering to lose its identity and that in the future it will have to work hand in glove with the liberal arts, then the shift is unlikely to be made. Others have argued that this will leave engineering where it is now and engineers will be perceived as technicians for the purpose of doing practical, technical work.

Distinguished engineers have sought to improve the status of engineering at the highest levels of political distinction. Other researchers from within and without engineering argue that engineering education has a key role to play and that if it is to do this it has to change. Davis considers a profession to be a "number of individuals sharing an occupation voluntarily organized to earn a living by serving some moral ideal in a morally permissible way beyond what law, market and ordinary morality require" in which case engineering educators are a sub-profession within the engineering profession. They are interdependent and for there to be change in the moral ideal of engineering education, if change is judged to be desirable, it will only be achieved if the profession as a whole regards it to be necessary.

Glossary

Accreditation – The process of external, quality review process used by higher education to scrutinize colleges, universities, or higher education programs for both quality assurance and enhancement; the external review and approval of an institution or school is done to see if the entity meets specific standards or requirements.

Allied health – Allied health professionals are involved with the delivery of health or related services pertaining to the identification, evaluation, and prevention of diseases and disorders; dietary and nutrition services; rehabilitation and health systems management, among others. Allied health professionals, to name a few, include dental hygienists, diagnostic medical sonographers, dietitians, medical technologists, occupational therapists, physical therapists, radiographers, respiratory therapists, and speech language pathologists.

International Classification of Functioning, Disability and Health – The International Classification of Functioning, Disability and Health, known more commonly as ICF, is a classification of health and health-related domains. These domains are classified from body, individual and societal perspectives by means of two lists: a list of body functions and structure, and a list of domains of activity and participation. Since an individual's functioning and disability occurs in a context, the ICF also includes a list of environmental factors. The ICF is WHO's framework for measuring health and disability at both individual and population levels.

Professional Doctorates – These are degrees sometimes called professional or clinical doctoral degrees; they are practice-based degrees in line with the 'traditional professional degrees' (medical doctor or lawyer); graduates of professional doctoral degree programs demonstrate a level of professional practice appropriate to the purpose of the degree and an expected and demonstrated level of scholarship contributing to the advancement of the profession.

Specialized accreditation – The process of external, quality review process used often in professional education to review programs or professional schools for both quality assurance and enhancement.

Introduction

As a broad-based term, allied health refers to a collection of fields educating practitioners at the associate, baccalaureate, masters, or doctoral levels. In the United States health care system, they represent more than 60% of the health care workforce providing diagnostic, rehabilitation, other therapeutic services, and access to or management of healthcare. For a sense of the scope of these fields, 7 of the 70 (or more) of them are detailed in **Table 1**, which reveals that these fields are high growth areas through 2016, all likely to have a disproportionate impact on education in the United States due to their high demand. Among these allied health professions, we focus on three as prototypical that have experienced rapid growth and change as emerging professions (occupational therapy, physical therapy, and speech-language pathology), which are identified in their own right.

How occupations emerge to become professions is fundamentally a social-political process that is strongly related to the relationship between the occupation and society that includes public recognition for those services that are essential, exclusive, and complex. Sociologists have often argued that medical dominance makes it difficult for other health professions to emerge as full professions. For the purposes of this article, we define emerging health professions among the multitude of allied health professions as those that are demonstrating increasing public recognition for their services, including direct access for those services; professional education at the graduate level in university, a growing research community, and proactive health policy efforts aimed at improving access and quality of healthcare. This article begins with a brief analysis of the genesis and evolution of the term allied health, followed by sections on regulatory issues such as accreditation, licensure, practice domains, and self-regulation; as well as educational institutions and educational trends.

Table 1 Listing of major professions in allied health with number of educational programs, number of existing practitioners, and projected growth based upon Bureau of Labor Statistics

<i>Profession</i>	<i>Number of accredited educational programs</i>	<i>Number of existing practitioners and growth projections from 2006–16</i>
Clinical laboratory science	470 programs	319 000 practitioners 14% growth
Health informatics and information management	NA	170 000 practitioners 18% growth
Nuclear imaging including nuclear medicine technology and radiation therapy	100 programs	20 000 15% growth
Nutrition and dietetics	281 baccalaureate programs 22 masters programs	57 000 9%
Occupational therapy	196 masters programs 5 doctoral programs	99 000 23%
Physical therapy	43 masters 166 doctoral programs	173 000 27%
Speech–language pathology	260 programs	110 000 11%

History of Allied Health

A simple definition of allied health is ‘all health care professionals other than doctors or nurses.’ The term is viewed as pejorative by some since it implies subjugation to medicine, but for practical purposes we will use the term in this article. The role of the American Medical Association (AMA) in allied health history is a critical element for understanding past and current challenges regarding cohesion and identity. Historically, while both occupational therapy and physical therapy had military origins and the need for reconstruction aides during and following World War I served to promote both of these disciplines, the financial difficulties of several early allied health professions caused them to turn to the AMA for support to develop and maintain their educational programs. For several decades, the AMA continued to be involved in helping define and regulate allied health as well as supervise and control its related practice. In 1966, the US Congress passed the Allied Health Personnel Training Act (P.L. 89-751). This legislation led to more focused attention on allied health fields essential for modern health services and was responsible for rapid growth in the number of allied health education programs from 2500 in 1966 to more than 8000 in 1980. During this period, educational programs in rehabilitation (occupational therapy and physical therapy) which were postbaccalaureate, graduate certificate programs resisted the movement of their programs into schools of allied health where the educational degree would be the baccalaureate. These graduate certificate programs were usually hospital based and affiliated with elite, private institutions of higher education.

There has been resistance from the emerging professions to the allied health designation and they have, as independent professional organizations, left this designation behind,

but not without a larger, continued political battle. The AMA still strongly influences who and what are considered real health professions compared to those in allied health professions. The AMA publishes an annual directory of accredited allied health education programs that includes 71 professions. Excluded from the AMA allied health list are medicine (allopathic), osteopathic medicine, dentistry, veterinary medicine, optometry, podiatry, pharmacy, chiropractic, clinical psychology, all levels of nursing education, and graduate degrees in health administration or public health.

Regulatory Issues

Accreditation

Accreditation is a process of external quality review that is used in higher education to scrutinize institutions and educational programs for quality assurance and quality improvement. There are six regional accreditation agencies for institutions of higher learning in the United States which are themselves regulated or recognized (not accredited) by the US Department of Education and by the Council for Higher Education Accreditation (CHEA). One recent challenge with regional accrediting agencies has been the rapid move and multiple requests for a change in degree offering at the institutional level. Several health professions have moved or are in discussion regarding a clinical doctorate degree (e.g., pharmacy, nursing, physical therapy, occupational therapy, and audiology). Given that a large number of health professions educational programs may not be in research intensive, doctoral institutions, but in primarily master's degree institutions, an accreditation review for the institution is required. This movement continues to generate dialog and controversy among

Table 2 Listing of accreditation agencies in the major fields of allied health

<i>Profession</i>	<i>Accrediting organization</i>	<i>Accrediting standards</i>
Clinical laboratory science	National Accrediting Agency for Clinical Laboratory Science	2006 National Accrediting Agency for CLS
Health informatics and information management	Commission on Accreditation of Health Informatics and Information management Education	AHIIM 2005 Standards
Nuclear imaging including	Joint Review Committee on Educational Programs in Nuclear Medicine Technology	JRCNMT Essentials, revised 2003
Nutrition and dietetics	Commission on Accreditation for Dietetics Education	2006 CADE
Occupational therapy	Accreditation Council for Occupational Therapy Education	January 2006 Final Draft of Standards for Accredited master's level Educational Program for the Occupational Therapist and Standards for an Accredited Educational Program for the Occupational Therapy Assistant
Physical therapy	Commission on Accreditation in Physical Therapy Education	2006 Evaluative Criteria for the Accreditation of Educational Programs for the Preparation of Physical Therapists
Speech/language pathology	Council on Accreditation in Audiology and Speech Language Pathology	2008 Standards for Accreditation of Graduate Programs in Audiology and Speech–Language Pathology

deans of graduate schools, schools of allied health or health sciences, and regional accrediting bodies.

In allied health education, a wide range of agencies accredit the education of allied health professionals. This means that an institution has not only a regional accreditor for the entire institution, but also specialty accreditation for many of the programs.

Historical Perspective

Central to all, however, is the development as an independent field of study or profession, moving from an allied health profession to an independent health profession. For the most part, accreditation agencies within the fields of allied health did not originally exist as separate or independent agencies. When some of the first programs in allied health were implemented, they were accredited by the Committee on Allied Health Education and Accreditation (CAHEA), which was part of the AMA. At one time, the AMA accredited 3000 educational programs working with 50 different national professional associations and 22 review committees. At that time, this made sense since most all of these fields were relatively young and developing professions, dependent upon the validity and power of medicine to support them – and hence the origination of the concept that these professions as allied with medicine. Within each of these allied health fields, there is a unique history of how development of a body of knowledge, sociology of professionalism in the profession, and educational methods and actions developed.

As these professions have matured in this manner, the move toward establishing independent accreditation agencies has evolved and, currently, all of the emerging health professions discussed in this article have their own

accreditation agency presented in **Table 2**. The result is that each profession has control of its educational standards, independent of medicine. In 1994, with the dissolution of CAHEA, the AMA ended their direct involvement with accreditation of allied health programs. The Commission on Accreditation of Allied Health Education Programs was formed and reviews and accredits programs across 21 health occupations.

Historically, accreditation educational standards in allied health have been most dominant in the United States. There is some movement, however, to expand the scope of some accreditation agencies in the United States elsewhere in the world. This is likely a future trend to watch as a form of globalization in action.

Licensure and Practice Domains

The development of independent accreditation agencies for these professions is integrally related to the related development of practice domains and licensure within these professions. Along with this growth of emerging professions practice domains has come development of paraprofessional or assistants who carry out the technical aspects of practice, allowing evaluation and decision making to be done by the professional. This section addresses these core practice issues: state regulation of the practice, professional turf issues, and the role of technical personnel.

Practice Acts

Accreditation agencies pertaining to a particular allied health profession depend, in part, upon data about the actual practice of the practitioners in the field to assist

in determining what should be included in educational programs, and therefore influencing accreditation standards and assessment of qualification for practice. The practice of any profession within a state in the United States is based upon the regulatory status in that state, usually designated as licensure or certification. State regulations pertaining to what a professional may and may not do in practice is typically based upon practice acts generated by the profession, groups of members within the profession, or federations of state boards across the profession. This means that in each of the states in the United States, there is a licensure or practice act that is based upon a model or scope of practice. The emerging professions (occupational therapy, physical therapy, and speech-language pathology) have licensure and established practice acts in every state.

Professional Turfs

For the most part, health care professionals are not educated to work in a team – and, hence, there is a lack of connection across health professionals. This disconnect in the United States is supported and reinforced by our insurance and billing systems, and our educational programs. The dominant educational paradigm is that every health care practitioner is educated in a single profession to be the best practitioner in that particular field. Very little, if any, education and experience is devoted to learning about other health care professions, how the health care system itself operates, how patients respond to and participate in the health care system, and how to work with other health care providers to improve patient health and wellness.

The net result of this approach is turf wars. At any given time, we might find dissension across health professions. Cross-purposes exist at the practice level and the educational level which is isolated from other health professionals. The issues will become more complicated with the consideration of paraprofessionals or technical personnel and respective educational settings.

Role of Assistants/Technical Personnel

Most of the allied health professions we are addressing in this article are educated in postbaccalaureate educational programs in 4-year universities or academic health centers. The three emerging professions upon which we focus (occupational therapy, physical therapy, and speech-language pathology) have some form of technical level of education that produces assistants to the therapist. The most structured and consistent technical programs are for occupational therapy assistants and physical therapist assistants. These assistants are similarly licensed or registered in each state, and similarly graduate from specialty certified programs. Most of these programs, however, are at 2-year

institutions and the graduates are – in fact – technicians and not professionals in the truest sense. This is another source of tension.

Ethics and Professional Responsibility

The concept of self-regulation of ethical standards is an important characteristic of professions. Codes of ethics are commonplace across allied health professions. Declaring a code of ethics, however, does not result in self-regulation. This requires the profession's obligation to serve the best interests of their patients, meet societal needs, and enforce the code. If we look at the historical evolution of the various codes of ethics in allied health professions, we can see a changing professional identity. For example, one of the first codes for physical therapists specifically cited is never criticize or disagree with the physician. The critical role of defining and creating a professional identity for these professions is further developed later in this article.

Evolving Professional Responsibilities

In the previous section that mentioned turf wars among all of the health professions, a key component of what all health care professions should focus on was neglected. The first and foremost responsibility of every health care provider is not to their respective profession or beliefs, but to their patient.

Access and Referral

A key element in the development of these emerging professions is direct access and referral to the health professional. Does the health professional need a referral from a physician or other designated health care providers? In physical therapy, there continues to be a strong professional association focus for legislative changes across states that allow direct access to physical therapists. In a different historical pathway, occupational therapy assumed they had direct access in the 1950s as the field began to work in communities, at that point believing they could work without a physician prescription. Thus, occupational therapy has always had direct access, while physical therapy is now working for it. Speech-language pathology also has direct access to clients. The exception for all three of these emerging health professions is the federal Medicare program. All three of these professions have been working together to make changes to the Medicare legislation that would eliminate the need for a medical referral for older patients seeking speech, occupational, or physical therapy services. Physician requirements for referral remain in place as a perceived cost-saving measure ensuring that Medicare beneficiaries receive medically appropriate care.

Educational Trends in Emerging Health Professions

Educational Institutions and Degrees

In addition to seeking control over setting educational standards and forming a profession-specific recognized accrediting body, there continues to be rapid changes in educational degrees in the emerging allied health fields. The primary rationale is that the expanding knowledge base and societal needs require professional education programs of sufficient depth and breadth. Starting as hospital-based programs, many of these fields have moved to baccalaureate programs and most consider master's and clinical doctoral degrees to be adequately prepared.

Physical therapy was one of the first allied health professions to move to the clinical doctorate (doctor of physical therapy, DPT). Now there are several health professions in active discussion or planning of advancing the level of the first professional degree, or the advanced practice degree. For example, occupational therapy has set a postbaccalaureate entry-level requirement; audiology now only accredits doctoral programs and will no longer recognize master's level programs; clinical laboratory science is working on implementing a clinical doctorate as the postprofessional degree; and nursing is moving to a clinical doctorate for the advanced nurse practitioner. Facilitating change for these health professions continues to be an arduous struggle and raises the question whether the predominant feminization of these professions plays a role in the tensions surrounding policy changes within organizations and institutions.

Faculty

The predominant model for faculty across allied health professions continues to be recruitment of an adequate number of clinicians to educational programs. The transition of health professions programs to professional education at the graduate level also places increased emphasis on scholarship. The rapid transition of programs has led many programs to a model of growing their own faculty and actively supporting doctoral-level education for their faculty.

Curriculum

Professional identity

Past curricular discussions often focused on the practical logistics of implementation such as how much content and number of laboratory hours. Currently, focus on professionalism and what it means to be a professional is perhaps the most visible and consistent theme underlying discussions and planning in professional education curricula in the maturing health professions. As these fields have converted their entry-level degrees to a postbaccalaureate

(master's or clinical doctorate), there continues to be an internal dialog and debate as to what this means in terms of depth and breadth of educational preparation. Much of this dialog is centered on role of professional identity and collaborative work in making professional judgments. As other mature professions, such as medicine and law, have refocused and emphasized curricular elements on formation of professional identity and professional commitments to meeting societal need, there is a commitment to focus on self-identity in the emerging health professions. Accreditation requirements, practice guidelines, and other professional documents have all moved well beyond teaching the code of ethics to include a broader and explicit focus on development or formation of a professional and professional responsibility.

Curriculum shift from technical application to knowledge, skill, and decision making

There is a dynamic shift in curricula in emerging health professions. A vast majority of professional textbooks are now written by faculty in the health profession. The foundation knowledge dimension of the professional curricula has grown. This foundation knowledge supports the primary components of the field. For example, occupational therapy has a strong base in the social and human sciences with multiple theory bases in the field, whereas physical therapy and speech-language pathology have more emphasis in the physical and biological sciences. Clinical courses have been redesigned with a clear focus on evaluation or examination of the patient/client as well as treatment interventions and evidence-based practice. Application of theoretical and conceptual models to practice situations is a routine part of the curriculum. All three of these emerging professions (occupational therapists, physical therapists, and speech-language pathologists) have adopted and use the International Classification of Functioning, Disability and Health. This conceptual model emphasizes prevention, function, activity, and participation along with consideration of the environmental and personal factors that may affect function, and is perhaps the single most unifying force for these professions on an international level.

An integrated model of clinical education or field experiences within the academic program has long been the standard in emerging professions. Historically, the educational environments for many of these programs were the hospital where the focus was on a tightly integrated model of knowledge, technical skill, and clinical practice. For most of the emerging professions, when they moved to a university setting, the model of an integrated model of clinical experiences (prelicensure), within the academic program remained. With increased emphasis on developing the thinking, decision making and judgment skills, and the technical skills, there is more discussion and models of

clinical education that would include a postlicensure internship.

Over the last decade, there has been rapid, continued growth of the central importance of clinical reasoning and the decision-making process for these emerging professions. There is no one shared model of clinical reasoning among these professions. While there may be common elements of application of core knowledge, patient-provider interaction, and a reflective inquiry process, the evolving models perhaps provide the best representation of the unique context and contributions of these professions. For example, the clinical reasoning models in occupational therapy have a strong emphasis on multiple forms of reasoning, including narrative, pragmatic, and ethical reasoning throughout the process of client interaction, while the reasoning models in physical therapy are more focused on the diagnostic process and patient self-management.

Pedagogy

Since their inception, the allied health professions have been focused on the development of proficient skills. In the emerging professions, the laboratory, skill-based component of teaching remains strong. While one of the continued challenges has been finding the balance between classroom teaching and laboratory teaching, there remains an essential for students to demonstrate fundamental, safe, clinical skills prior to entering a clinical situation. Skilled laboratory teaching frequently uses a case-based approach that integrates evaluation and examination process with development and performance of realistic interventions. The laboratory portion of the curriculum is tightly sequenced with the didactic component and requires ongoing and extensive collaborative faculty planning. The laboratory component of the curriculum also requires adequate space and supervision of students. It is not uncommon for faculty to have to divide a class into laboratory sections, thus creating a large number of faculty-student contact hours.

If one were to identify a signature pedagogy that represents the characteristic approach to teaching in the emerging professions that is adopted across educational programs, it is likely to be teaching psychomotor skills from multiple perspectives with a reflective component. Each skill requires performance, application, analysis, and teaching the skill across settings. Students must first learn how to perform the skill whether this is the performance of a daily activity or walking up stairs with an assistive device. The student must learn how to apply the skill and analyze the performance of the skill as they teach a client, patient, or family member. The analysis of what is needed for successful teaching or transfer of the skill goes well beyond the physical performance. Students then need to develop reflective insight and problem-solving ability as

they work to design an intervention that is well suited to the environmental context as well as the patients' beliefs, values, and expectations. They must reflectively monitor and assess ongoing intervention and family or societal participation.

Assessment

The model of practical, performance-based examination has been a long-standing assessment strategy in allied health education for clinical skills. Historically, the predominant model has a one-to-one testing situation where performance of clinical procedures was done directly on the faculty or on another student and then scored by the faculty member using some form of scoring rubric. Over time, the availability of facilities and technology for standardized assessments, particularly for programs that are part of academic health science centers, has contributed to the growth of standardized simulations such as the use of standardized patients and objective structured clinical examinations. Formative assessments of both performance and knowledge retention are common in these programs. A variety of test constructions are used across programs and there is more emphasis on case-based scenarios embedded in a standard multiple-choice test format as the national examinations have become increasingly more clinically based.

Clinical Specialization

All the three emerging health professions discussed in this article have some form of advanced specialization in place. The fields vary in the range and intensity of advanced specializations. However, for the most part, these advanced specializations currently occur outside of the academic settings. Typically, advanced specialization is based upon some degree of time and practice with particular areas of study and some sort of national certifying examination or process. These processes may be operated by the professional association or by private agencies.

Interprofessional Education

The international community of health professions in Canada, the United Kingdom, and Australia has established working models of interprofessional education facilitated by a national health care system that supports shared team-based competencies. Several of the US Institute of Medicine reports, including *Health Professions Education: A Bridge to Quality*, conclude that health professionals are neither adequately prepared in either academic or clinical settings to address changes in patient populations nor trained in team-based skills. In the United States, institutions that have schools of allied health or health professions are better able to implement

interprofessional sharing of core courses and learning experiences, although many logistic and professional challenges remain. The future belongs to those who can surmount these challenges and truly implement interprofessional education across health and human science professions.

Professions – Pharmacy

D E Beck, University of Florida, Gainesville, FL, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Clinical pharmacy – A health science discipline in which pharmacists provide patient care, leading to optimized medication therapy and the promotion of health, wellness, and disease prevention.

Experiential – The learning that occurs by accomplishing tasks and activities in the real-world or practice setting.

Fellowship – An organized and directed postgraduate training program that prepares an individual to become an independent researcher within a pharmacy practice specialty area.

Foreign Pharmacy Graduate Equivalency Committee (FPGEC) Certification Program – A program offered by the National Association of Boards of Pharmacy that allows foreign pharmacy graduates a mechanism for documenting that their foreign pharmacy degree is equivalent to one that is accredited by the American Council for Pharmacy Education.

Internship – A practical experience where an unlicensed individual, who is eligible for licensure as a pharmacist, works under the direct supervision of a licensed pharmacist.

Interprofessional – A reciprocal interaction and collaboration among several different health professionals who are from different health professions.

Medication therapy management – The services that are provided to a patient to optimize therapeutic outcomes and these services are either independent of or occur in conjunction with the provision of the drug product.

Patient-centered care – The direct care of the patient that involves establishing a covenantal relationship with the patient.

Pharmaceutical care – A patient-centered pharmacy practice in which the practitioner assumes responsibility for a patient's medication-related needs and is held accountable for this commitment.

Residency – An organized and directed postgraduate training program that focuses on a specific areas of pharmacy practice and the individual is under the direct supervision of a pharmacist-preceptor.

Introduction

Pharmacists have a unique role in assuring the safe use of medications. Over the years, the pharmacist's role has transitioned from a product focus, which centered on dispensing medications, to a patient-centered focus where the pharmacist shares knowledge with patients and other health professionals and, in the process, optimizes therapeutic outcomes for individual patients. Specifically, the pharmacist's role is evolving beyond dispensing the correct medication and providing counseling to responsibilities – such as providing comprehensive patient evaluations for preventing, identifying, and managing medication-related problems, collaborating with physicians in managing patients with chronic disease, and providing care that promotes health and wellness.

The change from a product focus to a patient-centered focus is still underway within the profession and the extent to which this change has occurred varies at a global level. Many countries refer to these more patient-centered care responsibilities as clinical pharmacy. Although more time is still needed for the profession to fully implement this change, it has already stimulated significant transformations in the licensure, professional code of conduct, the educational requirements, and pedagogy used in pharmacy education.

The goals of this article are to first provide an overview of pharmacy education at a global level and then provide a case study using the United States as an example to understand how changes in the pharmacist's role has impacted licensure and credentialing, the pharmacy code of conduct, progressive practice responsibilities, and pharmacy curricula. Finally, emerging issues related to the academic preparation of pharmacists are highlighted.

Pharmacy Education at a Global Level

At a global level, countries vary in the extent that this transformation has occurred among practicing pharmacists. Almost all countries require a pharmacy degree as a prerequisite for licensure and have a licensure process. Moreover, globally, a growing number of countries are placing greater emphasis on experiential learning and/or internships that prepare graduates for providing patient-centered care rather than just acquisition of knowledge related to pharmaceutical sciences. However, pharmacy

curricula and the degrees conferred greatly vary among academic institutions at a global level.

For example, in China, the entry-level degree into the profession is a 4–5-year bachelor of science (BS) degree. The focus of this degree is on pharmaceutical sciences and the traditional responsibilities of pharmacists. Most graduates are employed in research and development or as representatives for pharmaceutical manufacturers. However, in the last 10 years an increasing number of universities are offering a 5-year BS degree or a 6-year BS/MS degree in clinical pharmacy. Clinical pharmacy is growing in China and there is great demand for graduates of these programs.

In the United Kingdom, the 4-year MPharm followed by 1 year of supervised practical experience (preregistration) is required to become licensed as a pharmacist. Although not required, most programs include experiential coursework in the 4-year course of study. Most graduates enter the profession and practice in the community setting. With additional education and training, pharmacists can assume prescribing responsibilities. This role involves patient-centered care.

In Australia, a 4-year bachelor of pharmacy degree serves as entry into the profession. However, some universities now offer a graduate-entry master of pharmacy degree that requires 2 years of study and is an accelerated pathway for individuals who already have a bachelor's degree in a related discipline. Both bachelor and master degree graduates are required to complete approximately 12 months of internship which is called preregistration training. In Australia, most graduates practice in community pharmacies and hospital pharmacy departments and there is increasing emphasis on patient-centered care.

Across the Middle East, the 5-year BS pharmacy degree typically is required for entry into the profession. Jordan, Lebanon, and Saudi Arabia have moved to the doctor of pharmacy (PharmD) degree, which is typically a 6-year course of study. Advancement of practice has been slower in these countries. Hospital pharmacy typically requires a higher level of practice than that required in the community setting. Most pharmacy schools in the Middle East are revising their curriculums to include a greater focus on patient care and include more experiential education.

In Canada, a minimum of 5 years of postsecondary education is required to attain the BS in pharmacy degree. However, over the last decade there has been considerable discussion about changing the entry degree to the PharmD. Several pharmacy schools in Quebec now offer the PharmD as the entry-level degree. Most graduates in Canada work in community pharmacy settings and patient-centered care is a guiding principle for the profession. Pharmacists in Alberta have achieved prescribing privileges which requires a patient-centered focus of care.

To practice as a pharmacist in France, the *diploma d'état de Docteur* or doctor of pharmacy degree is required and it is awarded after 6 or 9 years of study. In the fifth year of this study, students complete a 1-year internship at a university hospital. During the fifth or sixth year, students specialize in both hospital and organizations pharmacy, and industrial and biomedical pharmacy; besides, they are exposed to specialized topics such as biotechnology, or medical biology (biological testing in analytical laboratories). Discussions are underway to revise these specializations so that one of them will place emphasis on clinical pharmacy.

In the United States, the entry-level degree changed from the 5-year BS pharmacy degree to the 6-year PharmD degree in 2000. For individuals who attended pharmacy school in the United States, District of Columbia, or Puerto Rico, the pharmacy degree must be from an institution that is accredited by the Accreditation Council for Pharmacy Education (ACPE). Individuals who received a pharmacy degree outside of the United States, the District of Columbia, or Puerto Rico may document their educational equivalency by completing the Foreign Pharmacy Graduate Equivalency Committee (FPGEC) Certification Program that is administered by the National Association of Boards of Pharmacy (NABP). The practice transformation and degree change have led to changes in licensure requirements, increased certification opportunities, the professional code of conduct, pharmacist's progressive responsibilities, and pharmacy curricula. The following case study highlights these points.

Case Study – United States

Licensure and Certification

To become licensed as a pharmacist in the United States, an individual must meet the multiple eligibility requirements established by the board of pharmacy in the state where the intended practice site is located. Since transition to the PharmD degree as the degree required for entry into the profession and the movement in the profession to a practice that is patient-centered, foreign graduates desiring to document educational equivalency are now required to have completed a BS degree that required at least 5 years of coursework compared to 4 years of coursework in the past.

In addition to attainment of a pharmacy degree, other licensure requirements include completion of internship hours. The type of practice activities and length of the internship vary significantly among the states.

Once individuals meet the eligibility requirements established by their board of pharmacy, they are permitted to sit for the two national examinations that are required for licensure. To become licensed in a state, individuals must successfully pass the North American Pharmacist

Licensure Examination (NAPLEX) and the Multistate Pharmacy Jurisprudence Examination (MPJE). Both of these examinations consist of multiple-choice test questions and are administered as a computer-adaptive examination. They are developed, administered, and scored by the NABP.

Once an individual satisfies all requirements for licensure within a state, the individual is eligible to practice in any setting. Most often, pharmacists in the United States practice in community, ambulatory, or hospital/institutional patient-care settings.

In the United States, certification is granted by the Board of Pharmaceutical Specialties (BPS) to pharmacists who demonstrate the abilities needed to accomplish evolving, advanced levels of practice. Individuals who attain certification typically assume positions that involve provision of patient-centered care and they also assume leadership roles in advancing practice within their setting.

Certification is not required to practice as a pharmacist. Instead, it is a voluntary process that confirms a practitioner has education, experiences, knowledge, and skills in a specific practice area that is well beyond that required for licensure. In addition to a written examination, some specialties require submission of a portfolio that documents practice knowledge and skills. There are currently five specialty practice areas recognized by BPS and others are planned to keep pace with the movement to patient-centered care. As certificates recognize evolving knowledge and skills, pharmacists who achieve BPS certification must recertify every 7 years.

Other credentials that infer advanced training beyond licensure are pharmacy residencies and fellowships. A pharmacy residency is an organized, directed postgraduate training program which focuses on a specific area of pharmacy practice. The demand for residencies has grown as the profession has moved to a patient-centered practice. Individuals complete a 1-year general residency and, if they desire additional expertise, may also complete a specialized residency that is also of 1-year duration. In all residencies, the resident is directly supervised by a qualified practitioner-preceptor. Residencies typically prepare pharmacists to implement and offer innovative pharmacy services. Pharmacy residents are also prepared to become involved in pharmacy management activities. Majority of pharmacy residencies are accredited by the American Society of Health-System Pharmacists (ASHP).

A pharmacy fellowship prepares an individual to become an independent researcher and it is a highly individualized program that is usually directed by a faculty member who is a recognized researcher. For example, a fellowship may prepare individuals for independent research in areas such as cardiology, critical care, neurology, psychiatry, or pediatrics. Individuals who enter a fellowship must also have prerequisite basic practice skills in the area of practice that is the focus of the fellowship.

Fellowships require a predetermined time period which is typically longer than 12 months.

Over the years, pharmacy fellowships have decreased in number. Increasingly, individuals who want to develop expertise in research complete a combined PharmD–PhD degree. This credential prepares them as clinical scientists for positions in academia and industry.

Professional Code of Conduct

The American Pharmaceutical Association (APhA) led the pharmacy profession in establishing the Code of Ethics in 1852. Since 1852, there have been multiple revisions with the most recent version adopted in 1994. The Code of Ethics describes the moral obligations and virtues that a pharmacist must demonstrate in order to accomplish the roles and responsibilities expected of a pharmacist. The most recent changes in the Code of Ethics align with transformation from a product- to a patient-centered practice.

The Code of Ethics provides pharmacists with guidance in establishing and maintaining relationships with patients, health professionals, and other members of society. The most recent Code conveys that the pharmacist is expected to have a covenantal relationship with a patient and promote the well-being of all patients in a confidential manner. In accomplishing this, the pharmacist is expected to be caring and compassionate while maintaining the autonomy and dignity of each patient. The Code also conveys the expectation that a pharmacist respects the values and abilities of other health professionals and also maintains interprofessional relationships with honesty and integrity. In addition, pharmacists are expected to maintain professional competence. Several sections of the Code also convey that a pharmacist must also serve community and societal needs and that sometimes it is necessary to balance the needs of patients and society.

The Oath of a Pharmacist was developed in 1994 and conveys many of the expectations outlined in the Code of Ethics. In addition, the profession has a pledge of professionalism. This pledge is frequently used in white coat ceremonies held early in a pharmacy education program to instill the conduct expected of a pharmacist. This pledge gives reference to the Oath of a Pharmacist and the Code of Ethics.

Progressive Responsibilities of the Professional

In the 1960s, a group of pharmacists were very dissatisfied with the traditional practice norms and also realized that healthcare needed pharmacists who could provide patient-centered care, such as evaluating a patient's medication regimen and individualizing medication therapy. As a result, the clinical pharmacy movement began.

In the 1970s and 1980s, the practice of clinical pharmacy grew as an increasing number of pharmacy schools offered the PharmD degree. Increasingly, this new generation of pharmacists developed innovative clinical services that included optimizing medication therapy of patients and becoming integral members of interprofessional healthcare teams. Many of these clinical pharmacists focused their practice in specialty areas such as critical care, pediatrics, internal medicine, and oncology. In institutional settings, these pharmacists led development of drug information centers, pharmacokinetic consultation services, and nutrition consultation services. Clinical pharmacy continued to evolve and is now considered to be a health science discipline.

In the 1990s, the pharmacy profession refined these responsibilities and services into a new concept of practice that embraced pharmaceutical care as a philosophy of practice. Pharmaceutical care is a patient-centered practice in which the practitioner assumes responsibility and is also accountable for a patient's medication-related needs.

By the beginning of the twenty-first century, pharmaceutical care had become an established philosophy within the profession. In addition, the academic requirements for entry into the profession in the United States changed from a baccalaureate to a doctor of pharmacy degree that included extensive preparation in the discipline of clinical pharmacy. However, the offering of patient-centered care by every pharmacist did not evolve because reimbursement for pharmacy services continued to be for the drug product and not for the provision of cognitive services.

In the early 2000s the US government initiated discussions with pharmacy leaders about the needs of the elderly population and medication therapy management (MTM) services were identified as a strategy to meet these needs. MTM includes services that are provided to a patient to optimize therapeutic outcomes and are either independent of or occur in conjunction with the provision of drug product. This strategy now provides opportunity for reimbursement of pharmacy services that include the provision of patient-centered care. The provision of MTM requires the pharmacist to exhibit pharmaceutical care as a philosophy of practice and apply knowledge and skills from the discipline of clinical pharmacy.

Increasingly, pharmacists are now providing MTM through contracts with self-insured employers, traditional insured groups, government programs, and individual payers. Not all patients require MTM services. Patients who are ideal candidates for MTM services include those who are receiving medications from multiple prescribers, taking more than four chronic medications, are not taking their prescribed medications, have high monthly medication expenses, recently been discharged from a hospital, and/or have at least one chronic disease (e.g., diabetes, asthma, or heart failure).

When providing MTM, the pharmacist conducts a medication therapy review in consultation with the patient or caregiver. Then, the pharmacist develops or updates a personal medication record for the patient. Next, the pharmacist develops a medication action plan that includes a list of medication-related issues (e.g., dosage change is indicated, another medication would be more appropriate, and adverse drug reaction), a plan for resolving each issue, and the individual responsible for action. Following development of a medication action plan, the pharmacist refers the patient to another health care provider if it is indicated. Finally, MTM services are documented in a consistent manner and a follow-up MTM visit is scheduled with the patient or caregiver if indicated.

Although community pharmacy settings were the initial setting for provision of MTM, pharmacists are now encouraged to expand and provide this service in all patient-care settings, including hospital admission, transition from the hospital to home, or admission to a long-term care facility. MTM is a new innovative practice for pharmacists and the MTM innovation is clearly in the early adopter stage and moving into the early majority stage. Although MTM is changing pharmacy practice, greater advocacy at all levels is needed to promote further growth.

In 2004, the Joint Commission of Pharmacy practitioners established a future vision of pharmacy practice statement that envisions pharmacy practice in 2015. Similar to the MTM innovation, this vision states that "pharmacists will be the health care professionals responsible for providing patient care that ensures optimal medication therapy outcomes." This statement defines:

1. the educational preparation needed by pharmacists to practice in 2015,
2. how pharmacists will practice, and
3. how pharmacy practice will benefit society.

With respect to the educational preparation needed by pharmacists, the statement emphasizes that pharmacists must be prepared to provide patient-centered and population-based care learning to optimized medication therapy. Pharmacists must also be able to manage health care system resources so they can improve therapeutic outcomes. In addition, they must be prepared to help patients promote their wellness, prevent diseases, and improve their health. Specific abilities that pharmacists must develop and maintain are:

1. patient caring;
2. an in-depth knowledge of medications and the pharmaceutical, biomedical, sociobehavioral, and clinical sciences; and
3. the ability to apply evidence-based therapeutic principles and guidelines, evolving sciences and technologies, and the legal, ethical, social, cultural, economic, and professional issues that are relevant to contemporary pharmacy practice.

Signature Pedagogy

In the United States, the PharmD degree requires a minimum of 2 years of defined preprofessional coursework and then acceptance into a pharmacy school where a professional curriculum, which is typically 4 academic years in length, is completed. A few pharmacy schools offer the professional curriculum in 3 calendar years.

The doctor of pharmacy curriculum offered by ACPE-accredited pharmacy schools enables students to achieve competencies needed to provide pharmacist-delivered patient care including MTM services. Accreditation standards further state that students must be prepared to ensure patient safety and optimal medication therapy outcomes of patients.

The professional curriculum develops in students the knowledge, skills, attitudes, and values needed to provide pharmacist-delivered care. Pharmacy schools are also required to prepare graduates so that they can identify changes that are needed in pharmacy practice and the health care delivery system and successfully implement improvements.

The ACPE accreditation standards have established professional competencies that must be achieved by graduates and these competencies align with the Joint Commission on Community Pharmacy Practice (JCCP) Vision 2015 statement for the pharmacy profession. Specifically, graduates must be able to:

1. provide patient care in cooperation with patients, prescribers, and other members of the interprofessional health care team,
2. manage and use resources of the health care system, and
3. promote health improvement, wellness, and disease prevention in collaboration with patients and other interprofessional team members.

In addition, the professional curriculum must prepare graduates to be self-directed, lifelong learners so that they can individually achieve evolving practice competencies across the span of their career. The Center for the Advancement of Pharmacy Education (CAPE) within the American Association of Colleges of Pharmacy has established a set of outcomes that enable achievement of these core competencies. These learning outcomes also encompass core competencies that the Institute of Medicine has established for the health professions.

The professional curriculum consists of didactic coursework that provides the necessary scientific and clinical foundation and experiential coursework. In the first 2.5–3 years of most professional curricula, the didactic coursework is offered along with experiential coursework called Introductory Pharmacy Practice Experiences (IPPEs). The remaining 1–1.5 years of the curriculum consist of experiential coursework which are called Advanced Pharmacy Practice Experiences (APPEs).

The didactic coursework offered in a professional curriculum must meet the criteria of good science, which infers that the coursework is evidence based, logical, convincing, explanatory, honest, testable, and systematic. This foundational coursework is drawn from the biomedical sciences, pharmaceutical sciences, social/behavioral/administrative sciences, and the clinical sciences.

The teaching and learning methods used in a curriculum must be appropriate for the stated learning outcomes. In addition, they must promote the development of critical thinking and problem-solving skills and also transition the student from a dependent to an active, self-directed, lifelong learner. During the first 1–2 years of the curriculum, the typical teaching and learning methods are lectures and large group discussions. Faculty members are expected to use active learning strategies as much as possible and encourage students to ask questions. However, during years 2–3 of the curriculum, the focus is on case-based learning and small group discussions. Other learning methods typically used in these years include guided group discussions, problem-based learning, laboratory experiences, simulations, and other practice-based exercises. Computer and instructional technologies are being increasingly used to promote the development of critical thinking and problem-solving skills. The fourth year consists of the practice experiences called APPEs.

Some pharmacy schools are using synchronous or asynchronous distance-learning technologies to deliver the curriculum across several campuses. However, outcomes that are not appropriately achieved through distance-learning technology must be taught using other teaching and learning methods.

Special Topics and Emerging Issues

Preprofessional Coursework

Some pharmacy schools are moving to requiring 3–4 years of preprofessional coursework so that the professional curriculum can focus on more advanced science coursework and students enter the professional curriculum with a higher level of maturity. However, evidence is needed to determine whether a longer preprofessional education leads to enhanced educational outcomes.

Experiential Coursework

The doctor of pharmacy degree requires an increased depth and breath of experiential learning coursework compared to the previous baccalaureate in pharmacy degree. Although this curricular change was implemented in 2000, maintaining a quality experiential program continues to be a challenge due to a shortage of preceptors and sites and other resources. To promote the development of faculty, who oversee experiential learning

programs and to promote quality experiential education, AACP has established the Academic-Practice Partnership Initiative. In addition, AACP and the American Society of Health-System Pharmacists collaborated on a study to assess the current status and future capacity of hospitals and health systems as experiential learning sites. The findings of this study call for the following:

1. standardization and coordination of experiential programs among pharmacy schools,
2. better preparation of practitioner preceptors to be effective teachers, and
3. establishment of partnerships that provide mutual value to the sites and pharmacy schools.

Professionalism

Transition of the pharmacy profession from a product-centered to a patient-centered practice and the economic issues related to healthcare and drug therapy have prompted pharmacy educators to give more attention to ethics and professionalism. To promote pharmacy student professionalism, a task force that involved the collaboration of the American Pharmaceutical Association of Students of Pharmacy (APhA-ASP) and the American Association of Colleges of Pharmacy Council of Deans (AACP-COD) published a white paper and cited research that the professional socialization of students is often inconsistent and this hinders their professional growth. The task force also provided recommendations related to recruitment, admissions, educational programs, and practice experiences. It also emphasized the important role played by practicing pharmacists in the professional socialization of students. In addition, other approaches that address the cognitive–moral development of students have been advocated.

Outcomes Assessment

Although pharmacy schools have created positions so that individuals can lead outcomes assessment and some schools have developed innovative models, most schools are struggling to meet the outcomes requirements for accreditation. With respect to measurement of learning outcomes, pharmacy schools currently have data from graduate performance on the licensure examination and data measuring student and graduation perceptions. However, pharmacy schools need assessment tools that will more effectively measure achievement of the core competencies.

Residencies as a Requirement for Practice

Some in pharmacy practice and pharmacy education believe that a 1-year residency should be required following graduation from a doctor of pharmacy program so that not only graduates are more fully prepared to provide

direct patient care but also the profession can achieve the Vision 2015 statement. However, others believe that a residency requirement should not be used to address needs such as a higher quality experiential curriculum and enhanced assessment of student performance. One challenge is that there are an insufficient number of residency sites to place all doctor of pharmacy graduates.

Curricular Delivery Methods

Technology continues to rapidly expand opportunities for improving learning and assessment. Pharmacy schools are now using a variety of synchronous and asynchronous technologies to deliver instruction across several campuses. Some pharmacy schools are now exploring how to enhance problem-solving skills and critical thinking through use of simulations and virtual learning. Research is needed to evaluate the effectiveness of these new delivery methods.

Teaching for the Complex Practice of Nursing

Glossary

Clinical reasoning and skilled know-how – One of three professional apprenticeships required for a practice discipline. Clinical reasoning and skilled know-how are enacted in clinical situations. All of clinical reasoning is an example of practical reasoning and a broader form of rationality compared to a narrow technical rationality in professional education as illustrated by such strategies such as trying to apply theory to practice with little or no interpretation or translation. Rational calculation is a formal and narrow approach to practical situations and is as illustrated by strategies such as cost–benefit analysis; formal standardized plans such as critical pathways; decision analysis; and formal criterial or snap shot reasoning, as used in scientific experiments.

Ethical comportment – The everyday ethical practice within a practice discipline. It includes actions, communication, respect, and fulfillment of the notions of good internal to the practice discipline.

Integration and integrative teaching – Teaching can be integrative in multiple ways but we focus on integrating the three professional apprenticeships, and integrating classroom and clinical teaching and learning. However, teaching for a sense of salience and understanding the nature of a particular clinical situation are also integrative, as is articulating and reflecting on experiential learning and situated coaching.

Situated cognition – The ability of a practitioner to stand inside a situation and reason about recent trends and trajectories in the patient and the situation. Clinicians take into consideration the context of the situation and take into consideration changing relevance over time.

Three professional apprenticeships of professional education – (1) The cognitive apprenticeship includes learning to think like a professional practitioner, and includes learning all the requisite science and theoretical knowledge in order to practice well in a professional discipline; (2) the skilled know-how and clinical reasoning apprenticeship is required to use knowledge in

practice and this includes situated cognition in particular unstructured practice situations; and (3) the ethical comportment and formation apprenticeship includes learning well, the first two apprenticeships, and enacting or instantiating the notions of good within the practice discipline.

Introduction

As do other professionals, nurses learn to use practical reasoning through experiential learning. They must learn clinical reasoning across time through transitions in the patient's clinical condition or concerns and/or through transitions in the clinician's understanding of the situation. Modern medicine depends upon the nurse's monitoring the patient's condition and adjusting therapies to the patient's physiological responses across time. This calls for situated teaching and learning across time, and the ability to recognize relevant changes in the patient's physiological responses.

As a practice discipline nursing education requires teaching and learning in three domains, or apprenticeships. One apprenticeship requires teaching and learning the knowledge base for nursing or how to think like a nurse. In another apprenticeship, nursing students learn skilled know-how and clinical reasoning that they will use in practical situations. In still another apprenticeship, students learn ethical comportment in the particular practice discipline. It is in this last apprenticeship that students undergo formation, or where they learn to see as and act in the capacity of, to be a practitioner in their profession. These apprenticeships are best taught as an integrated whole; once they are separated, students find it difficult to bring them back together. For example, teachers with their doctoral training in physiology may accept their domain-specific assumption of the discipline of physiology that pathophysiology should always be taught separately from normal physiology, but for nursing students, a focus on both in the same course might be more advantageous because nurses must recognize deviations from the normal and how to support normal physiology. While separating the two is probably useful

for teaching physiologists, it is not necessarily true for nursing where using physiological knowledge in actual situations is crucial.

Learning and performance requirements must be established for each discipline, as well as the best ways of integrating teaching in and out of classrooms and all three professional apprenticeships described above.

Nursing stands out in professional-educational programs because it has multiple educational pathways to practice. Nurses may enter through 2–3-year diploma programs, though there are only about 80 of these programs in existence in the US. They may also enter through community college programs where they must take at least 1 year of prerequisites for the nursing program and then at least 2 years of nursing. Due to oversubscription that requires waiting to get space in these programs, a community college education in nursing takes a minimum of 3 years and often as much as 5 years. The profession's preferred programs are the generic baccalaureate programs, and the second baccalaureate degree programs or the master's entry program for students with a baccalaureate degree from another field. All prelicensure student nurses are required to take the National Council Licensure Examination-Registered Nurse (NCLEX-RN) licensing exam. There is an increasing shortage and demand for nurses with a master's degree for advanced practice, and a doctoral degree for teaching. Nursing also has doctorate in nursing practice, which is an advanced doctoral degree that focuses on nursing practices. However, this article focuses on the education for the initial preparation as a nurse.

Domain and Practice-Specific Teaching and Learning: Nursing

Recent scholarship in nursing education has highlighted domain-specific teaching and the need to better understand the discipline's commonly used pedagogies. Nursing relies heavily on situated instruction and coaching in actual clinical practice situations. As the basis for instruction, faculty use situations students encounter, helping them interpret in new ways what they experience and act in new ways. They also rely on formative education where the clinician's perceptual and thinking capacities as well as skilled know-how are transformed by the demands and notions of good in the practice. Notions of good in the practice for nursing are the goals and aspirations generally agreed upon by nurses and include an ethos that emphasizes advocating for patients and their families. Nursing's signature pedagogy is coaching for situated understanding and action. As do clergy, nurses must develop their clinical imagination because they enter into unstructured, open-ended situations that require them to understand the situation and take action.

Formation in nursing requires practitioners to adopt role expectations as well as learn skilled know-how, new perceptual capacities, and situated thinking in action. The practicing professional literally sees new possibilities and concerns in practical situations in ways that never solicited their attention or action before. A nurse develops over time through experiential learning his perceptive ability to notice when things are not quite right or are not going according to usual expectations. A nurse develops also a sense of salience about what things in a situation must be addressed now and what can wait. This sense of salience in underdetermined practical situations is also experientially learned over time, and depends upon the teacher helping the student grasp and define the nature of clinical situations through coaching in the early phases of learning, and questioning during more advanced stages of learning. More advanced students have enough experiential learning to develop a beginning sense of salience and recognize recurring signs and symptoms and common meanings and concerns in practical situations. In learning, a practice the practitioner is formed to enact skilled know-how and their ethical comportment based upon their understanding of the situations and its demands for action. This, like all experiential learning, requires domain- and practice-specific teaching and learning.

Students learn the practice of nursing in the three apprenticeships of knowledge, clinical reasoning, and formation. They require the following:

1. Students must learn a sense of salience, situated cognition, and action in particular clinical situations.
2. Students must learn to use clinical reasoning and to think in multiple ways that include critical thinking.
3. Students must integrate what is presented in many different settings, including classroom, clinical, and skills or simulation laboratories.
4. Students must learn everyday ethical comportment through professional formation.

Teaching for a Sense of Salience, Situated Cognition, and Action

Nurse educators and students tend to valorize a narrow form of reasoning, where they try to teach students to stand outside of a given situation to take a snapshot view of a situation. However, nurses work in complex relatively unstructured clinical situations where they must learn to quickly recognize and assess what are most and less important in particular clinical situations. Students need to develop a sense of salience about what is relatively important and unimportant in any particular clinical situation. The heart of practical reasoning is understanding the nature of the situation. Faculty must help students to

recognize what is most urgent, most important, and less urgent in particular practice situations that are under-determined and change over time. Practitioners must first grasp the nature of the situation before they can act intelligently and prudently. For the first-year nursing student (the novice), the instructor must coach him to recognize what must be addressed during his care of a particular patient/family. The nurse educator must teach and coach students to develop their own situation-recognition capacities. It is not possible in actual complex practice situations for the student to build up a holistic grasp of the situation element by element. The most reduction and simplification that can be arranged for the student nurse is for the instructor to assign patients who are not in crisis, and who require relatively straightforward and simple interventions. Continued situated coaching is required in order for the student to grasp the changing relevance, and demands, resources, and constraints in particular situations. Eraut has called this a productive form of knowledge use and Lave and Wenger called it situated cognition.

In their classroom teaching, teachers often use models of how students should think about problems, such as models of critical thinking. They describe these as frameworks of thinking, such as decontextualized and mentalistic representations of critical thinking or the nursing problem-solving process. A framework of thinking though is not the same as thinking. This problem is not unique to nursing in academia. The critical-thinking agenda in college seeks to help students disengage from context bound, concrete knowledge to what is considered a higher form of knowledge that is made explicit, formal, operational, and more abstract and general. In doing so, educational programs may overlook tacit and embodied knowledge that is part of skillful judgment.

We advocate a robust respect for practical reasoning and approaches that teach students the habits of thought they need to exercise situated clinical judgments. Astute, engaged practical clinical reasoning requires well-educated graduates who take up a broader view of rationality, one that takes into account the particulars of a situation and values reasoning through transitions across time.

Teaching Clinical Reasoning and Thinking in Multiple Ways

Most academic settings emphasize the importance of critical thinking; however, in professional practices, critical thinking is bounded by practical reasoning and performance is based upon the best-available scientific evidence in the case of nursing. Critical thinking is best reserved for situations where the practitioner needs to reflect upon a received tradition or practice that is no longer relevant, or needs to be improved. It is also needed in situations of

extreme breakdown in understanding and actions, so that deliberative engaged reasoning no longer makes sense. Critical thinking is an essential, but not a sufficient thinking strategy for the practicing professional. Practitioners also need to be able to imagine future eventualities and to perform according to the best evidence available in under-determined open-ended situations.

Currently, critical thinking has become a catch-all phrase for all forms of thinking required in nursing practice. But this use of critical thinking is actually a misnomer that needs clarification so that nurse educators focus on multiple ways of thinking, with a much greater emphasis on clinical reasoning.

Thinking like a nurse requires clinical reasoning as well as critical, creative, scientific, and formal critical reasoning. Cynicism and excessive doubt, often the byproduct of overuse of reflective critical thinking, will not help the professional nurse or physician draw on appropriate knowledge and act in particular situations. Nor does critical thinking alone develop students' perceptual acuity or clinical imagination about using science, skilled know-how, and practical knowledge in particular situations. Clinical imagination is required for students to grasp the nature of patients' needs as they change over time. Likewise, narrative understanding and interpretation of clinical situations help to enrich the student's clinical imagination and reasoning about changes in the patient's condition over time. The need for teaching critical reflection, analysis, and thinking are essential to any education; however, they are best taught when teachers and students understand their goals and functions in relation to practice.

Integrative Teaching

Most schools of nursing radically separate classroom and clinical teaching. It is as if teachers assume that students acquire knowledge in the classroom and apply it to clinical practice, rather than draw on appropriate knowledge and interpret it for a given situation. A formal separation of clinical and classroom teaching makes learning unwieldy and uncoordinated. To make matters worse, many teachers present information about nursing theory, physiology, disease categories, signs, symptoms, interventions, and outcomes as layered taxonomies to be memorized. They try to force too much information into their lectures and often worry that they present is at too superficial a level. Many teachers presented theories and clinical knowledge as taxonomic naming systems are the most abstract and difficult for students to imagine how to use the knowledge in caring for patients. Few students can imagine how the classification systems can be used in their actual direct patient care. No one abstract theory can be directly applied, except the most technical physiological theories such as measuring blood gasses, or circulatory pressures and dynamics.

Ubiquitous is the use of elemental competencies, by which we mean when teachers expect students to perform, demonstrate, or present a given skill that is stripped of clinical context. The most common example of this approach occurs in skills laboratories. For example, it is useful to teach first-year nursing students how to take vital signs outside of a clinical situation. But the pedagogy of teaching from simple stripped-down examples to use in complex situations poses inherent limitations in any practice discipline. In order for a student to make a clinical assessment about, for example, a hypertensive patient in labor and delivery, the student very quickly needs to move on to interpreting information from the patient's vital signs and taking account of the particulars in the situation. Students must integrate what they learn from different settings – clinical, skills or simulation laboratory, and classroom – as a seamless whole.

Professional Formation

Nursing education engages theories about socialization, roles and role taking, role making, and role performance. While such ideas are useful in any practice discipline that must coordinate and link role functions with other disciplines and team members, we suggest a more robust view of changes in identity and self-understanding of the practitioner. Formation of student nurses occurs within their skilled practices and highly relational work that literally transform their ways of perceiving and acting in situations.

Many nursing students describe profound changes in their sense of identity and how the experience of skilled practice and highly relational work transforms the way they perceive and act. Students often identify particular learning experiences as affecting their capacity to act in future similar situations, increasing their self-knowledge and understanding, or reassuring them of their chosen profession. Student nurses talk readily about the interpersonal challenges they face in nursing.

Nursing students learn the skills of involvement – or the skills they will need to be involved with patients in appropriate and therapeutic ways – in particular assignments, usually in situations where patient well-being is at stake. Even before the student begins to develop the professional identity of nurse, he may find that the patient and family treat him as a nurse and automatically expect him to respond like a nurse. The following account from our own work illustrates how one student talked about learning nursing as a practice in this way:

Jennifer Student Nurse: I had this experience on our first day in the Mother/Baby, Labor and Delivery course. My professor said, 'Okay, *Jennifer*, you're going to have two couplets today. You're going to have four patients,' and,

back then, that was a big deal. So I was running around, head down. I did the assessments and I was really getting nervous because it was getting late and I still hadn't assessed the last baby yet. So I walked into the nursery and there was a nurse there who said: 'Oh, don't worry about that baby. I just assessed her and everything's fine.' And I remember standing there thinking, 'oh, good.' But then I said, 'I can't do that,' you know, 'I can't do that,' *and you can't do that*. . . . I opened up the blanket and looked in and sure enough, the baby was tachycardic, flaccid, and cold. That's the day I realized the awesome responsibility to do our job because that baby was then placed in the incubator and Intensive Care and was there for at least a week. And I'm thinking how many hours would it have been 'til somebody had actually, you know, discovered the baby's condition— Had I just listened to the staff nurse, as a student, and said 'okay, well the RN said she assessed the baby now, and she had documented her assessment.' But just because it was my patient assignment, as a student, I still had to go and do it [the assessment]. It was a good feeling to realize hey, I really can actually assess an infant and find something wrong. And I think that's the day I realized that you never—, you are responsible. I don't care if somebody else has that assignment. If you have anything to do with that patient you're responsible. . . . It was a day I realized that *even that early on* you're very important. . . . I still remember that day. So every day I go in to do assessment I think, nope, I'm doing everything. I don't care, head to toe, you know. We're not skipping over anything. So that was an important day. . . . They give you the tools and you really just have to go in there and do it and even though there are time constraints and there are always time constraints as a student, you know, it's worth getting in trouble for being behind rather than to put your patients' care in jeopardy. So that was an important lesson.

Jennifer's emphasis and tone of voice in telling the story point to the significance it holds for her as a student. One might imagine an expert nurse dismissing the incident in one sentence by invoking a rule about the necessity of frequently checking the infant's condition herself. The tone and emphasis of the seasoned nurse's voice would likely reflect the solidity of a well-formed practice assumption.

The clinical experiential learning Jennifer describes is formative for her. She locates the dawning of a new awareness and new agency within her choices and actions involving a particular infant, complete with all the attendant pressures and contingencies. No nursing faculty member intentionally plans such a risky learning experience. Even so, similar situations will likely repeat in different settings and with different patients in most students' clinical experience. Jennifer is awed by the infant's fragility and dependence on her vigilance and skill, and by the

responsibility this carries. She does not feel prepared to handle the situation, but she is pleased to find that she can do the right thing and make a significant contribution to an infant's life. In this situation, in response to what is demanded of a nurse, Jennifer moves from acting like a nurse to being a responsible nurse.

Jennifer identifies this experience as pivotal for her. It forms part of her habitus, in that it creates a way to act, a way of being in the world, and a new set of perceptual capacities associated with ways to respond both to the routines a nurse is expected to enact (always assess your own patients) and to unexpected clinical concerns (finding the baby flaccid and cold). The stakes are high. The infant's life is in her hands. Although the staff nurse may have been correct in her earlier assessment of the infant, infants can change rapidly. The import of the event is that Jennifer has learned, first hand, that she must take responsibility for her patients, and that she now knows that she can notice significant life-saving changes in an infant.

This experiential learning in the clinical setting integrates all three professional apprenticeships for Jennifer. In the course of her narrative, the student illustrates how she draws on her learning in the first and second apprenticeships. She notes the baby was tachycardic – knowledge gained from physiology – and flaccid – a clinical judgment learned in the physical-assessment skills laboratory. She also grasps immediately that it was imperative to act quickly, with her focus being on doing all that she could for the baby, thus illustrating her ethical comportment in the situation. Many such experiences shape the character and skill formation of a nurse over time.

Like Jennifer, many other students' narratives depicted their sense of responsibility being formed by confronting challenges where their own actions impacted the patient's survival.

Transformation and formation terms that borrowed from Carnegie's study of clergy education address the development of the senses, esthetics, perceptual acuities, relational skills, knowledge, and dispositions that takes place as student nurses form professional identity. A shift to a student-focused sense of transformation and reflection on formative experiences in nursing school enriches the student's sense of identity and self-understanding as a nurse.

Veterinary Education

K M Edmondson, Cornell University, Ithaca, NY, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Theriogenology – The branch of veterinary medicine concerned with the physiology and pathology of reproduction in animals, and with the clinical practice of obstetrics and gynecology.

Xenotransplantation – The transplantation of living cells, tissues, or organs from one species to another, such as from pigs to humans.

Introduction and Context

Veterinary medicine is the medical profession at the interface between animals and people. Although a majority of veterinarians provide medical care for pets and food animals, professional activities of veterinarians also include preventing the transmission of zoonotic diseases from animals to humans, wildlife preservation and conservation, and public health. The broad, comparative training veterinarians receive in the biological sciences prepares them to care for a wide range of animal species, and uniquely positions them to serve as valuable team members in the promotion of human health and protection of the food supply.

Within the global community, public awareness of the interrelatedness of animal and human health is increasing, as illustrated by emerging programs, such as the One Health Initiative, which recognize the synergy and potential benefits of promoting collaboration among physicians, veterinarians, and other scientific health professionals to develop global strategies to advance healthcare. Changing trends in pet ownership, the increasing value placed upon the bond between humans and animals, and the role of that bond in promoting human health, including mental health and well being, are also significant.

Veterinary medicine as a profession is in a state of transition. Not only has a significant gender shift occurred, but there is a trend toward increased specialization as well. According to the American Veterinary Medical Association (AVMA), 75% of today's veterinary students are female (in contrast to 55% in 1988), and more than one-third of all veterinary graduates seek advanced training in a wide range of specialty areas (more than twice the number seeking additional training in 1988). Consequently, faculty at veterinary colleges must consider how

to balance the need to train generalists with more specialized knowledge, and how to best prepare future professionals for an ever-changing world. As scientific knowledge increases, and the important roles veterinarians play in service to society become more visible, the expectations of new veterinary graduates also expand. The high costs associated with veterinary education, combined with significant student debt, heighten the challenges veterinary colleges face. This article presents the current status of veterinary education, discusses inherent themes that are common among veterinary colleges, and outlines future challenges.

Requirements, Accreditation, and Licensure

In the United States, a typical veterinary curriculum is 4 years in length and leads to the degree of doctor of veterinary medicine, or DVM. In the United Kingdom, Europe, and Australasia, students enter veterinary college following secondary school. Programs of study are usually 5 years in length, and lead to the degree of bachelor of veterinary science (BVSc).

Students in the United States and Canada have typically completed a baccalaureate degree prior to entering veterinary school. Some have completed advanced degrees. The academic requirements that applicants must fulfill are very similar to those required by schools of allopathic medicine or dentistry. In addition to substantial prerequisite coursework in the biological sciences and scores from standardized tests, prospective students are required to provide evidence of veterinary-related (and animal) experience, submit a statement of intent, and provide information related to their other activities and interests.

The number of colleges of veterinary medicine is relatively small (28 in the United States and five in Canada), and the average number of students per class is just under 100. Veterinary curricula follow the traditional Flexner model of medical education, with emphasis on basic science disciplines in the first 2 years, followed by instruction in clinical disciplines in the second half of the curriculum, including a year of practical clinical training. The majority of preclinical instruction is didactic, with supporting laboratory exercises. Clinical instruction follows the apprenticeship model of education: usually within the context of a teaching hospital, students rotate through a series of clinical services, supervised by clinicians, and are directly involved in medical case management. Preclinical disciplines common to veterinary

curricula include gross anatomy, histology, molecular genetics, physiology, pathology, microbiology, bacteriology, virology, parasitology, epidemiology, pharmacology, and embryology. Clinical disciplines include medicine and surgery, anesthesiology, imaging, population medicine, behavior, nutrition, and other specialty areas such as oncology, ophthalmology, neurology, cardiology, toxicology, dentistry, laboratory animal medicine, theriogenology, emergency and critical care medicine, and exotic animal medicine. Most schools in the US educate generalist veterinarians, but some allow students to focus on particular species.

Veterinary students, therefore, are expected to master a significant amount of material that includes a strong foundation of basic science and clinical knowledge, clinical skills, and professional behaviors. Their knowledge and skills are assessed through a range of approaches that include traditional written examinations (with essay, short answer, or multiple-choice questions), oral and practical exams, demonstrations, and, occasionally, student presentations. As there is no requirement for additional training, new veterinary graduates can be licensed to practice medicine following graduation. Skills labs are incorporated into the educational program with the expectation that students will become competent in performing many standardized procedures prior to graduation. Those who wish to pursue additional training may choose internships and/or residency training in one of the disciplines listed above. Internships are usually 1 year in length. Residency training lasts 2–3 years, and qualifies the individual to sit for a Board Certification examination in that discipline.

Since 1953, the Council on Education (COE) of the American Veterinary Medical Association has been the accrediting body for veterinary colleges in the United States and Canada. Although the COE makes all accreditation decisions, it is accountable through the AVMA to a governmental regulating body (the US Department of Education) and to a nongovernmental agency (the Commission for Higher Education Accreditation). In recent years, several veterinary colleges from other countries have sought and received accreditation from the AVMA. Currently, in addition to those in the United States and Canada, there are AVMA-accredited colleges of veterinary medicine in the United Kingdom, Australia and New Zealand, and in the Netherlands. To receive accreditation from the AVMA, each college must satisfy standards in 11 areas, and demonstrate the ability to provide students with the necessary resources for success within a high-quality program that meets the designated standards.

Once accredited, colleges receive full reviews every 7 years. Veterinary colleges in the United Kingdom are accredited by the Royal College of Veterinary Surgeons (RCVS), which conducts periodic visits every 7–10 years.

Other countries have their own systems for accrediting veterinary colleges. Those that are members of the European Union (EU) have considered a move toward

consistency or uniformity of their standards and curricula. The European Association of Establishments for Veterinary Education (EAEVE) and the Advisory Committee on Veterinary Training (ACVT) have developed a system for evaluating veterinary schools that applies to institutions within the EU. Beyond this, and based in part upon an effort to facilitate the globalization of animal disease control, a number of schools are supportive of recent initiatives to increase compatibility among veterinary education programs in different parts of the world. This is a complex undertaking, however, and is complicated by differences in organization, governance, financial structure, curricula, and overall costs.

A license to practice veterinary medicine signifies that the holder is competent to treat all animal species. For graduates of AVMA-accredited institutions, the North American Veterinary Licensing Exam, NAVLE, is required for licensure in all of the licensing jurisdictions in North America. In addition, some states require a State Board Examination. To maintain certification, some states require practicing veterinarians to participate in continuing education activities, while others do not. Graduates of non-accredited schools can seek licenses in the United States through two certification programs: the Educational Commission for Foreign Veterinary Graduates (ECFVG) which is operated by the AVMA, and the Program for the Assessment of Veterinary Education Equivalence (PAVE), which is operated by the American Association of Veterinary State Boards. Canada has its own certification requirements for graduates of international veterinary colleges, administered through the National Examining Board.

New veterinary graduates are expected to function independently, and to possess a level of competence in a wide range of clinical domains. They are expected to demonstrate attributes such as ethical behavior, compassion, respect, honesty, and responsibility, as well as knowledge of animal disease and wellness, diagnosis, management and treatment, and business practice. They are also expected to reason deductively, exhibit problem-solving skills, communicate effectively with others, and perform core clinical procedures (including standard surgical procedures). Graduates should have a continual thirst for new knowledge, the ability to critically examine new knowledge, and the ability to recognize the limits of their knowledge and skill.

Throughout their careers, veterinarians must adhere to a code of professional ethics. For veterinarians who belong to the AVMA, these are outlined in the Principles of Veterinary Medical Ethics. Local and state veterinary associations and licensing boards have additional rules governing professional conduct. The principles lay out expectations in the following categories: professional behavior; the relationship between the veterinarian, client, and patient; attending, consulting, and referring; influences on judgment; therapies; genetic defects; medical records; fees and remuneration; advertising; and euthanasia. The Veterinarian's Oath

comprises these elements, and includes additional language related to conservation of animal resources, promotion of public health, and the advancement of medical knowledge. In general, veterinarians are expected to relieve disease, suffering, or disability, minimize pain and fear, and to be honest, law abiding, and fair. Veterinarians should not engage in fraud, misrepresentation or deceit, and they should strive to enhance their image with respect to the public. They must be committed to improving their veterinary knowledge and skills, and be courteous, considerate, and compassionate.

Impetus for Change in Veterinary Education

In the past two decades, three major reports published within the veterinary profession contained recommendations for veterinary education. The earliest report, part of a national trend of curriculum reform efforts in medical education, was the Pew Report published in 1989 calling for sweeping changes for veterinary schools that redirected the emphasis on accumulating factual information toward a focus on how to find and use information, solve problems, and acquire essential skills and behaviors. It encouraged colleges of veterinary medicine to identify mechanisms for increasing students' responsibility for their education, for strengthening curriculum content in the basic biological sciences, and for providing students with the opportunity for in-depth clinical instruction. To better meet the needs of the public with regard to food safety and public health, the Pew Report also called for the inclusion of additional curriculum content. It encouraged veterinary colleges to make research activities a higher priority, and to place more emphasis on post-DVM education programs. Colleges of veterinary medicine were also directed to decrease enrollments, and to focus their programs on a smaller number of specialty areas, creating centers of excellence. The Report projected changes in the organization of veterinary education, particularly as it related to clinical experiences, and predicted that veterinary practitioners would contribute more to educational programs, and to the direct instruction of veterinary students.

In response, many veterinary colleges in the United States and Canada engaged in processes of curriculum review, and implemented a number of the Pew recommendations in the 1990s. Some schools experimented with and implemented different approaches to teaching. Following the lead of many medical schools, several veterinary colleges considered problem-based learning as an instructional approach. In an attempt to better integrate the basic science and clinical disciplines, to foster the development of clinical problem-solving skills, and to engage students in the learning process, many schools incorporated some aspects of this approach into existing

courses, or made structural changes to their curriculum to include parallel or capstone problem-based courses. A small number of schools implemented entirely new curricula that used problem-based learning as the predominant instructional approach in the preclinical years. Still others restructured their curricula and incorporated other forms of small group learning.

A common form of educational innovation among many schools was an increased reliance on various forms of computer-assisted instruction. Schools developed a wide range of educational resources during this period that supplemented or replaced material that had previously been taught didactically, and reduced the number of live animals there were used for teaching. Some schools developed tracking curricula that allowed students to focus on particular species or aspects of professional practice. Others changed approaches to clinical instruction to involve practitioners in innovative ways.

Ten years after the Pew Report, the influential KPMG Study was published and focused primarily on the future job market for veterinarians and veterinary services. Contrary to the Pew Report, the KPMG Study projected a shortage of veterinarians in some areas, calling for colleges of veterinary medicine to expand curricular offerings relative to the professional knowledge, skills, and behaviors that contribute to economic success in veterinary practice. These included communication skills, technical skills, information related to business and practice management, critical thinking, and lifelong learning skills. While primarily focused on the veterinary profession and not on education (only one of the six critical issues identified in the report related to education), the implications of this report for veterinary colleges were clear, and it served as the impetus for additional curricular changes.

In the time that has elapsed since the publication of the KPMG Study in 1999, a number of veterinary colleges in the United States, Canada, and around the world have taken significant steps to develop courses and curriculum materials focusing on client relationships and communication skills. In many instances, these initiatives have also led to a new consideration of clinical competency and outcomes assessment.

The third and most recent major report to impact veterinary education is the Foresight Report, published in 2007. The goal of the report was to determine a vision for the future of academic veterinary medicine, and to provide a basis for strategic planning and curriculum development. The Report contained a series of recommendations that included acceptance of the ideas that veterinary licensure in the future would be limited to selected focus areas, that colleges of veterinary medicine should collaborate, and that they should identify areas of focus or program emphasis. These recommendations were based upon the notion that the needs of society were increasing, and that veterinary colleges could only respond

to the changing needs of society through expansion. By encouraging colleges to work together, the recommendation to create centers of emphasis would allow veterinary medical education at large to respond, without requiring each college to expand its programs. With this, veterinary colleges were also asked to increase enrollments, so that the profession would be better able to respond to new demands and roles. In turn, accreditation standards would be modified, and limited to the requirements to teach a core program plus the areas of professional focus offered by an individual college.

The Report also encouraged colleges to capitalize on emerging technology to provide distance education and web-based instruction, and to develop opportunities for virtual training through the use of simulators. These would be used to train students, and for continuing education programs for practicing veterinarians wishing to further develop their skills, or to retrain for other areas within the profession. The Report also directed veterinary colleges to address the problem of student debt, particularly in segments of the profession or regions of the country that have the greatest need for veterinary care.

The Foresight Report generated lively discussion among veterinary educators, and the impact of its recommendations has not yet been fully realized. However, a key point in the Report focused on a national strategic plan for veterinary education that would be uniformly implemented, and it outlined possible models. Whether or not this is achievable in the coming decades remains to be seen.

Themes in Veterinary Education

Within the broad framework described above, a number of themes span veterinary education as a whole, and are also common to other professions. Perhaps the most familiar themes are the tension between breadth and depth, the need to integrate theoretical knowledge with practice, and finding ways to help students become comfortable with ambiguity in solving novel, ill-structured problems. All of these contribute to the development of professional expertise, and present challenges for teaching and learning. Many veterinary educators recognize the importance of integrating theory with practice, but few curricular alternatives have been offered for improving upon (or moving beyond) the apprenticeship model of educating. Educators have long incorporated various forms of real-world experience in their teaching to present new information, underscore the practical application of curricular material, and to enhance and extend student learning. For students at the university level, apprenticeships, field experiences, internships, and practicum experiences represent examples of the types of practical experiences many encounter as extensions (or even requirements) of their

formal education. However, the Flexner model for medical education (formal theoretical training followed by a period of supervised practical application) dominates veterinary education, at the expense of alternatives that may be effective for achieving these goals.

The research on meaningful learning supports a view of the development of expertise in veterinary medicine that helps students make meaningful and progressively elaborate connections between the knowledge they gain in a classroom and that acquired through field and clinical experience. The need to develop elaborate, valid propositional knowledge structures that provide a scaffold for subsequent knowledge gained through experience is consistent with research on learning in other domains, and with the Flexner model for medical education: acquisition of basic concepts, followed by practical application. While the characteristics of novices and experts (and their respective abilities) are now more clearly understood, models of medical expertise have lacked an account of the processes by which novices become experts. However, three factors are key:

1. the information to be learned must be appropriately structured,
2. the learning context must be clearly established, and
3. the learner needs to be actively engaged in the learning process.

The structure of most veterinary curricula inhibits, rather than facilitates, meaningful learning and the integration of theoretical with practical knowledge. The disciplinary boundaries imposed in most traditional curricular structures encourage students to compartmentalize their learning, and most traditional examination formats focus on the retention of factual information rather than on more complex cognitive processes. This problem is exacerbated by exhaustive content coverage, and the need for veterinary curricula to address comparative aspects of many topics, such as important species differences. Increased specialization in the clinical domain has also led to the addition of significant amounts of content, which are now identified as core and required of all students. Topics such as oncology, dentistry, and emergency and critical care medicine are relatively new additions to the veterinary professional curriculum, and require time within course syllabi that are already very full. As mentioned previously, the number of veterinary graduates who are electing to pursue additional postgraduate training through internships and residencies is also increasing. A shift away from the education of generalist veterinarians toward a more specialized model could provide increased flexibility in curricular structure that would also bring important benefits to student learning.

Another theme in veterinary education, which is common to medical educators, is the development and assessment of clinical competency. New accreditation

standards relating to the assessment of clinical competence have increased accountability for the acquisition of a broad range of skills, and in recent years, veterinary colleges have implemented initiatives to document the development of students' technical skills. The focus on clinical competency (which in its extreme form might be interpreted as promoting the view of veterinarian as technician) is in tension with the view of the veterinarian as scientist, and raises questions within the colleges about the appropriate balance between theoretical and practical knowledge. To meet accreditation requirements and continue to deliver curricula of sufficient breadth and depth that are sustainable over time, colleges must find ways to incorporate the assessment of multiple attributes (knowledge, skills, and behaviors) within existing courses and frameworks.

A common solution to a too-full curriculum is to shift the need for certain information or content downstream, by increasing program prerequisites. While this strategy can provide some relief in the short term, it could negatively impact admissions by increasing the requirements applicants are asked to fulfill. While the prerequisite courses required of applicants to veterinary colleges are not uniform, there are a number of requirements that are common. Large numbers of required courses, or variation among admissions requirements, can create undue impediments or obstacles for prospective students interested in preparing for a career in veterinary medicine. Moreover, for any profession seeking to attract the greatest number of applicants with diverse backgrounds, this is an important issue that must be considered.

Similar to medical education, there is an emphasis on the need to ensure diversity within the student body and, ultimately, the profession. Certainly, in order for the profession to more closely resemble the society it serves, the number of underrepresented minorities who pursue a veterinary career must increase. Diversity is important not only in terms of an individual's ethnic or cultural diversity, but also in terms of her or his area of interest within the profession. The profession needs applicants who are also interested in research, in rural practice, in food supply veterinary medicine, and in public health. The gender shift that has occurred in the past 30 years also has implications for the profession, related to the declining number of male applicants. The decline of any group of applicants is troubling, and is at least partially attributed to the salary levels of new veterinary graduates and student indebtedness. Financial considerations create additional challenges for attracting a large, diverse, and talented group of prospective students.

Another important theme in veterinary education is the use of animals in teaching. Animals are an essential component of veterinary education, but associated costs, availability of healthy animals and of cadavers, concerns for animal welfare, and the availability of technological

alternatives, such as models and simulators, can impact the number and type of experiences offered. Even for noninvasive procedures, such as animal handling and restraint, the availability of animals for teaching can be an issue. In addition, as veterinary medical teaching hospitals provide increasing levels of tertiary care, students' exposure to routine cases that are typical of primary care practice is becoming limited. Animal patients in veterinary teaching hospitals are seriously ill, and students are often relegated to the role of observer. Creative solutions, such as spay/neuter programs between animal shelters and veterinary colleges, can help address societal problems such as pet overpopulation, while improving a shelter animal's chances of being adopted and providing opportunities for students to develop important skills. However, programs such as this will not meet all needs, including the need for case material in certain subject areas.

Many of the veterinary schools in the United Kingdom and Europe have made strides in the use of synthetic models, providing cost-effective opportunities for students to learn important skills. Other schools have forged partnerships with veterinary practitioners, who serve as adjunct faculty while educating veterinary students in private practices. Particularly for food animals, this model for clinical instruction has been used successfully in many parts of the world. As the US population becomes increasingly urbanized and veterinary colleges open referral clinics in metropolitan areas, this decentralized model of clinical instruction may become more common.

Challenges for Veterinary Education

Additional challenges to those noted above include the costs associated with clinical instruction and the economic future of the teaching hospital; demographic trends that project large numbers of faculty members will retire from veterinary colleges in the next two decades; the educational impact of increased enrollments in colleges of veterinary medicine to meet anticipated workforce needs; implications of limited licensure on educational programs, including continuing education; and ethical challenges resulting from new scientific advancements. Other developments that result from discoveries in cloning, synthetic animal-cell-based protein foods, organ farming, and xenotransplantation not only hold promise for improving human health and food safety, but also pose ethical challenges that veterinarians will need to help society address.

The opportunity for veterinary educators to find creative and innovative approaches for meeting these challenges is large and growing, but will require bold initiatives and vision. Professional schools are responsible for responding to the needs of their stakeholders, but must also take the initiative to continually define and advance their professions. Veterinary colleges must be leaders in ensuring

that the profession continues to serve society, promoting human and animal health, and in preparing flexible, skilled graduates who are capable of solving problems many of us cannot anticipate today.

Abductive Research Methods

B D Haig, University of Canterbury, Christchurch, New Zealand

© 2010 Elsevier Ltd. All rights reserved.

Educational and social science researchers make use of different kinds of research methods and strategies. Some of them are inductive in nature. For example, the well-known triangulation strategy of constructive replication is designed to establish the generalizability of empirical relationships. It is, therefore, a strategy of enumerative induction. Other methods are hypothetico-deductive in nature. Structural equation modeling, for example, conforms to the hypothetico-deductive strategy of testing certain classes of latent variable models in terms of their empirical adequacy.

Less well known is a third class of methods that is abductive in nature. These methods differ from inductive and hypothetico-deductive methods in that they make use of explanatory considerations in order to judge the worth of research hypotheses and theories.

Although researchers frequently engage in explanatory reasoning, there is a dearth of codified abductive methods available for ready use in the behavioral sciences. Scientists use abductive methods to a limited extent, although they seldom refer to them as abductive methods. This article discusses three different abductive research methods that are of relevance to educational and social science research. The first of these – exploratory factor analysis – has been widely used in education, although it is not generally recognized as an abductive method. The second abductive method – known as the theory of explanatory coherence

(TEC) – is a promising approach to theory appraisal that can be used to evaluate empirically based educational theories. The third method – grounded theory – is a well-known approach to conducting qualitative research, but it tends to be regarded as an inductive method rather than as an abductive method.

Exploratory Factor Analysis

Exploratory factor analysis (EFA) is a multivariate statistical method designed to facilitate the postulation of latent variables that are thought to underlie – and give rise to – patterns of correlations in new domains of manifest variables. Intellectual abilities, personality traits, and social attitudes are well-known classes of latent variables that are the product of factor-analytic research. EFA uses multiple regression and partial correlation theory to model sets of manifest or observed variables in terms of linear functions of other sets of latent – or unobserved – variables. Despite being regarded by many as a latent variable method, its inferential nature is usually described as inductive. This is odd, because inductive inference – being descriptive inference – cannot take the researcher to theoretical entities that are different in kind from their manifest effects. Therefore, EFA is best understood as an abductive method of theory generation (Haig, 2005a) – a

characterization that coheres well with its general acceptance as a latent variable method.

EFA is well positioned to facilitate the drawing of explanatory inferences that can be described as existential abductions. Existential abductions enable researchers to hypothesize the existence – but not the nature – of entities previously unknown to them. The innumerable examples of existential abduction in science include the initial postulation of hidden entities such as atoms, genes, tectonic plates, and personality traits. In cases such as these, the primary thrust of the initial abductive inferences is to claims concerning the existence of theoretical entities in order to explain empirical facts or phenomena. Similarly, the hypotheses given to us through the use of EFA postulate the existence of latent variables such as Spearman's g and extraversion. It remains for further research to elaborate on the first rudimentary conception of these variables and their interrelation.

The factor-analytic use of existential abduction to infer the existence of, say, the theoretical entity g can be coarsely reconstructed in accordance with the following argument schema:

The surprising empirical phenomenon of positive correlations among different tests of ability is identified. If g exists, and it is validly and reliably measured by a Weschler intelligence scale (and/or some other objective test), then the positive manifold would follow as a matter of course.

Hence, there are grounds for judging the hypothesis of g to be initially plausible and worthy of further pursuit.

Note that the schema for abductive inference – and its application to the generation of the hypothesis of g – are concerned with the form of the arguments involved, not with the actual generation of the explanatory hypotheses. In each case, the explanatory hypothesis is given in the second premise of the argument. An account of the genesis of the explanatory hypothesis must, therefore, be furnished by some other means. It is plausible to suggest that reasoning to explanatory hypotheses trades on our evolved cognitive ability to abductively generate such hypotheses. Whatever its origin, an informative methodological characterization of the abductive nature of factor-analytic inference must appeal to the scientist's own psychological resources as well as those of logic.

Although EFA exemplifies well the character of existential abduction, it is, clearly, not an all-purpose method for abductively generating explanatory hypotheses and theories. With its focus on common factors, it can appropriately serve as a generator of elementary theories only in those multivariate domains that have common causal structures.

It is well known that EFA is a common factor-analytic model in which the latent factors it postulates are referred to as common factors. There is an important principle of

scientific inference – known as the principle of the common cause – which drives the nature and shape of the existential abductive inferences involved in EFA. The principle can be formulated concisely as follows: “Whenever two or more events are improbably, or significantly, correlated infer one or more common causes, unless there is good reason not to.” Clearly, the principle should not be taken as a hard-and-fast rule, for – in many cases – proper inferences with regard to correlated events will not be of the common causal kind. The qualifier, “unless there is good reason not to,” should be understood as an injunction to consider causal interpretations of the correlated events other than the common causal kind. For example, the correlated events might be related as direct causes, or they might be mediated by a third variable in a causal sequence. Understood in the context of theory generation, methods of existential abduction such as EFA should not be expected to achieve highly developed and well-validated scientific theories. At best, they deliver rudimentary theories that have initial plausibility. It is important to realize that these abductive methods enable us to justify the initial plausibility of the theories they spawn. The very process of the abductive generation of theories has a bearing on the first determinations of their worth, in that one appeals to the soundness of the abductive arguments employed in the introduction of theories in order to evaluate their early epistemic promise.

Relatedly, the nascent theories bequeathed us by methods like EFA postulate the existence of hidden causal mechanisms. They have the status of dispositional theories in that they provide us with oblique characterizations of the properties we attribute to things by way of their presumed effects under specified conditions. A move beyond the rudimentary nature of their dispositional characterization will require subsequent elaboration by other means.

The Theory of Explanatory Coherence

Inference to the best explanation is the name given to an important, but neglected, approach to scientific theory evaluation. This approach is founded on the belief that much of what we know about the world is based on considerations of explanatory worth. Being concerned with explanatory reasoning, inference to the best explanation is a form of abduction. It involves accepting a theory when it is judged to provide a better explanation of the evidence than its rivals do (Haig, 2009; Capaldi and Proctor, 2008). In science, inference to the best explanation is, often, used to adjudicate between well-developed, competing theories. The major point of inference to the best explanation is that the explanatory merits of explanatory theories should count in their favor.

Thagard (1992) has developed a detailed account of inference to the best explanation as a scientific method – one which helps a researcher to reliably appraise competing theories in terms of their explanatory goodness. This method is known as the *theory of explanatory coherence* (TEC). The theory comprises an account of explanatory coherence that includes a number of evaluative criteria and constituent principles, a computer program for implementing the principles, and various simulation studies that demonstrate its promise as a method of inference to the best explanation.

According to TEC, inference to the best explanation is centrally concerned with establishing relations of explanatory coherence. To infer that a theory is the best explanation is to judge it as more explanatorily coherent than its rivals. TEC is not a general theory of coherence that subsumes different forms of coherence, such as logical and probabilistic coherence. Rather, it is a theory of explanatory coherence where the propositions hold together because of their explanatory relations.

Relations of explanatory coherence are established through the operation of seven principles. These principles are: symmetry, explanation, analogy, data priority, contradiction, competition, and acceptance. The determination of the explanatory coherence of a theory is made in terms of three criteria. Within the TEC, each of these criteria is embedded in one or more of the seven principles. In this instance, the criteria are considered first.

Thagard determined that explanatory breadth is the most important criterion for choosing the best explanation. This criterion captures the idea that a theory is more explanatorily powerful than its rivals if it explains a greater range of facts.

The notion of simplicity that Thagard deems most appropriate for theory choice is a pragmatic criterion that is closely related to explanation; it is captured by the idea that preference should be given to theories that make fewer special or *ad hoc* assumptions. Thagard regards simplicity as the most important constraint on explanatory breadth; one should not sacrifice simplicity through *ad hoc* adjustments to a theory in order to enhance its explanatory breadth.

Finally, Thagard found that analogy is an important criterion of inference to the best explanation because it can improve the explanation offered by a theory. Explanations are judged more coherent if they are supported by analogy to theories that scientists already find credible.

Within TEC, each criterion is embedded in one or more of the seven principles. These principles are stated here informally in Thagard's words (Thagard, 2000: 43), and the accompanying comment on the principles closely follows his (1992) discussion of a more formal statement of those principles.

1. *Symmetry*. Explanatory coherence is a symmetric relation, unlike, say, conditional probability. That is, two propositions p and q cohere with each other equally. The principle of symmetry maintains that both coherence and incoherence are symmetric relations, unlike the nonsymmetric relations of entailment and conditional probability. The sense of coherence conforms to the ordinary sense of coherence as holding together.
2. *Explanation*. (a) A hypothesis coheres with what it explains, which can either be evidence or another hypothesis. (b) Hypotheses that together explain some other proposition cohere with each other. (c) The more hypotheses it takes to explain something, the lower the degree of coherence. Because the principle of explanation establishes most of the coherence relations, it is the most important principle in determining explanatory coherence. Principle 2a, with principle 7, acceptance, subsumes the criterion of explanatory breadth, which is central to determining the best explanation. Principle 2c accommodates the notion of simplicity which is an important criterion in theory choice.
3. *Analogy*. Similar hypotheses that explain similar pieces of evidence cohere. The principle of analogy is the same as the criterion of analogy just mentioned. It states that if similar propositions explain similar pieces of evidence, then they cohere with each other. The analogy must be explanatory in nature.
4. *Data priority*. Propositions that describe the results of observations have a degree of acceptability on their own. The principle of data priority maintains that claims concerning observations and empirical generalizations can stand on their own more successfully than explanatory hypotheses. Of course, they can be doubted, but the reliability of their production will often be sufficient grounds for their initial acceptance.
5. *Contradiction*. Contradictory propositions are incoherent with each other. This principle straightforwardly includes syntactic contradictions involving logical inconsistency and semantic contradictions involving inconsistency of meaning. The principle covers the negative relations that hold between contradictory propositions that actively resist cohering, and that are said to incohere.
6. *Competition*. If p and q both explain a proposition, and if p and q are not explanatorily connected, then p and q are incoherent with each other (p and q are explanatorily connected if one explains the other or if together they explain something). This principle claims that theories that explain the same evidence should normally be treated as competitors. In such cases, theories are regarded as competing if they are not explanatorily related. Noncontradictory theories may compete with each other.
7. *Acceptance*. The acceptability of a proposition in a system of propositions depends on its coherence with

them. This last principle asserts that propositions are accepted or rejected based on their degree of coherence with other propositions. The overall coherence of a system of propositions, or a theory, is obtained by considering the pair-wise coherence relations through use of principles 1–6.

The principles of TEC combine in a computer program, Explanatory Coherence by Harmany Optimization (ECHO), to provide judgments of the explanatory coherence of competing theories. This computer program is connectionist in nature and uses parallel constraint satisfaction to accept and reject theories based on their explanatory coherence.

The TEC has a number of virtues which make it an attractive theory of inference to the best explanation: It satisfies the demand for justification by appeal to explanatory considerations rather than predictive success; it takes theory evaluation to be a comparative matter; it can be readily implemented by – and, indeed, is instantiated in – the computer program, ECHO, while still leaving an important place for judgment by the researcher; and, it effectively accounts for a number of important episodes of theory assessment in the history of science. In short, TEC and ECHO combine in a successful method of explanatory coherence that enables researchers to make judgments of the best of competing explanatory theories. Thagard (1992) is the definitive source for a detailed explication of the TEC.

The behavioral and social sciences are replete with competing theories that might usefully be evaluated in respect of their explanatory coherence. However, their use of TEC to appraise the best of competing explanatory theories is yet to be undertaken.

Grounded Theory

Grounded theory (GT) is probably the most widely known methodological perspective on how to conduct qualitative research in the social sciences. Originally introduced by sociologists Barney Glaser and Anselm Strauss (Glaser and Strauss, 1967), GT is used extensively in education and related fields.

GT comprises a distinctive methodology, a particular view of scientific method, and a set of specific procedures for analyzing qualitative data and constructing theories from those data. The methodology provides a justification for regarding qualitative research as a legitimate – indeed, rigorous – form of inquiry. The view of scientific method adopted by GT is generally taken to be inductive in nature, although this is a contested matter. GT researchers gather non-numeric data from a variety of sources, including interviews and field observations. Once gathered, the data are analyzed using coding and theoretical

sampling procedures. A set of interpretative procedure are then used to assist in the construction of theory that emerges from, and is grounded in, the data.

In efforts to identify empirical social phenomena, and construct theories that are constrained by those phenomena, almost all accounts of GT adopt the three major strategies of data coding, memo writing, and theoretical sampling.

In GT, data gathering and data analysis are interactive. From the time data collection begins, grounded theorists engage in data analysis, which leads to further data collection, subsequent data analysis, and so on.

The first data analytic phase of GT begins with the coding of the data. This is undertaken to conceptualize the data by discovering categories into which they fit. The coding process has three phases: open coding, axial coding, and selective coding. In open coding, researchers describe the data by looking at it line-by-line. This strategy of focusing on small units of data, and their interpretation, encourages the development of a theoretical sensitivity to new ideas with regard to the data, and helps prevent the forcing of data into existing categories. Strauss (1987) maintains that when a full array of categories have been identified, one should undertake axial coding – whereby one puts the data back together again in new ways by making connections between the numerous categories. Following that, a selective coding step is implemented in which the researcher looks to systematically identify those categories that relate closely to the core category. The core category lies at the heart of the emerging theory and is central to its integration.

Although memo writing can occur at any stage of the research process, it frequently takes place between the coding of data and the writing of the initial draft of the research report. Memos are written to identify, develop, and keep track of theoretical ideas. Where relevant, they are recorded, recalled, and reworked to produce new theoretical memos. Memo writing becomes more systematic, focused, and intense as theory of greater density and coherence is produced.

Memos written with regard to data codes and theoretical ideas enable the researcher to identify gaps that require the collection of further data. For this, theoretical sampling is undertaken. With theoretical sampling – in contrast with traditional representative sampling – decisions concerning what data to collect, code, analyze, and interpret are directed by the emerging GT. Theoretically relevant events, activities, and populations are all sampled, and the comparisons between these are aimed at increasing the conceptual density and integration of the emerging theory. Thinking effectively with regard to data in theoretical terms requires an adequate degree of theoretical sensitivity. When the additional gathering and analysis of data no longer contribute to the understanding of a concept or category, a point of theoretical saturation

is reached. At this point, one stops collecting data in respect of a category and moves to consider another category or concept.

Consistent with the pragmatist influences on GT methodology, Strauss (1987) characterizes scientific method as a sequence of induction, deduction, and induction: grounded theories emerge inductively from the data, test predictions are then deduced from the theories, and, finally, the theories are inductively confirmed or disconfirmed.

Despite the considerable attention given to the exposition of data analysis in GT, it is difficult to fathom just how – and in what sense – GT is said to inductively emerge from, and be grounded in, the data. This is because the nature of the inductive reasoning involved is not described.

Glaser and Strauss have been criticized on the grounds that they advocate a return to a simple and unacceptable Baconian inductivism. On this interpretation, GT is depicted as a *tabula rasa* view of inquiry which maintains that observations are not theory or concept dependent. However, this is not Glaser and Strauss's position. In *The Discovery of Grounded Theory* (Glaser and Strauss, 1967), they explicitly disavow this view of inquiry – noting that the researcher requires a theoretical perspective in order to see and abstract from data. It is in the interest of obtaining emergent, diverse categories at different levels of abstraction that Glaser and Strauss would have the researcher hold all potentially relevant facts and theories in the background for some time. Clearly, this is a form of bracketing, not a *tabula rasa* conception of inquiry.

Although it is clear that Glaser and Strauss are not naive inductivists, the actual nature of the inductive relation that – for them – grounds emergent theories in their data is difficult to fathom. For Glaser and Strauss, GT is said to emerge inductively from its data source in accordance with the method of constant comparison. As a method of discovery, the constant comparative method is an amalgam of systematic coding, data analysis, and theoretical sampling procedures which enables the researcher to make interpretive sense of much of the diverse patterning in the data by developing theoretical ideas at a higher level of abstraction than the initial data descriptions. However, the notion of constant comparison is of little help in figuring out whether the inductive inference in question is enumerative, eliminative, or of some other form.

Given the pragmatist influence on GT methodology, it is not surprising that Strauss (1987) mentions the notion of abduction in his brief discussion of induction. Unfortunately, however, he refrains from including it in his discussion of the inductive generation of theory. In his mature writing, the American pragmatist Charles Sanders Peirce clearly distinguished between these two forms of inference. Both inductive and abductive arguments are ampliative, or content-increasing – in that their

conclusions contain more information than is contained in their premises. However, the type of ampliation is different for each. Inductive arguments are descriptive in character because they reach conclusions concerning the same type of manifest attributes mentioned in their premises. By contrast, abductive arguments reason from factual premises to explanatory conclusions, as when we reason from presumed effects to underlying causes.

A growing number of authors have characterized the creative inference involved in the generation of GT as abductive in nature (e.g., Haig, 1996; Reichertz, 2007) – that is, rather than viewing a GT as an inductive abstraction from data analysis, it is thought of as the result of explanatory inference to factors that transcend the data in a more fundamental way. On this view, the data analytic dimension of GT can reasonably be construed as inductive in nature. However, in order to explain the abstracted data patterns, the construction of GT needs to be thought of as abductive in nature.

Haig has gone further and suggested that the entire process of theory construction in GT can be cast in an abductive light (Haig, 1996, 2005b). On his account, the abductive nature of GT extends beyond theory generation to include theory development and theory appraisal. A strategy of analogical modeling is used to develop GT. Because analogical modeling increases the content of explanatory theories, the reasoning it embodies is referred to as analogical abduction. This reconstruction of GT adopts inference to the best explanation as the preferred approach to the evaluation of mature theories. Specifically, TEC – outlined earlier – is adopted, and the better of competing GTs is judged to be the one that is more explanatorily coherent.

Conclusion

The fundamental purpose of scientific inquiry is to detect and explain empirical phenomena. Social science methodology is replete with methods that help in the descriptive task of identifying empirical phenomena. However, in order to help researchers explain these phenomena, abductive methods such as those described in this article should be part of their methodological armamentarium.

Glossary

Between groups – Feature of research design that involves the administration of measures to different groups of participants as way to compare the effect of one study condition against another study condition.

Causal inference – The cognitive processes, rules of logic, empirical conditions, and theoretical assumptions that lead one to make assertions about the existence of cause and effect relations.

Counterfactual – The existence or construction of a set of investigative circumstances organized to satisfy the basic empirical conditions needed build an argument for cause and effect relations.

Implementation measure – An indicator that reflects the degree to which a given intervention was administered as intended.

Instrumentation – Any one of a variety of tools used to collect data.

Power – The probability that a statistical test will yield significant results to support the rejection of the null hypothesis.

Randomization – Research procedure in which individuals or investigative units (e.g., classroom, schools, school districts) have an equal chance of being allocated to one of several.

Treatment – An intervention selected to produce a desired set of outcomes.

Units – Entities of varying scale, from individuals to collections of individuals, that serve as study samples.

Within groups designs – Feature of research that involves the administration of measures to a single group of participants (on different occasions) as way to compare the effect of one study condition against another study condition.

All questions about research design, when correctly conceived, take the formulation of problems as their points of departure. As Karl Popper has argued, “[t]he progress of science lies, essentially, in the evolution of its problems” (Popper, 1994: 155–156). A concern for the advance of science must item from an understanding of the general form of the problem at hand, rather than from an allegiance to a particular design. With this in mind, the justification for field experimentation can be constructed

as a response to a foundational question. How might education be defined and what is the argument for the application of field experiments? Consistent with the perspective of pragmatism (see Dewey, 1938; Peirce, 1905), education may be defined as the intended and unintended configuration of cause and effect relations. The causes may be viewed as a set of characteristics held by individuals (e.g., students, teachers, and administrators) and groups of individuals with shared attributes, as a set of traits or practices followed by those individuals and groups, as the set of systemic variables such as school size school setting (e.g., urban vs. rural), school organization (e.g., decentralized governance), or school finance (e.g., funding models). The effects may be viewed as a set of valued educational outcomes, such as achievement scores, conceptual understanding, motivation, psychological well-being, or a host of other academic and nonacademic outcomes.

If evidence is to play a role in education by solving the problems of education, decisions about which aspects of education need to be retained, eliminated, or more widely disseminated depend on one’s inclination to view education as essentially causal. Within the research enterprise, the goodness of evidence depends on one’s ability to produce relatively unbiased estimates of the effect that selected characteristics and conditions of education have had on outcomes of interest. When education is defined in terms of cause-and-effect relations, field experiments are the best design option. No other design option has been shown to produce estimates of effect more accurately than field experiments. The process of randomly assigning educational units (e.g., students, classrooms, and schools) to different educational conditions offers the important benefit of randomly distributing the array of known and unknown characteristics evenly across study conditions. This is important because any one of such characteristics (and probably more than one) could interfere with the desire to accurately estimate effects of a given intervention or set of interventions. In the absence of random assignment, the possibility of systematic error linked to group differences becomes more pronounced. The production of reasonably unbiased estimates of effect, in combination with a well-developed theory of causal relations for a particular phenomenon, is what permits one to make the evidence-based assertion that a given set of educational conditions brought about a particular set of outcomes. Identifying the most productive configuration of cause–effect relations is of great interest, both to educational professionals who are in a position to select and

implement programmatic initiatives and to researchers who attempt to produce trustworthy estimates of the effects of those same initiatives.

At least since the work of Fisher (1926, 1935), experimental design has been regarded as the best option for producing reasonably unbiased estimates of the effects of a given intervention. Education, perhaps more than any field, has been slow to explore the inferential benefits afforded by experimental design. Until quite recently, it has been very difficult to locate significant numbers of experiments in the field of education (see Boruch *et al.*, 2002; Cook, 2001). In the United States, the passage of key legislation for both education program and for educational research produced a shift in the kind of research designs employed in the field of education (see Constanas, 2007). The passage of the Elementary and Secondary Education Act of 2000 and the passage of the Educational Sciences Reform Act of 2001 both highlighted the importance of randomized field trials. In the past few years, a new professional organization was formed, the Society for Research on Educational Effectiveness and a new peer-reviewed journal was founded, the *Journal of Research on Educational Effectiveness* (JREE). The new organization, along with its flagship journal JREE, places randomized field trials at the center of its work. The landscape of educational research has undergone a significant change over the past few years. The use of field experiments, which were relatively rare over the course of recent history, has been applied more regularly in the field of education. The purpose of this article is to describe the most critical design features of field experiments, to discuss a limited number of statistical issues, and to highlight the importance of planning and implementation. It should be noted that the article summarizes the design features of studies that randomly assign educational entities of varying scale (e.g., individuals, groups, and locations) to study conditions. There are a range of other methods that are also used to produce estimates of the effects of educational intervention that do not randomly assign educational units to study conditions. Such methods include, but are not limited to, quasi-experimental design (e.g., Cook and Campbell, 1979), interrupted time series (e.g., Bloom, 2003), regression discontinuity designs (e.g., Thistlewaite and Campbell, 1960), and propensity score matching (e.g., Rosenbaum and Rubin, 1984). Shadish *et al.* (2002) provide a well-detailed treatment of the full range of experimental and quasi-experimental design options that can be used to generate estimates of effect, with and without randomization.

Field Experimentation: An Overview

Field experiments are based on the inferential logic of laboratory experiments. There are two key characteristics of the laboratory-based experiments. One characteristic is

the construction of a controlled environment, one in which the conditions meant to produce a particular effect are carefully manipulated. All other conditions theorized to have an effect are held constant, to the extent they can be. Such environments are designed to be as free as possible from influences that would disturb the attempt to establish cause-and-effect connections between features of the manipulated environment and the observed outcomes of interest. A second key characteristic of laboratory experiments is that they employ the method of randomly assigning units to either a treatment condition or to a control condition. The units may be individuals, groups of individuals, or locations where individuals cluster (e.g., classrooms, schools, and school districts) (see Donner, 1988). The practice of random assignment is critical because it establishes a counterfactual condition, where a counterfactual represents an all-else-equals comparison (see Lewis, 1973; Mackie, 1974). This creation of a plausible counterfactual means that any observed difference of significant magnitude should be attributable to differences in the conditions that were intentionally manipulated. Outside influences (e.g., individual differences or group differences) that could interfere with the attempt to make such attributions should, in principle, be equally distributed across study conditions.

Markedly different from laboratory or controlled conditions under which laboratory studies are conducted, field experiments are conducted in natural settings where influences that are not integral to the explicit purpose of the investigation must be reckoned with. While field experiments are not characterized by controlled environments, the element of random assignment represents the foundational feature of this design option. Shadish *et al.* (2002: 12) define an experiment simply as "... a study in which an intervention is deliberately introduced to observe its effects." As a specific type of experiment, a randomized field experiment is a study which has two additional features. First, the feature of randomization requires that each of the entities that serve as the primary analytic entities (e.g., students, teachers, classrooms, and schools) has an equal chance of being part of the group that receives the treatment as it does of being part of the group that does not receive the treatment. The unbiased, random establishment of an intervention (or treatment) group and a nonintervention (or control) group is assured by randomly assigning the entities to their respective groups. Second, the reference to the idea of the field means that the study is conducted in everyday educational settings. The second feature places a particular set of demands on the investigator as he/she contemplates ways to deal with the inferential hazards wrought by an uncontrolled set of study conditions. Randomization, as a key feature of field experiments, addresses some of these challenges but not all. The way in which randomization is deployed along with other components of design provides a fuller response to the factors that cloud

the investigator's ability to minimize sources of bias, beyond selection bias. At least since the work of Fisher (1926, 1935), experimental designs that employ random assignment have been regarded as the best option for producing reasonably unbiased estimates of the effects of a given intervention. In their assessment of designs used within the field of education Schneider *et al.* (2007: 11) noted that "when correctly implemented, the randomized controlled experiment is the most powerful design for detecting treatment effects." Boruch and Foley (2000: 194) describe a randomized field trial as a "... study that attempts to produce a fair comparison of the relative effectiveness of two or more approaches so as to understand what works, for whom, and for how long."

While randomization is a necessary component of field experimentation, it is one of many design components to consider in the planning of a field experiment. If the aim is to increase precision and to minimize bias, the potential inequalities produced by differences between or among study samples represent only a single source of error. As Shadish *et al.* (2002: 256) noted "... random assignment is just one part of experimental design" and range of other important issues such as "scheduling of observations, the choice of treatments and comparisons, the selection of observations and measures, the determination of who should be the respondents, and the manner of assigning units to treatments."

Types of the Randomized Field Experiments Through the Lens of Internal Validity

In investigations of educational effectiveness, well thought-out research design is what allows one to separate, with a reasonable degree of confidence, treatment effects from a range of unwanted influences. Any one design type has an associated set of strengths and weaknesses that inhibit or facilitate an investigator's ability to draw inferences about the effect of a given intervention. With reference to research design, the ability to draw such inferences is best explained by the notion of internal validity (see Campbell, 1957; Campbell and Stanley, 1963; Cook and Campbell, 1979). Shadish *et al.* (2002: 55) describe nine different threats to the internal validity of a study:

1. ambiguous temporal precedence that indicates a confusion between the ordering of hypothesized cause and effects relations;
2. selection effects that produce differences in the characteristics of study samples (i.e., treatment vs. control);
3. history effects that admit a set of influences concurrent with the intervention;
4. maturation effects that account for change as a natural consequence of development of the entity (e.g., individual and group of individuals) under study;

5. regression effects that highlight the consequences of selecting entities at extreme points in a distribution on an outcome of interest (e.g., achievement and self-esteem);
6. attrition effects that exist when differential, nonrandom factors account for attrition observed between study groups;
7. testing exposure that produces change (pretest to posttest) as a consequence of being sensitized to attributes of interest experienced in a pretest;
8. instrumentation effects that produce changes in outcomes that may be incorrectly attributed to the intervention; and
9. additive and interactive effects that result from the more than one of the eight main threats to internal validity.

For a more comprehensive discussion of each of the threats to internal validity, as well as other components of validity that influence the strength of inferences (e.g., construct validity, statistical conclusion validity, and external validity) the reader is directed to Shadish *et al.* (2002: 33–102). The concept of internal validity is introduced here because it provides a useful point of access to consider the consequences of different design options.

There are a large number of designs that one may employ under the heading of randomized field experiments. Differences among the designs can be described in terms of the four features, expressed here in the form of four questions. First, was a pretest employed as part of the design? Second, was a control group employed and, if so, how many control groups were used to construct a counterfactual? Third, how many treatments were compared? Fourth, at what points were data collected and were data collected to draw inferences about discrete effects between two points in time or about growth over more than two periods of time? Using five common designs, **Table 1** illustrates how such questions are answered. The table also includes details related to the relative strengths and weaknesses of each design in terms of internal validity. It is important to note the designs and the details on internal validity are intended to be illustrative and not comprehensive.

In an educational setting, the most basic form of a randomized field experiment involves two groups, where one group receives the intervention that is under examination and the second group continues under the standard set of educational conditions (the control group, denoted as Ctrl). More complicated variations on this basic design are accomplished by adding more treatment groups, more control groups, and by varying the placement of data collections before, during, and after treatments. Following a design framework offered by Shadish *et al.* (2002), **Table 1** shows how the use of Tx groups, control groups, pretests, and posttests, vary across the four illustrative design types. What is important to notice in **Table 1** is that the addition

Table 1 A sample of design types: Observed effects, strengths, and weaknesses*

<i>Design type and Comparisons</i>	<i>Example of differences observed to assess various effects</i>	<i>Strengths and weaknesses of design type</i>
1. Tx with no control group Single group compared against itself over time with a single Tx, control group	Pretest–posttest = Tx^1 effects	+ Controls for between-group difference via repeated measures + Measures change – No counterfactual condition – No measure of maturation – Instrumentation effects unmeasured
2. Basic randomized design comparing two Tx Two Tx groups compared against each other at posttest, no pretest administered and no control group	Pretest (Tx^1)–posttest(Tx^2) = Comparison of two Tx effects	+ Controls for between-group difference via randomization – Does not measure change or maturation – No counterfactual condition – Instrumentation effects unmeasured
3. Basic randomized design comparing two Tx and a control Three groups compared against each other, no pretest administered	Posttest(Tx^1) – posttest(Ctrl) = Tx^1 effects Posttest(Tx^2) – posttest(Ctrl) = Tx^2 effects	+ Controls for between-group difference via repeated measures + Includes a counterfactual Condition – does not measure change or maturation – Instrumentation effects unmeasured
4. Pretest, posttest control group Two groups compared, one with Tx and one without	Posttest(Tx^1) – posttest (Tx^2) = comparative effects of Tx^1 vs. Tx^2 Pretest(Tx^1) – pretest(Ctrl) = initial group differences Posttest(Tx^1) – posttest(Ctrl) = Tx^1 effects Posttest(Ctrl) – posttest(Ctrl) = Maturation effects (Pretest () – posttest (Tx^1)) – maturation effects = Tx^1 taking maturation into account	+ Controls for between-group difference via randomization – Includes a counterfactual condition + Measures maturation/growth – Instrumentation effects unmeasured
5. Longitudinal design with pre-test multiple posttests and single Tx Two groups (or more) compared, one or more with Tx, one without control, with pretests and multiple posttests	Posttest(Tx^1) – posttest(Ctrl) = Tx^1 effects Pretest(Tx^1) – posttest(Ctrl) = initial group differences Posttest(Ctrl) – posttest Ctr ¹) = maturation effects Pretest (Tx^1) – posttest one Tx^1 = effects Posttest one (Tx^1) – posttest two Tx^1 = growth effects	+ Includes counterfactual + Instrumentation effects measured + Measures growth over time + Measure maturation + Measures instrumentation – Costly/time-consuming design

of control groups, the judicious placement of measures, and the opportunity to track change over time influence the strength of inferences that may be drawn from a given study.

The ability to draw inferences on the relative effectiveness of a given intervention requires that one has comparative data. The second column of **Table 1** shows, in simple notation, the kinds of comparisons afforded by the five designs. Some designs only allow the investigator to assess the effect of the intervention without assessing the effect of other factors that could cloud the clarity of the inferences drawn. The more comparisons afforded by a given design type, the better prepared the investigator is to separate intervention effects from nonintervention effects or effects introduced by threats to internal validity.

To provide a more specific illustration of the strengths and weaknesses of each design presented in **Table 1**, consider a field experiment on the effects of an intervention meant to improve early language skills among a group of students over the course of their first year of primary school. For such a study, one would be interested in determining how effective the new intervention is in comparison to the standard set of practices. The development of a design that will best support the investigator's attempt to separate the effects of the intervention from other effects is confronted with a number of immediate challenges. For the sake of illustration, let us consider three sources of interference connected to internal validity. First, knowledge of the language development for

primary school children suggests that, even in the absence of any intervention, language skills are likely to develop over the time (maturation effects). Second, exposure to a pretest is likely to have an impact on the development of language skills (instrumentation effect). Moreover, assume that this impact is amplified when offered in combination with the intervention. Third, the conclusions that may be drawn about growth depend on assumptions made about trajectory of language development over the course of the year. Consideration of these three sources of potential interference demonstrates the necessity of design that includes a first control group (to address maturation effects), a second control group with no pretest (to address the instrumentation), and the collection of data in a longitudinal format (to examine growth). A simple pretest, posttest design with no control group (design number one **Table 1**) would not permit the investigator to separate intervention effects from maturation effects. A design that included a control group in addition to the Tx group would help the investigator assess maturation effects, but the potential effects of instrumentation would not be known. Finally, a design that collects data at only two points in time (pretest and posttest) would not allow the investigator to measure growth in the most appropriate manner. The demands of inference (internal validity) combined with knowledge of language acquisition (construct validity) suggest that a pretest, posttest longitudinal design with two control groups would be the best option.

As previously noted, the description of design types offered here is not comprehensive as there are obviously wide variety of ways to organize a field experiment. Ultimately, decisions related to the use of a control group (or control groups), pretests, and posttests are made on the joint consideration of two sets of design issues, one of which is based in the logic of inference, while the other is based on the realities of the field settings. Design issues connected to the logic of inference reflect an ambition to design and conduct studies that can best anticipate threats to internal validity. Design issues connected to the realities of the field reflect an understanding of local contexts and a concern for the ethics of random assignment. The concern for ethics, while critical, is often overstated. There are many educational interventions, for example, in which enrolment in an educational program operates on a lottery. On other occasions, the implementation of an intervention is phased in over time, across a district or across a state.

Planning and Implementation Issues

On the surface, the steps required to initiate and complete a randomized field trial are no different than the steps followed for any form of education inquiry. For field

experiments, the critical difference is that attention is paid to the identification of factors that interfere with the ability to produce trustworthy knowledge claims about educationally important cause and effect relations.

The field of education is almost always politicized and the various constituents interested in education will be differently invested in the intervention that is under investigation. When working outside of laboratory settings, and across multiple sites, the range of logistical and political complexities (and these two set of challenges are often intertwined) encountered as investigators aim to conduct studies of the unpredictable, and often uncontrollable settings present as a special set of challenges. The existence of such issues, and others, means that investigators must take special care in the planning and implementation of randomized of field experiments.

Highlighting the complexity of field experiments, Boruch and Wothke (1985) described seven types of plans that investigators should consider as they aim to implement a randomized field trial, noting that “[n]o single plan or strategy will suffice given the diversity of programs and stakeholders involved in experimentation” (Boruch and Wothke, 1985: 99). Their planning schema specified that plans should be developed to:

1. incentivize organizational entities to participate in the study;
2. conduct a pilot study to test and improve upon all aspects of the design and implementation of the study;
3. ensure effective implementation of the design and monitor the quality of study procedures over the course of an investigation;
4. negotiate randomization plans and collaborate with the organizations;
5. develop alternative plans as a back-up plan in the event that study plans do not proceed as expected;
6. specify the exact conditions under which Tx and control groups will function and identify preexisting conditions that facilitate randomization; and
7. ascertain how the technical aspects of local conditions (e.g., school organization and school district administrative structures) may influence design decisions such as the level of randomization (e.g., individual level, classroom, and school level).

For a more extensive discussion of planning issues in randomized field experiments the reader is directed to Boruch and Wortke (1985).

Implementation Measures, Blocking, Design Effects, and Cluster Sampling

The task of randomly assigned entities to study conditions is an important strategy of field experimentation. It is, however, not the only strategy that may be used to enhance the

quality of inferences drawn from a field experiment. There are additional tactics and which, when used as part of randomization, can enhance the quality of inferences. Second, the tactic of blocking, which involves matching prior to randomization, will be introduced. Third, the existence of amplified levels of homogeneity observed within comparison groups (Tx or control) can distort estimates of effect (and decrease power; see Cohen, 1988). Fourth, settling questions about the most appropriate level of randomization introduces a special set of considerations about power and about having unit of assignment aligned with the unit of analysis. Each of three topics is reviewed briefly below.

Implementation Measures and the Fidelity of Interventions

The validity of claims made about the comparative effect of an intervention condition and a control condition depends largely on features of study design. There is, however, a basic assumption that must be questioned, one that is foundational and chronologically prior to the empirical study of intervention effects. The assumption concerns the distinctiveness and consistency of conditions features that allow one to characterize and distinguish between the intervention and control condition. The fact that one set of classroom conditions, for example, may be designated as the intervention and another set may be designated as the control provides no guarantee that the two conditions will be as different as the investigator hoped. In most studies that aim to compare one set of educational conditions to another, a good deal of variation can be found not just between conditions but also within. The fact that such variation exists should compel investigators to include implementation measures, both for the intervention condition and the control conditions. The inclusion of an implementation measure will help the investigator explain sources of variation within conditions, across sites, and or over time.

Blocking Prior to Randomization

The most important feature of field experiments involves the random assignment at some specified scale (e.g., individuals, classrooms, schools, and school districts) to a particular study condition. A second feature involves the use of a strategy to construct groups that possess similar characteristics of an attribute of interest, where an attribute of interest is known to, or hypothesized to, exert an influence on outcome variables. This useful strategy, referred to as blocking or matching, is important given that random assignment always provides an imperfect guarantee of true random allocation. Blocking involves the creation of subgroups constructed along dimensions that are thought to be of consequence for a particular outcome variable or set of outcome variables. Rather than leaving the distribution of

such characteristics, between study groups, blocking attempts to create reasonably equivalent groups (prior to randomization), at least for the set of characteristics that are believed to be connected to the outcome. Random assignment is still used to distribute other, unknown sets of impactful characteristics evenly between groups.

Cluster Sampling and Unit Congruence

Randomization may be applied at varying scales. Within educational settings, individuals, classrooms, schools, school districts, or clusters of larger sizes may be assigned to different study conditions. The decision about the appropriate scale of randomization is a function of three issues. The first issue, theoretical rationale, concerns the explanatory framework upon which the study and its questions are based – the question to consider here relates to the level at which the causal agent of the intervention is meant to function. The second issue, implementation constraints, concerns the conditions in the field. Here, one must confront feasibility issues and consider the issues related to contamination between study conditions.

There are two key points to bear in mind as one designs field experiments with the notion of clustering in mind. First, the decision about the level of randomization has a direct bearing on the unit of analysis. To make inferences at the group level when units were randomized individuals produces faulty inferences. This illustrates what Robinson (1950) referred to as the ecological fallacy. Valid analysis of field experiments requires that the unit of randomization be matched with unit of analysis. Second, the decision to sample clusters or groups, rather than individuals, introduces a special set of considerations that affect decisions related to power analysis (i.e., sample size requirements related to expected effects). It is important to know that the number of clusters has a more important bearing on power than does the number of individuals contained within groups (see Raudenbush and Spybrook, 1997).

Intraclass Correlations and Design Effects

It is long been postulated that individuals or entities that reside within particular locations (e.g., schools and school districts) are more likely to be similar to one another than are the groups or individuals observed between groups (see Kish, 1965). The problem of differences found between groups versus within groups is referred to as the intraclass cluster correlation (ICC). When the ICC is not taken into account, a sufficiently large ICC may produce two problems. First, a large ICC can produce inflated estimates of an intervention's effect. The problem of an inflated estimate is what Kish (1965) referred to as a design effect. Second, an inflated ICC introduces requirements related to sample size. The larger the ICC,

the lower the power. Understanding of the consequences of ICC into sampling decision can ensure that field experiments are not underpowered because of design effects. As part of the planning process of field experiments, it is helpful to consider the range of ICCs that are typically found in connection with a particular class of outcomes (see Hedges and Hedberg, 2007).

Conclusion

In 1971, the Social Science Research Council assembled a committee to examine the potential benefits and design feature of social experiments in the field of education (see Reicken and Boruch, 1974). The foreword to the report offered “a comprehensive statement of the promise and problem of social experimentation” (Sheldon, 1974: ix). Field experimentation is part of a larger evolving set of design decisions, analytic options connected to the process of inquiry as Sheldon noted, “experimentation is viewed as a cycle that begins with problem analysis; proceeds through the planning of an intervention, its development, experimental trial, and evaluation; and ends in either program implementation or in re-planning the intervention” (Sheldon, 1974: x). In the conclusion to her foreword to the report, Sheldon observed that “[s]ocial experimentation may develop into an extremely valuable tool for decision making or it may prove to be too unwieldy in dealing with complex social problems” (Sheldon, 1974: xi). Lipsey (1990: 175) argued that experimental design “. . . is one of our most probing and cogent tools for identifying the means by which people problems can be ameliorated and our collective quality of life improved.” With an emerging corpus of work that employs randomized field experiments the field of education may now be in the position to examine the potential benefits noted by Reicken and Boruch nearly four decades ago.

Glossary

Additive and interactive threats to internal validity – When the impact of a threat can be compounded by – or may depend on the level of – another threat.

Ambiguous temporal precedence – Inability to determine which variable occurred first, thereby, preventing the researcher from knowing which variable is the cause and which is the effect.

Attrition – When units drop out of the experiment after being assigned to treatment conditions.

Causal inference – Making a conclusion which claims that one variable or event causes another.

Construct – Concept or broad characteristic (i.e., intelligence or achievement).

Construct validity – How well researchers can infer that the research operations sufficiently represent constructs of interest.

Control group – Group in an experiment that has not been manipulated or did not receive an intervention.

Counterfactual – What would have occurred to the treatment group if they had not received the intervention.

Covariate – Extraneous variable that is related to the effect, but is not the cause of interest.

Covariate adjustment – Statistical correction that uses either an analysis of covariance or a multiple regression to account for a covariate to provide a clearer relationship between the cause and effect.

Cross-sectional – When data used in a study are measured all at once on a single occasion.

External validity – How well researchers can generalize causal relationships across units, treatments, observations, and settings.

History – When events occur simultaneously with the treatment and could affect the outcome.

Hot-decking – Data-imputation procedure that matches participants with missing data with those without missing data and uses the same available data value from the matched participant to substitute the missing value.

Instrumentation – When changes in the instrument used to measure responses provide different results for the outcome, appearing as if an effect occurred.

Intent-to-treat analysis – When people in the treatment condition who drop out of a study are assessed as if they had received the treatment.

Internal validity – How well researchers can make causal inferences with regard to the relationship between presumed causes and effects.

Last value forward – Procedure that uses the last available measure to replace a missing data value.

Matching – Pairing participants together based on similarity of a continuous covariate related to the outcome (i.e., pairing a control participant with a treatment participant of the same age).

Maturation – When a natural development over time occurs during the same time as the treatment and could affect the outcome.

Multiple imputation – Data-imputation procedure that predicts missing data values from the available data multiple times, statistical analyses are conducted on all data for each set of predicted values, and the multiple analyses are averaged to find a single estimate.

Operations – Specific methods used to measure variables of interest (i.e., using the Stanford–Binet to measure intelligence).

Posttest – Measure of an outcome (presumably an effect) made after a cause or intervention.

Pretest – Measure of an outcome made before a cause or intervention.

Propensity score – Conditional probability that a unit will be in a treatment condition given a set of observed covariates.

Random assignment – Assigning participants to experimental conditions (i.e., treatment or control groups) so that each participant has a known (and sometimes equal) probability of getting into each condition.

Regression to the mean – When participants are selected from their extreme scores, but have less extreme scores on other measures, appearing as if an effect occurred.

Selection – When systematic differences between unit characteristics in each treatment condition could affect the effect due to a nonrandom assignment procedure.

Single regression imputation – Data imputation procedure that predicts missing data values from the

available data using a regression equation; in a stochastic regression model, random error is added to the predicted value.

Statistical conclusion validity – How well researchers can conclude that cause and effect variables covary.

Stratifying – Grouping participants together based on similarity on a categorical covariate related to the outcome (i.e., grouping control participants with treatment participants in the same grade level).

Testing – When repeatedly exposing units to a test may permit them to learn the test, appearing as if a treatment effect occurred.

Threats to internal validity – Common reasons why researchers may be incorrect about the causal inferences they draw from experiments.

Treatment group – Group in an experiment that has received some sort of manipulation or intervention.

Weighting – Multiplying values (or weights) to individual outcome observations so that some observations contribute more or less to the overall effect; this is usually done as a statistical correction to adjust a flawed design.

Internal validity addresses how well researchers can make causal inferences about the relationship between predictive variables, presumed causes, and outcomes, their effects. Campbell and Stanley (1963) created a validity typology to provide a logical and objective way to evaluate the quality of causal inferences made when using randomized and quasi-experimental designs. Originally, they described only two types of validity: internal validity and external validity. The latter addresses how well causal relationships generalize across units (people), treatments, observations, and settings. Cook and Campbell (1979) later added statistical conclusion validity, which addresses the ability to establish that the cause and effect covary, and construct validity, which addresses the ability to infer that the research operations sufficiently represent constructs of interest.

Threats to Internal Validity

As part of their validity typology, Campbell and colleagues included threats to validity, common reasons within each type of validity that explain why researchers may be incorrect about the causal inferences they draw from experiments. Although Campbell and Stanley were the first to describe the threats, since then, Shadish *et al.* (2002) have added to and refined the threats to each of the validity typologies. Of the four types of validity,

threats to internal validity are most crucial in making causal claims from experiments. The threats to internal validity are described below.

Ambiguous Temporal Precedence

This is the inability to determine which variable occurred first, thereby preventing the researcher from knowing which variable is the cause and which is the effect. This commonly occurs when the cause is not manipulated and researchers measure the cause and effect on a single occasion. For example, Benner and Mistry (2007) used a longitudinal study to examine the influence of adult (i.e., mother and teacher) educational expectations on the academic achievement of low-socioeconomic-status students. According to the proposed model, adult expectations will cause the youth to form beliefs about expectations and competency in school which will lead to the youth's outcomes. Although the authors found direct relationships between both mother and teacher expectations and youth outcomes, they conceded that their study might suffer from ambiguous temporal precedence with the teacher-assessed variable. The data were cross sectional; therefore, it was not possible to know which variable, teacher influence or academic motivation, occurred first. Ambiguous temporal precedence can be avoided by using (1) cause and effect variables in which the order of occurrence is known, (2) designs that require that the cause be manipulated, or (3) a design that measures the cause and effect on two separate occasions – such as in a Cross Lagged Panel design described later.

Selection

This is when systematic differences between unit characteristics in each treatment condition could affect the effect due to a nonrandom assignment procedure – due to either self-selection or a criterion-based assignment. Selection most commonly occurs when it is not feasible or ethical to randomly assign participants to treatment conditions. For example, Gormley *et al.* (2005) investigated the effect of a pre-kindergarten program on academic success in the first grade. Rather than randomly assigning children to conditions, parents chose whether or not to enrol their children into the program. However, it is unlikely that children whose parents enrolled them in the program were identical to the children who were not enrolled. If the children in the treatment group were systematically different (i.e., raised by parents with high educational values) than children in the control group before the intervention, it is difficult to conclude that the significant effects found by the researchers can be attributed to the prekindergarten program. When selection is a plausible threat to validity, researchers can assess

the likelihood of its influence on an effect by using a pretest–posttest nonequivalent control-group design described below. To correct for the bias attributed to selection, a variety of statistical corrections can be made to account for the bias – assuming that the factors that influence the selection bias are known and measured.

History

This is when events occur simultaneously with the treatment and could affect the outcome. This is a concern in any field research study using a within-subjects design, since people cannot usually be isolated from outside influences that may affect the outcome. One way to determine whether or not history is a plausible threat is to add a control group to a within-subjects design, such as in a pretest–posttest control-group design. For example, Trautwein *et al.* (2008) investigated the relationship between physical self-concept and physical activity in children. Although all students showed a decrease in physical concept over a 15-month period, students in classes with high class-averages of physical ability tended to demonstrate a greater decline in physical self-concept over time. However, they could not rule out the possibility that other events or situations, such as a competitive sports season or parental demands, could have contributed to self-concept. Any additional, unmeasured variables that occurred concurrently with the physical education classes provide plausible evidence for history. To their credit, the researchers used a variety of methods to reduce threats to internal validity. They compared several levels of the treatment (class-average of physical activity), allowing for comparison groups; and they statistically controlled for several covariates that might have affected self-concept.

Maturation

This is when a natural development over time occurs during the same timeframe as the treatment and could affect the outcome. This is a similar problem as history, but is most likely to occur among any group of participants that will likely mature relatively quickly over the time that within-group measures are taken. Typically, maturation can be assessed employing the same methods used for history. However, an excellent example of controlling for maturation can be seen in the Santor *et al.* (2007) study on school-based interventions designed to help boys and girls with behavioral problems. When using different age groups to compare treatment and control groups, it can be difficult to know whether the results are derived from the intervention or are normal developmental changes. In this case, the researchers attempted to account for potential maturation by giving the intervention to

eighth graders and using seventh and ninth graders as the control groups. If they had found a reduction in behavioral problems for both eighth- and ninth-grade students, then maturation would have been a likely threat. However, because the effect was only found for the eighth graders, maturation could be ruled out as a threat.

Regression to the Mean (also Referred to as Regression or Statistical Regression)

This occurs when participants are selected based on their extreme scores, but have less extreme scores on other measures, appearing as if an effect occurred. This most often occurs when researchers use unreliable measures or heterogeneous units to match participants' treatment and control scores. This can occur either when the control score is a pretest measure taken from the same participant or if it is an outcome measure taken from another participant in a control group who is matched to the treatment participant using a matching variable. For example, Lau-Barraco and Dunn (2008) examined alcohol-treatment interventions among college students. They compared a positive expectancy challenge intervention to a traditional alcohol educational program and a control group with no intervention using expectancies in alcohol consumption and drinking behaviors as the outcomes. Individuals with extremely high pretest scores were most likely to demonstrate a difference in the outcomes. Since there were several individuals with drinking problems, the results were biased in favor of the intervention. In this case, regression to the mean could have been reduced by using participants whose outcome scores were more stable. In other cases, regression to the mean can be avoided by using more reliable measures or an aggregate of several measures to match treatment observations to control observations.

Attrition

Attrition occurs when units drop out of the experiment after being assigned to treatment conditions. This is less problematic if they drop out randomly (i.e., the reason they drop out is not related to the experiment) than nonrandomly. However, if participants who drop out of the experiment are systematically different in their responses than those who remain, this type of attrition – known as differential attrition – is a considerable threat to validity. An example of attrition is seen in DeNeui's (2003) study investigating the relationships between personality and participation in campus activities and sense of community. Although 314 individuals completed the first set of measures at the beginning of the school year, only 120 individuals completed the second set of measures at the end of the school year. Because those who

dropped out scored differently on two of the personality measures than those who remained in the study, differential attrition was evident. These differences might have led to his conclusion that students' sense of community did not increase over the school year.

Testing

Testing occurs when repeatedly exposing units to a test may permit them to learn the test, appearing as if a treatment effect occurred. This is likely to occur when an outcome is measured more than once from the same participants. For example, Powers Rock (1999) assessed the effects of coaching on the SAT I: Reasoning test. For the participants who had taken the Preliminary SAT/National Merit Scholarship Qualifying Test (PSAT/NMSQT) or the SAT more than once, Powers assessed the change in scores. Even after accounting for selection into conditions, they noted that many of those in the control group demonstrated an increase in SAT scores from previous testing. Therefore, it is quite possible that some students in both the treatment and control groups had benefited from taking previous or practice tests. Although testing can be reduced by increasing the amount of time between measures, a Solomon four-group design provides evidence as to whether or not testing has occurred.

Instrumentation

This occurs when changes in the instrument used to measure responses provide different results for the outcome, appearing as if an effect occurred. This often occurs when observations are taken over an extended period of time and a measure is revised. For example, Pettapiece (2007) used data that had been collected from a clinical sample over several years to assess growing behavioral problems in adolescents. When data collection began, clinicians were using the Personality Inventory for Children (PIC) to measure behavior. However, in 2001, the PIC-2 was published, and the clinics from which she obtained her sample replaced the PIC with the PIC-2. Therefore, part of her sample was measured using the PIC and part was measured using the PIC-2. If she had found an effect by comparing participants measured with the PIC to those measured with the PIC-2, the apparent effect may have been due to the change in the instrument, not due to an intervention. Although instrumentation can be avoided by using the same measure over time, this increases the likelihood of testing. One way to determine if instrumentation may be a threat to internal validity is to use the same methods used to test concurrent validity. Both the current and previous measures are given to the same participants at the same time (in a counterbalanced

order to reduce testing). The correlation between the measures should be close to one if the measures are giving the same results.

Additive and Interactive Threats to Internal Validity

These occur when the impact of a threat can be compounded by, or may depend on the level of, another threat. For example, Moss and Yeaton (2006) evaluated a program intended to improve college students' English-composition skills. To serve students who needed help the most, only those with low scores on a placement test were assigned to the treatment program. As a result of being in the treatment group, these students delayed enrolling in the required English courses. Students with high test scores were assigned to the control group and could enroll in the required English courses immediately. The effectiveness of the program was determined by comparing the grades from the required English courses between the treatment and control groups. Because those in the treatment group would have earned their grades a semester later than those in the control group, it is possible that other factors could have influenced the grades the treatment group received. For instance, having had an additional year in college could have permitted the treatment group to acclimate to college expectations and testing situations, giving the treatment group an advantage. This could have created an interaction between selection and maturation. History could have also added to these threats if students also learned how to improve their compositions skills through writing term papers for other classes.

Design Features

To reduce the risk of a threat occurring or to diagnose its presence and impact on internal validity, researchers can add certain features to basic designs to improve the validity of causal inferences made from experiments. These design features include (1) adding observations before (pretests) or after (posttests) a treatment to examine trends over time; (2) adding more than one treatment or comparison group to serve as a source of inference about the counterfactual (what would have occurred to the treatment group if they had not received the treatment); (3) varying the type of treatment, such as removing or varying a treatment; and (4) in the event that random assignment to conditions is not possible, using nonrandomized assignment methods that the researcher can control, such as a regression discontinuity design. Most experiments use one or more of these design features. However, the more elements that are included in designs, the more likely that researchers can diagnose or minimize the plausibility of threats to validity.

Designs that Improve Internal Validity

A pretest–posttest control group design assesses the likelihood that history and maturation are plausible threats to internal validity. Participants are randomly assigned to treatment conditions and all participants are measured at pretest, in which the outcome (or effect) is observed prior to an intervention (cause), and again at posttest, in which the outcome is measured after the intervention. The design can be diagrammed as:

$$\begin{array}{c} RO_1 XO_2 \\ RO_1 O_2 \end{array}$$

in which *R* indicates that participants were randomly assigned to conditions, *O*₁ is the pretest observation, *X* indicates that an intervention was administered, and *O*₂ is the posttest observation.

A two-factor, mixed-design analysis of variance (ANOVA) can be used to assess a treatment effect. A treatment effect is evident when there is a significant interaction between time of observation and treatment condition. If the intervention is responsible for the outcome, there will be a change in scores from pretest to posttest for the treatment group, but not for the control group. If there are changes in scores from pretest to posttest for both groups, then history and maturation are likely threats to internal validity.

Olusi (2008) used this design to study secondary school students' use of computers to solve mathematic problems. Participants were randomly assigned to either the experimental or the control group. The experimental group was taught mathematics using a computer-aided learning intervention and the control group was taught mathematics using their traditional method of instruction. All participants took a pretest and posttest of mathematic ability, allowing the researcher to assess how both groups changed over time. The treatment group had a greater increase in scores from pretest to posttest than the control group, indicating a treatment effect for the intervention.

A pretest–posttest non-equivalent control group design assesses the likelihood that selection is a plausible threat to validity. In this design, participants are not randomly assigned to treatment conditions nor do researchers know the mechanism for assignment; in many cases, participants self-select into conditions. Like in the previous design, participants are measured at both pretest and posttest. The design can be diagrammed as:

$$\begin{array}{c} NRO_1 XO_2 \\ NRO_1 O_2 \end{array}$$

in which *NR* indicates that participants were not randomly assigned to conditions.

The ANOVA used with the previous design is also used with this design. A significant difference between pretest scores indicates that selection is a likely threat.

If treatment and control groups are not equivalent before the intervention, any differences at posttest cannot be interpreted as an effect. To adjust for the threat to selection, a simple – but not always effective – solution is to use an analysis of covariance (ANCOVA), in which the dependent variable is the posttest scores and the covariate is the pretest scores. This analysis controls for the bias of the pretest scores; however, it does not account for any unobserved bias, variance that is not measured by the pretest scores, but which may contribute to the posttest scores.

McGarvey *et al.* (2004) used this design to study obese children of preschool age. The investigators had access to two similar state clinics that provided nutritional information and services to preschoolers. Rather than being randomly assigned, all of the participants in one clinic were assigned to the treatment condition and all of the participants from the other clinic were assigned to the control group. The treatment group received an intervention that focused on increasing healthy activities and the control group received standard clinical services. Both groups were administered batteries of pretests and posttests that measured daily activities, fruit and vegetable consumption, and physical activity. Because the treatment and control groups did not differ on any of the outcome measures (or most of the covariates) at pretest, selection was not likely to have threatened internal validity at posttest.

A solomon four-group design assesses the likelihood that testing is a threat to validity. In this design, participants are randomly assigned to one of four conditions: (1) treatment with pretest, (2) control with pretest, (3) treatment without pretest, and (4) control without pretest. The design can be diagrammed as:

$$\begin{array}{c} RO_1 XO_2 \\ RO_1 O_2 \\ RXO_2 \\ RO_2 \end{array}$$

A two-factor ANOVA is used to assess (1) a treatment effect – whether posttest scores from the treatment group were different from those in the control group; (2) a testing effect, whether the groups who received the pretest had posttest scores that were different from those who did not; and (3) whether taking a pretest interacts with treatment effects. A significant interaction between treatment and pretest suggests that exposure to the pretest may influence the treatment effect. If there is not an interaction, a significant main effect for treatment indicates that the treatment had an effect, and a significant main effect for the pretest indicates that pretest may influence posttest.

Kvalem *et al.* (1996) used this design to study condom use among high school students. Researchers randomly assigned 124 classes of students to one of the four groups described above. One of the treatment groups and one of the control groups were administered a pretest consisting

of a measure assessing behavioral activities. Two groups received an intervention in which the teens formed solutions to cope with negative behavior, and all of the participants were administered two posttests, 6 and 12 months after the intervention. At the 6-month posttest, researchers found that the group that received both the pretest and the intervention differed from the other three groups. Because there was no difference between the two control groups, the pretest alone did not contribute to the effect. However, because there was no difference between the two posttest-only groups, the treatment alone did not cause an effect.

A regression discontinuity design is a design that may be used to avoid selection, although it does not control or test for it. Participants are assigned to conditions by an assignment variable, which does not need to be related to the effect, but it must be continuous. A cut-off value, usually the mean of the assignment variable, is determined. Those who score above the cut-off are assigned to one treatment condition and those scoring below the cut-off are assigned to the other condition.

An ANCOVA is used to account for the relationship between the assignment variable and the outcome and provides an unbiased estimate of the treatment effect. If the treatment effect is statistically significant after accounting for the assignment variable, we can safely assume that the treatment is making its own contribution to the outcome without being confounded by other variables. Although this design still requires that the researchers control assignment, it is easier to account for variables that may influence participants' selection into conditions.

Moss and Yeaton (2006) used this design to assess the impact of developmental English programs within a college setting. Because their intervention was meant to improve English composition, researchers believed that students with deficiencies in composition would benefit most from this program. Therefore, they used English placement-test scores as the assignment variable. Those who scored below the university's score requirement were placed in the treatment group and those who scored at or above the requirement were placed in the control group. The treatment group took a developmental course in English composition before enrolling in the required English

courses, and those in the control group enrolled in the required English courses without additional assistance. The effectiveness of the program was determined by comparing the course grades between the treatment and control group, while accounting for the placement test scores.

A cross lag panel design assesses the likelihood that ambiguous temporal precedence is a threat to validity. This design is used when participants are not randomly assigned to conditions and the cause is not controlled by the researchers; therefore, it is not clear whether or not the cause preceded the effect. Both the cause and the effect are measured at two different time periods. In some cases, there is not a clear treatment or control group; instead, the cause may be the extent or strength of a characteristic and is measured by a continuous variable rather than a dichotomous one (Figure 1).

The relationships designated by the arrows can be measured by a path analysis or a series of correlations. If the cause did precede the effect, then the path coefficient (or correlation) between the cause at Time 1 and effect at Time 2 should be larger than the path coefficient between the effect at Time 1 and cause at Time 2.

Van de gaer *et al.* (2008) used this design to assess how class participation affected achievement in mathematics. Students were measured on four occasions as they progressed from the seventh grade through the twelfth grade. Path analyses (structural equation modeling) were used to predict achievement from participation and vice versa. As expected, researchers found a stronger relationship between the two variables when participation was modeled as the cause and achievement was the effect than when achievement was modeled as the cause and participation was the effect. Therefore, the researchers could reasonably conclude that participation preceded achievement in mathematics.

Statistical Adjustments

The best way to ensure internal validity is by using good research designs. However, there are cases in which using good designs may be unfeasible, either because certain assignment methods are not ethical or participants are

Figure 1 A Cross-Lag Panel Design.

unwilling to provide additional measures. One alternative when forced with a weak design is to statistically adjust outcomes. Common adjustments when selection is a threat include matching, stratifying, covariate adjustment, or weighting by a single variable, multiple variables, or an aggregate score of several variables, such as a propensity score. Ideally, the variables used for the adjustment should be related to both selection into conditions and the outcome of interest.

Because attrition can be difficult to control through designs, researchers must often correct for attrition using statistical adjustments. Many researchers simply exclude participants who fail to complete the treatment or the measures from analyses. While this is the simplest method and makes the fewest assumptions about unknown outcome values, dropping participants reduces statistical conclusion validity (i.e., statistical power) and external validity. Some researchers prefer to keep the participants with missing data, but assume that outcomes are either zero or do not change from pretest to posttest. A last-value-forward procedure uses the last available outcome measure for the subsequent, unobserved measure. In an intent-to-treat analysis, researchers analyze those assigned to the treatment conditions, but who dropped out, as if they had actually received the treatment. Both of these methods tend to underestimate true treatment effects, thereby affecting statistical conclusion validity. Another way to retain subjects with missing values is to impute missing data, in which researchers attempt to predict the missing values based on the available data. There are several methods for doing this (i.e., hot-decking, multiple imputation, and single regression imputation); however, all of these methods assume that data are missing at random – that is the values that are missing are not systematically different from the values that are present.

While statistical adjustments have been shown to reduce some of the threats to internal validity, each of these methods have their limitations and some may even reduce other types of validity in an attempt to control for internal validity. Therefore, researchers should always be encouraged to use good designs over elaborate statistics whenever possible.

Glossary

Counterfactual – What would have happened to the treated in the absence of the intervention.

Fixed – Time invariant.

Quasi-experiment – Investigation with experimental treatments or manipulations but without random assignment of subjects to the comparison conditions from which the impact of the intervention is inferred.

Selection bias – Probability that differences among treatment conditions could plausibly be attributed to preexisting differences among the treated.

Random Assignment and the Search for ‘What Works’

Evidentiary claims warranting action (e.g., the adoption of an educational policy, the enactment of a curriculum, the implementation of a school reform, the provision of funds to support the development of an intervention) typically require the strongest possible indication that the action taken will result in the desired outcome. Thus, the movements to promote evidence-informed policies and to establish what does and does not work to improve educational outcomes are closely linked to efforts to strengthen the scientific basis of educational research.

Random assignment to treatment conditions is an important technique for establishing the credibility of inferences regarding causal relationships among variables. Accordingly, many view random controlled trials (RCTs) as a necessary step in forging the chain of evidence that justifies the commitment of resources beyond proof-of-concept and efficacy studies to establish effectiveness and the potential scalability of an innovation. Random assignment is not, however, the only method for providing robust evidence of the probability that some effect was produced by some cause. Reviewed here are four other methods for approximating a random assignment condition: (1) regression discontinuity (RD) designs, (2) propensity score matching (PSM) techniques, (3) instrumental variables, and (4) fixed effects models.

The Role of Random Assignment in Investigating Relationships Among Variables

Evidence regarding relationships among variables may be descriptive (recording observations of the characteristics of the phenomenon or variables of interest), associative (describing the relationship between one set of changes and another), primarily by correlational analyses (that test the strength of that relationship), or causal (indicating which produces – and which results from – the other). The ability to assert a causal relationship between an intervention (such as a reading program) and an outcome (achievement) – in a more extended form, an intervention and variations in populations of interest (e.g., race, ethnicity, and gender) and other contextual variables (e.g., average classroom academic performance) – requires robust evidence of a strong probability that the former will produce an effect (a change) in the latter.

To produce such evidence, one must simultaneously rule out or control for factors (e.g., unexpected independent variables, or unexpected differences or differential changes in the study's subjects) that might otherwise contribute to observed changes in the dependent variable. Experimental trials, in which subjects and/or their contexts are deliberately manipulated, are designed to determine the probability that the independent variable (intervention or treatment) produces (is the cause of) an observed effect.

In ruling out alternative explanations for an observed effect, it is critical to ensure that those whose futures the investigator expects to alter when he/she intervenes by administering the intervention do not differ in important ways from those in the comparison (control) condition. The latter group provides an estimate of the counterfactual – what would have happened to the treated in the absence of the intervention. For this untreated group to serve as a reasonable proxy of the counterfactual in the treatment group, the two groups must be as similar to each other as possible on the full range of (observed and unobserved) characteristics that might alter the effect of the intervention. Investigators who select dissimilar subjects into their experimental and control groups introduce selection bias into their studies, thus constraining the internal validity of their findings.

Threats to the internal validity of a study's findings undermine the experimenter's ability to rule out (or reduce to a very low probability) the possibility that factor(s) other

than the intervention account for changes in the dependent variable. When internal validity is in question, a correlation between variables may be well documented, but assumptions regarding the causal nature of the relationship cannot be adequately supported and potential confounds cannot be excluded. (Threats to external validity also affect the confidence that can be placed in the intervention – in this case, confidence that the intervention will have similar effects in other settings, e.g., when introduced with different subjects, in different contexts.)

Random assignment of subjects to treatment and control conditions by definition addresses this problem by using an unbiased selection mechanism (chance) to reduce to zero the probability that preexisting differences among those who do and do not receive the intervention will affect the outcome. This is not the same as eliminating differences between treatment and control groups (sampling imbalances); instead, randomization yields comparably unbiased groups, such that with enough replications sampling differences can be identified and effects more accurately estimated. On average, any observed differences among treatment conditions will not be attributable to any preexisting differences across the groups, provided enough subjects are randomly assigned to the various comparison conditions.

Challenges and Costs of Employing Random Assignment in Field Settings

The circumstances which make it challenging to employ and/or maintain randomization in field studies are widely acknowledged and documented in the literature. The most forceful arguments against random assignment are those with a moral or ethical dimension. Examples include (1) the absence of proof of concept (i.e., instances in which the chain of evidence does not yet establish the likely benefit of the new alternative), so that moving to an experiment is too risky; and (2) situations in which the treatment is having extreme positive or negative effects on the population, calling for early termination of the experiment (e.g., a retention program that diminishes students' attendance).

Other challenges in achieving and maintaining random assignment include: (1) problems of implementation (e.g., treatment noncompliance and attrition); (2) the likelihood that spillover, bleeding, or contamination (when features of interventions become known and reproduced and/or their impacts affect those in the control group) will result in atypical responses; (3) the ability to document any non-intervention resources available to the control group that might not have been available to the treatment group, absent the experiment (to establish accurately the true comparison condition, and how well it actually approximates the counterfactual); and (4) the resources necessary

to implement and maintain random assignment in social settings. Careful consideration of the investigation's capacity to address these challenges helps to ensure resources channeled to educational research are likely to generate an appropriate rate of return (in the form of sufficiently robust evidence). Other challenges, not unique yet important to consider in planning RCTs, include (1) the capacity to detect treatment effects (e.g., sufficient information to estimate the number of subjects required to detect meaningful intervention effects – i.e., to conduct a statistical power analysis); and (2) the ability, in longitudinal studies, to track members of the treatment and control groups over time.

The RCT is an ideal mechanism for avoiding the challenge to internal validity posed by selection bias, and while there are acknowledged challenges to implementing RCTs in educational and other settings, there are also many resources available to those committed to random assignment; see, for example, Shadish *et al.* (2002). It is important to underscore, however, that random assignment does not address other potentially confounding factors. For example, history can only be satisfactorily ruled out as the potential cause of an observed change when other conditions are systematically controlled – for example, isolating subjects from other events that could produce (or affect the extent of) an observed effect. Thus, even an experiment with random assignment may not yield results warranting causal inferences. The question is whether causal inferences can be justified based on evidence from investigations without random assignment.

Four Methods for Approximating Random Assignment

Where random assignment is not feasible or possible, alternative techniques for assigning subjects to treatment conditions should be employed to reduce selection bias, thus increase the confidence that can be placed in research evidence.

Regression Discontinuity Designs

The RD design is generally considered as the best alternative to random assignment as this is the only other design capable of yielding unbiased estimates of average treatment effects (see Cook, 2008). Importantly, RD designs can be used to assess observational data in a way that mimics pretreatment assignment to unbiased groups. For example, students apply for scholarship aid based on their grades, test scores, etc. Then a committee decides the cut-point and selects those above the mean for the scholarship. Using an RD design, one outcome of interest would be if students not selected for scholarships continued in their program of study at the same level of success as those who received the scholarship.

First applied in education by Thistlethwaite and Campbell (1960), the RD design is one of a class of quasi-experiments – that is, investigations with experimental treatments or manipulations but without random assignment of subjects to the comparison conditions from which the impact of the intervention is inferred. Lord noted “If the individuals are not assigned to the treatments at random, then it is not too helpful to demonstrate statistically that the groups after treatment show more difference than would have been expected from random assignment – unless, of course, the experimenter has special information showing that the nonrandom assignment was nevertheless random in effect” (Lord, 1967: 38; cited by Tallmadge and Horst, 1976). In the RD, this special information is that individuals at the point of discontinuity in the predicted regression line are in effect randomly assigned to the treatment and control condition.

The logic of the RD design is that subjects immediately adjacent to a cutoff score on a continuous pretest assignment variable are sufficiently similar in other respects, that those assigned to the control group provide a reasonable proxy of the counterfactual for those assigned to the treatment group. In essence, the RD design assumes such cut-points to be arbitrary, so that the populations of individuals at, immediately above, and immediately below the cut-point are fundamentally similar in all other respects than their scores on the assignment variable.

Since groups thus comprised are probabilistically equivalent, comparing the groups’ posttreatment outcomes yields an unbiased estimate of the effects of an intervention (an observed discontinuity in outcomes warranting causal inference of a treatment’s impact). Such discontinuities are observed by controlling for prior achievement so that any jump in separate regression lines for the two groups at the point of assignment (seen when posttest scores are plotted on the vertical against pretest scores on the horizontal) is interpreted as a (simple, main) treatment effect. For example, Jacob and Lefgren (2004) compare students just above with those just below the criteria for promotion from third to fourth, and from sixth to seventh grades used by the Chicago Public Schools to investigate the impacts of summer school and grade retention on subsequent academic achievement. Ludwig and Miller (2007) use variations in funding levels across areas (counties) to examine impacts of the Head Start program.

Used prospectively, RD designs assign subjects to treatment conditions on the basis of cut-scores. Used retrospectively, RD designs mine observational data sets that record outcome variables of interest (e.g., student achievement on standardized test scores) for those previously assigned to various treatment conditions (e.g., participation in a summer bridge program, in a remedial instructional program, or in an accelerated instructional program) on the basis of a specified cut-score. In either case, the treatment assignment mimics a natural experiment.

The connection between preintervention status on outcomes of interest (scores on assignment variables) and treatment status – a defining feature of RD designs (and not characteristic of random assignment) – does have potentially negative consequences. Chief here are the larger sample sizes required to establish genuine intervention effects (i.e., to distinguish chance from actual differences between the treatment and control conditions). The minimum detectable impact (commonly expressed in effect size units) that a particular design has a high probability of documenting is calculated in a statistical power analysis. Such analyses have demonstrated that the sample size required to reliably detect these real (albeit minimal) impacts is substantially larger for RD designs than for studies in which subjects are randomly assigned to treatment status. Schochet concludes, in the case of clustered (e.g., school-based) designs frequently employed in educational impact evaluations, that “[s]chool sample sizes typically need to be about three to four times larger under RD than RA [random assignment] designs to achieve impact estimates with the same level of precision,” (Schochet, 2008: 33), a consideration which may render RD designs prohibitively expensive or otherwise impractical.

Other important questions to be considered in weighing the appropriateness of RD designs include:

- Can additional evidence on the sample just at, above, and below the cut-score be provided, or can additional selection criteria (e.g., matching procedures) be employed, to ensure their comparability?
- Are those near the cutoff sufficiently similar to others on the distribution to be considered representative of a (somewhat) larger group, or sufficiently different that they should be construed as a separate population (a key issue in considering the potential generalizability of the RD study findings)?

Cook (2008: 651) observes that “causal inference is most warranted near to the cutoff,” yet notes that “if the repertoire of sensitivity tests for functional form can be routinely extended to include a pretest, a matched but nonequivalent group or, at last resort, a nonequivalent dependent variable, then better counterfactual estimates of functional form will be possible and reliance on unobserved extrapolations will be less. By moving to a difference in differences strategy for RDD, we may achieve reasonable estimates of whether a causal conclusion should be limited only to the cutoff area.”

RD designs lack the statistical power of studies with random assignment, and are generally considered theoretically inferior to the latter. Such considerations notwithstanding, RD designs are widely acknowledged to be “superior to all other known causal methods” in the “circumscribed set of circumstances where an experiment might not be feasible” (Cook, 2008: 652) described above.

Propensity Score Matching

Another way to control for potential selection bias is to examine the outcomes of those whose tendency to receive a treatment is described in terms of a propensity score that balances analytic samples of the untreated against the treated on a range of observable characteristics that predict but are unaffected by participation. Developed by Rosenbaum and Rubin, the PSM technique acknowledges that the comparison condition could contain individuals never intended to receive the treatment. Thus, population average treatment effects distort understandings of the likely impact of the intervention on its intended audience. Propensity scores establish the tendency to receive the intervention (i.e., to be included in the treatment condition) given particular – observed – characteristics. These scores can then be used to compare to the treated a subset of the untreated whose outcomes more reasonably represent the counterfactual.

The capacity to isolate comparable groups with equivalent propensities to be selected into the treatment and control conditions requires: a comprehensive assessment of relevant pretreatment characteristics; extensive information on participants and nonparticipants; and confidence that a variety of assumptions can reasonably be made. For example, the data available to the investigator must be sufficient to warrant the assumption that all variables influencing both assignment and outcomes can be observed (“unconfoundedness,” see Rosenbaum and Rubin, 1983). Outcomes “must be independent of treatment conditional on the propensity score,” the conditional independence assumption (CIA), (Caliendo and Kopeinig, 2008: 38). In addition, every subject’s (potential) outcomes must be independent of others’ treatment status – the stable unit treatment value assumption (SUTVA, see Rubin, 1980; Holland, 1986) – including peer and general equilibrium effects (see Caliendo and Kopeinig, 2008: 66).

Caliendo and Kopeinig, who provide a helpful overview of the steps required, conduct a study employing PSM, including:

1. selecting the model and specifying the variables to be employed in estimating the probability of assignment;
2. choosing an algorithm for matching based on that propensity score (e.g., nearest-neighbor matching with or without replacement);
3. checking for overlap and common support;
4. checking the quality of the match; and
5. assessing the sensitivity of the estimates of treatment effects.

They also highlight practical considerations (e.g., opportunities to participate in multiple, heterogeneous programs or treatment states simultaneously) that can bedevil efforts to implement PSM. Luellen, Shadish, and Clark provide a general introduction to (and practical

advice for undertaking) propensity score analysis, and a comparison of “three different methods for computing propensity scores on a data set” documenting “the change in observable bias associated with each method relative to a randomized experiment consisting of participants from the same population as those in the quasi-experiment” (Luellen *et al.*, 2005: 549).

PSM is ideally suited for use in situations where random assignment to a treatment condition (e.g., retention in one or promotion to another grade, see Hong and Raudenbush, 2005) would be problematic, and where sufficient information is available to construct matched groups of treated and untreated subjects with equivalent propensities to be assigned to the treatment condition. The quality of the data available to the investigator is critical for PSM to succeed in approximating random assignment, making this technique particularly suitable in analyzing large-scale observational data sets. PSM is not a desirable approach, however, to approximating random assignment where credible information supports likely relationships of unobservables to outcomes.

Instrumental Variables

When propensity score matching’s strong assumption of unconfoundedness is not justified by the data available, steps to reduce selection bias must account for unobservables (see Caliendo and Kopeinig, 2008: 35). One way to do so is to introduce into the model a variable which prior knowledge suggests (1) has no independent relationship with the outcome variable of interest, (2) does have a (at minimum, associative) relationship with the independent variable, and (3) is not correlated with other (unobservable, omitted) variables that may directly effect the outcome (dependent) variable. In other words, the new – instrumental – variable is related to the dependent variable only indirectly, through its relationship to the independent variable.

Originally developed to address problems other than selection bias, instrumental variables “solve the omitted variables problem by using only part of the variability” in the hypothesized cause “– specifically, a part that is uncorrelated with the omitted variables – to estimate the relationship between” the hypothesized cause and the effect of interest (Angrist and Krueger, 2001: 73). In the example, this quote from Angrist and Krueger references, the hypothesized cause of an effect on earnings is schooling. The two instrumental variables employed to estimate a rate of return (the dependent variable, expressed in earnings) of schooling (the exogenous independent variable, operationalized as the highest grade of school completed) were birth date and compulsory schooling laws. Birth date (expressed by quarter of birth) was judged a valid instrument for schooling as it “is probably unrelated to the person’s innate ability, motivation or family connections” – other factors that might reasonably be hypothesized to

condition the effect of the treatment on the outcome of interest (Angrist and Krueger, 2001: 74). Compulsory schooling laws determine legal dropout ages. Such policies often produce natural experiments suitable for inclusion as instrumental variables in analyses of observational data.

Analytically, instrumental variables rescale (downward) the impact of the treatment on the outcome of interest to only that portion of the potential treatment effect associated with the instrument. Reducing the estimate of the effect of the treatment by focusing only on the variability in the intervention associated with the instrument controls for the possibility that other, unobserved variables might interact with the intervention to enhance/inflate its impact on the outcome of interest. When this scaled-down estimate concurs with an analysis (e.g., ordinary least squares (OLS) regression) of the relationship between the treatment and the dependent variable, one can more confidently infer that the magnitude of the effect is genuine, (i.e., not affected by omitted unobserved variables). Conversely, when the (scaled-down) instrumental variables estimates are substantially lower than those obtained from an OLS analysis, it would appear that unobserved variables do have important impacts on the dependent variable.

As demonstrated by Angrist *et al.* (1996), the instrumental variables approach can also provide “an alternative to a more conventional intention-to-treat analysis” – for example, when random (thus ignorable) assignment does not map directly to the (therefore nonignorable) treatment received. In such cases, treatment assignment can itself be used as an instrumental variable (see, e.g., Nye *et al.*, 2004: 247). Consider the case in which implementation challenges (e.g., noncompliance) mean randomization was not achieved as intended. In such cases, the investment in the planned RCT may be at least partially recovered if the assignment (e.g., families assigned to use vouchers) is associated with the treatment (e.g., voucher use) but independent of that treatment is not associated with the outcome of interest (e.g., school achievement), the conditions necessary to undertake an instrumental variables analysis (see Hedges, 2008).

The use of instrumental variables to rule out or confirm the likely effects of unobservables is not without criticism, for example, concerns that underlying theoretical relationships need not be specified in advance; that subjects may react differentially to the instrument, making it difficult to interpret estimates with heterogeneous responses (see, e.g., Angrist and Krueger, 2001; Imbens and Angrist, 1994). These concerns notwithstanding, Angrist and Krueger conclude that “instrumental variables methods often solve the first-order problem of eliminating omitted variables bias for a well-defined population,” (Angrist and Krueger, 2001: 78). Importantly, instrumental variables can be employed to address potential selection bias arising from unobservables with cross-sectional

(e.g., posttreatment) data only. For longitudinal and other dependent group designs (e.g., pre-postintervention studies), it may be desirable to employ fixed effects models.

Fixed Effects Models

A second approach to correcting bias in estimated treatment effects associated with unobservables is to adjust for the presence of time invariant (i.e., fixed) individual characteristics “that may be associated with selection in to the treatment group,” (Schneider *et al.*, 2007: 42). Examples of such invariant characteristics include the household characteristics of siblings who do and do not receive specific interventions, for example, attend Head Start in Currie and Thomas’ (1995) analysis of the impacts of that program. By examining the impacts of siblings from the same household who did and did not attend Head Start Currie and Thomas were able to account and control for the household effects which were treated as fixed (the same) for each sibling in the household. In this way, they were able to demonstrate that those who attended Head Start outperformed those who did not, despite the overall lower-than-average achievement of children in Head Start programs (see Schneider *et al.*, 2007: 43–44).

Fixed effects or “difference-in-differences” estimators assess first the differences between pre- and postintervention outcome measures “for each participant and non-participant,” then “the difference between the average pre-versus post-program change for participants and . . . non-participants.” The resulting “estimator of program impact will be free of selection bias if selection into the program depends on unobserved person-specific ‘fixed effects.’” (Human Resources and Social Development Canada (HRSDC), 1998). Another way in which data on individuals can be used to control for unobserved characteristics is if the same individuals participate in two treatment conditions. For example, Bifulco and Ladd (2006) analyzed longitudinal data on student achievement that included data on the type of school (regular public or charter) the student attended. As the data set captured results for students who at one point attended charter, at another point a regular public school, Bifulco and Ladd were able to attribute to the type of school outcomes that might otherwise have been attributed to fixed (time-invariant) student characteristics, ultimately concluding that “students in charter schools scored significantly lower in both reading and mathematics” (see Schneider *et al.*, 2007: 44).

Successful use of fixed effects approaches to address selection bias clearly place substantial demands on the data available to the investigator. In contrast to the instrumental variables approach, modeling fixed effects requires longitudinal data (a minimum of one pretreatment and one post-treatment observation; see Human Resources and Social Development Canada (HRSDC), 1998). In addition to the data required to conduct fixed effects analyses, the suitability

of this approach is critically dependent upon the assumption that the unobservables in question are, in fact, appropriately considered fixed (time invariant) over the course of the study period. Clearly, this is an assumption that will not always hold (e.g., the career orientation and ambitions that affect selection into and success in educational programs may change over time; the maternal personality that affects “the likelihood both of being employed and of having good child outcomes” (Schneider *et al.*, 2007: 42) may similarly shift from time to time, affecting assessments of the impact of mother’s employment on their children, see Human Resources and Social Development Canada (HRSDC), 1998; Currie, 2003). In such cases, variations on the approach (e.g., the difference-in-differences in growth rates estimator, see Human Resources and Social Development Canada (HRSDC), 1998; Moffitt, 1991) may be appropriate.

Conclusion

Both philosophical and practical considerations argue against the possibility of unequivocally establishing the true case of many of the effects educational policies and practices are designed to bring about. The appropriate standard for experimental studies in education, as in many other fields of inquiry, may thus be the capacity to generate compelling evidence that there is a sufficiently high probability the intervention will produce the desired outcome – that is, to warrant causal inference.

Investigations which incorporate random assignment to treatment conditions reduce the probability that differences among treatment conditions could plausibly be attributed to preexisting differences among the treated (selection bias). Random assignment assists investigators in inferring treatment effects, by ruling out one critically important alternative interpretation of the cause of an effect. For this reason, experimental trials incorporating random assignment (RCTs) have a critically important role to play in the production of robust evidence of the likely causal relationships among variables.

RCTs are not, however, the only – indeed at times they are arguably not the optimal – method of estimating causal effects; absent other controls, random assignment to treatment conditions may not be sufficient to warrant causal inference. To acknowledge this is not to argue against RCTs but rather to underscore the importance of matching method to research question and circumstance. Whether research designs that approximate or ensure random assignment of subjects to treatment conditions are preferable to each other in studies which seek to establish causal relationships among variables is contingent upon numerous factors. Considerations include:

- Is it more appropriate/desirable to generalize to (narrower) populations at or near the value used to assign

subjects to treatments? (In these cases, the RD design could be preferable to random assignment; see Schochet (2008) and Heckman and Vytlačil (2005) regarding evidence warranting marginal expansion of the intervention.)

- What resources are available to devote to recruitment of subjects to an intervention, and how receptive are potential subjects likely to be to assignment based on status on a specific variable (e.g., achievement)? (Where resources are limited and subjects perceive a logical relationship between assignment variables and interventions, RD designs may be easier to implement than random assignment; see Schochet, 2008.)

Proponents of RCTs are not wrong to insist this design be employed as often as research questions and resources combine to make this an achievable ideal. Studies that employ RD designs, propensity score matching, instrumental variables, or fixed effects models can be useful when RCTs are not possible. These four methods are particularly helpful in leveraging the knowledge in large-scale, representative, longitudinal observational data sets, advancing the generation of robust evidence regarding causal relationships. Our understanding of the factors that improve educational attainment would grow at a much slower pace, and our ability to leverage extant data would be severely curtailed if we do not explore multiple methods for estimating causal relationships among populations and outcomes of interest, such as instructional techniques and student achievement.

Glossary

Bias – A term usually referring to an unwanted or extraneous source of systematic variance affecting the standard error of a treatment effect that arises from several sources (see the definition for the glossary term ‘Internal validity’). Usually, minimized or controlled through methods of statistical adjustment or stringent experimental design procedures. Selection bias occurs when there is a different probability of a unit or individual being chosen to participate in a study or assigned to a treatment condition and the characteristics of that individual are confounded with treatment outcomes (e.g., skills, motivation, or preexisting conditions are not independent of the anticipated treatment outcome).

Causal inference – Also called causal propositions, but not the same as causal explanation or causal mechanism, it concerns the expected relationship between some event B that is anticipated to always occur when A happens. The inference or supposition of existence is based on expectation that if all other possible factors that induce a relationship between A and B have been controlled, then the absolute reason for B is always A. In terms of a manipulative account of causation based on experimental work defined as using *prima facie* and, often, probabilistic evidence to infer causal relations (A causes B when the experimenter induces A always).

Confounding – A means of describing relationships between events, where A is the manipulation and B the expected outcome from A. Confounding arises because some measure C is on the path from A to B and mixes its variability so as to “falsely obscure or accentuate the relationship between them” (MacKinnon *et al.*, 2000: 174). When these variances cannot be unambiguously tested, it is usually a sign of confounding. Controlling for the confounder, usually, provides an undistorted estimate of the true relationship between the predictor and outcome in question. Unlike mediators or intervening variables – which carry a causal connotation – confounders are not necessarily posited to cause the linkage between

predictor and outcome, (i.e., spuriousness) but are merely related to one or both.

Counterfactual reasoning – A term borrowed from eighteenth-century Scottish philosopher David Hume – a staunch advocate of empiricism in experimental methods – to indicate something that is contrary to fact. In experimental work, a treatment causes an observed effect or alteration on some designated outcome; the counterfactual is what would have happened to the subjects in the absence of a treatment effect (the subjects were designated controls and did not receive the treatment).

A counterfactual inference (based on qualitative distinction) is made experimentally when a treatment condition is pitted against a control group and all other potential factors that might contribute to group differences are made identical between the two groups through statistical control.

Effect – Defined as the difference between what did happen to a treated individual (unit) and what would have happened had the treatment not worked. Requires a counterfactual model in which comparisons exist between a group of individuals exposed to the treatment (observed result) compared to a reasonably similar group held back from receiving the same treatment (unobserved result). A stable phenomenon that scientists seek to explain in terms of behavioral regularities brought about through manipulation.

Internal validity – A system of checks and balances (deductive reasoning) that enables a researcher to make causal inferences about whether a treatment or intervention affects designated outcomes while at the same time eliminating potential sources of bias (i.e., third-variable alternatives). The benchmark criteria vary but have, traditionally, included unambiguous temporal precedence, contemporary history, testing, maturation, pretesting procedures, measurement (reliability), statistical regression, differential selection, mortality, contamination (diffusion of treatment), and compensatory responses (equalization, rivalry, demoralization, etc.).

Propensity score – The probability that an individual is assigned to an experimental treatment group conditional on the individual’s covariate information.

Derived as a single scalar function (like a discriminant function) to model a cluster of individual differences variability.

Randomization – A sampling design procedure to ensure that preexisting conditions of the experimental units or observations do not influence variability in the outcomes in question. Will also assure independence of errors at the level of unit of assignment and distribute any possible bias evenly across experimental treatment conditions. Best achieved when subjects are randomly selected, randomly assigned to groups, which are then further assigned randomly to the experimental treatment conditions.

Selection – The process of picking, choosing, or assigning individuals (units) from a larger reservoir to form a homogeneous sample with regard to experimental condition (i.e., treatment vs. control). When done to create two or more probabilistically equivalent groups using strategies of randomization, serves to eliminate bias that might interfere with rendering causal interpretations.

Treatment – A declaration or demarcation of an event manipulation that is oftentimes associated with a structured program, intervention, application, or specific exposure constructed to induce behavioral change defined in terms of a measured endpoint.

Introduction

Randomization is one of many tools researchers have made available to provide experimental control. The English statistician and geneticist Sir Ronald A. Fisher (1935) was one of the first to formally introduce the need for rigorous control in experimental research in order to attribute some element of causation. The emphasis on cause and the need for control arises from a focus on manipulation to induce change in behavior. The term intervention can be used interchangeably with program, treatment, or instructional method. Most common types of interventions in education consist of curricular instruction, programs intended to change behavior (in students, the teacher, or both), improve learning and/or achievement, enrich academic success, and so forth. In psychology, the term intervention is often synonymous with therapeutic engagement (individual or group) or some specified treatment modality (Freudian vs. cognitive-behavioral). In the medical sciences, the term treatment indicates a desired physical change (i.e., reduction in symptoms) through visceral manipulation (removing or adding tissue or bone) or physiological change obtained by invoking a pharmacological drug agent. In some cases,

for instance, with psychiatry, symptom reduction can be based on both pharmacological treatment and conjunctive psychotherapy with the goal of symptom amelioration. Regardless of discipline, all references to intervention seem to accentuate a manipulation that is meant to cause something to happen. When this occurs, a behavioral scientist wants to make attributions that the change in behavior was a direct result of some manipulation controlling for other possible sources of variability that may exert an influence. The most common form of a causal statement suggests that some form of a treatment designated as a factor in an experiment results in behavioral change. In its simplest form, the factor is given two levels – one designating experimentally treated participants and the other level connoting those individuals who were not exposed to the treatment. (Conceivably, we could apply the same treatment to the same physical entity requiring only one level; however, there are major drawbacks to this process. Concerns that need to be addressed in this type of design include temporal stability (consideration of constancy of response over time), causal transience (the effect of treatment A does not linger and influence treatment B), and unit homogeneity (all of the physical entities in the study are identical, and thus order of implementation would not be of concern). Were these assumptions valid, the method of differences would apply and randomization not required). For descriptive purposes, the term treated is used to indicate those individuals or experimental units exposed to the intervention (the nomenclature E is often used) and the term control or untreated used to capture individuals assigned to a comparison condition (here C is frequently used). Randomization speaks to the process of how individuals are assigned to the different treatment levels (E and C) and the techniques used to equilibrate both measured and unmeasured pretreatment characteristics during assignment. When a randomized field trial is implemented and all other factors considered (i.e., fidelity of implementation, contamination, and differential attrition, to name a few), it is considered the gold standard for asserting causal inference.

In the case of many educational interventions, a researcher is largely invested in finding out whether a select intervention or program of instruction works by improving academic performance or boosting achievement scores in a designated sample. Here then, the focus is on derivation of a meaningful effect that comes about by contrasting treatment conditions that perform in a specific time frame on a common benchmark. The level of bias in estimating this effect is thus, largely, determined by the method of assignment of individuals or units to the various experimental treatment conditions. All things considered, if participants assigned to either the treatment group (receiving the intervention) or a comparison control group has an equal probability of being assigned to their

respective treatment condition, then the study meets necessary – but not sufficient – conditions to assert some level of causal inference (and can be labeled true experimental or randomized). Should this occur, there is much less concern with selection bias or extraneous confounding nuisance factors that may influence the outcomes in question. One of the major assumptions of randomization is that treatment assignment method is independent of any systematic pretreatment differences that could be used to characterize participants. Maintaining this stringent condition reduces the influence of potential confounds and allows a researcher to make causal assertions about the program of instruction or intervention in question (all factors considered the program or instructional method identified as the treatment is the only variable that can cause the observed differences between the groups). It is easy to see then that the absence of randomization serves as a threat to the internal validity of a study and affects the processes through which scientists make inductive inferences.

This article outlines the requirements for randomization paying particular attention to the underlying philosophical arguments surrounding cause and effect. The article briefly describes the most commonly used methods for randomization, noting what these techniques net in terms of experimental control. In addition, the article offers several alternatives to randomized assignment in the event that such manipulation is not possible or would disturb the scientific evidence. Each strategy is discussed with regard to how it stands up against the gold standard of randomization as well as noting certain pitfalls that might be encountered with inappropriate use.

Purpose of Randomization

Philosophically speaking, one can never really know why something happens nor can one predict events with certainty. To an ever-mindful child, flipping a light switch is the sole reason why the light glows and no other ulterior explanation concerning voltage, impedance, and electric current is required. However, to the more sensitive and knowing adult mind, there is considerable more to the light burning incandescent than the flip of a switch. Even though scientists operate knowing full well that they cannot assert ultimate cause, there is still the desire to learn as much about the world and our human experience as possible. As part and parcel of this epistemological pursuit, scientists engage a logic of causation using an investigative system of reasoning (i.e., inductive, hypothetico-deductive, and abductive) that provides systematic methods to clarify knowledge. This system has undergone considerable change since early Greek philosophers argued about the necessary and sufficient conditions of causation – primarily because modern physical sciences (referring

mainly to quantum physics) have cast doubt on whether one will ever observe certain events to occur, but with available mathematical precision will know with certainty (or regularity) they do occur. In an axiomatic system, scientists postulate that things will occur and then through logical deduction gather observational data to strengthen the veracity of original postulates. In subatomic or elementary particle physics, the human mind can rarely truly see events as they unfold, but the same human biocomputing machine is capable of proceeding from axioms and postulates to gather data or evidence of patterns. As a result, the changing veneer of science has stimulated a more modern treatment of the philosophy of causation; one that has fabricated a reasoned stance from which we gather evidence of stable phenomenon.

As philosophical discourse on theories of causation unfolded, philosophers became more engaged in fashioning the particulars of causal inferences and backed off the need to equate causation with explanation. Greater emphasis was placed on the methods scientists use – both in the laboratory as well as the nature of experimental reasoning used to explain their findings. One outgrowth of this emphasis is critical rationalism, which provides epistemic criteria for a scientific method emphasizing not what one knows, but rather how one ascertains what one knows. According to critical rationalism, the goals of science are to rule out false impressions and eliminate inadequate or weak theories. Philosopher Karl Popper – responsible for explicating the tenets of critical rationalism – termed this emphasis on paring away improper explanations the falsification or refutability of a theory. No matter the level of experimental sophistication even that obtained in the hard physical sciences, a theory can never be proved as true; one merely probes the value of our theories as explanations of events. Good theories are the ones that withstand tests attempting to refute them (this has been termed the logic of falsification).

This stance makes all experimental work especially in the behavioral sciences really a statement of probability articulated in terms of how likely something can be attributed to a set of events. As part of the logic of scientific method an investigator frames the null hypothesis (the outcome Y is the same regardless of whether E vs. C was administered as a treatment) by a stated conditional significance level to minimize the probability that we would observe this event ($E - C = 0$) by chance alone. Stated differently, if an investigator sets the significance level $p < 0.05$, one could expect the event expressing no difference in treatment conditions (i.e., null hypothesis) to occur 5 times in 100 trials (i.e., chance findings); whereas, the other 95 times, the investigator rejects the null in favor of an alternative hypothesis ($E - C > 0$). The alternative is part of the success of science and occurs because of some systematic reason – likely an effect produced by the treatment in question. This logic of inference helps to frame the

importance of randomization because a researcher wants to avoid chance findings and also eliminate the potential that some systematic but unknown cause was responsible for the desired outcomes.

With this hypothesis-testing framework in mind, a scientist interested in predicting a specific outcome (effect) from an experimental manipulation must rule out that extraneous or unwanted sources of variation (also termed rival hypotheses, alternative explanations, or threats to the interpretation), and also present valid explanations for the outcome – even though these sources of variance were not, directly, part of the manipulation. If the connection between two variables is causal and all other possible contributing events are known, the scientist has taken great strides to ensure the internal validity of the study. If there are plausible threats to internal validity whatever they may be – with random assignment – they are distributed equally over conditions (the extraneous variable is equally like to occur among participants assigned to receive an experimental treatment as in those assigned to the control condition). Based on the principles of randomization, if a researcher were to sample a unit or individual from one level and compare this to a randomly selected unit obtained from another level (here we expressly state that the experimental treatment has two levels), all other factors considered these units would be comparable (this is even more true with repeated samplings). In essence, randomization grapples with differences in people or resources by selecting units or individuals irrespective of any prior existing conditions that may be confounded with the outcome. While randomization cannot offset many plausible and real threats to internal validity, it is a surefire method to eliminate selection bias as a counterfactual position.

Methods of Randomization

Random assignment occurs when the procedure for assigning units or individuals to conditions is based on chance. The most ubiquitous form of randomization involves a simple coin toss. Given the equal probability of obtaining a head or tail from any single independent toss of a fair coin, this represents the simplest way to randomize subjects to experimental treatment conditions. Rolling a fair die can also achieve the same result given the probability of obtaining any number on the face of a die is one-sixth and the probability of obtaining any particular number is governed by chance alone. Simple random sampling can also be accomplished using the lottery method – which involves placing an equal number of distinctly colored small objects into a receptacle of some sort. The process of assignment for simple random sampling involves reaching into the receptacle without looking and removing the objects one by one (without replacement). There is no set or defined way to remove

each object; they are just grabbed one by one. After each object is removed, it is assigned to an experimental group in some systematic fashion. For example, the first object pulled out can assign a subject to receive an experimental treatment and the second object pulled out assigns the next subject to the control group with each successive draw assigned in the same prescribed manner. The objects can be colored pieces of paper, paper with numbers scribbled on them that match up to student or patient identifiers, or colored marbles. If a study warrants three experimental conditions with two experimentally treated groups and one comparison control group, then three colors would be used to distinguish assignment procedures. In any of the examples provided above, a simple random number generator using computing resources can be used to create numeric lists. Subjects can then be assigned on the basis of whether their identification number matches the one appearing on a list. In the event that numbers are generated that do not match, these are discarded or ignored. A researcher would move down the list until a match is found and then assign the matched number to experimental condition. To avoid tedium, multiple numbers or ranges of numbers can be used to find suitable matches for personal identifiers (all numbers ending with 1 as in 2001, 3001, and so forth would be assigned to one condition while numbers ending in 2 as in 2562, 3472, and so forth would be assigned to a different condition until all participant's numbers have been exhausted).

In order to truly benefit from random assignment, there must be sufficient numbers of units (individuals) “relative to the variability between units” (Cook and Campbell, 1979: 5). Again, this reinforces the goal of random assignment to equilibrate any potential differences that might exist before a treatment is applied. Designing a process of random assignment around two participants – one male and one female – is unlikely to achieve the desired results, particularly if gender masks other meaningful causal attributes (i.e., sex-linked differences), or has direct relevance to the endpoint. While the need for sufficient sampling speaks directly to the issue of power, it also reinforces the emphasis on average behavior across a representative sampling.

Is Randomization a Panacea?

Despite the overall emphasis on randomization as a means to control extraneous and systematic variance in an experimental framework, there are some concerns that it is not the ultimate panacea. For instance, Cook and Campbell (1979) suggest “it is indeed false to claim that randomization controls for all threats to internal validity” (p. 85). Even with randomization, threats to internal validity can arise from study attrition (i.e., loss of subjects over time), differential attrition (unequal loss of subjects from treatment conditions), and compensatory reactions. The latter

situation, often, occurs if experimental assignment procedures are meant to remove any systematic differences that may result from some privileged resources such as those obtained through status or power (socioeconomically valued factors). In the case of compensatory rivalry, participants in the untreated control condition who do not receive the benefits of an intervention begin to make claims that they too should receive the intervention (and its benefits), and thus disrupt the experiment by creating their own desirable treatment to improve the designated outcomes. Compensatory equalization, often, arises when someone in a position of authority (i.e., management or school administration) decides that participants assigned to the control condition should benefit from an intervention, and thus contaminate the assignment procedure by distributing intervention materials. Compensatory rivalry can be attenuated by promising control participants that they will receive a delayed intervention or providing something of equal value that is unrelated to the target endpoint.

In many instances, randomization is not desirable, feasible, or permissible, and this has led to proliferation of quasi-experimental designs that use various methods to approximate equivalence between experimental units. The nonexperimental group design, interrupted time series design, and other remedies (matching, stratifying, masking or blinding, cutoff-based methods, and regression adjustment with covariates) are used to contrast a treatment condition and comparison group on some outcome of interest. While these remedies afford some element of control, they do not equilibrate preexisting conditions by design, but rather by statistical analysis procedures. Even with these refinements, it is better to actively deliberate about plausible threats to validity before designing a study rather than hoping some laundry list of experimental design procedures would eliminate entirely all threats to validity. The following section explores several commonly used methods that make adjustments for sample selection bias and create the specter of randomization: propensity scores and regression discontinuity (RD).

Propensity Score Method

Propensity scores offer an alternative to randomization with observational studies or quasi-experimental designs when a researcher wants to make causal statements. Without covariate adjustments, a researcher runs the risk of obtaining biased estimates and arriving at erroneous conclusions regarding treatment effectiveness. Proper covariate adjustments for propensity or balancing scores produce unbiased estimates for treatment effects even in the absence of randomization. A propensity score is a derived measure indicating the likelihood of a subject being assigned to the treatment group based solely on that subject's covariate information. In the case of two

experimental conditions, where individuals are assigned to either receive an intervention or assigned to some type of control comparison group, the propensity score method replaces the confounding covariate measures with a single coarse function that represents the conditional probability of treatment assignment. Derivation of a conditional probability (scalar propensity) score helps adjust any differences between groups (produces an unbiased estimate of average treatment effect) based on a known set of observed covariates (i.e., pretreatment measures).

In many cases, stratification (i.e., subclassification) of the sample based on at most a few covariates would be ideal. Comparisons could then be made between the different cells with the assumption that treatment and control participants are equally represented within each cell. However, oftentimes, the number of possible confounding covariates is large, leading to the likelihood of sparse cells containing either only treatment or control participants. This would truncate the possibility of estimating a treatment effect within the particular strata. In addition, proliferation of strata from excessive covariates creates problems with cross-classification and the inability to obtain proper diagnostics on joint distributions of regressors. When this occurs, propensity score methods provide an ideal means to achieve parsimonious representation of all the different observed or known characteristics that can differentiate treatment and control participants (i.e., this multivariate difference is akin to a linear discriminant function).

Under the stable unit-treatment value assumption, scalar propensity scores are akin to a missing data problem and will satisfy this condition if the treatment assignment is strongly ignorable given the balancing score (the scalar propensity based on a vector of covariates) – that is, the relationship between treatment assignment and the designated endpoint are conditionally independent of the covariates. With a propensity score adjustment, everyone in the population has an equal chance to be assigned to either the treatment or control group, irrespective of any predisposing characteristics (covariates). Once propensity scores are created – and using the *t*-statistic as a gauge – participants can then be iteratively balanced into homogeneous bins or subclasses based on the distribution of estimated propensity scores (five subclasses or quintiles appear sufficient). The end result is that individuals located within a bin have equal probabilities of being selected into either experimental condition (treatment vs. control), and can be considered to have been randomly assigned to their respective conditions. (The propensity score method is based on the notion of equality of variance/covariances within subclasses. If balancing is not achieved, then the model must be reformulated so that the likelihood of being assigned to treatment or control based on propensity scores is equal within a subclass.) Estimates of treatment effects can then be generated within each strata

(quintile) and averaged over the number of strata created. This approach works best with large samples given the expected distributional balance on the covariates in different strata or subclasses. With smaller sample sizes, the anticipated balance may come into question as would be expected with any sample shrinkage and corresponding inflation of standard errors.

Regression Discontinuity

The term regression discontinuity (RD) connotes a type of quasi-experimental design that relies on standard regression methods to obtain unbiased causal estimates of a treatment effect. In order to create boundaries for delineating assignment to experimental condition, an investigator will create a cutoff point using an assignment variable. The assignment variable cannot be caused by the treatment, but does not have to be a pretest score equivalent in form to the posttest (a posttest score is required). It is best – as a means of increasing power – that the assignment variable has minimal overlap with treatment and often multiple assignment measures in the form of an index will improve power. The sample is then divided into two components based on this cutoff score with those scoring on one side of the cutoff assigned to one experimental condition and those scoring on the other side assigned to a different condition. For example, students scoring below the cutoff point on the assignment variable (and, perhaps, showing a deficit in performance) can be designated to participate in a remedial program emphasizing reading or mathematical skills, or some type of instructional curriculum that can enhance their academic aptitude. Those students scoring above the cutoff point are considered the control or comparison group. A scatterplot depicting the assignment scores plotted on the X or horizontal axis and the posttest scores on the Y or vertical axis might show a vertical displacement at the cutoff score if the remedial program has an effect (i.e., the treatment improves participating students' performance), whereas no change or displacement would be expected if there was no effect. The displacement can be witnessed as either a shift in means reflecting treatment benefits measured in units of the outcome or a change in slope of the regression line at the designated cutoff point. Shifts – both in means or slopes – give the name RD and the size or magnitude of the discontinuity is the size of the effect resulting from the treatment. When there is no program or treatment effect, the functional forms of the slopes will be equivalent – holding all other factors constant.

Greater confidence is gained that the remedial program was responsible for the overall treatment effect if all students below (or above) the cutoff benefit equally from the treatment. It is essential to rule out model misspecification (nonlinearity) and to ensure the performance shift in the posttest scores is clearly demarcated by the cutoff; that is,

the same treatment benefit is not observed at other random places along the plot that could support rival interpretations. Moreover, rival hypotheses would have to achieve the precise same effect, using the same markers of performance, and under the same conditions without the benefit of the cutoff. Possible threats to internal validity would have to cause a discontinuity at the precise point of the cutoff and this is highly unlikely, although not implausible. Attrition (from one side of the cutoff) could reduce power and bias the sample as can history, which can influence participants on one side of the cutoff at the exclusion of others. One caution to using this method is the effect of restricted range on variance estimates commonly known as shrinkage. The way to offset shrinkage involves the use of multiple discontinuities to retain the original variances based on a broader range of values for the predictor measure. It is also unlikely that the students in the two boundary conditions would be matched on any aggregate characteristics as encountered with propensity score methods using observed measures. These gray areas make it unlikely that this method will produce efficient and stable estimates of treatment effectiveness without large samples, precise and meaningful cutoff points for assignment, and efforts at cross-validation.

Summary

Randomization affords researchers a clear method to ensure that any differences between units or individuals assigned to experimental conditions are by chance alone. It is an optimal design strategy to fend off certain threats to internal validity and provides the foundation for true experiments seeking to make valid causal inferences. When subjects have an equal probability of being selected and assigned to an experimental condition the unique characteristics they bring to the laboratory or field experiment are equated across treatment conditions. Simply put, the goal of randomization is to seek a level of equality of subjects prior to their assignment to experimental condition. When this occurs, researchers can then make more confident assertions whether a specific manipulation results in the anticipated treatment effect by design as opposed to happening by chance alone.

In the realm of educational studies, it is not always possible to assign students (or teachers) to treatment conditions using random assignment methods. In many cases, well-known studies examining the role of school vouchers, private versus public school education, efficacy of school-based drug-prevention, grade retention, and evaluations of many remedial instructional modalities to improve learning and achievement take shape as observational, quasi-experimental studies lacking the precision afforded by random assignment. These studies tend to be more economical and less cumbersome than randomized trials;

however, the absence of complete randomization hampers scientists' abilities to make valid causal inferences. In recent years, several alternative approaches have been proposed to accommodate the necessity of controlling nuisance factors that may diminish the authority of causal attributions. With these tools in hand, a researcher is much closer to being able to state that a certain manipulation resulted in a specific effect and thus reinforce the cause–effect relationship that is the backbone of all scientific effort.

Although several viable alternatives to randomization exist, two in particular are covered in this article (instrumental variables and fixed-effect methods as possible remedies to randomization are discussed elsewhere in the encyclopedia). Propensity scores provide a parsimonious and efficient remedy to the problem of obtaining unbiased estimates of treatment effectiveness by adjusting or balancing treatment group differences based on a single composite characteristic. Any bias associated with treatment condition assignment is controlled statistically through the covariate adjustment, and subjects are balanced on their propensity for selection. Importantly, models using this approach are only as valid as the model selection process used to include covariates in the scalar function. Hidden or missing covariates can differentiate participants in ways not considered and alter the statistical outcomes or at the very least undermine confidence in any causal interpretation.

Another remedy discussed in this article involves dichotomization of samples in a way that permits investigators to make meaningful comparisons or treatment contrasts as if the subjects had been randomly assigned to discrete experimental groups. While these variants on randomization have less stringent requirements for balancing preexisting differences, they still afford a means of comparison not available with subclassification or other covariate-adjustment methods. The technique of RD works on the assumption that oftentimes natural boundary conditions mimic random assignment to treatment conditions. With RD methods, an investigator formulates the designation (assignment) of experimental versus control groups based on students achieving just above (or below) a certain threshold on some benchmark performance criteria. As a special feature, the selection mechanism using the assignment variable cutoff point is fully known (i.e., there is no measurement error), and there is no hidden bias that can influence the estimate of the treatment effect. The elegance of this approach is that it can be mixed with randomization techniques, utilize multiple cutoff points, and incorporate more than one treatment. When certain assumptions regarding internal validity are met, the resulting estimate of treatment effect is virtually unbiased.

All told, despite differences in these two popular methods to approximate randomization, both are similarly geared toward removing extraneous variance or controlling for preexisting treatment group differences that might bias

the estimation of treatment effects. Random assignment is a major canon of experimental design but not the *sine qua non* that defines experimentation. Other important components include selection of the treatment, dosage, method of dispensing treatment, measuring and timing of effects, choosing participants, the nature of comparison, and assignment protocols. Even with these additional requirements, the goal of any experimental design or sampling strategy is still to ensure that causal assertions are not mistaken, implausible, or falsifiable.

Glossary

Confirmatory factor analysis – A restricted form of factor analysis that allows testing validity of psychological measures by imposing theory-driven parameters in terms of factor loadings, factor variance and covariance, as well as error variance and covariance.

Convergent validity – The degree to which multiple measurements of the same psychological construct correlate with one another.

Correlated uniquenesses – Consistent portions of measurement errors that are assumed to embody method effects in confirmatory factor analysis models that do not explicitly specify method factors.

Discriminant validity – The degree to which measurements of different psychological constructs are distinct from each other.

Halo – Cognitive bias with which perceptions of particular characteristics, personality, or attributes influence perceptions of other characteristics, personality, or attributes.

Methods – Particular ways of measuring characteristics, personality, or attributes of individuals.

Random error – Errors in measurements that occur due to chance alone.

Reliability – The degree to which multiple measurements to measuring instruments yield consistent scores.

Social desirability – Tendency to respond to survey items in ways that are deemed more socially acceptable and to be judged favorably by others.

Traits – Particular characteristics, personality, or attributes of individuals.

Validity – The degree to which a scale or an instrument actually measures the Psychological construct that it purports to measure.

Multitrait–multimethod (MTMM) designs refer to an approach proposed by Campbell and Fiske in 1959, which can be employed for validation of psychological measures (Campbell and Fiske, 1959). The MTMM designs rest on an assumption that valid yet independent measurement procedures used for assessing the same psychological construct would produce scores that necessarily correlate highly with each other. Stated differently, if any instrument

or assessment technique under consideration is a valid measurement tool for the psychological construct that it purports to measure, then the scores so produced will not only be reliable but also (1) correlate highly with scores of the same construct assessed with different measurement procedures and (2) not correlate highly with scores of different constructs, even if they are assessed with the same measurement procedures. The MTMM designs thus offer a convenient way of simultaneously examining convergent as well as discriminant validity of a given measure.

To apply MTMM designs, multiple traits (i.e., psychological constructs) need to be assessed using multiple methods – hence multitrait–multimethod. First, researchers assess the trait or the construct of interest for a group of individuals, using at least two or more methods among various instruments and assessment techniques available. It is recommended that maximally different measurement procedures be used to more clearly establish convergent validity. Second, the researchers assess at least one more construct for the same group of individuals with the same set of multiple methods. These additional constructs should be sufficiently distinct from the construct of interest to more accurately address the issue of discriminant validity. They must also be variables that can be adequately assessed by the set of measurement procedures selected. Third, correlation coefficients among the multiple constructs, each assessed with the multiple methods, are computed to generate an MTMM matrix. This MTMM matrix forms the basis for determining whether sufficient evidence exists for the convergent and discriminant validity of the measures under consideration.

Figure 1 shows a schematic representation of an MTMM matrix, showing three traits, traits A, B, and C, each of which is assessed with three methods, methods 1, 2, and 3.

Campbell and Fiske's Approach

As can be seen in Figure 1, the coefficients in an MTMM matrix can be divided into four distinct types. The first type of coefficients are the monotrait–monomethod or reliability coefficients presented in the three reliability diagonals enclosed in clear rectangular boxes. Theoretically, these coefficients are believed to represent correlations between the same construct assessed with the same method and hence, indicate reliability of each of the nine measures. Thus, r_{A1A1} , for example, represents the reliability coefficient for trait A assessed with method 1. The second type refers to the

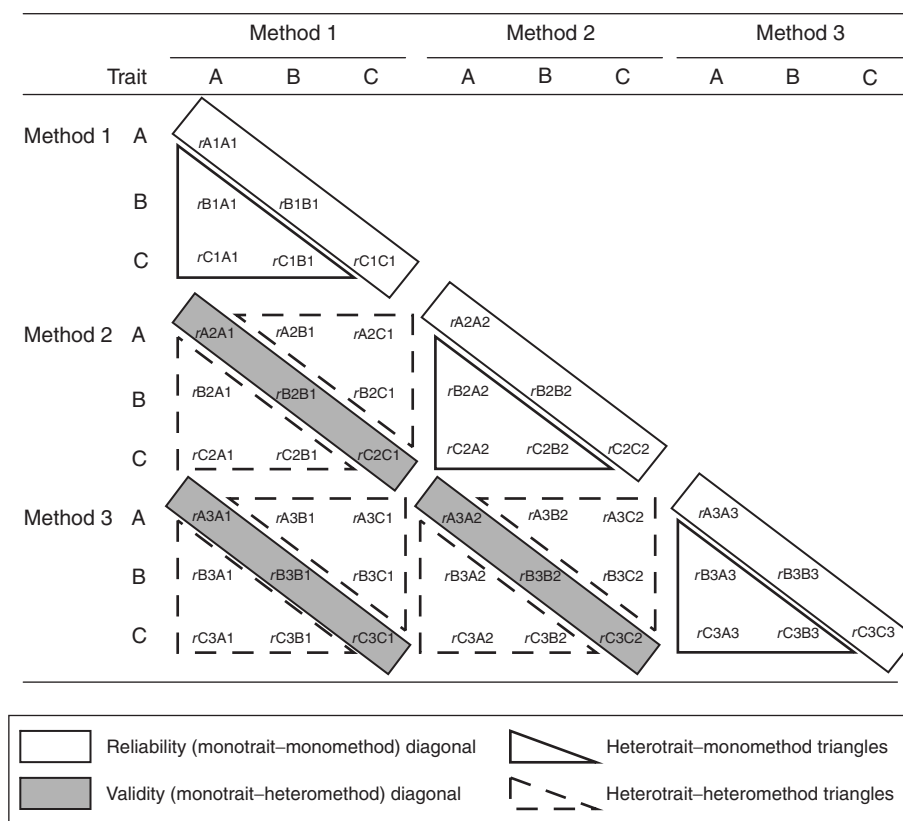

Figure 1 An MTMM matrix of three traits (i.e., traits A, B, and C) assessed with three methods (i.e., methods 1, 2, and 3). From Pedhazur, E. J. and Schmelkin, L. P. (1991). *Measurement, Design, and Analysis: An Integrated Approach*, p 76. Hillsdale, NJ: Erlbaum.

monotrait-heteromethod (MTHM) or validity coefficients displayed in the three validity diagonals presented in shaded rectangular boxes. These coefficients represent correlations between the same construct assessed with different methods. For example, r_{B2B1} represents the correlation between measures of trait B, each assessed with method 1 and method 2, respectively. The MTHM coefficients are also called convergent validity coefficients.

The third type of coefficients are the heterotrait-monomethod (HTMM) coefficients presented in the three solid triangles. These coefficients represent correlations between different constructs assessed with the same method and, as such, can be viewed to embody method effects. For example, r_{C2A2} and r_{C2B2} are the correlations between trait A and trait C and between trait B and trait C, respectively, all assessed with method 2. The fourth type includes the heterotrait-heteromethod (HTHM) coefficients encircled in the six dashed triangles, which indicate correlations between different constructs assessed with different methods. The coefficient, r_{B3C2} , indicates the correlation between trait C assessed with method 2 and trait B assessed with method 3. The HTMM and HTHM coefficients are also called discriminant validity coefficients. Campbell and Fiske proposed a set of criteria that can be applied when comparing the four types of coefficients in an MTMM matrix for assessing construct validity of psychological measures.

Campbell and Fiske regarded reliability as the correlation between measures of the same trait assessed with maximally similar methods and validity as the correlation between measures of the same trait assessed with maximally different methods. The coefficients in the monotrait-monomethod or the reliability diagonal, therefore, must be high to begin with because reliability is a necessary prerequisite for construct validity. As these measures share the same trait and the same method, values of the coefficients in the reliability diagonals are often the largest of all coefficients included in an MTMM matrix.

Provided that the measures are judged to be reliable, Campbell and Fiske's first criterion is that values of the coefficients in the MTHM or the validity diagonals must be sufficiently large to warrant further inspection of construct validity. Correlations between measures of the same construct assessed with different methods constitute primary evidence of convergent validity. Therefore, not only these validity coefficients must be significantly different from zero and sizeable in absolute magnitude but they should also be considerably higher than the coefficients in the HTHM or the HTMM triangles. These latter requirements constitute the second and third criteria, respectively.

The criterion that coefficients in the MTHM or the validity diagonals should be higher than those in the HTHM triangles represents one test of convergent validity. Theoretically, this should be the easiest requirement

to fulfill because the coefficients in the HTHM triangles share neither a common construct nor a common method. Because there is no theoretical reason to predict two distinct constructs to be correlated, especially when each of them is separately assessed with an independent measurement procedure, the HTHM coefficients are expected to be the lowest on average among the four types of coefficients presented in an MTMM matrix. Each of the coefficients in the validity diagonals must be higher than the coefficients in the HTHM triangles that are in the same row or the same column to the validity coefficient under examination. For example, the coefficient, r_{B2B1} , represents the correlation between measures of trait B assessed with two distinct methods, methods 1 and 2. This coefficient, r_{B2B1} , must be higher than the coefficients in the same row, r_{B2A1} and r_{B2C1} , as well as those in the same column, r_{A2B1} , r_{C2B1} , r_{A3B1} , and r_{C3B1} . If any of the coefficients in the HTHM triangles is as high as or higher than the coefficients in the validity diagonals, it indicates poor convergent validity.

The next criterion states that coefficients in the validity diagonals must also be higher than those in the HTMM triangles. It implies that the common variance due to traits must be larger than the common variance due to methods. Stated differently, measures of the same construct assessed with different methods should correlate more strongly with each other than measures of different constructs assessed with the same method. Using the coefficient, r_{B2B1} , again as an example, this coefficient must be higher than the coefficient such as r_{C1B1} , which denotes the correlation of trait B with trait C, both assessed with method 1, or r_{B2A2} , the correlation of trait A with trait B, both assessed with method 2. If coefficients in the HTMM triangles are as high as or higher than those in the validity diagonals, it suggests that a greater amount of variance is due to a common method rather than a common construct. For example, if the coefficient, r_{C1B1} , is higher than the validity coefficient, r_{B2B1} , then it implies stronger effects of method 1 compared to those of trait B. When the trait effects are even weaker than the method effects, it is difficult to claim there exists a sufficient degree of convergent validity.

Discriminant validity states that measures of different constructs, theoretically unrelated, should not be correlated. The criterion that the validity coefficients must be higher than the coefficients in the HTHM triangles can thus function as a test of discriminant validity as well. Discriminant validity is judged to be in jeopardy when measures of distinct constructs correlate too highly with each other. This principle applies equally to situations where the constructs are assessed with the same method or different methods. Assuming the same constructs are being assessed and hence the measures contain an equal amount of variance due to traits, the remaining variance in each measure can be thought of as being due to some factors related to methods and random error. When correlations between measures of distinct traits assessed with different

methods (i.e., the correlations in the HTHM triangles) are too high, appearing as high as or even higher than those between measures of the same trait assessed with an identical set of heteromethods (i.e., the correlations in the validity diagonals), discriminant validity is deemed not to be present. Similarly, when correlations between measures of distinct traits assessed with the same method (i.e., the correlations in the HTMM triangles) are as high as or higher than those between measures of the same trait assessed with the same method (i.e., the correlations in the reliability diagonals), discriminant validity of the measures is again called into question.

Finally, Campbell and Fiske proposed that the pattern of correlations among the traits should stay similar across methods. This criterion applies equally to all heterotrait correlations regardless of whether the traits are assessed with the same or different methods. For example, if r_{B1A1} is higher than r_{C1A1} , which is in turn higher than r_{C1B1} in the top HTMM triangle, then this pattern should hold in all other HTMM as well as HTHM triangles. This means that traits A and B should be most strongly correlated with each other, traits A and C should be next strongly correlated, and traits B and C should be least strongly correlated, irrespective of the methods used to assess these traits. Therefore, in the two HTHM triangles produced by methods 1 and 2, for example, r_{B2A1} and r_{A2B1} should be the highest correlations among the three coefficients within the same triangle, r_{C2A1} and r_{A2C1} the next highest, and r_{C2B1} and r_{B2C1} the lowest correlations, respectively.

The Campbell and Fiske criteria provided useful guidelines for judging the quality of measures of psychological constructs and had been widely employed in construct validation attempts. However, researchers have since pointed out several inherent problems associated with the criteria. The first such problem is an analytical one. The criteria require that one type of correlations (e.g., MTMM correlations) be higher than the other types of correlations and if certain type of correlations (e.g., HTHM correlations) are too high, then it poses a threat to construct validity. However, it is not clear how much higher the desired correlations must be compared to others to be acceptable or how high the unwanted correlation might be to be considered problematic. Visual inspection of MTMM matrices cannot provide helpful answers to these questions. The situation can become even more ambiguous when only some of the correlations in the respective diagonal or triangle are consistent with the criteria or when the particular MTMM matrix as a whole only meets some, not all, of the criteria stipulated by Campbell and Fiske.

The second problem is both conceptual and analytical in nature. The operational definition of maximally different methods to be employed in MTMM designs is vague. For example, if researchers ask a group of individuals to rate some aspect of their own personality and then ask their parents, siblings, or friends to rate the same aspect of those individuals' personality, do these ratings by the self

versus others comprise different methods, let alone maximally different methods? Further, even when sufficiently different methods are used, it is more likely than not that scores produced by these independent methods show some degree of correlation. Depending on the specific traits, subjects, and settings of the measurement, factors such as halo or social desirability might be in operation, rendering the correlation between any two measures to be much higher than warranted purely on the basis of the methods themselves. However, these effects can be neither controlled nor partitioned into different sources by simply inspecting the correlation coefficients visually, as suggested by Campbell and Fiske.

Alternative Approaches

To overcome the aforementioned problems associated with Campbell and Fiske's approach to MTMM analyses, several alternative approaches have been proposed. These alternative models include a confirmatory factor analysis model with trait and method factors, a confirmatory factor analysis model with correlated uniquenesses, and a direct product model.

Confirmatory Factor Analysis Model with Trait and Method Factors

Confirmatory factor analysis (CFA) of MTMM matrices has many important advantages to traditional MTMM analyses that rely upon less-than-systematic comparison of zero-order correlations among the measures as assessed. In general, CFA is a useful tool for testing theoretically driven relationships between variables. It is particularly useful in MTMM designs because, unlike measures in natural sciences, most measures in social and behavioral sciences contain sizeable measurement errors. CFA takes these measurement errors into account by correcting for possible attenuation due to imperfect measurements in estimating relationships among the measures. The CFA-TM (CFA-TM, confirmatory factor analysis model with trait and method factors) approaches further allow partitioning of the variance in each measure into trait, method, and random error components.

The general confirmatory factor analysis model is:

$$\Sigma = \Lambda\Phi\Lambda' + \Psi$$

where Σ is a population correlation matrix, Λ is a matrix of factor loadings, Φ is a matrix of factor correlations, and Ψ is a diagonal matrix of uniqueness variances. For the analysis of MTMM data, the CFA model is extended as shown below:

$$\Sigma = \Lambda_T\Phi_T\Lambda_T' + \Lambda_M\Phi_M\Lambda_M' + \Psi$$

where Λ_T and Λ_M are matrices of factor loadings for traits and methods, respectively. Similarly, Φ_T and Φ_M are matrices of trait and method correlations, respectively. As the correlations among observed variables (i.e., measures) are sum of trait and method factors, the model is an additive model (see Figure 2).

More specifically, the CFA-TM has the following advantages over Campbell and Fiske's traditional approach:

1. it explains the MTMM matrix by introducing latent constructs, rather than making an unrealistic assumption of perfect measurements;
2. it provides statistical testing of global model fit (i.e., whether or not the particular model with multiple traits and multiple methods, as specified, can be regarded as a valid representation of the relationships among the measures);
3. it provides statistical testing of convergent as well as discriminant validity; and
4. it decomposes the variance in each measure as being due to different traits, different methods, and error.

As such, researchers now consider CFA a far more defensible and informative approach than is Campbell and Fiske's original approach to the analyses of MTMM matrices.

Unfortunately, as the CFA-TM approach to MTMM matrices has become widespread, the frequency of problems associated with it has also increased. These problems

Figure 2 The CFA-TM approach to the MTMM matrix of three traits (i.e., traits SG, HG, and MC) assessed with three methods (i.e., methods TF, FC, and IS).

include nonconvergence, negative variances, nonpositive definite correlation matrices, and other ill-defined solutions.

Confirmatory Factor Analysis Model with Correlated Uniquenesses

To overcome the problem of ill-defined solutions frequently resulted from the CFA-TM applications, Marsh proposed CFA-CU (CFA-CU, confirmatory factor analysis model with correlated uniquenesses) approaches to MTMM matrices. In CFA-CU, method factors are eliminated from the model and correlated uniquenesses are specified instead (see **Figure 3**). The CFA-CU hence specifies correlations among the uniqueness terms of the measures that are assessed with the same method. The assumption is that the variance in each measure not attributable to a trait is due to either a method or random error and the systematic portion of this remaining variance (i.e., uniqueness) is attributable to the method used. By specifying uniquenesses of the measures assessed by the same method to correlate, it becomes possible to account for the shared method effects while avoiding the empirical difficulties commonly encountered in the CFA-TM approaches to MTMM matrices.

The mathematical model of the CFA-CU is identical to the general CFA:

$$\Sigma = \Lambda\Phi\Lambda' + \Psi$$

Specifically, the CFA-CU model differs from the CFA-TM model in the following two points: (1) the CFA-CU model does not include method factors and (2) Ψ contains uniqueness variances on the diagonal and covariances off the diagonal. Covariances among the uniquenesses represent method effects.

Based on extensive evaluation of the CFA-CU using empirical and simulated data, Marsh has reported that this approach converged to proper solutions in most applications. In particular, the CFA-CU approach can represent MTMM data more accurately when the effects of methods are not unidimensional. However, this approach is not without its limitations. The first shortcoming is that correlated method effects cannot be modeled. Because correlations are specified among the uniqueness terms of the measures assessed with a common method instead of latent variables representing the methods, correlations between different methods cannot be specified. The second shortcoming is that method effects can be confounded with random error.

Direct Product Model

Both the CFA-TM and the CFA-CU approaches assume an additive method effect on the trait factor. However, it has been pointed out that these CFA approaches ignore possible

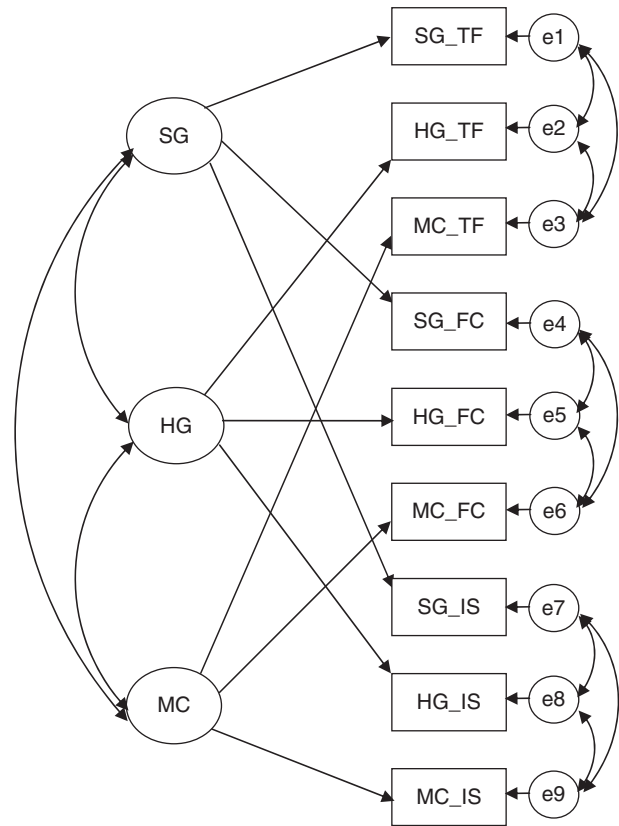

Figure 3 The CFA-CU approach to the MTMM matrix of three traits (i.e., traits SG, HG, and MC) assessed with three methods (i.e., methods TF, FC, and IS).

multiplicative trait–method interactions. In response to this issue, Browne proposed the direct product (DP) model, where the correlation matrix of measured variables can be defined as the direct product of a correlation matrix of traits and a correlation matrix of methods. The mathematical expression of the DP model is as follows:

$$\Sigma = D(P_M \otimes P_T + E)D$$

where Σ is a population correlation matrix, D is a diagonal matrix of communality, P_T and P_M are trait and method correlation matrices, respectively. Here, E is a diagonal matrix of uniqueness and \otimes is right direct Kronecker product. The DP model is less prone to the problem of ill-defined solutions because parameterization of trait and method variance is more parsimonious than it is for the CFA approaches.

Illustration of Data Analyses

The MTMM matrix from a study by Mosher, published in 1968, was re-analyzed here to illustrate the CFA-TM, CFA-CU, and DP approaches. **Table 1** presents an MTMM matrix of three types of guilt as measured by three types of self-reports. The three types of guilt are sex-guilt (SG),

Table 1 Multitrait-multimethod matrix from Mosher (1968)

		TF			FC			IS		
		SG	HG	MC	SG	HG	MC	SG	HG	MC
TF	SG	(0.95)								
	HG	0.28	(0.86)							
	MC	0.58	0.39	(0.92)						
FC	SG	0.86	0.32	0.57	(0.95)					
	HG	0.30	0.90	0.40	0.39	(0.76)				
	MC	0.52	0.31	0.86	0.55	0.26	(0.84)			
IS	SG	0.73	0.10	0.43	0.64	0.17	0.37	(0.48)		
	HG	0.10	0.63	0.17	0.22	0.67	0.19	0.15	(0.41)	
	MC	0.35	0.16	0.52	0.31	0.17	0.56	0.41	0.30	(0.58)

Note: $N = 62$. Numbers in parentheses are reliability coefficients.

TF, true-false; FC, forced-choice; IS, incomplete sentences; SG, sex-guilt; HG, hostility-guilt; MC, morality-conscience.

hostility-guilt (HG), and morality-conscience (MC) and the three types of self-reports are true-false (TF), forced-choice (FC), and incomplete sentences (IS).

Campbell and Fiske's Approach

In the MTMM matrix presented in **Table 1**, the bold-typed coefficients presented in shaded cells represent convergent validity (i.e., MTHM) coefficients. The coefficients boxed together by dotted lines (i.e., HTHM) and those by solid lines (i.e., HTMM) represent discriminant validity coefficients. Reliability (i.e., MTMM) coefficients are italicized and put in parentheses in the main diagonal.

The first criterion suggested by Campbell and Fiske for ensuring construct validity is that values of the coefficients in the MTHM or the validity diagonals should be significantly different from zero and sufficiently large. Visual inspection of the coefficients presented in shaded cells indicates this is indeed the case with the coefficients ranging from 0.52 to 0.90, although some of the coefficients are substantially smaller than others. The second criterion of Campbell and Fiske is that the validity coefficients should be larger than the HTHM coefficients. Again, visually comparing each validity coefficient with the coefficients in the same column or the same row within the HTHM boxes reveals this criterion is successfully met. The third criterion states that the validity coefficients should be larger than the HTMM coefficients, which also holds.

Campbell and Fiske's fourth criterion for validity dictates that the same pattern of correlations should emerge between traits, irrespective of whether they are assessed by the same or different methods. In the MTMM matrix presented in **Table 1**, the same pattern of correlations is indeed observed among the three traits across the

HTHM and HTMM triangles. Specifically, the highest correlation coefficient is observed between SG and MC, the next highest correlation coefficient between HG and MC, and the lowest correlation coefficient between SG and HG within each triangle. Out of the 27 correlation coefficients in the six HTHM and the three HTMM triangles, only two are exceptions to this trend. The correlation coefficient between SG and HG (0.39) is higher than that between HG and MC (0.26), when all of them are assessed with the forced-choice tests. The correlation coefficient between SG assessed with the force-choice test and HG assessed with the incomplete sentence test (0.22) is also higher than that between HG assessed with FC and MC assessed with IS (0.17). On the whole, one must conclude that validity of the measures is supported according to the Campbell and Fiske's criteria.

Confirmatory Factor Analysis Model with Trait and Method Factors

The CFA-TM was applied to the MTMM matrix using AMOS 7.0. As standard deviations are not reported in Mosher's original article, arbitrary values were chosen with one condition – similar values should be assigned to the variables assessed with the same method. We developed three nested models to demonstrate how to evaluate the convergent and discriminant validity of the trait factors.

Model 1 is a basic model in which three correlated trait and three correlated method factors are specified, as presented in **Figure 2**. Model 2 specified method factors only, without any trait factor. Model 2 is thus nested within model 1 with greater χ^2 values ($\Delta\chi^2 > 0$) and greater degrees of freedom ($\Delta df > 0$) than those of model 1. A significant difference in χ^2 values at the difference in

degrees of freedom between the two models can be taken as evidence of convergent validity because deterioration in model fit (e.g., greater χ^2 values of model 2) when trait factors are removed indicates the necessity of three types of guilt factors for adequately illustrating the response patterns to the three types of self-reports.

Similarly, we developed model 3 by fixing trait correlations in model 1 at unity. Therefore, model 3 is also nested within model 1 with greater χ^2 values ($\Delta\chi^2 > 0$) and greater degrees of freedom ($\Delta df > 0$) than those of model 1. Again, a significant difference in χ^2 values at the difference in degrees of freedom between the two models indicates evidence of discriminant validity. Significant deterioration in model fit (e.g., greater χ^2 values of model 3) when trait factors are treated as identical ($\phi = 1$) means that the trait factors are independent from each other. Stated differently, significantly poorer model fit with three identical trait factors demonstrates the necessity of treating the trait factors as distinct from each other for proper model definition.

Results show that the fit of Model 1 ($\chi^2 = 25.123$, $df = 18$) was reasonable to satisfactory. In evaluating the fit of CFA models, root mean square error of approximation (RMSEA) values less than 0.10 and Tucker–Lewis

index (TLI) and comparative fit index (CFI) values greater than 0.90 are typically regarded as indicating acceptable model fit. The values of RMSEA, TLI, and CFI for model 1 were 0.081, 0.966, and 0.983, respectively (note that error variances of the variables measured by a common method were fixed to be equal to solve the problem of improper solutions). In contrast, the analyses using models 2 and 3 produced improper solutions, indicating that the models could not be considered as reasonable representation of the empirical data. Together, these results argue for convergent as well as discriminant validity.

The magnitude of trait factor loadings also supports convergent validity. As **Table 2** shows, all trait factor loadings were relatively strong and statistically significant, ranging from 0.582 to 0.979.

Discriminant validity was evaluated by examining the trait and method factor correlation matrices according to Goffin's guideline. The guideline states that correlations greater than 0.71 in magnitude are of concern because values exceeding 0.71 indicate that the two variables share more than 50% of their variances. As **Table 3** demonstrates, none of the trait correlations were greater than 0.71. Therefore, discriminant validity for the trait factors was supported.

Confirmatory Factor Analysis Model with Correlated Uniquenesses

Here we demonstrate application of CFA-CU to the same MTMM matrix. We developed two nested models with correlated uniquenesses. Model 4 is a CFA-CU model with only trait factors. Instead of specifying separate method factors, uniquenesses of the variables assessed with the same method were correlated with each other (see **Figure 3**). We next developed model 5 by fixing trait correlations in model 4 at unity. As model 5 is nested within model 4, we were able to evaluate discriminant validity of the trait factors by comparing the two models.

As was the case in the CFA-TM application presented earlier, a significant difference in χ^2 between the two models indicates evidence of discriminant validity. Results show that the fit of Model 4 ($\chi^2 = 21.808$, $df = 21$) with three correlated yet independent trait factors was excellent. The values of RMSEA, TLI, and CFI were 0.025, 0.997, and 0.998, respectively (note that error variances of the variables measured by a common method were fixed to be equal to solve the problem of improper solutions). However, the analysis using models 5 produced improper solutions, indicating that the model with identical trait factors was not reasonable. This result supports discriminant validity of the three trait factors.

Evidence of convergent validity comes from the magnitude of trait factor loadings. As shown in **Table 4**, all trait factor loadings were strong and statistically significant, ranging from 0.639 to 0.948. Discriminant validity for the trait factors was supported, given that none of the trait correlations was greater than the 0.71 limit suggested by Goffin's guideline (see **Table 5**).

DP Model

In the DP model, convergent and discriminant validity can be evaluated by examining the correlations among

method factors and those among trait factors, respectively. Correlations among method factors that are substantially different from zero argue for convergent validity. Correlations among trait factors that are substantially lower than the upper bound of unity can be taken as evidence of discriminant validity. In addition, correlations among method factors should be greater than those among trait factors to further ensure discriminant validity.

Using a computer program called MUTMUM, the DP model was analyzed. The fit of the DP model was mediocre (RMSEA = 0.092). **Table 6** provides MUTMUM outputs.

To evaluate convergent validity, correlations among the method factors were examined first. They ranged from 0.755 to 0.963 and were substantially different from zero. A computer program called CONFID, included in the MUTMUM package, was used to construct a 95% confidence interval around each of these correlations to evaluate convergent validity statistically. The lower and upper limits of the confidence intervals were 0.884 and 0.989 for the TF-FC, 0.579 and 0.864 for the TF-IS, and 0.617 and 0.899 for the FC-IS pairs, respectively. None of the 95% confidence intervals contained zero, indicating that these correlations are all statistically significant at $\alpha = 0.05$. These results can be taken as evidence of convergent validity.

Similarly, 95% confidence intervals were constructed around correlations among the trait factors to examine discriminant validity statistically. The lower and upper limits of these 95% confidence intervals were 0.131 and

Table 4 Factor loadings from the CFA-CU model

		<i>Traits</i>		
		<i>SG</i>	<i>HG</i>	<i>MC</i>

SG	1.000		
HG	0.303	1.000	
MC	0.639	0.379	1.000

Table 6 Final estimates (MWL)

<i>Correlations among traits ($p \downarrow T$)</i>			
	<i>SG</i>	<i>HG</i>	<i>MC</i>
SG	1.000		
HG	0.353 (0.106)	1.000	
MC	0.610 (0.087)	0.461 (0.098)	1.000
<i>Correlations among methods ($p \downarrow M$)</i>			
	<i>TF</i>	<i>FC</i>	<i>IS</i>
TF	1.000		
FC	0.963 (0.022)	1.000	
IS	0.755 (0.071)	0.798 (0.069)	1.000

0.541 for the SG-HG, 0.411 and 0.753 for the SG-MC, and 0.249 and 0.631 for the HG-MC pairs, respectively. None of these confidence intervals contained unity and hence discriminant validity was supported. The correlational pattern that shows greater correlations among the method factors than those among the trait factors also argues for the discriminant validity of the traits.

Multivariate Longitudinal Data Analysis

H Liu, Beijing Normal University, Beijing, People's Republic of China

© 2010 Elsevier Ltd. All rights reserved.

Analysis of variance (ANOVA) and multivariate analysis of variance (MANOVA) have traditionally been used to analyze longitudinal or repeated measures data. However, these traditional methods are limited by the strict assumptions concerning missing data across time and the variance–covariance structure of the repeated measures. These methods are also limited because they focus on estimating developmental trends more than identifying and accounting for the individual variations in their development or change over time. For these and other reasons, longitudinal data analysis has in recent years been treated not as a special topic within the analysis of variance framework but as a modeling methodology within the larger multivariate data modeling framework. Key developments in this transition have resulted in three major longitudinal data analysis methods: hierarchical linear models (HLMs; Bryk and Raudenbush, 1992; Goldstein, 1995), latent growth modeling (LGM), and cross-lagged regression model (Jöreskog and Sörbom, 1979). These longitudinal modeling tools help researchers to interpret repeated measures data and formulate research questions that go beyond simply estimating growth trends. Researchers are interested in understanding how attributes of an individual change over time, how individuals differ in their attribute changes, and what accounts for the individual variations of the attribute change (Singer and Willett, 2003; Collins and Sayer, 2001). In this article, we review these three longitudinal data modeling methods by discussing the conceptual framework of each method, presenting empirical examples using the method and by discussing the relationships among the methods.

Multilevel Models for Multivariate Change

In general, multilevel models are used for analyzing hierarchically organized data. Longitudinal data can be considered to be hierarchical in that measurement occasions are nested within subjects. Raudenbush and Bryk (2002) and Goldstein (1995) provide detailed treatment of multilevel models. We consider the case that includes two response variables, X_1 and X_2 , each measured on four occasions. In the HLM framework, the response variables do not need to be measured at the same time points or for the same number of times. In specifying a multivariate multilevel model, the data are treated as if only a single outcome variable is measured. Let X_{itk}^* be a score for

individual i ($i = 1, 2, \dots, n$) at occasion t ($t = 0, 1, 2, 3$) on outcome variable k ($k = 1, 2$), and consider X_{itk}^* as if it were a single variable with aspects of its measurement defined by subscripts. We then define two dummy variables, δ_1 and δ_2 , one for variable X_1 and the other for X_2 . That is, where $\delta_1 = 1$ if a given measure is on X_1 , and $\delta_1 = 0$ otherwise; $\delta_2 = 1$ if a given measure is on X_2 , and $\delta_2 = 0$ otherwise. The data can be arranged as shown in Table 1.

A general representation of the multivariate multilevel model for change could be given as $X_{itk} = \sum_k \delta_k(\text{model})$. The model refers to univariate change,

$$X_{itk} = \sum_k \delta_k(\beta_{0ik} + \beta_{1ik}t + e_{itk}).$$

In this model, the trajectory trend (e.g., linear model) is assumed to be the same for different response variables. β_{0ik} is the intercept for individual i on outcome variable, X_k , $k = 1, 2$. β_{1ik} is the slope for individual i on outcome variable, X_k , $k = 1, 2$. t is the measurement of time (the values do not have to be the same for each individual or on each outcome variable). e_{itk} is the residual for individual i on occasion t for outcome variable, X_k , $k = 1, 2$. The intercepts and slopes for the k outcome variables are random variables, with their variations across individuals being modeled as the following:

$$\beta_{0ik} = \beta_{00k} + u_{0ik}$$

$$\beta_{1ik} = \beta_{10k} + u_{1ik}$$

Here β_{00k} and β_{10k} represent the fixed effects for the intercept and slope on the outcome variable, X_k , $k = 1, 2$, and u_{0ik} and u_{1ik} represent random variation of individuals around the mean intercept and slope, respectively, for the outcome variable, X_k , $k = 1, 2$.

The key to analyzing multivariate longitudinal data within the multilevel framework is to treat the data as if there is only one outcome variable. For each outcome variable X_k , a fixed intercept, β_{0k} , and a fixed slope, β_{1k} , are estimated. Random effects are estimated as the following: The residual variance, $\sigma_{ek}^2 = \text{var}(e_{itk})$; the intercept variance, $\sigma_{u0k}^2 = \text{var}(u_{0ik})$; the slope variance, $\sigma_{u1k}^2 = \text{var}(u_{1ik})$; the covariance between the intercept and slope, $\sigma_{u01k} = \text{cov}(u_{0ik}, u_{1ik})$. In addition, random effects are estimated for the covariance matrices of intercepts and slopes for X_1 and X_2 as the following: $\sigma_{u0102} = \text{cov}(u_{0i1}, u_{0i2})$ is the covariance of intercept on outcome variable, X_1 , and the intercept on outcome variable, X_2 ; $\sigma_{u0112} = \text{cov}(u_{0i1}, u_{1i2})$ is

the covariance of the intercept on outcome variable, X_1 , and the slope on outcome variable, X_2 ; $\sigma_{u1102} = \text{cov}(u_{1i1}, u_{0i2})$ is the covariance of the slope on outcome variable, X_1 , and the intercept on outcome variable, X_2 ; $\sigma_{u1112} = \text{cov}(u_{1i1}, u_{1i2})$ is the covariance of slope on outcome variable, X_1 , and the slope on outcome variable, X_2 .

The above describes the unconditional multivariate growth model, which can be extended to the conditional models that include individual-level variables as predictors of individual differences in the growth coefficients representing developmental change. For example, we can include the individual predictor, Z , into the equations involving the intercept and the linear slope to account for the individual-level variations in these two growth coefficients. The conditional model can be stated as the following:

$$\beta_{0ik} = \beta_{00k} + \beta_{01k}Z + u_{0ik}$$

$$\beta_{1ik} = \beta_{10k} + \beta_{11k}Z + u_{1ik}$$

where β_{01k} and β_{11k} represent the fixed effects of the individual variable Z on the random intercept and slope of outcome variable, X_k , $k = 1, 2$; u_{0ik} and u_{1ik} represent random residual variation of individuals of the intercept and slope, respectively, for outcome variable, X_k , $k = 1, 2$.

Table 1 The hierarchical structure of two variables measured on four occasions

Variables	δ_1	δ_2	Time
X_{i11}	1	0	0
X_{i21}	1	0	1
X_{i31}	1	0	2
X_{i41}	1	0	3
X_{i12}	0	1	0
X_{i22}	0	1	1
X_{i32}	0	1	2
X_{i42}	0	1	3

Data Illustration

The following data are used to illustrate the multivariate multilevel longitudinal data analysis procedures. Cognitive and general self-concept of primary school students in Hong Kong were measured four times at approximately 1-year intervals over the period from grade 3 to grade 6. The sample size was 264 (149 boys and 115 girls). The Perceived Competence Scale for Children (Harter, 1982) was used to obtain these self-concept measures. The scale has been used with other Chinese children of similar ages (Chang, 2003). Internal consistency reliability based on the present sample was 0.71, 0.73, 0.70, and 0.74 for times 1, 2, 3 and 4, respectively. The results from the unconditional model without the individual-level predictors are presented in **Table 2**.

The fixed effects in the multilevel model include mean intercepts and slopes of the two outcome variables, cognitive self-concept (CC) and general self-concept (GC). Because the four measurement occasions were coded as 0, 1, 2, and 3 for grade 3, 4, 5, and 6, the intercepts (2.689 for CC and 2.654 for GC) are interpreted as the mean level of the two self-concepts for grade 3. It can also be seen from **Table 2**, the linear slopes for cognitive self-concept and general self-concept are significant (−0.268 for CC and −0.333 for GC). The negative slope estimates suggest that, across all students, the mean level of cognitive self-concept and general self-concept decrease linearly from grade 3 to grade 6. For the random parameter estimates, all variances are significant, as shown by the variance estimates being at least several times their standard errors in magnitude. Thus, individuals showed statistically significant variations in their start levels (0.263 for CC and 0.251 for GC) and in the rates of linear change on the two outcome variables (0.031 for CC and 0.033 for GC). The correlation between the two intercepts is significant (0.419), suggesting that the level of cognitive self-concept at grade 3 is significantly correlated with the level of

Table 2 Fixed and random effects results for cognitive self-concept (CC) and general self-concept (GC)

Fixed parameters	Estimate	SE	t-Value	
CC intercept	2.689	0.034	79.088	
CC slope	−0.268	0.012	−22.333	
GC intercept	2.654	0.034	78.059	
GC slope	−0.333	0.013	−25.615	
Variance (diagonal), covariance (above diagonal), standard error (in bracket) and correlation (below diagonal) of the random intercepts and slopes				
Random parameters	CC intercept	CC slope	GC intercept	GC slope
CC intercept	0.263 (0.025)	−0.019 (0.007)	0.108 (0.019)	0.003 (0.007)
CC slope	−0.206	0.031 (0.004)	−0.010 (0.007)	0.003 (0.003)
GC intercept	0.419	−0.098	0.251 (0.025)	−0.026 (0.008)
GC slope	0.027	−0.092	−0.280	0.033 (0.004)

general self-concept in grade 3. The correlations between intercepts and slopes are negative (-0.206 for CC and -0.280 for GC), indicating that higher initial levels of self-concept are associated with faster decline over the 4 years from grade 3 to grade 6. The correlation between the two slopes is not significant, suggesting that the rate of decline is independent of these two domains of self-concept.

To account for some of these intercept and slope variations, we included individual-level predictor, gender. The results of this conditional model are presented in **Table 3**. The effects of gender on the intercept of CC (-0.307) and that of GC (-0.441) are statistically significant. Because gender was coded as 1 = male and 0 = female, the negative estimates suggest that the initial self-concept is lower for male than female students. Also shown in **Table 3**, gender does not have a significant effect on the linear slopes of the two self-concept variables (0.009 for CC and 0.048 for GC), suggesting that the linear decline in self-concept across 4 years does not differ between the two genders.

Latent Growth Curves Model

The latent growth curve model (LGCM) is built on the pioneering work by Rao (1958), Tucker (1966), Meredith and Tisak (1990), McArdle (1988), and McArdle and

Epstein (1987). The model is best depicted graphically as shown in **Figure 1**.

Figure 1 represents growth curves of two variables, X_1 and X_2 , measured on four occasions which are represented as 0, 1, 2, and 3. For each variable, we include an intercept and a slope (I_1, S_1 and I_2, S_2 for variables X_1 and X_2 , respectively). Parameter estimates of interest include slope loadings for each of the two variables ($\lambda_{10}, \lambda_{11}, \lambda_{12}, \lambda_{13}$ and $\lambda_{20}, \lambda_{21}, \lambda_{22}, \lambda_{23}$), two intercept means (M_{I1} and M_{I2}), two intercept variances (D_{I1} and D_{I2}), two slope means (M_{S1} and M_{S2}), two slope variances (D_{S1} and D_{S2}), correlations between intercepts and slopes ($r_{I1S1}, r_{I2S2}, r_{I1S2}, r_{I2S1}$), the correlation between the two intercepts (r_{I1I2}) and between the two slopes (r_{S1S2}). The corresponding equations are as follows:

$$X_{1t} = I_1 + \lambda_{1t}S_1 + e_{1t} \quad t = 0, 1, 2, 3$$

and

$$X_{2t} = I_2 + \lambda_{2t}S_2 + e_{2t} \quad t = 0, 1, 2, 3$$

This model implies that a single trajectory underlies growth in each variable across all measurement occasions. Thus, the model allows the identification and estimation of growth in each variable as well as the estimation of the covariance between the two growth slopes. However, the covariance or correlation is not time dependent, thus, ignoring possible interrelations among variables over time. This model is unconditional without individual-level predictors of change. Like the multivariate multilevel model discussed in the previous section, this unconditional model can be extended by including individual-level predictors, which can either be directly observed or latent constructs derived from multiple indicators. A conditional model using directly observed individual-level predictors is presented in **Figure 2**.

Table 3 Results of the effects of gender on the growth parameters for bivariate multilevel model

Dependent variable	Estimate	SE	t
CC intercept	-0.307	0.063	-4.873
GC intercept	-0.441	0.060	-7.350
CC slope	0.009	0.025	0.360
GC slope	0.048	0.026	1.846

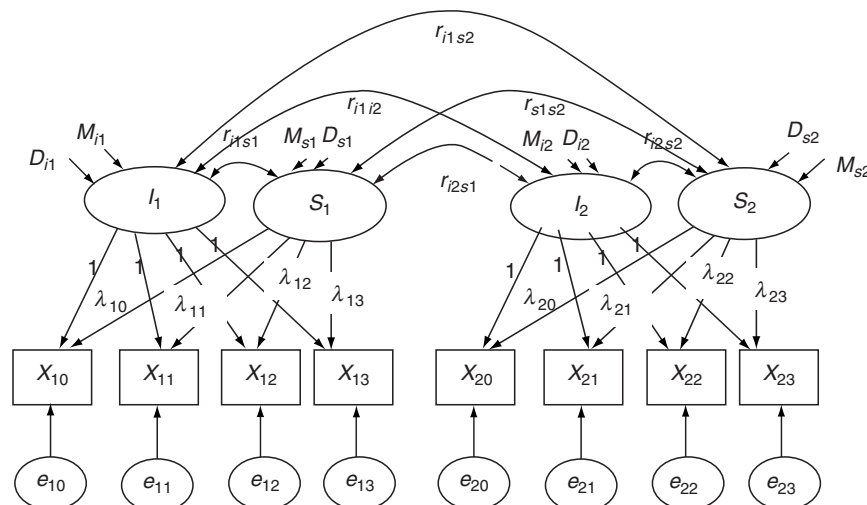

Figure 1 Path diagram of an unconditional bivariate latent growth curve model.

In this model, variable Z (in the SEM framework, variable Z can also be a latent variable measured by multiple indicators) is specified as a predictor of developmental trends, which are the intercepts and slopes of variables X_1 and X_2 , and variable Y is predicted by the same developmental trends, that is, intercepts and slopes of variables X_1 and X_2 . That is, individual-level variables can serve both as predictors of growth curves and as the outcome variables accounted for by the growth trends. This modeling feature is not available in the multilevel method of longitudinal analysis discussed earlier.

Data Illustration

The same data presented in the previous section were used to illustrate the use of multivariate growth curve

modeling. Table 4 presents numerical results. As shown in Table 4, the linear growth model yields a relatively good fit (chi-square = 61.504, $df = 22$; RMSEA = 0.082; CFI = 0.976; TLI = 0.969. Please note that the HLM model discussed earlier do not have these goodness-of-fit statistics). Some important parameter estimates of this model include initial mean levels of intercept (2.689 and 2.655 for cognitive self-concept (CC) and general self-concept (GC), respectively), deviations from the mean intercept (0.262 and 0.250 for CC and GC, respectively), slope means (-0.269 and -0.334 for CC and GC, respectively), slope deviations (0.030 and 0.032), the correlation between the two intercepts (0.418), and the correlation between the two slopes (0.093). The results of latent linear growth model are essentially identical to those obtained using multivariate multilevel method that is presented in

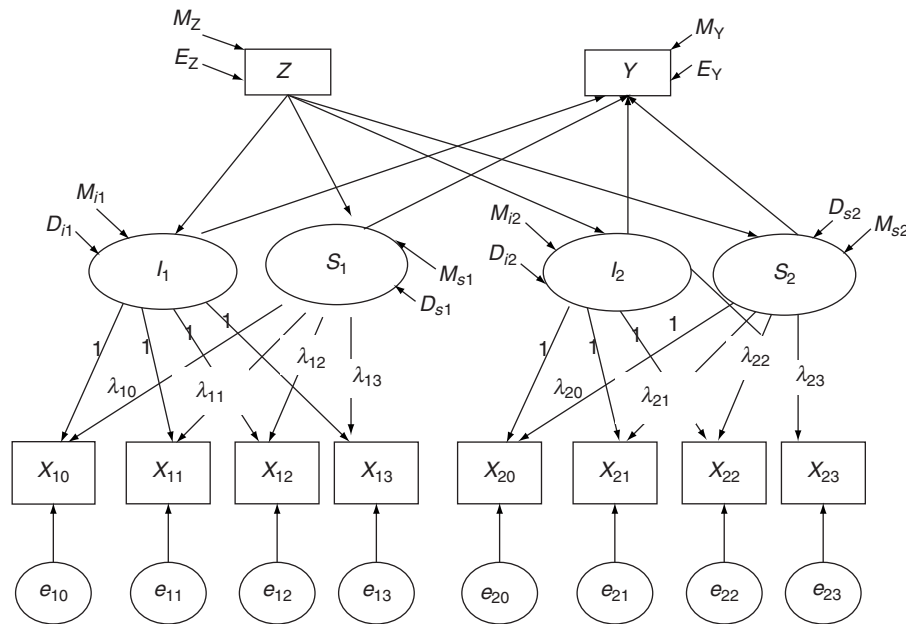

Figure 2 Bivariate LGM with individual-level predictor and outcome variables.

Table 4 Results from bivariate latent linear growth models for cognitive self-concept (CC) and general self-concept (GC)

<i>Fixed part parameters</i>	<i>Estimate</i>	<i>SE</i>	<i>t</i>	
Latent means				
CC Intercept	2.689	0.033	81.725	
CC Slope	−0.269	0.012	−21.885	
GC Intercept	2.655	0.033	80.695	
GC Slope	−0.334	0.013	−26.485	
<i>Variance (diagonal), covariance (above diagonal), standard error (in bracket) and correlation (below diagonal) of the random intercepts and slopes</i>				
<i>Random part parameters</i>	<i>CC intercept</i>	<i>CC slope</i>	<i>GC intercept</i>	<i>GC slope</i>
CC intercept	0.262 (0.025)	−0.018 (0.007)	0.107 (0.019)	0.002 (0.007)
CC slope	−0.206	0.030 (0.004)	−0.009 (0.007)	0.003 (0.003)
GC intercept	0.418	−0.098	0.250 (0.025)	−0.025 (0.008)
GC slope	0.027	0.093	−0.280	0.032 (0.004)

Table 2. The mirror differences are attributable to the use of the different software and fitting algorithms.

Gender was then included as an individual-level predictor of change. The results are presented in **Table 5**. Again, the results of gender as a predictor of the intercept and slope of growth are identical to those obtained earlier using the multilevel model. In this example, we did not include an outcome variable on the individual level to be predicted by the growth models. As shown in **Figure 2**, such variables can also be included in the growth curves model. Finally, this conditional multivariate latent growth model showed sound goodness-of-fit indicators (chi-square = 66.493, $df = 26$; RMSEA = 0.077; CFI = 0.976; TLI = 0.967).

Structural Cross-Lagged Regression Model

The structural cross-lagged longitudinal model based on the pioneering work by Jöreskog and Sörbom (1979) is depicted as a path diagram in **Figure 3**.

Table 5 Results from including gender as a predictor of growth trends of cognitive (CC) and general self-concept (GC) using multivariate latent growth model

Dependent variable	Estimate	SE	<i>t</i>
CC intercept	−0.308	0.063	−4.867
GC intercept	−0.442	0.060	−7.392
CC slope	0.009	0.025	0.359
GC slope	0.049	0.025	1.925

The model in **Figure 3** includes two variables, X_1 and X_2 , measured on four occasions. The observed scores, X_{1t} , $t = 0, 1, 2, 3$ and X_{2t} , $t = 0, 1, 2, 3$, are linear functions of latent scores (true scores), ξ_{1t} , $t = 0, 1, 2, 3$ and ξ_{2t} , $t = 0, 1, 2, 3$, plus measurement errors, e_{1t} , $t = 0, 1, 2, 3$ and e_{2t} , $t = 0, 1, 2, 3$. These relations are defined as

$$X_{1t} = \xi_{1t} + e_{1t} \quad t = 0, 1, 2, 3$$

and

$$X_{2t} = \xi_{2t} + e_{2t} \quad t = 0, 1, 2, 3$$

Each latent variable at time t is a function of three parts: (1) an autoregression (β_{x1} and β_{x2}), which represents the effect of the same variable on itself across two consecutive time points and constrained to be equal across times; (2) a cross-lagged regression (γ_{12} and γ_{21}), which represents the effect on one variable at a later time from the other variable at a previous time, and is also constrained to be equal across times; and (3) a residual which is allowed to correlate with the residual of the other variable at the same time point and is constrained to be equal across times. These relations are defined as

$$X_{1t} = \beta_{x1} X_{1t-1} + \gamma_{21} X_{2t-1} + \xi_{1t} \quad t = 1, 2, 3$$

and

$$X_{2t} = \beta_{x2} X_{2t-1} + \gamma_{12} X_{1t-1} + \xi_{2t} \quad t = 1, 2, 3$$

According to these equations, the autoregression and cross-lagged regression effects are parameters affecting the observed variables but not the growth functions derived from the observed variables over time. This modeling

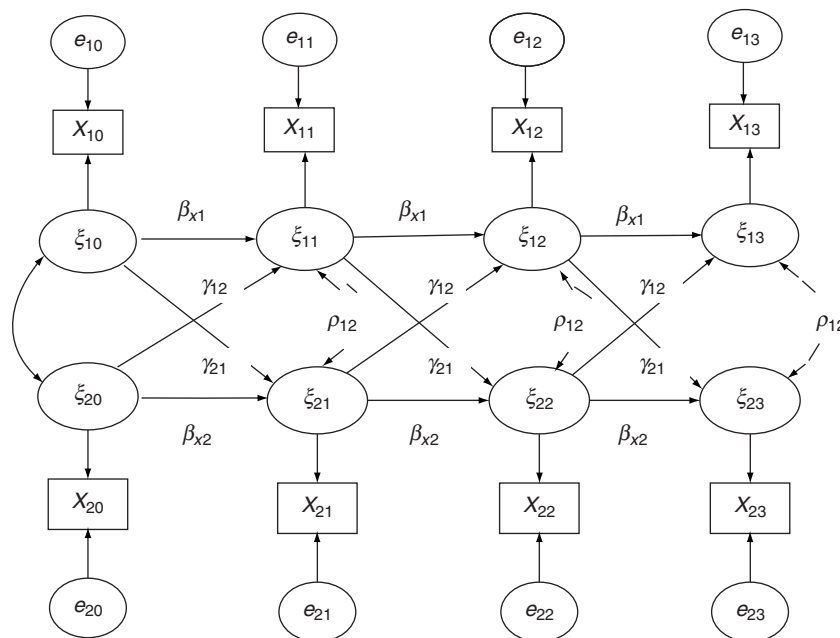

Figure 3 Path diagram of a bivariate cross-lagged regression model.

characteristic distinguishes the cross-lagged regression model from the other two growth models presented earlier. That is, we cannot directly estimate a growth function and directly account for the growth variations among individuals. The cross-lagged regression model approaches the growth or change question by examining each individual cross-lagged change. This cross-lagged change approach can be seen by re-writing the above equations into the first difference equations as the following:

$$\Delta X_{1t} = \beta_{x1}(\Delta X_{1t-1}) + \gamma_{21}(\Delta X_{2t-1}) + \Delta \zeta_{1t} \quad t = 1, 2, 3$$

and

$$\Delta X_{2t} = \beta_{x2}(\Delta X_{2t-1}) + \gamma_{12}(\Delta X_{1t-1}) + \Delta \zeta_{2t} \quad t = 1, 2, 3$$

where $\Delta X_{1t} = X_{1t} - X_{1t-1}$ represents the change of variable X_1 from time $t-1$ to time t , and $\Delta X_{2t} = X_{2t} - X_{2t-1}$ represents the change of variable X_2 from time $t-1$ to time t .

Again, the cross-lagged model defines growth by computing a series of intercorrelations to represent consecutive time change in observations but not by estimating a single statistical function to summarize the potential data trend from repeated observations. This characteristic makes the cross-lagged model not directly comparable with the other two models.

The structural cross-lagged regression model in **Figure 3** is the so-called unconditional model because we do not specify individual-level predictors to account for the series of cross-lagged intercorrelations. In fact, the model in **Figure 3** specifies only one variable that has repeated measurements over four time points. In such data structure, there is not even the distinction between predictor and outcome variables. They are both predictor and outcome variables depending on the time of measurement.

Like the other two growth models previously discussed, it is possible to formulate a conditional model by specifying individual-level predictors of the time series of intercorrelations. Different from the other two previously discussed models, the predictor variables can be time varying or time invariant. They can also be directly observed variables or latent variables derived from multiple indicators. **Figure 4** presents the simplest conditional model by including one directly observed and time-invariant predictor, Z . In the figure, Z is specified to predict the latent variables ξ_{10} and ξ_{20} but we can use Z to predict latent variables derived from all the time observations such as ξ_{11} , ξ_{21} , ξ_{12} , ξ_{22} , ξ_{13} , and ξ_{23} . In the latent cross-lagged regression model, the variable Z is defined to predict the measurements of different times but not to predict changes of measurements over time. The cross-lagged model is thus different from the other two growth models discussed earlier.

Data Illustration

The numerical results for multivariable longitudinal responses cross-lagged regression model is presented in **Table 6**. The model has satisfactory goodness of fit (chi-square = 30.112, $df = 26$; RMSEA = 0.024; CFI = 0.997; TLI = 0.997). As shown in **Table 6**, the autoregression effects for both variables are high (0.080 and 0.813 for CC and GC, respectively), suggesting strong stability across time. The cross-lagged regression from cognitive self-concept to general self-concept (0.080) is statistical significant, suggesting that the level of one self-concept in the previous year affects change in the other self-concept in the next year. The cross-lagged regression from general self-concept to cognitive self-concept is not significant

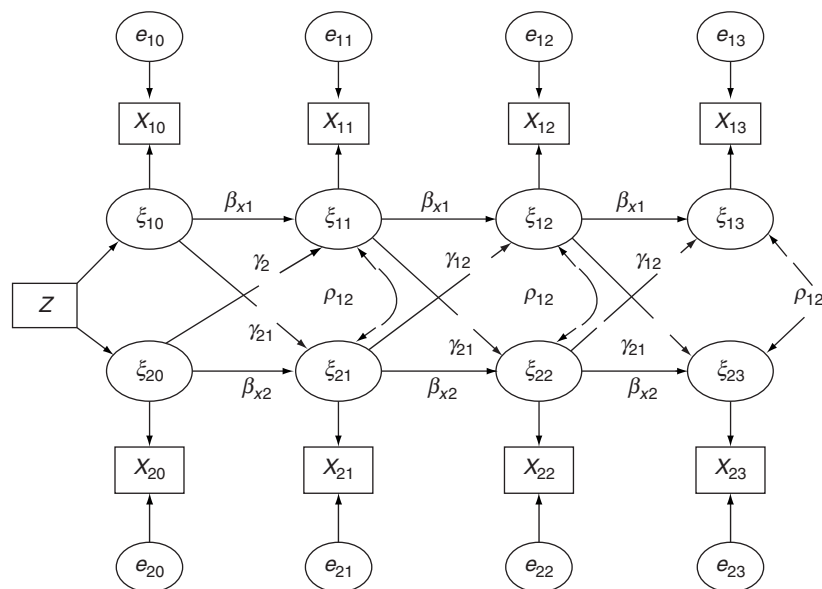

Figure 4 Path diagram of a bivariate cross-lagged regression model with one predictor variable.

Table 6 Results from cross-lagged bivariate model for cognitive self-concept (CC) and general self-concept (GC)

	<i>Estimate</i>	<i>SE</i>	<i>t</i>
Regression coefficient			
Auto-regression (CC)	0.866	0.024	36.509
Auto-regression (GC)	0.813	0.025	32.702
Cross-lag (CC → GC)	0.080	0.024	3.349
Cross-lag (GC → CC)	0.026	0.025	1.047
Variance			
σ_0^2 (CC)	0.279	0.024	11.489
σ_0^2 (GC)	0.285	0.025	11.489
σ_d^2 (CC)	0.141	0.007	19.900
σ_d^2 (GC)	0.143	0.007	19.900
Var_{dxy} (CC with GC)	0.002	0.005	0.492

Table 7 Results from including gender as an individual level predictor variable of cognitive self-concept (CC) and general self-concept (GC) using cross-lagged bivariate model

<i>Dependent variable</i>	<i>Estimate</i>	<i>SE</i>	<i>t</i>
CC at time 1	-0.294	0.062	-4.710
CC at time 2	-0.064	0.048	-1.345
CC at time 3	-0.040	0.047	-0.838
CC at time 4	0.052	0.047	1.107
GC at time 1	-0.454	0.059	-7.632
GC at time 2	0.001	0.048	0.025
GC at time 3	0.055	0.048	1.146
GC at time 4	-0.068	0.047	-1.433

(0.026). The variance of the two self-concept at the initial observation is high (0.279 and 0.285), whereas the residual variance is low (0.141 and 0.143), suggesting strong predictions across consecutive times. These results indicate that the changes in both variables are strongly influenced by their own changes, and there is a cross-lagged regression from cognitive self-concept to general self-concept.

Table 7 reports the results from the conditional model that includes gender as a directly observed individual-level predictor. Both the CC and GC are higher for girls, which was coded as 0, than for boys, which was coded as 1, (-0.294 and -0.454 for CC and GC, respectively). The direct effect of gender on cognitive self-concept and general self-concept from time 2 to time 4 are not significant (-0.064, -0.040, and 0.052 for CC; 0.001, 0.054, and -0.068 for GC). The cross-lagged regression model yields satisfactory goodness of fit (chi-square = 43.407, $df = 27$; RMSEA = 0.048; CFI = 0.991; TLI = 0.988).

Conclusion

In this article, we introduced three multivariate longitudinal methods namely the multilevel longitudinal model, latent growth curve model, and cross-lagged regression

model. A real data set was used to illustrate the operations of these methods, the interpretations of their results, and the differences and similarities among the three methods. Multilevel model analyzes longitudinal data within the HLM framework and the latent growth curve model analyzes longitudinal data within the SEM framework. However, these two methods use the same analytical approach to investigate developmental questions by estimating statistical functions of growth and by accounting for the variations across individuals in these growth functions. In our examples, we specified linear growth function by estimating the intercept and the linear slope. Other growth functions such as quadratic functions can be similarly estimated and modeled. These two methods yield identical results which are also presented in similar forms by the two programs. The cross-lagged method approaches growth differently by estimating a series of regression coefficients across times. This approach represents growth and development by focusing on changes over time and inter-correlations between variables across time. One advantage of the cross-lagged regression method that is absent from the other two methods is that individual-level variables may serve both as predictor and the outcome variables of the various regression coefficients representing change across time.

We presented the basic models of the three methods, whereas these models may be extended to include more advanced data analytic features (McArdle and Hamagami, 2001; Muthén *et al.*, 2002, 2003). One advanced data feature that all three methods have is to impute missing data. For the growth curve and cross-lagged method, missing data are usually handled by multiple imputations or multiple group analyses. The treatment of missing data is more complicated with the multilevel growth modeling method because of the nested nature of the data structure. However, the method can handle such unbalanced data where the space between repeated assessments is different among individuals. Finally, the examples we used are based on directly observed variables. To a different extent, all three methods can treat latent constructs measured by multiple indicators.

Quasi-Experimentation: Two Group Design

E Hong, University of Nevada, Las Vegas, NV, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Causal inference – The conclusion made based on the findings of a data analysis that an event or events caused a subsequent event.

Control group – A group of research units that does not receive a treatment in an experiment.

Experimental group – A group of research units that receives a treatment in an experiment.

Matching – A research procedure that equates two or more groups on one or multiple extraneous variables prior to experimentation in order to rule out their effects on the relationship between treatment and outcome.

Nonequivalent control group design – A quasi-experimental design in which research units are not randomly assigned to experimental and control groups.

Quasi-experiment – An experiment in which research units are not randomly assigned to experimental conditions.

Randomized experiment – An experiment in which research units are randomly assigned to experimental conditions.

The three main objectives of this article are to: (1) illustrate the major types of two-group quasi-experimental designs, (2) identify major threats to the validity of causal inferences involved in each design, and (3) illustrate how some of these threats are controlled by specific features of the designs. Although the title of this article reads ‘Two-group designs’ – reflecting that research engages one experimental group and one control group – quasi-experimentations can involve more than two groups. For example, one treated group and multiple untreated groups with different conditions, two treated groups and one untreated group, other combinations of groups are possibilities.

As with randomized experiment (also called true experiment; Rosenthal and Rosnow, 1991), quasi-experiment includes interventions or treatments manipulated by the investigator, pretests and/or posttests, and a number of groups in the study. Similar to randomized experiments, quasi-experiments are used to examine cause-and-effect relationships by testing hypotheses about manipulated variables – that is, the researcher manipulates the cause, and the effect is measured following the manipulation.

The most distinguishing feature between quasi-experimentation and randomized experimentation is that, in the former, participants (units) are not randomly selected and, often, they are not randomly assigned to treatment conditions. In educational research, randomized experimentation is limited for investigating problems encountered in classrooms and schools. It is not unusual that randomization is impossible to employ because randomization procedures can be disruptive to groups of individuals in existing conditions (e.g., classes or schools). Thus, experiments are conducted on volunteers, with some units selecting treatment for themselves (self-selection) or teachers, principals, or others deciding which units receive which treatment (administrator-selection) (Shadish *et al.*, 2002, 2007).

Although researchers have some controls over their scheduling of data-collection procedure, such as selecting measures or scheduling treatment, units in the control condition in quasi-experimentation may be different from those in the treatment condition in many nonrandom ways beyond the intervention provided to the experimental group (Campbell and Stanley, 1966; Shadish *et al.*, 2007). Therefore, manipulation or control is possible only on some of the relevant variables in quasi-experimentation.

In these situations, observed treatment effects may be caused by some sources – other than the treatment itself – that differ systematically. More threats to the validity of a causal inference between treatment and outcomes exist in quasi-experimentation than in randomized experimentation. Some systematic variations generated by sources other than the treatment could be alternative explanations for the observed effect. Due to these threats, findings from quasi-experimentations are not as dependable as those from randomized experimentations. Thus, the researcher using quasi-experimental designs must document potential sources for alternative explanations as closely as possible (e.g., students’ ability or previous achievement, students’ socioeconomic level, teachers’ experiences) and take measures to assess whether any of the alternative explanations account for the observed effect. To rule out possible alternative or rival hypotheses, the researcher may use a modified design that can detect alternative explanations.

In brief, educational researchers conducting quasi-experimentation should endeavor to build as much control as possible into the design, use available information to assess the similarity between experimental and control groups, and interpret outcomes in the context of the

information employed and the experimental conditions (Wiersma and Jurs, 2005).

This article introduces two-group designs (treatment and control groups) with or without pretests, their sources of invalidity, and ways to control some of the threats these designs incur. This article is divided into two sections: (1) two-group designs without pretest (i.e., posttest-only) and (2) two-group designs with pretest and posttest.

Two-Group Designs with Posttest-Only

As this article only includes quasi-experimentation, all groups are assumed to be formed nonrandomly. To indicate features of quasi-experimental designs diagrammed throughout this article, the following notations are used. The temporal order is indicated by the position of entities – from left to right. The broken line in the diagrams separates nonequivalent groups (experimental group vs. control group) – that is, since randomization has not been employed, the equivalence of units in the two groups is not assured.

E Experimental group

C Control group

X Treatment

O Observation (pretest or posttest)

Posttest-Only Design with Nonequivalent Groups

E X O₁

C O₂

In this design, participants in only the experimental group receive treatment (*X*). This design is weak and may not be used unless some data are available that can be used to assess the extent of pretreatment similarity between the two groups. Participants' initial differences in some important variables may have differential effect on observations (*O₁* and *O₂*). For example, participants in one group may be more motivated, more intelligent, or different from those of the other group in some systematic ways. Thus, selection bias is the most serious threat to the validity of a causal inference made from research results of this design and may be the most plausible alternative explanation to the observed effect. This design may best be employed when participants in the two groups are comparable and similar on the trait being measured before the treatment is given to the group, with documented data to examine the trait in question. Other potential threats to validity include history, instrumentation, maturation, subject attrition, diffusion of treatment, experimenter effects, subject effects, and statistical conclusion.

One reason for using this weak design over pretest–posttest design could be that pretest may sensitize participants and thus affect their responses to the posttest. For example, racial prejudice measured prior to a treatment (e.g., positive behavioral messages) may sensitize participants, thus affecting their responses to the racial prejudice measure observed following the treatment. If a treatment effect is found in this instance, the extent of the testing effect is difficult to isolate from the treatment effect.

However, this testing effect may be reduced when different treatment groups are compared, because the threat to internal validity (testing effect) is constant across groups. Shadish *et al.* (2002) summarize how the testing effects can be reduced, including examples of studies that employed a variety of control approaches (p. 116): administering alternative forms of a test (one at pretest and the other at posttest), using item-response theory (IRT) to calibrate different tests to the same scale, lengthening the time interval between pretest and posttest, using a Solomon Four Group Design to assess the presence and impact of such effect, using unobtrusive measures that are less reactive than self-report, using techniques such as the bogus pipeline, using retrospective pretests, and using explicit reference groups or behavioral criteria to anchor responding.

Shadish *et al.* (2002, 2007) suggest several approaches to improving posttest-only design with nonequivalent groups. This article illustrates three of the approaches that are, largely, applicable to educational research: (1) posttest-only design using proxy pretests; (2) posttest-only design using matching; and (3) posttest-only design using multiple control groups.

Posttest-only design using proxy pretests

E O_{A1} X O_{B2}

C O_{A1} O_{B2}

Instead of gathering pretest and posttest data on the same test, one can measure proxies for pretests. Proxies are variables that are conceptually related to – and correlated with – the posttest (Cook and Campbell, 1979; Shadish *et al.*, 2002, 2007). In the diagram above, *A* represents the proxy pretest and *B* the posttest. A misconception, often, found in the use of proxies is utilizing measures that may be related to an outcome but are not conceptually related to the outcome specific to the study. At times, proxy pretests are more relevant than a pretest on the outcome variable itself. For instance, when evaluating a statistics course with a medium-level difficulty for students who have not studied such statistics, a pretest on the medium-level statistics may not produce much variability. Instead, a proxy pretest of introductory-level statistics or

mathematical aptitude may be a better choice. Indexing selection bias and attrition bias will depend on the extent of correlation between proxies and the posttest.

Posttest-only design using matching

$E_{\text{matched}} X O_1$

$C_{\text{matched}} O_2$

Another way to reduce selection bias due to having no pretests is employing a matching approach to forming treatment and control groups. Matching is performed on correlates of the posttest. In the diagram above, E_{matched} and C_{matched} represent the two groups (E and C) that were matched on some correlates of the posttest.

The purpose of matching (or blocking) is to form the two groups with participants whose characteristics on the matching variable are similar, thus yielding similar scores on the matching variable. As with proxy pretests, matching variables should be correlated with the posttest. The matching technique has been used frequently in twin studies (Ashenfelter and Krueger, 1994).

Shadish *et al.* (2002) list various methods used for matching (p. 119). Exact matching yields exactly the same score for units within a match – which is difficult to achieve when samples are small or if the distribution of participants in each group on the matching variable is unbalanced. When matching variables are measured in very fine gradations, exact matching may not be a good choice. Caliper matching uses scores within a defined distance of each other. The distance can be measured in various ways, yielding information for Mahalanobis distance matching or nearest-neighbor matching (Hill *et al.*, 2000; Rosenbaum, 1995). Other matching methods include index matching, cluster group matching, benchmark group matching, and optimal matching (Shadish *et al.*, 2002, 2007).

Although matching is used to decrease selection bias, in quasi-experimentation its use can be quite problematic. Matching can be a very useful addition to random assignment. However, matching in quasi-experimentation is, often, not effective when it is not conducted carefully. For example, matching performed on an unstable or unreliable variable can be more harmful than helpful (Shadish *et al.*, 2002). When the populations being matched do not overlap completely on the matching variable, the outcome may result in an unpredicted direction (Campbell and Erlebacher, 1970). This occurs more often when the matching variable has a large amount of measurement error and has an imperfect correlation with outcome. In addition, with an incomplete overlapping population for matching variable, statistical regression can occur. Marsh (1998; cited in Shadish *et al.*, 2002) compared a gifted and talented population with a control population for the evaluation of programs for gifted and talented children.

Matches were obtained from the overlap between the lower end of the gifted and talented population and the upper end of the control population (i.e., match did not overlap completely). Statistical regression occurred at the posttest – with children attending the gifted and talented program regressing upward toward their population mean and those in the control group regressing downward – making the gifted and talented programs look more effective than they might otherwise have been. Using as many relevant variables as possible is also an important item to consider for matching.

It is important to form experimental and control groups, prior to matching, that are as similar as possible (D'Agostino and Kwan, 1995). As indicated, matching on unstable and unreliable variables is more harmful than useful. One can improve reliability of matching variables by creating a composite of many variables taken at the same time. For example, the researcher may use an average of several test scores measured prior to the treatment as a matching variable. When using more than one variable, a multivariate composite may be used for matching. The importance of using better matching procedure cannot be stressed enough. As Shadish *et al.* (2002) conclude, “The days of simple matching on single variables that are not reliably measured should be left completely behind” (p. 122).

Posttest-only design using multiple control groups

$E X O_1$

$C_A O_{A2}$

$C_B O_{B2}$

... ..

$C_N O_{N2}$

In the diagram above, A through N represent multiple control or comparison groups. The control groups do not receive treatment, whereas the experimental group does (X). However, these control groups are selected from populations with similar characteristics of the experimental populations except for certain conditions that separate them from the experimental group. For example, Bell *et al.* (1995; cited in Shadish *et al.*) compared an experimental group that received job training with four comparison groups. Research participants in the four groups had distinct characteristics that separate them from those of the experimental group: those who failed to apply for the program; rejected applicants; accepted applicants who failed to show; and those who started treatment but dropped out. Including such groups in a study enables the researcher to index the magnitude of hidden biases that may present (Rosenbaum, 1995). In the study by Bell *et al.* (1995), if the four comparison groups are as different from one another as they are from the treatment group, the result indicates that the treatment effect is not significant.

In many research situations, the direction of bias in each control group is known when compared to the treatment group. In such cases, the researcher may be able to bracket the treatment effect within a range of known biases. Bracketing controls – advanced by Campbell (1969) and Shadish *et al.* (2002, 2007) – involves selecting a group predicted to outperform the treatment group and another group predicted to underperform it. The finding on the treatment effect becomes strengthened if the treatment group outperforms both groups.

Two-Group Designs with Pretest and Posttest

Although including control groups in quasi-experiments (designs described above) is useful in making causal inferences, designs with a control group – as well as pretest – increase chances to detect the cause-and-effect relationship, if, in fact, there is such a relationship. Pretest measures can be taken on the same outcome variables as the posttest or on variables that are highly related to the outcome. Pretests provide the researcher with information that can be used to detect threats to validity (e.g., selection bias) by revealing whether and to what extent the two groups differ initially.

Pretest–Posttest Control Group Design

$E O_1 X O_2$

$C O_1 O_2$

This is the most common design widely used in quasi-experimentation. The design has been previously termed the “nonequivalent control-group” design by Campbell and Stanley (1966), the “untreated control-group design with pretest and posttest” by Cook and Campbell (1979), and “untreated control-group design with dependent pretest and posttest samples” by Shadish *et al.* (2002, 2007). As indicated in the diagram, the experimental group (E) receives treatment (X), whereas the control group (C) does not. Because data on both pretest and posttest are collected on the same participants, samples become dependent. Although selection bias exists due to using nonequivalent (nonrandomized) groups, the researcher can explore the direction and magnitude of the selection bias using pretest measures. Pretest scores can be used for statistical control or to generate gain scores (Wiersma and Jurs, 2005). Threats to the validity of this design include selection, statistical regression, and instrumentation. In addition, the existence of pretest differences indicates that selection may combine with other treatments additively or interactively. Such interactive threats include selection-maturation,

selection-instrument, selection-regression, and selection-history (Shadish *et al.*, 2002).

A selection-maturation interaction-threat exists if participants in one group learn faster or grow more tired than participants in another group. Shadish *et al.* illustrate patterns of research outcomes that may reveal the plausibility of threats. A fan-spread model of maturation occurs when the nonequivalent groups grow apart over time – from the center out to the edges at different average rates in the same direction. Fan-spread happens because measured variances grow systematically over time. Standardization of scores may reduce the fan-spread effect (Shadish *et al.*, 2002). However, when self-selection or administrator-selection into the treatment group represents selection bias in such a way that treatment condition is selected for participants who are, for example, more motivated to improve, it is likely that the treatment group improves at a faster rate for reasons that are not related to treatment. In such instances, score transformation will not be able to differentiate the treatment effect from this alternative explanation (i.e., selection-maturation interaction). Shadish *et al.* offer a few analytic clues for detecting a fan-spread type of maturation (p. 140). First, if the selection-maturation interaction is the reason for the mean difference between groups, then the differential growth shown between the experimental and control groups should also take place within groups. If higher-performing members of the group with the higher pretest scores grow faster than lower-performing members of the same group, then the selection-maturation threat may be the alternative explanation. Second, plot pretest scores against possible maturational variables (e.g., years of teaching experience) for the two groups separately. If the slope of the regression equation is not homogeneous, growth rates of the two groups differ. This differential growth is not due to treatment, obviously, since the treatment has not taken place yet.

Another outcome of possible selection-maturation interaction is demonstrated when change or growth does not occur in the control group (Shadish *et al.*, 2002). One might question why is it that behavioral change occurred only in the experimental group while even a slower rate of behavioral change did not take place in the control group? Again, analyses performed within groups may help detect the plausibility of selection-maturation threat. If, for example, years of teaching experience in a study with teachers may be the possible variable causing the differential growth between two groups (i.e., the treatment group has more teachers with longer careers in education), then the number of years can be used to split the data. On the other hand, if participants in the treatment group demonstrate behavioral changes whether they are novice or experienced teachers, the plausibility of selection-maturation explanation decreases.

Another pattern of outcome that involves selection-maturation threat is when the control group outperforms

the treatment group. Although the causal relationship from this type of outcome is mostly interpretable, the reasons for the initial difference should be carefully examined for possible selection-maturation threat. Using the same example, teachers in the control group had more years of teaching experience as compared to teachers in the experimental group.

As mentioned earlier, additional threats caused by selection bias combined with other sources of invalidity include selection-instrumentation, selection-regression, and selection-history. A selection-instrumentation threat occurs when the instrument (e.g., rater) changes differently for the experimental and control groups. For example, two observers rate classroom behavior of children prior to and following the introduction of a behavior-modification intervention to the experimental group. The differential change in the instrument occurs when the observer in one group becomes bored or tired over time. In this case, the mean difference found in the posttest could be the result of selection-instrumentation effect. The selection-instrumentation threat can be increased when the pretest scores have different beginning points – especially when the extent of initial group difference is large, the pretest-posttest change is great, and floor or ceiling effects occur (i.e., group means are close to one end of the scale).

A selection-regression threat occurs when one group has more extreme scores on the pretest than the other group. For example, in a study that experiments with a new instructional approach to reading, a group gets a disproportionate number of children with low reading ability. This group will likely have a posttest mean that will regress toward the population mean, thus giving the appearance that this group gained more than did the other group, although the gain may not be from the treatment.

Lastly, a selection-history threat occurs when an event or events occur between pretest and posttest that affect one group more than another. Participants in the two groups who differ initially (i.e., selection bias) react differently to an event (i.e., history). In the study introduced above – a new instructional method for reading – the experimental group happens to be composed of quite a few children whose parents tutor for reading. If the mean posttest score of the experimental group were higher than the control group, it could be misleading since one cannot isolate the effect by the treatment.

Shadish *et al.* (2002, 2007) describe several approaches to improving pretest-posttest design with nonequivalent groups. This article illustrates three designs that are largely applicable to educational research: (1) pretest-posttest control group design with multiple pretests; (2) pretest-posttest control group design using switching replications; and (3) pretest-posttest control group design using a reversed-treatment control group.

Pretest-posttest control group design with multiple pretests

$E\ O_1\ O_2\ X\ O_3$

$C\ O_1\ O_2\ O_3$

A two-pretest design is illustrated in this section. O_1 and O_2 are the same pretest administered at two different time points. Note, in the diagram, that the intervals between O_1 and O_2 and between O_2 and O_3 (posttest) are the same – which is a preferred method in analyzing the treatment effect as it provides information to address possible threats to validity. A selection-maturation threat can be examined in this design for the control group by comparing the growth rates between O_1 and O_2 and between O_2 and O_3 (posttest). Whether the rate of growth from O_1 to O_2 continues between O_2 and O_3 without the treatment can be assessed, although changes in the instrument between the two intervals make the comparison less ideal. In addition, the group difference in the pretreatment growth can be examined with the addition of the second pretest in order to evaluate the plausibility of selection-maturation threat. Presence of regression effects can also be assessed with the double pretest if the O_2 score is uncharacteristically low or high compared to O_1 , in either group (Cook and Campbell, 1979; Shadish *et al.*, 2002).

Pretest-posttest control group design using switching replications

$E/C\ O_1\ X\ O_2\ O_3$

$C/EO_1\ O_2\ XO_3$
