Leadership: Authentic

P T Begley, Pennsylvania State University, University Park, PA, USA

© 2010 Elsevier Ltd. All rights reserved.

Authentic leadership is a metaphor for professionally effective, ethically sound, and consciously reflective practices in educational administration. It alludes to a knowledge-based, values-informed, and skillfully executed leadership. Leadership by definition refers to practices that extend beyond the usual procedural context of organizational management. Authentic leadership implies a genuine kind of leadership – a hopeful, open-ended, visionary and creative response to social circumstances, as opposed to the more traditional dualistic portrayal of management and leadership practices characteristic of now-obsolete research literature on effective principal practices (Begley, 2001). Moreover, in recent years, management has been negatively portrayed as mechanistic, relatively shortsighted, and a precedent-focused enterprise. An integrated image of leadership and management more in keeping with current times is a values-informed leadership – a form of leadership that acknowledges and accommodates, in an integrative way, the legitimate needs of individuals, groups, organizations, communities, and cultures – not just the organizational perspectives that are the usual focus of most leadership literature. It is a perspective that has, in recent years, been explored by several other scholars, including Taylor (1991), Duignan and Bhindi (1997), and Starratt (2004). The innovative dimension being proposed here is the adoption and application of a values and valuation process perspective to educational leadership to make the objectives of administration more understandable, compelling, and achievable. It is in this context that authentic leadership is proposed as the outcome of self-knowledge, sensitivity to the orientations of others, and a technical sophistication that leads to a synergy of leadership action (Begley, 2001, 2003).

Relationship of Valuation Processes to Authentic Leadership

There are essentially three ways in which valuation processes relate to authentic leadership. The first is as an influence on the cognitive processes of individuals and groups of individuals. Understanding how values reflect underlying human motivations and shape subsequent attitudes, speech, and actions is essential knowledge for any person in a leadership role. Leaders should know their own values and ethical predispositions, as well as be sensitive to the value orientations of others. The second way in which valuation processes relate to leadership practices is as a guide to action, particularly as supports

to resolving ethical dilemmas. Ethics are highly relevant to school leadership as rubrics, benchmarks, socially justified standards of practice, and templates for moral action. The third way in which valuation processes relate to leadership is as a strategic tool that leaders can employ to build consensus among the members of a group toward the achievement of shared organizational objectives. In this sense, leaders literally use ethics as a leadership tool in support of actions taken. Authentic leadership is therefore grounded in the understanding or interpretation of observed or experienced valuation processes as well as in ethical decision-making processes.

Research on principal valuation processes (Begley and Johansson, 1998) and problem-solving processes (Leithwood and Steinbach, 1995) demonstrates that administrators tend to employ ethics as a guide to action under certain conditions: in situations of high stakes and urgency, when consensus is impossible, when responding to unprecedented situations, and for certain hot-button social issues which tend to quickly escalate debate to a point where people seek refuge within an ethical posture. Ethics may be consciously or unconsciously employed in such situations. A typical application for ethics is as a personal guide to action, particularly as a support to resolving ethical dilemmas. However, there are more strategic and collective applications for ethics. One of the most common in a school or school district setting is using an ethic as a focus for building consensus around a shared social objective. These collective and strategic applications of ethics may be the more common manifestation of this value type in the administration of schools and school districts, as well as in the corporate sector. However, this is yet to be confirmed empirically by any systematic research beyond that conducted by Langlois (2004).

The Valuation Processes of Individuals

In order to understand the relationship between motivation and values, and between values and authentic leadership actions, it is helpful to conceptually situate values within the context of one person's being using a simple onion figure. **Figure 1** (Begley, 2006) is an adaptation of a graphic originally proposed by Hodgkinson (1978, 1991, 1996).

Beginning from the outside, the first ring represents the observable actions and speech of the individual. Leaders and people in general intuitively rely on the clues provided by the actions and attitudes of others to derive

Figure 1 Values syntax. From Begley, P. T. (2006). Self-knowledge, capacity and sensitivity: Prerequisites to authentic leadership by school principals. *Journal of Educational Administration* 44, 570–589.

predictive insights into the nature of the values others hold. This is a generally sound strategy, but has the same limits to its reliability in day-to-day life as it does in a research context. Political leaders, principals, teachers, parents, and children regularly demonstrate through their speech and actions that their observable actions may or may not be accurate indicators of their underlying values. Individuals often articulate or posture certain values while actually being committed to quite different ones. In both the research and the leadership context, the implication is clear. The validity and reliability of interpretation is best enhanced by sustained periods of observation and multiple measures.

The next ring or layer of the figure represents attitudes. Attitudes can be thought of as the membrane between values and the observable actions or speech of an individual, or the permeable boundary of personality that acts as the interface between the psychological and physical world. They are the predisposition to act specifically as a result of values or value systems acquired previously and elsewhere (Begley, 2001). For example, the attitudes of educators toward students encountered in their professional setting may change when they become parents, with young children of their own. Conversely, when we look across a career, we can see that the values of an individual in one role as a teacher, principal, or professor readily spill over as attitudes into other social roles. The strength of this extended influence can be residual in nature, a significant spillover of effect, or intrude to such an extent that it overrides or neutralizes the influence of a

second value or value system. Hodgkinson (1991) also suggests that attitudes can often be detected in the body language of posture, gait, or unconscious muscular tensions. They are outward and visible signs of inner and invisible inclinations.

The next layer represents the actual values held or manifested by an individual. For example, while one person might prefer a glass of beer to a glass of Shiraz, another might prefer a chat with friends in the staff lounge to reading the newspaper, or working independently over working in a group, or a monarchical system of government over a republican system. A school leader might gravitate toward relatively controlled approaches to delegating authority over more open styles of distributed leadership. A teacher might prefer computer-mediated instruction to workbook exercises, or instruction individualized to students' needs as opposed to a teacher-centered curriculum. The important thing to keep in mind is that identifying these values is one thing, while knowing why they are held is quite another. Making that latter judgment requires going deeper into the onion.

Between the values layer and motivational base layer of the figure is a category that can be labeled available knowledge or understandings. The kinds of knowledge referenced here are acquired through life experiences, professional training, and reflection, and provide a linkage and context between the motivational bases and the specific values adopted by the individual. The contention here is that, as a result of experience, training, and/or reflection, an individual responds to basic motivations by adopting particular value positions that will support the fulfillment of that basic motivation in a specific way. These responses are manifested through actions or speech selected by the individual to achieve the valued objective. People vary, of course, in terms of the skills and sophistication they can bring to bear on achieving their objectives. This is generally applicable to all aspects of human enterprise. Consider how an experienced school administrator, consensually motivated as a professional to achieve a complex set of educational objectives, might employ a carefully orchestrated collaborative school-improvement project to achieve these educational objectives. By contrast, a less-experienced administrator, with the same desire to build consensus among the faulty, but responding to different knowledge or the absence thereof, might decide a memo is all that is required to achieve the same objective.

The motivational base layer of the onion figure provides the key to understanding the nature and function of values as influences on leadership. This is the motivating force dimension behind the adoption of a particular value which, working out through the layers of the figure, shapes attitudes and potentially influences subsequent actions. Hodgkinson (1978, 1991, 1996), proposes that there are four basic motivational bases: personal preference

or self-interest, an inclination toward consensus, an inclination toward or concern for consequences, and an inclination toward transrational ethics or principles. These four motivational bases are relatively broad and arbitrary distinctions. In application, individuals can manifest a predisposition toward one motivational base over another, or adopt more than one motivational base when responding to a given situation. Research conducted in several countries on the valuation processes of school administrators (Begley and Johansson, 1998) suggests that the normative motivational bases for administrative decision making are the rational domains of consequences and consensus. Self-interest is infrequently acknowledged as a motivation, predictably because professional activity is publicly accountable. Ethics and principles tend to be employed relatively infrequently as motivational influences on the cognitive processing of individuals. Leaders do, however, regularly employ ethics as strategic supports to a collective leadership process. The distinction being made here is between processes where leaders use ethics for strategic purposes as opposed to being ethical.

The final layer at the center of the figure is the self—the biological self as well as the existential or transcendent self. The formation of the self and its relevance to authentic leadership is something which also warrants some attention.

Arenas of Leadership: Sources of Influence, Values, and Conflicts

The external influences on leadership and education in general can be thought of as coming from multiple social sources. Some of these influences can take on the status of values when they are perceived as conceptions of the desirable with motivating force (Hodgkinson, 1991). Unfortunately, our personal values as well as those of the profession, organization, community, and society are not necessarily consistent or compatible with each other. As a result, these influences and values derived from the various arenas of our environment can generate inconsistencies and conflicts. A second onion figure (see **Figure 2**) is used to illustrate these distinctions. These are the interactive environments within which valuation processes and administration occur. They are also the source of personal, professional, and social values, as well as the source of many of the conflicts people encounter in life.

Within the figure, the individual is represented within the center ring and extending through all the rings. His or her character is the outcome of many transient influences as well as relatively more enduring values acquired from multiple arenas.

The second ring from the center represents the arena of groups and other collective entities including family, peers, friends, and acquaintances. The third ring, profession, represents a more formal arena of administration that is

Figure 2 Arenas of influence. From Begley, P. T. (2006). Self-knowledge, capacity and sensitivity: Prerequisites to authentic leadership by school principals. *Journal of Educational Administration* 44, 570–589.

closely related to the second ring, but is given special emphasis here because of its relevance to the professional context that is the focus of this article.

The fourth ring, the organization, represents the arena that is traditionally of most concern to academics and practitioners in the field of educational administration. Much of the literature of educational administration and most of the corporate literature are grounded within the organizational perspective, adopting it as a primary reference point for administrative activity.

Moving further outward in the figure, one encounters the arena representing the greater community, society, and culture. Within recent decades, school administrators have learned that it is necessary to pay a lot more attention to the community as a relevant administrative arena and source of influence on school leadership (Leithwood *et al.*, 1992). The increasing diversity of our societies and a general trend toward globalization have highlighted society and culture as relevant arenas of administrative activity.

A final, sixth ring is included to accommodate notions of the transcendental – God, faith, spirituality, and even extra-sensory perception. Spirituality is of considerable importance to many individuals and has begun to attract the attention of more scholars as an important influence on educational leadership. Even administrators who do not subscribe to a spiritual dimension as a source of influence on their own daily lives are well advised to keep this arena in mind, even if only because others associated with their professional roles do so. A leader who wants to understand the motivations of those he/she is supposed to lead will be sensitive to all potentially significant categories of influence.

Complications

Having made the case for authentic leadership through the adoption of a values perspective on problem-solving and decision-making processes, and having outlined the conceptual framework underpinning these assertions, the rest of the article is devoted to the consideration of several specific complications that emerge as implications.

Inauthentic or False Leadership

As already stated, research findings (e.g., Begley and Johansson, 1998) confirm that the relevance of principles or ethics to a given administrative situation seems to be prompted in the minds of school administrators by particular circumstances. These circumstances include: situations where an ethical posture is socially appropriate (e.g., the role of the arts); situations where consensus is perceived as difficult or impossible to achieve (e.g., an issue involving ethnic bias); or situations when high stakes and urgency require decisive action (e.g., student safety). There is also some evidence to suggest that school leaders use ethics in strategic applications as ways to develop group consensus, and as a basis for promoting compliance with minimum need for evidence (Langlois, 2004). These are all examples of authentic leadership and ethically sound applications of ethics to leadership situations. However, one only has to survey the newspaper, or work in any organization, or live in any community for a time, to readily detect situations where ethic-based postures can be unethical or socially unjust. For example, ethical postures may be unethical in application when they are used to impose a culturally based ethic on people from another culture. It is equally unethical to employ ethics as a justification for otherwise reprehensible action (e.g., flying passenger jets into skyscrapers). The common political or organizational tactic of adopting an ethical posture to veil a less-defensible value is also a violation of ethics. In addition, fundamentally, it is unethical to employ a culturally derived ethic as the justification for trumping basic human rights. The implication is that using ethics is not always ethical. Such is the nature of ethics when they are adopted as guides to action. Transrational values (Hodgkinson, 1978, 1991, 1996) of any sort, and ethics and principles in particular, are rather vulnerable to multiple interpretations in application from one social context to another. In educational leadership situations, the application of an ethical posture in arbitrary ways (e.g., democratic process or the will of the majority) can often produce outcomes that are far from ethical (or democratic). The essential, and often absent, component that would make adherence to a value genuinely ethical is dialog.

Cross-Cultural Issues

Distinctive, unique, or minority-based social conditions may be obscured, veiled, or blurred by the perspectives

and language adopted to describe social processes. In many respects, this is a natural outcome and limitation of language as a means of assigning meaning to concepts and events, or the bounded rationality that occurs when models and frameworks are applied to complex social situations. This is also an outcome of general human inclinations to generalize the specifics of one context to the point that they become automated as a cognitive schema or a set of abstract principles (Begley, 1996). Similarly, a number of scholars, notably Allan Walker and Clive Dimmock, believe that the field of educational administration has developed along ethnocentric lines, dominated by Western perspectives emanating mostly from the United States and United Kingdom (Dimmock and Walker, 1998; Walker and Dimmock, 1999; Walker, 2003). The consequences are a risk that the generalized experiences of one country may be inappropriately assumed to be instructive to practices in radically different contexts. As societies become more globalized, and as the exchange of information among international scholars becomes more widespread, the implications become more urgent. Many administrators are discovering that some of their society's most cherished ethical foundations sometimes must be carefully re-examined in terms of how they are interpreted as well as their appropriateness to social circumstances. As our communities and societies become more diversified, school administrators must become more sophisticated in their leadership and more sensitive to the value orientations of others. For their part, researchers must move beyond their traditional orientation toward generalization and description to also consider the deeper matters of intent and motivational base. Once again, what emerges as the critical implication is the need for dialog and negotiation of meaning among stakeholders in professional educational settings.

Conclusion

It is not enough for school leaders to merely emulate the values of other principals currently viewed as experts. Leaders in schools must become reflective and authentic in their leadership practices. There is no reliable catalog of correct values that school leaders can adopt as solutions for the dilemmas of administration. School leadership situations are much too context bound to permit this kind of quick fix. School leaders need to be reflective practitioners. The first step toward achieving this state is, predictably enough, to engage in personal reflection (Coombs, 2004). The adoption of a values perspective on school leadership can transform this rather idealistic advice into something specific enough for school administrators to act upon. However, once a degree of improved self-knowledge has been achieved through personal reflection, administrators must then take the next step

toward authentic leadership. That is, they must strive to develop sensitivity to the value orientations of others in order to give meaning to the actions of the students, teachers, parents, and community members with whom they interact. This is both a personal quest for the leaders as well as a collective one for the organizational unit for which the leader is responsible. The authentic leader needs to work strategically to engage the school community in a collective and ongoing dialog on the dilemmas of professional practice and the social problems of the community. Authentic leadership occurs when understanding the value orientations of others provides leaders and the professionals as well as the community members to whom they are accountable with information on how they might best influence the practices of others toward the achievement of broadly justifiable social objectives.

Leadership: Democratic

J Møller, University of Oslo, Oslo, Norway

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Democratic school leadership is a relational concept which must be contextualized. It is situated in a democratic governance structure and policies that aim at educating students for citizenship in a democratic society. Depending on the cultural context and the people involved education for democracy can be framed differently, and the exercise of democratic leadership in practice varies greatly from school to school (cf. Blase *et al.*, 1995). Besides, schools have increasingly become sites of disputes with parents claiming the rights of their children to special education programs, to special treatments, to exceptions to school policies, etc. (Starratt, 2004). Some will emphasize democracy-creating, which involves building the conditions for and encouraging democratic participation. Others will highlight democracy-doing, which includes collective decision making, voting, and the initiative by all members in a community (Woods, 2005). Much of the disparity can be linked to the complexities of the social organization of a school and to the fact that images of school leadership must be analyzed in relation to historical distinction and sociocultural contexts (Møller and Schratz, 2008).

My approach to conceptualization is that democratic leadership is a moral activity which cannot be fully grasped without including a discussion of what we mean by an education based on democratic values. It implies that the primary responsibility of education is to create democratic citizens, a conviction that a more democratic and egalitarian organization of society is both possible and desirable, and that education can have an important role to play in attaining this kind of society (cf. Grace, 1995, Banks *et al.*, 2005). Becoming a knowledgeable and engaged citizen, who is responsive to diversity within and across nations, is a process, and education should facilitate the development of students' consciousness and agency. It requires both knowledge about democracy and experiences of democracy through democratic leadership in practice. Neither is sufficient alone.

Education for Democracy

Scholars have theorized extensively about issues of democracy. Dewey's (1937) writings about lived democracy and his vision of a great community, Habermas' (1987) theory of communicative rationality and Arendt's (1958) vision of a

provisional community where the public space is identified with plurality have all figured prominently in these views.

In short, democracy means rule by the people, drawn from the Greek word *demos* which signifies people and *kratos* which implies rule. Democracy consists in two complementary ideals, one involving equal distribution of the power to make collective decisions, the other equal participation in collective judgment (Warren, 2002). In other words, it is not only equality of votes, but also equal and effective opportunity to participate in processes of collective judgments. Many consider deliberation to be the ideal way of making collective judgments because it requires reasons to be developed and justifications to be given and opinions to be cultivated. It seeks to provide space for the political deliberation of moral issues. It is a theory of the procedures that allow moral conflicts to be argued, and disputes over norms are dependent upon deliberation for valid resolutions (Warren, 2002).

Dewey extended the concept by saying that democracy is a way of living together as well as a kind of government. For Dewey (1937), educational institutions have an important role to play in helping the development of the individual's character. His view of democracy rests on a certain faith in the capacity of human nature. The development of truly democratic communities is restricted by our inability to critically examine currently held assumptions, and these habits are learned in schools. Therefore, it is only through considerable political learning that students can recognize their potential and become citizens who are capable of deliberating about what they are doing, set goals and priorities for themselves, and work for the common good. The best way to teach and learn democracy, Dewey says, is to practice it.

In education, critical theorists such as Apple (2000) and Bates (1989) have analyzed the relationship between society and education within the conception of a critical democracy, focusing on who is included within a community, and who is left out. They underscore that a community is always constituted within specific historical conditions and against a background of political interests. According to Apple and Beane (1999), the central concerns of democratic schools include the open flow of ideas that enables people to be as fully informed as possible; a faith in the individual and collective capacity of people for resolving problems; use of critical reflection to evaluate ideas, problems, and policies; concern for the welfare of others and the common good; and concern for the dignity and rights of individuals and minorities.

In a similar way, Furman and Starratt (2002) underscore that establishing a forum for democratic participation is not sufficient. In addition, democracy “requires the *ability* to listen, understand, empathize, negotiate, speak, debate and resolve conflicts in a spirit of interdependence and working for the common good” (p. 118). In other words, education for democracy implies engaging the students in reasoned deliberations. They argue for a new understanding of the idea of democratic community. This understanding should be based on the acceptance and celebration of difference rather than the nostalgic striving for homogeneity, and include key concepts like interdependence and the common good. Moreover, they make a claim about a strong moral sense as a basic component of a democratic community that values sociality itself, a reverence for open inquiry and critique, a respect for individuals, and the interdependence of all. They emphasize the need for a school curriculum that is compatible with these moral dimensions.

In sum, the following themes are common to many definitions of education for democracy: (1) recognizing the basic value and rights of each individual; (2) taking the standpoint of others into consideration; (3) deliberation in making decisions; (4) embracing plurality and difference; and (5) promoting equity and social justice.

Conceptualizing School Leadership

Not only education for democracy is contested, but also our understanding of leadership varies widely. A line may be drawn between those who frame principalship as the key to school development (Hallinger and Heck, 1996; Leithwood *et al.*, 1990), and those who emphasize leadership as taking place in the interactions between people and their situations (Foster, 1986; Hargreaves and Fink, 2006). A relational perspective implies that school leadership is not necessarily synonymous with a particular position; it may come from school principals, teachers, or others; in other words, it is distributed within the organization and stretches over the school’s social and situational contexts (Spillane *et al.*, 2004; Gronn, 2002).

The distributed perspective, which implies that the leadership capacity lies not only within individuals, but is also constituted by the institutional arrangements, culture, and relationships, is currently gaining terrain. However, even though many argue for the potential of distributed leadership, studies often demonstrate a focus on how the principals develop personal styles and courage relative to the perceived and actual pressures (Day, 2007; Leithwood *et al.*, 2006). Moreover, the model of system leadership, which is now emerging and is associated with distributed leadership as a concept, has paradoxically a strong individual and heroic focus. Hopkins (2006), a strong promoter of this model, underlines that system leaders are those head

teachers who are willing to shoulder the system-leadership roles and care about and work for the success of other schools as well as their own. It entails that school leaders should take greater responsibility for neighboring schools as well as their own, and the vision of shared leadership is turned into even higher individual expectations to head teachers.

Critical theorists such as Anderson (1996), Bates (1989), Blackmore (1996), Foster (1986), and others have argued that the dominant traditions of theory and practice in educational administration often serve to justify uncritical patterns of organizations and control in schools that both mirror and reinforce the dominant patterns of inequality in the wider society. For instance, Foster has claimed that

... the concept of leadership has been chewed up and swallowed down by the needs of modern managerial theory. The idea of leadership as a transforming practice, as an empowerment of followers, and as a vehicle for social change has been taken, adapted and co-opted by managerial writers so that now leadership appears as a way of improving organizations, not of transforming our world. (Foster, 1989: 45)

This does not mean that leadership and management are separate, however. If management is viewed as maintaining the school organization, and leadership is seen as developing the school, in practice, they overlap (Harris *et al.*, 2007).

Comparing Democratic Leadership with Distributed Leadership

Distributed and democratic leadership have much in common, but the two concepts also provide different frameworks on leadership practice (cf. Harris *et al.*, 2007). A main distinction can be drawn between a normative and a descriptive way of framing leadership. Democratic leadership implies that one of the main responsibilities of school leaders is to build educational institutions around central democratic values such as promoting equity and social justice in the school as well as in the wider community. It emphasizes that the underlying principles and values of a democratic approach need embedding in both management and leadership practices. Both need to reinforce and uphold a focus on social justice and a concern for the welfare of others, including the dignity and rights of minorities and individuals. Putting empowerment as a central principle involves balancing power and trust whether in the area of leadership or management. It means creating a stimulating learning environment where pupils flourish and develop as citizens.

While democratic leadership requires serious attention to the value base of leadership practice and the processes that create and sustain social justice, empowerment, and

community, distributed leadership is a descriptive way of conceptualizing the phenomenon or a conceptual framework for thinking about the work of leadership. It is a way of conceptualizing how leadership practice takes shape in the interactions between leaders and followers in their situation. As such, it is an analytical perspective which provides a lens for generating knowledge about how leadership is practiced. Similar to democratic leadership, it is about dispersed activity in which initiative circulates widely. However, while distributed leadership can be understood as a helpful descriptive or analytical conception that has a potential of highlighting some ideas across different societies, the value base is not necessarily linked to social justice and an education based on democratic values as is the case with democratic leadership. As Woods (2005: 23) has emphasized, democratic leadership grows from a concern with philosophical, political, and sociological questions that surface with the idea of opening the boundaries of leadership, and translating into practice the ideals which form an integral part of democratic rationalities.

Distributed leadership, as developed by Gronn (2002) and Spillane *et al.* (2004) is helpful as an analytical perspective, but it becomes problematic when it is used a normative concept simply as another way of referring to democratic leadership. Figure 1 demonstrates how distributed and democratic leadership represents different frameworks and also how they overlap and have certain concepts in common (cf. Harris *et al.*, 2007).

The two lenses both focus on leadership as interaction and communicative action and are closely linked to a sociocultural perspective on learning, but the value base is explicitly connected to social justice and equity within a framework of democratic leadership.

Empirical Studies of Democratic School Leadership

Statements about democratic missions for schools have been found in policy statements in most countries since the twentieth century, but it is an empirical question to what degree these missions influence schooling. How do such democratic missions unfold in practice? Empirical studies in support of democratic school leadership tend to

Figure 1 The relationship between distributed leadership and democratic leadership.

be case studies, and such approaches to research will not produce a universal list of what characterizes a democratic leader. However, it may enhance a better understanding of what goes on in schools and provide examples of how the conditions on which a democracy depends might be established in different contexts. For this purpose, a few studies have been selected.

Such examples are, for instance, given in the book *Democratic Principals in Action* (Blase *et al.*, 1995), where the authors have presented a series of portraits of eight principals, who are struggling to move toward more democratic forms of school administration. When the book was published all the school principals were members of the League of Professional Schools in Georgia. This league's purpose was to establish democratic decision-making structures to promote teacher involvement in school-wide instructional and curricular decisions (Blase *et al.*, 1995). The stories of the eight principals did not represent perfect role models. On the contrary, these principals were not perfect, and shortcomings and confusions were apparent among them all. Their stories do however show that democratic leadership can be framed differently, depending on the people involved and the context, and that they were struggling daily to fulfil their vision. However, they shared common orientations:

- They all tried to encourage teachers' involvement in decision making about instruction and were committed to the principle of sharing power with others.
- They were all child centred and strongly committed toward improving teaching and learning and supporting teachers.
- They all had trust in teachers' motives.
- They all had the ability to listen and to communicate openly.

Their personal satisfaction was linked to seeing growth in teachers and programs. They talked about the pride they felt because of what they had achieved from working together. However, the relationships with school boards were problematic. The principals were caught between traditional central-office expectations and teachers' new expectations for participation in decision making. Transforming organizational and cultural structures required a great deal of time over the long term. There was no quick fix.

Several studies have been carried out on the effects of the League of Professional Schools in Georgia, and a summary is provided by Allen and Glickman (2005). In their review of these studies they emphasized that although the studies showed that leadership did not lie only with the individuals, the principal's leadership seemed crucial for the school's development. For instance, interviews with all veteran League principals indicated that these principals had stopped trying to be fixers, and instead they enabled other's efforts to reach solutions to problems. In addition,

they modeled involvement in curriculum, staff development, and student learning. They exhibit trust and respect for teachers and encouraged involvement from a wide range of people. Interviews with teachers reinforced this picture. A survey of principals and teachers in 46 League schools also confirmed that implementing the League's framework had resulted in improvement of student learning and faculty learning.

The task ahead is not just about formulating a vision for democracy and inclusiveness. This is illustrated by a case study based on observations in two Norwegian schools over a period of 9 months. The study explored the negotiation of meaning and manifestations of leadership working for democracy in a multiethnic environment (Vedøy and Møller, 2007). Both schools had a strong commitment to comprehensive education and social justice, inspired by social democratic politics for promoting equity. However, the analysis demonstrated clear differences in creating challenging learning environments for all students, and these differences were closely linked to the leadership approach by the principal at the local school. Through an implicit discourse of pluralism based on goodness and caring, and with a focus on deficits, the principal at one of the schools actually suppressed democratic processes to the development of diversity in the school. The other school provided an example of how the principal, through an explicit discourse of critical multiculturalism based on respect, opened up for democratic processes and learning. Based on the findings, it is argued that the principal plays a pivotal role for including all stakeholders in the work for democratic schooling.

These findings echo Shields' (2006) analysis of how schools work for promoting social justice. Her study explores some of the challenges experienced by both practitioners and researchers attempting to work within political frameworks in which educational discourse is dominated by discourses of accountability, high-stakes testing, and a new standard of scientific research. Her analysis is drawn from interviews with 12 practicing educators in three schools. All three principals had a reputation for promoting social justice. In her investigation she uses three different story lines in which principals and teachers describe some of the challenges presented to them in their roles and how they have addressed them in practice. Her analysis clearly shows how the different story lines used by the participants in the study demonstrate differences in ways in which principals and teachers both incorporate theoretical perspectives and navigate dominant discourses of high-stakes accountability and scientific research. The first story focused on the deficit and neither the principal nor the teachers expected high levels of student achievement. As such, their deficit thinking masqueraded their talk about social justice. They had a negative focus on the students and their inability to improve their performance on test scores. In the second story the educators tried to make a difference

for the individual students, but the school did not seem to address the learning environment in a systemic way. Thus, the teachers remained isolated islands of success. The third narrative demonstrated that there is not necessarily a dichotomy between discourses of social justice and high academic achievement on the part of the students. This school could serve as an example of school-wide transformation and success. According to Shields, the knowledgeable principal was crucial for such an achievement. She had a clear sense of purpose related to how to create a learning environment in which all children may not only feel they belong, but also in which they may be successful. Moreover, she was able to engage her staff in extensive dialog about how to make meaningful change to make sure that the decisions were grounded in theories of social justice.

Other researchers have examined whether the means used to achieve the democratic purpose of schooling by the educational authorities were consistent with the end. For instance, Mulford (2004) explored this aspect in terms of principal training in Australia. In his analysis he concluded that different initiatives and strategies at national level seemed to reinforce this purpose, but this was not the case at state level in Tasmania. He has provided examples which show how it was expected that the school leaders should promote democracy in schools, but the principals were not themselves treated in a democratic way by their employer. In other words, many of those who were telling schools what to do were often unwilling to accept responsibility for their advice, blaming everybody else for lack of success. Common excuses were budget cuts or change of government.

Similar, an analysis of successful school leadership in Norway has shown that despite the democratic rhetoric in policy documents, it often seems difficult to make democratic dreams into reality. Competition and individualism are on the rise in the society and valued over cooperation and interdependence. Schools are expected to fulfil a mission which the wider society has dumped in practice, and learning is talked about as being part of an economic exchange between a provider (teacher) and a consumer (student). However, simultaneously, the study demonstrates that schools can still support activist professionals who counteract the tendency toward an economic way of thinking about education (Møller, 2006, 2007). The study showed how principals, in collaboration with teachers, continually worked to mediate government policy and external changes so that they could be integrated with the school's values about developing a more just society. Specific democratic values such as establishing open communication between staff and students; creating opportunities for student decision making and deliberation; a personal commitment to making a difference in students' lives; and establishing an ethic of care for individuals as well as a concern for the common good were enacted through the leadership at the school. As such, the study provides an example of

democratic school leadership in practice, with particular attention to the distribution of power and leadership in the school, student voice in the decision-making process, their opportunities for open dialogs, and the conditions that must be in place for students to develop as citizens.

Summary

Empirical studies can provide examples of how the conditions on which a democracy depends might be established, and serve as an inspiration for democratic leadership working for democracy in different contexts. However, the task ahead is not just about modeling and developing democratic practices within the school. It is also about challenging the wider power structures in which the school is embedded, and committing oneself to work for social change. Today, there are evidences of a widespread erosion of public trust in representative democracy in many countries, and the September 11 has recast the debate on multiculturalism and led to a review of what we understand by democracy (MacBeath, 2004). We know not only that poverty is closely linked to student achievement, but also that schools can make a difference in students' lives. As a consequence, teaching about and for democracy cannot be a theoretical notion. Teacher and student learning mirror one another, and democratic leadership includes a consideration of the ways in which external social structures are reproduced through the administration of schooling.

More research that helps us to understand leadership for socially just and democratic communities is needed. Democratic leadership is a slippery subject for research because it is so closely related to how we understand democracy in schools. Education based on democratic values is an ideal, a moral purpose toward which teachers and school leaders strive. It is about practice and processes, and it cannot be reduced to a tidy definition because it is necessary to focus on the links between democratic leadership practice and normative concepts of social justice and democratic schooling (Furman and Shields, 2005). It cannot be captured unless context is taken into account. Historical work can explain the past and anthropological work can examine culture, but there is also a need for understanding that what is happening at the school level is embedded and subsumed in wider social structures of power. What occurs in schools is necessarily contextualized. In addition, such research requires a careful examination of one's own beliefs and practices as researchers.

Leadership: Instructional

The Evolution of Instructional Leadership

Instructional leadership has its first roots in the teaching role of the head teacher of the school. As schools grew in size, their head teachers or principal teachers took on additional management responsibilities (Cuban, 1988; Tyack and Hansot, 1982). During the first decades of the twentieth century in the United States, the growth of education management as a profession saw conscious efforts to promote the status of school managers by emphasizing their managerial – as opposed to their instructional – responsibilities (Tyack and Hansot, 1982). This resulted in a continuing tension between the key roles of school leaders that persists to this day.

Cuban (1988), for example, identified instructional, managerial, and political roles that he asserted were equally relevant to work of successful school leaders. While acknowledging the importance of the instructional leadership role, Cuban contended that there is a DNA in the principalship that exerts an undeniable force on the occupant of the role to attend to managerial and political responsibilities and often to place them above the instructional role. He further suggested that attempts by principals to focus too tightly on the instructional role alone would be short-lived and potentially counter-productive.

The first significant attempt to clearly define conceptually and study empirically what we today term instructional leadership was undertaken by Gross and Herriott (1965) in a large-scale study of elementary school principals in the United States during the 1960s. These scholars formulated the construct of executive professional leadership (EPL) and developed associated measures for use in empirical research. They also reasoned that school leadership entailed working with educational professionals in the improvement of their schools and that attempts to lead would require a focus on the educational process of the school. Therefore, the foci embedded in their EPL construct and instrument included the principal's attention to educational standards, teachers' professional development, school goals and values, and the principal's role in helping to create meaning in the work of teachers. Gross and Herriott (1965) found positive correlations between EPL and three key outcomes: staff morale, the professional performance of teachers, and pupils' learning (pp. 150, 151).

These empirical findings were among the first systematically derived findings concerning the effects of

instructional leadership in schools. While these findings stimulated further interest in instructional leadership, Gross and Herriott's own discussion of the implications of their study frame tensions in this role in terms that resonate 40 years later.

Our findings bear upon a basic controversy over the role of school principals. For years they have been exhorted by their state and national associations and their superiors to make the most of their position; but recently the leadership conception of their role has been challenged as unrealistic and inappropriate. Principals, say the critics, should not engage in efforts to influence teachers' performance but simply provide routine administrative services; otherwise school administrators invade the teachers' professional autonomy. (Gross and Herriott, 1965: 151)

The EPL findings paved the way for future studies of the role of principal in school change and improvement during the 1970s. However, the true emergence of principal instructional leadership grew out of research on instructionally effective schools conducted during the mid- to late 1970s (Brookover and Lezotte, 1977; Edmonds, 1979; Rutter *et al.*, 1979). These studies found a clear association between instructionally effective schools and evidence of strong instructional leadership carried out by the school principal (Bossert *et al.*, 1982; Dwyer, 1986; Edmonds, 1979; Hallinger and Murphy, 1985a; Leithwood and Montgomery, 1982). Notably, publication of these findings came at a historical moment when policymakers, especially in the USA, were concerned about declining levels of school performance.

Subsequently, these research findings touting the importance of instructional leadership were widely disseminated during the 1980s. With these findings in hand, policymakers in the USA took steps to encourage all principals to strengthen their capacities in carrying out this role in order to make their own schools more effective. Critics identified holes in this logic (e.g., Barth, 1986; Cuban, 1988), as well as important limitations of the underlying research (Bossert *et al.*, 1982; Cuban, 1984). Nonetheless, by 1990 in the United States instructional leadership had become a normatively preeminent role that principals who wished to be effective were expected to fulfill.

Instructional leaders – goal oriented – were described as strong, directive principals who had been successful at turning around schools operating in difficult circumstances (Bamburg and Andrews, 1990; Bossert *et al.*, 1982;

Edmonds, 1979; Hallinger and Murphy, 1985a, 1985b, 1986). They defined a clear vision for the school focused primarily on the improvement of student academic outcomes (Bamburg and Andrews, 1990; Cheng, 1991, 1994; Glasman, 1984; Goldring and Pasternak, 1994; Hallinger and Murphy, 1986; Heck *et al.*, 1990; Leithwood *et al.*, 1990; Leitner, 1994; O'Day, 1983). The effective instructional leader was able to align the strategies and activities of the school with the school's academic mission (Bamburg and Andrews, 1990; Bossert *et al.*, 1982; Cheng, 1994; Cohen and Miller, 1980; Dwyer, 1986; Glasman, 1984; Goldring and Pasternak, 1994; Hallinger *et al.*, 1996; Heck, 1992, 1993; Heck *et al.*, 1990; Jones, 1983; Leitner, 1994).

Instructional leaders led through a combination of expertise and charisma. These were hands-on principals, hip-deep in curriculum and instruction (Cuban, 1984), and unafraid of working directly with teachers on the improvement of teaching and learning (Bossert *et al.*, 1982; Dwyer, 1986; Edmonds, 1979; Hallinger *et al.*, 1996; Hallinger and Murphy, 1986; Heck *et al.*, 1990; Leithwood *et al.*, 1990). Instructional leaders were viewed as a minority of principals who somehow managed to overcome the multiple pressures that push principals away from curriculum, instruction, and the classroom.

It is notable that during the 1980s relatively little reference was made to teachers, department heads, or even to assistant principals as instructional leaders. There was little discussion of instructional leadership as a distributed function to be shared beyond the role of the principal. This reflected a heroic view of this leadership role fostered by the imagery of the effective school literature as well as by intent of policymakers on implementing instructional leadership as a policy solution to problems of school performance.

During the 1990s, an emerging focus on teacher professionalism led to reconsideration of the instructional leadership role in schools. The idea that a single leader could fulfill the complex requirements of the instructional leadership role was questioned. The arguments raised by earlier critics such as Cuban and Barth resurfaced as the rhetoric of broad research findings bumped up against the reality of practicing instructional leadership in real schools. Several core issues pressed for the development of a view of instructional leadership as a shared or distributed role in schools.

- Under the emerging systems of school-based management, principals were being asked to take on ever greater responsibilities which further precluded a unitary focus on instructional leadership.
- The technical expertise required for instructional leadership was often beyond the capacity of any single individual in the school.
- The size and complexity of secondary schools made it difficult, if not impossible, for the principal to carry out

all of the tasks as described in the work of instructional leaders in smaller elementary schools.

- Contingency theories of leadership, selected empirical studies, and the wisdom of practitioners all supported the conclusion that the specific model of instructional leadership derived from research on instructionally effective elementary schools serving low-income children was not generalizable to all schools.

Consequently, during the late 1990s researchers turned toward the development of shared models of instructional leadership (Barth, 2002; Day *et al.*, 2001; Jackson, 2000; Lambert, 2002; Marks and Printy, 2004; Southworth, 2002). We will review the instructional leadership construct in light of this historical evolution.

It is interesting to observe and note that this heroic view of the principal as instructional leader is being resurrected at the present time by those who argue that principals should have or acquire a deep understanding of subject matter and how to teach it. Elmore's (2000) argument for such a view has received considerable attention among policymakers, and a compelling strand of research has demonstrated differences in how leaders interact with their colleagues based on their pedagogical content (usually mathematics) knowledge (e.g., Nelson and Sassi, 2005; Stein and Nelson, 2003).

While these authors acknowledge the possibilities for the distribution of such leadership, most of their cases and illustrations are focused on principals. This resurrection, it should be noted, comes at a time when principals are expected to work much more closely with parents and external community members, manage relationships with increasingly demanding teacher unions, balance shrinking budgets, and respond to a blizzard of accountability-oriented paperwork. This call for greater pedagogical content knowledge also comes as fewer and fewer teachers see much incentive for assuming what is increasingly being viewed as an impossible job.

A Conceptual Definition of Instructional Leadership

Following development of the EPL model by Gross and Herriott (1965), several notable models of instructional leadership were proposed, all grounded in the effective schools research base (see Andrews and Soder, 1987; Bossert *et al.*, 1982; Hallinger and Murphy, 1985; Leithwood *et al.*, 1990; Leithwood and Montgomery, 1982; Van de Grift, 1987; Villanova *et al.*, 1982) during the 1980s. A model proposed by Hallinger and Murphy (1985) has been used most frequently in empirical investigations (Hallinger, 2001; Hallinger and Heck, 1996a, 1996b). This model, similar in general terms to the others noted above, proposed three

dimensions for the instructional leadership role of the principal: defining the school's mission, managing the instructional program, and promoting a positive school learning climate (Hallinger, 2001; Hallinger and Murphy, 1985a). These three dimensions were further delineated into ten instructional leadership functions (see **Figure 1**).

Two functions, framing the school's goals and communicating the school's goals, comprise the first dimension, defining the school's mission. This dimension concerns the principal's role in determining the central purposes of the school. It describes the principal's role in working with staff to ensure that the school has both a broad inspiring mission as well as clear, measurable, time-based goals focused on the academic progress of students. It is also the principal's responsibility to communicate these goals so they are widely known and supported throughout the school community.

Within this model, the process of goal development was considered less critical than the outcome. Goals could be set by the principal or in collaboration with staff. The bottom line, however, was the school should have a clear, inspiring, academic vision that staff support and incorporate into their daily practice. This picture of goal-oriented, academically focused schools contrasted with the typical situation in which schools were portrayed as pursuing a variety of vague, ill-defined, and sometimes conflicting academic and nonacademic goals (March, 1978; Weick, 1976, 1982).

The second dimension, managing the instructional program, focuses on the coordination and control of instruction and curriculum. This dimension incorporates three leadership (or what could also be termed management) functions: supervising and evaluating instruction, coordinating the curriculum, and monitoring student progress. This dimension requires the principal to be deeply engaged in stimulating, developing, supervising, and monitoring teaching and learning in the school. Obviously, these functions demand the principal to have expertise in teaching and learning, as well as a commitment to the school's improvement. It is this dimension that requires the principal to become hip-deep in the

school's instructional program (Blasé and Blasé, 1998; Bossert *et al.*, 1982; Cuban, 1984; Dwyer, 1986; Edmonds, 1979; Marshall, 1996).

The third dimension, promoting a positive school learning climate, includes several functions: protecting instructional time, promoting professional development, maintaining high visibility, providing incentives for teachers, developing high expectations and standards, and providing incentives for learning. This dimension is broader in scope and purpose than the other two. It conforms to the notion that effective schools create an academic press through the development of high standards and expectations for students and teachers (Blasé and Blasé, 1998; Bossert *et al.*, 1982; Purkey and Smith, 1983).

Instructionally effective schools develop a culture of continuous improvement in which rewards are aligned with purposes and practices (Barth, 1990; Blasé and Blasé, 1998; Glasman, 1984; Hallinger and Murphy, 1986; Heck *et al.*, 1990; Leithwood and Montgomery, 1982; Mortimore, 1993; Purkey and Smith, 1983). Finally, the principal must model values and practices that create an environment and support the continuous improvement of teaching and learning (Dwyer, 1986; Hallinger and Murphy, 1985b).

Empirical Research on Instructional Leadership

Several reviews of the educational leadership literature by Hallinger and Heck (1996a, 1996b, 1999) found that instructional leadership was the most frequently studied model of school leadership during the past quarter century. Although theoretical interest in instructional leadership originated in the United States, research on instructional leadership has been extensive and global in scope. Important contributions have been made by researchers outside of the United States in North America, Europe, and Asia (e.g., Cheng, 1991, 1994; Day, 2002; Jackson, 2000; Leithwood and Jantzi, 1999; Mortimore, 1993; Southworth, 2002; van de Grift, 1989, 1990).

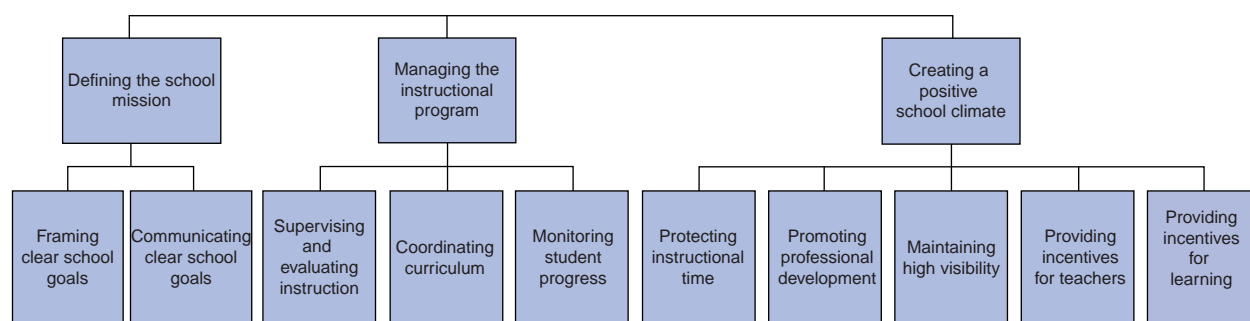

Figure 1 Instructional management framework. From Hallinger and Murphy (1985).

Research Trends

The most frequently used conceptualization of instructional leadership was developed by Hallinger during the early 1980s (Hallinger and Murphy, 1985a). Over 120 empirical studies have been completed using this conceptual model and related instrumentation – the principal instructional management rating scale (Hallinger, 2001 (it should be noted here that this paper has since been updated in 2007 but has not been presented or published. The figures presented here reflect the updated numbers from the most recent analysis in 2007)). This affords a useful perspective on development of interest in this leadership construct.

Although early studies of instructional leadership using the *PIMRS* were conducted almost entirely in the United States, subsequent studies have spanned North America, Europe, and Austral-Asia. If we break the period from 1983 to 2007 review into 5-year periods, it is possible to see the trend of scholarly interest in instructional leadership since the inception of the effective schools movement in the early 1980s. (It should be pointed out that the studies reviewed in the Hallinger papers consisted entirely of doctoral dissertations that used the *Principal Instructional Management Rating Scale* developed by him in 1982: 1983–1988 17 studies; 1989–1994 43 studies; 1995–2000 29 studies; 2001–2006 33 studies.)

This trend demonstrates a strong consistency of interest in the topic of instructional leadership over this 25-year period among scholars in educational administration. The first half of the period reviewed, 1983–1994, shows the growing interest in instructional leadership following the emergence of the effective schools movement. While interest waned somewhat during the mid-1990s, interest in studying this role of the school principal has remained quite stable since then.

Research Findings on Instructional Leadership

Scholars have conducted a substantial body of international research on instructional leadership since 1980. While the quality of the research remains somewhat uneven, the scope far exceeded prior efforts at understanding principal practice in this domain (Bridges, 1982; Hallinger, 2001; Hallinger and Heck, 1996a, 1996b). Consequently, there is a more systematic knowledge base today than existed 30 years ago.

This body of research has yielded findings concerning the:

- effects of personal antecedents (e.g., gender, training, and experience) and the school context (school level, school size, school SES) on instructional leadership;

- effects of instructional leadership on the organization (e.g., school mission and goals, expectations, curriculum, teaching, and teacher engagement); and
- direct and indirect effects of instructional leadership on student achievement and a variety of school outcomes.

Interested readers are referred to other up-to-date sources (Day *et al.*, 2001; Hallinger, 2001; Hallinger *et al.*, 1996; Hallinger and Heck, 1996a, 1996b; Leithwood *et al.*, 1990; Marks and Printy, 2004; Southworth, 2002; Witziers *et al.*, 1983). In brief, the following conclusions from research on instructional leadership warrant specification.

The preponderance of evidence indicates that school principals contribute to school effectiveness and student achievement indirectly through actions they take to influence school and classroom conditions (Hallinger and Heck, 1996a, 1996b, 1999). The size of the effects that principals indirectly contribute toward student learning though statistically significant is also quite small. While a small contribution may be meaningful, it is wise to keep in mind the strength of the treatment in relation to the desired outcomes when policymakers focus on the selection and training of school leaders as a strategy for large-scale change (March, 1978).

The most influential avenue of effects concerns the principal's role in shaping the school's mission (Bamburg and Andrews, 1990; Goldring and Pasternak, 1994; Glasman, 1984; Hallinger *et al.*, 1996; Hallinger and Heck, 1996a, 1996b, 2002; Hallinger and Murphy, 1985b; Heck *et al.*, 1990; Marks and Printy, 2004). This finding is important in that the effect of the vision/mission variable is strongly substantiated by research on leadership outside of education (e.g., Kantabutra, 2003).

The school context has an effect on the type of instructional leadership exercised by principals (Hallinger and Heck, 1996a, 1996b; Hallinger and Murphy, 1985b, 1986; Mulford and Silins, 2003). This finding is consistent with Bridges' (1977) assertion that principal leadership be viewed as both an independent and dependent variable also find empirical support. In particular, the role that principals play in mission building appears to be influenced by features of the school context (Bamburg and Andrews, 1990; Hallinger and Heck, 2002; Hallinger and Murphy, 1985b, 1986; Scott and Teddlie, 1987). Successful instructional leaders work with other stakeholders to shape the purposes to fit the needs of the school and its environment.

Instructional leaders also influence the quality of school outcomes through the alignment of school structures (e.g., academic standards, time allocation, and curriculum) and culture with the school's mission (Barth, 1990, 2002; Dwyer, 1986; Hallinger and Heck, 1996a, 1996b; Leitner, 1994; Southworth, 2002). Instructional leaders both lead through building a mission and manage through activities that increase alignment of activities with those purposes.

This again finds support in the more general leadership literature (e.g., Kantabutra, 2003; Kotter, 2002).

In 1980, popular images of instructional leadership portrayed principals as evidencing active hands-on involvement in classroom. It is interesting, however, to note that relatively few studies have actually found instructional leaders displaying this type of hands-on supervision of classroom instruction (Hallinger and Heck, 1996a, 1996b). Where principals do get actively involved in instructional supervision, it tends to be at the elementary school level (Braughton and Riley, 1991; Heck *et al.*, 1990; Hallinger and Heck, 1996a, 1996b). The preponderance of studies instead suggests that principal effects on classroom instruction operate through the school's culture and by modeling rather than through direct control through the supervision and evaluation of teaching.

Significant progress has been made over the past 30 years in understanding the nature of instructional leadership in schools. As a research topic scholars have studied the role extensively and with a variety of frameworks and methodologies. There is little evidence to support the view that on a broad scale at either the elementary or secondary school level, principals have become more significantly engaged in hands-on directed supervision of teaching and learning in classrooms.

Yet, if we define instructional leadership broadly to focus on the dimensions of defining a school mission and creating a positive school culture, the picture is somewhat different. Research on instructional leadership suggests that these dimensions of the principal's leadership role are becoming integrated more firmly into the principal's role behavior (Hallinger, 2004).

Toward Shared Instructional Leadership

Since the turn of the millennium, a global tsunami of educational reform has refocused the attention of policymakers and practitioners on the question: How can we create conditions that foster the use of more powerful methods of learning and teaching in schools (Caldwell, 2006; Hallinger, 2003; Jackson, 2000; Murphy, 2000)? This global focus on the improvement of learning and teaching has once again brought instructional leadership to the fore (Gewertz, 2003; Hallinger, 2003; Huber, 2003; Stricherz, 2001a, 2001b).

What should these instructional leaders be concerned with? A broad reading of the literature on instructional leadership that has emerged over the past 25 years would have instructional leaders focus on:

- creating a shared sense of purpose in the school, including clear goals focused on student learning;
- fostering the continuous improvement of the school through cyclical school development planning that involves a wide range of stakeholders;

- developing a climate of high expectations and a school culture aimed at innovation and improvement of teaching and learning;
- coordinating the curriculum and monitoring student learning outcomes;
- shaping the reward structure of the school to reflect the school's mission;
- organizing and monitoring a wide range of activities aimed at the continuous development of staff; and
- being a visible presence in the school, modeling the desired values of the school's culture.

However, the experience of policymakers and practitioners who have sought to exercise instructional leadership over the past 25 years provides a more realistic starting point. Contextual and structural constraints embedded in schools as organizations and in the DNA of the principalship suggest the need for a less heroic and more grounded conception of the instructional leadership role. Moreover, both practical experience and research findings suggest suitability of conceptualizing instructional leadership as a role to be shared by the principal with others in the school (Barth, 2002; Ogawa and Bossert, 1995).

This point was captured by Lambert (2002) who contends that, "The days of the lone instructional leader are over. We no longer believe that one administrator can serve as the instructional leader for the entire school without the substantial participation of other educators" (p. 37). Thus, several different writers have attempted to integrate these constructs into a variant referred to as shared instructional leadership (Barth, 2002; Day *et al.*, 2001; Donaldson, 2001; Jackson, 2000; Lambert, 2002; Marks and Printy, 2004; Southworth, 2002).

While several of the scholars cited here have written eloquently about the possible forms this might take, the most ambitious attempt to study shared instructional leadership empirically was undertaken by Marks and Printy (2004). Their study examined both instructional leadership and its major competitor for the attention of school leaders, transformational leadership (e.g., Leithwood and Jantzi, 2006). Their conclusion points the way toward bringing together both of these major approaches to school leadership by addressing both teachers' commitments and engagement (the transformational leadership focus) as well as the focus on student learning (the instructional leadership focus).

Although it is too soon to know whether the findings from the research by Marks and Printy will be replicated by others, their conclusion points the way toward one possible avenue of reconciliation for these constructs:

This study suggests that strong transformational leadership by the principal is essential in supporting the commitment of teachers. Because teachers themselves can be barriers to the development of teacher leadership (Smylie and Denny, 1990), transformational principals are needed to invite

teachers to share leadership functions. When teachers perceive principals' instructional leadership behaviors to be appropriate, they grow in commitment, professional involvement, and willingness to innovate (Sheppard, 1996). Thus, instructional leadership can itself be transformational. (Marks and Printy, 2004)

A second approach to understanding the relationship between these leadership models may lie in contingency theory (Hallinger, 2005). In a review of the literature on principal effects, Hallinger and Heck (1996a, 1996b) concluded that it is virtually meaningless to study principal leadership without reference to the school context. The context of the school is a source of constraints, resources, and opportunities that the principal must understand and address in order to lead. Contextual variables of interest to principals include student background, community type, organizational structure, school culture, teacher experience and competence, fiscal resources, school size, and bureaucratic and labor features of the school organization (Bossert *et al.*, 1982; Hallinger and Heck, 1996a, 1996b).

The contingent characteristic of leadership must be explicitly incorporated into theoretical models (Hersey and Blanchard, 1969). Leadership must be conceptualized as a mutual influence process, rather than as a one-way process in which leaders influence others (Bridges, 1977; Graeff, 1997; Jackson, 2000; Leithwood and Jantzi, 1999). Effective leaders respond to the changing needs of their context. Indeed, in a very real sense the leader's behaviors are also shaped by the school context.

Thus, one resolution of the quest for an integrative model of educational leadership would link leadership to the needs of the school context. Jackson (2000) and Fullan (2002) have observed that school improvement is a journey. The type of leadership that is suitable to a certain stage of the journey may become a limiting or even counter-productive force as the school develops (see also Hersey and Blanchard, 1969). Schools at risk may initially require a more forceful top-down approach focused on instructional improvement. Instructional leaders would typically set clear, time-based, academically focused goals in order to get the organization moving in the desired direction. They would take a more active hands-on role in organizing and coordinating instruction.

The practice of instructional leadership has benefitted from theoretical and empirical developments of the past 25 years. Nonetheless, the same tensions evident in the practice of this role suggested by Gross and Herriott in the 1960s and echoed by Cuban in the 1980s remain relevant today. We suggest that future development of instructional leadership in schools will benefit from recognition of its complexity as well as from understanding leadership as an organizational phenomenon (Ogawa and Bossert, 1995).

Leadership: Transformative

C M Shields, The University of Illinois at Urbana–Champaign, Champaign, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

The words promise, liberation, hope, empowerment, activism, risk, social justice, courage, or revolution do not automatically evoke images of educational leaders in charge of schools and systems, working within the dominant political and bureaucratic frameworks of the twenty-first century. Yet, all of these concepts are at the heart of transformative leadership – the concept to be explicated here. Transformative leadership (as opposed to either transactional or transformational leadership) takes seriously Freire's (1998) contention "that education is not the ultimate lever for social transformation, but without it transformation cannot occur" (p. 37). Transformative leadership begins with questions of justice and democracy; it critiques inequitable practices and offers the promise not only of greater individual achievement but of a better life lived in common with others. Transformative leadership, therefore, inextricably links education and educational leadership with the wider social context within which it is embedded.

This article provides an overview of the development of transformative leadership as a theory in its own right, distinct from transformational leadership; it demonstrates how both theories emerged from Burns' (1978) seminal book, *Leadership*; and explains how the terms, although originally often used synonymously, have developed into distinct theories – each with its own advocates, critics, and body of literature. The article concludes with an assessment of some of the strengths and weaknesses of transformative leadership and its potential to move the field of educational leadership forward in a time of conflict, confusion, and chaos.

Origins

Formal studies of educational administration and leadership owe much to the long history of work in other fields; nevertheless, in the middle of the last century, educational administration became a field of study in its own right. The futility of early efforts to identify physical traits, personal abilities, and individual attributes determinant of good leadership (interpreted most frequently as effective rather than moral) is well known, as are the attendant critiques of related great-man studies and rational, technical, positivist theories of leadership. Two early attempts to move beyond individual traits and characteristics of leaders were Burns' (1978) conceptions of transactional and transforming leadership. Transactional

leadership expressed the values and relationships often still associated with rational and technical forms of scientific management. Transforming leadership emphasized the ends of leadership as it sought to unite people around organizational goals.

These theories are well known, although the ways in which the latter concept has led to both transformational leadership and transformative leadership are less explored. The article clarifies this distinction, with particular emphasis on the latter – transformative leadership – as holding the most promise and potential to meet the needs of complex, diverse, and beleaguered education systems. **Table 1** demonstrates clearly, the deep differences among the three theories (transactional, transformational, and transformative) that have, in various ways, dominated the field of educational leadership for the last 30 years.

Ethical Leadership

Burns' concept of leadership requires a desire to "deal with leadership as distinct from mere power-holding and as the opposite of brute power" (p. 4). In Burns' conception, an amoral leader is an oxymoron. For that reason, Burns argues, "naked, power wielding can be neither transactional nor transforming; only leadership can be" (p. 20). Here, we note the centrality of moral and ethical behavior in Burns' conception of leadership. He begins his treatise by calling for a consideration of how both power (composed of motive and resources) and power relationships are central to comprehending the "true nature of leadership" (pp. 11–12). At the same time, neither transactional nor transformational leadership, as it has come to be known through the subsequent work of Bass (1985), Bass and Avolio (1994), Leithwood and Jantzi (1990, 1999), and others is adequate to address the challenges inherent in educating all students to high levels of personal intellectual development or of creating the civic capacity required for full participation in democratic society. Neither explicitly attends to the moral and ethical issues related to power relationships that may perpetuate inequity and inequality in organizations, although the moral dimension is more recognized in transforming leadership than in its transactional partner. To be a leader, according to Burns, is to induce "followers to act for certain goals that represent the values and the motivations – the wants and needs, the aspirations and expectations – *of both leaders and followers*" (p. 19, italics in original). Further, when

Table 1 Distinctions among three theories of leadership

	<i>Transactional leadership</i>	<i>Transformational leadership</i>	<i>Transformative leadership</i>
Foundation	An exchange	Meet the needs of complex and diverse systems	Critique and promise
Emphasis	Means	Organization	Deep and equitable change in social conditions
Processes	Immediate cooperation through mutual agreement and benefit	Understanding of organizational culture; setting directions, developing people, redesigning the organization, and managing the instructional program	Deconstruction and reconstruction of social/cultural knowledge frameworks that generate inequity, acknowledgment of power and privilege; dialectic between individual and social
Key values	Honesty, responsibility, fairness, and honoring commitments	Liberty, justice, equality, and effectiveness	Liberation, emancipation, democracy, equity, and justice
Goal	Agreement; mutual goal advancement	Organizational change; effectiveness	Individual, organizational and societal transformation
Power	Mostly ignored	Inspirational	Positional, hegemonic, tool for oppression as well as for positive action
Leader	Ensures smooth and efficient organizational operation through transactions	Looks for motive, develops common purpose, and focuses on organizational goals	Lives with tension and challenge; requires moral courage, activism
Related theories	Bureaucratic leadership, Scientific management	School effectiveness, School reform, School improvement, Instructional leadership	Critical theories (race and gender), Cultural and social reproduction, Leadership for social justice

he states that “transcending leadership is leadership engaged” (p. 20), he is pointing the way for transformative leadership which is inextricably engaged with the wider society.

which leadership eschews patronage in favor of rules and principles, can be clearly seen. Transactional leadership, for Burns, focuses on the means of leading, while transforming leadership implies a focus on the ends.

Transactional Leadership

Although Burns is often considered the originator of the concept of transactional leadership, it is important to note its origins in Weber’s (1924) earlier discussion of bureaucracy in which he discussed the categories of rational, legal, hierarchical power. Although Weber attempts to counteract the kind of bargaining that resulted in patronage and favoritism, there can be little doubt that he favored a kind of transactional legitimacy based on positional and not personal authority and on a formal code of administrative decision making and practice. To overcome favoritism and capriciousness, Weber advocated transactions based on knowledge and a systematic application of rules including rules of exchange.

Burns’ (1978) transactional leadership is also based on exchanging one thing for another: jobs for votes, subsidies for campaign contributions, and overtime work for increased pay. Its dominant values relate to means – “honesty, responsibility, fairness, and honoring commitments – without which transactional leadership could not work” (p. 426). The continuity between transactional leadership and Weber’s articulation of bureaucratic principles, in

Transforming Leadership: The Root of Confusion

Transforming leadership, as conceived by Burns (1978), occurred when the leader “recognizes and exploits an existing need or demand of a potential follower. . . , looks for potential motives in followers, seeks to satisfy higher needs, and engages the full person of the follower” (p. 4). “Transformational leadership,” he states (using the term to apply to the work of transforming leaders), “is more concerned with *end-values*, such as liberty, justice, equality” (p. 426, italics in original) – all aspects of both transformational and transformative leadership theories today. The focus on the moral purposes or ends of leadership has led to both transformational and transformative concepts. It is patently obvious that both theories of leadership – transformational and transformative – have at their heart the notion of transforming something. Indeed, to transform, according to most dictionaries, is to change in form, appearance, or structure, or in nature, condition, or character, usually with connotations of changing for the better. The Random House dictionary lists, as adjectives related to the verb transform and the noun transformation, both the words transformational and

transformative. As both theories of leadership emerged, it is little wonder that the two terms have frequently been used synonymously to describe educational leadership and that this lack of clarity has led to considerable confusion.

Moreover, although Burns most frequently used the term transforming leadership, he also used the words transformation and transformational; surprisingly, the term transformative, often associated with his work, is markedly absent. Nevertheless, the implications of his conception of transformation are directly related to transformative leadership. For example, he stated that “revolution is a complete and pervasive transformation of an entire social system” (p. 202) and later emphasized the need for “real change – that is, a transformation to the marked degree in the attitudes, norms, institutions, and behaviors that structure our daily lives” (p. 414).

Transformative Leadership: Roots in Other Social Sciences

Interestingly, the word transformative has been used with more clarity in other areas than in educational leadership where it is relatively recent. In healthcare and related social-service areas, transformative approaches are quite common. Duncan *et al.* (2006) advocated transformative curriculum in relation to an interdisciplinary approach to the education of healthcare professionals in South Africa; Evans *et al.* (2007) supported supplementing ameliorative approaches with transformative approaches by human service organizations. The latter distinguish between “incremental, developmental, evolutionary, or ‘first-order’ change” and “transformative, discontinuous, revolutionary, or ‘second-order’ change in human systems” (p. 332). Watkins’ (2000) used the concept of transformative leadership to describe a fourfold approach to nursing administration and healthcare.

Transformation in Education

The notion of transformation has led, in education, to concepts such as transformative teaching, the transformative classroom (Duncan and Clayburn, 1997), transformative curriculum, transformative material activity (Miettinen, 2006), and so forth. One particularly well-developed use of the term, explicated subsequently by numerous writers in the field of adult learning, is Mezirow’s (1991, 1996) transformative learning theory that outlines a process of effecting change in one’s frame of reference. The original focus was on individual learning prompted by self-reflection as a tool for deep and lasting personal change, but the concept has been expanded to emphasize the need to deconstruct and reconstruct knowledge frameworks as well as to “develop an

appreciation of our own culture and the associated privileges and powers” (Taylor, 2006: 92). Davis (2006), for example, emphasizes that transformative learning “involves the acquisition (or manipulation) of knowledge that disrupts prior learning and stimulates the reflective reshaping of deeply ingrained knowledge and belief structures” (p. 1). Franz (2002) reports that her findings related to effective staff partnerships included “eight types of transformative learning” (p. 1). Sterling *et al.* (2007) write about science camp for children of socioeconomically disadvantaged urban citizens as being a transformative experience both for students and their parents – changing the way they see themselves as learners and their self-assessment of their ability to attend college.

Others invoke the notion of transformative learning as it relates to increased gender equity and transformative gender justice. Keddie (2006a) calls for a “transformative approach that seeks to challenge and rework (rather than normalize and reinscribe) boys’ narrow conceptions of gender” (p. 111). She argues (Keddie, 2006b) that transformative gender justice remedies social disadvantage “through problematizing and restructuring the underlying frameworks that generate such disadvantage” (p. 401). Stromquist (2006) argues that

If education is such a powerful tool for economic and social betterment, we would expect that public policy would seek to make education accessible to all, to provide education of high quality and to distribute education equitably at all levels (p. 145).

She continues to say that “the acquisition of intellectual skills and habits by women is conducive to social change” (p. 149). King and Biro (2000) call for transformative learning to start with a disorienting dilemma and for it to “progress through a dynamic pathway of stages . . . [to a] final reintegration of a new frame of reference” (p. 19). MacKinnon (2000) argues that transformative educational practice must be based on a pedagogy of social justice (p. 11).

The common elements in these transformative approaches include the need for social betterment, enhancing equity, and for a thorough reshaping of knowledge and belief structures – elements that reappear as central tenets in the concept of transformative (although not so necessarily in transformational) leadership. Transformative concepts and social justice are closely connected through the shared goal of identifying and restructuring frameworks that generate inequity and disadvantage. Transformative ideals also owe much to the work of Freire (1970, 1998) who used the terms transform, transformation, and transformative to describe the changes that may occur as a result of education. Freire calls for personal, dialogic relationships to undergird education, because without such relationships, he argues, education acts to deform rather than to transform. He states, “Each time the ‘thou’ is

changed into an object, an “it,” dialogue is subverted and education is changed to deformation” (1970: 89).

Transformative Leadership: The Evolution of a Theory

Transformative leadership as a theory has developed in ways that are congruent with these uses of transformation and transformative learning in other fields of social science and education. It has also developed in ways that are consistent with Burns’ understanding of social change, of leaders who “build advocacy and conflict into the planning process in response to pluralistic sets of values” (p. 420). It incorporates Burns’ emphasis on purposeful moral leadership, as well as his acknowledgment that leadership necessarily includes an understanding of historical and social causation, of power wielding, and political power (pp. 433–434).

One of the first writers to discuss transformative educational leadership was William Foster (1986). His belief was that leadership “must be critically educative; it can not only look at the conditions in which we live, but it must also decide how to change them” (p. 185). Although perhaps ahead of his time (as discussed by Starratt (2004) in a retrospective essay commemorating Foster’s life and legacy), Foster’s advocacy of leadership that both transforms and empowers is central to today’s notion of transformative leadership.

In 1986, Bennis wrote an article titled ‘Transformative power and leadership’ in which he identified three factors as components of transformative power: the leader, the intention, and the organization and defined the transformative power of leadership as “the ability of the leader to reach the souls of others in a fashion which raises human consciousness, builds meanings, and inspires human intent that is the source of power” (p. 70). Acknowledgment of the effects of power is increasingly advocated and clarified in the emerging theory of transformative leadership, although writers will soon call for an understanding of power, not simply as an inspiring force, but also as a force that both implicitly and explicitly perpetuates hegemonic and dominating behaviors, cultures, and structures.

Capper (1989), in a paper advocating a more inclusive approach to democratic schooling for severely disabled students, drew on Aronowitz’ and Giroux’s (1985) notion of a transformative intellectual, and identified the need for the school administrator to be a transformative intellectual to encourage social justice and to practice “transformative leadership which can transcend the intellectual bias in democratic schooling to the benefit of all students and staff” (p. 5). Capper also cites Giroux’s and McLaren’s definition of a transformative intellectual as one who attempts

to insert teaching and learning directly into the political sphere by arguing that schooling represents both a struggle for meaning and a struggle over power relations. . . one whose intellectual practices are necessarily grounded in forms of moral and ethical discourse exhibiting a preferential concern for the suffering and struggles of the disadvantaged and oppressed (1986, in Capper, p. 9).

In these early articulations, we see the beginning of the major divergence between transformational and transformative leadership theories: the former focuses primarily on what happens within an organization while the latter is also concerned with the broader social and political sphere, recognizing that the inequities and struggles experienced in the wider society affect one’s ability both to perform and to succeed within an organizational context.

This distinction emerged gradually during the 1990s, with much writing still using the terms transformational and transformative interchangeably and synonymously. Sagor (1992), for example, wrote about three transformative leaders – principals who made a difference by using the three building blocks of “transformational leadership” (p. 13). Bates (1995) used the term transformative leader, but in a way more aligned with current transformational leadership, as he emphasized the work of leaders who reshaped and focused corporate culture carrying workers along with the vision (p. 11). Day *et al.* (2001) also perpetuated the confusion by continuing to use the terms interchangeably, alluding to the work of Leithwood and Jantzi as transformative leadership and then making reference to Burns’ (1978) transactional and transformational concepts (pp. 19–20). Sergiovanni (1990) again references Burns and states that “transformative leadership is first concerned with higher order psychological needs for esteem, autonomy, and self-actualization and, then, with moral questions of goodness, righteousness, duty, and obligation” (p. 23). A few pages later, Sergiovanni equates the concept he then calls transformational leadership with the notion of “value-added leadership” (p. 25). His appeal to psychology is important here as it soon helps to distinguish the development of the two strands of leadership. Transformative leadership, in the next decade, sheds most of its psychological trappings and focuses much more directly on sociological and cultural elements of organizations and the wider society in which they are embedded.

Quantz *et al.* (1991) outline many of the tenets of what has come to be known as transformative leadership. They argue that traditional theories of leadership are inadequate for democratic empowerment and that “only the concept of transformative leadership appears to provide an appropriate direction” (p. 96). Before clarifying their use of the term, they stipulate that the literature is still somewhat unclear about its meaning, and that the term requires critical reinterpretation (p. 96). Although they, too, fall at one point into the trap of using both terms interchangeably

(p. 97), their work is firmly grounded in the critical elements that distinguish transformative-leadership theory from formulations and characteristics of transformational leadership. They posit that schools are sites of cultural politics that serve both to reproduce and perpetuate the inequities inherent in gender, race, and class constructs and which “confirm and legitimate some cultures while disconfirming and delegitimizing others” (p. 98). They go on to argue that because organizations must be based on democratic authority, transformative educational leaders must learn to diminish “*undemocratic power relationships*” (p. 102, italics in original) and use their “power to transform present social relations” (p. 103). Transformative leadership, they assert, “requires a language of critique and possibility” (p. 105); a “transformative leader must introduce the mechanisms necessary for various groups to begin conversations around issues of emancipation and domination” (p. 112).

Transformative Leadership Today: A Theory of Critique and Possibility

Thus, despite confounding of the terms transformative and transformational into the present decade, it is clear that as early as the mid-1980s with the work of Aronowitz and Giroux (1985), Foster (1986), Quantz *et al.* (1991), and others, a theory of transformative leadership grounded in the twin concepts of critique and possibility was emerging. The increasing clarity and the developing body of literature associated with the concept of transformative leadership continue to emphasize and reinforce these two ideas. Weiner (2003) drawing, as have many others, on Freire’s work, emphasized both the individual and collective nature of transformative leadership. He wrote:

transformative leadership is an exercise of power and authority that begins with questions of justice, democracy, and the dialectic between individual accountability and social responsibility (p. 89).

The differences between the foregoing statement and Leithwood’s (2009, this volume) statement that transformational leadership has four dimensions (setting directions, developing people, redesigning the organization, and managing the instructional program) demonstrate how much the two theories have diverged in terms of central preoccupations and emphases. Although it would be wrong to conclude that either theory precludes either instructional excellence or social responsibility, there are clear distinctions between the ways in which leaders subscribing to each theory conceptualize, interpret, and approach these tasks. Weiner delineates the responsibilities of the transformative leader to instigate structural transformations, to reorganize the political space, to understand the relationship between

leaders and the led dialectically (and not hierarchically). He also calls for leaders to

confront more than just what is, and work toward creating an alternative political and social imagination that does not rest solely on the rule of capital or the hollow moralism of neoconservatives, but is rooted in radical democratic struggle (p. 97).

A fundamental task of the educational leader in this tradition is to ask questions about, for example, the purposes of schooling, about which ideas should be taught, and about who is successful. Critique lays the groundwork for the promise of schooling that is more inclusive, democratic, and equitable for more students. It is “antiracist, antisexist, antihomophobic, and responsive to class exploitation” (Weiner, p. 100).

Weiner (2003) makes the important additional point that transformative leaders always experience the challenge of having “one foot in the dominant structures of power and authority.” Where this not the case, they would not likely have attained the formal recognition as leaders that casts them as “willing subjects of dominant ideological and historical conditions” (p. 91). At the same time, transformative educational leaders work from within dominant social formations to exercise effective oppositional power, to resist courageously, to be activists and voices for change and transformation. They must be willing to

take risks, form strategic alliances, to learn and unlearn their power, and reach beyond a “fear of authority” toward a concrete vision of the work in which oppression, violence, and brutality are transformed by a commitment to equality, liberty, and democratic struggle (p. 102).

At the beginning of the twenty-first century, other educational researchers and theorists took up the task of articulating, and advocating for, transformative educational leadership (see Anderson, 2004; Dantley, 2003; Shields, 2003a; Tillman, 2005). For example, Shields (2003b) critiqued the typical silence of educational leaders that tends to pathologize differences, stating that

transformative educators and educational leaders must address issues of power, control, and inequity; they must adopt a set of guiding criteria [...] to act as benchmarks for the development of socially just education; and they must engage in dialogue, examine current practice, and create pedagogical conversations and communities that critically build on, and do not devalue, students’ lived experiences (p. 128).

Many of these theorists also cite the work of Astin and Astin (2000) who associate transformative leadership and societal change, saying:

We believe that the value ends of leadership should be to enhance equity, social justice, and the quality of life; to expand access and opportunity; to encourage respect for

difference and diversity; to strengthen democracy, civic life, and civic responsibility; and to promote cultural enrichment, creative expression, intellectual honesty, the advancement of knowledge, and personal freedom coupled with responsibility (p. 11).

Brown (2004) combines adult learning theory, transformative learning theory, and critical social theory in her development of a framework for the preparation of educational leaders that would emphasize transformative leadership. Once again, key elements of this framework include the need to address issues of power and privilege, dialog aimed at disequilibrium that results in meaningful change, and a call to activism.

The Current State of Transformative Leadership Theory: Problems and Promises

By the end of the first century of the twenty-first century, the theory of transformative leadership has been consistently articulated as a form of leadership grounded in an activist agenda, one that combines a rights-based theory that every individual is entitled to be treated with dignity, respect, and absolute regard with a social justice theory of ethics that takes these rights to a societal level. It emphasizes the socially constructed nature of society and the attendant outcome “that certain individuals occupy a position of greater power and that individuals with other characteristics may be associated with a higher likelihood of exclusion from decisions...” (Mertens, 2007: 87). Transformative leadership, therefore, recognizes the need to begin with critical reflection and analysis and to move through enlightened understanding to action – action to redress wrongs and to ensure that all members of the organization are provided with as level a playing field as possible – not only with respect to access, but also with regard to academic, social, and civic outcomes. In other words, it is not simply the task of the educational leader to ensure that all students succeed in tasks associated with learning the formal curriculum and demonstrating that learning on norm-referenced standardized tests; it is the essential work of the educational leader to create learning contexts or communities in which social, political, and cultural capital is enhanced in such a way as to provide equity of opportunity for students as they take their place as contributing members of society.

Not unexpectedly, the theory is not without its critics as well as its advocates. It is sometimes believed to be too idealistic, too demanding, and to place too much responsibility on the shoulders of educators and educational leaders for redressing global ills. Some argue that a focus on power, equity, and social justice can only occur at the expense of intellectual development and accountability.

These arguments are countered by those who posit that addressing issues of equity *is* the only way to transform education to achieve the success of all students – a goal that, although elusive, is at the heart of most current educational leadership theories. In addition, the tensions identified earlier by Weiner of needing to work within the system to effect transformation cannot be overestimated and can certainly not be discounted.

Perhaps the most salient criticism, and one that remains to be addressed in the coming years, is that although there is a considerable body of conceptual work, there is little empirical research related to transformative leadership: few studies have operationalized transformative leadership and examined its impact in real-life settings. (This is, of course, in opposition to the extensive empirical work already completed with respect to the sister theory of transformational leadership.) One exception is the nationally funded Te Kotahitanga project operating in New Zealand to effect transformation that leads to increased success on the part of Maori students (see Bishop *et al.*, 2003). There, a strong focus on leadership and power distribution, attitudes and positions, and on what might be termed critical democratic pedagogies is demonstrably overcoming the traditional achievement gaps between Maori and Pakeha (white European) New Zealanders. Other studies, in recent years, include those by Glanz (2007), Hoffman and Burrello (2004), Kose (2007), McLaughlin (1989), Shields (2009), and Theoharis (2007) – although there are still nuanced variations in the understanding and use of the theory. Much work, however, remains to be done to realize the potential of transformative leadership.

Concluding Thoughts

Unlike transformational leadership, which has the most potential to work well when the organization and the wider society in which it is embedded are synchronous, transformative leadership takes account of the ways in which the disparities in the outside world create inequities in the internal operations of educational organizations. Moreover, because these inequities are apparent almost everywhere with respect to schooling – both in developing and developed countries – many researchers and theorists advocate transformative leadership as a way forward. The dual focus on critique and promise emphasizes the need to do more than bemoan current failures. Transformative educational leaders need to act with courage and conviction to bring about the promise of education as apprenticeship that teaches students, as Greene (1988) states, to be “citizens of the free world – having the capacity to choose, the power to act to attain one’s purposes, and the ability to help transform a world lived in common with others.” Transformative educational

leadership not only works for the good of every individual in the school system; at its heart, it works for the common good of society as well.

Strategic Leadership

B Davies and B J Davies, University of Hull, Hull, UK

Introduction

What do we understand by strategic leadership? Strategic leadership is not a new categorization or type of leadership; rather, it is best considered as the strategic element within the broader leadership paradigm. Initially, a definition of strategy can make use of five concepts. First, it is concerned with the idea of direction setting. To decide on the direction for the institution, it is necessary to understand its history and its current situation (Garratt, 1995: 2). Second, strategy, while very often associated with planning in traditional definitions (Fiddler, 1996), might better be thought of as a perspective, as a holistic way of looking at things. Third, strategy does not get involved in the detail day-to-day activities but is concerned with broad major dimensions of the organization. Fourth, a medium to longer term time framework is useful when considering strategy. A final useful concept is that strategy can be used as a template against which to set shorter term planning and activities (Davies, 2006, 2009).

Defining leadership presents a challenge owing to the expanding amount of literature in the field from which it is drawn. The forms of leadership are extensive and terms such as symbolic leadership, transformational leadership, learning-centered leadership, constructional-leader leadership, emotional leadership, ethical leadership, distributed leadership, invitational leadership, entrepreneurial leadership, and sustainable leadership are but a few. So where does one start? Bush and Glover (2003: 10) in their review of the leadership literature for the National College for School Leadership (NCSL) define leadership as "... a process of influence leading to the achievement of desired purposes. It involves inspiring and supporting others toward the achievement of a vision for the school which is based on clear personal and professional values." Strategic leadership can be seen to comprise elements of the traditional definitions of leadership but critically it is broad in scope, its impact is felt over long periods of time, and usually involves fundamental organizational change.

The Nature and Dimensions of Strategic Leadership

This section considers the nature and dimensions of strategic leadership by examining what strategic leaders do to promote a strategic approach. Davies (2003: 303) has

identified the problem in isolating essential characteristics of effective strategic leaders:

The difficulty in reviewing the literature, or interpreting the results of my current research, is that it is not always easy to distinguish the characteristics of 'good leadership' from those of 'strategic leadership'.

In an attempt to resolve this difficulty, it is possible to use the work of Boal and Hooijberg (2001: 516) who identify eight activities associated with strategic leadership as:

1. making strategic decisions;
2. creating and communicating a vision of the future;
3. developing key competences and capabilities;
4. developing organizational structures, processes, and controls;
5. managing multiple constituencies;
6. selecting and developing the next generation of leaders;
7. sustaining an effective organizational culture; and
8. infusing ethical value systems into the culture.

We have translated Boal and Hooijberg's eight points into the following categories, which in terms of leadership characteristics are concerned with:

- developing the strategic and organizational process(es) (1, 2, 4);
- leading and developing people (5, 6);
- developing the culture and value system (7, 8); and
- developing distinctive competences of the organization (3).

These elements are supported by other writers. Bolman and Deal (1991) suggest there are four leadership functions to serve four aspects of organization structural leadership, human resource leadership, political leadership, and symbolic leadership. There is an element of match between the two sets; for example, strategic and organizational processes could be defined as Bolman and Deal's structural leadership; similarly, the culture and value system could be represented as symbolic leadership, and developing people can be represented as human resource leadership. Bolman and Deal do not identify the importance of a strategic leader for developing core competences. Sergiovanni (1984) proposes a model of five leadership forces to explain how the head's leadership is related to excellent school performance: technical, human, educational, symbolic, and cultural. Unlike Bolman and Deal, Sergiovanni does not identify political leadership as an important element. Cheng

(2002: 56–57) based his five-dimension model of strategic leadership on a combination of the ideas of Bolman and Deal (1991) and Sergiovanni (1984). This is a useful synthesis when considering strategic leadership. He asserts that strategic leadership must have a concern for the development of each of these aspects as follows:

- developing positive relationships and enhancing staff commitment (human);
- developing clear goals, organizational structures, and holding people to account (structural leadership);
- building alliances and encouraging participation in decision making (political);
- inspiring and stimulating leaders to pursue organizational vision and building new values (cultural leadership); and
- directing the learning and teaching curriculum and professional improvement (educational leadership).

Encouraging participation in decision making could be considered as an aspect of the leader establishing a strategic process (developing the strategic and organizational process(es) from first bulleted list). Cheng highlights all the areas and gives a useful definition of ‘political’. It is important to add another point, a concern with developing networks to the original synthesis which can be summarized as, strategic leaders are concerned with:

- the strategic and organizational process;
- people;
- the culture and value system;
- distinctive competences of the organization; and
- networks.

Strategic Leaders Are Concerned with Developing Strategic and Organizational Processes

Cheng (2002: 64) asserts that “strategic leadership in an educational institution can be considered as leadership for initiating, developing and maintaining the strategic process”. What is needed then is a leader who will inspire and challenge, enacting the strategic process, not just talking about it. Hitt *et al.* (1998) argue that “organisational success depends on strategic flexibility”. This flexibility would enable a school to respond quickly to altered conditions and expectations and to take advantage of future opportunities. Boal and Hooijberg (2001: 518) pose the question “does strategic leadership matter?” Their answer is:

Strategic leadership does indeed matter. . . it seems to us the real question is not whether it matters but rather under what conditions, when, how and on what criteria.

They believe that when a leader makes a decision is just as important as what decision or action is taken. Bartunek and Necochea (2000) define the ability to take

the right action at a critical time as Kairos time. Boal and Hooijberg (2001: 528) suggest that strategic inflection points create a kairotic moment and it is during these moments that learning and change are possible if only the leader possesses the discernment to take notice and the wisdom to act.

Javidon (1991), quoted in Korak-Kakabadse and Kakabadse (1998: 10), suggests that “visioning depends on understanding existing realities (culture, history, formative context) and developing a clear sense of direction for the organisation”. As a leadership skill, it would seem that the leader’s own personal values and ideas are paramount in this process and the skill involves making it real for others. Leaders therefore need to understand themselves and the values they hold and be able to nurture quality communication. De Pree (1993: 99) classifies this lavish communication found in organizations with cultures which promote truth and do not suppress or limit the distribution of information. Making a vision real for others needs skills of conviction and passion, and it involves emotion. Boal and Hooijberg (2001: 516) state that “strategic leadership focuses on the creation of meaning and purpose for the organisation”. Strategic leadership therefore is concerned with the “development of the organisation as a whole which includes its changing aims and capabilities” (Selznick, 1984: 5).

Strategy can be defined as the art of making intelligent choices. Educational leaders need to make intelligent choices. Strategy should be a process of discovery, part of self-evaluation and self-improvement processes. Bennett (2000: 3) suggests that “vision used to be sufficient of itself, but it is no longer”. The ability to think big and imagine the impossible requires passion, in addition to vision. Establishing the processes may not be enough, strategic leaders may require a dedication beyond the normal in order to transform a culture or re-engineer the approach to learning. A personal enthusiasm or fervor may be required.

Strategic Leaders Are Concerned with Leading and Developing People

It is important to find a way to build a connection between thinking and action. The concept of a learning organization helps here: an organization of people who are attuned to changes and able to respond to them have valuable insights into how individuals and groups learn and how to convert this knowledge into organizational action. Pietersen (2002: 181) states that all learning organizations have developed a “culture of giving” which “fosters teamwork, experimentation, learning, and knowledge sharing”.

More recent leadership theories focus on transformational (Leithwood and Jantzi, 1999) and visionary leadership, which emphasize the interpersonal processes between leaders and followers. Boal and Hooijberg (2001: 526) suggest that research into transformational leaders stress upon factors such as intellectual stimulation and inspiration.

Cheng (2002: 53) found two recurring elements of leadership in various definitions: “first, leadership is related to the process of influencing others’ behaviour; and second, it is related to goal development and achievement”. This view is reflected in the previous discussion on the process of strategy; leaders need the skills to be able to influence people and their actions and they need to direct those actions through setting goals and creating meanings. This resonates with the perspective of transformational leadership, where a leader is proactive about the future view, shaping members’ beliefs, values, and attitudes while developing strategies for the future. Bass (1985) identified that transformational leaders, in educational settings, motivate people to do more than they are originally expected to do by raising their level of awareness and getting them to go beyond their own self-interest for the sake of the team or the organization. Strategic leadership, therefore, is about altering attitudes, values, and beliefs, all of which influence the culture of an organization.

Digman (1990) defines strategy as “the organisation’s pre-selected means or approach to achieving its goals or objectives, while coping with current and future external conditions”. He considers that strategy has a corporate dimension, that of achieving objectives, and as previously discussed, a functional operational dimension, but Digman also identifies that strategy has a future dimension. He contends that organizations have to consider why they exist and how they function in society. This dimension determines the relationships the organization has with those who have an interest in what the organization does and how it does it. This would form the framework within which the other types of strategies operate. The implication from this view is that many people are involved in strategic decision making at any one time. Digman refutes this since he believes that the way decisions are made means that decisions are taken at the corporate level. He believes that a decision is the “result of a stream or sequence of inputs and actions by a number of people.” Everyone shapes the decision but the managers or executives make the choice.

Hambrick (1998) argues that strategic leadership occurs in an environment embedded in ambiguity, complexity, and informational overload. It is important therefore for strategic leaders to recognize new information, analyze it, and apply it to new outcomes; in other words, leaders need the ability to learn. Boal and Hooijberg (2001: 517) call this absorptive capacity and argue that leaders “have a unique ability to change or reinforce existing action patterns” within the organization. Therefore, they should create an organizational context where learning can take place. They define the ability to change as adaptive capacity. Boal and Hooijberg (2001: 518) add a third key element to their essence of strategic leadership – that of managerial wisdom which they define as the combination of discernment and Kairos time. Discernment

is the ability to perceive variation in the environment and to develop an understanding of the social relationships and behavior of the participants. Kairos time is the critical moment (time) when key decisions can and should be made. Gardner (1985) and Sternberg (1985) talk about interpersonal intelligence or social intelligence. The key components, and therefore necessary skills, of this area are social awareness or empathy and social skill or conflict resolution. Sternberg (1985) usefully extends this definition suggesting that social intelligence is not just the ability to understand but also the ability to act on that understanding of others.

Strategic Leaders Are Concerned with Developing the Culture and Value System

Whittington (2001: 55) suggests that “being a good strategist is not necessarily enough. Leadership is about more than just fitting strategy to the . . . environment; it is about fitting yourself to the social environment”. As Dahrendorf (1959) put it, “to be successful means to be liked, and to be liked means, in many ways to be alike”. It is possible for the unliked leader to be successful in the short term, but long-term success needs the support of all, which is more likely to be given when the values are shared and those involved have like ideas, direction, and values. Bennett (2000: 1) supports this view: “to some extent the culture reflects the style and personality of the school’s leader”.

Boal and Hooijberg (2001: 528) suggest that “many of the new theories of leadership appear context free”. It would appear that they do not consider how the environment or organizational context influences the process.

In the competing values framework, Quinn (1980) argues for multiple measures of effectiveness at multiple levels of analysis. The second dimension is control, social actions focused on clarity of goals versus flexibility, social actions focused on being adaptive to people and the external environment. The model recognizes that leaders face competing demands of those with an interest in the organization. The two dimensions define four quadrants and eight leadership roles which highlight ways in which leaders can handle the competing requirements. The model highlights the necessity of a leader’s capacity to change. “Leaders who have a large repertoire of leadership roles at their disposal and know when to apply these roles are more likely to create effective change than leaders who have a small repertoire of roles and who apply them discriminately” (Boal and Hooijberg, 2001: 530).

Society has very high expectations of schools and is increasingly looking to them for moral leadership and social responsibility. Schools are seen to be the place where children are able to experience consistent moral role models (Davies and Brighouse, 2008). This has always been the case but in an increasingly diverse society, with diverse values, the expectations on school leaders are

increasing and this complexity must be reflected in the skills of the strategic leader.

Strategic Leaders Are Concerned with Developing Distinctive Competencies

Quinn (1980: 85) argues that the competing values framework reflects different perceptual biases that influence how we see social action. This idea has important relevance for schools since one of the dimensions it highlights is the internal versus the external focus. This double focus distinguishes between social actions, which satisfy internal effectiveness, criteria such as employee satisfaction, and social actions focused on satisfying external effectiveness. The external effectiveness is defined as market share and profitability, which does not easily relate to the school context but there is a tension between the internal effectiveness, as stated and the external accountability of judgments made about school effectiveness. Pietersen (2002: 9–10) identifies three strategic questions:

- What is the environment in which the organization must compete and win?
- What are the few things our organization must do outstandingly well to win and go on winning in this environment?
- How will we mobilize our organization to implement these things faster and better than our competitors?

If we translate these questions into school terms, we see that the leaders in a school need to understand the environment in which the school functions, what the school needs to focus on in order to succeed in that environment, and how leadership stimulates the participants to implement the decisions jointly arrived at. Education is inextricably linked to our understanding of intelligence and of learning. New forms of understanding are emerging and leaders must be able to devise strategies for developing learning. As Bennett (2000: 3) states “school leaders must develop a curriculum which ensures that cognitive and emotional development work in harmony”. The distinctive competency for leaders must be related to developing children’s learning.

Strategic Leaders Are Concerned with Developing Networks

Strategic leaders are not only interested in the internal functions of the organization but also the role of the organization in the community and the impact of the wider education field. These different interactions may require different behaviors. Bennett (2000: 2) suggests:

Schools have already developed far from the hierarchical model of local authority control. . .now strategic development is of less importance too. Even the typical three-year

plan, with twelve months firm and two years draft, cannot survive in an age of uncertainty. The importance of strategy will remain, but it is through relationships, and not plans that it will be exercised.

Therefore, the nature and the quality of the leader’s relationships could be critical for the school. These relationships will be both internal and external – the local community, partnerships in business, and the ability to secure funding in the latest local and national bidding rounds. Success is becoming dependent on establishing relationships and securing benefits from those relationships.

Is This All?

Boal and Hooijberg (2001: 529) suggest that “the three cornerstones of strategic leadership are the capacity to learn, the capacity to change and managerial wisdom.” Throughout this discussion, the personal qualities of leaders have been discussed, for example, the values they hold, the ability to inspire and stimulate, their social intelligence, the ability to be passionate. All of these qualities affect the way a leader learns and is able to change. Sanders (1998: 5) supports the view that strategic leaders need the ability to change and learn by asserting that mastering chaos, complexity, and change requires new ways of seeing and thinking. Whittington (2001: 43) suggests that “leaders need an enduring sense of purpose and a continuous sense of motivation”. Boal and Hooijberg (2001: 532) suggest that most leadership researchers agree that leaders need to have important interpersonal skills such as empathy, motivation, and communication. Bennett (2000: 3) expands the importance of personal values:

If moral leadership is to be exercised and pedagogy re-engineered with any degree of success, then future leaders will need a firm set of personal values. No doubt many will have their own lists, but integrity, social justice, humanity, respect, loyalty and a sharp distinction between right and wrong, will all need to be included. Strategic relationships will soon flounder unless such a value system is held with conviction and exercised on a regular consistent basis.

Although not specifically included in Bennett’s comprehensive list, social intelligence is important for strategic leadership because the process of decision making, solution implementations, and organizational improvement are rarely free of emotion. Social intelligence includes having a thorough understanding of the social context, and is defined by Gardner (1985: 9) as the ability “to notice and make distinctions among other individuals. . .in particular among their moods, temperaments, motivations and intentions”. Hence, a key component of social intelligence is the ability

to discern emotions both in self and in others. Gardner identifies this as intrapersonal intelligence and interpersonal intelligence (1993). The ability to build the involvement of others and to resolve conflicts will be increasingly vital in the context of developing strategic relationships and finding creative solutions. Bennett (2000: 4) also identifies the importance of strength and courage; “visionary projects, delivered with passion, will fail unless the leader has the ability to counter adversaries and remain confident until the conclusion has been reached”. These personal skills underpin the five dimensions of strategic leadership.

Davies *et al.* (2005) in a major national study in the UK researched how strategic leadership contributed to sustainable strategic success in schools. The schools in their research which achieved ongoing success in student achievement and organizational development have leaders who undertook certain activities and possessed certain characteristics. Their taxonomy is shown in **Table 1**.

This provides a framework for both individual leaders reflecting on their strategic-leadership skills and also a developmental framework for aspiring leaders.

Conclusion

We started this section by stating that strategic leadership needs to consider three factors: it is broad in scope; its impact is felt over long periods of time, and usually involves fundamental organizational change. The challenge for strategic leaders is to develop the five dimensions of strategic leadership in such a way to meet these three factors. However, it would be a mistake to think that operational short-term planning and management is in conflict with

longer term strategic leadership. A critical idea is that strategic leadership provides a template against which to set short-term actions and activities. Leaders and managers who are aware of the long-term direction of the organization should take short-term actions that not only deal with the immediate challenges but build capacity for longer term development. By doing this, strategic leaders can build a sustainable progress for their organizations that is rooted in the realities of the present but develops an effective vision for the future.

Teacher Leadership and Organizational Development

A Harris, University of Warwick, Coventry, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Leadership remains firmly centerstage in contemporary discussions about organizational change and development. It seems that no modern concept has been more powerfully received in the consciousness of those concerned with school reform and improvement than leadership. Effective leadership has long been identified with school improvement and transformation (Leithwood *et al.*, 2006; Fullan, *et al.*, 2007). Research has shown that leadership makes a difference to organizational and individual learning outcomes (Day *et al.*, 2007).

Current theorizing about leadership reinforces the view that leadership is not the preserve of one individual but is a “social influence process whereby intentional influence is exerted by one person (or group) over other people or groups to structure the activities and relationships in a group or organization” (Yukl, 1994). Such collective action resonates closely with the theory of distributed leadership which is generating much interest within the contemporary leadership field (Spillane *et al.*, 2001; Harris, 2007).

Work by Spillane *et al.* (2001) suggests that distributed leadership is a way of understanding leadership that focuses upon interaction and the exploration of complex social processes. It implies that the practice of leadership is one that is shared and realized within extended groupings and networks (Spillane *et al.*, 2001; Harris, 2004; Gronn, 2000). In this sense, leadership is best understood as “practice distributed over leaders, followers and their situation” (Spillane *et al.*, 2001: 13). This distributed view of leadership “incorporates the activities of multiple groups of individuals in a school guiding and mobilizing staff in the process of instructional change” (Spillane *et al.*, 2001:13).

Distributed leadership theory implies collaborative individualism where individuals work collaboratively to act upon and transform systems. Other researchers have similarly argued for a form of constructivist leadership (Lambert, 1998) where leadership is primarily about teachers learning together, and constructing meaning and knowledge collectively and collaboratively. Most recently, Crowther *et al.* (2009: 38) have argued for parallel leadership – a process whereby teacher leaders and their principals engage in collective action to build school capacity. It embodies mutual respect, shared purpose, and allowance for individual expression. Crowther *et al.* (2000) suggest a division of leadership responsibilities where principals assume primary responsibility for strategic leadership and

teachers assume primary responsibility for pedagogical or instructional leadership.

Implicit within current leadership theory is the central idea that leadership is something many people are able to exercise and that leadership is not the realm of certain people in certain parts of the organization (Ogawa and Bossert, 1995: 225). Teacher agency, instruction, and collaboration are implicit within the distributed span of leadership, even though this connection is rarely made (Harris and Muijs, 2004).

Teacher Leadership

The idea of teacher as leader has not only gained widespread popularity in recent years, but has also become gradually embedded in the language and discourse of organizational change and improvement. The ascendancy of teacher leadership has been prompted, in part, by new understandings about organizational development and by the new theories of leadership such as distributed leadership. Contemporary interest in teacher leadership also stems from the fact that its central tenet aligns with broader discussions of professionalism and by association, a professional model of change premised upon teacher enquiry, knowledge generation, and internal accountability (Elmore, 1990).

This article draws upon two major reviews of the teacher leadership literature to evaluate and assess the empirical strength of this knowledge base (York-Barr and Duke, 2005; Muijs and Harris, 2003). Initially, it considers different interpretations and definitions of the term teacher leadership and subsequently explores evidence relating to the impact and outcomes of teacher leadership.

Defining Teacher Leadership

It is clear from the international literature that there are overlapping and competing definitions of teacher leadership. Reviews of the literature (Muijs and Harris, 2003; York-Barr and Duke, 2004) reinforce that many conflicting and competing definitions of the term teacher leadership prevail and persist. As York-Barr and Duke (2005: 260) note, “in writing about teacher leadership, many authors readily assert its importance but usually fail to define it.” Similarly, in their review of the leadership literature Leithwood and Duke (1999: 45) state that it is important to be clear from the outset that what has been

learned about leadership in schools over the last century has not depended on any clear, agreed upon definition of the concept, as essential as this would seem at first glance. Inevitably, the lack of a precise definition has resulted in teacher leadership becoming a catch-all phrase for any form of teacher activity associated with change or development (York-Barr and Duke, 2005: 260).

In their review of the literature, Leithwood and Duke (1999) identified six categories of leadership: transformational, moral, instructional, participative, managerial, and contingency. Looking at each category, it appears that teacher leadership is most closely related to instructional and participative forms where leadership equates with the behaviors of teachers as they engage in activities directly affecting the growth of students (Leithwood and Duke, 1999: 47). In their work, Katzenmeyer and Moller (2001: 17) define teacher leaders as teachers, who are leaders within and beyond the classroom, who identify with and contribute to a community of teacher learners and leaders, and influence others toward improved educational practice. Boles and Troen, (1994: 11) characterize teacher leadership as a form of collective leadership in which teachers develop expertise by working collaboratively.

Muijs and Harris (2003) suggest that there are four discernable dimensions of the teacher-leadership role:

- The first dimension concerns the way in which teachers work with and across school boundaries and structures to establish social linkages within the community (Acker-Hocevar and Touchton, 1999). This brokering role remains a central responsibility for the teacher as leader as it ensures that links within and across schools are in place and that opportunities for meaningful development among teachers are maximized.
- A second dimension of the teacher leader role focuses upon participative leadership where teachers work collegially with other teachers to encourage the examination of instructional practices (Walsey, 1991).
- A third dimension of teacher leadership in school improvement is the mediating role. The literature suggests that teacher leaders are important sources of instructional expertise and information because they demonstrate high levels of instructional expertise (Snell and Swanson, 2000).
- The final and most important dimension of the teacher leadership-role is forging close relationships with individual teachers through which mutual learning takes place. The evidence shows that as leaders, teachers build trust and rapport with colleagues, establish solid relationships, and influence school culture through these relationships (Little, 1990, 2000).

In one of the most extensive studies on the work of teacher leaders, Lieberman *et al.* (2000) focused on what teachers actually did when they assumed leadership positions designed to provide assistance to other teachers.

This research found that the work of lead teachers was varied and largely specific to the individual context of the school. The authors concluded that restructuring school communities to incorporate leadership positions for teachers necessitated teacher leaders taking certain actions. These included placing a nonjudgmental value on providing assistance, modeling collegiality as a mode of work, enhancing teachers' self-esteem, using different approaches to assistance, making provisions for continuous learning and support for teachers at the school site, and encouraging others to provide leadership to their peers.

In summary, from the literature there are a number of important things to highlight about the definition of teacher leadership:

- First, teacher leadership is associated with the creation of collegial norms among teachers that evidence has shown can contribute to school effectiveness, improvement, and development.
- Second, teacher leadership equates with giving teachers opportunities to lead, which according to research has a positive influence upon the quality of relationships and teaching within the school.
- Third, at its most practical, teacher leadership means teachers working as instructional leaders influencing curriculum, teaching, and learning.
- Finally, teacher leadership is associated with re-culturing schools where leadership is the outcome of the dynamics of interpersonal relationships rather than just individual action.

There is an implicit assumption made in much of the literature about the positive impact of teacher leadership upon individual and organizational outcomes but the evidence of such effects, especially at the levels of classroom practice and student learning are sparse (York-Barr and Duke 2005: 282). The next section considers the evidence from the literature about the impact of teacher leadership upon organizational and individual outcomes.

The Impact of Teacher Leadership: The School Level

The findings from the literature about the impact of teacher leadership at the school level are rather variable and inconsistent. Some studies indicate strong school-level effects (Griffin, 1995) while others indicate the negligible influence of teacher leadership upon the school level. The greatest support for a relationship between teacher leadership and organizational change can be located within the school effectiveness, improvement, and reform literature. Here evidence suggests that generating teacher leadership, with its combination of increased collaboration and increased responsibility, has positive effects on transforming schools as organizations (Hargreaves, 1991; Little, 1990; Rosenholz, 1989; Little, 2000). In the

most effective schools, Pellicer *et al.* (1990) found that instructional leadership was a shared responsibility of teachers and principals. Other studies also report positive effects of teacher participation in decision making such as increased teacher motivation and decreases in teacher absenteeism (Rosenholz, 1989; Sickler, 1988).

Recent research has highlighted that an organization's ability to improve and sustain improvement largely depends upon its ability to foster and nurture professional learning communities or communities of practice (Stoll and Louis, 2007). Linked to the idea of communities of practice, school-improvement advocates have suggested that schools should operate as professional learning communities. Hargreaves (2003: 3) suggests that:

professional learning communities lead to strong and measurable improvements in students' learning. Instead of bringing about 'quick fixes' or superficial change, they create and support sustainable improvements that last over time because they build professional skill and the capacity to keep the school progressing.

This idea of professional learning communities embraces the notion of teacher leadership as it is assumed that teachers will be the catalysts for change and development within a professional learning community.

In summary, the literature confirms the positive effects of teacher collaboration upon organizational development and change. Where teacher leadership manifests itself in the development of trusting and collaborative relationships with colleagues, there is evidence that it does positively influence school culture and can generate the conditions where instructional and organizational development flourish.

The Impact of Teacher Leadership: The Teacher Level

The literature reveals that by far the most discernible and powerful effect of teacher leadership is on teacher leaders themselves. There is some evidence to support the assertion that as teachers lead, they grow in leadership skills and organizational perspectives (Ryan, 1999). Research findings also suggest that empowering teachers to take on leadership roles enhances teachers' self-esteem and work satisfaction, which in turn leads to higher levels of performance due to higher motivation, as well as possibly higher levels of retention in the profession (Katzenmeyer and Moller, 2001; Ovando, 1996).

As highlighted earlier, the nature and quality of leadership within schools has been found to be an important condition for maximizing school effectiveness and improvement. Yet, the relationship between teacher leadership and teacher effectiveness is generally implied in the literature rather than proved. The evidence shows that schools where achievement is higher tend to be more

confident in allowing teachers to take on leadership roles. As one US study showed, improving student outcomes appeared as a condition for, rather than a result of, teacher leadership (Dickerson, 1992).

Teacher leadership has been reported to have effects on teacher practices at the classroom level. Research by Ryan (1999) revealed a high level of perceived impact on instructional practices of colleagues. Smylie's (1994) review of re-designated teacher work and its effects on classroom practice drew two primary conclusions. First, that change in classroom practices was more likely to occur among those teachers whose work was redesigned that is, the teacher leaders, and second, changes in classroom practice were more likely to occur when initiatives were collective, as opposed to individual.

In summary, the findings from the available studies suggest there is evidence that teacher leadership is positively related to changes in teachers' classroom practice and their instructional effectiveness.

The Impact of Teacher Leadership: The Student Level

In their review of the literature, York-Barr and Duke (2005) found only five studies that directly examined the effects of teacher leadership on students. Research by Ryan (1999) studied three schools where it was found that the teacher leaders were perceived to be having a positive effect on students. In contrast, Louis and Marks (1998) did not discern a direct relationship between teacher empowerment and student learning but strongly supported the argument that empowerment did positively influence teachers' efforts to improve instruction. Taylor and Bogotch (1994) found no significant difference in terms of student attendance, achievement, or behavior between schools with high degrees of teacher participation in decision making as opposed to schools with low degrees of teacher participation in decision making. The other two studies conducted by Leithwood and Jantzi (1999; 2000) explored the effects of school and teacher leadership on students' engagement with school. This research found no statistically significant relationship between teacher leadership and student engagement. However it did conclude that teacher leadership outweighs principal leadership effects before taking into account the moderating effects of family educational culture.

Research by Silins and Mulford (2002) concluded that student outcomes are more likely to improve where leadership sources are distributed throughout the school community and where teachers are empowered to lead. Similarly, a study of 86 US middle schools, found that both teacher professionalism and collegial leadership were positively related to improved student outcomes (Hoy *et al.*, 1998). Other work by Lemlech and Hertzog, (1998) has suggested that encouraging teachers to take

on leadership roles positively affects self efficacy and behavior which subsequently influences student-learning outcomes. Recent research by Harris and Muijs, (2004) found an indirect relationship between teacher involvement in decision making and improved student outcomes.

In summary, while the teacher leadership literature confirms a link between teachers' collaborative practice and improved teacher behaviors, a direct link between teacher leadership and student outcomes is less strongly established.

Coda

The literature suggests that a number of ways in which teacher leadership can be developed and enhanced in schools.

- Time needs to be set aside for teachers to meet to plan and discuss issues such as curriculum matters, developing school-wide plans, leading study groups, etc.
- Rich and diverse continuous professional development is required for teacher leadership to flourish. The evidence would suggest that professional development for teacher leadership needs to focus not just on the development of teachers' skills and knowledge but also on aspects specific to their leadership role. Skills such as leading groups and workshops, collaborative work, mentoring, teaching adults, action research, collaborating with others, and writing bids need to be incorporated into professional development (and indeed initial teacher training) to help teachers adapt to the new roles involved (Katzenmeyer and Moller, 2001).
- Structured programs of collaboration or networking need to be set up to ensure that teacher leaders can fully develop their leadership potential (Clemson-Ingram and Fessler, 1997; Gehrke, 1991). Through collaborating with teachers in other schools, engaging in trialing new teaching approaches, disseminating their findings to colleagues, and engaging in action research, the potential for teacher leadership has been shown to be significantly enhanced (Darling-Hammond *et al.*, 1995).

The teacher leadership literature points toward the beneficial effects of teacher leadership; however, the empirical evidence upon which to base some of these claims remains limited. While the teacher leadership literature is vast with over hundreds of potential sources for consideration, including books, articles, chapters, and other media, there are acknowledged limitations with this particular body of literature (York-Barr and Duke, 2005; Muijs and Harris, 2003). However, despite these limitations, there is evidence to suggest that teacher leadership can have a positive impact on teachers' self-efficacy, instructional knowledge, and professional relationships. The evidence would also support the positive benefits to

other teachers and endorse a strong relationship between teacher leadership and organizational development.

Understanding How Leadership Influences Student Learning

K Leithwood, University of Toronto, Toronto, ON, Canada

B Levin, University of Toronto, Toronto, ON, Canada

Introduction

This article describes a selected set of conceptual and methodological issues associated with developing a better understanding of the links between school leadership practices and student learning. We provide a general framework for thinking about these links and unravel some of the key challenges associated with each part of the framework.

A General Framework

Most efforts to understand the relationships between leaders' practices and student learning have assumed that leader effects are primarily indirect (e.g., Silins and Mulford, 2002a; Hallinger and Heck, 1999). Based on this assumption, one of the primary challenges for those trying to understand how leadership exercises its influence on students is to identify the most promising variables mediating and moderating leaders' effects. A second significant challenge is to uncover the nature of the relationships among these variables and between leaders and such variables.

Figure 1 is a framework for helping to understand the links between what leaders do and their influence on student learning. This figure indicates that leadership practices or behaviors have direct effects on potentially a wide range of variables which stand between or mediate the effects of leadership when those effects are determined to be student learning. **Figure 1** also includes a set of moderating variables. These are features of the organizational or wider context in which leaders' work that interact with leadership practices and/or mediating variables. These interactions potentially change the strength or nature of relationships between the leadership practices and mediating variables or the mediating variables and student learning.

Leadership Practices

In an extensive review of research on educational leadership up to 1999, Leithwood and Duke (1999) found evidence of five distinctly different types of leadership models reflected in that literature.

- Instructional leadership focuses on the behaviors of teachers as they engage in activities directly affecting the learning of pupils. The more fully developed models in this category (e.g., Hallinger, 2003) also include attention to broader sets of organizational variables, such as school culture or climate, thought to influence teachers' classroom practices.
- Transformational leadership focuses on the commitments and capacities of organizational members, as well as their willingness to engage in extra effort on behalf of their organizations. While the bulk of the evidence about this approach to leadership has been collected in non-school contexts (e.g., Avolio and Yammarino, 2002), educational researchers have recently begun to redress this imbalance (e.g., Nguni, 2005; Lunenburg, 2004).
- Moral leadership is concerned with the ethics and values of those exercising leadership. Specifically, it aims to clarify the nature of the values used by leaders in their decision making and how conflicts among values are best adjudicated (Begley and Johansson, 2003; Begley and Leonard, 1999). A strand within this approach to leadership specifically aims to promote democratic values and the empowerment of a large proportion of organizational members (e.g., Johansson, 2003; Starratt, 2003).
- Participative leadership shines a spotlight on group decision-making processes. Educational research inquiring about this approach builds on a strong foundation of research in other sectors dating back to seminal studies in the early 1930s (e.g., Mayo, 1933) about increases in organizational effectiveness associated with greater participation of employees in meaningful decisions about their work. The extensive body of research on teacher participation in decision making reasonably can be viewed as part of the body of evidence about this model of leadership (e.g., Conley, 1991). Rapidly growing literatures on both teacher leadership (Harris and Chapman, 2002; York-Barr and Duke, 2004) and distributed leadership (Gronn, 2002; Spillane *et al.*, 2000) are the most recent evolutions of this approach.
- Managerial and strategic leadership encompasses a range of tasks or functions found in the classical management literature (reviewed in Rost, 1991), including tasks such as coordination, planning, monitoring, and the distribution of resources. Educational literature from the United Kingdom reflects a far greater interest in this form of leadership than does the North American literature. Addressed much more extensively in the UK

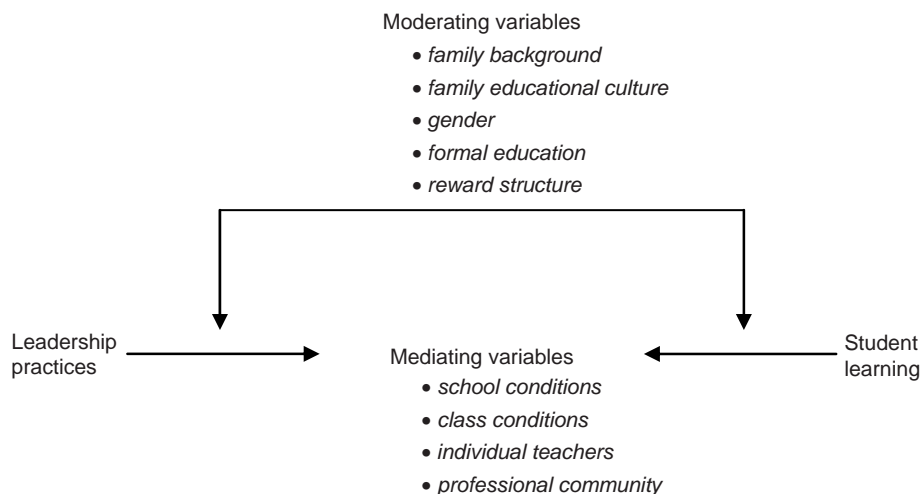

Figure 1 A framework for helping to understand how leadership influences student learning.

than in the North American literature as well is the entrepreneurial, creative, and change-oriented strategic leadership sometimes thought to be the exclusive purview of those occupying senior levels of the organizational hierarchy (Yukl and Lepsinger, 2004) (see, e.g., the special issue of *School Leadership and Management* (2004, vol. 24, no. 1) edited by Brent Davies).

- Contingent leadership emphasizes the need for leaders to be responsive to the unique demands of their organizations and the contexts in which those organizations function. While this approach is quite mature in both education and noneducation sectors (e.g., Blake and Mouton, 1964), its original conception was limited to a very small number of dimensions along which leadership styles could vary in response to context (primarily the initiation of structure and demonstrations of consideration for employees). Current leadership research continues to call for more sensitivity to the context in which leaders work and greater flexibility on the part of leaders across a much larger number of dimensions (Yukl and Lepsinger, 2004).

With the exception of instructional leadership, all of the approaches to leadership explored by the educational research community are also active areas of research in other sectors. However, academic leadership research (term used in reference to systematic, theoretically informed, empirical inquiry about leadership – as distinct from the highly popular genre of leadership literature which is autobiographical, anecdotal, and/or exclusively case based) in these other sectors reflects an additional range of approaches or models. For example, Dansereau *et al.* (1995) identify a total of 13 approaches to leadership nested within four categories they refer to as classical, contemporary, alternative, and new wave approaches.

Some education sector leadership models have been specified in detail and tested with instruments which are quite well developed. This is the case, for example, with

Hallinger's instructional leadership model (see Hallinger and Murphy, 1985), Leithwood's transformational school leadership model (Leithwood and Jantzi, 2000) and Marks and Printy's (2003) synthesis of both of these forms of leadership. Several versions of Bass' (1985) *Multifactor Leadership Questionnaire* have been used extensively to study the transformational leadership effects primarily in nonschool organizations, but in schools and districts, as well (e.g., Nguni, 2005). Many other instruments are available for measuring leadership, especially for doing so in noneducation organizations (Clark and Clark, 1990).

Without diminishing their many other contributions, one limitation of some of the most widely cited reviews of leadership effects on student learning is that they confound estimates of such effects by failing to distinguish among alternative approaches to, or models of, leadership (e.g., Hallinger and Heck, 1996b). Other reviews seem to infer comprehensive assessments of leadership effects while actually limiting themselves to the behaviors associated with a particular model of leadership (e.g., Witzier *et al.*, 2003). Furthermore, some original studies of leadership effects use secondary data sources originally created for other purposes, typically estimating the effects of potentially incoherent or incomplete models of leadership. Virtually all large-scale quantitative leadership effect studies in education restrict their attention to only part of what it is that leaders do.

These shortcomings in the actual measurement of leadership point to the importance of clearly specifying those leadership practices which are hypothesized to affect student outcomes. Failure to do this arises for both practical and conceptual reasons. Practically, available resources will often press researchers and evaluators to rely on existing evidence, evidence that is an imperfect match for their purposes. Conceptually, a major source of the problem is lack of agreement about the nature of leadership, as we discussed earlier.

Student Learning

Students' academic achievement, as it is typically measured, is just one of the several indicators of student learning. Others of a more long-term nature include graduation rates, drop-out rates, and engagement in school, for example. These two sets of outcomes are quite different. Achievement measures reflect pupils' skills and knowledge in a specific curriculum domain. Secondary school graduation rates, however, reflect not only specific curricular goals but also course selection decisions, course load, exam difficulty, and the like.

Achievement test scores are necessarily informed by pupils' entire previous school careers, as well as their personal lives. Indeed, there is a strong case to be made that the important outcomes of education are, in fact, the broader and longer-term measures such as participation in further or higher education, employment, and other measures of social participation. Many people care far more about these kinds of outcomes than they do about, for example, science test scores at age 15. Broader measures tend to present fewer data problems.

Nonetheless, the current preoccupation with student test scores, as the dependent measure of choice in inquiries about leadership effects, is not likely to go away anytime soon. So what are the challenges associated with this measure of student outcomes?

While purpose-built achievement measures could be used by researchers (although they would have their own limitations), in practice, levels of funding as well as government policies mean that most research studies end up using existing measures. These measures are typically part of national, state, or provincial student testing programs with three well-known limitations as estimates of leadership effects.

One of these limitations is the narrow focus of such testing programs. Most large-scale testing programs confine their focus to math and language achievement with occasional forays into science. Technical measurement challenges, lack of resources, and concerns about the amount of time for testing explain this typically narrow focus of large-scale testing programs. But this means that evidence of leaders' effects on student achievement using these sources is evidence of effects on pupils' literacy and numeracy. There is evidence, however, that leadership effects are of a different magnitude for even these two areas of achievement.

A second limitation of many large-scale testing programs is lack of reliability of their results at the school level. Most testing programs are designed to provide reliable results only for large groups of pupils. So as the number of pupils diminishes, as in the case of a single school or even a small district or region, few testing systems claim to even know how reliable are their results (e.g., Wolfe *et al.*, 2004). Researchers would do well to limit

analysis of achievement to data aggregated above the level of the individual school or leader.

Difficulties in estimating change are a third limitation of attempting to use the results of large-scale tests for research designed to assess leadership effects. Monitoring the extent to which a school improves the achievement of its pupils over time is a much better reflection of a school's (and leader's) effectiveness than is its annual mean achievement scores. Technically, however, arriving at a defensible estimate of such change is difficult. Simply attributing the difference between the mean achievement scores of this year's and last year's students on the province's literacy test to changes in a school's (and/or leader's) effectiveness overlooks a host of other possible explanations such as cohort differences, test differences, and differences in testing conditions.

Linn (2003) has demonstrated that these challenges to change scores become less severe as change is traced over 3 or 4 years. The lesson for those attempting to better understand leader effects is to rely on changes in student achievement over relatively long periods of time.

Variables Mediating Leadership Practices and Student Learning

We have already alluded to the commonly held assumption that the effects of leadership on student learning are largely indirect; **Figure 1** is based on this assumption. This is most obviously the case for leadership exercised by those in roles outside the classroom such as principals or head teachers. For the leadership of people in these roles to affect student learning, they must exercise some form of positive influence on the work of other colleagues such as teachers, as well as on the key conditions or characteristics of their organizations that, in turn, have a direct influence on students. These people and conditions are the mediating variables in **Figure 1**. Leaders potentially have a direct relationship or influence on these variables, and these variables, in turn, have a direct influence on student learning.

One recent review of literature summarized an extensive body of empirical evidence collected largely in North America about four categories of mediating variables which can be influenced by school leaders and which have a positive influence on student learning including school conditions (e.g., organizational culture and school structures), classroom conditions (e.g., teaching loads), individual teacher characteristics (e.g., pedagogical content knowledge) and teachers' professional community (Leithwood *et al.*, 2004). Silins and Mulford (2002b), among others, have also provided convincing evidence of the important mediating effects of organizational learning processes.

Variables Moderating Leadership Effects

The direct effects of leadership on mediating variables, as well as the indirect effects of leadership on pupils, are depressed, neutralized, or enhanced by some features of the situation or context in which leadership is exercised. For example, the same leadership practice may have quite different effects on teachers, depending on their gender, age, amount of experience, or levels of stress. So these are potential moderating variables.

Since moderating variables help explain how or why certain effects will hold, careful attention to moderating variables is a key part of understanding leadership effects on students, something that has been badly neglected in educational leadership research to date. Indeed, such inattention to moderating variables is one of the more plausible explanations for contradictory research findings and the general skepticism that often follows about the potential of research to provide clear guidance for policy and practice.

The important influence of moderators also provides an explanation for why an apparently effective leader in one school can become a struggling or ineffective leader when moved to another school. Differences in the new context react negatively to the leaders' habitual ways of doing business.

A final point about moderators concerns the basis on which a variable is assigned moderator status in a research study. The same variable might be defined moderator, mediator (or even dependent) variable status depending entirely on the theory or framework used to guide a leadership effects study. For example, teacher trust is often treated as a moderating variable in leader effects research. On the other hand, trust is also viewed as a dependent measure in leadership studies when researchers are curious about the forms of leader behaviors which promote its development (e.g., Kouzes and Posner, 1995). Trust is also conceived of as a mediating variable in studies concerned with the effects of leader behaviors on employees' acceptance of decisions (Tyler and Degoe, 1996). The theory-driven nature of moderator designation means that the examples of moderating variables provided here should be understood as an illustration of what is of theoretical interest to leadership researchers not as a category of unique variables.

The most frequently used moderating variables in studies of leadership effects on pupils are student and family background characteristics. Indicators of wealth (e.g., student eligibility for free or reduced lunch at schools) and/or socioeconomic status (e.g., parental occupation and minority status) are typically used to represent these variables. However, other moderating variables are evident in recent educational leadership effects research. For example, Leithwood and his colleagues used family educational culture as a moderating variable on the grounds that it is

the feature of student and family backgrounds that most directly influences the learning of pupils (Leithwood and Jantzi, 1999; Leithwood *et al.*, 1999). Marks and Printy (2003) incorporated into their study, as moderators, classroom compositional variables related to student gender and ethnicity.

Other examples of potential moderators can be found in recent reports of research carried out in both education and noneducation sectors. Our own scanning of such reports suggests at least five categories of promising moderators. The first category, pupils, includes a range of features associated with pupils' family background, family educational culture (OECD, 2004), and pupils' gender and ethnicity. The second category, teachers, includes gender, formal education, and tenure (age and experience have been included here). Additionally, part of this category are teacher ethnicity, beliefs and values, morale, trust, and the confidence they have in their leaders, as well as teachers' leadership prototypes. Two characteristics of leaders themselves are evident in the literature at present, leader gender and their level in the organizational hierarchy.

Five features of the organization have been conceptualized as moderators, including school size, what it is people are rewarded for, and opportunities for job enrichment. The difficulty of the tasks people are expected to accomplish, the interpersonal dynamics among people in the organization, and the availability and use of information in decision making are also identified as moderators in this category. Finally, in the category of organizational context, the nature of other stakeholders in the school or district and their relationships with the school, as well as the policy environment in which the organization finds itself, have been reported as moderators of the amount and nature of leaders' influence.

Conclusions

This article has described selected conceptual and methodological challenges associated with better understanding how and to what extent school leadership influences student learning. We offered suggestions about how each of these challenges might be addressed.

Although not discussed earlier in the article, there is an additional challenge which has been largely ignored to date and crosses the challenges we have identified to this point. It is the unit of analysis challenge. Most empirical leadership research in school contexts has treated the school as the unit of analysis. Even though it is rarely awarded serious attention, however, most of this research also has found greater within-than between-school variance in student achievement explained by leaders' influence.

These findings challenge the prevailing view that leaders have relatively uniform effects on the schools, as a

whole. There are two quite plausible explanations for the findings as well.

One explanation is that leaders treat their individual colleagues quite differently, for example, awarding much more discretion to those that they trust than those they do not. This explanation adheres closely to our actual experience in organizations and receives substantial support from a body of research, now well developed outside the education sector called the leader-member exchange theory (e.g., Erdogan and Liden, 2002; Graen and Uhl-Bien, 1998). A second explanation is that a largely common set of behaviors engaged in by leaders is interpreted quite differently by leaders' colleagues. This explanation also aligns closely with our actual life experiences (think of the different accounts provided by multiple witnesses of the same car accident). Furthermore, it has been extensively explored through information-processing approaches to leadership (e.g., Hall and Lord, 1998; Lord and Maher, 1993).

Neither leader-member exchange theory nor information-processing approaches to leadership, however, are reflected in the current corpus of evidence about educational leadership and its effects on students. Research reflecting both of these theoretical lenses would contribute substantially to our further understanding of the complex relationship between school leaders and student learning.

Glossary

CRS – Comprehensive School Reform.

Ecological fallacy – A widely recognized error in the interpretation of statistical data, whereby inferences about the nature of individuals are erroneously inferred from aggregate statistics collected for the group to which those individuals belong.

EPPE – Effective Provision of Pre-school Education Project.

NICHHD – National Institute of Child Health and Human Development.

OECD – Organization for Economic Cooperation and Development.

PIRLS – Progress in International Reading Literacy Study.

PISA – Programme for International Student Assessment – OECD.

SEN – Special educational needs.

SER – School effectiveness research.

SES – Socioeconomic status.

STAR – Student Teacher Achievement Ratio Study (Tennessee).

TIMSS – Trends in International Mathematics and Science Study.

UN – United Nations.

Development. (OECD), World Bank, etc.). Education is both affected by and influences the process of globalization in different ways in different contexts. In many societies the prime concern is to increase access to education and information technology, achieve the goal of universal primary education for all children and, in particular, improve the education prospects of girls and those living in poverty. The education of girls is seen to promote health goals for children, reduce population growth, and enhance economic prosperity in developing countries. In other contexts the prime concerns are to raise quality and standards, including increasing participation rates in further and higher education, and promoting lifelong learning.

Raising standards of achievement is seen as fundamental to economic performance and the promotion of democratic engagement in many countries. Education reform is given a high profile as governments attempt to modernize their education systems to face the challenges of the twenty-first century, and demand greater returns for their investment in education in terms of higher student achievement levels. International surveys of student achievement such as Progress in International Reading Literacy Study (also known as PIRLS), Trends in International Mathematics and Science Study (often shortened as TIMSS), and Programme for International Student Assessment (PISA) receive considerable media coverage with the creation of league tables of country results. They have become increasingly influential with governments concerned to boost both their nation's average attainment levels and reduce the variation in attainment within their country, particularly the equity gap in achievement between different groups of students. The political impact of low performance has been considerable, for example in both Denmark and Germany major reviews of their education system were conducted in response to poor

Increased awareness of the interdependence of societies, and the destabilizing impact of poverty and environmental degradation has led to a greater focus on promoting equity as a policy goal for many governments and transnational organizations (United Nations Organization (UNO), Organization for Economic Cooperation and

performance in PISA 2000 and, interestingly, both countries adopted a school effectiveness research (SER) framework to inform their reviews.

The contribution of SER to understanding variations in school performance, the role of school leadership, and its implications for promoting quality in education and raising standards are explored later in this article. First, attention is paid to define concepts and terms used in studying educational equity.

Defining Educational Disadvantage

Attempts to define equality and equity in education and the role of disadvantage draw on notions of social justice and social inclusion. Foci include:

- formal equality of access/provision;
- equality of circumstance;
- equality of participation; and
- equality of outcome.

A helpful discussion is provided by the UK government's *The Equalities Review* (2006).

In most education systems students from disadvantaged backgrounds (especially those from minority ethnic origins and those experiencing a range of social disadvantages such as low income, parents lacking qualifications, unemployed or in low socioeconomic status (SES) work, poor housing) are more likely to experience educational failure or underachievement. Nonetheless the size of the equity gap in achievement is wider in some systems than others, as is shown in international achievement studies and this is linked to broader structural features related to social processes and the characteristics of different education systems.

West and Pennell (2003) explore the concept of underachievement noting that some psychologists define this as the discrepancy between measured intelligence (IQ) and attainment in educational tests. They see this view as controversial since it proposes IQ as the main determinant of differences in achievement, and can be seen as circuitous since all IQ tests are, to some degree, tests of achievement themselves. An alternative approach is to use statistical measures of the relative differences in attainment between various social or ethnic groups as an indicator to identify relatively low-attaining groups.

Most studies in the political arithmetic tradition measure absolute differences in attainment between specific groups of students to identify the size of the equity gap. But this may not illuminate the factors that underlie such differences and their definition. Low attainment does not just relate to minority ethnic group background in a uniform way. There are significant variations in attainment between different minority ethnic groups, some outperforming majority students and others significantly

underperforming. Subgroups of students may show different profiles with black African students showing higher attainment levels than black Caribbean students, Chinese and Indian students typically showing high levels of attainment, and Pakistani or Bangladeshi students relatively low levels in the United Kingdom, for example. Within this, there can be within-group differences, the gender gap being larger for some ethnic groups. Other factors, particularly refugee status, time spent in the education system, whether first-, second-, or third-generation status are also important. Language is a powerful determinant with second-language status associated with lower attainment overall; differences exist within this category too though – bilingual students fully fluent in the majority language often show high levels of attainment whereas those not fully fluent often show lower attainment and reduced adjustment in school. The size of the equity gap differs between countries and the particular groups with low attainment vary in relation to economic, historical, and cultural factors that affect educational opportunities (tribal, religious, or caste systems often show a powerful association with achievement patterns especially in developing societies).

Factors associated with low attainment can be divided into broad categories such as individual characteristics (age, birth weight, gender); family SES characteristics (particularly family structure, parents' qualification levels, health, occupational level, whether in paid work, and income level); community and societal characteristics, both local and national (neighborhood context, cultural expectations, social structural divisions especially in relation to social class); and educational experiences related to preschool, school, and peer characteristics (including access, quantity, and quality of provision). In addition, the influence of family cultural capital, especially the powerful impact of the child's home learning environment in the early years, can be an important predictor of attainment.

Low educational attainment is linked to the concept of social exclusion where individuals or groups of people, often concentrated in specific areas or localities, experience a combination of linked problems such as unemployment, poor skills, low participation rates in further/higher education, poor housing, high crime, and bad health. A range of area-based intervention policies have been developed to address the geographical clustering of disadvantaged groups, and this often includes targeted interventions in education. In many developing countries a regional and/or a rural-urban divide in educational attainment levels and opportunities is evident, with rural poverty linked to the achievement gap; this leads to aid and regional development policies often with an education as well as an employment focus. In developed countries, a common problem involves the concentration of disadvantaged groups in inner city urban areas and this has also led to targeted educational interventions.

The strategy of positive discrimination was first introduced with Title 1 Program or war on poverty in the United States in 1965. The program intended to improve the basic skills of students from low-income groups and focused on schools with high concentrations of these students. Similar policies of education priority were followed in many western European countries including the Netherlands and England. More recent policy interventions in England with a strong area focus include Education Action Zones and Excellence in Cities involving schools, and Sure Start aimed at families with young children (Karsten, 2006).

The concept of multiple disadvantage focuses on the ways clusters of characteristics, each associated with an increased risk (likelihood) of low attainment, can have a cumulative if not a directly additive effect, while the intergenerational transmission of disadvantage is illustrated by the concept of the cycle of disadvantage, where poor opportunities in childhood lead to poor outcomes as adults including early child-bearing, lack of social mobility, and poverty thus perpetuating the divide. Multiple disadvantages can include a range of individual and family factors and also neighborhood characteristics such as living in an area with many other disadvantaged families. Low attainment is thus seen as a consequence of different combinations of disadvantage for particular groups (though this does not mean that all disadvantaged individuals have low attainment, as discussions of the ecological fallacy imply) (The ecological fallacy refers to the misinterpretation of statistical data, arising from drawing inferences about the nature of individuals from aggregate statistics collected for a group to which an individual belongs. For example, although typically there is a group difference in average attainment levels between high and low SES groups of students, some individual low SES students will show better attainment levels than some high SES students). Research indicates that multiply disadvantaged groups are significantly more likely than others to be identified as having some form of special educational need (SEN) at school and thus requiring learning support. In addition to strong links with low attainment, disadvantage (particularly multiple disadvantage) is associated with poorer educational outcomes on a range of other indicators including attendance, behavior, school exclusion, and early school-leaving.

The OECD (1995) defined those at risk as referring to children and youth who are in danger of failing at school or making a successful transition to work. Poverty is probably one of the greatest risk factors of poor life chances due to persistent associations with negative outcomes including school failure, teenage pregnancy, poor health, and violent crime. Cox (2000) argues that it is the multiplicative and interactive nature of risk factors that gives the concept of educational disadvantage its complexity.

The Role of Early Education

Neurological research indicates that extreme deprivation stunts normal brain development in very young children and supports the view that early experiences have a profound impact on later developmental outcomes. Longitudinal early intervention studies have pointed both to the damaging effects of early disadvantage on later school and adult life experiences and also to the benefits of high quality early childhood intervention programs for the most disadvantaged. (Barnett, 1995). In the 1960s, the High/Scope Perry Preschool Project targeted children from low-income African-American families and provided them with a comprehensive preschool program including education and health and family support services. Three- and four-year-old children attended the preschool program 5 days a week, two and one-half hours a day, for three-quarters of the year. Teachers also made home visits. The follow-up of the High/Scope intervention indicated lower incidence of crime, better jobs, and better social and emotional adjustment for those involved in comparison with an equally disadvantaged control group (Schweinhart *et al.*, 1993).

Sylva (2000) summarizes the benefits of good early childhood education as boosting cognitive skills that underpin academic learning personal attributes that give a child confidence, curiosity, and perseverance; and social commitment that binds the child to the community. Research by the National Institute of Child Health and Human Development (NICHD) (2002) in the United States has pointed to the benefits of high quality and longer duration of preschool for children's cognitive and several aspects of social development, while in England the Effective Provision of Pre-school Education Project (EPPE) longitudinal research indicates that preschool quality and duration are important for both improved cognitive and social behavioral outcomes, concluding that preschool is an effective intervention that helps to counteract the impact of educational disadvantage (Sylva *et al.*, 2004). In particular, good preschool experiences reduce the risk of later identification of SEN at primary school. Poor quality preschool offers few benefits by contrast, especially for disadvantaged children.

The Influence of Schools

There is increasing interest in the ways educational influences may compound existing inequalities related to student background, through unequal access to particular types of school, or differences in the quality of provision and the experience of teachers, for different groups of students. Policies of early selection and divisions into

academic and vocational schools are strongly associated with a larger equity gap in attainment, in international comparisons of PISA data. In addition, within school, differences can lead to unequal access to the curriculum through tracking, streaming, and setting arrangements resulting in concentrations of poor and minority students in lower tracks. A study of multiplying inequalities in the United States showed that unequal opportunities to learn science and maths contributed to unequal outcomes for disadvantaged groups (Oakes, 1990). School inspection has also indicated an association between poorer quality educational experiences and level of disadvantage of a school's student intake (Matthews and Sammons, 2004). High-poverty schools have more difficulty in recruiting and retaining teachers and in the United States such schools are found to employ significantly more teachers from less selective training institutions and with poorer grades (Wayne, 2002).

Other structural features are also relevant, for example, the STAR project in Tennessee pointed to benefits of smaller classes for younger age groups and particularly for disadvantaged (black and low-income) students (Pate-Bain *et al.*, 1992). Studies of summer regression in attainment indicate a sharp drop in performance in math and to a lesser extent in reading for low-income students over the summer holiday. The explanation given is that low-income students have less opportunity than others to pick up or maintain skills learnt at school. This feature is particularly marked in systems with long summer breaks, such as the United States. It has led to experiments such as summer schools, and proposals to have several short rather than one long holiday. Other developments such as full service schools (in the United States) or integrated community schools/extended schools in the United Kingdom seek to promote multi-agency working, linking health, social services, and education to support students, families, and communities and promote better educational outcomes.

Influential studies during the 1960s to early 1970s claimed that the particular school attended by a student had little influence on the educational outcome in comparison with factors such as IQ, race, and SES (Coleman *et al.*, 1966; Jencks *et al.*, 1972). The focus was thus on structural inequalities rather than on the way schools could contribute to either exacerbating or ameliorating inequities in outcomes. Subsequent research in a growing number of countries has pointed to the existence of significant school effects, while acknowledging the important influence of student background (Teddlie and Stringfield, 2000; Stevens, 2007).

SER seeks to disentangle the complex links between the student's dowry (the mix of abilities, prior attainments, and personal and family attributes) which any young person brings to school, from those of their educational experiences, and explore the way these jointly influence their later attainment, progress, and development. The main foci are the impact of social institutions

(including size of school effects), characteristics that promote better educational outcomes, the influence of context, the processes of institutional change, and the long-term impact of schooling on life chances (Sammons, 1999).

Early SER research in the United States incorporated explicit aims concerned with equity and excellence and focused on the achievement in basic skills (reading and numeracy) of poor/ethnic minority children in elementary schools. An effective school is defined as one in which the students progress further than might be expected from consideration of its intake. An effective school thus adds extra value to its students' outcomes, in comparison with other schools serving similar intakes. Effectiveness is thus a retrospective, relative concept that is both outcome- and time-specific.

A systematic meta-analysis concluded that net school effects (after control for intake) are larger for mathematics than language outcomes, and largest for studies based on composite measures of achievement. Effect sizes are generally greater in studies of developing countries where variations in quality and resources between individual institutions tend to be wide. On average, schools account for around 5–18% of the achievement differences between students after control for initial differences, but classroom level or teacher effects tend to be substantially larger than school effects. It concluded that "Schools matter most for underprivileged and/or initially low achieving students. Effective or ineffective schools are especially effective or ineffective for these students" (Scheerens and Bosker, 1997: 96).

Social and affective measure such as student attendance, attitudes, behavior, motivation, and self-esteem are also important in their own right but can act as intermediate outcomes, which affect, and can themselves be influenced by students' attainment and progress (Carneiro *et al.*, 2006; Cunha *et al.*, 2005; Feinstein, 2000). Relationships may be reciprocal. Improving a student's attainment and confidence as a learner can improve self-esteem, engagement, and attitudes to school and vice versa. Young students with low attainment are more at risk of developing poor attendance, and poor self-esteem and behavior as they grow older and move into secondary school, thus early intervention is vital, particularly for disadvantaged children.

The importance of school for emotional well-being is receiving attention. Students' perceptions or feelings of school connectedness have been shown to reduce adolescent emotional distress (Resnick *et al.*, 1997). Other research has identified relationships between students' sense of their school as a community and lower involvement in problem behaviors such as drug use and delinquent behavior and increased psychological resiliency (Battistich and Hom, 1997).

Three key questions relevant to the promotion of greater equity in education provision form the foci of much SER:

Table 1 The processes of effective schools

1. The processes of effective leadership	Being firm and purposeful Involving others in the process Exhibiting instructional leadership Frequent personal monitoring Selecting and replacing staff
2. The processes of effective teaching	Unity of purpose Consistency of practice Collegiality and collaboration
3. Developing and maintaining a pervasive focus on learning	Focusing on academics Maximizing school learning time
4. Producing a positive school culture	Creating a shared vision Creating an orderly environment Emphasizing positive reinforcement
5. Creating high and appropriate expectations for all	For students For staff
6. Emphasizing responsibilities and rights	Responsibilities Rights
7. Monitoring progress at all levels	At the school level At the classroom level At the individual level
8. Developing staff skills at the school site	Site-based Integrated with ongoing professional development
9. Involving parents in productive and appropriate ways	Buffering negative influences Encouraging productive interactions with parents

- Effective in promoting which outcomes?
- Effective for which student groups?
- Effective over what time period?

They provide a basis for monitoring at both the system level and for individual schools and can be used for school improvement planning and evaluation with the promotion of equity in mind (Sammons, 1999).

Characteristics of Effective Schools

The correlates of effectiveness identified by SER have been identified in a number of reviews (Teddle and Reynolds, 2000) and nine aspects are highlighted (see Table 1).

Characteristics of Ineffective Schools

Stoll and Fink (1996) review characteristics of ineffective schools and highlight:

- lack of vision;
- unfocused leadership;
- dysfunctional staff relationships; and
- ineffective classroom practices.

Ineffective classroom practices were characterized by:

- inconsistent approaches to the curriculum and teaching;
- generally lower expectations for students of low SES;

- an emphasis on supervising and communicating about routines;
- low levels of teacher–student interaction;
- low levels of student involvement in their work;
- student perceptions of their teachers as people who did not care, praise, provide help, or consider learning as important; and
- more frequent use of criticism and negative feedback.

The features of structured teaching have been identified as particularly relevant to promoting cognitive attainments in the basic skill areas especially for socioeconomically disadvantaged groups (Muijs and Reynolds, 2005).

The Role of School Leadership

School effectiveness research has drawn attention to the importance of school leadership as a key characteristic of effective schools (see Table 1) and leadership judged to be poor is a well-documented feature of ineffective schools according to inspection evidence in the United Kingdom (Matthews and Sammons, 2004). School improvement research has highlighted the principal's role in the turn-around of ineffective schools and its importance for schools in disadvantaged contexts. A review by Leithwood *et al.* (2006) highlighted seven strong claims about school leadership:

- school leadership is second only to classroom teaching as an influence on pupil learning;

- almost all successful leaders draw on the same repertoire of basic leadership practices; and
- school leaders improve teaching and learning indirectly and most powerfully through their influence on staff motivation, commitment, and working conditions.

The LOSLO study in Australia shows how leadership influences both organizational learning (OL) directly and, through this, teaching and learning and student outcomes (indirectly). It indicates that leadership needs to be distributed amongst a range of school personnel not just focused on the principal, and that four factors defined OL in schools:

- a trusting and collaborative climate;
- a shared and monitored mission;
- taking initiatives and risks; and
- ongoing, relevant professional development (Mulford *et al.*, 2004).

In a review for the OECD, Mulford (2003) draws attention to the increased importance attached to the role, recruitment, and development of school leaders for the improvement of education and evidence of their impact on teacher and school effectiveness and, through this, on student outcomes (see Mulford and Silins, 2010; Silins and Mulford, 2007).

While the challenges facing schools serving disadvantaged communities are greater, the characteristics of successful schools in such contexts are not radically different from those reported by SER as a whole. Research on high-achieving low-income secondary schools in Canada concludes that they improve educational outcomes by stressing clear expectations and through supportive structures and services, which motivate students and emphasize the importance of leadership (Henchey, 2001). A study of high-attaining Welsh primary schools in disadvantaged settings similarly points to important features of primary school culture and leadership (James *et al.*, 2006). In a review of improving schools in socioeconomically disadvantaged areas Muijs *et al.* (2004) argue that there are a number of strategies that support improvement in disadvantaged contexts including a focus on improving the quality of teaching and learning for all students as the core business of the school, effective distributed leadership, creating an information-rich environment, a positive school culture, learning environment, and a strong emphasis on continuous professional development.

Comprehensive School Reform (CSR) models designed to promote improvement have received considerable attention and investment in the United States. A meta-analysis shows that CSR is equally effective in relatively lower- and higher-poverty schools, and that achievement effect sizes increase over time with longer participation by schools. The strongest evidence of effectiveness was found for three models: Direct Instruction, School Development Program, and Success for All. The successful

expansion of CSR shows that research-based models of improvement can be brought to scale across many schools and varying contexts (Borman *et al.*, 2003).

Conclusions

Health, housing, income, and the home-learning environment remain powerful influences on students' educational outcomes and joined-up policies aimed at combating social exclusion are called for. Positive educational experiences in the early years seem to be particularly important in combating disadvantage. Effective schools that boost academic attainment and promote prosocial attitudes and behaviors, and a positive self-image, also have the potential to improve the life chances of disadvantaged students. SER indicates that school effects (positive or negative) are strongest for disadvantaged students and the knowledge base is particularly relevant to schools serving disadvantaged groups. School leadership is identified as a key factor associated with school effectiveness and improvement, especially important for the improvement of schools in disadvantaged contexts.

Hopkins and Levin (2000) argue that education reform in many systems could learn much from the SER tradition and evaluations of school improvement. They conclude that reform requires extra resources linked to clear plans for improvement based on the best available evidence and that policy alignment needs to be both vertical and horizontal, focused on supporting instructional goals and strategies and reducing the equity gap in achievement.

The Every Child Matters agenda in the United Kingdom and No Child Left Behind in the United States suggest a new policy commitment to promote greater equity and greater recognition of the need for additional resources and better strategies to enhance the life chances of vulnerable groups. However, controversy remains as to the extent that schools and educational interventions can be expected to compensate for persistent structural inequities in society. In England considerable success in promoting the improvement of weaker schools has followed intense policy priority and interventions, but although attainment standards have risen markedly for all groups of students the equity gap between disadvantaged and advantaged groups remains large (Sammons, 2008).

Leading/Managing Schools in Communities Made Poor

Across the world, compulsory schooling has historically benefited some children more than others. Despite the rise in the overall level of mass education, as evidenced in the continued elevation of the school-leaving age, the children who do not get their fair share of education are overwhelmingly from families and neighborhoods where there are low levels of both income and formal education (Anyon, 1997; Berliner, 2006; Burniaux *et al.*, 1998; Fincher and Saunders, 2001; Fitz *et al.*, 2006; Flaherty *et al.*, 2004; Foster *et al.*, 1996; Rainwater and Smeeding, 2003; Teese, 2000). Of course, education provides an avenue for social mobility for a minority of such children (Hills and Stewart, 2005; Marshall *et al.*, 1997); however, there is a persistent and stubborn nexus between social inequality and the unequal distribution of educational qualifications across the population.

The historical polarization of cities, states, and provinces (Murphy and Watson, 1994; Pacione, 1997), and waves of urban regeneration (Bryson and Winter, 1999; Lupton, 2003) and migration (Brah *et al.*, 1999), means that there are recognizable localities and neighborhood schools where there are concentrations of children living in poverty, and where the everyday norm is that of economic and social deprivation and exclusion (Gough *et al.*, 2006). However, poverty is not confined to inner cities. It is found in rural areas and regional towns (Elder and Conger, 2000; Kenway *et al.*, 2006), in indigenous communities where the cumulative effects of colonialism still take a large human toll (Rowse, 2002), and in outer urban areas, towns, and villages, where manufacturing industries have decamped to more profitable climes, leaving their workforce behind (Allen *et al.*, 2000; Fine and Weis, 1998). However, all of these locations, despite their differences, do share some common characteristics – as do their citizens and their schools. These commonalities – the patterns produced by social, economic, and cultural structures and changes – provide the basis for this article.

Poverty creates particular challenges for both positional leader/managers and functional leaders (Kugelmass, 2004) who are charged with reforming the schools that serve neighborhoods made poor. These are:

- the challenges of dealing with the everyday realities of lives in poverty;
- the challenges of the material realities of disadvantaged schools; and
- the challenges of making a difference.

This article addresses each in turn and subsequently considers some consequences for leader/managers.

The Challenges of Working with and for Poor Children and Families

Living in poverty has both material and relational effects on the people who endure it as their everyday experience (see graphic details in Charlesworth, 2000; Peel, 2003; Shirk *et al.*, 1999). We are accustomed to think of these effects as hunger and ill health, but Lister (2004) points out that unacceptable hardship also produces disrespect, humiliation, shame and stigma, assault on dignity and self esteem, othering, denial of human rights, diminished citizenship, lack of voice, and powerlessness. Wilkinson (2005) suggests that these experiences are the consequences of inequality, rather than poverty *per se*.

Children and young people who live with poverty/inequality cannot leave these feelings and experiences at the school gate. They are inevitably in school. Teachers and school leaders respond to the realities of lives in poverty in various ways, not all of them positive or productive. One of the most consistent research findings in schools serving families and communities made poor is that educators (including policy makers) mobilize a deficit discourse to describe poverty/inequality effects (Comber, 1998; Shields *et al.*, 2005; Valencia, 1997). Two of the most commonly held beliefs are that:

1. Poverty is due to laziness and “they” could get jobs if they wanted. The reality is that many families depend on below-poverty-line welfare payments (Saunders, 1996; UNICEF, 1996) and poorly paid semiskilled work (Ehrenreich, 2001; Newman, 1999; Toynbee, 2003). Such poverty is often persistent and hard to shift (Mishel *et al.*, 2005).
2. Parents do not value education; they do not have books at home and cannot/will not help their children with their homework.

Yet, studies (Connell *et al.*, 1982; Duncan and Brooks-Gunn, 1997; Ellsworth and Ames, 1998; Newman, 1999) consistently show that the vast majority of poor families understand the importance of education and schooling success and do try to help their children stay at school and do well.

Deficit views translate into educational solutions which are at best remedial, and which at worst simply reproduce the inequitable achievement gap (Connell, 1993). Children who seem to take more time to learn are slowed down further through the use of instructional methods which use small, linear steps to teach concrete functions (Anyon, 1980). At the same time, their more

affluent counterparts have engaging lessons which require the use of complex concepts and creative tasks. The decelerating pedagogies of poverty (Haberman, 1991) actively widen the achievement gap.

Leaders/managers who work from a deficit position do establish classroom reform, welfare, and counseling programs (see Payne, 1998), but fail to build connectivity (Deforge and Abouchaar, 2003) between school and home. Communication with families is characterized by disrespect and paternalism (Tatto *et al.*, 2001), and necessary transactions are enacted with an eye on efficiency (de Carvalho, 1997), rather than on building relationships. Parents/carers are helped, while compared unfavorably with middle-class families who are now highly skilled in maintaining the benefits they accrue from the achievement gap (Ball, 2003; Devine, 2004; McGrath and Kuriloff, 2004; Power *et al.*, 2002).

Research suggests that working-class children have word, number, image, and knowledge resources and practices equal, but different to those of their middle-class peers (e.g., Comber *et al.*, 2001; Dyson, 1993; Freebody *et al.*, 1995; Hill *et al.*, 1998; Moll, 1992). This body of work argues that parents are unable to do the kind of complementary education work on which success at school largely depends (Griffith and Smith, 2005) because the school does not recognize their specific resources and practices. What is required, therefore, is a not only a shift to inclusive school approaches to home-school relations and classroom pedagogies but also school and system tests which measure what all children know, rather than what some do not (Cairney, 2002; Comber *et al.*, 2001; Daspt and Weaver, 2000; Finn, 1999).

Leader/managers with a socially just approach set out to counter deficit views. They establish ethnographically oriented professional development, helping teachers to get to know their students and the complex, positive, and negative realities of their everyday lives (Frank, 1999; Gordon, 2002). They support teachers to find, value, build on, and incorporate family and community knowledges, understandings, ethical practices, and literacies into the school curriculum and pedagogies (Brooke, 2003; Gonzales *et al.*, 2005; Johnson *et al.*, 2005; Kamler and Comber, 2005; Romano and Glascock, 2002). They see the school as an important site for building social capital within the community and work with community leaders to mobilize community strengths and assets (Driscoll and Kerchner, 1999; Gold *et al.*, 2005; Kilpatrick *et al.*, 2002). Leader/managers committed to this approach allocate funding for specific community liaison staffing, offer school premises for community use and dedicated rooms for parent and community meetings, and allocate some of their own time to making connections with families and community leaders (Allen and Martin, 1992; Epstein, 1994; Pettit, 1980). However, this kind of community orientation is not easy to maintain at the same time as building an achievement culture, which ultimately

means that young people must physically and socially move away from the neighborhoods in which they grow up (Miron and Lauria, 2005).

Within the context of this broader curriculum and community development approach, the specific needs of some troubled and stressed lives can be attended to, and integrated health, welfare, and educational services can be tailor-made for specific children and groups (Thomson, 1999). However, care needs to be taken that interagency approaches do not reinforce welfarism, the domination of professionals over those that they aim to assist (see contrasting approaches in Anning *et al.*, 2006; Williams and Pritchard, 2006). Leader/managers may also find that they spend significant amounts of time in interagency partnership meetings out of their schools. This means that other staff must take up the leadership/management slack. While this can be good experience for middle managers, it can also lead to resentment about the invisible boss. Leader/managers must carefully mediate these external and internal pulls and pushes, and make the benefits of external connections and projects very clear and demonstrable to children.

The Challenges of Everyday Life in Disadvantaged Schools

Schools serving neighborhoods made poor are not on an equal footing with their more comfortable counterparts. Despite the unique nature of each school there are common patterns brought about by the conjunction of school mix (Thrupp, 1995), public policy agendas, and neighborhood effects (Thomson, 2000).

Family unemployment/underemployment/tenuous employment (the local working out of global economic shifts and macro- and microeconomic reform policies of the national and state governments) plays out in schools in a range of ways – many students have no money for educational expenses; some children are the only ones in their household who have to get up regularly everyday and frequently do not; some parents show acute levels of anxiety and depression arising from their lack of security – this is manifest in health problems and angry outbursts in schools. There are young people who firmly believe that they will not find any work at all, and they see little point in compliance to school rules or in application to curriculum. This produces significant behavior problems which are seldom adequately addressed by vocational programs (Ball and Lamb, 2001). There are also often regular and disillusioned unemployed visitors to schools, urging their younger counterparts to join them in the mall. Many students also have to work part time and these wages are often a necessary addition to the family income; however, casual work requirements of employers generally conflict with homework and regular attendance requirements.

The increase in the numbers of diverse families, many of whom are dependent on government income support, particularly those for lone parents and those designated as the working poor with young children, are manifest in disadvantaged schools. Significant numbers of children have to deal with the pressures of living in domestic situations which are not only unstable, but also strained from serious financial worries. Disadvantaged schools report regular incidences of “staying with grandma,” and children moving between family members. There is often significant family and student transience, and some children exhibit evidence of considerable insecurity and anxiety.

Low-income neighborhoods often become trapped in vicious downward spirals, in which those who are able to move out, do, and those who have no choice stay put. Small businesses close, and those who move into the area do so because it is all they can afford. Such areas often have a large quantum of housing funded from the public purse, some of which may be available for emergency shelter. Such neighborhoods also often become home to continuing intakes of refugees fleeing intolerable political situations. Schools in such localities face additional demands for translation and interpreting and support in a range of welfare- and immigration-related activities (Thomson *et al.*, 2004); in addition, there are sometimes significant shortfalls caused by the levels of resources available compared to the demand for services.

Such circumstances have a major impact on the schools that serve poor communities. They must do more with less (see Abu El-Haj, 2006; Kozol, 1991; Lupton, 2004; Riddell, 2003; Thomson, 2002). They are often financially worse off than schools that service more comfortable neighborhoods. They can raise little money from parents through voluntary contributions, and from fundraising and sponsorship. Their buildings are more likely to be aging and unable to cope with the demands of contemporary curricula. In addition, because they are located in neighborhoods where many experience the alienating and depowering effects of poverty/inequality, they are also more likely to experience ongoing vandalism which eats away cash which might otherwise be directed to major developments. There are other costs too. Working with children with stressed lives is tiring. Working with children who are more likely to be unhealthy might mean that teachers are more exposed to infectious diseases. Schools are likely to have higher staffing bills, resulting from illness and stress. A proportion of children who suffer poverty/inequality require a great deal of time and attention. This is time given by teachers, and by those in formal leadership positions, as well as those responsible for counseling and welfare. Making this time available inevitably means some redirection of instructional, curriculum development, and school reform time to discipline and welfare matters (Manicom, 1995). In order to maintain good social order and to meet the needs of particular

children, disadvantaged schools are likely to spend more on remedial and counseling support staff than that allowed for through targeted poverty funding.

Leaders/managers in disadvantaged schools also often have to manage a series of short-term policy programs intended to support change. While additional funds are welcome, multiple accountabilities for multiple programs with different time frames – each of which seeks to demonstrate that it is their particular intervention which produces change – are not. Often, such policy strategies are competitive, causing leader/managers in disadvantaged schools to spend disproportionate amounts of time on entrepreneurial activities as they attempt to garner more funds and assistance for their schools.

Schools in disadvantaged areas also have considerable difficulty with teacher turnover, which in turn results in: difficulties in pacing, sequencing, and consolidating children's learning; planning and sustaining reform; and building the trust of children and the families in their school. Senior manager/leaders must therefore be highly skilled in staff recruitment, selection, and retention. They must find and keep key staff, such as heads of department and team leaders, who do not possess rigid and reductive approaches to curriculum, pedagogy, and assessment. These key middle leaders have day-to-day responsibility for the ongoing work of adapting, developing, and trialing approaches to learning and teaching that do not simply reproduce unacceptable educational differences. They are essential partners in the collective achievement of educational/instructional reforms and school redesign (Gunter, 2005; Spillane, 2006) and must be able to cope with the inevitable ambiguities and tensions of such work (McInerney, 2005).

Finally, leader/managers must live with and plan for the reality that at least some of their most experienced teacher leaders will leave on a regular basis for more senior positions in other schools and in the wider system. As Hargreaves and Fink (2006: 48) puts it, such schools face an ironic change dynamic in which either the sustainability of innovation is sacrificed, as key leaders move out to carry the reforms to other parts of the system, or reform across the system is prevented by maintaining the presence of creative leaders within the single school. The role of disadvantaged schools in producing not only leaders, but also reforms for the wider system, is rarely acknowledged in policy and therefore not remunerated. It remains a necessary reality for leader/managers to anticipate and plan for in their staffing strategies in order to sustain change.

The Challenges of Making a Difference

Contemporary policies which frame the work of leaders/managers in disadvantaged schools focus heavily on the

ways in which education can assist people in poverty to climb out of the poverty trap and into new forms of knowledge and service work. The solution for people living in conditions of poverty seems to be that their schools must do better.

There is significant debate about how much this can be done. Studies on school effectiveness and school improvement have demonstrated that school effects make a relatively small difference in the distribution of achievement. Classroom effects are greater, but the income–parent education nexus is still a powerful indicator of likely educational achievement (Slee *et al.*, 1998; Stoll and Myers, 1998; Teddlie and Reynolds, 2000). Simply raising the level of achievement of children in poverty is also insufficient if the levels of achievement of the remainder of the population increase at a greater rate. The gap actually widens (see Power *et al.*, 2003).

Some educational researchers suggest that the answers to closing the gap might lie outside education in employment, regeneration and income support, housing, transport and health policies, and politics (Anyon, 1997, 2005; Berliner, 2006; Levin, 2003, 2006; Rothstein, 2002; Thomson, 2002). However, recognizing that there might be limitations to what can be done in schools does not mean that the task of improving students' learning and formal outcomes in disadvantaged schools should be abandoned (West and Pennell, 2003; Whitty and Mortimore, 1997). Rather, it is a matter, as Thrupp (1999) suggests, of being realistic about what can be achieved.

The task for leaders/managers in disadvantaged schools is to maintain a sense of efficacy while also being sanguine about what can be achieved. They must help the staff to maintain a collective and individual pragmatic optimism, an equilibrium which is neither wildly idealistic (translated into inappropriate demands on students and themselves) nor cynically negative (translated into lowered expectations and resistant divisive behaviors with colleagues) (Ainscow and West, 2006; Harris *et al.*, 2006). In England, and some parts of Canada and the USA, where there are narrow targets for learning outcomes on standardized tests and exams (see debate on targets – Fullan, 2006; Hargreaves and Fink, 2006) and media and policy naming and shaming of schools that allegedly fail (Fink, 1999; Hargreaves, 2004; Johnson, 1999; O'Connor, *et al.*, 1999), this is no easy matter.

Leader/managers can take some comfort in taking a modest approach to reform. Even small improvements are significant when translated into individual children's profiles and trajectories. They can be the difference between passing and failing, between getting and not getting the grade required to get into the vocational course of choice, and between getting into university and not. Measuring the achievement gap at the macro level can obscure the micro material benefits that can result when apparently paltry shifts are made.

Implications for Leader/Managers

Leaders/managers must have knowledges and practices that are up to the task of closing the gap – even if it is only a little.

Studies of unsuccessful heads (e.g., Baker, 2005) suggest the adverse impacts of: inconsistency in approach to students; poor communication; lack of attention to basic management and forward planning; refusal of the public symbolic acts of positional leadership (assemblies and so on); and unwillingness to face problems. By contrast, writings by and about successful leader/managers (Hampton and Jones, 2000; Monroe, 1997; Stubbs, 2003; Winkley, 2002) show a complex tangle of school, the everyday lives of children and their families, and broader social, political, cultural, and economic forces. Successful leaders demonstrate, in the face of adversity, a notable sense of agency and purpose which is profoundly ethical, and just (Scapp, 2006; Starratt, 2003).

There are a number of typologies of leadership practices for schools serving deprived communities (e.g., Harris and Chapman, 2002; Keys *et al.*, 2003; Leithwood and Steinbach, 2002; Ofsted, 2000), as well as various theorizations of leadership practices (e.g., Brighouse and Woods, 1999; Lingard *et al.*, 2003; National College for School Leadership, 2005; Ryan, 2003, 2005; Shields, 2003; Shields and Edwards, 2005). Headteachers in London (National College for School Leadership, 2005) examined and named their own key knowledges and practices as: enduring resilience, focus and simplicity; community engagement; open and connected leadership; leading learning; filtering, judging and acting; accountability and consistency; and purposeful influencing. They highlighted personal qualities, such as courage and conviction, as well as professional practices focused on organizational and classroom learning and keeping the bureaucracy on side (cf Haberman, 1999; Lyman and Villani, 2004).

Starting from the cultural diversity of students, Shields (2003) takes the view that leaders must develop cultural expertise that is both intellectual and lived. She argues for a headship that is as theoretically sophisticated as it is practically sensitive. She suggests that heads need to understand debates about justice and multiculturalism and to explicitly position themselves and their actions in the school in an ethicopolitical manner. She promotes the idea of grounded dialog and thinking of the school as a public sphere (Shields and Edwards, 2005). Ryan (2003, 2005) argues not for distributed leadership, but for anti-hierarchical schools in which the different contributions of people with different skills and perspectives are honored. He outlines levels of potential involvement, the different roles that students, parents, and teachers might take, and possible areas of participation. He suggests that questions of inclusion and diversity, again related to the populations of urban schools, are keys to successful reform.

In case this is all too serious, Peacock (2005), writing about the process of getting a school out of special measures, points to the importance of a sense of fun and some joy.

The teachers were exhausted. I gave them non teaching time and quality feedback so that they knew they had a voice and were being listened to. Whereever possible their requests for new resources were responded to and the school began to feel more loved.

The children were demotivated. Determined to show them that things could be different, we brought in drama specialists, artists, a teenage rock band, anyone we could think of to enliven the atmosphere, everyone needed to know that this school could be an exciting place to be. These visits gave the staff the opportunity to witness their children responding differently and provided rich CPD opportunities that were nothing to do with criticism of their teaching or providing targets for improvement. (Peacock, 2005: 6)

Peacock's example clearly shows how leading and managing must be thought and done together, and how an emphasis on the feelings and beings of the teachers and children are an important avenue to addressing teacher's deficit views of children, and the children's sense of alienation.

However, it is critical that these theorizations of leadership are not translated into the notion of the rescuing charismatic hero/heroine. Researchers in the US (Spillane *et al.*, 2003; Spillane and Zoltner-Sherer, 2004) and Australia (Gronn, 2003) have demonstrated something of what is actually involved in distributing leadership. Halverson (2003), for example, focuses on the role of policies, practices, and programs as the activities which do the work of initiating and sustaining distribution. Spillane *et al.* (2003) highlight structures such as meeting agendas and timetables which serve to construct and regulate activity through framing and supporting the ways in which people come together regularly to accomplish particular tasks. It is systems such as these which are potentially associated with what Leithwood and Reihl (2003) call building organizational structure and culture – and what many heads would simply call management. Money, time, meetings, information, policies, publications, rewards, and sanctions are important sites for a head teacher's change practices. Working on management issues is often a key activity for heads in schools that are judged to be in serious weaknesses or in special measures. National College for School Leadership (NCSL) associate Brown (2002) looked at the first 100 days of a head in a such a situation and noted how much of her time had to be spent simply making the school functional by addressing secretarial support, plant, and resourcing.

It is important to remember that the work that leaders/managers in disadvantaged schools find most rewarding is

educational reform and community development. The burdens of managing scarce resources and fielding demands for tracking and monitoring of multiple projects take too much of their time, and they welcome the opportunities they get for engagement with the real work of educational change. Finding ways to minimize administrative tasks through the use of staff other than teachers, or through redesigning the leadership/management systems of the school (Thomson and Blackmore, 2006), are critical to leader/managers being able to maintain a focus on the prime purpose for their work – that of making some difference.

Achieving this kind of agency is difficult. Current research issues document the increasing weight of managerial responsibilities on all leader/managers (Blackmore and Sachs, 2008; Hartley, 1997; Wright, 2001), suggesting that the profession is increasingly reluctant to take on the task of leadership/management in adverse circumstances. This is particularly true in schools that serve neighborhoods made poor, where there is evidence that they receive fewer applications for leadership vacancies than other schools (Barty *et al.*, 2005; Pounder and Merrill, 2001). Given the importance of leadership in school reform, this shortage of applicants bodes poorly for the prospects of closing the gap. The looming leadership/management supply issue is one which families and children at the bottom of the socioeconomic pecking order depend on us to resolve.

Principals Role in Restructuring Schools

G M Crow, Indiana University, Bloomington, IN, USA

K D Peterson, University of Wisconsin-Madison, Madison, WI, USA

From Restructuring to New Structures

The school principal's role has undergone significant changes since the last edition of the international encyclopedia was published. Since our last description, the principal's role in restructuring schools and the complexity of both the role and the context in which this occurs have increased. The importance of the knowledge society, the globalization of society, and the increasing demographic diversity of schools have called for new, or at least changed, roles for school principals. Clearly, the specific nature of these changes varies with national and regional contexts; but internationally too, the roles of principals are changing (Cheung, 2000; Crow *et al.*, 2002; Earley and Weindling, 2004). In this article, current changes in the nature of school improvement and the resulting changes in the principal's roles, relationships, rules, and results are identified. The article ends with an identification of implications of these changes for research, policy, practice, and preparation.

Current Changes in the Nature of School Improvement

Although there are several changes in the nature of school improvement, four major movements have been identified: re-culturing, professional learning communities, distributed leadership, and social justice. These four movements are believed to be especially important for understanding how the principal's role has changed. These movements and other external pressures on principals, however, create tensions and conflicts within the role, which will also be identified.

Reculturing

The first major change in principals' roles is centered on the ways these school leaders shape the cultures of their schools. While many countries are increasingly pressing schools to become more tightly structured, more focused on outcomes and accountability, the school principal is being pressed to be more managerial and administrative. Nonetheless, researchers (Deal and Peterson, 1999; Fullan, 2001; Gurr *et al.*, 2006) point out that schools, like other organizations, must attend to the culture of the organization. Reinforcing and, where necessary, reculturing school

cultures are crucial roles of principals. Shaping the school culture means being able to read, assess, and reinforce key elements of the underlying norms and values, rituals and ceremonies of the school (Deal and Peterson 1999). Principals must be managers – structuring roles and responsibilities, implementing school improvement plans and so forth – but they also must be symbolic leaders reinforcing fundamental norms and values in their daily meetings, decisions, and interactions.

Professional Learning Community

The second major change in the nature of school improvement is the creation of professional learning communities. This strategy emerged from at least two ideas: teachers as professionals and organizational learning. The perspective of teachers as professionals focused on the unique knowledge and skills and the need for teachers to have the appropriate discretion to diagnose student needs and identify and implement responses to those needs. Rather than treating teachers as lone professionals isolated in their classrooms performing these diagnosis, identification, and implementation tasks, the literature on professional learning communities emphasizes the community of professionals who work together to promote student learning. This idea emerged from the organizational learning literature (Senge *et al.*, 2000) that emphasized the importance of the social rather than individual construction of knowledge and learning environments. This literature also acknowledges that student learning occurs throughout the school rather than only in the classroom. McLaughlin and Talbert (2006) define teacher learning communities as “teachers’ joint efforts to generate new knowledge of practice and their mutual support of each others’ professional growth” (p. 75). The characteristics of professional learning communities have been identified (Louis *et al.*, 1996; Scribner *et al.*, 2002; Smylie and Hart, 2000), as fostering collaboration, de-privatizing practice, and committing to shared values around student learning.

Principals have a special role in these professional learning communities. Crow *et al.* (2002) note that principals must nurture the intellectual capacity of teachers rather than view themselves as the only source of ideas, help teachers develop a common mission, and advocate for the schools in the face of external challenges (p. 198). Earley and Weindling (2004) identify the cultural role of

principals in learning communities that includes questioning the status quo, affirming the knowledge of all individuals in the organization, and distributing leadership. McLaughlin and Talbert (2006) found that principals who were unwilling to share control with teachers or who de-valued teacher contributions undermined school improvement efforts.

Distributed Leadership

A third major adaptation in the nature of school leadership is the attention to distributed leadership. Distributed leadership, different from the focus in the 1990s on the structural notion of shared leadership, focuses on the interactions and actions of the principal and staff that move school improvement forward (Spillane, 2006). The distributed leadership paradigm suggests that principals and teacher leaders should focus on the artifacts, routines, policies, and social interactions that move the school forward, improve practice, and enhance learning (Leithwood and Jantzi, 1998; Spillane, 2006). This model seems to suggest that school principals need a deeper understanding of the social, cognitive, and contextual factors that combine to produce outcomes. The focus in the school becomes more on the practice of leadership than the school administrator. School principals therefore need to learn how to spread leadership routines across tasks, processes, and interactions.

Social Justice

A fourth shift in the nature of school improvement is an emphasis on social justice, specifically ensuring equitable educational outcomes and closing the achievement gap (Gillborn, 2001; Ladson-Billings, 2006). Although equity is not a new concept in school improvement, government mandates and advocacy movements have raised the stakes. For example, the US Congress's No Child Left behind Act has, at the least, increased the rhetoric and the expectations that all students can and should learn. Although the Act and other similar governmental mandates are clearly contested in educational and political arenas, the resulting demands on principals are more intense than before.

In addition to government mandates, advocacy activities geared to raise the consciousness of policymakers, educators, and the public to reverse the oppressing and privileging tendencies within education, that disadvantage student groups based on race, ethnicity, gender, sexuality, language, or disability, have increased. These activities, both inside and outside educational organizations, have added a new element to the principal's role and require greater attention to how these student groups are impacted by school and societal forces (Skrla *et al.*, 2004).

Conflicts/Tensions in School Improvement

These four recent changes in the nature of school improvement are contested areas, routinely debated in various educational arenas. For school principals, they create at least three types of conflicts or tensions in advancing school improvement and student learning.

Accountability and Professionalism

A major tension that exists in the school reform literature in general and for the principal's role in supporting reform is the potential conflict between accountability and professionalism. Accountability is an international phenomenon (Leithwood and Earl, 2000), but is multifaceted and involves different contexts, such as government agency, local educational authority, school site council, and parent board/association (Marks and Nance, 2007). Even within, for example, the government context, accountability may involve different approaches, for example, market, decentralization, professionalization, and management (Leithwood, 2001). As Leithwood maintains, professionalism may be a type of accountability. Frequently, the tension and conflict are between other approaches, such as managerial or market accountability and professionalism. Major governmental initiatives in several countries around increasing student achievement for all students have intensified accountability by raising the stakes by connecting the increase in student test scores to student graduation and to school resources. In addition, some governmental initiatives have connected the increase in achievement scores to job security or performance pay for educators.

As noted previously, one initiative in new school reform agendas has been professional learning communities that emphasize a stronger, discretionary role for teachers and administrators. This professionalism argues for valuing the expertise and practical knowledge that teachers develop over time and the need for teachers to have the discretion to use this knowledge in responding to the individual and unique needs of their students. Professionalism places the decision-making role in the hands of educators rather than regulators or the market.

On the face of it, there are major inconsistencies and contradictions between some forms of accountability and professionalism. One seems to place decision-making authority in the hands of regulators and policymakers, while the other places it in the hands of educators. Emphasizing accountability seems to diminish professionalism. However, the tension is not necessarily this simple. As Hargreaves (2003) has argued, there is a difference between standardization and standards. A managerial accountability approach that emphasizes standardizing not only the

outcomes but also the processes of education clearly diminishes the importance of the educator's discretionary role. By contrast, accountability that emphasizes the need for research-based standards that can be used by educators to guide and evaluate their practices toward advancing learning for all students, does not necessarily contradict professionalism. The future of this apparent tension will depend on regulators, governing boards, and educators as they develop balances in standards that reflect and inform educator practices. However, the various accountability demands on schools "creates significant leadership dilemmas (Wildy and Loudon, 2000), and school leaders attempting to respond to their government's demands for change can be excused for feeling that they are being pulled in many different directions simultaneously. They *are* being pulled in many different directions simultaneously" (Leithwood, 2001: 228).

New Expectations for Tight or Loose Coupling

The structures of schools appear to be changing in terms of their structural coupling. For many decades, schools in the United States, for example, were allowed to be relatively loosely coupled, with considerable flexibility accorded to teachers and principals regarding curriculum, instruction, and the expectations for student achievement, for example, the types of students expected to learn (Weick, 1976). Recently, US policymakers at all levels have increased the outside expectations for: tighter design of curriculum (state standards), required instructional strategies (such as direct instruction), and specific targeted student achievement guidelines (No Child Left Behind Act). In the US, this change in the structural requirements of schools has put pressure on principals to become more administrative, bureaucratic, and evaluative. Interestingly, in some countries, for example, Taiwan, that had employed tightly aligned curriculum and assessment for decades, there is a movement to reduce governmental reigns, allowing schools to develop locally relevant curricula (Hughes and Stone, 1999). Principals in these countries must now engage in less of the administration of existing programs to more work on innovation and creation of emergent programs. Neither approach to restructuring, from loose to tight or from tight to loose is easy or simple and produces tensions for principals.

New Forms of Organization

Recent approaches to restructuring have involved new forms of schools, such as charter schools, middle college high schools, and schools-within-schools. These different forms are changing the roles of principals. Charter schools in countries such as the United States and Canada (O'Reilly and Bosetti, 2000) are designed to be free from the majority of curricular and assessment requirements

of the government. In these schools, principals often must be able to establish a coherent vision and set of administrative structures, actively recruit students, engage in marketing practices, and work with a governance board. But some researchers have noted the tendency for these schools to ignore fairness and equity considerations (Hausman, 2000). Middle college high schools were developed to serve disconnected youth who have shown some academic potential but have dropped out of school or are likely to. Located on college campuses, these small (100–140 students) high schools meet on an innovative schedule, offer regular and college classes, provide more personalization and counseling, and a chance to both graduate from high school and gain college credits (Grier and Peterson, 2007; Weschsler, 2001). Principals in these schools must seek new organizational structures, connect on an individual basis with disaffected youth, and find ways to foster a culture of support and personalization. Finally, the small-schools movement has encouraged the development of schools-within-schools. In these contexts, principals must become innovators and school design experts who are able to develop a unique mission and set of structures within the same building as another school. In these settings, principals must blend and balance educational leadership with political leadership as they negotiate use of space, facilities, and equipment.

Resulting Changes in the Principal's Role

In the previous edition of the international encyclopedia, new roles, relationships, rules, and results that principals confronted were identified. In this section, these areas are discussed but shifts are suggested that have resulted from the contemporary changes in the nature of school improvement and the conflicts/tensions in school improvement identified earlier in this article.

New Roles

Changes in the Political Role of Principal

The changes and tensions we identified earlier have created new political roles for the principal to facilitate school improvement and advance student learning. These involve both internal and external roles. Through facilitating professional learning community and distributed leadership, the principal is confronted with an increase in potential conflicts over values and resources. Although involving more people in the collaboration and decision-making process has significant benefits as the research on professional learning communities has demonstrated, costs of time, coordination, and resource allocation exist and many of these involve potential conflicts (Crow, 1998). In addition, the principal's political role in advocating for social justice

and the rights of all students to learn can confront the principal with resource and ideological conflicts.

The principal's political role also changes in external terms. The demands of accountability and the tension between different accountability contexts and approaches, for example, market and professionalism, (Leithwood, 2001; Marks and Nance, 2007) set up potential conflicts among groups such as district/LEA administrators, governmental regulators, parents, out-of-school social service experts, and teachers. These political conflicts can involve disagreements that require the principal's attention and expertise in resolving conflicts around allocating resources, defining achievement goals, and balancing achievement and social justice.

Changes in the Cultural Role of Principal

The restructuring of schools from loosely coupled (Weick, 1976) organizations to more tightly structured, standards-based educational settings actually accentuates and extends the culture-shaping role of principals (Deal and Peterson, 1999). With schools tightening their curriculum, increasing their external accountability requirements, and, at times, defining instructional approaches in the classroom, being able to assess and nurture a professional school culture is even more important. Principals are required oftentimes to re-culture existing school norms so they match the standards-based rules and responsibilities. In fact, using data for decision making and school improvement is a useful and important task, but one that is new to many school cultures. Therefore, principals and teacher leaders will need to find ways to reinforce, articulate, and support new cultural norms and traditions.

Changes in the Environmental Role of Principal

Many of the new forms of school organization as well as accountability demands have changed the environmental role of principals. Clearly, principals have for several years held a role beyond the school. However, as Crow *et al.* (2002) note, market competition and accountability among other forces have required the principal to become more entrepreneurial and to take on a larger societal role. These environmental roles involve reminding teachers and parents of external expectations, such as market or governmental interests, advocating for social justice in communities, and educating community, regulatory, and policymaking audiences of student and teacher needs and perspectives.

Changes in the Instructional Role of Principal

The combination of changes in the specificity and focus of student learning outcomes, standards-based curriculum reform, the availability of computer-managed student

achievement data, and intense accountability systems have substantially changed the instructional role of principals. Increasingly, principals are expected to be highly skilled users of computer-based statistical analyses of student achievement data. Principals and their teacher leaders now must know statistical fundamentals, be able to identify critical questions related to student achievement, and then analyze quantitative student performance data. Additionally, they need to be able to use those analyses to drive school improvement, planning, curriculum refinement, and instructional changes. These new roles require sometimes new and sometimes deepened skills in the use of data for decision making, computer skills, an understanding of statistical reasoning, and complex knowledge of the change process that is often not taught in preparation programs. Moreover, principals have the additional instructional role of removing barriers to teachers' use of data for instructional decision making (Ingram *et al.*, 2004). In some cases, this involves resolving conflicting policy demands and creating technical cultures that support norms of data use.

New Relationships

The new roles that have been identified for contemporary principals imply new relationships as well. The number and diversity of stakeholders to which the principal must relate have increased dramatically (Crow *et al.*, 2002). In addition to school and community stakeholders, principals must interact with other social service and healthcare professionals involved in students' well-being and with regulators and policymakers seeking to ensure student and educator productivity. In addition to the increasing number and diversity of stakeholders, the internal and external boundaries of schools are blurring. For example, students are increasingly taking college courses before they complete their high school graduation. Community groups see the school as a pivotal agency and resource to influence policy and implement programs. The school is increasingly an ideological battleground, with the principal confronting disputes, advocating student and family interests, and forming alliances.

New Rules

These new roles and relationships more frequently arise without rules or with new, fluid rules. Principals face these conflicts and tensions without the scripts common to school leadership practice in the past. The rapidity of change in a knowledge society, the demands for customized responses, and the contextualization of leadership require principals to think quickly, create unique responses, and be ready to adjust their responses to constantly changing circumstances.

(Crow *et al.*, 2002). In addition, the new rules of the principalship demand not heroic, sole leadership practice, but shared and distributed practice. As Murphy (2000) argues, this involves leadership from the middle, rather than the top.

New Results

The principal's role in restructuring for school improvement now exists in a context with a new set of expected results. Internationally, this varies with national context and purpose. In many settings, the importance of student achievement for all students is more pronounced than before. Principals and other educators are expected to ensure student learning not only for the most able or even the average, but for all students. This result, however, is being contested as educators, regulators, policymakers, and other interest groups confront the ideological and resource consequences (Ladson-Billings, 2006). Increasingly, educators, parents, and others are expanding the notion of student achievement to include affective components in which principals are expected to include civic, esthetic, and affective instructional goals as well as other sociopsychological effects such as student engagement in school (Leithwood and Earl, 2000). In other international contexts, the results take on a more governmental perspective in which schooling is a vehicle for nationalistic visions, norms, and strategies (Hughes and Stone, 1999; Tsai, 2002). As education is recognized as a powerful instrument for furthering governmental initiatives and interests, the principal's role takes on a different set of results and the principal becomes an agent of the state with responsibility to promote national objectives.

Implications

Internationally, the late 1990s and early twenty-first century has been a period of rapid and widespread change in educational policy and practice. These changes and the press for restructuring schools have necessitated the rethinking of principals' roles and practices. Clearly, given these changes there is considerable need for systematic, field-based studies of these changes on the daily work of principals, on the nature of leadership in these new contexts, and on the interaction of new structures and new behaviors. At the same time, there is a need for the reconsideration of preparation, licensure, and the professional development of school leaders. Preparation needs to be reconfigured to address the new realities of the work. Licensure, in settings where it is used, needs to be redefined to address the continued changes that will occur. Finally, professional development of principals needs to be deepened and expanded to reflect the wider array of

demands coming from the new relationships, new rules, and new results expected of school principals.

School Reform and Restructuring: Self Managing School

B J Caldwell, Educational Transformations Pty Ltd, Melbourne, VIC, Australia

© 2010 Elsevier Ltd. All rights reserved.

Most systems of public education around the world have included decentralization of decision making in their plans for school reform or restructuring. There is a seeming paradox in that there has also been significant centralization. The Organization for Economic Cooperation and Development (OECD) explained it in these terms:

An important factor in educational policy is the division of responsibilities among national, regional and local authorities, as well as schools. Placing more decision-making authority at lower levels of the educational system has been a key aim in educational restructuring and systemic reform in many countries since the early 1980s. Yet, simultaneously, there have been frequent examples of strengthening the influence of central authorities in some areas. For example, a freeing of 'process' and financial regulations may be accompanied by an increase in the control of output from the centre, and by national curriculum frameworks (OECD, 2004: 34).

Decentralization of decisions to schools goes by several names including self-management, school-based management, or local management. Nomenclature varies from country to country and self-management is the term used in this article.

Definition

A self-managing school is a school in a system of education "to which there has been decentralized a significant amount of authority and responsibility to make decisions related to the allocation of resources within a centrally determined framework of goals, policies, standards and accountabilities. Resources are defined broadly to include knowledge, technology, power, materiel, people, time, assessment, information and finance" (Caldwell and Spinks, 1998: 4, 5).

It is important to distinguish between self-management and autonomy, independence or privatization of schools. The extent of decentralization in self-management is constrained by the requirement that self-managing schools operate in a centrally determined framework. Such schools continue, by and large, to be built, owned, operated, and funded by a public authority. There is, however, increasing interest in creating autonomous schools within systems of public education. Charter schools in Canada and the United States are examples; however, there are still constraints on their operation by the public authorities that

established them in the first place or that could close them for any reason. Majority of schools in the Netherlands are owned and operated by a nonpublic authority but receive their funds from government. It is unconstitutional and, therefore, illegal to differentially fund schools on the basis of ownership. This is an example of a long-standing system of self-managing schools that may be privately owned and operated. Normally, private, nonpublic, or independent schools are self-managing schools and this article is primarily concerned with those in systems of public education.

Trends

The trend to self-management is part of a general trend to decentralization in public education as summarized in the opening paragraph. What follows is drawn from surveys conducted by the OECD among its 30 members and 20 partner nations and published in an annual report on indicators of performance. The 2004 report (OECD, 2004) included information on trends in centralization and decentralization. It considered the locus and mode of decision making in four domains. Locus referred to which of six levels decisions were made: national, state, regional, municipal, local, or school. Mode referred to which of four ways decisions were made: full autonomy at the level concerned, consultation with other bodies at that level, independently but within a framework set by a higher authority, or other. The four domains were organization of instruction, personnel management, planning and structures, and resources.

The report compared patterns in 1998 and 2003 and found that "in 14 out of 19 countries decisions are taken at a more decentralized level in 2003 than in 1998." The following points summarize the major findings as far as decentralization to the school level is concerned:

- Decisions are more often taken at the school level in the Czech Republic, England, Hungary, New Zealand and the Slovak Republic and in particular in the Netherlands where all decisions are taken at the school level.
- Decisions on the organization of instruction are predominantly taken by schools in all OECD countries, while decisions on planning and structures are mostly the domain of centralized tiers of government. The picture is more mixed for decisions on personnel management and allocation and use of resources.

- Just less than half of decisions taken by schools are taken in full autonomy, about the same proportion as those taken within a framework set by a higher authority. Decisions taken by schools in consultation with others are relatively rare. Schools are less likely to make autonomous decisions related to planning and structures than related to other domains. (OECD, 2004: 21, 22)

Care should be taken in interpreting some of these patterns, as there are important differences within countries. This is particularly the case in Australia that is reported as being one of the most centralized. In Australia, like Canada and the United States, constitutional powers for making laws in relation to education lie with the states (provinces in Canada), with the Australian Government able to influence arrangements through its powers to make grants to the states. The statement that the country is highly centralized is a generalization that cannot be applied to all of the states. It does not apply to states that have shifted significant authority and responsibility to the school level in recent times. In Victoria, for example, 94% of the state's recurrent budget is decentralized to the school level for local decision making, albeit within a centrally determined framework, and this level exceeds that in England and New Zealand that are reported as being highly decentralized.

The aforementioned countries of Australia, Canada, England, New Zealand, and the United States, or states/provinces or districts therein, include some of the high-profile examples of self-managing schools. Apart from the general patterns among OECD members described above, there are also noteworthy examples in partner or observer nations. For example, decentralization including school-based management is a major feature of nationwide reforms in the Philippines and Thailand (partners) and in Israel (observer).

Driving Forces

Changes in patterns of decision making are partly explained by new directions in education policy. The OECD report cited above provided the broad context:

Changing social and economic conditions have given education an increasing central role in the success of individuals and nations. Human capital has long been identified as a key factor in combating unemployment and low pay, but there is now also robust evidence that it is associated with a wide range of non-economic benefits, including improvements in health and a greater sense of well-being . . . The benefits of education have driven increased participation in a widening range of learning activities – by people of all ages, from earliest childhood to advanced adulthood. As the demand for learning grows and become more diverse, the challenge

for governments is to ensure that the learning opportunities provided respond to real, dynamic needs in a cost-effective manner (OECD, 2004: 11).

While these factors explain much of the energy in educational reform, there are other reasons that account for the trend to self-management since the late 1960s. Many of the landmark social, political, and religious movements of the 1960s and early 1970s spawned much interest in empowerment. These were the years of social unrest, as seen in the student riots in Paris in 1968, protests against the Vietnam War, and Vatican II. By the end of the 1970s, there were important developments in school-based management in Canada and the United States. A review in 1977 identified four factors, working singly or in combination, representing demands for increased sensitivity to local needs and problems, reversal of the effects of size and centralization, accountability and professionalism, and a desire for participative management (Caldwell, 1977). One of the noteworthy reforms of this period was in the Edmonton Public School District in Alberta, Canada, known initially as school-based budgeting because the major part of the district's budget was decentralized to schools for local decision making. There is further mention of Edmonton later in this article because of its pioneering approach to needs-based formula funding of schools that continues as an exemplar.

These same forces were at work in Australia, which has traditionally been considered to have a highly centralized system of education. Reports of distinguished scholars were highly critical of the arrangement (Kandel, 1938; Butts, 1955). While there were precursors at the state level, the seminal event in shifting the balance of centralization and decentralization was the release of the report of the Interim Committee of the Australian Schools Commission (1973), generally known as the Karmel Report. Decentralization, or devolution as it was referred to at the time, was elevated to the status of a value that underpinned its recommendations. The seven values were devolution of responsibility, equality, diversity, public and private schooling, community involvement, special purposes of schools, and recurrent (lifelong) education. Most developments in self-managing schools, including the far-reaching reform in Victoria, cited earlier, can be traced to these reforms of the 1970s.

The local management of schools in England had its foundation in the community education movement several decades before the major thrust of the Education Reform Act of 1988. The notion of community empowerment ran through many of the developments in several counties about this time, being essentially part of a liberal democratic tradition. However, the tenor of debate changed profoundly with the passing of the 1988 Education Reform Act under the Thatcher Conservative Government. This was the era in which the government endeavored to weaken the power

of unions and wind back the influence of the state. Market reforms were in the ascendancy and self-managing schools were seen by many as being part of this movement, despite their foundations in an earlier period. Robust criticisms were mounted (Smyth, 1993).

The 1980s and the 1990s marked a struggle on the merits of the approach, especially in Australia, England, and New Zealand. In Victoria, for example, momentum in the early 1980s under a moderate left-of-center Labor Government stalled in the late 1980s with resistance by unions to proposals to decentralize most of the budget and significant authority at the school level in respect to the selection of staff. In the 1990s, a change in government to the right of center resulted in more than 90% of the state's budget for government schools being decentralized for local decision making. There were similar developments in New Zealand. However, much of the sting in the debate and its ideological overtones were removed when a return to left-of-center governments produced little change. In England, under the Blair New Labor Government elected in 1997, the self-management reforms of the previous Conservative Government were extended, so that more than 90% of the budget for schools has been decentralized. Similarly in Victoria, where the approach was extended when a left-of-center government was returned to power, and in New Zealand, although there has been some weakening of school authority in that country.

Issues

There are four major issues in the contemporary implementation and critique of self-managing schools: (1) the extent to which there has been an impact on learning; (2) the mechanism that is used to allocate funds from the center to schools; (3) whether the decentralization of funds to the local level has increased the opportunity for corruption in the use of public funds; and (4) the impact of self-management on the role of the principal and other school leaders.

Link to Learning

There was often a demand for evidence that self-management led in cause-and-effect fashion to improved student outcomes. It was sobering to note the consistent finding in early research that there appeared to be few, if any, direct links between local management, self-management or school-based management, and learning outcomes (Malen *et al.*, 1990; Summers and Johnson, 1996). Some researchers noted that such gains are unlikely to be achieved in the absence of purposeful links between capacities associated with school reform, in this instance, self-management, and what occurs in the classroom, in learning

and teaching and the support of learning and teaching (Bullock and Thomas, 1997; Cheng, 1996; Hanushek, 1996, 1997; Levačić, 1995; Smith *et al.*, 1996; OECD, 1994).

A review of research suggests that there have been three generations of studies and it is only in the third that evidence of the impact of decentralization on outcomes has emerged, provided that certain conditions are fulfilled. The first generation was in times when impact on learning was not a primary or even secondary purpose. The second generation was when such purposes may have been to the fore but the database was weak. The third, emerging in the late 1990s and gathering momentum in the early 2000s, coincides with a preeminent concern for learning outcomes and the development of a strong database (Caldwell and Spinks, 1998; Caldwell, 2002, 2003, 2005).

Woessmann undertook a comprehensive study of why students in some countries did better in the Trends in Mathematics and Science Study (TIMSS) and found a powerful connection between decentralization of decision making to the school level and student achievement (Woessmann, 2001). It is a connection that has been affirmed in subsequent results in the Programme for International Student Assessment (PISA). Schleicher identified decentralization as one of several policy levers for student achievement. He found that, in the best-performing countries:

- Decentralized decision-making is combined with devices to ensure a fair distribution of substantive educational opportunities
- The provision of standards and curricula at national/sub-national levels is combined with advanced evaluation systems
- Process-oriented assessments and/or centralized final examinations are complemented with individual reports and feedback mechanisms on student learning progress
- Schools and teachers have explicit strategies and approaches for teaching heterogeneous groups of learners
- Students are offered a variety of extra-curricular activities
- Schools offer differentiated support structures for students
- Institutional differentiation is introduced, if at all, at later stages
- Effective support systems are located at individual school level or in specialized support institutions
- Teacher training schemes are selective
- The training of pre-school personnel is closely integrated with the professional development of teachers
- Continuing professional development is a constitutive part of the system
- Special attention is paid to the professional development of school management personnel (Schleicher, 2004).

While a balance of centralization and decentralization is evident in the above, it is important to note that, even in contemporary times, there may be no impact on learning unless purposeful links are made to the student and classroom levels. There is a need to ensure an impact across all schools in a system. Fullan *et al.* (2006) demonstrated the limits to improvement under self-management by describing how gains in literacy have plateaued in England, and how decentralization of decision making in Chicago, Milwaukee, and Seattle has not led to large-scale improvement: “They contain glimpses of what will be required, but they fail to touch deeply day-to-day classroom instruction, and to touch it in a way that will get results for all” (Fullan *et al.*, 2006: 6). They proposed a system to lift the performance of schools to achieve a breakthrough, comprising three components: personalization, professional learning, and precision. “The glue that binds these three is moral purpose: education for all that raises the bar as it closes the gap” (p. 16).

Needs-Based Funding

A key issue is the determination of a funding mechanism to allocate resources from central sources to schools in systems of self-managing schools through mechanisms known variously as global budgets or student resource packages. Allocations typically include a per capita component, with weights that differ according to stage of schooling, and needs-based components that reflect student and school characteristics. Allocations for the per capita component generally reflect historical approaches, especially in respect to a class rather than student focus and assumptions about student–teacher ratios. Allocations that reflect school characteristics invariably take account of size and economies of scale; location, especially in remote or rural settings; and stage and specialization in schooling, where there are different resource requirements. Allocations that are more student focused typically take account of the socioeconomic status of the families or communities of students and the extent of special education needs, including disabilities and impairments. The pioneering system of self-managing schools in Edmonton, Alberta continues to provide a template. Good progress was made in the 1990s in several countries. Levačić and Ross (1999) provide a summary of approaches in Australia, Canada, England, New Zealand, United States, and Wales.

By 2007, attention was shifting in extensively decentralized systems of self-managing schools, especially in Australia and England, to how allocations from the system to the school level could take account of efforts to secure success for all students in all settings and to personalize the learning experience as far as possible. Critically important is how resources, once received, are best allocated at the school level. Student-focused planning models are emerging (Caldwell and Spinks, 2008).

Opportunities for Corruption

An important issue is whether the introduction of self-management with decentralization of funds to schools leads to corruption at the local level. This was the subject of a major study of the International Institute for Educational Planning (IIEP) of the United Nations Educational, Scientific and Cultural Organization (UNESCO) (Levačić and Downes, 2004). Case studies were provided of formula funding for schools under conditions of decentralization in Australia (Victoria), the United Kingdom (England), Poland (Kwidzyn and Swidnik), and Brazil (Rio Grande do Sul).

The reason for the study was stated in the following terms. “Given that the proportion of the national budget devoted to education is significant for both developed and developing countries, it is essential that public funds be directed effectively and used for the purposes for which they are allocated. The misuse of public funds is a serious matter both in terms of ethical and criminal implications of the abuser and in terms of the deprivation of funding inflicted on students” (Levačić and Downes, 2004: 15). The focus was on practice in systems of self-managing schools. Particular attention was given to transparency, the accurate collection of data, the avoidance of fraud, and the need for a range of auditing procedures at different levels. Few instances of fraud were uncovered in the study.

Recommendations were concerned with training, preparing manuals of financial procedures, removing opportunities for collusion, designing an agreed format for financial reporting across the system, local monitoring that is frequent and independent of the principal and administrative staff, the use of independent auditors, external checking of statistics that are used in determining allocations, and clarity in explanations of funding formulae so that they can be readily understood by all stakeholders. The report concluded that “formula funding for schools reduces the potential for corruption by increasing transparency as the amount each school should receive and the basis for this is public knowledge” (Levačić and Downes, 2004: 145).

Impact on the Workload of Principals

A final issue is concerned with the impact of self-management on the role of the principal and other leaders at the school level. A study was conducted in Victoria (Department of Education and Training, 2004) on the workload in government (public) schools and its impact on the health and well-being of the principal and assistant principals. On workload, the number of hours per week for principals in Victoria was similar to that for principals in England, as reported in a survey at about the same time, being about 60 h per week. In both places, this is well above the average of leaders and managers in other professional

fields in several European nations (about 45 h per week). The report contained evidence of a negative impact on the emotional and physical well-being of principals.

There is also evidence that fewer people are seeking appointment to principal in countries with self-managing schools. In England, for example, a typical school seeks a new principal once every 7 years, which means about 14% advertise each year. The number advertising in 2005 was 12%, with about one-third unable to make an appointment after the initial advertisement. Education Data Surveys (EDS) reported that re-advertisement reached record levels (Smithers, 2006). Despite the workload and declining numbers seeking to be principals in some countries, it is clear from the results of surveys over a decade that most serving principals in systems of self-managing schools would not wish to return to more centralized arrangements (Bullock and Thomas, 1997; Caldwell and Spinks, 1998; Department of Education and Training, 2004).

Issues related to workload and willingness to serve include the preparation and ongoing support of principals and other school leaders, and these are addressed in the final section.

Prognosis

Self-managing schools have been one manifestation of a general trend to decentralization in public education in many countries since the late 1960s, with momentum gathering as the twentieth century drew to a close. The practice was introduced for a range of reasons but much of the heat from often contentious debates about its efficacy was dissipated in the early years of the twenty-first century, as most governments and system authorities settled on the enhancement of learning as its primary purpose. The logic of the argument was relatively straightforward: each school contains a unique mix of student needs, interests, aptitudes, and aspirations and those at the school level are best placed to determine the particular mix of all of the resources available to the school to achieve optimal outcomes (Cheng, 1996; Caldwell, 2003). Early research was generally unable to confirm the logic, either because the design of the reform did not include a connection to learning, or because the database on student achievement was poorly constructed, thus thwarting any effort to determine the connection. Research at macro- and micro-levels tends to confirm the association but it requires purposeful efforts by a skilled profession to make it effective. The agenda for the next decade and beyond will include a high priority on these efforts, especially if emerging success in a growing number of schools is to be scaled up across an entire system.

Early efforts in self-management placed the focus on management, with particular attention being given to

planning and resource allocation. It is understandable that preparation and professional development programs for leaders and managers at the school level tended to focus on these. However, with heightened expectations for schools, especially in terms of success for all students in all settings, the focus will continue to shift to leadership and the building of professional capacity to achieve an alignment of curriculum, pedagogy, and resources with the mix of learning requirements at the school level. In this context, the student becomes the most important unit of organization rather than the classroom, school, or school system (Caldwell, 2006).

If practice through the first decade of the twenty-first century is a guide, leaders in self-managing schools will need to be adept at drawing on all of the resources of the community to meet expectations, and these include intellectual capital, social capital, spiritual capital (broadly defined), as well as financial capital (Caldwell and Spinks, 2007). It will be a more demanding role than ever before and it is likely that new roles will emerge, extending those which made their appearance at around this time in England, with an executive head becoming a person of influence across a number of schools. Remuneration levels will be high. Support will be drawn from a range of sources and the central, regional, and district offices in systems of public education will need to take on stronger support roles than in the past.

System Leadership

D Hopkins and R Higham, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Introduction

System leaders are those headteachers who are willing to shoulder system wide roles in order to support the improvement of other schools as well as their own. Such system leadership is a new and emerging practice that embraces a variety of responsibilities that are developing in England either locally or within discrete national networks or programs. When taken together these roles may have the potential to contribute to a more school-led, rather than government-prescribed, education system. This article elaborates this concept of system leadership and illustrates its potential power as a catalyst for systemic renewal in three ways. First, it provides an initial conceptualization of system leadership and raises a series of concerns about the way the concept is being interpreted. Second, by drawing on research in England, it proposes taxonomy of roles that system leaders are currently assuming. Third, and based on these analyses, a potential model for system leadership is suggested and the tensions involved in further developing the concept are explored.

Defining System Leadership

The concept of system leadership is one that has recently caught the educational imagination. Take for example, these quotations from two significant opinion makers. The first from the general secretary of the Association of School and College Leaders in England and the other from a leading educational commentator whose work has a global reach.

Dunford (2005) in a recent address to the National Conference of the Specialist Schools and Academies Trust (SSAT) argued that:

The greatest challenge on our leadership journey is how we can bring about system improvement. How can we contribute to the raising of standards, not only in our own school, but in others and colleges too? What types of leaders are needed for this task? What style of leadership is required if we are to achieve the sea-change in performance that is demanded of us?

In *Systems Thinkers in Action*, Fullan (2004) argued that:

a new kind of leadership is necessary to break through the status quo. Systematic forces, sometimes called inertia, have the upper hand in preventing system shifts. Therefore,

it will take powerful, proactive forces to change the existing system (to change context). This can be done directly and indirectly through systems thinking in action. These new theoreticians are leaders who work intensely in their own schools, or national agencies, and at the same time connect with and participate in the bigger picture. To change organizations and systems will require leaders to get experience in linking other parts of the system. These leaders in turn must help develop other leaders within similar characteristics.

These quotations share three implicit assumptions. The first is that if we are ever to achieve sustainable education change, it must be led by those close to the school; the second is that this must have a systemic focus; and the third is that system leadership is an emerging practice. (As we will see, the conceptual concerns of system theory for relationships, structures, and interdependencies Katz and Kahn (1976), Senge (1990), Campbell *et al.* (1994) underpin the contemporary work of system leaders in practice.) There is also an implicit tension between system leadership being a national policy or a professional movement. This dichotomy, as we will see, has profound implications for the prospect of sustainable educational reform.

In *Every School a Great School* (Hopkins, 2007) it was suggested that the five striking characteristics of system leaders, those distinguishing them from broader collaborative activity, are that they deploy their experience, knowledge, and skills to:

- actively lead improvements in other schools and measure their success in terms of student learning, achievement, and welfare, both to raise the bar and narrow the gap(s);
- commit staff in their own and other schools to the improvement of teaching and learning, engaging them deeply in the organization of teaching, learning, curriculum, and assessment so as to ensure learning is increasingly personalized for students;
- lead the development of schools as personal and professional learning communities, building relationships across and beyond each school to provide a range of learning experiences and professional development opportunities;
- lead work for equity and inclusion through acting on context and culture, not only in response to poverty but also to employ educational resources to help give communities a greater sense of aspiration and empowerment; and

- manage strategically the impact of the classroom, school, and system on one another, understanding that in order to change the larger system one has to both engage with it in a meaningful way and manage subsequent change at a school level.

It is a compelling proposition that such leadership holds significant potential to contribute to systemic educational improvement. This is an idea that has been positively advocated over the past 4 years by government ministers. David Miliband, member of the parliament (MP), for example, when minister of state for school standards in the England, saw that the development and deployment of cadre of system leaders could go a long way to responding to the key challenges he had identified for school leadership as part of a new relationship between schools and government (Miliband, 2004). This included raising productivity in education, effecting greater social justice, and ensuring sustainable improvement (Miliband, 2003).

Taken together, this combination of informed comment and progressive government policy suggests that the concept of system leadership is an idea whose time has come. One can summarize these aspirations in saying that:

- by being willing and able to work for the success and well-being of students in other schools as well as their own, system leaders can show how self-managed schools, emerging from an era of competition, might work together for greater social equity;
- by seeing collaboration with other schools and agencies as vital to delivering on aims that individual schools cannot achieve by themselves, system leaders can create alternative solutions to a range of educational challenges that have traditionally become the responsibility and preserve of the central apparatus of the state; and
- by starting from the problems and solution of schools themselves, rather than those identified by others, system leaders can show how professionals might take more control of educational reform and contribute directly to a broader renewal of the education system.

However, before we get too carried away with too much enthusiasm for the concept of system leadership, we need to admit that much of the well-intentioned advocacy is based on aspiration and a few early individual cases rather than systemic evidence. Above all, and perhaps most significantly, it is not actually clear what or how many system leadership roles are currently being undertaken. Possibly as a result of being a relatively new professional practice, there appears to have been no attempt to date to document how system leadership is being enacted. In an attempt to correct this situation, research is reported in this article (Hopkins and Higham, 2007) that provides an initial perspective on the nature of system leadership in England in mid-2006. Based on this analysis, a taxonomy

of system leadership roles are outlined; an initial conceptualization and model of what effective system leaders do is proposed; and finally the key emerging challenges for the future development of this practice are explored.

Taxonomy of Roles

The research cited above pointed to five distinct yet overlapping categories of system leadership and leads to the following taxonomy.

First, are those headteachers who develop and lead a successful educational improvement partnership between several schools. These are most usually focused on a set of specific themes that have clear outcomes and reach beyond the capacity of any one single institution. Examples include partnerships on curriculum design and specialisms, including sharing curricular innovation, 14–19 consortia, and behavior and hard-to-place students. While such partnerships often currently remain in what is commonly referred to as soft organizational collaboratives, some have moved to harder more formalized arrangements in the form of (co)federations (to develop stronger mechanisms for joint governance and accountability) or education-improvement partnerships (to formalize the devolution of defined delivery responsibilities and resources from their local authority). As a result of recent legislation, such groupings now have the possibility of forming independent school trusts.

Second, are headteachers who choose to lead and improve a school in extremely challenging circumstances. A dual objective of system leadership is to both raise the bar and close the gap(s) in systemic student achievement. As such a key task is to change contexts in our most challenging circumstances by choosing to lead and improve low-achieving schools and then sustain them as high valued-added institutions over a significant period of time.

Third, are those headteachers who partner another school facing difficulties and improve it. This includes both executive heads and leaders of more informal improvement arrangements who are differentiated from category 1 on the basis that these leaders work from a lead school into a low-achieving or underperforming school (or schools) that require intervention. Executive heads provide an example. They are responsible for two or more schools that have either entered into a federation or a local (often time-bound) agreement focused on a lead school working to improve a partner.

Fourth, are headteachers who act as community leaders to broker and shape partnerships or networks of wider relationships across local communities to support children's welfare and potential. In related research, our colleague Matthews (2006) conceives of four key dimensions to this work as organizing resources for learning from the community, widening learning experiences beyond the

school, drawing support for child and family welfare into the school or network, and providing for the lifelong learning needs of the community.

Fifth, are those head teachers who work as change agents or expert leaders. The focus is on providing practical knowledge and guidance as well as the transfer of best practice within a formalized school-improvement program. This is currently the most numerous category and includes national-leadership roles developed within centrally organized programs such as School Improvement Partners, Consultant Heads, and/or National Leaders of Education.

What Effective System Leaders Do

In establishing taxonomy of the five key areas of identified system-leadership activity, what seems increasingly important is how these leaders actually work – for, as we are keenly aware, their work often enters new territories that have novel challenges and no well-rehearsed solutions.

An important perspective on this is offered by Heifetz's (1994) concept of adaptive leadership. Heifetz's argument is that leaders increasingly require skills that move beyond traditional management solutions for technical problems to provide adaptive responses to challenges without easy answers. Technical problems, such as how to teach numeracy, and their solutions will of course remain vital. But system leaders will also need to work adaptively to lead people and organizations beyond restrictive boundaries, perceived wisdoms, and entrenched cultures where they exist as obstacles to improvement.

This theme also underpins Fullan's (2005) exposition of the role he believes school leaders will need to play as system thinkers in action if sustainable large-scale reform is to be achieved. This, Fullan argues, will necessarily involve adaptive challenges that "require more sophisticated leadership" (p. 53). For Fullan, examples of this new work include: leading and facilitating a revolution in pedagogy (p. 57); understanding and changing the culture of a school for the better (p. 57); relating to the broader community, in particular with parents; and integrating and coordinating the work of social service agencies into the school as a hub (p. 61). This will demand:

above all ... powerful strategies that enable people to question and alter certain values and beliefs as they create new forms of learning within and between schools, and across levels of the system. (Fullan, 2005: 60)

These demands are further illuminated in theory by Senge (1990) who argues that for organizations to excel, they have to become learning organizations in which "new and expansive patterns of [system] thinking are nurtured ... and where people are continually learning to see the whole together" (p. 3). To Senge, the key to

becoming a learning organization is for leaders to tap into people's commitment and capacity to learn at all levels, so that broader systemic interdependencies and how to change them effectively can be made clearer (Senge, 1990: 4).

There is a loud and clear read across here from system theory to the key areas of system-leadership activity we have already identified. There is also a sense of a shared, central skill set for system leaders that needs to be effective and reflects the established literature on educational leadership (for a comprehensive review see Leithwood *et al.*, 1999).

There is also however a real concern about the increasing tendency in the literature to distort the generic competencies of leaders through celebrating singular aspects of the role. Leithwood *et al.* (2004: 4) express this worry succinctly:

... we need to be skeptical about the "leadership by adjective" literature. Sometimes these adjectives have real meaning, but sometimes they mask the more important themes common to successful leadership, regardless of the style being advocated.

These are wise words and of course it has not escaped our notice that we ourselves are in danger of being hoisted by our own petard. In defense, we would claim that the concept of system leadership is embracing rather than esoteric. This claim is made on three grounds. First, the concept of system leadership as we have seen locates itself within the general literature on systems theory and thinking and as such is inclusive rather than exclusive. Second, as we shall see shortly, system leadership is a theory of action that embraces a catholic range of disciplines in order to exert its power (see, e.g., Elmore, 2004; Leithwood *et al.*, 2006). As hopefully is becoming clear, system leadership will only exert any influence to the extent that it focuses on teaching and learning (i.e., is instructional), shares its authority with others (i.e., is distributed) and so on. To reiterate, system leadership as a concept is integrative rather than exclusive.

This discussion emphasizes the focus on the key capabilities required by system leaders. Inevitably, this demands the development of hypotheses as we move inductively from our data. Here we have found it helpful to draw on Leithwood and Riehl's (2003) core leadership practices in proposing an initial outline of the capabilities system leaders bring to their role. This is set out in **Figure 1**.

Building on these key capabilities, and combining them with the range of identified roles, it is possible to offer a model of system-leadership practice that emerges inductively from the actions of a research sample of system leaders. This is set out in **Figure 2**.

The model exhibits a logic that flows from the inside-out. At the center, leaders driven by a moral purpose related to the enhancement of student learning, and seek to empower teachers and others to make schools a critical force for

Core practices	System leadership components
Setting direction	<p>Total commitment to enable every learner to reach his/her potential with a strategic vision that extends into the future and brings immediacy to the delivery of improvements for students.</p> <p>Ability to translate vision into whole school programs that extend the impact of pedagogic and curricular developments into other classrooms, departments, and schools.</p>
Managing teaching and learning	<p>Ensure every child is inspired and challenged through appropriate curriculum and a repertoire of teaching styles and skills that underpin personalized learning.</p> <p>Develop a high degree of clarity about and consistency of teaching quality to both create the regularities of practice that sustain improvement and to enable sharing of best practice and innovation.</p>
Developing people	<p>Enable students to become more active learners, develop thinking and learning skills, and take greater responsibility for their own learning. Involve parents and the communities to minimize the impact of challenging circumstances on expectations and achievement.</p> <p>Develop schools as professional learning communities, with relationships built and fostered across and beyond schools to provide a range of learning experiences and professional-development opportunities for staff.</p>
Developing the organization	<p>Create an evidence-based school, with decisions effectively informed by student data, with self-evaluation and external support used to seek out approaches to school improvement that are most appropriate to specific contextual needs.</p> <p>Extend an organization's vision of learning to involve networks of schools collaborating to build, for instance, curriculum diversity, professional support, extended and welfare services, and high expectations. In so doing, build a school's capacity to support wider system-leadership roles.</p>

Figure 1 A conceptualization of key system-leader capabilities.

improving communities. This is premised on the argument already made, that sustainable educational development requires educational leaders who are willing to shoulder broader leadership roles – those who care about and work for the success of other schools as well as their own.

It is also clear from our research that system leaders share a characteristic set of behaviors and skills. As illustrated in the second inner ring of **Figure 2**, these are of two types. First, system leaders engage in personal development usually informally through benchmarking themselves against their peers and developing their skill base in response to the context they find themselves working in. Second, all the system leaders we have studied have a strategic capability; they are able to translate their vision or moral purpose into operational principles that have tangible outcomes.

Taken together these two central circles of **Figure 2** reflect the core practice of setting directions as noted in **Figure 1**. As is denoted in the third ring of the model, the moral purpose, personal qualities, and strategic capacity of the system leader find focus in three domains of the school detailed above – managing the teaching and learning process, developing people, and developing the organization.

Finally, although there are a growing number of outstanding leaders that exemplify these qualities and determinations, they are not necessarily system leaders. A system leader not only needs these aspirations and capabilities but in addition, as seen in the outer ring of the model, works to change other contexts by engaging with the wider system in a meaningful way. We have included in the outer ring, the range of roles identified from the research that focuses on improving other schools, sharing curriculum innovations, empowering communities, and/or leading partnerships committed to enabling all schools to move forward. The model represents a powerful combination of practices that give us a glimpse of leadership in a new educational landscape. Realizing that landscape, however, may also require a bigger shift within the broader education system.

Developing System Leadership

It is clear that the practice of school-led system leadership will bring new challenges and roles for school leaders and

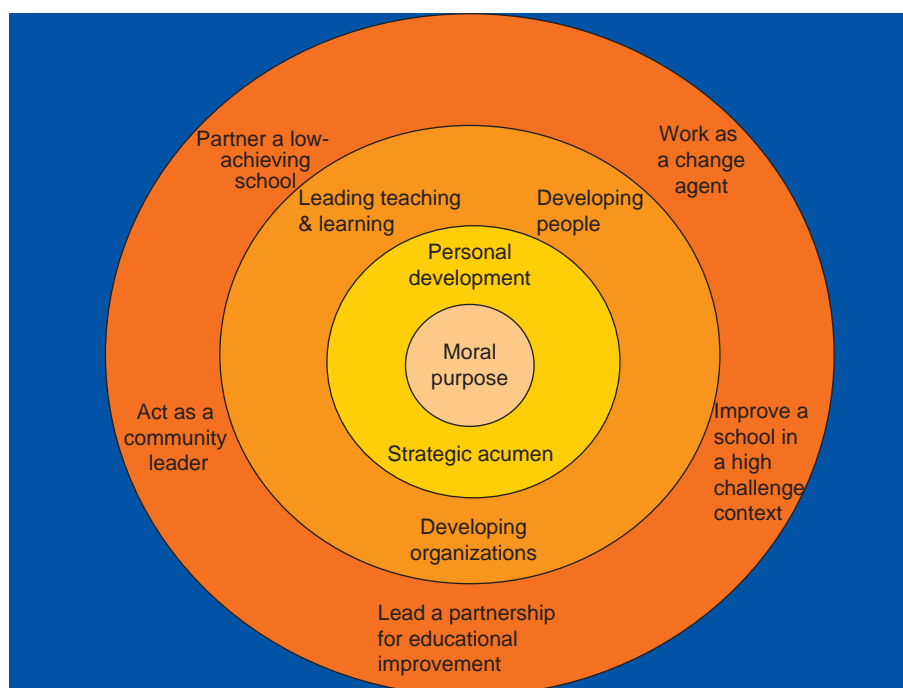

Figure 2 A model of system-leadership practice.

their schools. What is less clear is what this might mean for other system actors, most notably government. If school leaders are to take on wider responsibilities for system reform, how should a government work to develop such activity? Would a real and authentic commitment by government to do so inevitably mean a rebalancing of roles, agency, and control between schools and the government? In considering these issues, we now turn finally to explore some of the key systemic challenges for government.

As we have seen, fundamental elements of system leadership are the more authentic collaboration on and transfer of school-improvement intelligence and leadership best practice by experienced leaders. These are inherently professionally led, bottom-up solutions. Yet, they are also solutions to problems that have traditionally been the responsibility and preserve of the central apparatus of the state. This includes the deeply ingrained workings of the accountability, funding, and governance systems that place the unit of an individual school at their center. It also includes the location of agency and incentives, and the focus of support and professional development.

In considering these tensions, it is worth briefly returning to a distinction that was identified earlier between system leaders working in national programs and those working in locally organized often *ad-hoc* roles. The majority of school-level system leaders operate in national programs that have incentivized activity through organization, funding, and professional development that have in turn created new opportunities for headteachers. This is the enabling state at work. It is an important step toward rebalancing

agency by making it more possible for headteachers to lead technical and adaptive solutions in a widening professional domain of cross-school and system improvement.

Yet, within these opportunities, we may already be witnessing limitations of government-led activity. For, while new leadership roles emerge, the government's tendency to check and control does not seem to significantly diminish. This tendency is related to a focus on effectiveness and value for money. But it also seems to betray a government that has yet to develop sufficient trust in the profession. The result is less-than-intelligent accountability and at the extreme, a tick-box bureaucracy, rather than dynamic system reform.

A greater degree of freedom exists on the other side of the divide, in the roles we identified as being locally developed, often *ad hoc* and contextually responsive. In such activity, professionals not only deploy their experience and skill to lead improvements, they also define the terms on which such activity is undertaken and sustained. In this way, it is understandable why a number of our respondents conceived of these roles to be a more authentic form of system leadership. With no single framework or protocol, a range of models is developed in relation to specific needs (and times). Some centrally driven momentum is sacrificed, but on the principle that system leadership must inherently be a professionally led agenda. Furthermore, from this perspective, the role of an enabling state becomes focused on reducing barriers to collaboration and wider policy disincentives, with national agencies providing bespoke professional development to individual

system leaders. But there are limitations here too. Momentum seems to be significantly sapped by the time taken and energy used to develop and agree to the relatively procedural project and governance structures that underpin these roles. There will be concerns for rigor if effectiveness is not clearly defined or where an individual system leader does not have a wider perspective on emerging best practice.

There are of course variations to this bottom-up/top-down dialectic. For instance, strategic local-leadership partnerships already exist between headteachers and local authorities. In one such model, the authority retains legal responsibility for value for money while delegating decision making to a partnership of headteachers who bring coherence and accountability to local collaboration. A perspective on how these (and other) possibilities may inform current professional action and government influence will be dependent on a range of criteria. If, however, a shared criterion is to develop effective system leadership in a growing number of schools, then the following three suggestions for more short-term action may prove instructive:

1. *Incentivize rather than legislate.* The traditional response has been intervention and management from government, national agencies, or local authorities. The argument here is that this leadership now needs to come more from headteachers themselves or from agencies committed to working with them in authentic ways. It is clear that the more bureaucratic the response, the less likely it will work. A more lateral approach may be to create the conditions within the system to promote system leadership and collaborative activity through, for example, adjusting accountability requirements and funding for capacity building. With the right incentives in place, schools will naturally move toward these new ways of working and mold them to the context in which they operate and to the challenges they face.
2. *Place the agency close to the school.* There are now in England, at least three emerging change-agent roles within the system – National Leader of Education and School Improvement Partners – whose remit is specifically school improvement. The intention that must be maintained is that instead of creating a new bureaucracy, their brief is increasingly focused on facilitating relationships between schools to maximize the potential of purposive collaboration. This approach to school transformation is made increasingly possible by the highly sophisticated data now available on school and student performance. It enables groups of schools to identify (1) issues where they share both strengths and weaknesses, that is, their capacity for sharing and (2) common issues where they are likely to need some external input.
3. *Use school independence collaboratively to tackle inequality.* The underlying assumption here is that if state schools

are to become increasingly independent of local control, they must also be encouraged to work collaboratively. To tackle local inequalities, which have been entrenched during two decades of quasi-market reforms, a crucial condition is that all schools increasingly accept responsibility for the education of students within their geographic area. For example, this may enable the best of practice in the most successful federations to apply across other schools and to bring together a range of policy initiatives to give a real bite to local renewal.

A Final Word

This article has provided a conceptualization of system leadership and mapped the current system-leadership landscape based on data gathered in England in 2006. Although based on the English experience, the analysis may have a wider application. It has been demonstrated that system leadership can contribute decisively to a full range of government and local agendas by sharing of expertise, facilities and resources, innovation and creativity, leadership and management, and vocational education and skills support. In addition, a full range of children's-services agendas and constructive links between parents and schools, businesses, and further higher education providers and schools may be best served by such arrangements. The collective sharing of skills, expertise, and experience creates much richer and more sustainable opportunities for rigorous transformation than can ever be provided by isolated institutions.

We have also seen, however, that the notion of system leadership itself is not unproblematic. There is evidence to show that replicating best practice from one school to other is not easily achieved. It is clear that there are limits to headteachers working across the system without becoming distracted from sustaining improvement in their own schools. There are also significant contradictions within, and tensions between, government-led system leadership and demands for giving school leaders more agency to take the lead. Above all, there is a lack of evidence to demonstrate that school leaders engaged in system thinking and action can consistently provide solutions to complex systemic problems. Yet, while the whole idea of system-level reform is territory that is neither clearly charted nor uncontested, it is as we have seen, terrain that is beginning to be productively explored both in practice as well as theory by the new breed of educational-change adventurers.

Glossary

Bonding – The means by which a community develops social capital through developing homogeneity and exclusivity.

Bridging – The means by which a community develops social capital by engaging with other communities through inclusive relationships.

Community – Any human social enterprise which obtains its identity through a geographical, social, religious, intellectual, or historical sense of shared identity.

Find and fix – A management strategy which is essentially reactive - waiting for things to go wrong and then repairing them.

Predict and prevent – A strategy which uses measurement to predict failure in a system so allowing for early intervention to prevent the failure occurring.

Social capital – The extent to which a community (qv) is effective in terms of the quality of networks, social relationships and interdependent, collaborative approaches to social life.

Trust – A pivotal component of social capital which can be best understood in terms of confidence, consistency and integrity in human relationships.

new bottles or re-branding to keep up with changing intellectual fashions. There is little doubt that the publication of Putnam's (2000) *Better Together* has led to widespread debate and interest. This article seeks to clarify social capital as an intellectual construct, to consider its implications for education, and then to review its potential impact on our current understanding of educational leadership.

The central thesis of this discussion is that social capital provides an integrated conceptual framework to amalgamate two areas which have historically been seen as distinct – the school as an organization and the school in its environment. For a generation educational policy, research and practice have focused on the school as an autonomous institution with models of school effectiveness and school improvement being descriptive and/or normative of the school *qua* school. This led in turn to a model of the school managing its boundaries with an emphasis on various permutations and applications of commercial models of marketing. This autonomy was reinforced in turn, noticeably in England and parts of the USA, by a model of accountability which was institutionally focused, performance related, market orientated, and made no concessions to social or environmental factors. Underpinning these elements was the widespread hegemony around the nature of professional autonomy which was extrapolated into institutional autonomy.

A range of trends have led to a questioning of the school as an autonomous and self-referential institution:

- the plateauing of performance with existing strategies demonstrably not working in certain systems;
- recognition of the correlation between social justice, child well-being, and high academic performance;

Introduction

To the cynic the current growth in interest in the concept of social capital might appear as a classic case of old wine in

- the stubborn nature of the tail of underachievement in some school systems and its failure to respond to existing policies and nostrums;
- increasing awareness of the high correlation between social factors and educational attainment and achievement;
- recognition of the benefits of networks and clusters in securing improved outcomes; and
- increasing concern about the viability and sustainability of existing patterns of school organization given demographic changes in the teaching profession.

The recognition of these trends has coincided with the growth in awareness and understanding of social capital as both an explanation of how societies and organizations work and a strategy to secure improvement and effectiveness in both.

In reviewing the implications of social capital for educational leadership this article focuses on the following themes:

- social capital as an intellectual construct,
- defining social capital,
- implications for systems and schools, and
- implications for educational leadership.

Social Capital as an Intellectual Construct

The provenance of the current usage of the concept of social capital can be attributed (with increasing confidence) to Bourdieu, Coleman, and Putnam respectively: through the work of these writers the concept has grown in clarity, specificity, availability, and applicability. In *Reproduction in Education, Culture and Society* (Bourdieu and Passeron, 1970), the concept of different types of capital is introduced as a way of describing and explaining power relationships in society and the dominance or subordination of certain groups via the interaction of class relationships and cultural norms.

Coleman's interest in social capital emerged from a concern to explain the factors influencing educational achievement – notably through an understanding of social inequality:

...social capital is the set of resources that inhere in family relations and in community social organization and that are useful for the cognitive or social development of a child or young person. (Coleman 1994: 300)

Coleman introduced the concept of social capital as being primarily concerned with the nature and quality of relationships, networks, and attitudes. His work is also significant because of its empirical basis.

Bowling Alone (Putnam, 2000) is the tipping point in terms of awareness of the concept of social capital and the widespread adoption of the concept as a means of

explaining the relative success or failure of societies. Putnam defines social capital as the:

...connections among individuals – social networks and the norms of reciprocity and trustworthiness that arise from them. In that sense social capital is closely related to what some have called “civic virtue.” The difference is that “social capital” calls attention to the fact that civic virtue is most powerful when embedded in a dense network of reciprocal social relations. (p 19)

For Putnam, social capital is about reciprocity, trustworthiness, mutual obligation, networks, and community. It is Putnam who makes the explicit link between social capital and community – talking of them as conceptual cousins. Putnam specifically reinforces Coleman's emphasis of the importance of social capital to education:

Child development is powerfully shaped by social capital. ...trust, networks, and norms of reciprocity within a child's family, school, peer group, and larger community have wide-ranging effects on the child's opportunities and choices and, hence, on his behavior and development. ...Social capital keeps bad things from happening to good kids. (Putnam 2000: 296)

...social capital is second only to poverty in the breadth and depth of its effects on children's lives.

(Putnam 2000: 297)

Since 2000, the concept of social capital has become increasingly available and understood as both a means of describing and explaining the nature of society and as the universal panacea – it seems most of the world's ills will be cured by increasing the level of available social capital.

In spite of this wide-ranging acceptance, there are problems with the concept of social capital. For example, in spite of Putnam's empirical base, is social capital anything more than a metaphor? It could be argued that it is as elusive as happiness or wellbeing – measuring the components does not describe the total human experience. Equally, there is a problem in equating human experiences with capital when used in an economic sense – social capital is simply not the same as economic capital – and the same is true of human or intellectual capital. In the final analysis, economic capital is money – which can be measured, transferred, and substituted. There are those in education who find introducing the notion of capital into any discussion of educational issues offensive. However, even in business there are significant changes in thinking taking place:

The new art and science of wkinomics is based on four powerful new ideas: openness, peering, sharing, and acting globally. These new principles are replacing some of the old tenets of business. (Tapscott and Williams, 2006: 20)

Thus, competition is replaced by collaboration, secrecy by sharing, hierarchy by lateral relationships, all in the

context of an international perspective and open communication. In many ways, Tapscott and Williams are describing a process in some businesses that is very similar to the one that is being advocated for schools in this article.

There is an increasingly robust empirical base to inform the discussions about social capital and this base is growing in terms of validity and reliability. Although the debate about social capital is growing in analytical integrity, much of the language that surrounds it remains normative and subject to a wide range of complex and contingent variables. It remains very difficult to develop a historical, geographical, or cultural comparative framework to fully explore and understand the dynamics of social capital. Thus, much of the debate about the nature of community tends to be normative rather than analytical.

Putnam's work is compelling because of its intuitive appeal – we want to live in communities. What he describes corresponds to the archetype of how we want to be. Yet, accepting the problems with capital, there are issues with social capital in terms of political power, ethnicity, gender, and, fundamentally, the changing nature of society. Is social capital a historical phenomenon, descriptive of a stage in the evolution of society which we are nostalgic about in the same way that we might mourn the loss of the comforts and certainties of childhood? Just as Christmas cards depict scenes and images that exist only in a utopian collective consciousness that owes more to reminiscence therapy than any view of reality, so also, the debate about social capital can be self-indulgent and idealized.

If social capital is only a metaphor, then it is a very useful and robust metaphor; however, its evidential base is sufficiently rigorous to allow us to use it to explore, analyze, explain, and act on the many social dimensions of education and schooling.

Defining Social Capital

The purpose of this section is not to problematize what social capital might be, but rather to see it as a theory-in-action and explore how it might inform the key debates about the nature of education and educational leadership. The scholarly writing on social capital tends to eschew detailed itemization of its components. An inductive reading of Putnam (2000) on social capital and Delanty (2003) on community produces the following criteria for social capital expressed through the concept of an effective community:

shared norms and values;
sophisticated networks and relationships;
volunteering and community action;
civic participation and engagement;
interdependence and reciprocity;
open communication;

trust;
shared rituals and symbols; and
common aspirations.

This list is not intended as a set of prescriptive criteria but rather as a means of identifying the significant variables that define a community. Their relative significance varies according to context. However some, particularly in an educational context, do seem to have relatively greater significance. For example, there is a very well-established consensus that any community or organization is successful to the extent that there is an alignment on norms and values. A shared ethical foundation expressed in clear values and consistent moral behavior seems fundamental to any human endeavor. There is robust evidence that points to successful schools having a clear sense of identity based on common values; the lack of such a sense of shared identity is the negative corollary that often explains failing schools.

Equally there is a growing recognition of the centrality of trust in social interactions. There is an interesting parallel between countries with high levels of trust and societies in which children have high levels of well being as shown in **Table 1**.

The work of Bryk and Schneider (2002) has demonstrated the influence and significance of trust at institutional level – they point to direct correlations between trust and academic achievement:

That is, even after controlling for differences among schools in various aspects of school context, student composition, and teacher background, we still find strong effects linking changes in relational trust to improvements in academic productivity. (pp 113–114)

As a social resource for school improvement, relational trust facilitates the development of beliefs, values, organizational routines, and individual behaviours that instrumentally affect students' engagement and learning.

(Bryk and Schneider 2002: 115)

Thus it may be that a focus on social capital provides a potent strategy to focus on the issues identified in the introduction of this article.

It is easy to see how the above criteria for an effective community could be applied to almost any successful human enterprise – a village, a suburb, a sports team, a

Table 1 Levels of social trust and child well-being

military unit, a criminal gang, and a terrorist group. It is these last two examples that point to one of the problems with social capital – it is morally neutral. The criteria could well describe a high performing school, but they could also describe the most anti-social street gang. Much of the writing about social capital assumes a liberal, democratic, and pluralist context – it is both a product of and a reinforcing agent for such hegemony. However, if taken out of our consensual context, then it could well be used to undermine all that is taken for granted in much of the literature. Even where there is an apparent moral consensus, it can often be very fragile (e.g., New Orleans in the aftermath of Hurricane Katrina in 2005). Perhaps the important point here is that it is not just a matter of having shared norms and values but resolutely reviewing why they are held as well as what they are.

Social capital is what creates a community, yet there is debate as to what constitutes a community – is a family a community? Are the supporters of Manchester United (found in the most remote parts of the world) a community? Does geographical proximity constitute a community? Are the contributors to this volume a community? It seems that it is not enough to be within shouting distance (Aristotle's definition of a civic society) to be a community, or to wear the same uniform, or not to meet together regularly. What makes the difference according to Putnam (2000) is the way in which communities cohere and interact.

Of all the dimensions along which forms of social capital vary, perhaps the most important is the distinction between bridging (or inclusive) and bonding (or exclusive). Some forms of social capital are, by choice or necessity, inward looking and tend to reinforce exclusive identities and homogeneous groups. Examples of bonding social capital include ethnic fraternal organizations, church-based women's groups, and fashionable country clubs. Other networks are outward looking and encompass people across diverse social cleavages. Examples of bridging social capital include the civil rights movement, many youth service groups, and ecumenical religious organizations. (p 22)

Bonding social capital constitutes a kind of sociological superglue, whereas bridging social capital provides sociological WD-40. (Putnam 2000: 23)

It is the extent to which there is bonding of all the criteria listed above that an effective community will function. According to the type of community, bonding will often have to be extended into bridging: a key proposition of the next section of this article is that schools have become very good at bonding but will need to engage in bridging to respond to the challenges identified in the introduction to this article. A contemplative order of nuns will only be concerned with bonding; a mendicant order of friars will live their lives by bonding and bridging. Bonding is

characterized by introversion and homogeneity, bridging by extroversion and heterogeneity – it is very difficult to reconcile such polarized imperatives; yet, the complexity of modern society may require leadership that integrates these apparently contradictory imperatives.

Diamond (2005) tells the tragic story of the medieval Scandinavian settlement in Greenland that starved to death over a winter because their cultural norms and social expectations prevented them from learning from their Inuit neighbors. Bonding made them a community, failure to bridge meant that they died within sight of help. The same issue may, in less-stark terms, be facing schools. The focus on social capital is essentially recognition of the basic interdependence of all people and all human endeavors. At its most basic, social capital is about recognizing common humanity as the basis of human activity, and education is no exception to this.

Implications for Systems and Schools

Perhaps the most significant issue raised by a focus on social capital is the debate around the variables that influence educational success, however defined. A focus on the significance of the community helps create a new perspective on the work of educational leaders:

At present, the tragedy of school change is that only about 30 per cent of the explanation for variations in school achievement appears to be attributable to factors in the school. . . Perhaps it is now time for leaders to lead their schools and exert their influence far beyond the school walls. . . (Moreno *et al.*, 2007: 5)

The movement from bonding to bridging represents a fundamental challenge to prevailing orthodoxies concerned with the nature of national education systems and the basic premise on which most schools operate. In both cases, the system and the school tend to operate in parallel with other services but not, in any way, integrated with them. The classic image is that of the silo – provision for children and young people can be seen as a number of silos (education, social services, health, housing, etc.) – each operating according to its own model of professionalism, bureaucratic systems, culture, priorities, and sense of purpose. Education systems work by bonding, so do schools. This is manifested in cultural and organizational territorial imperatives and models of professional autonomy which define the dominant models of most public sector organizations. This also explains much of the orthodoxy around school improvement, as the Audit Commission (2006) of the United Kingdom describe it:

Traditional school improvement activity has tended to concentrate on teaching and learning at individual school level. Critical though this is, by itself the approach is limited. . . (p 2)

They argue that the reason for this is:

Children's educational underachievement is linked with a wide range of deprivation factors: low parental qualifications, low family income, ill-health, family problems and wider community factors such as low aspirations and unemployment. (p 4)

This leads to their, somewhat radical, assertions that:

Because of this, improving schools and improving the prospects of the most disadvantaged pupils in schools is not a matter for schools alone. . . (p 7)

And:

School improvement and renewal are inseparable issue from neighbourhood improvement and renewal, particularly in the most disadvantaged areas. While schools are profoundly affected by their neighborhoods, the equally have a key role in promoting cohesion and building social capital. (p 7)

The movement to bridging, in order to respond to the issue of social capital, requires a paradigm shift of the most profound nature. In essence, this involves a movement from parallel silos to integrated services. The specific implications of this movement might be summarized as follows:

1. A reconsideration of core purpose: a movement away from education systems and schools being focused on academic attainment and outcomes to a more holistic and integrated approach to maximizing life chances.
2. The restructuring of services: the realignment of provision to reflect the focus on holistic approaches, that is, the subsuming of education and other services concerned with children and young people into one coherent and interdependent strategy. One implication of this would be all relevant data about every child will be available to all professionals.
3. Shared resources: schools, in particular becoming community resources rather than just collections of classrooms functioning for about one sixth of the year. This implies community access on equal terms (rather than on a grace and favor basis) and schools sharing accommodation with other public services, for example, social services, police, health promotion, and services for all age groups.
4. Integrated strategies: moving away from piecemeal national policies randomly applied to the development of specific cross-community initiatives focusing on issues such as intervention in the early years, healthy living initiatives, drug abuse programs, teenage pregnancy, etc. Further strategies might apply to the socially disadvantaged, the elderly, the unemployed, etc.
5. Changes in roles: recognizing that the education of a child or young person is more than just delivering the curriculum.

Fundamental to all of the above is a switch in culture which can best be summarized as a movement from find and fix to predict and prevent. Education systems and schools have long worked on a philosophy of cure rather than prevention: early years' provision compensates for inadequate family life; primary education compensates for the lack of early years' provision; secondary schools remediate the failings of primary schools; universities and employers bemoan the time they have to spend compensating for the inadequacies of secondary schools, and when all else fails, prisons provide basic education.

The data that we now have on the impact and significance of social capital in terms of life chances and educational success allows us to begin to formulate strategies based on identification of potential failure based on predictive evidence and intervention strategies to prevent or minimize such failure. However, the professional culture and prevailing policies in many countries are rooted in cure rather than prevention – witness the relative spending on health promotion and surgical intensive care and early years' provision and higher education. It is no coincidence that the professional silos of health and education give higher status to the consultant and professor than workers in health promotion and early years' workers.

A practical example of cautious and tentative moves in the direction being advocated above is the every-child-matters strategy, the related Children Act (2004) and the Children's Strategy in England. They do represent a significant realignment of the public services in terms of purpose, structure, and roles; but in terms of both principle and practice, they have to work alongside the prevailing culture of academic standards based accountability – which makes no concessions to the issues emerging from the impact of social capital on educational achievement. It is rather like two tectonic plates grinding away, generating a great deal of heat, but with the new continent yet to emerge.

The OECD PISA (2007) studies have demonstrated a high correlation between educational and academic success and countries with relatively lower levels of social disadvantage. Putnam (2000) makes an explicit and direct connection between states in the USA with high social capital and states with higher educational outcomes. It may be that the emphasis on school improvement has to be matched, or exceeded, by investment in social improvement.

Implications for Educational Leadership

Although beset by semantic differences, there is a clear consensus across the canon of educational leadership that the primary focus of educational leadership is the school *qua* school. Most models of effective leadership in education, accountability structures, and professional, contractual, and social expectations focus on the school as an organization. The dominant themes of most programs preparing school leaders are focused on internal effectiveness

with phrases such as boundary management or marketing being used to describe relationships with factors external to the school.

In the policy context, this has led to the focus on school improvement with an emphasis on enhancing the performance of the individual school by addressing its internal processes and structures. The concentration on parental choice as a mechanism for improving performance in some school systems has tended to reinforce institutional autonomy by introducing competition – for those who are able to exercise choice in the marketplace.

There are thus contradictory imperatives at work but the issues are very clear:

These new theoreticians are leaders who work intensely in their own schools, or national agencies, and at the same time connect with and participate in the bigger picture. To change organizations and systems will require leaders to get experience in linking to other parts of the system. These leaders in turn must develop other leaders with similar characteristics. (Fullan, 2004: 9)

We need to develop a new generation of leaders who come to the task with a different understanding of the job and with a different skill set than previously required. Being masters of space and place must yield to proficiency with connection, communication and collaboration. (Houston, 2004: 2–3)

In systems thinking, those at both local level and at the centre take into account each other's world, i.e. their world-view enlarges. Recall Senge's phrase – "a shift in mind from seeing ourselves as separate from the world to connected to the world"... (Fullan, 2004: 12)

However this is more than a realignment of roles and responsibilities; it is a fundamental reorientation of what it means to be an educational leader.

The hardest part of sustainable leadership is the part that provokes us to think beyond our own schools and ourselves. It is the part that calls us to serve the public good of all people's children within and beyond our community and not only the private interests of those who subscribe to our own institution. ...Sustainable leadership is socially just leadership, nothing simpler, nothing less.

(Hargreaves and Fink, 2006: 158).

In essence, introducing social capital and community into the complex equation that defines educational leadership requires a movement from bonding to bridging across the system, in the school and at a personal moral and emotional level. In practical terms, this means leaders developing the knowledge, behaviors, and qualities to bond and bridge in the following contexts:

- the school as a community;
- relationships with other schools;

- relationships with other agencies and aspect of provision for young people;
- links with employers and universities;
- engagement with international partners; and
- engagement with families and the immediate community that the school serves.

Of course, most schools will already be involved in many of these areas. The important point is the basis on which they are involved, that is, moving from bonding to bridging; from organizational effectiveness to community development; from marketing and liaison to building networks – all rooted in developing and nurturing communities rich in social capital.

This perspective has numerous implications for our understanding of educational leadership. It is not so much a matter of redefining leadership as realizing the core knowledge, behaviors, and qualities. The themes that would seem to be most significant might include:

1. moral leadership which is committed to education as social justice and an overarching belief in securing equity and excellence for all;
2. clarity of purpose which focuses on the education of the whole person – not just the academic achievement of the student;
3. the ability to build trust through consistency, credibility, and confidence expressed primarily in authentic relationships;
4. working through networks and building complex coalitions through consent and consensus rather than control;
5. Sharing leadership by moving from leadership as personal status to leadership as collective capacity across the wider community; and
6. The willingness to work as social entrepreneurs, building social capital in communities and acting as an agent for social change.

These themes, in turn, imply a movement away from positional power to moral purpose, from personal status to collective authority, from control to consent and, most significantly, from the institution to the system – from bonding to bridging.

Networked Learning Communities School-to-School Collaboration as an Essential Component of a System Reform Strategy*

Glossary

Education action zones (EAZs) – A government program aimed at raising pupils' standards of achievement in areas of social and economic disadvantage by providing additional support to groups of schools and other partners to work collaboratively. The program focused on achievement in key curriculum areas: literacy, numeracy, information and communications technology, personal and social development, and professional development.

Excellence in cities (Eic) – A support program delivered locally by schools working in partnership with their local authority. It targeted deprived areas of the country seeking to transform urban secondary education by developing strategies and resources focused on teaching and learning, behavior and attendance, and leadership.

Innovation unit (IU) – The unit in England established by the government to foster practitioner-led innovation. Its role is to stimulate, incubate, and accelerate innovative practices on behalf of wider system learning and policy learning. Now in its second phase of development, most of IU's programs use the disciplines of the next-practice methodology that it has developed.

National College for School Leadership (NCSL) – The world's first national agency established in 2001, for the purpose of developing and supporting all aspects of school leadership. It seeks to grow and support current and future school leaders so that they can have a positive impact both within and beyond their schools.

Networked learning community (NLC) – A group of schools committed to interdependent working and learning on behalf of all the children they served, within the program. For the duration of the NLC program they became a new unit of educational meaning, a larger organizational form, and broader educational community. They also committed to making their learning and practice more widely

available, not just to the other schools in their NLC, but also to the wider system.

The 20th century was the century during which we built large institutions to do things for people. The 21st century is the century in which we help people to do things with and for one another

(Stephen Heppell).

Some Things We Know

There is a delightful saying in the organizational learning literature, attributed to Peter Senge, in which he notes that there are some organizations that remain steadfastly unable to learn what everyone in the organization knows.

Systems are like that, too. Some things we all seem to know, but the systems we work in are impervious to that collective knowledge. For example, it is widely accepted that the historical model of public-service change – centrally designed and delivered technorational strategies – will no longer work. The historical architecture of delivery, control, and accountability has had its time. We need a new way.

The English education system contains almost 24 000 individual school units, all relatively autonomous (one to another), yet accountable to central expectations through a national curriculum, national improvement strategies, key stage testing, centrally set target-and-inspection regimes. Local market accountabilities, through league tables and parental choice, follow on from these. Together, during the 1990s, these forces combined to foster system as a marketplace and to render schools more competitive than collaborative. Institutional success became a survival requirement, a stronger imperative than collective success.

Across the English-speaking world, the dominant school-improvement models utilize similar characteristics: schools designed on factory production principles; the profession layered and structured; the system tiered – a hierarchy of school, local authority (or school district), state, and national agency. Policy is mandated, practices are prescribed, and outcome targets specified. The logical route to improvement appears to be to strengthen delivery mechanisms and tighten accountabilities through targets, inspection, financial incentives, and consumer choice.

Such top-down-, outside-in-change approaches are seductive, because they appear to work well in the

* "An earlier version of this paper was published by the centre for Strategic Education in Melbourne in its Seminar Series as paper No. 156"

short-term – the system mobilizes itself around the targets, teachers teach to the tests – but then, as we have seen with England’s national strategies, improvements stall. Even more important, although this reform model raises general levels of attainment in the short term, it fails to close the gap in educational achievement between the most and least advantaged.

The paradigm is wrong for the times. Contemporary change needs are too rapid, knowledge is too ubiquitous, contexts of knowledge application are too diverse – and centrally coordinated strategies are unlikely either to be responsive enough, or to be sensitive to the unique challenges of these diverse circumstances. Such strategies do not stimulate or harness practitioner innovation and ownership. Worse, over time, they denude the system of its energy and creativity – its own innovative capacity.

In a sentence, not only are overcentralized reform strategies intrinsically unsustainable, they are also, over time, capacity denuding.

Much We Do Not Yet Know

There is an increasingly widespread view that a more collaborative, adaptive, and long-term problem-solving approach to educational change is the way to go. Sustainable improvement requires a shift to a different model: one which emphasizes capacity building; which spreads and uses leadership widely; which enables and encourages rapid knowledge transfer; which fosters and utilizes practitioner innovation and creativity; and which values system learning and builds for sustainability. The problem is, we just do not yet have the tools and know-how to orchestrate such a pervasive change.

Part of the resistance is that England’s policymakers are heavily influenced by history of reform – particularly the more permissive 1960s and 1970s – which would seem to tell us that random, unstructured, and unconnected innovation does not serve the system well either. Past experience (it says) suggests that unfettered innovation is unlikely to achieve the common purpose and connectivity required to bring coherence and alignment to system-improvement efforts.

Despite these reservations, there is a history in the UK, from different governments, of policies designed to stimulate collaboration, from technical and vocational education initiative (TVEI) more than 20 years ago, through education action zones (EAZs) and excellence in cities (EiCs), to more recent examples. Most have been heavily prescribed from the center, mandated, overly incentivized or resource dependent, and targeted at the most intractable problem areas – inner cities and schools perceived to be failing. They have tended not to be models designed to be either sustained or scaled. At best, the jury is out as to what we learn from these collaborative policy models,

but any sense that there was, as we entered the twenty-first century, a cumulative body of knowledge from them would be fanciful (Demos, 2000). The history of reform in this area has not encouraged the accumulation of a body of learning – what evaluations exist tend to be focused on outcomes rather than learning.

So, on the ground we do not yet have the practice knowledge or the ways of spreading it if we did. At the center, the system is not well served by its own research history from previous initiatives, nor, if we are honest, informed by best available public knowledge, particularly that from other sectors, where collaborative norms are more fully developed. Most tellingly, even if there were clearer understandings about the characteristics of disciplined collaboration, the current architecture of reform gets in the way. You cannot mandate collaborative practices through delivery and accountability levers.

The opposite question: “What is the role of policy and the machinery of state in promoting and supporting emergent, adaptive, locally owned collaborative arrangements?” is the theme addressed in this article.

This was the situation we faced in 2000. Both logic and evidence from practice were indicating that purposeful collaboration between schools could be more conducive to organizational learning than competition. We wanted to know what effective collaboration looked like, and also how it could be incentivized, mobilized and supported – the conditions that would optimize success.

Our belief was that networks of schools engaged in orchestrated and disciplined networked learning offered an alternative way of providing connection and alignment around the multiple concerns facing education. In fact, we argued that networked learning offered a highly effective method of adaptation and integration. We were confident that it would improve outcomes for young people.

These grounded beliefs lay at the heart of what England’s National College for School Leadership (NCSL) set out to achieve in the networked learning communities (NLCs) program (Jackson, 2003, 2005), a system-wide development and enquiry program.

The Networked Learning Communities Program

The NLC program was a system-wide development and research initiative involving 137 networks (1500 schools) that took place between 2002 and 2006. It was specifically designed to inform system learning and national policy, as well as to provide practice evidence about network design and implementation issues, network size and type, facilitation and leadership, formation processes and growth states, brokerage, and system support and incentivization. It sought to generate evidence about how and under what conditions networks can make a contribution to raising

student achievement and attainment, about the leadership practices that prove to hold most potential for collaborative learning and about the new relationships emerging between networks as a unit of engagement and their local authority and community partners.

There were six strands to the basic framework of the NLC design and, unlike traditional delivery approaches, it was designed from the inside out. The six levels of learning were:

- pupil learning (a classroom-learning focus);
- adult learning (professional learning communities);
- leadership learning (shared and distributed leadership opportunities);
- organizational learning (new organizational norms);
- school-to-school learning (networked learning); and
- network-to-network learning (lateral-system learning).

Each network additionally elected to engage other appropriate partners, usually one or more from a higher education institution (HEI) or local authority (LA) or community partner. There were also four further non-negotiables:

- moral purpose – a commitment to success for all children (If you do not care almost as much about the success of children in other schools as you do about those in your own, this would not be the program for you.);
- shared leadership (e.g., co-leadership);
- enquiry-based practice (evidence and data-driven learning); and
- adherence to a model of learning.

This model of learning provided a program-wide discipline and analytical template for what we called networked learning (Figure 1).

The use of this model of learning in support of collaborative joint work practices (networked learning) proved to be a very powerful discipline for networks of schools in the program. Participants across schools agreed a shared

purpose and content focus for their learning – something more aspirational than they could achieve alone.

Networked learning takes place when individuals from different schools in a network come together in groups to engage in rigorous and challenging joint work activity informed by the public knowledge base, using their own know-how and co-constructing knowledge together, as described in the three-fields learning model. In doing so, they are involved in four distinct learning processes:

1. Learning from one another (exchange): where groups capitalize on their individual differences and diversity through sharing their knowledge, experience, expertise, practices, and know-how.
2. Learning with one another (joint work): where individuals learn together, notice that they are learning together, co-construct learning, and make meaning together. Collaborative practitioner enquiry and collaborative learning about recent research are good examples of this activity.
3. Learning on behalf of: where learning between individuals from different schools is undertaken on behalf of other individuals within their school and network – or the wider system.
4. Meta-learning: where individuals are additionally learning about the processes of their own learning and the way that the system learns in ways that build sustainable capacity.

Such collaborative learning in networks has been shown to expand professional identity, from the school as a unit of community to the locality (the wider network) as a unit of educational community. Contextual relevance focuses activity on local change. Changes in teachers' knowledge and understanding and changes in school-level behavior and classroom practice are intermediate outcomes. The ultimate purpose of networked learning is to improve student learning, achievement, and attainment. Wider benefits also include improved confidence and self-esteem among participants, enhanced motivation, a richer sense of professional efficacy, broader professional identity (and liberation from context), and a capacity routinely to engage in wider professional partnerships.

These features begin to answer inevitable questions about cost benefit. There is no doubt that the early phases of collaborative activity are hard and typically not cost effective. The new kinesthetics of collaboration run against the grain of historical practices and we have to learn how to do it well. However, if viewed not as a short-term test of efficacy, but as a necessary phase of the learning process, the value is cumulative.

When practitioners within a network come together, it takes an effort of will and discretionary effort. They need no persuading that the engagement has to be made worthwhile in terms of changed practices and learning gains. Strikingly, the final evaluation of the program found a

Figure 1 Three fields of knowledge.

direct correlation between levels of involvement and pupil achievement gains – the more staff involved in the network, the more gains for students.

Alternative Approaches to Incentivization and Implementation

Launched as a design framework at a series of regional continuing professional development (CPD) conferences in the autumn of 2001, the groundswell of support for the NLC program took those of us leading the program by surprise. It captured a moment. The profession was clearly weary of a climate of competition, outside-in change programs, normative improvement agendas, and externally generated accountability systems. There was a feeling that we needed to create space in the system for local creativity, lateral learning, and accountability, distributed leadership and the sharing of practice. Having achieved short-term improvements through the externally generated reform agenda, the next phase would take on different and less-predictable shapes. It would occupy different directions of travel, too, being less outside-in than inside-out; less top-down than lateral in direction; and less one (the center) to many than many (the network) to many (other networks).

Informing this, an explicit set of beliefs invited participation (NCSL, 2003). The logic sequence proved persuasive. The first was that normative notions of intelligence are out of date – that all children can be intelligent and powerful learners if schools can learn how to enable it. It is not any longer children that fail in the system so much as the system that fails young people. Sufficient is now known that every child can be a powerful learner. Second, schools, teachers, and leaders who aspire to continuous learning look beyond their own school – recycling existing internal knowledge is a poor foundation for growth. Collaboration (teachers and schools working together rather than competing negatively) is the route to learning and is professionally motivating. Third, the knowledge and the will exist but coherent models, a facilitative policy environment, and a commitment to learning at all levels of the system are required to make it happen. Finally, there is no profession with greater leadership potential than teaching to achieve these things.

The program therefore asked schools to form interdependent networks, to work with and for one another for the benefit of all children, the schools, and the communities they serve. It was formulated as a design intervention, and the design was theoretically and practically informed. The development team utilized both the literature base and practice base, visiting 14 locations around the world to build from best available knowledge. The prototype model (and the challenges of its implementation) was then further co-developed through a sequence of seminars

with practitioners, experts, potential participants, and consultants from both education and beyond.

In the end, what that design meant in practical terms on the ground was to be locally determined – not as an indulgence, but because we believed that they would know best. Networks were supported to co-construct their own responses: their local architecture, the focus of their collaboration, and the enquiry engagement relevant for their context. The aim was to develop involvement, engagement, and spread of leadership, not to prescribe structures.

In support of this, there were some uncharacteristic dimensions to the implementation components of the program. Documentation was minimal and intended to support local efforts rather than to meet central requirements. There was funding for the program, but networks had to match it in kind – showing that they were putting effort and resource into new ways of working and network-dedicated activity. We asked for finance templates (expected network spend), but the only audit was to declare variances – we were interested in how emergent learning shifted spending decisions and why. There was to be no external review for 2 years; instead, networks were expected to formulate their learning into artifacts such that knowledge could be shared with other networks. What review existed was self- and peer review. Networks were encouraged to visit one. Talking about what did not work was valued as highly as what did.

Another feature was that networks could not have one leader – co-leadership was the experimental model for the first year, and one which none of the 137 networks moved away from in subsequent years. These co-leaders operated as system leaders within the network.

Even the process of writing submissions was unusual and emphasized learning values. Regional submission-writing seminars were held during which representatives from potential networks helped one another to design proposals through peer critique and the exchange of ideas. (What is the best idea that you have had today? We would like you to give it away to everyone else in the room.) Formative feedback was given on written proposals – redrafting based on feedback encouraged. The final assessment phase (given that we received 150 proposals – more than 10 times what was expected) involved presentation to peer-review teams, the thinking being that ideas would be shared and disciplines learned from the assessment process.

Throughout the program, the central team operated as a surrogate intermediate system, but with an emphasis on their role as knowledge brokers. The networked learning group was tasked with three core goals:

1. the development of good networks;
2. learning about networked learning; and
3. enabling learning to inform the wider system.

As such, direct support for networks and the facilitation and brokerage of lateral learning and exchange were

significant early tasks. Increasingly, the synthesis of program knowledge and the design of tools, protocols, and publications to support both program and wider system learning were an increasing part of the work.

What Did We Learn?

Three sections from the 3-year external evaluation of the NLC program are illuminating to frame this section. The first, the one that matters most to most people, states that networks made a difference for young people. They worked in raising standards of achievement:

There is a connection between the participation in a network and improvement in pupil attainment. The study provides evidence that when networks of schools work together, there is an impact on pupil learning. The number of people in the school who are active in the network was positively correlated with pupil outcomes. . . . and the level of network attachment was related to change in pupil outcomes. . . . Network attachment was also correlated with intermediate outcomes of changes in thinking and practice in schools

(Earl *et al.*, 2006).

The second explicitly links collaborative and joint work with learning and change:

An important and necessary finding in this study was the emergence of a new factor for both schools and networks that we have called “rigorous and challenging joint work”. It is high order collaboration. It requires participants to suspend judgement, challenge their assumptions and intentionally seek out new information in the quest for ideas and practices that work. Rigorous and challenging joint work may be at the heart of the power of networks. Networks can provide the forum for colleagues to address genuinely new, and often difficult, ideas in a safe environment, away from the risk of censure or even retribution in their daily place of work

(Earl *et al.*, 2006).

The third links learning and leadership – both distributed and formal:

Trust relationships and mutual challenge are the things that make the links in networks; tapping explicit (public) knowledge and exposing tacit (private) knowledge provide the process; and leadership, both formal and distributed, can create the forums and provide the necessary support and capacity building opportunities to move the process forward

(Earl *et al.*, 2006).

If this is an overview of external evaluation findings, our work at NCSL also helped us to pick out a more finely grained set of learning points along the way. The first is a

set of verities. As stated earlier, the NLC program drew from best available knowledge worldwide. In accumulating that body of evidence, certain themes recurred which were subsequently further validated through the program’s work.

These verities are, chiefly, that collaboration relies on voluntarism and having a compelling reason to work together – one that accords with the strong moral purpose of the teaching profession. Networks also require good internal leadership. As for all organizational forms, leadership is critical, but it manifests itself differently when influence and facilitative support (rather than positional authority and hierarchical status) are key characteristics. In addition, networks benefit from external brokerage and critical friendship. Given these conditions, networks expand access to good ideas and enable greater sharing of professional knowledge.

Our ongoing process of learning and research throughout the program helped us to understand the challenges, the dynamics and the rewards of collaboration more deeply. Research (internal and external to the program), evaluation activities, network reviews, program-wide enquiries, sustained facilitator engagement, and the involvement of a number of respected international associates together yielded a huge body of evidence. This in turn has allowed us to expand the boundaries of what is known about successful collaboration.

A full account exists elsewhere (Jackson, 2005). In summary, we learned that new ways of working together emerge with difficulty and at high early transaction cost; that trust is an important issue for networks, but it is more an outcome of rigorous joint work than it is a precondition; that some of the motivational energy for participants stems from the acquisition of a sense of expanded professional identity; and that networked learning surfaces the reciprocity and generosity which is at the heart of a professionally collaborative culture.

Moreover, and importantly, networks spread leadership influence. They act both to distribute leadership and also liberate new types of leaders. These leaders understand their connection to the wider profession – learning on behalf of (mentioned above) was a major motivator for knowledge exchange and joint work activities. As such transfer of practice is far too naive a concept to describe the knowledge-exchange processes in networks. Collective problem solving, joint work projects, collaborative enquiry – in short, a range of innovation and knowledge-creation activities – better describe the learning processes. Perhaps unsurprisingly, this expanded leadership capacity accentuated rather than diminished the significance of formal leaders (school headteachers), whose capacity to enable and empower the participation of others, to gatekeep network outcomes within their own school – and to model commitment to networked learning – was directly correlated to success. The eternal

evaluation finding that gains for students in schools positively correlated with formal leader engagement with the network was no surprise.

Where successful, NLCs created new units of meaning, locality provision for young people – and new units of engagement for local authorities and other external partners.

Beyond this, there are some more tentative propositions that emerged from the NLC work and which bear the warranty of experience more than research.

Perhaps most importantly, we came across the well-established problem of causality – how can networks prove that they are making a difference greater than the sum of their parts and, when they do, how can they take the credit for it? We were able to show that pupils in the 1500 NLC schools made statistically significant attainment gains greater than those in schools not in NLCs, but proving causality is another matter!

We knew that voluntarism was vital, but we now believe it can be orchestrated with the help of intermediaries. Since the start of the program, some local authorities have implemented learning networks across all their schools, co-designing local solutions with groups of schools. Good system-brokerage skills are a vital part of this work and local authorities as system designers might be one of the differentiating skill sets for the future.

Successfully orchestrating participation also relies on a structural architecture built around shared challenges and goals for learning, and in which people are prepared to experiment with new communication channels that break the traditional, hierarchical mould. Logic tells us that ICT should play a vital role in that process, and yet there are very few examples of it being integral to the success of networks. As that suggests, networked learning is most likely to work when participants unlearn some of their old practices and embrace new ways of working. Those in positional roles enshrining institutional power have the most challenging unlearning agendas.

Finally, variability of commitment is another inherent and perhaps inevitable challenge for learning networks. It is, of course, for all organizations, but it is more visible in networks. Accommodating those variances while still retaining collective buy-in and commitment to core purposes is a key leadership skill for network leaders.

What Did We Learn about Implementing and Facilitating Networks?

The team that supported the NLC program – NCSL's networked learning group – was itself trying to explore what role intermediary bodies could play in catalyzing and supporting networks on the ground. Its performance was a potential model for organizations like local authorities in developing collaborative work.

There is no doubt that we did some things well. The program was both theoretically and practically informed (McCormick, 2004). We succeeded in generating a compelling design, underpinned by values, which motivated engagement. The co-design orientation, and subsequent co-development work, stimulated new relationships between system partners. We did not have the answers, so these were learning relationships. The model of learning was a seriously important shared discipline. The development team brokered lateral connections and stimulated peer-to-peer learning.

If improved outcomes for children are the critical determinant of success, then the external evaluation shows that this was achieved. If creating a body of knowledge is the yardstick, then it is fair to say that, as the program progressed, we wrestled – successfully on the whole – with the challenges of real-time learning now manifested in our tools and publications. The legacy of products and materials is quite probably of national and international significance.

We never, of course, pretended (or wanted to pretend) that we had the answers, or that everything was successful. This was a program committed to learning through doing, and we were open about our uncertainties and failures with the networks, just as we asked them to be open with one another. With the clarity of hindsight, we could have done a number of things more effectively.

In retrospect, the NLCs design came to be too close to a brand. In proposing NLC as an ideal prototype to support development, we unwittingly gave the impression that we were proposing this model as the single, or best way forward. Again, also with the wisdom of hindsight, our central infrastructure grew too large. Networked systems can be supported with a minimum of central capacity by utilizing leadership from the front line – and in so doing grounding decisions and thinking in the experience of practice. Our central infrastructure did not assist us to sustain the co-development orientation in the eyes of networks, either.

Two early decisions proved to be only partially wise. First, the networks received nominal funding for the first 3 of the 4 years. That may have been a mistake. We wanted to stimulate new capacities and ways of working and knew that some funding would help. So it did, but a proportion of networks saw the removal of funding as a barrier to sustainability. No funding could have been the way to go.

Second, we knew that baselining at the outset would be crucial to evaluating achievements. We wanted each network to take ownership of its own baselining strategy and we developed tools to scaffold that work. Looking back, that work was pretty variable, not least because the networks were at such a formative stage when asked to do it.

The last reflection links into the concluding points below. The network learning group was itself a part of a national agency, NCSL. In common with many innovators, we felt under siege early on, felt that we were challenging historical practices and were in turn being

challenged by those who were skeptical or threatened by the program. We could have integrated our work into the college more effectively – and as a result had less influence there than might have been possible.

That is an honest appraisal. The final section makes some equally honest concluding observations about barriers to taking collaborative practice to scale across entire public-service systems.

Conclusion

Systems can seem dumb. It is difficult for them to learn what is widely known, not least because the system's learning structures are themselves a part of the problem.

Enough is known. It is not primarily lack of knowledge that prevents collaborative working – either between schools or across services. The NLC program alone has created a huge store of evidence and learning and there are other rich sources of knowledge, both in this country and abroad. In a system configured for one-to-many rather than many-to-many dissemination, though, there are certainly problems making what knowledge we have widely available sufficiently quickly, at scale, to support emergent practices.

In addition, the issue of scale is also a part of the problem. In her internationally regarded study on scale Coburn (2003) identifies four dimensions in which we lack a resolute theory: depth, sustainability, spread, and shift in reform ownership. The third of these poses interesting challenges for the support of a collaborative system. About spread she says:

Rather than thinking of spread solely in terms of expanding outward to more and more schools and classrooms, this emphasis highlights the potential to spread reform-related norms within the district. At the district level, spread involves the ways in which reform norms and principles influence district policies, procedures, and professional development.

This is clearly a conundrum. We know from our own work that a network-based system requires brokerage and support. There is a crucial facilitation role for local authorities and a critical role in generating facilitative policy at a national level. To make the shift, both local and national agencies will have to internalize the challenging norms and principles of a more networked and collaborative system. But local and national government often appear irretrievably hierarchical and bureaucratic.

Returning for a moment to the epigraph at the start of this piece, Stephen Heppell referred to the organizations set up in the twentieth century to do things for people. As we seek to liberate collaborative arrangements, to help people to do things with and for one another, what could well stand in the way are those same organizations, hierarchically

structured, culturally siloed, relatively impermeable to learning, set up to provide answers, and to believe that they know best.

In addition to the external evaluation, as a part of the wider research program, we also commissioned a study on the role of local authorities in supporting school networks. Aubyn Howard in the report from this piece of work writes:

Networked learning is part of a system-wide shift towards a more collaborative and interconnected way of working – the system local authorities support is becoming more networked. Alongside this, LAs are also being asked to network internally to deliver Every Child Matters. However, many don't know either how to do this or how to reconfigure to support school-to-school networks – why would they? Moving into networked learning mode themselves (within services, between services or agencies and between LAs) such that they model practices and apply them in new forms of engagement with networks of schools, is a good way to start. This means embracing collaboration, networking and learning within the way they work. (They) need to engage in a deeper internal process of organisational and cultural change if their efforts to model networking and work differently in support of ECM are to be sustained

(Howard, 2006).

If this applies to local authorities, it is equally applicable to national agencies, to government, and to the structures of the civil service. The critical orientation for change is a learning orientation. This means engagement with front-line collaborative practices, not to provide answers, not to hold to account, or to bureaucratize, but to learn how better to accommodate risk, and to provide enablement and support. It is a role of system broker and shaper, and it is a very different orientation.

Networks and Communities of Knowledge

T Schuller and H Theisens, Centre for Educational Research and Innovation, OECD, Paris, France

Introduction

The production and transmission of knowledge has always involved networks and communities. The band of young men surrounding Socrates, the academia of Plato, the medieval monasteries, the cathedral schools, the guilds, universities, and scientific disciplines are all examples of communities and networks of knowledge. However, while knowledge has always played an important role in human societies, the term knowledge society refers to the fact that knowledge has now moved to the economic and social core of our societies and that the speed of knowledge creation, accumulation, depreciation, and dissemination has accelerated (OECD, 2004). The communities and networks that produced and transmitted knowledge in past tended to be rather closed, homogeneous, and were either small (Socrates) or institutionalized (universities). With knowledge now central to society and economy (and both readily available and necessary for many people), the communities and networks that produce and transmit knowledge have become more heterogeneous and less institutionalized. The overall context, therefore, is one where it becomes increasingly important to understand the formal and informal mechanisms through which knowledge is created, transmitted, and validated.

Knowledge Production and Its Context

The rise of the knowledge society is the result of a number of different but interrelated trends. The whole process of knowledge production and use has strongly accelerated due to the steep decline in the cost of replicating and transferring information (OECD, 2004). Due to the ongoing mechanization of manual labor and the growth of the service sector, knowledge has become increasingly important as a production factor. These developments have been made possible and have also been driven by an increasingly educated workforce. Lately, the effects have been fortified by globalization: for many developed countries, knowledge-intensive production (and related innovations) is one of the major competitive advantages left, compared to developing countries with lower production costs. However, the balance of advantage here is changing fast as large countries such as China and India catch up.

There are several further features of this general trend:

- the growth of the service sector in all OECD economies and the weight of highly educated knowledge workers in this sector;
- the massification of higher education and the fast growth of academic research since World War II;
- the growing importance of knowledge-based innovation as an essential element for economic success (and the increasing spending on research and development (R&D) as a result), in the context of global competition;
- loss of a monopoly position of universities and academies when it comes to knowledge development and the transmission of high-level knowledge; this is now spread over a multitude of organizations (e.g., companies, think tanks, nongovernmental organizations (NGOs)); and
- the development of a knowledge infrastructure connecting these different knowledge organizations, especially via the Internet acting as a fast-growing repository of codified knowledge, to which search engines provide easy access.

As a result of these developments, different forms of knowledge production are coming into existence. Increasingly, knowledge workers are generating and transmitting knowledge outside the formal knowledge institutions like universities. Gibbons *et al.* (1994) describe these phenomena as new modes of knowledge production (they refer to mode 2 as opposite to mode 1). This new mode-2 knowledge production is marked by:

- an increase in the number of potential sites in which knowledge can be created (not only universities, but independent research centers, government agencies, laboratories, think tanks, consultancies, and in the interaction of all of these);
- the linking of sites together in a variety of ways – electronically, organizationally, socially, informally – through the functioning networks of communication;
- the simultaneous differentiation at the linking sites, of fields and areas of study into finer and finer specialties, but at the same time greater interdisciplinarity; and
- a strong focus on problem-solving as a central goal of knowledge production.

While mode-2 knowledge production refers mainly to new forms of knowledge production (in the terminology of mode 1: research), learning in this new situation is transformed too. With the advent of the knowledge

economy, learning becomes an integral part of economic processes. Communities and networks are important collective mechanisms through which such learning takes place.

New Knowledge Relationships

The combined impact of the importance of knowledge, the speed of change, and the fragmentation of the sites for knowledge production poses challenges for the production, accumulation, and transmission of knowledge. With knowledge workers dispersed through a great number of different organizations, with very different traditions and objectives, there is the question of whether the traditional mechanisms for knowledge reproduction are still operating. Recent literature has abundant descriptions of different responses to this challenge, and a plethora of related concepts.

Organizations have always been learning in the sense that they have always needed to respond to unforeseen changes. When new technologies were incorporated in the production process, unforeseen problems needed to be solved by developers, producers, and users; in other words, the organization learned by doing and using. However, this kind of learning often remains localized; its results do not spread beyond the boundaries of the firm and are only relevant and understandable in the context in which the learning took place. One reason for this is that while the cost of replicating information has been reduced to almost nothing, thanks to modern technology, reproducing knowledge remains a far more expensive process. Many cognitive capabilities are not easy to articulate explicitly or to transfer to others, as tacit knowledge (Polanyi, 1976). This is why knowledge reproduction has traditionally relied on some version of the master-apprentice system, or on interpersonal transaction among members of the same profession or community of practice. These means of reproducing knowledge were at the heart of many professions and traditions, but they fail to operate when social ties unravel, when contact is broken between older and younger generations, and when professional communities lose their capacity to act in stabilizing, preserving, and transmitting knowledge (OECD, 2004). In this situation, new forms of knowledge production, with results that allow for generalization (beyond the boundaries of closed and homogenous communities) may be needed.

These new patterns of knowledge production and learning are developing already; Lundvall (2006), Piore and Sabel (1984), and Granovetter (2000), for example, point to networks of small- and medium-sized firms that allow users and producers to interact and share what they have learned from producing and using each others' products. In several fields, from high-performance sports equipment to computer software, users are joining in the

design process, pooling their knowledge and experience in order to enable producers to meet their needs more closely (Hippel, 2006). These are the kinds of changing relationship which will characterize at least some future networks. In interacting and sharing their learning outcomes, beyond the boundaries of their own firms, producers and consumers need to formulate their knowledge in ways that makes it understandable outside its original context. This generalization of the learning outcomes then creates the possibility of sharing learning outcomes with many actors in a network.

Most of the new forms of knowledge production and learning identified in the literature share the use of the concepts of networks and communities. Networks can be loosely defined as a set of actors (persons or organizations) linked by ties or relations of a specified type. A tie or relation between actors has both strength and content. The content might include information, advice, or friendship, shared interests, or memberships and typically some level of trust. In this article, we are concerned with professional networks and particularly with the flow of information through the networks. The level of trust is important though because it lowers the transaction costs within the networks and facilitates the sharing of information (see section entitled 'Social capital and communities of knowledge').

The concepts of community and network are often used interchangeably in the literature. The distinction is a fluid one. Communities tend to be smaller, more homogenous, and with stronger ties in which people share a common set of values. Networks are larger, less homogenous, have weaker ties, and more plurality of values. This provides us already with a number of dimensions on which communities and networks can be classified, that is, size, strength of tie, and degree of homogeneity. In addition, we can examine the extent to which the community is defined by occupational or professional identity; the extent to which it is bureaucratically organized; its geographical dispersion; the degree to which technology defines the mode of communication within it; and the degree of its disciplinary boundedness or spread.

Other aspects of a slightly different kind refer to the values and orientations displayed: for example, whether the network has primarily a commercial orientation; its legal or official status; and the extent to which members of the community define their identities with reference to it.

There are certainly other dimensions that could be added. Network analysis is a methodology that is beginning to assume a new lease of life, as novel techniques allow a more sophisticated empirical mapping of their scale and nature. The essential point is that networks of different kinds will play a significant part in defining the extent to which knowledge is generated and transmitted.

Social Capital and Communities of Knowledge

One systematic way of looking at communities of knowledge is by using the social capital theory. At a societal level, this is primarily associated with the work of Robert Putnam (1993, 2000), but other literature in this area deals very closely with networks, notably that of Burt (1982) on structural holes. The relationship between social capital and education has been explored in social theory by Coleman (1998) and Bourdieu (1986), and in an international policy context by OECD, exploring the interaction between human and social capital (OECD, 2001). Social capital as a concept is often defined specifically in terms of networks, stressing the norm-laden nature of relationships within and between them. A common differentiation of types of social capital is into three basic forms (Woolcock, 1998):

- bonding social capital, which refers to relations within or between relatively homogenous groups;
- bridging social capital, which refers to relationships within or between relatively homogenous groups; and
- linking social capital, which refers to relationships between people or groups at different hierarchical levels.

These are not mutually exclusive, that is, a community can be high on both bonding and bridging forms. Analyses that explore the interaction between these different types of social capital can be very fruitful for determining the dynamics of knowledge creation and use (Schuller, 2006). Thus, networks that are strong on bonding but weak on bridging may be powerful creators of knowledge within quite well-defined frameworks, such as an established research group with high levels of commonality in the members' approach to research and understanding of the field. However, a community that also includes bridging social capital may be more open to an infusion of new ideas and to the intellectual challenges that come from exposure to different approaches, and benefit from this in the longer term. As for the application of knowledge, this may depend in part on how far linkages to higher levels of power exist; but often network structures may allow such hierarchies to be side-stepped. In short, there is no single ideal combination of these different forms of social capital in the construction of communities of knowledge.

One crucial function of social capital is its deployment of trust. Some level of trust is implicit in almost any concept of community (though maybe less so for networks, where the interdependence is weaker). The importance of trust is in its capacity to help members of the community of knowledge to assess and validate knowledge as it evolves: in other words, to scrutinize knowledge claims, for example, from other researchers, or from practitioners or policy-makers, and by drawing on the community's resources to

enable members to decide on the quality or level of knowledge. This function of critical validation is especially important in the face of the tidal waves of information and misinformation that slosh around the electronic world. The validation is not only a matter of truth determination, but also of selection, utility, and application. A community of knowledge draws on its members' collective experience and intelligence to decide which of the huge range of possible choices of knowledge is likely to be most favorable. It reduces the cost of information, both in searching and verification and raises the levels of reliability. These are valuable both financially and psychologically. Trust also promotes the sharing of ideas, because it diminishes fear of intellectual theft. Intellectual property is an increasingly recognized form of asset in knowledge societies, and this brings with it a growing complexity in how such an asset is to be managed and this includes issues related to ownership, distribution maintenance, and exploitation. One of the strengths of the open source movement is its ability to promote the accumulation of knowledge by providing a normative and legal framework within which people can share ideas, in the expectation that such sharing will result in improvements to the asset without it being appropriated for individual gain at the expense of a common good.

High Levels of Bonding: Communities of Practice

Communities of knowledge with high level of bonding social capital develop a common language, common approaches to problem solving, etc., which reduce the transaction costs and greatly stimulate the exchange and creation of knowledge. Foray (OECD, 2004) argues that there are three elements that constitute the basics of such a community. First, a significant number of a community's members combine to produce and reproduce new knowledge. Second, the community creates a public space for exchanging and circulating the knowledge. Third, new information and communication technologies are intensively used to codify and transmit new knowledge. He goes on to argue that communities characterized by these three components tend to be fundamentally geared to knowledge-driven production. The advantages of this are:

- the communities facilitate interaction, which increases the possibilities for learning and development of knowledge;
- in order to be able to exchange ideas, knowledge must be codified, which leads to greater storage and communication capacity and makes it possible to develop new cognitive approaches;
- quality control is assured because each member can reproduce, test, and criticize new knowledge;

- everyone has access to the knowledge produced and, therefore, the same items will not end up being reinvented; and
- learning productivity is made greater by the fact that an individual can learn to learn by reproducing the knowledge of others.

An example of communities with high levels of bonding is what Lave and Wenger (1991) have termed communities of practice. Knowledge production is about collective practices that may or may not be formalized. It involves learning that takes place within certain contexts. The links between knowledge production and learning is apparent on the surface, but not always recognized. A community of practice defines itself along three dimensions (Wenger, 1998):

- its content, that is, what it is about as a joint enterprise continually renegotiated by its members;
- its mode of functioning, that is, the types of engagement that bind members together into a social entity; and
- its capability, that is, the shared repertoire of routines, vocabulary styles which members develop over time.

The overlap with some of the dimensions already identified is evident, but the emphasis is different. Reference to communities of practice shifts attention to the ways in which people work together, and it places the accent on the close connection between knowledge and activity. In other words, the community is formed and continually reformed not only through the exchange of abstract knowledge, but also through the activities which constitute the ways in which members of the community relate to each other. Lave and Wenger's interest is in how educators form such communities; it therefore extends the range to include relationships between teachers and learners, although without placing them in two separate categories.

High Levels of Bridging: Open Source Communities

Networks of knowledge rich in bridging social capital are important, in that they bring together ideas, values, and approaches from potentially very different groups and individuals. The combination and recombination of these ideas is a great potential source of innovation. Granovetter (1973) referred to this as "the strength of weak ties." His illustration is the fact that people find jobs not through sources strongly tied to them (i.e., in their community) but through more peripheral contacts. This is so because it is those individuals further removed who have access to very different communities and can form a unique bridge to these other communities. While

networks may be less dense and ties less strong, this also makes for a greater inclusiveness, increasing the likelihood that ideas developed in very different communities are shared.

More recent technological developments have enabled the growth of new forms of communities of knowledge with potentially high bridging social capital. One outstanding example is the development of the open source movement and, following on that, of the emergence of open educational resources. The open source is a community-based approach to software developing based on voluntary participation and voluntary selection of tasks. Anyone can join an open source project, and anyone can leave at any time. The collaborative development process of open source software, strongly simplified, starts with a software developer trying to solve a problem he or she is facing. The developer needs a particular application that does not exist and decides to write it and invites others, who might have the same problem, to collaborate. The collaborators propose new features, modifications of the code or bug fixes that might or might not be accepted by the original developer. Small projects might have simple decision-making processes; larger ones develop hierarchies of gatekeepers, developed on an implicit principle of meritocracy.

Open educational resources (OERs) are digitalized learning materials placed on the Internet with free access. OERs are a much more recent phenomenon than the open source movement that inspired these. It is, therefore, uncertain whether its further growth will take a quite different path. However, in any case, OERs are beginning to have an impact on education. More and more educational institutions, including elite ones, are moving to create OERs, for reasons of prestige, position, or social responsibility. Developments are also taking place from the bottom up, as individuals from very different backgrounds join together over the net to pool their knowledge and experience in the form of learning materials (OECD, 2007) on a permanently evolving basis. The spread of OERs is potentially significant in terms of opening up access to educational materials worldwide; it also poses a number of issues in relation to sustainability, ownership, and intellectual property.

One of the most significant features of the OER trend is the way in which its potential to be open and free depends nevertheless on the existence of a clearly defined framework within which those terms are to be understood. Access to the materials does not bring with it access to teaching or to certification: the fact that the materials from all courses taught at MIT (and now many other universities) are available freely on the web does not mean that anyone can sign up for a course there. Nor does the fact that OER materials can be remixed, modified, and then retransmitted mean that anyone can

appropriate them. Membership of the OER community can take a number of forms, some quite ideologically connected to collective improvement, and some geared to organizational change or other motives. It is a good illustration of how loose and diverse networks can be.

System Level Networks: The Triple-Helix and Brokerage Institutions

On a system level, high bonding social capital is less probable because of size-related issues (and, therefore, to the social and spatial distance between individuals) and the diversity within many systems. Increasingly though, as a consequence of several developments, like the shift in knowledge production from mode 1 to mode 2, bridging social capital becomes an important aspect of successful research and innovation systems.

Etzkowitz and Leydesdorf (2000) introduced the concept of the triple-helix to refer to the new relationships between university, industry, and government. In their analysis, there is an increasing collaboration and overlap of mission between these three formerly separate spheres. This has many different aspects. For example, within universities there is increasing stress on collaboration with industry; this has resulted in developments like intermediary offices, spin-off firms, and science parks. At the same time, science-based companies can no longer afford to be isolated organizations. In an increasingly global and competitive environment, firms need to access sources of knowledge and technology outside their own organizational boundaries. Companies are increasingly working together with universities and even other firms and government laboratories as a potential source of useful knowledge and technology. These kinds of cooperative developments are often encouraged by government both at the regional and national levels. Of course, there are also conflicts of interest and issues about intellectual property and its relation to basic research.

All of this means that the linear model of innovation, a one-way flow from fundamental to applied research and to product development is replaced by new ideas and alternative models based upon interdisciplinarity and spiral feedback links between technology and science. The essence of the triple-helix model is that the interconnection between industry, government, and science has resulted in a layer of tri-lateral networks and hybrid organization that not only in itself is in permanent transition, but it also permanently challenges the three founding systems of this layer.

In the field of education, this process can be observed in the increasing interest in strengthening links between educational researchers, policymakers, and practitioners (OECD, 2007a). This reflects in part a concern in many

countries over the weakness of education as a knowledge-based service. Ironically, education, in spite of being the basic producer of most knowledge-generators, does not seem to draw systematically and extensively on a knowledge base.

One approach to tackling this has been to set up various agencies or initiatives designed to improve these linkages, sometimes referred to as brokerage agencies. There are practical and specific goals, such as to strengthen the quality of the research on which policy is based. The aim is often also to expand the capacity of the research community, making more explicit (less tacit) the kinds of rules which govern, or ought to govern, research and bring in a wider range of stakeholders. Arguably, this trend exemplifies a move to shift the education research community from bonding to bridging. The point here is that, there is a conscious attempt to extend and diversify the member of communities whose function it is to expand and strengthen the knowledge base of education as a service.

Conclusions

Important work needs to be done in making some of the research findings on networks and communities of knowledge relevant to educational policymakers and leaders. This would entail moving from describing and analyzing already existing networks and communities to thinking about how communities and networks can be created, successfully sustained, and steered in the right direction. Two major issues stand out here.

A first main issue is the relationship between traditional policy instruments, such as regulation, funding regimes, and inspection, on the one hand, and communities and networks on the other. Leadbeater (2005: 22) warns that the collaboration needed for effective networks “can be held back by regulation, inspection and funding regimes that encourage schools to think of themselves as autonomous, stand alone units.” Levin (NCSL, 2005b: 6) agrees with this point of view, pointing out that there “are inevitable tensions between the idea of learning networks, which are based on ideas of capacity building as a key to reform, and . . . reform through central policy mandate.”

A second important question is: what does leadership mean in the context of horizontal and fluid networks? Mulford (2007) points out the importance of leadership for the creation of both bridging and bonding social capital. Leadership in this context involves activities such as ensuring the participation of the right kind of people (courting) in networks and ensuring that, once trust is established, parameters are set for collaboration, resources are secured, and, at all times, a critical mass of enthusiasts participate fully in the network (aligning). In other words, leadership, of a very particular nature, is of key importance for effective networks and communities of learning.

However, the relation between formal leaders and communities and networks of knowledge is not problem-free. Traditionally, leaders derive their authority from their position in formalized hierarchies. Authors like Edith Rusch (2005) point out the inherent conflicts between fluid networks and the formal system. Structures are seen as malleable in networks but fixed and hierarchical in the system. Conflict is open and valued in networks, whereas it tends to be hidden and feared in the system. Communication is open and unbounded in networks, but controlled and closed in the system. Leadership tends to be fluid in networks, whereas it is hierarchical and assigned in the system. At least some of these tensions need to be resolved for leaders to be effective in networks and communities of knowledge.

It would be easy to oversimplify the place and functions of networks and communities of knowledge, just as it is easy to indulge in simplistic rhetoric about knowledge societies. Key needs are for further refinement of the typologies of the mechanism for the development and exchange of knowledge; further empirical application of models to explore the trajectories – including decline as well as growth – of different communities; and the impact on the quality, distribution, and utilization of knowledge in different social and occupational contexts.

School Community Relations

R L Crowson and E B Goldring, Vanderbilt University, Nashville, TN, USA

© 2010 Elsevier Ltd. All rights reserved.

A movement to establish clear standards for school performance and use standardized tests of student achievement to assess that performance is at the heart of recent educational reform in the US. The central objective of these reforms is to improve the quality of schooling, particularly to improve the educational attainments of those students who have tended to be left behind by the schools and the larger society.

The standards movement in the US is regarded as a top-down initiative with much federal government involvement. This is rather unusual within a system of schooling long celebrated for local control. Despite the increased federal role in education, there has also been a resurgence of localism in the early twenty-first century. Particularly, there has been a resurgence of interest in the bottom-most unit in the educational hierarchy: the individual school and its surrounding community or neighborhood. Generally known as the new localism in education, this restored emphasis on the local school site, and its community relationship is by no means breaking away from the emphasis upon national standards and their attainment. A primary focus upon student learning and upon measurable evidence of school effectiveness in instruction remains a central objective. Explorations of how schools and communities can be linked and can interact successfully around both student learning and school improvement provide the driving questions in studies of the community relationship in the new localism paradigm.

As an approach to understanding and using the school–community relationship to improve learning, the new localism covers much territory. Four broad categories are central:

- a sense of place and a new pedagogy of place in education;
- the importance of community capacity and social capital in learning;
- communities and families as key instructional resources; and
- a new local politics of partnership and empowerment in education.

This article addresses each in turn and considers some actions for leaders in education.

A Sense of Place and a Pedagogy of Place

In the opinion of many scholars, the new localism starts with a concept of place (Driscoll, 2001; Smith, 2002;

Gruenewald, 2003). Interestingly, a longtime criticism of localism was that the schools and their clientele can all too easily be seriously constrained by the cultural myopia, the prejudices and narrowness, and the restricted range of norms and values that characterize their closely surrounding communities. From this perspective, it was a central mission of the educator to broaden horizons, introduce children to competing values and perspectives, and open minds to a much wider world than they tend to find in their own neighborhoods. A sense of place from this perspective was a limiting, not an enlarging, concept.

Perspectives have changed, and a rediscovery of the importance of place is emerging. Researchers and educators are recognizing that while the schools do need to widen horizons for their students, the schools are indeed embedded in their communities, and much that defines or characterizes the community is embedded in the schools. Family values, local dialects and language patterns, area lifestyles, neighbor-to-neighbor linkages, day-by-day patterns of activity, physical surroundings, the nature of the neighborhood economy, and neighborhood safety/security – all matter, and matter in ways that influence the work of the schools.

In an examination of the concept of place, Driscoll (2001) identified four central dimensions: (1) Place has a territorial dimension, a topography that is characterized by particular features and which can often be fixed in our long-term memories. (2) Places have boundaries, which provide roots and help us to mark the known from the strange and unfamiliar. (3) Places are endowed with social and cultural meanings, a socially constructed source of cultural socialization and behavioral learning for us. (4) Places have a temporal quality – helping us to organize the past, present, and future, and often help share experiences across generations.

What are the key implications of a sense of place for the schools? Again, Driscoll (2001) suggested a set of four implications: (1) Schools as spaces matter, signifying their own place in the community as centers of children's development and learning. (2) School boundaries matter, respecting the neighborhood as an integrative whole without establishing a fortress mentality that keeps other influences out. (3) History and culture matter, wherein the (often unique) cultural narrative of a community is also embraced by the school. (4) Roots matter, helping children learn who they are by virtue of where they are.

Smith (1998, 2002) and others (Gruenewald, 2003a, 2003b; Martin, 2001; Theobald and Curtiss, 2000) have

translated the concept of sense of place into suggestions for a curriculum of place-based education. Some early forays involved arming students with cameras to capture what they might personally see in their own neighborhoods. Other early efforts in the mid-1990s, as noted by Smith (2002: 589), involved students in in-depth explorations of their nearby natural environments, investigating the regional cultures in their part of the nation, some service learning and real-world problem solving vis-à-vis their communities, and explorations into work lives and occupations in their communities.

A central objective of place-based education, summarized by Smith (2002: 594), is to “resituate learning within the context of communities,” strengthening “children’s connections to others and to the regions in which they live.” This effort reconnects, rather than separates children from the world, serving both individuals and their communities.

Beyond the design of curricula, another example of place-based learning is supplied in Morris’ (2002) study of a single African American community in St. Louis and its longtime relationship with the neighborhood school, Farragut Elementary. In describing what he refers to as a communally bonded school, Morris (2002) identifies a tie between a low-income minority population and its academically strong elementary that transpired for many decades.

Among the key elements of place that specifically drew the school and community together, noted Morris (2002), were a number of actions. First, they cultivated intergenerational and cultural bonds, especially supported by the school’s tradition of serving as a site for historical and cultural celebrations for the community. This led to such an extremely low incidence of faculty turnover that children often received teachers who had taught their parents. Second, they reached out to families with many parent-invited functions and special events. There was a tradition by the school’s longtime principal to attend nearly every wedding, graduation, and funeral occurring in the community. Third, they emphasized personal and symbolic excellence, with teachers playing parent-like roles as they expected high-quality achievement as well individual-level responsibility. The school was positioned as a church-like substantial pillar of the black community.

The Importance of Community Capacity and Social Capital in Learning

There was a rapid expansion of efforts to coordinate children’s and family services throughout the United States from the late 1980s on. With roots in some of the Great Society interventions of the 1960s, many realized by the 1980s that several service needs of families and their children in poverty circumstances were not being met; these unmet needs could be interfering with

children’s opportunities for successful learning (see Kirst, 1989; Levy and Copple, 1989; Kagan and Neville, 1993).

An added problem was that the few available services to families were frequently so haphazardly delivered and so widely fragmented that little improvement in the lives and educational opportunities for children in poverty seemed likely. Following both state legislation (starting in New Jersey, Kentucky, and California) and major private foundation support, concerted efforts to provide coordinated services to families developed quickly across the US (see Smrekar and Mawhinney, 1999).

The services ranged widely from health clinics to family counseling, employment training and assistance, parenting classes, English-language learning, and housing/welfare assistance. As the services movement matured a bit, attention turned to the addition of programs of direct assistance to students via after-school tutoring, youth-development programs, summer schooling, pre-schooling, and day care (see Behrman, 1999; Jacobson, 2000). The services were sometimes school based, with facilities located on school grounds often in mobile units. In other places, they were school linked, that is, the services were held in other social-service agencies with efforts to bridge effectively between multiple service providers (e.g., churches, libraries, and boys and girls clubs) and local schools.

It was quickly discovered that the coordination of children’s services, particularly the coordination of the school-based variety, was extraordinarily difficult to achieve (Crowson and Boyd, 1993; Smylie *et al.*, 1994). Additionally, some major foundation funding was discontinued in the mid-1990s, amid disappointing results (White and Wehlage, 1995). Perhaps most significantly, a realization developed that the delivery of added professional services to families falls far short of the full scope of efforts needed to strengthen families and improve learning opportunities for children (Schorr, 1997; Driscoll and Kerchner, 1999; Boyd and Crowson, 2001).

By the late 1990s, a paradigm shift developed in the services movement that has continued on into the twenty-first century. First, interest began to focus on community development in place of service delivery. Key goals of community development include improving the economic, social, and cultural capital of the communities, along with the abilities of communities to use their capital to assist in the learning and development of the community’s children. Second, the movement has refocused interest around strengthening communities in order to strengthen the schools with a direct pedagogical emphasis upon evidence of improved learning.

An excellent exemplar of the shift from services to capacity for learning is found in the UK. In what British authorities prefer to identify as joined-up thinking, close to 25 education action zones (EAZs) were announced by the New Labour government in 1998, with a second round

of zones added a year later. The EAZ concept is built upon community development partnerships between an array of private, voluntary, and public agencies representing many societal sectors (e.g., business, health, welfare, recreation, church, and police; Power, 2001). There is typically close partnering with the schools and often, an identification of standards for EAZ success, such as achievement gains, improved school attendance, and reduced school leaving (Storey, 2005).

In the EAZs, there is also a deinstitutionalization of learning (Power, 2001: 24). The idea of deinstitutionalizing learning represents an effort on the part of each zone to take learning out of the sole responsibility of the classroom toward extended learning opportunities throughout the community. This is often achieved through partnerships with a local airport, engineering and construction firms, a local trucking company, or local retailers. The idea of creating extended learning systems for communities, which include, and also go far beyond the schools, has also been proposed in the US, in a 2007 report by a special task force funded by the Mott Foundation (Greifner, 2007).

An important issue in extended learning is how to pay for it. Increasingly, the twin notions of capacity and extended learning have led to an interest in extended funding. Picus *et al.* (2002) discovered that less than half of the money spent on children's education in Los Angeles and in many communities can be accounted for in the funding allocated to neighborhoods by the public schools. Many additional resources, with important learning consequences, flow out of the work of childcare servers, after-school offerings, nonprofits, youth services, city agencies, and, of course, family-to-family spending.

Picus *et al.* (2002) proposed an examination of the total public resources spent on children and families in specific geographical areas, and proposed further some financial rethinking around the idea of a children's budget for education in place of the traditional school-to-school budget. One major city that has come close to implementing this concept is Toronto, Canada – which produces an annual report card on children, tracing allocations of family services by census tract across the city, linking these data to trends in school achievement over time zone by zone.

The notion of capacity, in providing communities with opportunities to influence children's learning, is not limited to economic resources and investments. Sanyal (1994) draws upon the work of Hirschman (1971) in noting that the social construction of hope in a community can be a powerful developmental force. A community's capacity to monitor the institutions that serve it also represents an important strength, one that emerged as a key element in the empowerment of low-income communities in Shirley's (1997, 2001) research into Texas' Alliance schools. Another important element is the connective

capacity of communities (Yoshikawa *et al.*, 2006), wherein networks of families influence learning opportunities by helping one another, helping with elements such as neighborhood security, and passing on information to one another. Franklin and Savage (2004) documented the remarkable connectedness that often characterized African American communities and their drive toward educational advancement in the US, in predesegregation times (see also Anderson, 1988; Franklin, 1992; Walker, 1996).

While capacity is a term often used at the community level to describe the resources available for learning, the closely related and equally important concept of capital is typically used at the family level of analysis (Coleman, 1987, 1988). The financial capital available to a family is rather self-evidently important, for there can be wide variations in the resources that families, on their own, devote to their children's education. Human capital is not uncommonly regarded as the central measure of educational accomplishment for both individuals and the larger society. For individuals, human capital is often measured in terms of school attainment as a representation of earnings potential.

Cultural capital casts a wide net around learning-related patterns of child rearing, language use, family values and priorities, lifestyles, traditions, and concepts of right or wrong. Cultural differences, once commonly viewed as deficits by many educators, are now much better understood as frequent sources of cultural strengths. These strengths can be drawn upon in their own right and in their own way for improved learning (see Lareau, 1987, 1989; Trueba, 1999, 2002). Finally, social capital represents an important element of family access to resources by virtue of their connections, networks, and interactions with other members of the community (see Coleman, 1988; Putnam, 2000, 2002; Putnam and Feldstein, 2003). Social capital is used by parents in navigating their way through the structures and processes of schooling, and in their own involvement in school activities (Sheldon, 2002).

What is especially important in the school–community relationship is the ability of the school to activate the social capital of families in the surrounding community. Two terms used frequently in the consideration of activating and extending social capital are: bridging and bonding. Bridging attempts to bind across social distances; it is important, observe Putnam and Feldstein (2003: 279), “for reconciling democracy and diversity,” and for engaging successfully in the “tough task of fostering social ties that reach across social divisions.” Bonding social capital reflects the ties that link individuals or groups who do have much in common. Through bonding, community members reinforce shared identities, norms and values, traditions, likes and dislikes, and togetherness. The term can reflect the time parents and children share and interact together, including the time parents and children spend on learning activities (Coleman, 1988).

Communities and Families as Instructional Resources

Once held at arms length by school administrators, the realization today is that communities and families are vital parts of the learning equation. From a conceptual perspective, this realization owes much to advances in cognitive science, particularly with the development of a well-focused body of recent inquiry into how people learn (Bransford *et al.*, 2000).

Often labeled the new science of learning, the cognition theory understands that knowledge is best mastered when it is developmentally scaffolded onto preexisting knowledge, the lion's share of which learners bring to school from home and community contexts. The community context can both help and hinder in-school learning, but at the very least, argue Bransford (2000) and others (see, Driscoll and Goldring, 2006; Melaville *et al.*, 2003), the school should seek to understand the out-of-school context and should use that context effectively in its own instructional programming. A community-centered approach to instruction is urged, wherein both a deep understanding and a wide use of the nonschool environment are central to the school curriculum. Melaville *et al.* (2003: 27) note "effective learning occurs when schools, after school programs, and other organizations use the resources and challenges of the community as a living textbook for learning."

A community-centered approach to schooling proceeds from the ecological understanding that each community is a web of learning environments. Rather surprisingly, despite increasing interest in and attention to the community context, there has not yet developed an exceptionally strong knowledge base for educators to draw upon in using the community effectively as an instructional resource.

Traditionally, the focus in attempting to strengthen the school-community relationship has been upon the use of partnerships and collaborations (see Henry, 1996; Rigsby *et al.*, 1995). However, not every part of a community will or can partner. Yet, many nonpartnering elements in the community are still quite essential to learning. Thus, the renewed goal is to seek to engage the community instructionally, rather than to partner with it.

Four key areas of school-community engagement are generally found in today's learning environment: (1) programming to meet the needs of children, (2) the active engagement of parents in learning, (3) linkages with other community institutions in assisting the work of the schools, and (4) actions to help build a community's capacity for learning.

Schools throughout the US have increasingly been drawn, often through legislative mandates, into taking responsibility for attending to the special needs of children and youth. This has required deeper relations with an array of other social service agencies such as welfare,

housing, health, nutrition, and delinquency prevention and treatment. The current emphasis upon student achievement in educational reform provides an added incentive to help those with difficulties in learning. Thus, a much wider array of service relationships are now found helping families in areas such as financial and legal services, counseling, medical care, tutoring, English-language learning, and after-school programming (Springate and Stegelin, 1999).

As never before, parent involvement is accepted and encouraged in schools throughout much of the US. The usual array of homework activities has been broadened in many locales to include assistance to families with parenting skills, access to family support services, counseling assistance, legal services, and the like (Springate and Stegelin, 1999; Epstein *et al.*, 2002). Traditional roles for parents in the school have been to assist at ceremonial levels of involvement. However, over time, roles for parents in learning activities within the school have broadened considerably to visiting classrooms, tutoring, and performing aide roles (Sandell, 1998). Increasingly, the schools have also become more comfortable with advisory and governance roles for parents. Most recently, in some schools, parents are able to play a direct role in school evaluation or assessment (Springate and Stegelin, 1999).

Some scholars have expressed a concern that the overall level of civic engagement between families and community institutions, including the schools, is on the wane (see Skocpol and Fiorina, 1999). Other observers claim that the learning-related engagement of broad-based community institutions (from faith-based to business to community organizations, to health care, to the non-profits) remains strong and is, in fact, on the increase (Chadwick, 2004). Both observations may be true. Communities vary enormously in their sense of themselves as an engaged, education-minded collectivity. Chadwick (2004) notes, however, that an engaged community tends to demonstrate greater social capital, an added commitment to education, and improved student achievement.

Finally, an engaged community can increase its capacity for learning – with interorganizational connections, and broker organizations that help to negotiate relationships for improved learning. These communities can also develop specialized partnerships with specific organizations toward well-defined ends such as a coalition of police, youth organizations, neighborhood-watch volunteers, and business leaders to help reduce crime (Chaskin *et al.*, 2001).

A Local Politics of Partnership and Empowerment

The new localism in education is also reflected in altered political relationships at the community level, and in new

approaches to the empowerment of the school clientele. Two models that have surfaced most impressively in the twenty-first century are: (1) an alliances approach to community organizing for school improvement (see Shirley, 1997, 2001; Crowson, 2003) and (2) a preferences or choice model of client empowerment (see Berends *et al.*, 2007).

Much of the community organizing that characterized early efforts attempted to empower individual communities toward taking charge of their local institutions, including the schools. These efforts heavily focused upon organizational enemies, with a confrontational style that could often be quite successful in bringing inequities to light and in calling public attention to unmet needs. Much of this approach, however, was heavily based upon alienation, rather than cooperation. The result was often brief, without lasting cooperation. By the late twentieth century, this old-style activism began to be replaced by a much less confrontational style in community organizing. There was a movement toward a strategy of working with community institutions, rather than against them. Interestingly, many of the alliance initiatives in the US that used community organizing around improving the public schools came out of the early leadership of faith-based institutions.

Shirley (1997, 2001) described, in depth, some of the first community alliances that developed in low-income neighborhoods in the state of Texas. These alliances used a strategy that often started with small goals such as seeking an added school crossing guard at a busy corner, and subsequently continued on to greater and greater activity and engagement in school improvement. Shirley noted that by mid-2001, a network of community alliances in Texas had grown to nearly 150 schools, all based in some of the poorest communities in the state. The alliances approach to community organizing around school reform has subsequently spread to other states around the US. The public- and private-sector cooperation found in the alliances arena is quite similar to the EAZs effort in the UK.

Also widespread in the US is a strategy for school improvement through local empowerment that relies heavily on the choices and educational preferences of individual families. The capacity to vote with one's feet, that is, to exit a low-performing school to a private school or move to a higher-performing school district has long been available to families of means, those who can afford such a move. A rationale of the current choice movement in the US is that the same set of options should be available to lower-income families. The rationale continues, with a belief that the availability of choice creates competitive pressures upon the public schools to improve.

Choice options have become increasingly available across much of the US, in the form of a steadily growing array of magnet schools, charter schools, and, to a somewhat lesser extent, voucher-supported schools. The numbers, along with the terms and conditions of their

development, vary considerably from state to state. The federal education reform legislation in the US allows students attending under-performing schools to transfer to charter schools, with the money following the student to the charter school. The district is responsible for transportation as well. Kirst (2007) has observed that charter schools had spread to 40 states in the US between 1991 and 2005, but only 21 of the states have strong charter laws permitting and encouraging significant expansion and innovation.

The choice phenomenon has grown so rapidly in the US that many of the larger implications for communities remain to be fully investigated. In some early inquiry, Smrekar and Goldring (1999) found that individual families do not tend to choose to move toward a new and better school, but choose instead to move from a school with which they are dissatisfied. The same authors expressed a concern about a possible paradox of choice, in which individual preferences and one-family-at-a-time empowerment can result in a loss of connections in the geographic community (Smrekar and Goldring, 1999). Nevertheless, observe DeBray-Pelot *et al.* (2007), school choice advocacy remains extremely lively in the US, and currently transcends traditional (left-right) ideological positions.

By no means is the US alone in the use of choice- and market-oriented approaches to school reform and to local-level empowerment. West and Hind (1997) note that across much of the world, there has been a press toward greater reliance on the market in educational improvement (see also Glenn, 2007). In examining parental choices among state-maintained secondary schools in London, West and Hind (2007) found clear differences by type of secondary school in school composition across racial, ethnic, and income divisions. Glenn (2007), in examining choice programs adopted by Denmark, France, and Spain, notes that there are deep questions surrounding school choice in finding a balance point in empowerment between local autonomy and governmental accountability.

Summary

Centralizing tendencies, with emphases upon national standards and outcomes-based accountability, have provided a foundation for recent school reform, particularly in the US. At the same time, there has been a restoration of considerable interest in the basic unit of education: the individual school site and its surrounding community. Described as the new localism, this restored interest in the school-community relationship is rooted in the central objective of improved opportunities for student learning. Four broad categories that focus on improved learning in the school-community relationship and the new localism have emerged: (1) the role of place in

education, (2) the importance of local capacity and capital in learning, (3) the community and the family as instructional resources, and (4) an emerging politics of the school–community relationship around two very different models of alliances and choice.

In the opinion of many scholars, the new localism starts with a concept of place. Schools matter as places in their communities, and places matter as social and cultural settings for the schools. Represented in the concept of place are important developmental elements in learning – such as cultural socialization, the development of a sense of roots, shared experiences and memories, and socially constructed patterns of behavior and language. A pedagogy of place-based education has also emerged from the place concept, with the central objective of resituating learning for children within the context of their communities and strengthening the connections of children to other persons in their communities.

It has been thoroughly recognized for some time that some communities are less able than others to provide the elements of capacity and capital that facilitate successful learning in school. Efforts to compensate for weakened capacity characterized state and national assistance to schools and communities in the US from the 1960s on, and further characterized efforts to provide coordinated children's and family services (or full-service schooling) in many areas later in the century. A paradigm shift has occurred in twenty-first-century efforts to generate added community capacity and social capital. The shift is well represented in programs in the UK which engage actively in community development. These initiatives are often an array of public and private partnerships geared toward capacity development and the institutional extension of learning opportunities community-wide, beyond just the schools.

A new science of learning is a natural accompaniment to the new localism. It recognizes that learning in school environments builds, or is scaffolded, upon learning that comes initially from home and community contexts. This perspective also takes into account the realization that each community is a web of learning environments that includes, but is by no means limited to, the school. It furthermore recognizes that successful schools can develop out of and profit mightily from outreach efforts to bring about active engagement of parents, community institutions, local leadership, profit sectors, and the non-profits into sets of learning connections.

The new localism is also represented in community empowerment, but best represented in two quite different models at present. Alliances of community institutions and the schools, using community organizing toward shared school-improvement efforts, have gained increased attention and credibility, particularly across the US and England. Simultaneously, the empowerment of individual families and students through the use of choice has gained considerable interest across many nations of the world.

The consequences of choice for communities and the consequences of using market forces as the key vehicle to improve opportunities for learning remain to be fully understood; however, these topics are currently receiving considerable research attention along with a good bit of policy experimentation around the globe.

Social Capital, Educational Institutions and Leadership

S Kilpatrick and S Johns, University of Tasmania, Launceston, TAS, Australia

The idea of social capital has enjoyed a remarkable rise to prominence. The concept now sits alongside other forms of capital (such as economic and human) as an accepted contributor to our individual, community, and national well-being. International bodies such as UNESCO, OECD, and World Bank have engaged in extensive conceptual, empirical, and policy-related work in the area (Isham *et al.*, 2002) and a number of websites are devoted entirely to the area. However, the application of the concept of social capital to educational institutions has been limited.

Yet, schools, universities, and other educational institutions are taking on a much broader role than just educating students. Schools and universities are enduring institutions in our communities. As a result of the changing nature of Western society and the weakening of social institutions including the family and church (Coleman, 1988; Driscoll and Kerchner, 1999) there is an expectation on the part of the public and governments that educational institutions will contribute to the greater good of the communities in which they are located. By building social capital, educational institutions can play a community development role that will create and promote better opportunities for students and other community members.

What Is Social Capital?

In a recent analysis of contemporary academic literature in the area, the World Bank (Grootaert *et al.*, 2004) found that social capital has been discussed in two related but different ways. The first approach was subjective or cognitive in nature and referred to the resources (such as information, ideas, support) that individuals were able to procure by virtue of their relationships with other people (Portes, 1998). The second approach was structural in nature and referred to the type and extent of one's involvement in various informal networks and formal civic organizations (Putnam, 2000).

However, social capital is defined most simply as the norms and networks that enable people to act collectively (Woolcock and Narayan, 2000). It is a set of resources that resides in the relationships among people that allows them to share their knowledge and skills, or human capital. Sharing of knowledge and skills is facilitated by structures, procedures, and mechanisms that bring people together in places and environments that encourage and

support interaction (Coleman, 1988). Social capital is simultaneously drawn on and reproduced (used and built) in collaborative action. The quality and nature of social capital depends on the qualitative dimensions of the social interactions in which it is produced, such as the extent and quality of trust, reciprocity and shared values, and norms (Falk and Kilpatrick, 2000). Social capital is associated with social cohesion and civic participation.

Field (2005) argues that social capital is an independent variable that explains some variations in learning. People's social relationships play a vital part in their capacity for learning. Social connections help generate trust between people, and thereby foster the exchange of information and ideas. People's networks are learning resources, which can give them greater access to and enhanced capabilities of using, information and skills. Schuller (2007) argues that human capital which is not linked to social capital is harder to acquire and its value is harder to realize.

Social capital is a useful lens for analyzing lifelong learning and its relationship to community development (Kilpatrick *et al.*, 2003). Community social infrastructure, in particular organization structures, rules and procedures, opportunities for meeting, and human infrastructure, influences the effectiveness and efficiency of networks and associated norms. Schools, universities, and other educational institutions are significant pieces of community social infrastructure, and their leadership and staff are part of a community's human infrastructure that can forge and maintain networks and share and influence norms.

The concept of social capital is multidisciplinary, drawing on sociology, economics, political science, and education. From the sociological perspective, Bourdieu (1983) identified cultural, symbolic, and social capital, all of which he regarded as disguised forms of economic capital. Coleman (1988) applied social capital in analyzing how the family, schools, and community generate human capital. Trust emerged as an important dimension of social capital in Putnam's (1993) work on the relationship between differing civic traditions and democratic effectiveness in Italy. Work by the OECD and others (Schuller, 2001) has found that social capital enhances the effectiveness of physical and human capital; it oils the operation of industries, organizations, and communities by facilitating access to networks. Trust smoothes negotiations and so reduces transaction costs.

There are three types of social capital networks or ties. Bonding networks are ties with like others, typically family, friends, or members of a tribe. Bridging networks connect acquaintances or others in similar positions in different groups or communities, that is, those outside the close social or work circle. Linking ties are between those in different social groupings, or levels of the power hierarchy (Woolcock, 1999). Strong bonding social capital can act to exclude groups or individuals if it is not balanced by sufficient bridging ties, and is referred to as the dark side of social capital (Schuller, 2001).

Building and Using Social Capital

Social capital is built through interactions within and outside communities or groups. Falk and Kilpatrick (2000) identified two kinds of resources which people bring to interactions that are intended to result in some action for mutual benefit: knowledge and identity resources. Knowledge resources are a knowledge of who, when, and where to go for advice or resources and knowledge of how to get things done. Knowledge resources relate to networks, and an understanding of procedures and how people work effectively together. Identity resources are being able and willing (committed) to act for the benefit of the group or community and its members. Identity resources include self-confidence, norms such as reciprocity, trust, and values

and visions that are shared between the parties in the interaction. Falk and Kilpatrick's model of building and using social capital is reproduced in **Figure 1**.

Opportunities for individuals and groups to interact are important, because they allow people to use their social capital for mutually beneficial actions, and also help build or strengthen social capital. However, the quality of the outcomes possible from interactions depends on the quality of the social capital resources that are used.

Social capital has been criticized as difficult to measure, which it has been argued has reduced its uptake and application in policy. In addition, a number of studies that have attempted to link schools to the development of community social capital have been criticized because of their largely qualitative nature (e.g., case studies), or lack of specific measurement indicators. There are, however, a number of well-accepted indicators:

- voluntary participation;
- trust;
- reciprocity;
- shared norms, values, attitudes, and vision;
- network extent and structure;
- acceptance of diversity; and
- identification with the community.

Educational institutions have two spheres of influence in terms of using and building social capital: (1) building social capital within the education institutional community

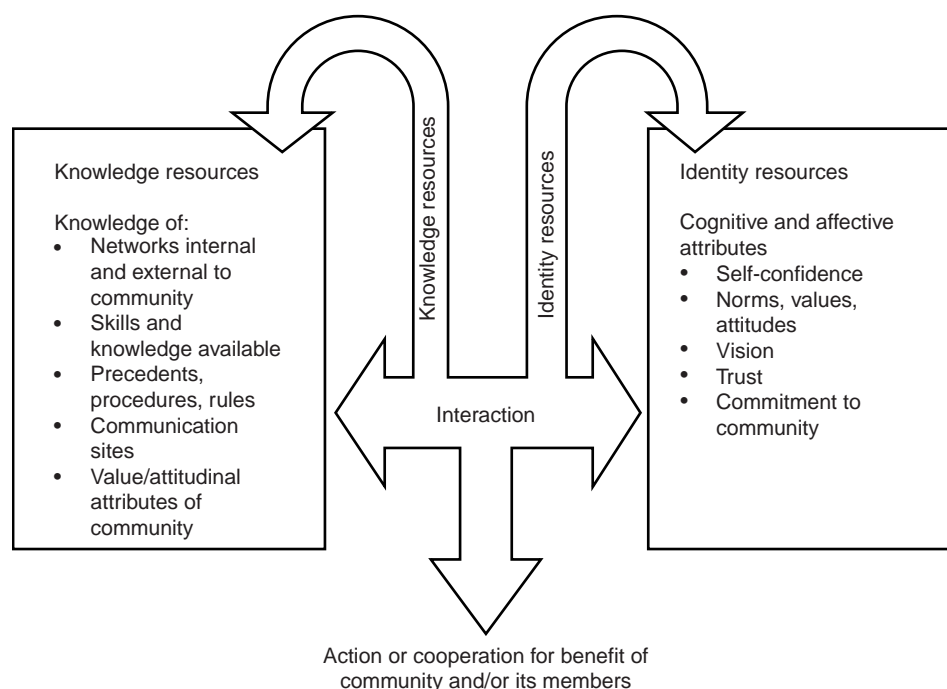

Figure 1 Building and using social capital. From Falk, I. and Kilpatrick, S. (2000). What is social capital? A study of interaction in a rural community. *Sociologia Ruralis* 40, 87–110.

(students, staff, parents) and (2) building social capital between institutional community and broader community. As the first is well documented in the research on learning organizations and professional learning communities, this article concentrates on the second sphere of influence, building social capital between institutional community and broader community.

Why Should Educational Institutions Build Community/Regional Social Capital?

The ability of leadership of the institution and community to draw on and build community social capital through collective learning, can deliver benefits to both. Educational institutions can supply the human infrastructure that makes collaborations and partnerships work. This includes enabling and supporting others to participate in the leadership process. The benefits for educational institutions and the community can be summarized as follows.

1. Benefits for educational institutions
 - Benefits for staff: responsibility for learners is shared within the community; drawing on and sharing knowledge and skills from a wider pool than just staff.
 - Benefits for students: increased access to employment and social networks, sense of identity and belonging within the community; building of inter-generational trust.
2. Benefits for community
 - Benefits for parents: social, health, well-being outcomes when schools are community hubs for delivery of services; development of social support networks.
 - Increased access to institutional facilities or shared institution–community facilities that may not otherwise be available locally; schools as hubs for lifelong learning for all.
 - Industry benefits from customized or targeted education and training provision for local needs.
 - Regional universities contribute to skilled regional workforces. They also bring a research capacity to their home locations that is rarely available elsewhere in the region. Research projects carried out locally can provide an opportunity for regional communities to examine their practices through a different lens. Research presents many opportunities for regional universities and their communities to learn together.

Regions where educational institutions, especially universities, business, and other organizations work and learn

together are more economically successful (Maskell, 2000). Social capital has been cited as the missing link in explaining the different economic success achieved by nations (and regions) with similar patterns of physical and human capital. There are similar relationships between social capital and social, cultural, and environmental benefits. It is no accident that much of the schools and social capital research focuses on either low socio-economic status or rural schools where the need to expand opportunities and build community is greatest. By virtue of their location within communities, and their place within a broader power hierarchy, educational institutions facilitate access to linking social capital for individuals and communities.

How to Build Social Capital between Education Community and Broader Community

Models

There are numerous examples of community engagement with educational institutions resulting in the building and use of social capital. These tend to fall into three broad groupings.

The first broad grouping is the educational institution as a community center or hub. Different models of educational institutions as community hubs exist, ranging from community use of educational facilities, to the delivery of health and welfare services through and with a school. Although specific terminology such as full-service schools, schools at the center, health-promoting schools and university–community engagement tend to come in and out of favor at various times, effective models demonstrate the critical role of educational institutions in building individual, family, and community social capital. Educational institutions promote community cohesiveness and identity through school/university-based events.

The second broad grouping is authentic learning opportunities with(in) the community. The move toward the increased use of learning opportunities within the community is reflected in community-based projects undertaken by school, technical and further education and university students, and vocational or technical education and training opportunities where students combine study at an educational institution with workplace experience. Evidence suggests that these activities have a range of social and economic benefits for individuals and communities such as increased youth retention in rural communities, the provision of lifelong learning opportunities for adults and more positive attitudes to education and learning within the community, and opportunities for employers to contribute to the community.

The third broad grouping revolves around the creation of new knowledge with the community. Institutions such as universities increase the research capacity of the community to connect to the global economy.

The Process

The development of social capital derives from a common purpose or vision between the educational institution and the community, and a process in which leadership is gradually shared between educational institution and community. Triggered by a need or opportunity, the process moves through an informal initiation stage that builds the foundation for a linkage or project to address the need or opportunity, towards a more formal development stage (see **Figure 2**).

Effective leadership for implementing institution–community partnerships goes further than involving or consulting with all stakeholders during the decision-making process. Rather, effective leadership for partnerships is a collective process during which educational institution and community go about developing and realizing shared visions. The stages of the leadership process for implementing school–community partnerships (**Figure 2**) illustrate how leadership gradually shifts from being the responsibility and domain of individuals early in the process, to a collective or group responsibility. That is, the vision of individuals at the trigger stage gradually shifts to a shared group (institution and community) vision during the initiation and development stages. The group develops a sense of ownership and common purpose in relation to the linkage

and, therefore, they have a vested interest in ensuring its maintenance and sustainability.

Criticism can be leveled at the project-based nature of many social capital building activities, and the associated fixed-term resourcing, leading to the question of whether such activities are sustainable in the long term or whether they create a culture of dependency. Schorr (1997) highlights the need for a systemic approach to the social capital building initiatives of educational institutions, to ensure their sustainability and replication.

A range of factors influences the extent to which educational institutions are able to develop the social capital of their communities. Those cited as having particular significance include the policy environment, resourcing issues including continuity of staffing, and leadership.

In many Western countries, there has been a move over the past decade or more, toward the development of government policy at all levels to support increased engagement between educational institutions and their communities. While such policy legitimizes community engagement activities by schools and other institutions, tension is created when there is a mismatch between policy and practice. Issues such as privacy legislation and public liability provide further challenges. Developing effective partnerships requires educational institutions and communities to learn together how to adapt, mould, and shape policy to support their vision, and to take risks when necessary.

Continuity of personnel is a key determinant of effective community engagement by educational institutions (Kilpatrick *et al.*, 2002). Rural and regional educational institutions and low socioeconomic schools, in particular,

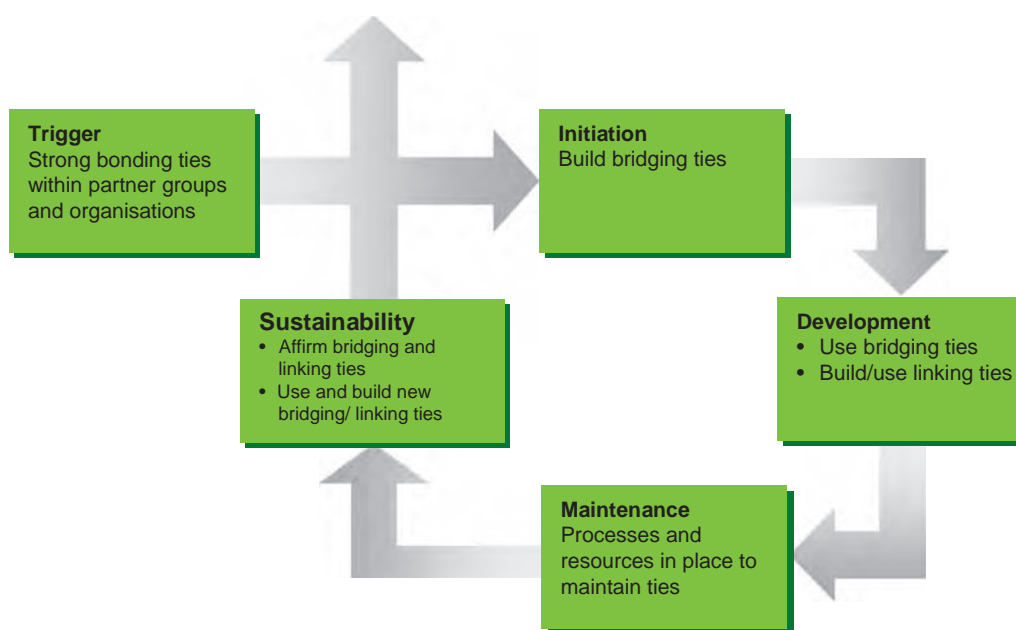

Figure 2 Building social capital through development of partnerships.

face challenges in terms of staff continuity, given their relatively high staff-turnover rates. Continuity of resources impacts on all stages of community engagement by educational institutions, but is vital as initiatives move from the development to the sustainability stage.

Leadership and Social Capital

There is increasing recognition by effective educational leaders of the value and legitimacy of community social capital outcomes, in addition to teaching and learning outcomes, and student outcomes (Mulford and Johns, 2004). Key players in unlocking and building social capital are formal educational leaders with a firm commitment to lifelong learning and a view of the community as one of a number of resources available to the school. Their roles include developing the leadership capacity of others within and external to the educational institution, and facilitating organizational learning.

In addition to the formal leaders, evidence (Kilpatrick *et al.*, 2002) suggests that effective community engagement is facilitated by boundary crossers, who speak the language of the educational institution and community, and are able to move freely between the two. Formal educational leaders recognize and nurture boundary crossers as integral to the process of community engagement.

Indicators of effective community engagement by educational institutions that use a social capital approach include the following:

- Educational leaders are committed to fostering increased integration between educational institution and community.
- Educational institution has in-depth knowledge of the community and resources available.
- Educational institution actively seeks opportunities to involve all sectors of the community, including boundary crossers, and those who would not normally have contact with the institution.
- Educational leaders display a leadership style which empowers others within the school and community and facilitates collective visioning.
- Educational institution and community have access to and utilize extensive internal and external networks.
- Educational institution and community share a vision for the future, centered on their youth and other learners.
- Educational institution and community are open to new ideas, willing to take risks, and willing to mould opportunities to match their vision.
- Educational institution and community value the skills of all in contributing to the learning of all.
- Leadership for engagement between educational institution and community is seen as the collective responsibility of the institution and community.

- Educational institution and community both view the institution as a learning center for the whole community, which brings together physical, human, and social capital resources.

Social Capital and Education in the Future

The concept of social capital is still as relevant as it was in the 1990s when it came to prominence. It underpins or is closely linked to concepts that have more recently found favor in the educational literature including learning communities, capacity building, and community engagement. The research evidence reviewed in these areas is clear in its strong support for social capital. The outcomes are impressive, not the least of which are improved student engagement, academic performance and later life chances, improved teaching and learning, reduced within-school variation, retention of teachers in the profession, and increased individual and community capacity to influence their own futures.

A way forward is to see the task of establishing learning communities as developmental, starting with the building of social capital (see Figure 3). A message is that those in educational institutions and their communities must learn how to lose time in order to gain time. Awareness of, and skill development in group and organizational processes is a first step in any effective change. Instead of others trying

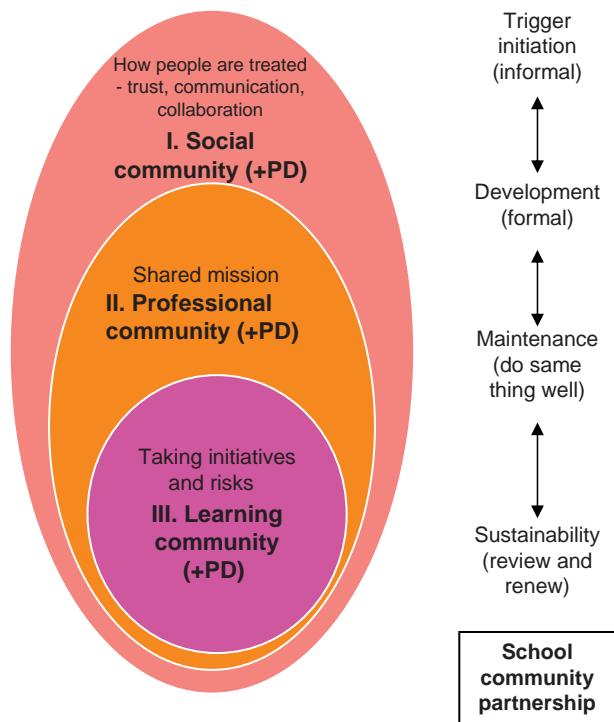

Figure 3 Social capital as the basis for learning communities.

to insert something into a school's or community's culture, the school and its community, and especially its leadership, should first be trying to help that culture develop an awareness of and a responsiveness to itself.

In brief, the position taken identifies three major, sequential and embedded elements in successful and ongoing school reform. It takes the two elements in the definition of social capital – groups, networks, norms, and trust – and for productive purposes, extends them to include a third element, learning. The first element in the sequence relates to the social community, how people are communicated with and treated. Success is more likely where people act rather than are always reacting, are empowered, involved in decision making through a transparent, facilitative, and supportive structure, and are trusted, respected, encouraged, and valued (see oval I in **Figure 3**). It is a waste of time moving to the second element until this social community is established. The second element concerns a professional community. A professional community involves shared norms and values including valuing differences and diversity, a focus on implementation and continuous enhancement of quality learning for all students, de-privatization of practice, collaboration, and critical reflective dialog, especially that based on performance data (oval II). But a professional community can be static, continuing to do the same or similar thing well. The final element relates to the presence of a capacity for change, learning, and innovation, in other words, a professional learning community (oval III).

Each element in this model, and each transition between the elements, can be facilitated by appropriate leadership and ongoing, optimistic, caring, nurturing training programs. Also, each element is a prerequisite for the other – as the ovals-within-ovals or eggs-within-eggs diagram implies, they are embedded within each other with only the emphasis changing. For example, when learning is occurring there is still a need to revisit the social community and the professional community, especially where there has been a change of personnel and/or a new governmental direction announced.

Using this analysis of social capital to understand the importance of, challenges to and developmental nature of communities, can assist in better translating the research into policy and practice. It can help us:

- understand better and be able to take action on the intricacies involved in moving an educational institution or community, or part thereof, from where it is now to becoming truly a place of ongoing excellence and equity without those in educational institutions and communities being bowled over by the demands for change that surround them;
- target appropriate interventions to ensure more effective progression through the stages. In targeting interventions, recognition will need to be given to the fact that it is a journey and that actions at one stage may be

inappropriate, or even counterproductive, at another stage; and,

- support the position that an educational institution and/or community will need to be evaluated differently depending on the stage it has reached (Mulford, 2007).

Leadership and Technology

C F Webber, University of Calgary, Calgary, AB, Canada

Information and communication technology has transformed societies around the world. The introduction of radio in the first half of the twentieth century meant that news and information could spread worldwide within hours rather than days, weeks, or even months. The subsequent widespread adoption of television in the 1950s and 1960s opened windows on cultures and lifestyles that were dramatically different from those of viewers and challenged previously unexamined assumptions, beliefs, and values. As powerful as the influences of radio and television were, they were relatively minor compared to the combined effects of millions of portable computers and databases linked by Internet providers around the globe.

Computer technology has reshaped virtually every aspect of society, from business and industry to social services, entertainment, and education (Gaudelli, 2006; Krug, 2004). For citizens of all ages, portable computers that integrate the functions of a web browser, telephone, television, and radio are part of the most ordinary aspects of daily life such as checking train schedules, reading newspapers, watching favorite television shows, ordering groceries, and communicating with friends and family.

What follows is a description of current and possible relationships between technology and educational leadership. It is not a discussion that focuses on technology *per se* but, rather, on the potential of information and communication technology to build leadership capacity.

Reshaping Education

Within the educational world, information and communication technology is perceived as the most powerful change

agent in recent memory (Davies, 2002; see **Figure 1**). While educators learn to use hand-held computers to increase school security, access student information databases, document disciplinary procedures, and respond to e-mail from parents (Barrera and Warner, 2006; Brazell, 2005; Maxwell, 2006), they also facilitate the adoption of assistive technologies for students with learning and physical disabilities (Carnahan, 2006; Jeffs *et al.*, 2006; Quinn, 2003).

At the same time, expanding global access to information, ideas, and perspectives means that educators and learners in every content area and every part of the world must address challenges to disciplinary boundaries previously imposed by parameters such as culture, time, and space (Robertson and Webber, 2002). For instance, traditional classroom activities are now complemented by computer software that allows learners to access external people and information sources (Collins, 2001; Krumsvik, 2005). Social-networking software facilitates the formation of online communities that promote information sharing and collaboration among teachers and learners. Examples of social networking software include weblogs or blogs where the participants' comments to one another are archived and publicly accessible, wikis that allow website visitors to edit content, instant messaging and text messaging using computer software or telephones, and podcasting of multimedia files for recording and viewing at the convenience of recipients (Lamb and Johnson, 2006).

Social networking software brings together individuals with widely varying worldviews. They use different languages, may hold competing values, and live diverse lifestyles. At its best, social networking software may encourage the development of what Banks (2004) described as cosmopolitanism or global competency, and

Figure 1 The educational impact of technology.

contribute to what Krumsvik (2005) called “a more open, authentic, and contextual learning environment” (p. 41). In fact, Elmborg (2006) cautioned that those who argue in favor of learning environments based on a single culture and single language risk being perceived as defensive and reactionary, and speculated that national identities dependent upon common cultural artifacts truly no longer exist.

Information and communication technology also has led to a reconsideration of how we define literacy. In the past, literacy was defined in relation to communicating within a particular community. However, social networking and information-gathering software have led to the need for multiple literacies that permit communication across cultural contexts (Elmborg, 2006).

The relations between schools and their communities have been changed dramatically by information and communication technology. Ideally, the use of technology in schools is shaped through public deliberations among educators, students, and community members, and also viewed from a critical perspective in order to optimize the benefits for learners. However, schools must also determine the pedagogical relevance of specific aspects of technology, become comfortable with the ambiguity and confusion generated within the community by constantly changing technology, and address the negative manifestations of technology, such as cyber bullying, which spill into the community (Webber and Mulford, 2007).

New software and widespread Internet access mean that educators must consider the benefits and challenges associated with several forms of instruction: traditional face-to-face instruction, hybrid or blended courses that integrate online and face-to-face teaching, online classes that are delivered entirely through the Internet, distance education that may not only use electronic tools but also

take the form of paper-based correspondence classes, and e-learning that incorporates instructional activities that are technology mediated in some way (Tallent-Runnels *et al.*, 2006). These overlapping instructional formats are complex and require different teaching skills and knowledge from those associated with traditional teaching.

Finally, it is important to note that a strong technology infrastructure does not guarantee positive outcomes for the members of educational communities (Krumsvik, 2005). In fact, the impact of technology on education has been viewed with some suspicion and skepticism (Gaudelli, 2006). Nonetheless, technology has dramatically altered how people live their lives, including how young people and adults learn.

The Need for Leadership

There is an unprecedented need for effective educational leadership due to, for example, widespread public demand for accountability, cost effectiveness, and educational improvement (Lepard, 2002). Such expectations are complex; however, at least there is a body of theoretical and empirical literature developed over many years that educational leaders can use. Nevertheless, educational leadership related to technology use is a field of study that is less mature and, therefore, it can be more difficult for school leaders to decide how technology use should be implemented (Geer, 2002; Sivan, 2000).

Nonetheless, promising efforts to provide educational technology guides for school leaders have emerged. The Technology Standards for School Administrators Collaborative (2001) has outlined six broad standards for school administrators that have been widely adopted throughout North America (e.g., Donlevy, 2004). The first standard is leadership that fosters a shared vision for technology use. A technology vision provides the base for short- and long-term planning, policy development, and resource allocation. Second, educational leaders should facilitate the integration of technologies that promote teaching and learning. Optimal use of technology should aim to improve student achievement, meet diverse learning needs, and promote higher-order thinking. Third, educational leaders should model appropriate use of technology that enhances communication and collaboration within school communities, nurtures effective professional development, and facilitates ongoing school improvement. Fourth, educational leaders should manage and support educational technology by ensuring system compatibility, allocating sufficient financial and human resources, and integrating plans and policies to maximize efficiency. The fifth standard relates to the assessment and evaluation of technology use in teaching and learning activities. For example, educational leaders should use technology to gather, interpret, and communicate data

that can be used to improve instruction, plan professional development, and inform staffing decisions. Last, educational leaders should possess a thorough knowledge of the social, legal, and ethical aspects of educational technology. That is, educational leaders should strive to ensure equitable access to technology for students and teachers, plan and enforce the responsible use of technology, promote technology use that is safe and ethical, and create policies that address copyright and intellectual property issues.

A rubric for linking educational technology with educational leadership proposed by Webber (2003a) extended the Technology Standards for School Administrators Collaborative (2001) standards by juxtaposing conservative and educative technology leadership. A conservative framework was described as based on standardization, predictability, and resistance to change. Within such a framework, educational leaders focus on technology *per se*, provide clear role definitions for learners and educators, attend to individual learning, react to emerging technologies, and pay much attention to resource acquisition and management. In contrast, leaders operating within an educative framework aim for technology use that is flexible, fragile, and a potentially high reward for learners. That is, educative leaders focus not on technology itself, but on its use as an instructional tool. They focus on vision building, problem solving, and innovation. The leaders seek engagement rather than compliance, offer ongoing professional development and cross-institutional and community boundaries, and make decisions that are transparent and sensitive to the needs of the learning community as well.

Webber (2003b) also described four leadership dimensions of learning networks supported by educational technology: professional, role, environmental, and emotional. The professional dimension was characterized by a focus on learning possibilities and role flexibility that allowed leadership to emerge from all sectors of a learning network. This dimension was also described as evidence based and future oriented. The second dimension outlined the role of leaders as challengers of standardization, intellectual explorers, entrepreneurs, politicians, and networkers. The third dimension focused on how leaders relate to their professional environments as they differentiate, for example, between seeking equity by treating everyone the same and positioning for equity by providing resources and opportunities strategically. Other environmental considerations include learning from and moving beyond the past and, also, providing opportunities for cross-role participation in learning initiatives so that students, teachers, parents, and community members can engage in overlapping activities that meet related learning needs. The fourth dimension relates to the emotions associated with active engagement in learning networks made possible by educational technology. Leaders must be prepared to deal with the passion and curiosity associated with learning

that fosters enhanced creativity, demands sensitivity and compassion, and promotes caring.

Other aspects of the leadership required by new technologies include the ability to serve as an effective change agent. While some school systems may present insurmountable challenges for educational leaders who seek to create new learning opportunities for learners through the use of technology (Hunter, 2001), leaders with the ability to facilitate successful change can achieve significant cultural and structural shifts in educational communities (Hartnell-Young, 2006). Successful change agents are able to master the tasks of acquiring and maintaining appropriate technological tools and of finding time and money to deliver meaningful professional development (Staples *et al.*, 2005). They avoid models of change that are primarily top-down and build ownership for change among key stakeholders (McGrail, 2006). Finally, they understand that effective change processes increase the likelihood that learning opportunities will be optimized for both students and teachers (Lai and Pratt, 2004).

Teacher Leadership

The widespread use of information and communication technology in schools has established a clear need for professional development among teachers (Copeland and Gray, 2002; Hunter, 2001). Just as literacy skills for students have been redefined because of technology, teachers must also develop literacy skills that permit them to navigate, assess, and utilize information sources effectively, which is to understand what Elmborg (2006) called a new grammatical system for communicating using new technology.

Technology skills are only part of what Johnson (2006) described as skills for the knowledge worker. However, new technology can facilitate the development of basic skills such as understanding visual imagery, numeracy, and effective communication, which form the framework around which higher-order thinking skills can be constructed. Discipline and profession-specific skills build upon basic skills to form a breadth of knowledge that spans the social and physical sciences, literature, and history. Basic technology skills also promote higher-order thinking skills that lead to independent learning and social responsibility, and foster conceptual skills such as the abilities to think holistically, synthesize information, and create meaning. It is essential that teachers access professional development that helps them to develop the skills of knowledge workers so they can create coherence across the curricula they teach, the technologies they use with students, and the larger mission of the school community (Staples *et al.*, 2005).

Creating educational coherence is a complex task in the information age because technology has changed teaching and learning from what most teachers were trained to do.

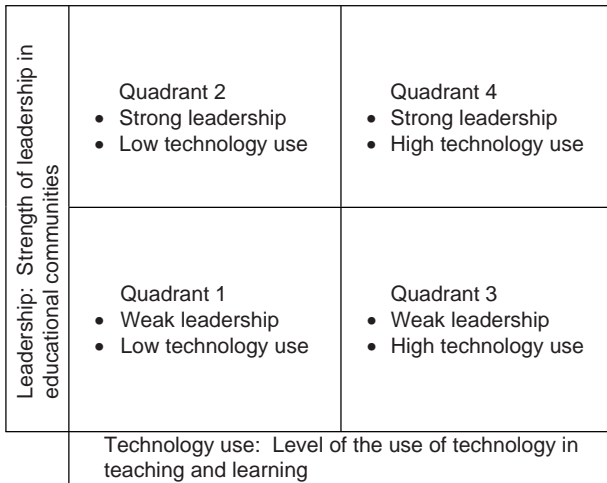

Figure 2 A framework for considering educational leadership and technology.

Teachers now are called upon to be educational entrepreneurs (Webber, 2005a) who are able to innovate, network, work in synchronous and asynchronous environments, and demonstrate concurrent local, national, and global cultural literacies. They are also expected to create educational organizations which serve as knowledge centers that integrate traditional and technology-mediated instruction.

Figure 2 portrays the relationship between educational leadership and the integration of technology in schools. In **Quadrant 1** schools, little use of technology is made by teachers, and educational leadership is ineffectual. Strong leadership exists in **Quadrant 2** learning environments; however, it is not focused on technology and teachers realize little of the potential of technology as a learning tool.

Teachers may use technology in **Quadrant 3** schools, but there is little academic coherence or shared understanding of a pedagogical rationale for utilizing it. In **Quadrant 4** schools, strong leaders facilitate the integration of appropriate technology into classroom practices so that teachers and support staff can optimize student learning.

Technology and Leadership Development

Successful leadership in the information age is largely dependent upon access to relevant professional development (see **Table 1**). In particular, it is essential that educational leaders, including principals and teachers, be able to access professional development that leads to the development of a strong sense of agency, enhanced altruism, critical analysis skills, and emotional engagement with learning (Robertson and Webber, 2002). Challenges for educators include a lack of time in their workday to participate in professional development initiatives (Hunter, 2001; Lai and Pratt, 2004). The challenge is greater for principals

Table 1 Desirable technology-mediated leadership development

Attributes	Evidence
Quality reflected in	Role-appropriate content Compelling e-learning format
Access that is	Timely Flexible
Opportunities to	Shape the learning experiences Engage Reflect Network locally, nationally, and internationally
Support infrastructure that	Invites Builds community Attends to stages of learning Reflects cross-role and cross-cultural understandings
Results in	Strong sense of professional agency Enhanced altruism Critical analysis skills Emotional engagement with learning

because the most professional development programs that address the use of educational technology are designed for teachers rather than for principals (Adsit, 2004).

Since many professional and academic organizations seek to address professional learning needs by using technology-mediated delivery formats, several frameworks for assessing e-learning programs have been proposed. For example, Killion (2002) suggested that educators seeking professional development consider several criteria, including their personal learning readiness, content quality, and flexibility of access. Other criteria include the form of e-learning, level of interactivity, technical support, and the esthetics of online interfaces.

Adsit (2004) suggested that educators considering technology-mediated professional development become knowledgeable about different levels of technology integration. That is, they should consider the suitability of low-tech/low-interactivity professional development that utilizes basic technology such as word processing, electronic handouts, videotapes, and audiotapes versus medium-tech/medium-interactivity programming that relies upon, for example, listserv and message boards. High-tech/high-interactivity professional development uses synchronous discussion groups, multimedia, interactive e-learning programs, and synchronous teleconferencing or videoconferencing. Adsit (2004) also urged educators to seek programs that promote reflection and reduce professional isolation.

Most leadership development programs are offered by universities, departments of education, and professional organizations. However, educators now have the option of participating in technology-mediated leadership development programs delivered literally from around the world

(Robertson and Webber, 2002). Therefore, leadership development programs should be assessed according to whether they promote active participation in national and international learning networks using highly interactive technologies. Another criterion suggested by Robertson and Webber (2002) is the degree to which programming facilitates cross-role dialog that expands the cultural literacy of participants to include a range of educational, community, and business settings. Delivery formats ought to include synchronous and asynchronous components that reflect an understanding of the time zones of participants and their wide range of professional obligations. Further, participants in leadership development programs should be able to engage with providers in shaping the design, delivery, and evaluation of programming so that it is relevant and useful. In other words, educational leaders need to experience leadership development activities in which they acquire the skills and knowledge needed to do similar work in their schools and communities.

Providers of technology-mediated leadership development programs should anticipate that participants require access to a support infrastructure that meets their information and administrative needs (Webber and Clark, 2006). That is, educational leaders need support in order to move beyond familiar leadership practices. They ought to feel that they are part of an inviting and supportive learning environment; therefore, community building is an essential aspect of leadership development. Providers should anticipate that participants in leadership development initiatives will move through a predictable pattern that begins with a focus on the managerial aspects of the initiative, such as how the program is organized and what is expected of participants. The second stage of participant development is likely to focus on the context of the leadership program. That is, educational leaders will want to know the forms of literacy and the skill sets that are required. They must also acquire the ability to critically analyze theoretical and empirical aspects of the program. The third stage is personal and it is characterized by self-reflection about who the learner is and the type of professional growth that is desired. Participants seek a deeper understanding of their personal strengths and challenges. In the fourth stage observed by Webber and Clark (2006), learners express concern about how others in the leadership development initiative are affected by their participation. They also seek to be considerate of the challenges that other participants face because of professional responsibilities and geographic locations.

The content of technology-mediated leadership development ought to include some of the components of educational leadership programs delivered in more traditional ways: leadership theory, change and influence in education, educational environments, and globalization (Webber, 2005b). Technology-mediated leadership development allows for a rich discussion of leadership theory,

for example, because participants can be from contexts with quite different ways of considering interpersonal communication, gender, diversity, ethics, and values in leadership and management. Similarly, the consideration of change theory will be enriched by the different organizational cultures and governance structures represented by participants. The environments in which participants work will have different political attributes and varying forms of accountability. Further, globalization will have disparate effects upon participants from venues where legal, cultural, and technological features vary. It is important that technology be kept in the background and that content and learning processes be the primary focus.

Technology-mediated leadership development is likely to contain cross-cultural components because of the ability of educational leaders to participate from many parts of the world (Webber and Robertson, 2004). Thus, the benefits of participation may include an increased ability to understand one's local educational context in relation to other settings. Other results can include heightened self-awareness, reduced professional isolation, and resistance to conformity. However, it is possible that participants may come to some naive conclusions about their own and other cultures. Another benefit of cross-cultural dialog may be a shift from ethnocentricity to cross-cultural understanding. As a result, participants may gain insight into the tension between tradition and innovation, recognize the limits of their personal cultural literacy, have more realistic understandings of the educational practices of other nations, and develop a degree of cultural humility. A corresponding caution is that some participants may come to believe incorrectly that they can remove cultural bias from their worldviews. Other benefits that may accrue to participants in technology-mediated, cross-cultural leadership development programming, according to Webber and Robertson (2004), may include the use of new technological learning tools, identification of previously unseen connections between schools and the larger community, heightened emotional engagement with work, and a higher level of altruism. These benefits may be accompanied by an unrealistic sense of power that, in the absence of an ongoing support infrastructure, may dissipate rapidly following the conclusion of the leadership development opportunity.

Social and Legal Challenges

As educational leaders engage with technology in their professional development and daily practices, they may be challenged by a set of social and legal issues that confront educators in many nations. For example, Berliner (2006) outlined the ongoing educational challenges posed by poverty in his country, the United States. While not writing specifically about educational technology, Berliner's cautions, nevertheless, are germane. Clearly, poverty

has a major impact on the access of learners to high-quality schools, including those where technology plays a major role in teaching and learning. When the barriers of poverty are combined with associated factors of race and language, the result is a serious challenge to the potential benefits of technology-enhanced learning environments.

Davies (2002) raised parallel cautions about the ability of some students, families, and schools in England to afford access to technology and the danger of a widening educational gap between rich and poor. Davies went so far as to ask if technology will unite or divide society because of disparities in access. Clearly, educational leaders have an obligation to seek wider access for students and colleagues in disadvantaged circumstances.

In addition to social justice issues, technology raises legal challenges. Quinn (2003) noted that technology changes so rapidly that legislators and policy makers are unable to keep pace. As a result, there is widespread uncertainty about how educational leaders ought to address challenges of freedom of speech and personal privacy, for example. School communities are also confronted with the need to create policies to address plagiarism, intellectual property rights, software licensing, and cyber bullying (Geer, 2002; Quinn, 2003; Shariff, 2004).

Conclusion

New technology has led educational leaders to reconsider major aspects of their practice, including the configuration of people involved in teaching and learning in school communities, the leadership principles that guide their work, the difficult questions that must be addressed, and

the possibilities for future directions in teaching and learning (Robertson and Webber, 2004).

Figure 3 depicts the influence of technology on professional practice and the learning community. School communities now require teachers with both technological literacy and content knowledge. It is not enough for teachers to have content knowledge and satisfactory classroom teaching skills. They must now possess the ability to select appropriate software, utilize relevant databases, and link learners from local venues and from afar in meaningful ways. They need to know enough about instructional design, multimedia, and web development to accomplish their work and support the work of their students besides knowing how to access technological support. In addition, teachers must organize, nurture, and promote technology use in their content areas. Therefore, educational leaders must know how to form teaching communities that can satisfy the academic and technological needs of learners.

While recruiting and retaining teachers who are academically and technologically knowledgeable, educational leaders need to be guided by a set of important understandings. For example, technology means that much of the work of school leaders is visible not only to the local community, but also to the world because so much of it is publicly accessible. Most schools in the Western world have websites that contain large amounts of information about members of the school community and district websites often summarize important data about the system. Provincial and state departments of education routinely display summaries of school-by-school achievement test results. Even satellite photographs of individual schools are publicly available worldwide in databases simply by typing in a school address. Thus, educational leaders need to be comfortable with the public nature of their work and use

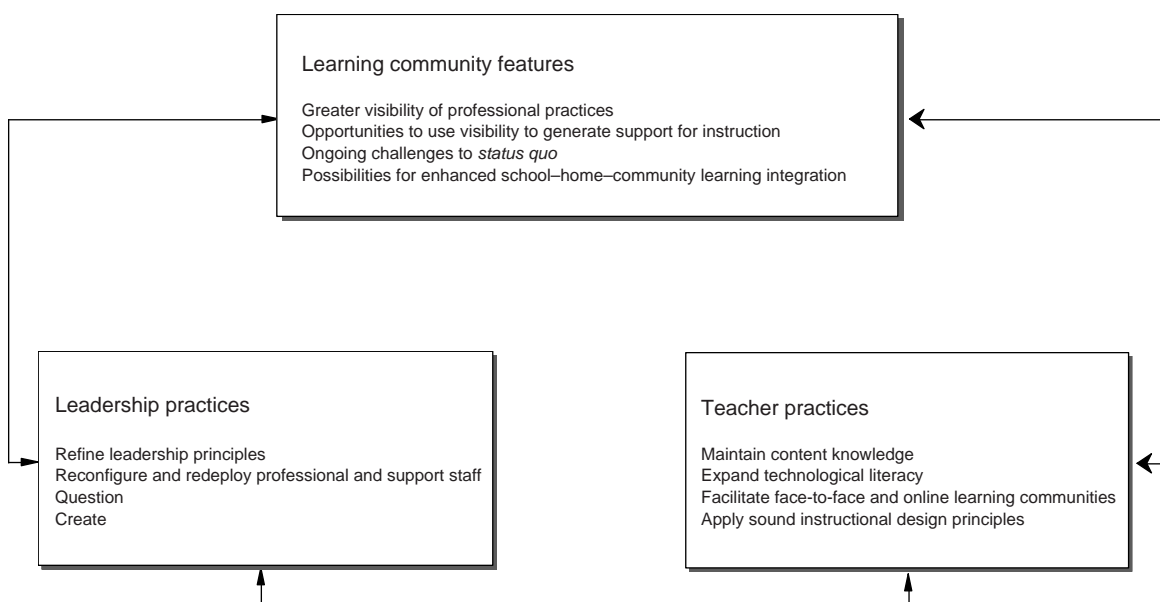

Figure 3 The influence of technology on professional practice and the learning community.

their visibility to promote support for instructional improvement. Similarly, educational leaders need to understand that technology should complement and not determine academic content and instructional practices, that online learning communities have the potential to be even stronger than traditional learning communities, and that technological infrastructures must be sustainable.

Educational leaders must have the capacity to recognize and address important questions raised by technology. For instance, leaders should strive to determine how face-to-face teaching can be balanced with e-learning to meet the needs of learners in their particular school communities. Leaders need to ask how commercial software enhances or limits learning success and if cross-cultural collaboration by students and teachers is mutually beneficial. When the *status quo* is challenged by technology, principals must ask if the *status quo* is beneficial or driven by unexamined beliefs and assumptions.

School leaders must pursue and be open to questions and possibilities opened by new information and communication technology. For instance, are new configurations of publicly and privately funded educational support appropriate? Further, are schools the most appropriate venue for all learners all the time or should technology-enabled combinations of school-, home-, and community-based schooling be considered?

Finally, leadership skills required in technologically supported educational environments include technological literacy, inventiveness, networking capacities, entrepreneurialism, and cosmopolitanism.

A Brief History of Change Theory

The history of organizational change can be traced to both sides of the Atlantic Ocean. In fact, as far back as 1920, the Tavistock Institute of Human Relations in London used concepts taken from psychoanalytical theory in order to better understand group dynamics. While the professional literature of organizational change did not emerge as an interdisciplinary field of study until the 1960s, the social, political, psychological, and educational ideas of B. F. Skinner (i.e., behaviorism), John Dewey (i.e., experimentalism), and Kurt Lewin (i.e., social theories) could already be observed in educational research and practices. The latter's works influenced the next generation of US researchers, Rogers (1962, 1965), Miles (1964, 1965), Clark and Guba (1965), Haverlock and Benne (1965), and Bennis *et al.* (1969), among others – whose ideas on planned change preceded implementation theory (Berman, 1981).

Internationally, Walker's (1970) *Theory and Practice in Educational Administration* became a landmark argument for the development of a theory as well as improving the practice of educational administration in Australia, but also throughout the British Commonwealth. Other key international contributors to the development of an understanding of the role of the educational leader as an agent of change and innovation included Ray Bolam in the United Kingdom (Bolam and Pratt, 1976) whose work specifically addressed the issue of innovation in schools and Thomas B. Greenfield in Canada (Greenfield, 1974), who suggested that human organizations, rather than having a natural order, were characterized by complexity, uncertainty, and the vagaries of human behavior. In other words, the field of administration, almost a decade prior to Fullan's conclusion, recognized and accepted that all aspects of change were in part deliberate while at the same time emergent or resulting from human interactions (Greenfield, 1974). Organizations began to experiment with new research and development centers, sending workers for external training laboratories, as new academic fields of study from organizational sociology to leadership development emerged. Scholars such as Argyris (1982) and Argyris and Schon (1978) began to pose questions about whether organizations could learn from their actions. Thus began the systematic study of organizational and managerial changes and innovation grounded in theories of action and use.

The 1970s and 1980s saw a focus on empirical change study research evolving from US national/federal innovative efforts (see Rand Corporation Study research by Berman and McLaughlin, 1979; McLaughlin, 1990) and local school-based efforts that promoted new concepts and designs of professional development (i.e., Fullan and Pomfret, 1977; Fullan, 1982). During this same period, within Europe, Ray Bolam, Per Dalin, Michael Huberman, and others—all acknowledged by Fullan (1982) influenced the direction of research. It is interesting to note that in the 1980s and 1990s, when discussions of the changing nature of leadership were at their height, the most innovative activities that emerged were driven from the top down. During this period, the intervention of government into the knowledge and management issues surrounding schools led to perhaps the greatest period of change in school history. Within half a decade, the Thatcher government in England (local management of schools), the Lange government in New Zealand (tomorrow's schools), and the Kennett government in Victoria, Australia (schools of the future), had all instituted radical forms of self-managing schools (see Caldwell and Spinks, 1988, 1992, 1998), that rapidly became a model for a structural change in education that swept the world, with charter schools in the USA and various levels and forms of decentralization in many countries of the world. This was essentially a political activity, fueled by the school effectiveness research which strove to show that schools could make a difference, but was often misinterpreted by government bodies as only schools can make the difference (Reynolds, 1994). Although context issues have been accepted and are now being studied by those involved in the school effectiveness and school improvement research to the point where the definition of effectiveness might need further interpretation (see Townsend, 2007), governments remain attached to the simplistic views of the concept, which led to the school indicator research (Kochan, 2007), to guide the accountability systems in place. Fuhrman (2003) argued that accountability systems were school indicator systems with sanctions.

The rival tensions of top-down and bottom-up reform offered two completely different roles for school leaders. With respect to government intervention, the school leader became the implementer of decisions made by others, whereas shared decision making, school-based management, and self-managing schools all looked to leadership

to develop the capacity of others. These dual roles for the school leader involved implementing innovations dictated from above (e.g., new school structures, new funding mechanisms, new administrative arrangements, and new curriculum and assessment) to respond to the new accountability regime, versus implementing local innovations, with the teachers, students, parents, and local community that addressed the needs of the students in the schools they led. Sergiovanni (1989, p. 39) approached this duality as follows:

Because of the unpredictability of the world and the limits of human rationality, it makes sense to emphasize building capabilities of people first, encouraging them to develop ways and means for using their capabilities, than it does to develop plans and then seek the know-how and commitment to implement the plans.

Barber (2002, cited in Caldwell, 2006) labeled the above tensions as uninformed prescription in the 1980s which became “informed prescription” in the 2000s (pp. 50–51). Glennan *et al.* (2004) took a more holistic approach. They argued, “an important part of the principal’s role as school improvement leader is the active management of change from above (e.g., mandates from the district office) and below (requests or demands from teachers)” (p. 20). Their work suggests that leaders’ dual roles require seeking resources and support from district staff, while simultaneously fostering and monitoring teachers’ implementation of reform components within the classroom. Their research indicates a “strong, positive relationship between the quality of principals’ leadership and the extent to which schools implemented whole-school designs” (p. 20). These tensions across roles, rules, and relationships inside of educational institutions and policy debates suggested that educational leadership and educational innovation are to be considered as a unique context both socially and politically.

If so, then exercising educational leadership becomes more than a deliberate, cognitive act; rather, educational leadership is an act that requires courage, or the ability of the leader to act differently, if not disruptively (Schlechty, 2007). That is, “the kinds of innovations required [inside of educational institutions] will likely exceed the present social systems’ capacity to sustain them. These changes will necessarily be disruptive...” (p. 222). One way to begin to do this is to stimulate a particular kind of dialog (Brown *et al.*, 2005), one that opens up the possibility of seeing the world through the collective wisdom of all participants and shares what they already know. Dalin (1996), a scholar from Norway, asked educators pointedly whether they believed they had the capacity to create the secondary schools required to respond to the external changes that marked our entry into the twenty-first century. Simply put, Dalin inquired, “Can schools learn?” and “What will it take?” Furthermore, he challenged educators to examine how their deeply held assumptions about, “Who is the teacher? Who is the student? Where is

the school? And, what is the curriculum?” that may serve to hold them back or move them forward and into the future.

To get to the heart of the fundamental questions posed by Dalin, change theories which focus on a either a bottom-up or top-down approach may limit our leaders’ abilities to ask the type of provocative questions that enable them to find fresh solutions that lead to creative and innovative responses. Hargreaves and Fink (2005) suggested that educators must make deep structural changes to schooling that impact current practices. These deep changes require examining how we organize ourselves in schools for teaching, learning, and leading. If we continue to frame change from traditional approaches of top-down reform, and do not ask the tough questions, then, we continue to control and confine information, actions, and ideas tightly, within bureaucratic and hierarchical organizational structures that limit innovative responses. Likewise, bottom-up reform may, too, be more of a reaction to the hierarchical pressures from above than offering thoughtful responses and innovative responses; in other words, we may find ourselves in a no-win situation unless we challenge existing practices and power relationships (Schlechty, 2007; Snyder *et al.*, 2000).

Changes that emanate from outside the school system rest entirely on the shoulders of the leadership within schools to implement successfully, often without funding and the needed discretion to hire the right personnel. Frequently, mandated changes trump how leaders can spend their time to listen to the needs both inside their schools and outside their schools (Bogotch and Brooks, 1994). At odds, these traditional approaches to change have locked leaders into sidestepping how to respond to unplanned events – or emergence – where required actions which are not mandated take less precedence and can easily be ignored. These evolving events, which cannot be controlled or predicted, and may, therefore, be disregarded by educators, may furtheracerbate their being out of step with the realities of the world. Said differently, the institutional contexts of schooling become the educators’ total view of reality, shutting out other perspectives (Bogotch *et al.*, 1996).

Taking action based solely on political expediency rarely leads to innovation and deep change (Bogotch *et al.*, 1995). By operating within boundaries of shared values (Barth, 1990), conceptualizing organizational change as a collective pursuit, the paradigm shifts away from bureaucratic and control mechanisms to emergence and adaptation (Lincoln, 1985) that positions change theory not only within the new sciences, but also within the new meanings of educational theory (see Biesta, 2006; Blake *et al.*, 1998). Staying within the traditions of hierarchical and bureaucratic structures may well limit innovation into the future, reducing actions that serve only to mollify the powers that be. Innovation requires more response-ableness and a collective vision (Hargreaves and Fink, 2006).

Complex Systems' Frameworks

In contrast to contextual and institutional realities, Maguire *et al.* (2006), in their comprehensive review of the literature on complexity science and organizational studies, asserted:

Peters (1987) argues that organizations should be 'thriving on chaos'; and Nonaka (1988a: 72) maintains that that 'the self-renewal strategy of an organization lies in its ability to manage continuous dissolution and creation of organizational order' (p. 173).

Chaos and complexity theories, derived from these new sciences such as quantum physics and evolutionary biology, offer us a fresh lens to view change as adaptation and to view unplanned change – that is, emergence – as learning through actions taken and reflected upon. Importantly, relationships form primary building blocks to construct new ways of responding to these unanticipated changes (Wheatley, 1992). Leaders' work, therefore, calls for ways to build the needed connections with others that engenders trust in their abilities to work together to address issues that arise (Argyris and Schon, 1974).

Specifically, positioning leadership within a theory of chaos and complexity theories views leadership as neither top down or bottom up. Rather, the intersection of leadership, implementation, and innovations becomes grounded in the leader's ability to forge strong connections with others, to establish and promote listening systems, to engender trust that promotes meaningful dialog that leads to creative solutions. What is often left unresolved, however, is the dichotomy between forging common and shared understandings and collective agency and action within shared meanings versus the acceptance of "intrinsic but complementary differences" (Gould, 2003, p. 247).

Serious attention to all members of the set may well unify our mental lives by forging a consensus on values and results. However, such a consensus could only emerge from independent contributions, knitted together by serious and generous dialogue among truly different, and equally valid, ways of knowing, each responsible for a swatch on wisdom's quilt, with the swatches abutting and interfingering in gorgeously complex patterns of interaction (pp. 255–256).

The alternative to the binary top-down and bottom-up perspective was succinctly captured by Stephen Jay Gould (2003) who introduced the term consilience, literally meaning jumping together (pp. 247–260). Gould explained how distinct worlds can contribute to building new theories based on differences, not reductionism in policy and practice. The logical and the intuitive are allowed jump together as equally valid and necessary approaches to knowing and understanding and acting

upon what is actually going on. We can observe this line of research in Hargreaves and Fink (2004) who have attempted to describe their findings outside the binary opposites and conjunctions previously used by Fullan (1982). For example, to understand sustainability with respect to planning and preparing for leadership succession, the authors are mindful of maximizing a leader's ability to remain in schools so long as change is evident. Here, the authors recommend moving from the leader as an individual to distributive models of leadership so that continuity does not rest with any one individual or end with succession. In fact, all of their findings have that jumping together quality: shared vision, linking school and community leaders to ideas of social justice, obtaining both intrinsic rewards and extrinsic incentives, promoting diversity and variation, building strategic alliances, and establishing system supports.

These considerations might lead to where "the distinction between leaders and followers blurs," where although "school principals might still have overall responsibility for the ongoing work of the school, teachers, students, and parents all play leadership roles in terms of making decisions, acting on decisions made and taking responsibility" that requires the school to "change its focus from one where teachers teach, students learn and parents support, to one where everyone in the school contributes what they know (teach), and works towards common goals (support), one of which has to be the ongoing improvement of what the school does (learns)" (Townsend and Otero, 1999: 57).

Whether these principles of sustainability or the many choice options in and surrounding education, such as institutionalized schooling, homeschooling, deschooling (Illich, 1971), or notions of a learning organization (Senge, 1990), who built on and extended ideas of scholars such as Argyris and Schon (1978) and Emery and Trist (1965) (see also Silins and Mulford, in press) can result in complex relational and dialogic patterns of knowledge is both under-theorized and understudied. One futuristic research question to emerge from this line of thinking is whether national and local educational systems can empirically embrace the Wiki philosophy of editing and re-editing already existing content knowledge?

Although many studies substantiate how deep changes in a school's culture necessitated educators working collaboratively, what is often lost is how collaborations enable participants to co-construct and co-evolve their futures together – futures that impact the achievement patterns of students and permit educators to respond positively to changes in their distinct local and national environments. Looking at educational leadership and change through the lenses of chaos and complexity theories requires that we study different communities of practices (Wegner, 1998; Wegner *et al.*, 2002) that support formal and informal knowledge networks.

Re-Conceptualizing Educational Innovation

“Innovation is a noble pursuit” (Caldwell, 2006: 44) in the sense that educational reformers have tried to position public education as a fundamental human right. Unfortunately, education does not necessarily hold this position of public legitimacy in all societies of the world; moreover, educational innovations are not always linked to the primary purposes of education, but rather have been viewed in a limited way to the core technologies of teaching and learning. Thus, new school structures, new instructional methods and technologies, new funding mechanisms, new administrative arrangements, new curriculum and assessment, etc. connect to the practices of educators – but only contingently and on the margins. What is missing, therefore, for theorists such as Fullan and Goodlad (2004) among others, is the deliberateness of educational innovations as necessary for the purposes of public education as complex systems. What we mean here is that it is important to reposition the world of education as fundamental and also distinct from other institutionalized worlds, including the world of business.

The ethic of business is hard work, productivity, market competition, and profit (Drucker, 1985; Kouzes and Posner, 1991). Repeatedly, Drucker (1985) distinguishes a successful innovation from a bright idea. “I know of not one such ‘flash of genius’ that turned into an innovation. They all remained brilliant ideas” (p. 133). That is, innovations have to work in the present with people who can understand them. To the extent that the social system becomes relevant and aligned with the economic needs of people, innovation has to do with instrumental motivation and personnel issues in terms of keeping workers satisfied and focused on the job (Kouzes and Posner, 1991).

In contrast, innovations in education are inextricable not only from sociopolitical systems (House, 1981), present structures (Schlechty, 2007), and individual needs, but they are also relevant to the past, present, and future uses of knowledge, which is “something that hasn’t happened yet, but which [educators] are looking forward to” (Townsend, 2003: 17). Miles (1964) asserted that innovation was “*always* operant in relation to a given social system” (p. 14). Gittell and Hollander (1968) conceptually placed innovations at the center of education because it is “‘always present in some degree in all school systems’ (p. 3) even though its meaning and significance may be minimal” (cited in Bogotch *et al.*, 1995: 7). Thus, Bogotch *et al.* (1995) argued that “the concept of innovation is fundamental to social organizations such as schools. Innovations are not just a matter of structural rearrangements or technical advances, but rather are a new foci on social dynamics, management and people” (pp. 6–7). The argument is that educational innovations must be fundamental

to the many sociopolitical systems not just instrumentally used to crush the competition – as in business.

Beare (2006) recently advanced the argument beyond older systems’ thinking:

The leaders we admire are. . . frequently impatient with the merely functional, the technical, the tidy. They seem to be discomfited with what is, driven by a nagging discontent, and consumed by a compulsion to revise, remodel, and improve things. They have the explosive combination of insatiable restlessness about what is orthodox, conventional and acceptable, together with the ability to handle and invent ideas and to synthesize them in a new way which makes them coherent and persuasive for others. In doing so, they break open the boundaries (p. 8).

However, what makes Beare’s description somewhat problematic with respect to innovations, educational or otherwise, is that empirically, the attributes of innovations influence their adoption and acceptance (Rogers, 1962, 1995). Rogers identified four attributes of relative advantage of an innovation: compatibility, trialability, observability, and less complexity. The compatibility of the innovation refers to the degree it is consistent with existing values, past experiences, and the needs of the potential adopters. The complexity of the innovation is the degree to which it can be readily understood by most members of a social system. The innovation’s trialability refers to the degree to which it can be experienced with on a limited basis. The observability of an innovation refers to the degree to which its results are visible to others. In each of these attributes, the tensions of practicality, institutionalism, and change emerge – which are as relevant inside of rational bureaucracies as they are inside of complex systems. According to Diamond (2006), the perceived attributes of an innovation and its characteristics help explain different rates of adoption. The innovation’s *relative advantage* is the degree to which an innovation is perceived to be better than the idea it supersedes. What is then needed is a discussion of how educational leadership can respond, socially and institutionally, to these influences and constraints in order to create new ways of learning.

Beyond Societal and Institutional Barriers

Grounded in the ideas presented here, we can summarize the many sociopolitical challenges facing educational leaders in the twenty-first century:

1. To re-establish the international legitimacy and social capital of public education as a basic right (i.e., on principle) as well as reflecting societal goods (i.e., as different cultural and societal values).
2. To re-assert the capacity of educators to not only manage educational systems, but also renew and

co-construct complex systems with new patterns of knowledge diffusion and dissemination; when innovations are not institutionalized, the external mandates and educational leadership (see Cuban and Useem, 2003) work against genuine accountability, educational responsibility (Biesta, 2006), trust (Argyris and Schon, 1974), and innovation.

3. To develop theories of educational action and innovations that jump together the tensions between deliberate efforts and emergent unpredictable happenings; school development should be seen as ongoing changes that promote innovation through social networks and building new *Wiki*-like dialogs that challenge knowledge, positional hierarchical roles, and relationships.
4. To reconnect the purposes and processes of public education (not just schooling) to the needs and desires of citizens regardless of the different and disparate human conditions. That is, leadership and education are valid in all contexts.
5. To sustain leadership and innovations beyond a single individual, single location in time and space. Here, we note the limits of the leader's ability to control, plan, and predict human behaviors. Rather, leaders must rely upon systems of values and beliefs that underpin actions and create social networks of learning, for others to interact, and share information and power.

The lens of complex theories is thus necessary to go beyond societal and institutional barriers that have limited educational theory, the educators' capacity for learning and change, the educational systems' willingness to learn and transform with social, political, and economic realities. While the terms we chose to use here differ from the vocabulary of planned change, implementation theory, the barriers imposed externally onto education through government authorities continue to limit educational leaderships' ability to make changes for the right reasons – namely social capital and the public good.

The Progress of Educational Change: A New Integration

We have argued for the uniqueness of education institutionally and socially and therefore, we further assert that educational leadership and innovation demands a new theory. In *Re-imagining Educational Leadership*, Caldwell (2006), following Drucker (1999), sees the need to balance innovation with abandonment (p. 117). In other words, we must be cognizant of history as we think and act in the present. Therefore, without denying past successes, it is important to continuously start afresh, not unlike the newly hired CEO of Toys R Us who talks of transforming the traditional notion of toys to a world in which children (of whatever age!) play with gadgets. The distinction we

see here is not the traditional toys versus gadgets or toys and gadgets, but rather the jumping together of toys/gadgets. The point we are making is that we must in our educational theories and practices go beyond binary opposites (i.e., transitioning from one world view to another by abandoning the past), and going beyond compound conjunctions of two ideas without seeing the necessity for changes in both of the original ideas. We refer to this phenomenon in terms of wiki-like editing of existing knowledge. With respect to leadership and change, however, the argument suggests that we engage in mobilizing change despite the fact that existing models cannot provide us with definitive answers. Thus, we turn to the critical importance of intuition in real time by paying active attention to our surroundings for answers that cannot be derived from rational mindsets alone. (We are indebted to our Florida Atlantic University colleague, Mr. John Hardman for this insight.)

In **Table 1**, we have reconfigured Fullan's 1982 conclusions taken from *The Meaning of Educational Change*. Fullan, to whom we all owe much in terms of our ideas on change, divided his conclusions into two categories – transitions, that is, moving from x to y (column 1) and co-joining, that is, adding x to y (column 3). We have inserted in between our own two columns where we have re-conceptualized these categories in terms of Gould's notion of consilience, jumping together, or x/y (columns 2 and 4).

Thus, the transition from cognitive to social development no longer covers the range of possibilities in terms of teaching, learning, or leading. The developmental stages and grade and age-level configurations evolve culturally and behaviorally with demonstrated changes in the brain. The transitions of alignment of curriculum and processes as well as the privatism of learning – so necessary for routine matters and benchmarks, no longer spans the range of knowledge and skills needed by children, adults, and educators around the world today. The role of professional development in education still stands as one of Michael Fullan's major contributions to understanding education and change. We must now, however, take these notions further to collective learning and wisdom into developing social networks and communities of learning and practices that reflect diversity and differences. Such changes demand new skills and understandings that can make change possible across different settings. Finally, while we might take issue with the dichotomy of grandeur and incremental changes, we, too, see the need for making small deliberate changes inside of institutional routines, roles, and responsibilities that promote time, leadership, and meaning into the lives of educators, as teachers, leaders, and students. Only then, in the present moment, can we demonstrate to those who study schools and educational relationships that our practices in fact reflect human dignity and the capacity for us to learn, grow, and change.

Table 1 A reconceptualization of Fullan's categories using 'consilience'

<i>Fullan's binary opposites (transitions)</i>	<i>Jumping together</i>	<i>Fullan's compound conjunctions</i>	<i>Jumping together</i>
Cognitive vs. social development goals	The whole child/the whole person	Time and change	Knowing the past/acting in the present/unafraid of the future
Fidelity vs. variation	Human differences/uniqueness/human interactions/uniqueness	Leadership and change	Capacity building for self and other/substantive changes within a single generation
Privatism vs. professional development	Self/other/culture/social capital and the public good	Meaning and change	Everyday procedural justice in schools through asking, questioning, testing assumptions, experimenting on knowledge content, and critiquing educational practices
Specific vs. generic capacity for change	Student/teacher/administrator as learner/educator/leader	School and society	Combating injustices through education practices
Grandeur vs. incrementalism	Big bright idea/workable little idea		

Conclusion

Following futurists such as Toffler, Caldwell (2006) sees accelerated changes for the world's schools (p. 192). Consistent with our own thesis, Caldwell does not see this as the future of top-down and bottom-up logics, but rather, as a future of synergies, social networks, technology, and learning in real time. Many of the binaries that Fullan conceptualized in 1982 have been transformed; others have been reified in practice. We again ask, why? The answer for us cannot be found in the effectiveness or efficiency of linear models of diffusion or dissemination as rational systems or as scaling up of reforms. Rather, the challenges we face are located in ourselves as educators and our ability to develop the intellectual capacity to become educational leaders for ourselves and for others across societies.

In part what is given in teaching, in the initiation into a culture, is a gift that cannot be refused. What we come to know in this way precedes the possibility of our autonomy. Closer to us than we can readily acknowledge, it is familiar, occasioning a kind of love, as perhaps for things close to the heart (Blake *et al.*, 1998: 88).

The future of educational leadership implementation of innovations must remain largely unknown if it is to advance nations beyond their societal and institutional barriers. Not only must the results be different for students and citizens, but also must be the paths taken by educational leaders.

Leadership: School Improvement

R H Heck, College of Education, Honolulu, HI, USA

P Hallinger, Asia Pacific Centre for Leadership and Change, Hong Kong Institute of Education, Hong Kong

© 2010 Elsevier Ltd. All rights reserved.

Overview of Leadership for School Improvement

School change and improvement have been well studied over the past several decades (Louis *et al.*, 1999). Over time, researchers' conceptualizations of school change evolved to incorporate a variety of different lenses for understanding the role of leaders in school improvement.

Conceptualizing School Improvement

Interest began with a focus on the diffusion and adoption of educational innovations from the 1930s to the 1960s and shifted toward studying planned change efforts during the 1960s and 1970s as national governments sought to implement ambitious policy mandates, curricula, and programs in schools. During the 1980s, researchers interested in change and school improvement centered their attention on studying the internal nature of effective, innovative, and successful schools. In the 1990s, the focus of researchers shifted away from school effectiveness and toward the role of leadership in initiating and sustaining longer-term site- and classroom-level changes and improvements. Finally, most recently, during an era dominated by concerns for accountability and improved student learning, studies of school improvement have become centrally concerned with the role of leadership as the key catalyst for change.

Today, there exists a strong expectation that school leaders can and should be held accountable for improvement of the school's academic performance and improvement (Hallinger and Heck, 1996, 2002; Heck and Hallinger, 2005; Leithwood, 1994; Leithwood *et al.*, 2004; Slegers *et al.*, 2002; Southworth, 2002). As Teddlie and Reynolds (2000) concluded in an review of international studies of school effectiveness, "we do not know of a study that has not shown that leadership is important within effective schools... Indeed, 'leadership' is now centrally synonymous with school effectiveness for many, including many operating within the school improvement paradigm also" (p. 141).

Despite these broad-stroke conclusions concerning the central role of leadership in school improvement, there remain significant challenges in interpreting this literature (Louis *et al.*, 1999). Indeed, we must note at the outset of this article that despite the frequency of its use, there is no commonly accepted definition of the term school improvement. It has been defined variously as the

successful implementation of a program, changes in teacher behavior, transformation of the school's culture, an alteration of a school structure, or an increase in student learning or school effectiveness (Clark *et al.*, 1984; Firestone and Corbett, 1988; Fullan, 1982; Heck and Hallinger, 1999; Leithwood, 1994; Louis *et al.*, 1999). School improvement studies, taken as a whole, have been important in providing information about the process of improvement even if they have been less successful in documenting how improvement processes affect student outcomes (Fullan, 1991; Hall and Hord, 1987; Louis, 1994; Reynolds and Teddlie, 2000).

In addition to acknowledging the diversity of ends that define our understanding of school improvement, there is also disagreement over the means that educators may choose to facilitate improvement (Louis *et al.*, 1999). School improvement processes have been described as complex, multidimensional, and dependent on the relationship between the school, its community, and its cultural context (Hallinger, 1998; Hallinger and Kantamara, 2001; Hallinger and Leithwood, 1998; Meyer and Rowan, 1977; Sarason, 1982). Conceptualizations of school improvement, therefore, must go beyond adopting an innovation, changing a structure, copying the practices of successful schools, or implementing new management systems such as site-based management (Barth, 1986, 1990; Crandall *et al.*, 1986; Cuban, 1984; Fullan, 1992; Sarason, 1982).

School improvement efforts are, however, a study in contrasts. The past several decades have seen school improvement efforts organized around the adoption of a curricular program, the implementation of teacher development programs, planned school improvement and school development programs, development of schools as learning organizations, and whole-school adoption of an organized set of teaching and learning practices. Despite this variety in approaches, a consistent theme emerging from research across this domain over a period of decades is the importance of leadership in facilitating improvement efforts (Berman and McLaughlin, 1978; Firestone and Corbett, 1988; Fullan, 1982, 2000, 2001; Fullan and Pomfret, 1977; Hall and Hord, 1987; Leighton, 1996; Leithwood, 1994; Leithwood *et al.*, 2004; Leithwood and Montgomery, 1982). School leaders play a central role in initiating internal changes in schools, providing direction and support, and sustaining those changes over time by linking the internal and external environments of the school (Firestone and Louis, 1999; Fullan, 2001; Meyer

and Rowan, 1977). Indeed, based upon experience and research of the past five decades, it is possible to conclude that sustained school improvement in the absence of evidence of leadership is a rarity.

Conceptualizing Leadership

For the purpose of examining leadership and school improvement, we define leadership as a process of influence by which leaders (i.e., school principals and others within the school) identify a direction for change, develop strategies for action (formally or informally), and facilitate the efforts of teachers and other stakeholders that lead to improvement of identified outcomes. Although improved student learning is often the outcome most salient to policymakers, a wide range of other outcomes have also been studied as outcomes of school improvement efforts. These include student engagement, attendance, and persistence; and changes in teacher behavior and successful implementation of curricular programs.

Up until the 1990s, most research conducted in this domain focused on the role of the school principal in facilitating change and improvement. More recently, however, scholars have sought to conceptualize leadership for school improvement. This has resulted in a focus on multiple roles and shared responsibility of various people in the school (Barth, 1999; Lambert, 1998, 2002; Marks and Printy, 2003) or as a characteristic of the organization (Ogawa and Bossert, 1995).

Frames for Understanding Leadership for School Improvement

A review of the empirical literature on school improvement suggests several different models have dominated theory and research on leadership for school improvement from the late 1970s through the present (e.g., Firestone and Corbett, 1988; House, 1981; Louis *et al.*, 1999; Van den berg and Vandenberghe, 1986; Van Velzen *et al.*, 1985). In the first *Handbook for Research in Educational Administration* (Boyan, 1988), Firestone and Corbett (1988) provided a review of the extant research on efforts directed at planned school change. Planned change focused on intentional systematic efforts to modify some aspect of the school's organization or practice. Consistent with House (1981), they identified three perspectives describing research on school change: rational-technical, political, and cultural.

Rational-Technical Perspectives on School Improvement

A technical-rational view dominates the literature on educational change and school improvement. There was

and continues to be a common perception – especially in the educational policy community – that school improvement derives primarily from externally imposed efforts of policymakers at higher levels of government (e.g., federal and state levels). The means used by policymakers consist of a combination of laws, policies, mandates, grants, training programs, and curriculum projects (e.g., Berman and McLaughlin, 1978). Within this model, leadership is synonymous with the school principal. As middle managers operating in a hierarchical system, they represent the staff members holding primary responsibility for implementing change efforts initiated at other governmental and organizational levels. As Firestone and Corbett (1988) summarized this view, principals were "...central to change because they are best placed structurally to establish, or at least affirm, norms for the whole school" (p. 337).

Consistent with rational-technical theories of organizations, this conceptual framework assumes that strong linkages should exist between the goals and intentions of policymakers and managers, the activities of staff, and student outcomes (Bolman and Deal, 1992; Scott, 2002). Underperforming schools have often been documented as evidencing unclear goals and a loose coupling between management and teaching and learning activities (Weick, 1976). From this perspective, school improvement consists of processes and activities designed to tighten the linkages between goals, activities, and outcomes (Murphy *et al.*, 1984, 1985).

In rational-technical models of planned change, the principal's leadership is without question the most critical lever available to policymakers interested in strengthening these linkages (Fullan, 1982, 2001; Murphy *et al.*, 1984, 1985). Principals exercise leadership for school improvement through goal setting, often incorporated into formal school-improvement programs and projects. These school-improvement processes themselves reflect a rational orientation toward organizations that entails planning, organizing, directing, coordinating, and controlling school-level activities designed to achieve specific goals and produce intended outcomes (Scott, 2002).

This rational-technical model of leadership for school improvement is perhaps best reflected in the effective schools literature which emerged during the 1980s. Findings from studies of instructionally effective schools for the urban poor were often loosely translated into prescriptions for the improvement of all schools (Brandt, 1982; Clark *et al.*, 1984; Edmonds, 1979; Levine, 1991; Mortimore, 1993; Rutter *et al.*, 1979; Stoll and Fink, 1996). A key finding from this body of related literature concerned the presence of strong principal instructional leadership in schools that were producing better-than-expected learning outcomes for traditionally underachieving student populations (Edmonds, 1979; Bossert *et al.*, 1982). This picture of strong instructional leadership contrasted sharply with prior research that found principals to

be largely disconnected from the technical core activities of teaching and learning in schools (Bossert *et al.*, 1982; Cuban, 1984). This led to prescriptions for school principals to become more actively engaged as instructional leaders. Cuban (1984) portrayed this picture of instructional leaders as hip-deep in matters of curriculum, instruction, and school improvement.

Notably, within this frame, school improvement was defined implicitly as oriented specifically toward the improvement of student learning outcomes. As the school-effectiveness studies were cross-sectional, however, this approach left open the question of whether and how instructional leaders could help schools increase their effectiveness over time through various improvement strategies (Barth, 1986; Cuban, 1984; Hallinger, 2003; Jackson, 2000; Slegers *et al.*, 2002).

A strong focus on instructional leadership continues to dominate the rational-technical approach into the present era, although with some adaptations. More recent views of instructional leadership, while accepting the importance of the principal in the process of school change, have highlighted constraints on the principal's time, educational expertise, and moral authority in assuming sole responsibility for leading school improvement (Barth, 1986, 1990; Blasé, 1993; Cuban, 1984; Hall and Hord, 1987). This recognition has led to a broadening of the instructional leadership construct to incorporate other key leaders in the school. The result has been a conceptualization of instructional leadership as a responsibility shared among by the principal with other school administrators and teachers (Barth, 1990; Hallinger, 2003, 2005; Lambert, 1998, 2002; Kleine-Kracht, 1993; Marks and Printy, 2004).

Political Perspectives on School Improvement

Yet, even as support for the importance of leadership as a key factor in school change emerged, other scholars called into question the underlying assumptions of the planned change model of school improvement (e.g., Barth, 1986; Berman and McLaughlin, 1978; Cuban, 1984, 1990; Fullan and Pomfret, 1977; Sarason, 1982; Weick, 1976). For example, the Rand studies during the 1970s highlighted the difficulty of actually implementing reforms to change educational processes across levels of educational systems. This research found that features of the local district and school site contexts moderated the implementation process to determine the outcomes of school-reform efforts (Berman and McLaughlin, 1978). As McLaughlin (1990) and Cuban (1990) later suggested, the nature, amount, and pace of change at the individual school is a product of local factors that are often out of the control of higher-level policymakers.

Political values and interests at the local level often conflict with the underlying purposes of reform mandates imposed from higher levels of the system. Schools are

characterized by multiple goals, diverse instructional strategies, and a relatively high degree of teacher autonomy (Barth, 1986, 1990; Cuban, 1990; Weick, 1976). This results in informal negotiation over the goals and strategies of school improvement. Based on these observations of school improvement in practice, researchers reconceptualized school improvement as a process of mutual adaptation, rather than as one of rational-technical imposition of change (Berman and McLaughlin, 1978).

Subsequent scholarship highlighted the role of micro-political processes within the school system as a key dimension influencing school improvement. This research recast the role of school leaders in school improvement from that of instructional or transformational leaders to that of negotiators, blending the needs and interests of various stakeholders (e.g., principals, teachers, parents, and the wider community) to determine goals and strategies and to allocate resources (Blasé, 1993; Bolman and Deal, 1992). The political frame challenged the dominant view of school improvement as a rational, top-down, goal-oriented process. It refocused attention on the role of leaders in interpreting local values endorsed by the school community and in working collaboratively with teachers (Blasé, 1993; Ogawa and Bossert, 1995).

We would also include critical and feminist perspectives on leadership within this framework on school improvement. These approaches again question the underlying assumption of school improvement as a goal-oriented process directed toward student achievement. Instead, these perspectives refocus attention on how well-intentioned school-improvement efforts can reinforce social inequities at the school level (Anderson, 1990). They examine the means through which dominant social values and shared meanings about unjust school processes (e.g., student grouping and access to curriculum) develop and seek to document the outcomes. They often involve a critique of existing social relationships and advancement toward desired ones (Keith, 1996).

One role of school administrators has been to legitimize their functions as allocators of social values, often consciously or unconsciously institutionalizing societal inequities. These perspectives reframe the role of leaders as questioning the underlying purposes of schooling and refocusing the efforts of schools into increasing social justice. Although these perspectives help us see school leadership in facilitating school improvement in more expansive and diverse ways, they have been less influential to date in terms of changing school-improvement practice.

Cultural Perspectives on School Improvement

Like the political frame, cultural-institutional approaches question the underlying assumptions of rational-technical models of school improvement (Bolman and Deal, 1992; Cuban, 1990; Deal, 1990; Sarason, 1990). Researchers

employing these alternative lenses again have remarked on the observed gap between intentions and results of large-scale reform efforts. Sarason (1982) characterized this perspective as “the culture of the school and the problem of change.” Numerous features of the local school culture – its decision-making structure, predominant values, past experience with change, administrative support, program focus, and other normative practices of the principal, teachers, and students – affect the implementation of improvement programs and activities.

From this perspective, improvement is defined in terms of reshaping normative structures within schools so that change can take root. Cultural perspectives on school change, view school improvement as a process of capacity building and growth rather than program implementation (Fullan, 2002, 2003; Stoll and Fink, 1996). In contrast to the rational–technical frame which has tended to emphasize instructional leadership, the dominant leadership perspective within the cultural frame has been transformational leadership (Leithwood, 1994; Leithwood and Jantzi, 1999, 2000).

The transformational model of school leadership (or models that focused on leadership as an organizational quality) was often associated with efforts to change the school’s culture as a means of changing its outcomes (e.g., Leithwood, 1994; Leithwood *et al.*, 1993; Mulford and Bishop, 2003; Pounder *et al.*, 1995; Rowan and Denk, 1984; Silins, 1994). The central distinction between the transformational and instructional leadership models is that instructional leadership focuses more on first-order changes in classroom practice, while transformational leadership targets second-order changes in the school’s culture (Hallinger, 2003, 2005).

Transformational leaders seek to build a shared vision for the school, foster staff collaboration and learning, develop norms that support continuous improvement, and increase involvement in decision making as means of implementing and sustaining school improvement (Barth, 1990; Fullan, 2001, 2002; Leighton, 1996; Leithwood *et al.*, 2004; Louis and Miles, 1990; Mulford and Bishop, 1997; Mulford and Silins, 2003; Stoll and Fink, 1996). Recognizing that change is driven from the bottom-up as well as from the top-down, there is again an emphasis on the distribution and sharing of leadership responsibilities within the school (Barth, 1990; Blasé, 1993; Fullan, 2002, 2003; Lambert, 2002; Stoll and Fink, 1996).

Studies of transformational school leadership have documented ways in which principals and teacher leaders develop conditions that support school improvement. Such studies have focused on a broader set of outcomes than just student learning, including staff development, collaborative culture, changes in teacher attitudes and behaviors, professional community, teacher commitment, and student engagement (e.g., Leithwood *et al.*, 1993; Leithwood, 1994; Leithwood and Jantzi, 1990, 1999; Marks and Printy, 1996;

Mulford and Bishop, 1997; Mulford and Silins, 2003; Silins, 1994; Silins and Mulford, 2002; Wiley, 2001). The results of these studies have generally confirmed the important role principals and school leaders play in facilitating the development and implementation of school cultures that support school improvement (Leithwood *et al.*, 2004).

In recent years, school improvement has also come to be viewed in a broader global perspective. Studies of educational change in different nations raised awareness of how the cultural contexts of different countries influence goals and strategies for school improvement. Although recognition of contextual differences represents a significant advance in and of itself, less progress has been made in defining how the role of leadership differs across cultures (Dimmock and Walker, 2000; Hallinger and Kantamara, 2000; Hallinger and Leithwood, 1998). This set of issues will undoubtedly engage the attention of the next generation of scholarship as research on school improvement expands into a truly global enterprise.

Challenges in Facilitating School Improvement

Reviews of previous research provide evidence that school leadership can influence school improvement as measured by various different outcomes (e.g., Hallinger and Heck, 1996, 2002; Heck and Hallinger, 2005; Leithwood, 1994; Leithwood *et al.*, 1982, 2004; Teddlie and Reynolds, 2000). Over time, a broader range of studies investigating both leadership and school improvement have emerged. These reflect increasingly diverse epistemological views which raise different research questions and employ different methods for conducting empirical research (Heck and Hallinger, 2005). At present, there is growing policy concern for identifying improvement strategies that are successful at improving levels of student learning over time (Slegers *et al.*, 2002) at the same time that a growing set of scholars question the underlying assumptions of the rational–technical approaches to school improvement (Day *et al.*, 2001). With respect to this more narrowly defined improvement objective, it is important to note limitations in the knowledge base concerning leadership for school leadership.

The positive contributions attributed to school leadership – specifically that of the principal – for improving student learning derive from two general types of studies. The first type is cross-sectional studies of school effectiveness. The second type consists of studies of school change and school improvement projects that observed leadership as a key factor in successful school improvement projects, but which were not explicitly designed to test this as a causal variable. The paucity of systematic longitudinal studies designed to test the contribution of leadership to school improvement leaves unanswered

important questions of causality as well as how school leaders actually facilitate efforts to improve student learning outcomes over time (Heck and Hallinger, 1999; Slegers *et al.*, 2002; Smylie and Hart, 1999).

What remains is to put together various pieces about features of improving schools. Bolstered by stronger theory about organizational change, scholars would inquire into how school processes can be altered in ways that result in improved outcomes. This research would also seek to describe how school leadership can facilitate improvement processes over time. More specifically, how and why do improvement strategies succeed (e.g., Hallinger and Heck, 2002; Louis *et al.*, 1999; Ouston, 1999)? Sustained inquiry about changing school processes and their impact on student learning over time will be required to fill in the gaps in our understanding of how leadership facilitates school improvement.

Our discussion of leadership and school improvement suggests several challenges for further research. First, the school effectiveness literature may have overemphasized the role of school leadership in influencing school improvement – especially as associated solely with school principals. A persisting criticism of this research has been a lack of theory in actually guiding schools toward achieving increased effectiveness (Day *et al.*, 2002; Ouston, 1999; Smylie, 1994). There is ample support for the notion that leadership is an organizational property (e.g., Ogawa and Bossert, 1995), with groups of individuals sharing responsibility for managing changes successfully (e.g., Berman and McLaughlin, 1978; Louis and Miles, 1990). This suggests broadening the investigation of leadership and its effects beyond the principalship (Hallinger and Heck, 2002; Leithwood and Jantzi, 1999, 2000).

Rather than focusing on generalized theories of school leadership and school improvement, scholars may be well advised to focus on building more domain-specific theories of how leadership affects various types of school outcomes not necessarily limited to student learning (Leithwood *et al.*, 1996). It remains to develop greater continuity in purposes and methods in order to find linkages and effects of school leadership on improvement outcomes. Studies in various settings define the goals of the research quite differently, and there is little consistency in terms of the types of contextual variables that may be important to consider (Hallinger and Heck, 1996; Teddlie and Reynolds, 2000). We noted that knowledge development seems to occur primarily in domains where there are externally driven demands for school accountability and increasing student learning (Heck and Hallinger, 2005).

Second, although various schools of scholarship would certainly disagree, we assert the need to place student learning at the center of research on school improvement (e.g., Heck and Hallinger, 2005; Leithwood *et al.*, 2004). This priority reflects a global concern for ensuring improvement in learning results for students. Unfortunately, to date

neither school effectiveness nor school improvement research has addressed what must be done to improve school outcomes (Ouston, 1999). This type of investigation will require improved use of theory about how these processes unfold in schools and greater use of longitudinal data collection. As Willms (1992) has noted, improvement in student learning is a more salient outcome than level of school outcomes measured at one point in time. Slegers *et al.* (2002) suggest that growth in student outcomes has not yet been applied often enough as a dependent variable in studies to be able to evaluate long-term effects.

Studying school improvement over time requires being able to link individual student data to teachers and (or) schools over several measurement occasions. This has made it more difficult to obtain data on both outcomes and changing school process variables that might affect school improvement since it often exceeds the current capacity of educational assessment systems (Heck, 2006). Besides the technical details of appropriate data collection, focusing on how leadership facilitates student learning will involve untangling the conceptual confusion about the types of contributions made by school leadership. Leithwood *et al.* (2004), for example, have made one recent attempt to propose a model of leadership and student learning that can serve as a framework for further empirical investigation.

Third, in our recent review of research on leadership and organizational mission (Hallinger and Heck, 2002), we noted that cognitive perspectives on leadership identify variables such as vision, mission, and goal setting as important in the improvement process. Vision and corresponding goal setting have been identified as important avenues of influence for school improvement (Hallinger, 1998; Hallinger and Heck, 2002; Leithwood, 1994; Leithwood *et al.*, 1998; Slegers *et al.*, 2002). This is closely associated with mediating teacher variables such as commitment to change, collaboration, and participation in decisions about school improvement (Hallinger and Heck, 2002). As Ouston (1999) argues, the school-improvement literature has noted the importance of variables such as school culture, goal setting, planning, and evaluation. Rarely, however, has any attempt been made to develop a dynamic model of school processes, although this is frequently mentioned as being desirable.

Finally, there is a need to determine the proper targets of improvement strategies. There is considerable difference of opinion about where efforts should be most appropriately placed. Changing teacher instructional behavior suggests an emphasis on classrooms, since teachers have a direct impact on student learning (Teddlie and Reynolds, 2000). The literature on large-scale reform efforts to affect outcomes, however, suggests that changing teaching practices is difficult to accomplish (Slegers *et al.*, 2002). At the school level, there is only mixed evidence that professional learning (especially because of the interacting effects of context) or site-based management have

measurable impacts on student outcomes (e.g., Smylie and Hart, 1999). Research does indicate, however, the role of leadership in terms of redefining norms and educational processes is significant (Hallinger and Heck, 2002; Leithwood *et al.*, 2004).

Other more recent proposals emphasize targeting the district and state and local educational levels simultaneously and interactively in order to sustain school improvement (Barber and Fullan, 2005; Fullan *et al.*, 2006). This approach to leadership for school improvement combines features of the rational–technical, political, and cultural perspectives on school improvement and has emerged out of a process of learning from putting research into practice in several large educational systems. As Fullan asserts, “It has become increasingly clear that leadership at all levels of the system is the key lever for reform, especially leaders who (1) focus on capacity building and (2) develop other leaders who can carry on” (Fullan, 2006: 33). This conclusion certainly finds support in the literature on leadership for school improvement. The implementation of tri-level school improvement efforts in large educational systems could provide the opportunities needed for the type of empirical investigation that we have suggested is necessary for furthering our understanding of the role of leadership in school improvement.

Organizational Learning in Schools

Introduction

In the 1990s, a veritable explosion of books and journal articles on organizational learning (OL) in business (e.g., Senge, 1990; Easterby-Smith *et al.*, 1999) contrasted with a small but increasing number of educational writers taking up the OL baton (e.g., Argyris, 1993; Miles, 1993; Watkins and Marsick, 1993; Fullan, 1993; Louis, 1994; Keating, 1995; Cousins, 1996; Leithwood and Louis, 1998; Mulford, 1998). These writers were followed by an even smaller number of educational researchers (e.g., Louis *et al.*, 1995; Mitchell, 1995; Hajnal *et al.*, 1998; Leithwood *et al.*, 1998; Marks *et al.*, 2000; Silins and Mulford, 2002a; Voulalas and Sharpe, 2005). Toward the end of the 1990s, Leithwood and Louis (1998: 7) pointed out that while the logical case for OL was compelling, “empirical support for the claim that increases in such learning will contribute to organizational effectiveness or productivity is embarrassingly slim” and that a “review of empirical research on organizational learning in schools alone would make a very quick read indeed.”

Why the growing interest in OL in schools? Almost 30 years ago, Argyris and Schön (1978: 320) argued that those intervening in organizations “have had to recognize that their main challenge is not to help an organization become more effective at the performance of a stable task in the light of stable purposes, but rather to help an organization restructure its purposes and redefine its task in the face of a changing environment.” In a similar vein, but more succinctly stated, Senge’s (1990) learning organization (LO) focuses on “continually expanding its capacity to create its future” (p. 14). Argyris and Schön (1978: 331) gave elementary importance to “an organization’s capacity for conscious transformation of its own theory of action, and to individuals’ ability to appreciate and transform the learning systems in which they live.” The better organizations are at organizational enquiry or learning, the more likely they “will be able to detect and correct errors, and to see when they are unable to detect and correct errors” and the more likely they “will be at being innovative or knowing the limits of their innovation” (Argyris, 1993: 1).

What Is OL?

Consistent with the reasons for the growth of interest in OL, Leithwood and Aitken (1995: 63) defined OL in

schools as “... a group of people pursuing common purposes (individual purposes as well) with a collective commitment to regularly weighing the value of those purposes, modifying them when that makes sense, and continuously developing more effective and efficient ways of accomplishing those purposes.” According to Fullan (1994: 5), in schools that demonstrate OL, two things are key, “learning is considered both ‘essential’ (important) and ‘integral’ (linked) to goals and activities.” Keating (1995: 20) pointed out that the area of OL had many descriptions and case studies, but little comparative or systematic research. He believed that “key elements noted by thoughtful observers can be summarized.” For Keating, these elements included: coordinated group effort toward commonly shared goals; active commitment to continuous improvement and to the diffusion of best practices throughout the organization; horizontal networks of information flow to help bring together expertise as well as links with the external world; and the ability to understand, analyze, and use the dynamic system within which the staff functions.

Mitchell (1995: 47) also believed that much of the work on OL was “theoretical in nature, based on literature reviews and anecdotal reports rather than on empirical evidence.” She noted that, in her reading of the OL literature, she was reminded of the story of the three blind men trying to describe an elephant from a different vantage point. Nevertheless, Mitchell (1995) concluded that there are points of convergence including the following set of indicators of school OL: developing a spirit of trust; developing common understandings; developing shared vision; sharing information openly and honestly; engaging in collaborative practices; engaging in professional learning and growth; using reflective self-analysis to raise awareness of assumptions and beliefs; examining current practices critically; understanding the inevitability of conflict; engaging in dialog in order to understand the frames of reference of others; raising sensitive issues for discussion; experimenting with new practices; changing personal frames of reference if warranted; managing differences of opinion through inquiry and problem solving; understanding systemic influences and relationships; and correcting disruptive power imbalances.

In Mitchell’s (1995) subsequent research in an urban Canadian elementary school, she found that a school operating effectively as an LO could be described using four processes, three basic assumptions, and three distinct

phases. To quote Mitchell, of the four processes, two cognitive and two affective:

The cognitive processes of reflection and conversation enabled the teachers to become aware of their practices and of those of their colleagues, to assess the desirability of those practices, and to discover new possibilities. The affective processes of affirmation [of each other as professionals] and invitation [into school deliberations] served to create positive working relationships by affirming the professional capabilities of individuals and by valuing the contributions of all staff members. (Mitchell, 1995: 223)

These four processes were founded upon three basic assumptions (Mitchell, 1995: 226): “that each individual was responsible for the welfare of the group and the success of the school; that diversity among individuals was recognized, honoured, and valued; and that psychological safety would be maintained in group deliberations.” Finally, these four processes moved through three phases (Mitchell, 1995: 226): “naming and framing to clarify positions and opinions; analysing and integrating especially when new ideas are opened up for possible experimentation; and applying and experimenting.” Indicators of OL synthesized from the literature by Mitchell (1995: 231) were found to emerge differentially at each of the three phases thus implying that “these behaviours and processes do not develop overnight, but rather build on one another over time”. This developmental nature of OL highlighted for Mitchell (1995: 243) “the importance of the ‘naming and framing’ and ‘analysing and integrating’ phases.” The comfort level with OL grew as teachers developed their own understandings about the concept, analyzed their own practices in the light of those understandings, and applied appropriate aspects of what they had learned.

In related work, Boyd and Hord clustered the indicators of schools as professional learning communities (PLCs) into five functional groupings (Boyd and Hord, 1994; Hord, 1997): shared values and vision; collective learning and application; supportive and shared leadership; supportive conditions; and shared personal practice (with a strong and unwavering focus on student learning). Subsequently, other researchers examined the conditions that foster the development of these five dimensions in schools that successfully improved student learning (Hord, 2004; Hipp and Huffman, 2003). Bolam *et al.* (2005) identified eight characteristics of schools that were PLCs: inclusive membership; mutual trust, respect, and support; openness, networks, and partnerships; shared values and vision; collective responsibility for pupils’ learning; reflective professional inquiry, collaboration focused on learning; and group as well as individual professional learning. A number of external and internal factors facilitated or inhibited these characteristics, including the internal school processes of resources and structures, promotion of professional learning, evaluating

and sustaining the PLC, and leadership. These characteristics and processes were found to be exhibited in varying degrees depending on where a school was placed on the sequence of starter, developer, or mature PLC as judged by the percentage of staff involved in key PLC activities.

From an extensive review of the noneducational and educational literature, including Senge’s (1990) seminal model of the five disciplines of OL (mental models, shared vision, personal mastery, team learning, and systems thinking), Silins *et al.* (2002) defined OL as schools that: employed processes of environmental scanning; developed shared goals; established collaborative teaching and learning environments; encouraged initiatives and risk taking; regularly reviewed all aspects related to and influencing the work of the school; recognized and reinforced good work; and provided opportunities for continuing professional development. This seven-factor structure, used to generate questionnaire items for a large research project on leadership for organizational and student learning in Australian high schools, was not supported empirically. Instead, a four-factor nested model of OL was supported comprising a trusting and collaborative environment, a shared and monitored mission, taking initiatives and risks, and ongoing, relevant professional development. Subsequent case study analysis suggested that the first three of these factors were sequential (Mulford *et al.*, 2004).

The emergence of consistent lists of identifying the characteristics of OL can be noted. In addition, some of the interrelationships among these characteristics are becoming clearer. For example, from a within-the-organization focus, the identifying characteristics tend to describe a journey rather than a destination. The first stage involves developing common understandings, honesty, and trust through dialog, sharing, and managing the inevitable conflict. These learning processes are then employed to link to the outside, examine current practice critically, and develop shared values as well as a vision for the school. The processes, the content (or identified changes), and shared values are employed to actually make the changes identified, thus taking initiatives and risks while continuously learning and improving. The stages of the journey are sequential and cyclical, lifting practice through renewed commitments and improved abilities (Silins and Mulford, 2002a).

In summary, OL in schools can be defined as a school staff’s collective commitment to a continuous journey pursuing, monitoring, and, where necessary, changing and improving shared processes and purposes.

Why Is OL Important?

Louis (1994: 20) argued that existing models of change management in education were inadequate and that the

OL model was more promising because the “image of change that emerges in the organizational learning paradigm has elements of both managed change (organizational learning is affected by structure and leadership) and anarchy (the emergence of alternative paradigms and the selection of a new paradigm is a chaotic, largely unpredictable process).” She noted that the concept had the “potential for helping to think about the problem of how schools change basic assumptions about ‘what it is we do here’ when demands for significant reforms are made” (Louis, 1994: 9). The conclusions of a 5-year longitudinal study of policy implementation in the Canadian province of British Columbia (Leithwood, *et al.*, 1995) confirmed that individual and collective learning processes (OL) best explained the variation in the productivity of schools. Collective learning processes were measured through interviews and included exchange of information through informal discussions among colleagues, experimentation with new practices, and joint planning and teaching. Newman and Wehlage’s (1995) influential research on successful school restructuring concurred, arguing the need for schools to become LOs by building organizational capacity.

The demands of fundamental and rapid change make sense of the shorthand statement that learning is change, as does the emphasis on active dialog among those with diverse points of view. To speak only with people sharing the same perspective runs the risk of those involved not being moved to thoughts of something better (Greene, 1995). The emphasis on the quality and character of human relationships and the necessity for individuals, groups, and organizations to construct meaning for themselves is appealing. This presumes the rejection of imposing one’s will on others for successful change. Louis (1994) argued that the principles of OL should shift discussion of educational problems away from blaming and finger-pointing to a consideration of systemic barriers to learning by those actually involved in change.

This emphasis on learning within a school might create an environment where the practice of the most effective teachers can be used to support and develop others’ work. Greater consistency in the range of opportunities that learners experience during their education is especially important given that variation in performance within schools has been found to be 4 times as great as variation in performance between schools (OECD, 2000). During 2003–04, 24 UK schools belonging to the National College for School Leadership’s Leadership Network (Connor, 2005) explored this issue of within-school variation. Researchers found schools applying a range of strategies to reduce this variation. Grouped into four themes, these were: the collection, analysis, interpretation, and use of data; the development of strategies that focus on teacher learning through, for example, the focused observation of specific aspects of practice; proposals for

curriculum reform, especially ensuring a relationship with the interests and preferences of learners; and the development of middle leaders, and facilitating learning from the innovative practice of others in the school.

What Are the Effects of OL?

Argyris (1993: 1) pointed out that in contexts such as those facing education today, organizations “have the most difficulty at learning when the problems are difficult, and embarrassing or threatening, in short, precisely when they need learning most.” Harassed and harried, caught on Deal’s (1990: 145) “high-speed carousel of change,” most schools and the systems in which they reside may not have the time, energy, or inclination for understanding, let alone developing, OL. Although the current research output on OL in schools is small, it is impressive and goes some way to countering Leithwood’s and Louis’ (1998) criticism that whether OL will contribute to organizational effectiveness or productivity is still to be empirically determined. Across a number of countries and school levels, OL has been clearly shown to be linked to school leadership, successful school improvement and innovation, school development, including collective teacher efficacy, and/or a range of student outcomes. A representative sample of this research is summarized in what follows.

A number of studies have linked OL and school leadership. A study of six Canadian schools by Leithwood *et al.* (1999) considered promising sites of OL, including four secondary schools, and found that school leadership practices had among the strongest direct and indirect influences. Those practices included identifying and articulating a vision, fostering the acceptance of group goals, structuring the school to enhance participation in decisions, providing intellectual stimulation, and conveying high expectations, that is, practices associated with transformational leadership. Such uniformly positive contributions of school leadership to OL have been confirmed by Sheppard and Brown (2000) and Silins and Mulford (2002a, 2002b).

Further studies link OL and successful school improvement initiatives and innovation. Hajnal *et al.* (1998) sought to identify successful school improvement initiatives and indicators of institutionalization in 93 Canadian schools. They concluded that leadership and OL were critical to school improvement. Leadership required attention to school and personal matters. School matters included a shared vision, resources, and an environment supportive of change. Personal matters included paying attention to individual differences, facilitating and empowering, encouraging collaboration, and building an environment of trust and care. OL required established practices that supported extensive collaboration, individual learning, and a clear

vision for the school. Sheppard and Brown (2000) collected data in two Canadian high schools with national reputations as innovative schools. Despite strong existing shared staff knowledge structures and the immediacy of teachers' work environments, the schools were found to gradually take on the domains of knowledge that Fullan (1995) argued were required for OL. Teachers and their administrators established partnerships with outside groups, which resulted in significant additional funding and new program initiatives, took ownership of the change process, and formalized collaborative structures. In time, the staff came to focus directly on teaching and learning, even though this was not their starting point. Eventually, the staff evolved into continuous learning communities, taking responsibility for their own professional development. Finally, the staff adopted programs targeted at the needs of all students.

Additional studies linked OL and school development, including teacher efficacy. Johnston's (1997) case studies of three Australian high schools with OL characteristics identified four key elements as instrumental in their development: an inclusive collaborative structure; effective communication channels; integrated and inclusive professional development programs; and learning-focused leadership. The latter was described as empowering (all within the school could be leaders) rather than heroic or hands on leadership. Ross *et al.* (2004: 177) found that "the strongest effects on collective teacher efficacy" were characteristics associated with OL, including "shared school goals, school-wide collaboration, fit of plans with school needs, and empowering school leadership." Studies have also documented a strong link between perceived teachers' collective efficacy and differences in student achievement. Bandura (1993) demonstrated that the effects of collective efficacy on student achievement were stronger than the direct link between socioeconomic status (SES) and student achievement. Goddard *et al.* (2004) found that even after controlling for students' prior achievement, race/ethnicity, SES, and gender, collective efficacy beliefs have stronger effects on student achievement than student race or SES. Goddard *et al.* (2004: 420) calculated, for example, that "a 1 SD increase in collective efficacy is associated with a gain of about 0.25 SD in terms of the number of students who pass high-stakes assessments in 12th grade." Goddard (2002) had also found that where teachers have the opportunity to influence important school decisions, they also tend to have stronger beliefs in the co-joint capability of their staff.

Finally, and most crucially, are studies linking leadership, OL, and student outcomes. Mawhinney *et al.* (2005: 5) examined how, "under pressures of accountability, districts in United States ... are undertaking research to support their development of strategic actions to foster organizational learning in schools." In a study of all teachers ($N=2448$) and administrators ($N=17$) employed

in 49 schools (31 elementary, nine middle, and eight high schools), Mawhinney *et al.* (2005) found collective efficacy and PLC (using a measure of OL) are positively related with the strongest relationships being with dimensions of shared values and vision, collective learning and application of that learning, and supportive conditions. While only two variables, the students' previous year's proficiency and collective efficacy beliefs, were significant predictors of student reading proficiency, "teachers who perceive their schools to be characterised by shared leadership, focused vision, collaborative work, shared observation, and supportive conditions also perceive their colleagues to be effective in bringing about student learning" (Mawhinney *et al.*, 2005: 20). Elementary, low-poverty, and white schools as well as female teachers perceived the highest levels of collective efficacy.

In the first study of its kind, Wheelan and Tilin (1999) examined the relationships between 292 teacher perceptions of staff group effectiveness and development and the actual levels of productivity in ten USA elementary, middle, and high schools. A survey measured the group development (from inclusion and dependency to conflict and counterdependency, trust and structure, and, finally, work and productivity) and data were gathered on student grades, standardized test scores, and the degree of parental involvement. Wheelan and Tilin (1999: 77) "found significant relationships between ... group development level and maths rank, reading rank and total achievement rank (a combination of maths and reading)." The staff in schools, classified as high in reading and total rank, has significantly lower scores on conflict and significantly higher scores on trust and structure as well as on work and productivity stages of group development. In addition, those high on trust and structure as well as on work and productivity also reported higher levels of parental involvement.

Marks *et al.* (2000) selected 24 predominantly urban, economically disadvantaged elementary, middle, and high schools in USA, where restructuring had been particularly thorough, in which to collect data using a battery of quantitative and qualitative instruments. Controlling for gender, race, ethnicity, SES, and student ability, the researchers examined the relationships among three dependent variables, authentic academic achievement (the sum of student scores in mathematics and social studies on analysis, disciplinary concepts, and elaborated written communication), National Assessment of Educational Progress (NAEP) achievement (a test of basic knowledge and skills in mathematics and reading/writing), and authentic pedagogy (a composite measure combining teachers' scores on observed classroom instruction and assessment tasks), and the independent variable, capacity for OL. Capacity for OL involved six dimensions: school structural conditions (school size, extent of decentralized governance, and the amount of

time teachers spend meeting with colleagues); teacher empowerment; shared commitment and collaborative activity; knowledge and skills (including school-oriented staff development, openness to innovation, and pedagogical content knowledge); supportive leadership; and feedback and accountability. Marks *et al.* (2000) found that 18–26% of the dependent variables were attributable to differences among schools. A school's capacity for OL was a strong predictor of success on the measures of authentic achievement, NAEP achievement, and pedagogical quality. They concluded that the capacity for OL supports the central teaching and learning activities of the school. However, they warn that the presence of only some of the dimensions of this capacity is not sufficient to activate OL. In the related area of PLCs, an almost 3-year research by Bolam *et al.*, including 393 surveys and 16 case study schools in England, also found

a positive, though weak, link between full expression of PLC characteristics and pupil outcomes – in particular value added performance... attendance, interest in learning and actual learning, as well as on the individual and collective professional learning, practice and morale of teaching and support staff. (Bolam *et al.*, 2005: iii)

Identified by reviews in the area (Bell *et al.*, 2002; Leithwood *et al.*, 2006) as one of the most thorough examinations of the relationship between leadership, OL, and student learning is the longitudinal Leadership for Organizational Learning and Student Outcomes (LOLSO) project. The LOLSO research on 96 Australian high schools involving over 5000 year-10 students and 3700 teachers (Silins and Mulford, 2002a, 2002b, 2004; Silins *et al.*, 2002; Mulford *et al.*, 2004) found that leadership that makes a difference has been found to be both position based (principal and transformational) and distributive (administrative team and teachers). However, both were indirectly related to student outcomes. OL, defined (not unlike collective teacher efficacy) by a trusting and collaborative environment, shared and monitored mission, supporting initiatives and risks, and providing appropriate professional development, was the important intervening variable between leadership and teacher work and, subsequently, student outcomes. That is, leadership contributed to OL, which in turn influenced what happened in the core business of the school – the teaching and learning. It influenced the way students perceived teachers organizing and conducting their instruction, and their educational interactions with, and expectations for, their students. Pupils' positive perceptions of teachers' work directly promoted their participation in school, academic self-concept, and engagement with school. Pupil participation was directly and pupil engagement indirectly (through retention) related to academic achievement. School size was negatively linked, while SES and, especially, student home educational environment, positively linked to these relationships.

Constraints

Effective OL involves those in a school taking responsibility for outcomes. Yet, how do those in schools share responsibility for outcomes/learnings/problems when several matters are not within a school's control? Levin (1994: 48) points out that “arguably, the most powerful educative (and miss-educative) forces in our society lie outside the school system” and that “educational reformers might direct their efforts with greater effect to the mass media, popular culture, and the emerging Information Superhighway [sic].” Hargreaves (1995: 12) goes further in suggesting that, “the dynamics of blame. . . the claim that we share responsibility for all our problems seems . . . pernicious. Schools and teachers have to deal with many mandates they do not control. Public schools are not bounded systems.” Voulalas and Sharpe (2005) conducted interviews with 22 Australian metropolitan principals identified by district superintendents as taking action to help their schools become LOs. They found that respondents lacked a clear understanding of LOs and that traditional hierarchical school structures and cultures, lack of implementation time, and difficulty in obtaining the support of staff and parents were major barriers to implementation.

How can we better handle the potential incompatibility between accountability and empowerment (Glickman, 1990) faced by schools? Teacher empowerment without accountability can lead to anarchy, whereas accountability without empowerment can lead to subservience. The OL in schools' literature suggests that to succeed in a rapidly changing and increasingly complex world, it is vital that schools grow, develop, adapt, and take charge of change so that they can control their own futures (Gitlin and Margonis, 1995; Stoll *et al.*, 2003). OL involves a different way of operating than many are used to. Accountability necessitates a movement away from external, extrinsic compliance to intrinsic, shared responsibility. Rusch (2005) reinforced this movement by identifying competing institutional scripts that act as barriers to OL in school systems. Structures in OL networks are malleable, not fixed or hierarchical as in traditional systems; conflict is open and valued rather than hidden and feared; communication is open and unbounded rather than controlled and closed; leadership is fluid rather than hierarchical or assigned; relationships are egalitarian rather than meritocratic; and knowledge is based on enquiry and valued for the learning that takes place rather than based on expertise and valued for the extent of knowledge. Gitlin and Margonis (1995) suggested that if schools are to become effective at OL, then at least one of the grammars of schooling, that is, how they use time, will need to be profoundly reviewed. Louis *et al.* (1995) and Lieberman (1995) made this same point, as did Mitchell (1995: 231) when she pointed out that the behaviors and processes required for effective OL “do not

develop overnight, but rather build on one another over time.” Specifically, Mitchell (1995: 243) found that her first phase of building effective OL, naming and framing, “is an active process, and teachers need time to talk about and to reflect on initiatives. We could be forgiven for wondering whether the fundamentals of education – teaching and learning – have been displaced for those inside and outside schools. Has displacement occurred because the improvement of interpersonal relationships, curriculum, and instruction call for delayed gratification, with the signs of progress not easily detected?”

Conclusion

Reporting on research in 200 business organizations, Redding and Catalanello (1994: xiii) stated that “the quality of strategic plans did not seem to have much to do with companies’ ability (or lack of ability) to change. Nor did the degree of effort devoted to the implementation of strategic plans . . . what seemed to matter most was the organization’s readiness for change.” These authors concluded, as have Beer *et al.* (1990), Drucker (1995), Kanter (1991), and Mintzberg (1994), that “fundamental organizational change most often results from journeys of learning – of setting out in a direction, of gaining new insights and making discoveries en route, of going back, adjusting old maps, developing revised plans, and taking new actions” (p. 7). This emphasis on learning, seeing journey’s of learning, learning one’s way forward, and learning as change, involving dialog and constructed meaning, is consistent with the reasons for the growing interest in, definitions of, research on, and continuing advocacy (e.g., Collinson *et al.*, 2006) of OL in schools.

OL deserves closer attention since it is argued that schools need to become LOs to fully engage staff and students as well as to meet the heightened multiple expectations now placed on them (Mulford, 2003). New types of relationships evolve between students, teachers, and leaders within OL schools based around a reasonably common set of characteristics that include a trusting and collaborative environment, a shared and monitored mission, supporting initiatives, risk taking, and ongoing, relevant professional development. These characteristics of OL have been found to be staged and built over time. For example, one message that emerges is that those in schools must also learn how to lose time in order to gain time. Awareness of, and skill development in, group and organizational processes is the first step. Instead of others trying to insert something into a school’s culture, the school, and especially its leadership, should first be trying to help that culture develop an awareness of, and a responsiveness to, itself. Success is more likely where people act rather than always react; are empowered; involved in decision making through a transparent, facilitative, and supportive

structure; and are trusted, respected, encouraged, and valued. Somech (2005) found that an interesting catch-22 situation developed when teachers simultaneously possess high levels of personal and team empowerment in that high team commitment can place constraints on a teacher’s individual autonomy and his or her personal empowerment. Somech (2005: 260) concluded that teachers “might achieve a ‘win-win’ situation if the norms of the profession of teaching do not translate autonomy into isolation and if collaboration is not perceived as violating teachers’ freedom.”

While collaboration does not necessarily suit or benefit everyone in a school (Johnson, 2003; O’Neill, 2000), it is a prerequisite for success (e.g., for the success of: high school English departments (Fuller *et al.*, 2005)); school-based management (Murphy and Beck, 1995); and integration of information and communication technology (ICT) (Robertson *et al.*, 2006). In addition, a trusting and collaborative environment (or naming and framing to clarify opinions or inclusion, dependency, conflict, counterdependency, and trust) is a necessary prerequisite, but not the end of the process. It is important to heed Dalin and Rust’s (1983: 91) warning that it “is fatal to assume that the school is learning only if it is undergoing change. More crucial is its ability to monitor its own system constantly, and accept as well as reject new practices and new products as they are found to be appropriate and inappropriate (that is, to be a learning organization).” The second stage concerns a professional community. A professional community involves a shared mission and shared norms and values including valuing differences and diversity, a focus on implementation, and continuous enhancement of learning for all students, deprivatization of practice, collaboration, and critical reflective dialog, especially that based on monitoring and performance data. However, a shared and monitored mission (or analysis and integration of structure, work, and productivity) is also not the end of the process.

The final stage relates to the presence of a capacity for change, and innovation. It means using the trusting and collaborative environment and a shared and monitored mission as a safe base from which to venture forth to take the initiative and risks. In brief, it is about the journeys of learning, learning one’s way forward, and learning as change. All stages are required for effective OL, with each stage and each transition between them able to be facilitated by appropriate leadership and ongoing, optimistic, caring, nurturing professional development.

OL offers a way for a school to make sense of paradox, to ride the seesaws of change (Handy, 1994) and increased diversity, to establish and maintain a sense of connectedness, direction, and continuity, and reduce variation in performance. OL offers the potential of stability for change, an opportunity for schools to move ahead without losing their roots (Peters, 1987). In other words, it is a change

strategy with the potential to address current change agendas. Essentially, it is a change strategy worthy of further development and analysis. Care will be needed, however, especially in cross-cultural situations. Our world is shrinking. Access to international information, institutions, and expertise increases the likelihood of policies and solutions to problems employed in one national context to be considered for use in other nations. Hallinger (1995) is one of a growing number who question this development. He wonders why, for example, “Western treatises on the nature of leadership . . . are often transferred across cultures with relatively little concern for cultural validity” (Hallinger, 1995: 4). It may be that, compared with the Western emphasis on separateness, things, individuality, the answer, and short time frame, Chinese cultures (Senge, *et al.*, 1994), for instance, with their greater appreciation of the interconnectedness of life, processes, community, interdependencies, and long time frame, or Scandinavian countries (Johansson, 2004), with their priority for democratic school leadership, would be more amenable to the concept of OL than the Australian and North American material that dominate this article.

Professional Learning Community

L Stoll, University of London, London, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Capacity – An individual's, group's, or organization's ability to engage in and sustain learning and improvement.

Co-construction of knowledge – Jointly creating new understanding and meaning.

Collective knowledge creation – Whereby a learning community interacts, engages in serious dialog and deliberates about information and data, interpreting it communally and distributing it among them.

Collective learning – In which a community interacts, engages in serious dialog and deliberates about all the information it has and data it collects, interpreting it communally and distributing it among themselves and collectively creating new knowledge.

Collegiality – Joint work promoting the kind of interdependence between colleagues that allows serious challenge and adjustment of practice.

Community of practice – A community focused on a topic of shared interest where participants gradually absorb and are absorbed in a 'culture of practice,' giving them exemplars, leading to shared meanings, a sense of belonging and increased understanding.

Deprivatization of practice – Opening up one's practice to the scrutiny of others.

Distributed leadership – Reciprocal leadership actions of a number of people; teachers and others involved in the practices of leadership.

Interdependence – Belief among members of a community that achieving better teaching practices would be considered impossible without collaboration.

Micropolitics – Internal politics and power issues within a community's relationships.

Reflective dialog – Conversations where tacit knowledge is converted into shared knowledge.

Reflective professional inquiry – Seeking new knowledge by frequently examining practice, through mutual observation and case analysis, joint planning and curriculum development, applying new ideas and information to problem solving and solutions that will address students' needs.

Social capital – Groups, networks, norms, and trust that are available to people to help them achieve their goals.

Despite shades of interpretation in different contexts, there is increasing international consensus that the term professional learning community broadly refers to an inclusive and mutually supportive group of people with a collaborative, reflective, and growth-oriented approach toward investigating and learning more about their practice in order to improve students' learning. The history of exploration is relatively recent with its main origins in North America, and largely focuses on schools and teachers within schools. The last few years, however, have seen greater attention in many countries from researchers, trying to gain greater nuanced and contextualized understanding of professional learning community, and policymakers who view its potential for the capacity building needed to implement educational reform. This has led to the development of various programs and initiatives promoting the development of professional learning communities. This article probes the meaning and purpose of professional learning community, membership, identified characteristics, levels of impact, and process and processes of development.

Meaning and Purpose

By examining the words making up the term, it is possible to see its theoretical underpinnings and its development.

Community

Core to the concept is the notion of community. The focus is not just on individual teachers learning, but of a sociocultural notion of learning within a collaborative community context – the notion of collective learning in a community of practice (Wenger, 1998). Features of communities – shared beliefs and understandings, interaction and participation, interdependence, concern for individual and minority views, and meaningful relationships through personal connections – are important to a professional learning community. The cultural norms of community are those of collaboration, interpersonal caring, and mutual support. Shared memory develops and is passed on to newcomers, and those involved view the group as a serious collective enterprise.

Professional

The word professional emphasizes that the community's work is underpinned by: a specialized and technical

knowledge base; a service ethic that orients members toward client needs; strong collective identity through professional commitment; and professional autonomy through collegial control over practice and professional standards (Talbert and McLaughlin, 1994). Changing notions of professionalism have also served to strengthen the link between the development of professionals and the development of the whole school in which they are located (Hargreaves, 1994), with increasing interest in understanding whole-school professional community in secondary schools.

Learning

Although described as a professional community of learners (Astuto *et al.*, 1993), much of the research in the United States still focuses on what has become known as professional community. Insertion, more recently, of the word learning has coincided with a shift in emphasis toward the objective of improvement – a learning community with a collective purpose of enhancing student learning. Here, for some investigators and proponents, there is a connection with other fields of study, including school improvement and social learning theory. Traditional forms of professional development emphasize opportunities for individuals to hone their knowledge and skills in and out of their school settings. Other means of collaborative learning in the workplace – including peer observation, coaching, and collaborative forms of action research – are now also being examined by some of those studying professional learning community. Collective learning in the context of professional learning communities also involves social learning, and working together toward a common understanding of concepts and practices. What is held in common does not supplant what teachers learn individually but supplements it and collaborative professional learning to support and spread learning throughout the entire community.

Nature of Membership

During the 1990s, those exploring professional community were largely concerned with schools and departments as mediating contexts for teaching, and concluded that these can differ strikingly from one another in the strength of their professional community. Examining professional community within high school departments highlighted how professional community can operate at different levels within a school, and parallels can be drawn with other work exploring differences in the culture of subject departments. Due to its smaller size, professional community within an elementary school is more usually concerned with the whole school.

A broadening of perspectives has begun to emerge of who might be counted as members of a professional learning community. Some would still argue that professional learning community should be interpreted as referring to

groups of teachers supported by leaders. Within this perspective, allowances are sometimes made for attention toward the involvement of support staff including counselors and teachers' aides, both of who have previously been seen as having a peripheral role to play in school development.

Another variation broadening the meaning of professional learning community is based on the argument that the increased complexity of a fast-changing world has brought new challenges for schooling that are too great for those in any one school to address alone. The idea of community here is extended to a network of schools, operating as a wider professional learning community, or learning network. These networks differ from those serving teachers with particular shared interests, such as subject networks, in that their focus is on whole-school change (Veugelers and O'Hair, 2005). In this sense, networks of principals, with a shared focus on specific school-wide change, would also be included within this category. Notably, it appears that more successful networked learning communities are ones that link and support professional learning communities within schools, where the school's professional learning community is the strong local locus for changes in practice but is enhanced by the strength of ideas and support from the learning network.

The third variation takes as its starting point the argument that schools exist within a wider social context. Other people with a valid stake in making a difference to students' learning and life chances therefore need to participate in professional learning communities. Expanding the concept of professional learning community in such a way means the inclusion of a wider range of members and drawing on broader knowledge bases than traditional teaching knowledge bases (Stoll and Louis, 2007). Some current investigations in this area include links between schools and their local communities, and connections within schools and school districts of staff from different agencies, including, for example, health and social welfare. Here, the issue of relationships and building social capital comes to the forefront. In particular, it highlights the necessity of bridging and linking social capital, where connections are made with people who bring different backgrounds and values and where power differentials may get in the way of equal relationships. For a professional learning community, this may mean challenging the status system of whose knowledge counts most. Work thus far in this area suggests that the difficulty of doing this cannot be underestimated.

Broadening perceptions of professional learning communities means rethinking notions of specific location for professional learning community. Professional learning communities can cross boundaries, both the social differentiations that develop between groups within the school, and the clearer borders that separate the school's members from those in the community and in other schools. As with any boundary crossing, expanding ideas about who belongs presents challenges to the existing culture.

As the notion of broadening perceptions of professional learning community is new and contested, the focus of the remainder of the article largely relates to the knowledge base about professional learning community within schools.

Professional Learning Community Characteristics

There is no universal consensus on the precise characteristics of professional learning communities, but analysis of the literature suggests that they share five key characteristics or features, which operate together. These are:

1. *Shared values and vision.* A shared vision, sense of purpose, and focus on all students' learning that is undeviating is critical to ensure that individual autonomy does not reduce teacher efficacy when teachers cannot count on colleagues to reinforce objectives. This shared value base is intended to provide a framework for shared, collective decision making.
2. *Collective responsibility.* Members of a professional learning community consistently take collective responsibility for student learning. Such collective responsibility appears to help sustain commitment, putting peer pressure and accountability on those who do not contribute equally, and eases isolation.
3. *Reflective professional inquiry.* In a professional learning community, members seek new knowledge by frequently examining their practice, through mutual observation and case analysis, joint planning, and curriculum development. They also engage in reflective dialog, conversations where tacit knowledge is converted into shared knowledge, and then regularly apply new ideas and information to problem solving and solutions that address students' needs. Deprivatization of practice (Louis *et al.*, 1995) lies at the heart of this.
4. *Collaboration.* Staff are involved in developmental activities that go beyond superficial exchanges of help or assistance and have consequences for several people: for example, joint review and feedback. Feelings of interdependence are central to such collaboration: achieving better teaching practices would be considered impossible without such collaboration. While micropolitics may exist, conflicts are managed more effectively, fitting with the notion that in communities, divergent views are expected.
5. *Group, as well as individual, learning is promoted.* All teachers are learners with their colleagues, and professional self-renewal is a communal feature. Collective learning is also evident, through collective knowledge creation (Louis, 1994), whereby the school learning community interacts, engages in serious dialog, and deliberates about information and data, interpreting them communally and distributing them among themselves.

Impact

Interest in the impact of a professional learning community is focused at a number of different levels. Historically, the main focus was on improving teachers' morale and practice, with further interest in the difference professional learning community might make for the whole organization. More recently, attention is also increasingly being turned toward the impact on students. Debate rages about whether professional community is and should be outcome oriented, rather than a significant goal in its own right. The argument on one side is that the value of community has to be unraveled from instrumental values of improving measurable student outcomes because community is concerned with the quality of life in schools. By contrast, others take a stand that all improvement and development efforts in schools must have an ultimate goal of improving outcomes for students.

Enhancing Teacher Morale

With issues of an aging teaching staff and teacher recruitment facing schools in many countries, this form of impact has an appeal. Job satisfaction is clearly important, and it appears that professional learning community can sometimes act as a buffer against the kind of issues causing teachers to leave the profession. Being able to feel part of a school-wide community may have greater resonance in today's world that is characterized by loss of traditional neighborhood community, changing family structures, greater mobility, and uncertainty about meaning and values.

Teacher Learning and Improvement in Practice

Changing what teachers do in the classroom has been one of the greatest challenges of school improvement. This is a major goal of professional learning community. Increasingly, international evidence suggests that where professional learning community is developed, teachers' knowledge base can be enhanced and there is a significant impact more generally on teachers' classroom work. It seems that in schools with a genuine sense of community, an increased sense of work efficacy leads to increased classroom motivation and work satisfaction, with subsequent increases in collective responsibility for student learning. The path between professional learning community and improvement in practice is, therefore, not necessarily direct. Rather, professional learning community appears to foster change in practice by creating an environment that supports innovation and experimentation, and this is what actually promotes teacher learning (Bryk *et al.*, 1999).

Sustained, collaborative continuing professional development is highlighted as one mechanism for promoting professional learning community. Studies on its effect on

teaching and learning conclude that collaborative professional development opportunities frequently have a positive impact on: teachers' confidence; their beliefs in their power to make a difference to students' learning; enthusiasm for collaborative working, despite initial anxiety about opening up their practice to the potential scrutiny of others; and commitment to changing practice and willingness to try new things. Several features of collaborative professional development, working in combination, appear to be linked to these positive outcomes. These include: use of external expertise linked to school-based activity; observation; feedback, frequently based on observation; emphasis on peer support rather than leadership by supervisors; scope for teacher participants to identify their own learning focus; processes to encourage, extend, and structure professional dialog; and processes for sustaining professional learning over time to enable teachers to embed the practices in their own classroom settings.

Organizational Capacity Building and Improvement

A recent major interest of policy makers is capacity building to ensure that educational reform is implemented, spread throughout the system and has a positive impact on students' outcomes. The level of the school is important here because it is the level at which performance is judged in many countries and jurisdictions. Improvements in individual teachers' practice does not change practice in whole schools. Understanding the means by which learning and development is dispersed throughout schools has, therefore, been seen as something of a holy grail. It is now generally agreed that professional learning communities may provide at least some of the answers because, where they are functioning at a high level, they appear to have the capacity for learning, inquiry, change, and innovation. It is generally thought that this is because they are a means to achieving long-term cultural change in an organization. Establishing lasting collaborative cultures that constantly focus on building the capacity for continuous learning and improvement are critical in a complex and fast-changing world. They are also particularly important in helping spread and sustain improvements in individual teachers' practice and morale.

Student Outcome Oriented

Some proponents are clear that the goal is not being a professional learning community, but to enhance students' learning. While teacher learning is considered important, the purpose of promoting staff learning is seen as maximization of the learning of students. Taken from this perspective, increases in staff morale and improved practice become intermediate outcomes. Analyses of student achievement in

schools have begun to indicate that the presence of professional community centered on student learning makes a significant difference to measurable student achievement (e.g., Bolam *et al.*, 2005). A lesser subject of exploration has been whether standardized achievement tests are the right measures of the difference made by professional learning community to students' learning or whether broader measures of student engagement with the school as a learning community might be more appropriate indicators. This partly depends on the focus of the professional learning community, and studies of smaller professional learning communities, in this case subject departments, have found specific links between a professional learning community orientation of the teachers and improved results in the specific subjects. The aggregate of extensive research in the school effectiveness tradition, however, has suggested that while intermediate variables like the professional relationship between staff and extent to which they work collaboratively are significant, they account for less variation in effectiveness than other within-school factors directly related to the teaching and learning process (Creemers, 1994).

Development of Professional Learning Community

Considerable effort has been and continues to be channeled toward gaining greater understanding of the specific processes involved in developing professional learning community, as well as the process of development over time. Approaches differ, with some carrying out sets of research projects over a period of years, and others evaluating the efforts of development projects based on earlier research. More is known about specific processes of professional learning community development than how the actual process of change occurs over time.

Processes of Professional Learning Community Development

Developing professional learning communities depends on working on a number of processes. While there is no precisely agreed set of processes, and some differentiation between researchers in what might be described as characteristics, features, or processes, there is concurrence about the broad nature of the kinds of processes involved.

Leadership of learning

There is general agreement that developing professional learning community depends on active support of leadership at different levels. In particular, principal commitment distributed leadership and coordination of professional learning appear significant.

Principal leadership

Through their leadership and management, principals create the conditions within which professional learning community either thrives or is diminished. The school principal has a major impact on the nature of school culture, and the kind of deep learning processes on which professional learning community depends are best supported and nurtured in a culture that values these types of processes and creates opportunities for them to occur. Promoting high expectations and teacher as well as student learning are critical facets, and there is also evidence that modeling learning can be important. Closely connected is an orientation toward, and promotion of a culture of, inquiry. This is particularly evident in more recent studies carried out during a period where access to, and expectation about use of, data are increasingly part of schools' reality.

Distributed leadership and leadership of professional learning

Given that collective responsibility is a key feature of professional learning community, and with the nature of demands on school leadership having intensified, it is perhaps not surprising that accomplishing workplace responsibility depends on reciprocal leadership actions of a number of people (Gronn, 2003). Exploration of this aspect of professional learning community is at a relatively early stage, with some suggestions that teachers' pedagogic leadership may work in parallel with principals' strategic leadership.

With the inclusion of the word learning in the expression, has come a greater focus on teachers' professional learning and, along with it, some attention to the leadership and coordination of professional learning activities. Here, what has increasingly been seen across a number of Organization for Economic Cooperation and Development (OECD) countries is a greater alignment between the focus on developing individual teachers' practice and a focus on managing the development of the whole school as a learning community as part of a more general approach to school change and improvement (Centre for Educational Research and Innovation (CERI), 2001).

Other social resources

Developing professional learning community is a human and emotional enterprise with all of the associated complexity of bringing about change, and there is agreement that making effective use of human and social resources is a key dimension. Working together productively depends on positive relationships and collegiality, joint work promoting the kind of interdependence between colleagues that allows serious challenge, and adjustment of practice (Little, 1990). Some commentators are quick to point out that there is no necessity for personal friendships, but a dynamic of dysfunctional relationships has been shown to

have a negative effect on a school. Without a climate of trust and respect from colleagues, teachers do not feel safe to take the risks associated with collaboration, open dialog and deprivatization of practice. Cautions are offered, however, that if trust provides a context for predictability, stability, assurance, and safety, it can inhibit innovative activity by keeping individuals satisfied with their current situation. Furthermore, it is possible to romanticize the notion of collegiality while, in reality, a political dimension of change means that the balance of power in relationships, both between teachers and between teachers and leaders can affect the nature of collaboration and the potential for real collegiality.

Structural resources

Schools are bounded by structures that shape their capacity to develop a professional learning community. In particular, the consensus appears to be that time, space, communication mechanisms, and interdependent roles are important. Teacher talk and exchange about and joint reflection on professional issues are critical elements of the collaborative activity necessary to develop professional learning community. The provision of time is required to facilitate this, as well as a physical structure where it is easier for colleagues to connect on a regular basis. Physical proximity has been found to facilitate opportunities for professional exchange. This is one reason why it is generally more challenging to develop professional learning community across a whole secondary school when teachers are based in subject departments that are often located some distance from the whole faculty lounge and share workrooms with colleagues in their subject department. Regular meetings with agendas focused on learning, and team teaching or collaborative lesson design, appear to be other structural mechanisms often cited as aids to development of professional learning community.

Promotion of learning

It could be argued that learning in professional learning communities can be assumed, but the evidence suggests that professional community, per se, can be a means by which weak practice is distributed and recycled among colleagues. Some models of professional learning community processes, therefore, specifically emphasize teacher-learning processes, some of which derive from sociocultural theories and others which are more aligned with learning and, in particular, social learning theories.

Professional development, work-based learning, and inquiry-based learning

Those who include the promotion of professional learning and development opportunities have argued that if the professional learning community is to be intellectually vigorous, members need a solid basis of expert knowledge and skills, strongly emphasizing the professionalization of

teachers' work through increasing expert knowledge. It is now generally agreed, however, that traditional forms of continuous professional development, consisting of short training courses, do little more than raise awareness of issues. By contrast, professional learning based on self-development, reflective practice, and work-based learning supported by peers is now widely seen as more effective.

With a broader definition of professionalism, and increased accountability, data analysis and use are now an increasingly important part of teachers' jobs in many countries and jurisdictions and are viewed in some models as forms of professional learning. As more data and evidence become available to schools, developing an inquiry orientation toward analysis and use of student and other data appear to take time, although where professional learning community is more developed, data collection and analysis appear to become part of an iterative process of reflection, and change.

Collective learning through knowledge creation and transfer

Learning within professional learning communities involves active deconstruction of knowledge through reflection and analysis, and its reconstruction through action in a particular context, as well as co-construction through collaborative learning with peers. Wenger (1998) proposes that when learning in communities of practice, participants gradually absorb and are absorbed in a culture of practice, giving them exemplars, leading to shared meanings, a sense of belonging, and increased understanding. Professional learning community is distinguished by an emphasis on collective learning. While effective teaching and learning depends on individual teachers, in addition, individual knowledge, skills, and attitudes are combined in a collective enterprise. Organizational learning theory also offers insights about these connections, suggesting that as the school community interacts, engages in serious dialog, and deliberates about all the information it has and data it collects, they interpret it communally distributing it among themselves and collectively creating new knowledge. Dialog also appears to be a key link, being seen as the process through which the gap between individual and organizational learning is bridged.

As the definition of professional learning communities begins to broaden, some models are also beginning to include processes whereby those within a specific organizational community interact and draw on colleagues in other parallel communities and other external agents, although this aspect is at an early stage of exploration.

Developmental Process over Time

A recent avenue of investigation is considering how a professional learning community may go through different phases of development. Models differ. Sequential

patterns of stages of organizational life cycles have also been examined, although there has been some question as to whether these can be applied to development and sustainability of learning communities where a key goal is continuous learning rather than implementing a specific change initiative. Others draw on the knowledge base about stages of educational change and levels of use of innovations, examining how the characteristics and processes involved appear to change over time as the professional learning community broadly moves through the phases. Inevitably, it is not a linear path and there is some suggestion that it is a more fluid, rather than fixed, entity, perennially evolving with accumulating collective experience (Bolam *et al.*, 2005), although little is still known about sustainability. The attempt of such research is to map how the professional learning community develops and grows, variously with a view to informing policy and/or helping practitioners and change facilitators identify and plan for the development of a professional learning community through the provision of research-based materials and guidelines. There is some suggestion that, where a broader perspective of professional learning community is taken, building of social capital is necessary before attending to other processes of professional learning community development (Mulford, 2007), but this remains to be tested. It may be, however, that a community has to be at a certain stage of readiness before it is able to embark on the collective learning that characterizes professional learning community.

Summary

Professional learning community, therefore, suggests that the focus is not just on individuals' learning but on professional learning within the context of a cohesive group, that focuses on collective knowledge and growth, and occurs within an ethic of interpersonal caring that permeates the life of the community. In essence, professional learning community implies that what colleagues do together outside of classrooms is critically important in supporting what they do inside to promote student learning, as well as to enhance their own and their school's development. It is a cultural way of working oriented toward and building capacity for continuous and sustainable learning. The general assumption by those exploring the area, as well as proponents with policy intentions, is that working toward professional learning community is a worthwhile endeavor, although not one without many challenges. There remains, however, concern that an overriding demand for evidence of student achievement outcomes will taint serious attempts to enhance teacher learning and growth within a supportive community and overshadow what might, otherwise, be a potentially profound mechanism for educational change.

Transformational School Leadership*

K Leithwood, University of Toronto, Toronto, ON, Canada

© 2010 Elsevier Ltd. All rights reserved.

Introduction

This article briefly describes the roots of transformational leadership and summarizes evidence of its effects. A school-specific formulation of this approach to leadership is then briefly outlined. The article concludes with a consideration of several common criticisms of this form of leadership.

The Roots of Transformational Leadership

The roots of transformational leadership are often attributed to James McGregor Burns' (1978) Pulitzer Prize-winning book entitled simply *Leadership*. In this book, Burns argued that transforming leadership "occurs when one or more persons *engage* with others in such a way that leaders and followers raise one another to higher levels of motivation and morality" (1978: 20). Such a conception of what effective leadership aims to accomplish diverged radically from the more common view of the day in which leaders engage in an exchange relationship with followers based on followers' individual, typically monetary, and otherwise extrinsic interests.

Following Burns's lead, Bernard Bass (1985) provided a more specific formulation of transformational leadership which, along with a survey-based measure, has enjoyed by far the greatest empirical attention in the ensuing several decades. Bass' initial formulation of transformational leadership consisted of five dimensions serving transformational purposes – charisma, inspirational leadership, individualized consideration, and intellectual stimulation. Bass' formulation also included several transactional dimensions reflecting the exchange relationships on which other leadership conceptions were based – contingent reward, management-by-exception, and *laissez-faire* leadership. Through these sets of practices, Bass claimed that transforming leaders:

convert followers to disciples; they develop followers into leaders. They elevate the concerns of followers on Maslow's (1954) needs hierarchy from needs for safety and security to needs for achievement and self-actualization, increase their awareness and consciousness of what is really important, and move them to go beyond their own self-interest for the

good of the larger entities to which they belong. The transforming leader provides followers with a cause around which they can rally (1985: 467).

Bass also argued that transformational leaders can be directive or participative, authoritarian, or democratic, depending on the context. In contrast to Burns' (1978) original view, Bass also claimed that transformational leadership augments rather than substitutes for transactional leadership. Finally, unlike many earlier theories of leadership which emphasized rational processes, transformational leadership theory emphasizes emotions and values, attributes importance to symbolic behavior, and conceptualizes the role of the leader as helping making events meaningful for followers (Yukl, 1989).

In addition to writing that refers explicitly to transformational leadership, writings about charismatic, visionary, cultural, and empowering concepts of leadership can be viewed as part of a transformational orientation, an orientation which assumes that the central focus of leadership ought to be the commitments and capacities of organizational members. Higher levels of personal commitment to organizational goals and greater capacities for accomplishing those goals are expected to result in extra effort and greater productivity.

Effects of Transformational Leadership

Evidence from studies in both school and nonschool contexts justifies continuing interest in this form of leadership. For example, meta-analyses of research in mostly nonschool contexts (Dumdum *et al.*, 2002; Lowe *et al.*, 1996) indicate that the overall effects of transformational leadership are typically positive and significant, although those effects are much stronger for subordinate perceptions of effectiveness than for objective measures of effectiveness, such as a company's financial performance.

A recent review of 32 studies of transformational leadership in school contexts (Leithwood and Jantzi, 2005) found positive and significant effects on teachers, for example, several forms of teacher commitment, teacher job satisfaction, changed classroom practices, collective teacher efficacy, and pedagogical or instructional quality. This form of leadership, the review indicated, also has a positive influence on elements of the school organization including its culture, planning, and strategies for change and organizational learning. While still limited in amount,

* Some sections of this paper are based on Leithwood, Day, Sammons, Harris, and Hopkins (2006).

evidence about transformational approaches to school leadership are reported to have promising effects on several important types of student outcomes (e.g., Leithwood and Jantzi, 1999; Silins and Mulford, 2004).

Transformational Leadership for Schools

This section provides an account of transformational leadership specifically designed for school organizations. The account draws on a substantial strand of work carried out by the author and his colleagues over a 15-year period aimed at developing a school-specific model of transformational leadership. By now, this model is extensively specified and evidence of its consequences reasonably well documented (e.g., Leithwood and Jantzi, 2005). One of the unique features of the model is its incorporation of leader behaviors associated with other approaches to leadership but which are both compatible with transformational intentions and demonstrably effective in both school and nonschool organizations. The model has four major dimensions – setting directions, developing people, redesigning the organization, and managing the instructional program – each of which includes three or four more specific sets of practices.

Setting Directions

This category of practices carries the bulk of the effort to motivate leaders' colleagues (Hallinger and Heck, 1998). It is about the establishment of moral purpose (Fullan, 2003; Hargreaves and Fink, 2006) as a basic stimulant for one's work. Most theories of motivation argue that people are motivated to accomplish personally important goals for themselves. For example, such goals are one of the four sources of motivation in Bandura's (1986) theory of human motivation.

Three more specific sets of practices are included in this category, all of which are aimed at bringing a focus to both the individual and collective work of staff in the school. Carried out skillfully, these practices are one of the main sources of motivation and inspiration for the work of the staff.

Building a shared vision

Building compelling visions of the organization's future is a fundamental task included in both transformational and charismatic leadership models. Bass' (1985) inspirational motivation is encompassed in this practice, a dimension that Podsakoff *et al.*, define as leadership behavior "aimed at identifying new opportunities for his or her unit. . . and developing, articulating, and inspiring others with his or her vision of the future" (1990: 112). Silins and Mulford (2002) found positive and significant effects of a shared

and monitored mission. Harris and Chapman's (2002) small-scale study of effective leadership in challenging schools in England found that the alignment of staffs' and heads' values and vision was a key to success. Locke (2002) argues that formulating a vision for the organization is one of eight core tasks for senior leaders and a key mechanism for achieving integration or alignment of activities within the organization.

Fostering the acceptance of group goals

While visions can be inspiring, action typically requires some agreement on the more immediate goals to be accomplished in order to move toward fulfilling the vision. Building on such theory, this set of practices aims not only at identifying important goals for the organization, but also doing so in such a way that individual members come to include the organization's goals among their own. Unless this happens, the organization's goals have no motivational effect. This set of practices includes leader relationship behaviors "aimed at promoting cooperation among [teachers] and getting them to work together toward a common goal" (Podsakoff *et al.*, 1990: 112).

In school settings, improvement-planning processes are among the more explicit contexts in which these behaviors are manifest. One of the 11 effective managerial behaviors included in Yukl's multiple linkage model, encompasses a portion of these practices. Planning and organizing include: "Determining long-range objectives and strategies. . . , identifying necessary steps to carry out a project or activity. . ." (1989: 130). This apparently rational planning process cannot be affected without attention to fostering acceptance of group goals.

High-performance expectations

This set of leadership practices is included as part of direction setting because it is closely aligned with goals. While high-performance expectations do not define the substance of organizational goals, they demonstrate the leader's values and, as Podsakoff explains, "the leader's expectations of excellence, quality, and/or high performance" (Podsakoff *et al.*, 1990: 112) in the achievement of those goals. Demonstrating such expectations is a central behavior in virtually all conceptions of transformational leadership.

Developing People

The three sets of practices in this category make a significant contribution to motivation. Their primary aim is capacity building; however, capacity building refers not only to the knowledge and skill staff need to accomplish organizational goals, but also to commitment and resilience, the dispositions needed to persist in applying

that knowledge and skill (Harris and Chapman, 2002). Individual teacher efficacy is arguably critical to these dispositions and it is a third source of motivation in Bandura's (1986) model. People are motivated by what they are good at. In addition, mastery experiences, according to Bandura, are the most powerful sources of efficacy. Therefore, building capacity which leads to a sense of mastery is highly motivational, as well.

Providing individualized support/consideration

Bass and Avolio include, as part of this dimension, "knowing your followers' needs and raising them to more mature levels...[sometimes through] the use of delegation to provide opportunities for each follower to self-actualize and to attain higher standards of moral development" (1994: 64). This set of behaviors, claims Podsakoff *et al.* (1990), should communicate the leader's respect for his or her colleagues and concerns about their personal feelings and needs (emotional understanding and support). This is a set of practices common to both the two-dimensional models of leadership (Ohio state, contingency theory, and situational leadership theory), which include task orientation and consideration for people. Encompassed by this set of practices are the supporting, and recognizing and rewarding managerial behaviors associated with Yukl's (1989) multiple linkage model, as well as Hallinger's (2003) model of instructional leadership. This set of leadership behaviors has attracted more leadership research outside of schools since the 1960s than any other.

Intellectual stimulation

Behaviors included in this dimension include encouraging colleagues to take intellectual risks, re-examine assumptions, look at their work from different perspectives, rethink how it can be performed (Avolio, 1994; Podsakoff *et al.*, 1990), and otherwise "induc[e]...employees to appreciate, dissect, ponder and discover what they would not otherwise discern..." (Lowe *et al.*, 1996: 415–416). Waters, Marzano, and McNulty (Marzano *et al.*, 2005; Waters *et al.*, 2003) include challenging the *status quo* among the practices contributing to leader effects on students.

The leader's role in professional development has been found to be especially important for leaders of schools in challenging circumstances (Gray, 2000; Harris and Chapman, 2002). However, there are many informal, as well as formal, ways in which such development occurs, reflecting current understandings of learning as constructed, social, and situated. All models of transformational leadership include this set of practices. A considerable amount of the educational literature assumes such practices on the part of school leaders, most notably the literature on instructional leadership which places school leaders at the center of instructional improvement efforts in their schools (e.g., Day *et al.*, 2000; Stein and Spillane, 2005).

Providing an appropriate model

This set of practices entails leading by example. These are practices also associated with models of authentic leadership (Avolio and Gardner, 2005) and include demonstrating transparent decision making, confidence, optimism, hope, resilience, and consistency between words and deeds. Locke (2002) claims that core values are established by modeling core values in one's own practices. Both Hallinger (2003) and Waters *et al.* (2003) note the contribution to leader effects of maintaining high visibility in the school, a visibility associated with high-quality interactions with both staff and students.

Also encompassed by this dimension is Bass' idealized influence, a partial replacement for his original charisma dimension. Avolio (1994) claims that leaders exercise idealized influence when they serve as role models with the appropriate behaviors and attitudes that are required to build trust and respect in followers. Such modeling on the part of leaders "sets an example for employees to follow that is consistent with the values the leader espouses" (Podsakoff *et al.*, 1990: 112).

Redesigning the Organization

There is little to be gained by increasing peoples' motivation and capacity if working conditions will not allow their effective application. Bandura (1986) theorizes that beliefs about the setting in which one is working is a fourth source of motivation. People are motivated when they believe the circumstances in which they find themselves are conducive to accomplishing the goals they hold to be personally important. The three more specific sets of practices included in this category are about establishing the conditions of work which will allow staff to make the most of their motivations and capacities.

Building collaborative cultures

A large body of evidence has accumulated since Little's (1982) early research which unambiguously supports the importance of collaborative cultures in schools as being central to school improvement, the development of professional learning communities, and the improvement of student learning (e.g., Louis and Kruse, 1998; Rosenholtz, 1989). Additional evidence clearly indicates that leaders are able to build more collaborative cultures and suggests practices that accomplish this goal (e.g., Waters *et al.*, 2003). For leaders of schools in challenging circumstances, creating more positive collaborative and achievement-oriented cultures is a key task (West *et al.*, 2005).

Connolly and James (2006) claim that the success of collaborative activity is determined by the capacities and motivations of collaborators together with opportunities for them to collaborate. Success also depends on prior conditions. For example, a history of working together successfully will sometimes build trust, thus

making further collaboration easier; whereas a history of unsuccessful attempts to collaborate will reduce trust. Trust is increasingly recognized as a key element in encouraging collaboration. People are more likely to trust those with whom they have established good relationships (Bryk and Schneider, 2002; Louis and Kruse, 1995). Participative leadership theory and leader–member exchange theory are concerned with the nature and quality of collaboration in organizations and how to manage it productively.

Leaders contribute to productive collaborative activity in their schools by being skilled conveners of that work. They nurture mutual respect and trust among those involved in collaborating, by being trustworthy themselves, ensure the shared determination of group processes and outcomes, help develop clarity about goals and roles for collaboration, encourage a willingness to compromise among collaborators, foster open and fluent communication among collaborators, and provide adequate and consistent resources in support of collaborative work (Connolly and James, 2006; Mattessich and Monsey, 1992).

Restructuring

This is a set of practices common to virtually all conceptions of management and leadership. Organizational culture and structure are two sides of the same coin. Developing and sustaining collaborative cultures depend on putting in place complementary structures, typically something requiring leadership initiative. Practices associated with such initiatives include creating common planning times for teachers and establishing team and group structures for problem solving (e.g., Hadfield, 2003). Hallinger and Heck (1998) identify this variable as a key mediator of leaders' effects on students. Restructuring also includes distributing leadership for selected tasks and increasing teacher involvement in decision making (Reeves, 2000).

Building productive relationships with families and communities

Shifting the attention of school staffs from an exclusively inside-the-school focus to one which embraces a meaningful role for parents and a close relationship with the larger community was identified during the 1990s as the biggest change in expectations for those in formal school leadership roles (e.g., Goldring and Rallis, 1993). More recently, Muijs *et al.*, (2004) have identified this core practice as important for improving schools in challenging circumstances. Attention to this focus has been encouraged by evidence of the contribution of family educational cultures to student achievement in schools (e.g., Coleman, 1966; Finn, 1989), the increase in public accountability of schools to their communities through the widespread implementation of school-based management

(Murphy and Beck, 1995), and the growing need for schools to actively manage public perceptions of their legitimacy (e.g., Mintrop, 2004).

Connecting the school to its wider environment

School leaders spend significant amounts of time in contact with people outside of their schools seeking information and advice, staying in tune with policy changes, and anticipating new pressures and trends likely to have an influence on their schools and the like. Meetings, informal conversations, phone calls, e-mail exchanges, and Internet searches are examples of opportunities for accomplishing these purposes. The extensive number of network learning projects facilitated by the National College of School Leadership in England provides especially powerful opportunities for connecting one's school to its wider educational environment (Jackson, 2002) as do those in other countries. Referring to it as networking, Yukl includes it in his multiple linkage model of leadership as one of the 11 critical managerial practices. He describes this practice as "Socializing informally, developing contacts with people who are a source of information and support, and maintaining contacts through periodic interaction, including visits, telephone calls, correspondence, and attendance at meetings and social events" (1994: 69).

Bringing in external support may also be a productive response to schools engaged in significant school-improvement projects (Reynolds *et al.*, 2001).

Managing the Instructional Program

Both Burns' (1978) and Bass' (1985) conceptions of transformational leadership include several different sets of transactional leadership behaviors built on exchange theory. These behaviors have proven to be among the most problematic features of transformational leadership theory as it has been subject to empirical tests. One element of Bass' formulation (contingent reward) has almost always behaved as a transformational practice and most of the remainder makes little or no contribution to important outcomes of leadership. For this reason, the author and his colleagues have replaced transactional leadership with managerial practices in their school-specific model of transformational leadership. When these managerial practices, four in total, have been included in research on school leadership effects, they have proven to be consequential (e.g., Leithwood and Jantzi, 1999) in creating stability and strengthening the organization's infrastructure.

Staffing the program

Although not touched on by Hallinger (2003) or Waters *et al.* (2003), this has proved to be a key function of leaders engaged in school improvement. Finding teachers with the interest and capacity to further the school's efforts is

the goal of this activity. Recruiting and retaining staff constitute a primary task of leading schools in challenging circumstances (Hargreaves and Fink, 2006).

Providing instructional support

This set of practices, included in both Hallinger's (2003) and Waters' *et al.* (2003) research on effective leadership, includes supervising and evaluating instruction, coordinating the curriculum, and providing resources in support of curriculum, instruction, and assessment activity. West *et al.* (2005) indicate that, for leaders of schools in challenging contexts, focusing on teaching and learning is essential. This includes controlling behavior, boosting self-esteem, and talking and listening to pupils. It also may include urging pupils and teachers to place a strong emphasis on pupil achievement. Such an academic climate makes significant contributions to achievement (De Maeyer *et al.*, 2006).

Monitoring school activity

Waters *et al.* analyze associated leadership effects on students with leader monitoring and evaluating functions, especially those focused on student progress. The purposeful use of data is reported by West *et al.* (2005) to be a central explanation for effective leadership in failing schools (see also Reynolds *et al.*, forthcoming). Hallinger's (2003) model includes a set of practices labeled monitoring student progress. Monitoring operations and environment is one of Yukl's (1989) 11 effective managerial practices. Furthermore, Gray (2000) reports that tracking student progress is a key task for leaders of schools in challenging circumstances.

Buffering staff from distractions to their work

A long line of research has reported the value to organizational effectiveness, of leaders who prevent staff from being pulled in directions incompatible with agreed-on goals (Copland, 2003; DiPaola and Tschannen-Moran, 2005; Dwyer, 1985). This buffering function acknowledges the open nature of schools and the constant bombardment of staff with expectations from parents, the media, special interest groups, and the government. Internal buffering is also helpful, especially buffering teachers from excessive pupil-disciplinary activity.

The four sets of leadership practices in this category provide the coordination for initiatives stimulated by the other core leadership practices. They help provide the stability which is so necessary for improvement to occur.

Conclusion

In his summary of transformational approaches to leadership, Northouse (2007) identifies five common criticisms of transformational approaches to leadership. First, some

have argued that this approach to leadership lacks conceptual clarity, meaning that its dimensions and associated practices overlap with other views of leadership. The school-specific model described in this article is especially guilty of this quality. However, this is a criticism only if the goal is to distinguish one model of leadership from another. If, as in this case, the goal is to develop a model of leadership that incorporates practices which reflect the best evidence about what works, then lack of distinguishing features is inevitable and certainly not a weakness.

A second criticism is that transformational approaches treat leadership as a personality trait rather than a set of practices that can be learned. This is a legitimate complaint of models that include a charismatic dimension. At least some forms of charisma depend on the possession of attractive personality traits. However, many models of transformational leadership no longer include charisma. The school-specific model described in this article includes only behaviors or practices that almost anyone with an interest in leadership could learn or improve on.

Some have also criticized transformational leadership as being elitist. This criticism seems to have arisen because much of the research literature in nonschool contexts has focused on the leadership of those at the top of the organizational hierarchy. The model outlined in this article includes practices that can be widely distributed throughout the organization; recent evidence suggests that they often are (Leithwood *et al.*, 2003; Leithwood *et al.*, 2007). This evidence is also a response to the criticism that transformational approaches reflect heroic images of leadership.

A final criticism is that this form of leadership has the potential for abuse. Early descriptions of transformational leadership sometimes cited, as examples, highly influential leaders who, nevertheless, pursued morally and socially unacceptable goals – Hitler, for example. Considerable effort has been made since those early writings to craft an account of transformational leadership in pursuit of morally and socially desirable ends, an authentic as opposed to inauthentic or pseudo-transformational form of leadership (Bass and Steidlmeier, 1999; Price, 2003). Generally, charisma-free models are less susceptible to this criticism.

Both the demonstrably positive effects of transformational leadership and the insubstantial nature of its apparent limitations argue for continuing to further develop and assess this leadership approach.

“From a psychological view, attention includes changes from sleepiness to high alertness, from focused OR to a single object to unfocused awareness of the general scene, from responsiveness to external event to responses driven by the achievement of a particular goal.”

(Posner and Rothbart, 2007a: 16)

A child's ability to direct his or her attention drives awareness; only objects and events attended to will enter the child's mind. In this sense, attention processes are essential for learning and cognitive development. Attention influences and is, in turn, influenced by various brain systems, an interaction that creates priorities affecting both perception and action. Thus, alertness and the way attention regulates, or is regulated by brain functions become highly relevant for all domains of learning. Without attention it becomes difficult, if not impossible, to take in new and important information. We, adults and children, are active in selecting what to attend to and what to ignore – a process that becomes more and more voluntary during development.

The view of an infant as passive, incapable of communicating and remembering, and unaware about self and others has changed radically during the last 50 years. Typically, developing infants have a sensory system, which makes them capable of perceiving and interacting with the environment promoting communication, emotional

exchange, and signals for caretaking. In addition to this sensory system, they use their own body as a vehicle, not only for exploration of themselves, that is, building sensory motor schemas, but also for assembling information about other individuals. To learn from and understand other people and socially relate to them is crucial for a healthy development. Therefore infants' face processing is seen as an early indicator of this social attending. Newborns prefer face-like patterns suggesting an innate mechanism favored in brain processing. Furthermore, by 4 months infants look longer if there is a mutual eye gaze with the adult compared to averted eye gaze. Also, auditory perception in 6-month-old infants is linked to sensitive detection of human voices, such as discrimination of phoneme segments, both in native and foreign languages. However, at the age of 12 months this ability declines showing that early on our brain is prepared for a general language acquisition, but that exposure to one language with its specific prosodic and phonetic patterns reduces this capacity.

Attention in Infancy

All sensory systems are functional at or before birth and of these, the visual system is probably both the best-understood and least-mature system. It is actually a difficult

task for the newborn infant to respond to visual stimuli. When a newborn infant acts on complex visual information, as evident when the neonate imitates facial movements, the infant responds in spite of the fact of the immaturity of the visual system: Jerky eye movements make it hard to control vision and it is difficult for the immature system to capture fast-moving objects. In short, the infant's control of fixation is mostly not under voluntary control at birth and, during the first months of life, infants cannot resist being drawn to certain patterns. Visually, the newborn infant is attracted to high spatial frequencies (e.g., checkerboard pattern and edges), to slowly moving objects (moving stimuli are more attractive than static ones), and to face-like patterns. The attraction to edges provides necessary input for the visual cortex to develop (input helps to organize cell columns in visual cortex) while the attraction to face-like patterns guides the infant toward the social world.

All nonvisual sensory systems are also functional at birth but their role in early attentional processes is less well studied, although auditory attention probably is as important as vision for early development. Hearing is essential both for language learning and for making the social world interesting. The newborn infant recognizes human voices at birth (in fact, a fetus can learn to identify the mother's voice several weeks post-partum) and the melody of the mother tongue is identified within the first weeks. The human voice, especially the female voice, attracts the infants' attention both to the social world and to language.

Selective Attention

Selective attention develops rapidly over the first months of life. The newborn infant has less oculomotor control, less control over attentional shifts, and is attracted by salient details in perceptual displays. A neonate is not able to understand a partly occluded object as a unity and reacts only to direct visible information. It becomes a very difficult task if the neonate must identify a center-occluded object – the infant sees only the top and the bottom part of the object – in order to solve a task. This does not imply that a newborn child is not able to take in the relevant information, only that during the first months of life, perception and attention is more driven by environmental input (exogenous processes) coupled with biologically driven subcortical processes. Slowly, vision becomes more and more cortically controlled, acuity develops, the visual field increases, the eyes become better coordinated and inspection times decrease. A shift is usually seen around 2–3 months making the infant more visually competent when inspecting new objects, and, maybe most important, the child now becomes able to partake in prolonged face-to-face interactions with the caregiver.

The problem with perceptual completion, to see an object as a whole in spite of the fact that it is partly

occluded, also changes during the first months of life. Some capacity is observable already at 2 months but it is not until 4–5 months that the ability to solve perceptual-completion problems can be expected to be robust. Interestingly, children at 3 months seem to be in a transition phase. A recent study (Amos and Johnson, 2006) identified two groups of children, perceivers and non-perceivers: the children who were able to perceive unity (i.e., they solved the perception-completion task) used a more efficient strategy when solving a visual search task. These differences may stem from the possibility that the two groups reflect different stages in early brain development. Selective attention makes it possible for the child to become an active participant in his/her development and early differences in this ability might have an impact on later cognitive development.

The capacity to attend selectively is also related to disengagement, an ability that develops rapidly over the first months of life. As depicted in **Figure 1**, infants younger than 2 months tend to focus on one stimulus at a time. If a second stimulus is added to the visual display while the first stimulus is still visible, the infant is more or less unable to make a gaze shift. However, by 3–4 months, this is no longer a problem.

Selective looking and habituation have dominated research on infant attention. Generally, the length of looking declines during infancy, especially from 3 to 4 months and onward. Younger infants need longer inspection time (familiarization) than older infants; studies indicate a negative correlation between visual recognition and the inspection time needed. Selective attention has also been used to study auditory attention (e.g., the ability to discriminate between specific sound signals or between mother's voice and a stranger's voice).

Phases of Attention

Behavioral Phases

Attention in infancy is usually described as made up of three or four distinct phases representing different underlying processes (see **Figure 2**): The first phase, AR (AR), reflects the physiological readiness of the organism to react to any stimuli. Usually AR varies from deep sleep to active wakefulness through several intermediate phases. A characteristic of the young infant is that state changes occur often and rapidly, which affects the manner in which early attention is modulated. Without adequate AR, no attention can take place. During the second phase, usually called orienting (OR) or selective attention, the infant's attention is directed toward specific stimuli, that is, an interesting event is identified and the system becomes prepared for further inspection. Sustained attention (SA), phase three, reflects a phase of active information processing or encoding. SA is often described as a voluntary

Figure 1

Figure 2

process and it has been linked to anterior brain systems. The final phase of attention, attention termination (AT), on the other hand, is linked to disengagement processes reflecting continuous looking after cessation of any active information processing. AT has been proposed to reflect the posterior brain system identified by Posner and colleagues and the disengagement processes have been observed to be a stronger prediction of recognition than sustained attention, at least for static stimuli.

Attention: Brain Networks

A recent attempt by Posner and Rothbart (2007b) to integrate behavioral studies of attention with current

findings within cognitive neuroscience identifies three neural networks that underlie central aspects of attention: orient, alert, and executive attention.

Alerting signifies that the child is in a state of readiness for reacting to new incoming stimuli. From a biological point of view, alerting has been linked to subcortical processes (thalamus) as well as to right parietal and right frontal areas. Norepinephrine is the main neurochemical modulator. . .

Orienting means that attention aligns with incoming sensory signals and that some information is selected. It is activated by posterior parts of the brain, mostly the parietal lobe (e.g., the superior parietal lobe) but also some frontal (frontal eye fields) and subcortical areas

(superior colliculus). The main neurochemical component is acetylcholine.

Executive attention indicates the ability to monitor responses, thoughts, and feelings, processes that not only involve mainly anterior brain areas (frontal cortex) but also some parts of the basal ganglia. It is hypothesized that executive attention plays an important role in the ability of the developing self to regulate positive and negative affect. Dopamine is the main neurochemical modulator.

The more posterior parts of the attentional system develop relatively early. Thus, the young infant is more able to alert and orient than to show executive attention, although it takes time for these systems to become fully mature as well. The first signs of the executive system can be noted toward the end of the first year, but it will take 8–10 years for it to reach adult-like levels.

All three networks – especially the executive network – are essential for the infant to develop an ability to display effortful control, that is, to self-regulate one's own behavior.

Aspects of Attention

Novelty

Novel objects and novel locations affect attention from birth although the parallel process of familiarity also exerts a strong influence on attention during the first months of life. Behaviorally, novelty preference can be reliably observed from approximately 4–6 months of age. Identification of new information leads to faster and more reliable OR, activates the alerting system, recruits available relevant brain resources (working memory and sustained attention), and prepares the system to encode a new file (transfer information to long-term memory).

The identification of a new object is governed by two processes. The first process to emerge is the ability to identify a new location. This ability is related to the control of eye movements and is, in some form, present at birth. It is observable through inhibition of return (IOR), which means that the visual system resists going back to a previous location; new locations are more attractive. The second process, the identification of a new object, is a slower-developing visual skill. It is usually established by 4–6 months and is related to the development of object recognition. This ability is observable through visual recognition memory.

Visual Recognition Memory

From 3 to 4 months and onward, the infant's ability to process new information has proved to be robust. This can be shown in paired-comparison experiments or tests when the child's preferential looking pattern is observed. Typically, a child prefers new information (a novel stimulus) in

comparison with familiar information, which makes it possible for the researcher to calculate a novelty preference score. This score provides an index of the child's visual recognition memory, because the child has to remember the familiar target in order to show a preference for the novel one. Measures of novelty preference/visual recognition memory in early infancy have been found to be a significant predictor of later intelligence quotient (IQ) as well as of nonverbal communication and language (e.g., Colombo, 1993; Bornstein and Sigman, 1986). As an example, it has been reported that visual recognition memory measured in infancy predicts receptive language at 3 years even when controlling for general IQ. These results suggest that attentional and memory capacities tapped by visual recognition memory as measured by novelty preference are important for later developing communication skills.

Visual recognition memory seems to tap into the very basic functions of our nervous system but exactly how these early attentional and memory processes affect later cognitive processes are still unexplained. One clue to an explanation has been proposed by Colombo and collaborators who found that, at 4 months, attention termination explained more of the observed variance in a novelty recognition task than sustained attention. The research group interprets their findings as supporting the "hypothesis that individual differences in the disengagement underlie the relation between look duration and cognitive performance in early to mid infancy" (Colombo *et al.*, 2001: 1605).

Face Processing

Human infants show a preference for faces right from birth, a tendency that seems to be especially strong for moving face-like stimuli (Johnson, 2005). This has been interpreted by some as indicating a pre-wired system molded by evolution. Such a system is described as being controlled by subcortical parts of the visual system functional at birth making the face a highly salient stimulus for the newborn. Thus, the child is endowed with an in-built perceptual attention grabber for faces. Although the propensity for faces among newborns is not debated, the mechanism is. In a series of studies, Simion and co-workers have provided support for an alternative view. They argue that the infant is not born with a pre-wired schematic configuration for faces but with a "domain-general bias towards configurations with more elements in the upper than lower half (i.e., top-heavy patterns)" (e.g., Cassia *et al.*, 2004: 379). The conflict between these two contrasting views is not resolved; we still do not know exactly how to describe the mechanism responsible for making newborn babies especially attracted to the human face.

Furthermore, observations also suggest that infants are better at processing female than male faces, a finding that probably stems from the fact that infants have much more experience in processing female faces. However, conclusive studies addressing this interpretation are still lacking. Finally, over the course of the first year, infants begin to process naturally looking faces in the same fashion as adults do; that is, they analyze faces in a holistic gestalt-like fashion. While 4-month-old children focus more on internal facial features, 10-month-old children use a holistic strategy. Children at 6 months seem to be in a transition phase using both strategies.

Attention and Learning

The Directed-Attention Model

Memory span of objects is around one item at 6 months and two to three items at 1 year. This means that infant learning and infants' complex social responses are carried out with a memory and attention system that is very limited compared to older children and adults. A model for how this can be achieved has been proposed by Reid and Striano (2007) who outlines a five-stage directed-attention model of infant social cognition. The model describes five perceptual stages that infants typically will master within the first year of life. The model is tentative but provides an ambitious attempt to integrate known perceptual and cognitive abilities and skills with the amazing social competence seen in the human infant. In brief, the proposed stages or phases are:

1. *Detection of socially relevant organisms.* Infants are born with a nervous system that directs them toward the social world. They are sensitive to distinctions between animate and inanimate objects, they prefer moving stimuli to static, biological motion to nonbiological motion, they are sensitive to the human voice, to rhythm, and they imitate (mimic) facial gestures.
2. *Identification of socially relevant organism.* The process to differentiate individual persons starts immediately at birth. The newborn infant rapidly learns to identify the mother's voice, smell, and face. More complex responses, such as imitation, are also used early on (from 6 weeks) to identify persons.
3. *Assessment of the locus of attention.* Once the socially relevant organism has been detected infants start to "attend towards characteristic that index the locus of attention of the observed organism" (Reid and Striano, 2007: 105). Eye and head movements provide important information to the infant in early social interactions. The infant's predisposition to enter into the social interactions with the caregiver is probably driven by intrinsic and biologically based motives to communicate with other humans.

4. *Detection of object-oriented attention.* Already at 4 months infants can use an adult's gaze to learn about objects and, by 8–9 months, objects become parts of highly motivating joint-attention encounters. Objects or an aspect of the environment that has been highlighted through joint attention with an adult will become more salient to the infant who will direct more of his or her attention to those objects/areas. The first sign of an emerging declarative memory is observed at 6 months through the child's ability to act on a memorized representation after a delay (deferred imitation).
5. *Inference of goals and/or prepare response.* Toward the end of the first year, infants begin to respond differently to accidental and intentional action. The child now starts to understand that people have goals that motivate their actions. The capacity of working memory increases, which makes it possible for the child to hold more than one piece of information online simultaneously.

Dyadic Attention

The interaction between a parent and the infant is characterized by rhythm, intimacy, and emotional exchange, the so-called proto-conversations. This interaction is encouraged by the mother through smiles and increased gaze in such a way that the interaction is prolonged and infants are active partners in this interaction, creating turn-taking sequences. Both mother and infant are sensitive to the contingency and quality of this interaction and have already created expectancies of specific patterns of communication from each other. This is evidenced by using still-face conditions where mother is either not responding to infant's communication or by using double-video-technique showing pre-recorded interaction creating unsynchronized turn-taking from both partners. Furthermore, infants very early learn to anticipate, not only contingent communicative patterns, but also contingent behavior from their mothers. When infants' distress is accompanied by parents soothing, the association between AR, parents' response, and subsequent relief is easily learned – soothing is anticipated by the infant already at 4 months of age.

This intrinsic communication with human beings could not be enhanced without the infant exploring the physical environment. With an increasing ability of motor control, the child will experiment with its own actions on objects such as mobiles and thereby develop an early understanding of agency according to physical cause and effect. With the growth of contingent perception, the infant is able to accompany this physical agency into detection of cause and effect/reciprocity with partners into further developed nonverbal turn-taking sequences – both vocal and with objects (like pushing a ball back and

forth). This means that infants are able to coordinate their attention with another person and understand the framework in which communication takes place between two persons.

Triadic Attention/Joint Attention

Nine-month-old infants begin to understand that actors are pursuing goals and they combine the awareness of outside objects, events, and persons in order to share and coordinate their attention or perception of goal activities, the so-called joint attention. By performing joint activities such as building a tower of bricks or rolling a ball back and forth, the infants understand the concept of sharing goals. This is accompanied by attention skills such as following the other persons' eye-gaze or pointing in order to direct others' attention to objects in the surrounding, or trying to modify a persons' behavior with gestures.

Attention skills that are initiated by the child (e.g., pointing) develop slightly later than behaviors that are responses to others (e.g., gaze-following). The capacity to direct another persons' gaze to objects by the infants' own interest develops between 9 and 12 months and infants can use the pointing gesture for different purposes, for both sharing attention and requesting.

It has been argued that declarative pointing, in contrast to imperative pointing, relies on the understanding of others as mental agents and is driven by a motivation to share attention and interest with other persons; it has therefore been suggested to be especially difficult. In typically developing infants, the motivation to share attention and interest is probably strong and declarative gestures are common, in contrast to children with social impairments like autism. Experiment with 12-month-olds has revealed that the social context is crucial for the amount of points the infant makes. Only when the adult was active in sharing the infants' attention to the event the infant pointed at, the infants' pointing increased. The interpretation of this result was that the infant did not only want to direct the adult's attention, but also wanted to share this attention.

It has been shown in several studies that the capacity for joint attention is an important precursor to later-developing language and cognitive skills. Together with early memory measures (e.g., visual recognition memory and deferred imitation) joint attention probably lays the ground for later-emerging social cognition including intentional understanding.

Understanding Intentions

Humans are special in their capacity to understand others' intentions. This is obvious when children pass false-belief tasks when they are about 4 years old. It can be argued that infants, by the time they begin to follow

and direct others attention, have acquired some understanding of others as intentional agents and that other people act on the basis of their own view of the world. From 6 months of age, infants follow another person's gaze to objects in the surrounding environment but they have been shown to pay more attention to where the head is turning, while older infants pay more attention to the eyes indicating understanding of the adult's intentions. When adults turn to an object with their eyes open or closed it was observed that infants by the age of 12 months looked at the target if the adult turned to it with open eyes but did not do so if the person turned to it with eyes closed.

Furthermore, studies have revealed that infants in their second year understand the intention behind an action and not only the action they actually have seen; when 18-month-old infants were observing an action that the adult failed to perform they did not imitate the failure, instead they performed the complete action. Another evidence for early intentional understanding is that 9-month-old infants show anger and distress toward an adult who is unwilling to give them a toy, but not to an adult who is unable to do it.

Compensatory Systems and Plasticity

Questions have been raised whether the sensory system can compensate for a deficit in one area, since it is striking how blind people can use auditory and tactile cues for orienting themselves and getting information. In one study, it was shown that spatial tuning of tactile attention is more accurate in early blind compared to sighted individuals when areas for Braille reading are stimulated, suggesting a compensatory scaffolding for individuals who have experienced visual deprivation from birth or early infancy. The plasticity of the brain making it possible to overcome deficits may be underlined by the fact that the sensory systems work together, especially, according to the dimensions of space, time, and intensity. This so-called redundant, amodal information is seen as a cornerstone of perceptual development, for example, when an adult takes a child's hands and uses them for clapping, auditory, visual, and tactile systems are involved, discerning both rhythm and rate to the child.

Conclusion

With increasing age, looking and attention come more and more under voluntary control. The child becomes more able to decide what to focus on; he or she will, by 4–5 years of age, be able to choose to attend to information even if it is boring. However, attention never becomes completely voluntary. Processes like novelty preference and habituation influence attention throughout life.

In the future, knowledge might be increased by detecting specific genes influencing attention, maybe even specific genes for each network or various attentional processes (see Posner *et al.*, 2007). This might help us gain a better understanding of how attention develops, how experience and biology co-act to create alertness and sustained attention, or the ability to initiate attention in another person – knowledge that will also be highly relevant for children with known disabilities such as ADHD or autism spectrum disorders.

Concept Learning

S J Unsworth, San Diego State University, San Diego, CA, USA

In what follows, we use concept to refer to a mental representation and category to refer to the set of entities or examples picked out by the concept. It is generally accepted that instances of a concept are organized into categories. Almost all theories about the structure of categories assume that, roughly speaking, similar things tend to belong to the same category and dissimilar things tend to be in different categories. For example, robins and sparrows both belong to the category bird and are more similar to each other than they are to squirrels or pumpkins. Similarity is a pretty vague term, but most commonly it is defined in terms of shared properties or attributes. Although alternative theories assume concepts are structured in terms of shared properties, theories differ greatly in their organizational principles.

Theories of Concept Representation and Learning

The Classical View

The classical view assumes that concepts have defining features that act like criteria or rules for determining category membership. For example, a triangle is a closed geometric form of three sides with the sum of the interior angles equaling 180°. Each of these properties is necessary for an entity to be a triangle, and together these properties are sufficient to define triangle.

A fair amount of research has examined people's knowledge about object categories such as bird, chair, and furniture and this evidence goes against the classical view. Not only do people fail to come up with defining features, but also they do not necessarily agree with each other (or even with themselves when asked at different times) on whether something is an example of a category. Philosophers and scientists also have worried about whether naturally occurring things such as plants and animals (so-called natural kinds) have defining features. The current consensus is that most natural concepts do not fit the classical view.

The Probabilistic View

The major alternative to the classical view is the probabilistic view which argues that concepts are organized around properties that are characteristic or typical of category members but crucially, they need not be true of all members. That is, the features are only probable. For

example, most people's concept of bird may include the properties of building nests, flying, and having hollow bones, even though not all birds have these properties (e.g., ostriches and penguins). The probabilistic view has major implications for how we think about categories. First, if categories are organized around characteristic properties, some members may have more of these properties than other members. In this sense, some members may be better examples or more typical of a concept than others. For example, it has been found that the more frequently a category member's properties appeared within a category, the higher was its rated typicality for that category. Robins were rated to be very typical birds and penguins rated as very atypical birds. A second implication is that category boundaries may be fuzzy. Nonmembers of a category may have almost as many characteristic properties of a category as do certain members. For example, whales have a lot of the characteristic properties of fish, and yet they are mammals. Third, learning about a category cannot be equated with determining what the defining features are because there may not be any.

Typicality: Central tendency versus ideality

Is typicality only based on central tendency? Although typicality effects are robust (and problematic for the classical view), other research shows that the underlying basis for typicality effects may vary with both the kind of category being studied and with the population being studied. While the internal structure of taxonomic categories is based primarily on the central tendency (or the average member) of a category, the internal structure of goal-derived categories, such as things to wear in the snow, is determined by some ideal (or the best possible member) associated with the category. The best example of snow clothing, a down jacket, was not the example that was most like other category members; instead, it was the example with the maximum value of the goal-related dimension of providing warmth.

One might think that ideals will only come into play when the category of interest lacks the natural similarity structure that characterizes common taxonomic categories, such as bird, fish, and tree. However, for tree experts (people who know a lot about trees, such as landscapers, parks workers, and taxonomists), the internal structure of the category tree is organized around the positive ideal

of height and the negative ideal of weediness. The best examples of tree are not trees of average height but trees of extraordinary height (and free of weedy characteristics like having weak limbs, growing where they are not wanted, and being susceptible to disease).

Indeed, research does suggest that people who have considerable knowledge in a domain tend to base typicality judgments on ideals and not on the number of typical features. For example, for Itzá Maya adults living in the rainforests of Guatemala, the best example of bird is the wild turkey which is culturally significant, prized for its meat, and strikingly beautiful. The fact that US tree experts based typicality on ideals suggests that it is not just that the Itzá have a different notion of what typicality means. It has also been found that Native American and European American fishermen's typicality judgments were based on ideals, although those ideals differed somewhat across groups.

Prototype versus exemplar theories

If categories are not represented in terms of definitions, what form do our mental representations take? One suggestion about how concepts are represented is known as the family resemblance principle. The general idea is that category members resemble each other in the way that family members do. A simple summary representation for such a family resemblance structure would be an example that possessed all the characteristic features of a category. The best example is referred to as the prototype.

In a prototype model of categorization, classifying a new example is done by comparing the new item to the prototype. If the candidate example is similar enough to the prototype for a category, it is classified as a member of that category. More detailed analyses, however, show problems with prototypes as mental representations. Prototype theory implies that the only information abstracted from categories is the central tendency. A prototype representation discards information concerning category size, the variability of the examples, and correlations among attributes, and people can use all three of these types of information.

An alternative approach, which is also consistent with the probabilistic view, assumes that much more information about specific examples is preserved. This approach appropriately falls under the general heading of exemplar theories. Exemplar models assume that people initially learn some examples of different concepts and then classify a new instance on the basis of how similar it is to the previously learned examples. The idea is that a new example reminds the person of similar old examples and that people assume that similar items will belong to the same category. For example, suppose someone is asked whether large birds are more or less likely to fly than small birds. He/she will probably answer "less likely," based on retrieving examples from memory and noting

that the only nonflying birds one can think of are large (e.g., penguin and ostrich).

Quite a few experiments have contrasted the predictions of exemplar and prototype models. In head-to-head competition, exemplar models have been considerably more successful than prototype models. Why should exemplar models fare better than prototype models? One of the main functions of classification is to allow one to make inferences and predictions on the basis of partial information. Relative to prototype models, exemplar models tend to be conservative about discarding information that facilitates predictions. For instance, sensitivity to correlations of properties within a category enables finer predictions: from noting that a bird is large, one can predict that it cannot sing. In short, exemplar models support predictions and inferences better than do prototype models.

More recent research has pointed to three major limitations of these simple forms of prototype and exemplar models:

1. they have narrowly focused on categorization and have paid little attention to how other conceptual functions, such as communication and inference, may affect concept representation and learning;
2. they view learning as a passive accumulation of statistical information rather than an active learning that may reflect particular learner goals; and
3. they pay little attention to how theoretical notions and causal reasoning organize learning.

With respect to the second point, we have just reviewed evidence from a number of populations, indicating that typicality is driven by ideals and that later learning builds on earlier learning. If category ideals tend to be learned first then they will have an important role in the development of categories, and modelers are beginning to shift to this more active view of learning. With respect to the role of theories, there is evidence that using (abstract) similarity relations may be likely to be a strategy of last resort, used only when more relevant information is unavailable. Let us examine the theory view in a bit more detail.

The Theory View

A number of researchers have argued that the organization of concepts is knowledge based (rather than similarity based) and driven by intuitive theories about the world. The idea that concepts might be knowledge based rather than similarity based suggests a natural way in which concepts may change – namely, through the addition of new knowledge and theoretical principles. There is also good evidence that these theories help determine which abstract and observable features learners pay attention to. We have a different set of categories for mental disorders now than we had 100 years ago, in part because our

knowledge base has become more refined. Often knowledge of diseases develops from information about patterns of symptoms to a specification of underlying causes. For example, the advanced stages of syphilis were treated as a mental disorder until the causes and consequences of this venereal disease were better understood. Recently, it has been shown that clinical psychologists organize their knowledge of mental disorders in terms of rich causal theories and that these theories (and not the atheoretical diagnostic manual they are supposed to use) guide their diagnostic classification and reasoning.

Domain Specificity

Several constraints have been hypothesized to mold concept formation in different domains, including the domains of biology, psychology, mathematics, and physics. The current consensus is that the potential for variation in conceptual knowledge across cultural communities is mediated by universal constraints on learning and the ways in which they interact with culture-specific experiences. Concepts are the building blocks of thought and one way to understand the flexibility of concept learning is to consider whether people in different cultures think differently. Usually, this question is tied up with the question of whether and how language influences thought and we will not give a separate treatment of this issue. Of course, if thought processes of two cultural groups were radically incommensurable, one would quickly realize that there were dramatic differences but feel at something of a loss to explain them. The fact that one part of learning a foreign language involves finding out what term or word is used in that language to refer to bird, or fish, or chair, or Tuesday, or mother suggests that comparable concepts and categories are in play. Nevertheless, culture affects learning and knowledge construction. Rather than provide a comprehensive catalog of the various principles constraining knowledge construction in each domain, we present a few detailed accounts of cultural research on concept formation, using for illustration cross-cultural conceptions of plants and animals (the domain of folk biology) and counting and calculation (the domain of folk mathematics).

Concept Learning in the Domain of Biology

The field of folk biology is blessed with many intriguing and important issues that lend themselves to an analysis in terms of culture and cognition. Biological concepts are believed to be processed and organized according to evolved cognitive structures that are functionally autonomous with respect to biological information, and for this reason are thought of as belonging to a separate domain of cognitive processing. Building on decades of work in

ethnobiology, research has shown that a few key principles guide the recognition and organization of biological information in similar ways across cultures, although important variation is produced by differences in expertise and other cultural factors.

First, there is marked cross-cultural agreement on the hierarchical classification of living things, such that plants and animals are grouped according to a ranked taxonomy with mutually exclusive groupings of entities at each level. For instance, across cultural groups, the highest level of taxonomic organization includes the most general categories, such as the folk kingdom rank (which includes groupings, such as plants and animals), and lower levels distinguish between increasingly greater degrees of specificity (e.g., life forms, such as tree or bird; generic species level, such as oak or blue jay). Furthermore, the generic species (in local settings the vast majority of genera are represented by a single species, so we use this term) level appears to be consistently privileged for inductive inference when generalizing properties across plants and animals (it is the most abstract level for which inductive confidence is strong and only minimal inductive advantage is gained at more subordinate levels). There is also cross-cultural agreement in the assumption that the appearance and behavior of every generic species is caused by an internal biological (and usually unspecified) essence that is inherited from the birth parents and is responsible for kindhood persistence in the face of physical and developmental transformation.

However, there is also considerable variability within these universal constraints in concept formation as a function of both experience with the natural world and cultural salience (two highly related factors). For instance, the basic level (the level at which they possess the greatest knowledge) for urban undergraduates is the life form (e.g., bird, fish, and tree), but for groups that have more direct experience with the natural environment and greater expertise, the basic level corresponds to the generic species level.

The remarkable cross-cultural agreement in the structure of folk biological organization is, at the same time, culturally variable. Correlations across groups of 0.70 appear quite strong but explain less than half the variance. Although some of these differences might be attributed to experience, other findings implicate cultural differences. For instance, when asked to sort biological kinds into categories, individuals from different communities vary not only in their taxonomic sorting but also in the degree to which they spontaneously sort along ecological dimensions. This difference is not as predictable on the basis of expertise alone. For example, Menominee Native American fisherman and European American fishermen, who both live in rural Wisconsin and have equivalent expertise about fish and fish habitats, differ in that Menominee fishermen are significantly more likely to sort in terms of ecological relationships.

Similar differences in ecological orientation have been found for children from these communities, such that Menominee children were more likely to reason about shared properties between living things using ecological relations, relative to rural European American children. In turn, rural European American children were more likely to employ ecological-based reasoning for shared properties than were urban children. In short, differences in ecological orientation reflect a confluence of experience-based and culturally based factors in folk biological thought.

Cultural differences in cognitive processing, concept representation, and behavior can be thought of as reflecting routines of practices or habits of the mind. Cultural groups establish practices over time, and the history of these practices may lead to regularities in the ways groups participate in the everyday activities within their communities. These practices may be associated, implicitly or explicitly, with different epistemologies that determine what sorts of things are presupposed, go without saying, and seem natural. For example, European Americans tend to conceive of nature as something external, to be cared for, and respected; in contrast, Native Americans are more likely to see themselves as part of nature. These sorts of presuppositions are likely to be embedded in curricula and school practices and represent a challenge to students from cultures and communities that do not share them.

Cultural practices are not immutable, static traits that are attached to participants (a view which can lead to overly deterministic views of cognition), but exist in tension with emergent goals, practices, and situationally specific affordances. Thus, one might design a biology curriculum for Native American students emphasizing ecological relationships, but then build on this base to suggest the value of other forms of organization (e.g., taxonomic). There is increasing evidence that taking advantage of the cultural practices that children bring to the classroom leads to better motivation, identification with learning, and academic performance.

Concept Learning in the Domain of Mathematics

Folk biological research has tended to compare different cultural groups and to identify robust similarities (and differences) in reasoning and representation. Studies of mathematical concepts have expanded on this strategy by using developmental comparisons and analyzing similarities between human and nonhuman species to identify universal or core principles. The domain of mathematics spans a wide variety of concepts, including numerosity, geometry, trigonometry, and so on.

We will limit our review to numerosity, counting, and calculation. A great deal of evidence suggests that for humans and other species there are evolved principles that assist in the representation of numerosity, and

that different principles can constrain representations in particular ways, depending on the set size of elements. Importantly, however, it has been proposed that the systems for large and small numerosity can interact for humans in ways not possible for nonhuman species. Number words and verbal counting may link together systems for small and large numerosities so that, through counting, distinctions can be made between large numerosities that differ in as little as one element.

The flexibility in concepts of numerosity afforded by natural language leads to questions about variability in representations of numerosity and counting as a function of language and other cultural inputs. Some innovative research has examined the different counting systems that have emerged in different cultural communities throughout the world. For instance, before contact with Western culture in 1940, the Oksapmin people in the West Sepik province of Papua New Guinea used a 27-body-part count system, beginning with the thumb on one hand and enumerating discrete points along the upper half of the body (including head and shoulders) and ending on the little finger on the other hand. Counting past 27 involves moving back along the same 27 points until the desired numerosity is reached. In addition, as individuals become more involved in the cash economy, this counting system becomes coopted for arithmetic calculations in addition to or in the place of enumeration and, in some cases, is even transformed to a base-10 system. Although cultural differences in counting systems are well established, not much work has examined the impact of these systems on the representation of numerosity.

Other research has examined the ways in which mathematical concepts, such as calculation processes and representations, are shaped by context-specific goals and culture-specific practices. For instance, grocery shoppers engage in mathematical calculations in response to specific shopping-related goals, and these calculations depend on the resources and environmental tools available to the shopper in the grocery store. Examples have been reported in which a shopper who, upon suspecting a price error for a block of cheese, sorted through a bin of cheese to find a block of similar weight and noted the difference in price that confirmed his suspicions. Had the bin of cheese not been available, the shopper would have had to mentally calculate the correct price based on listed-price-per-weight information.

An important issue is the relation between these sorts of out-of-school goal-related strategies and in-school mathematics learning. Community-specific goals can lead to a greater frequency and, therefore, greater proficiency for some calculations over others. For example, research has shown that 10–12-year-old children in Brazil with little or no education, who sold candy in urban streets, were highly likely to use ratio calculations during vending activities and were better at ratio comparisons than same-aged

children with formal education experience. Other work has revealed that African American middle school and high-school students vary in the extent to which they engage in mathematical calculations to evaluate basketball performance because of differences in the structure of the practice of basketball and level of commitment to basketball. High-school students were more likely to calculate formal statistics (such as average and percent) of their own and others' basketball performance, and these calculations were higher when ways of keeping and reporting basketball statistics were increasingly available to students. This work points out that the players' use and approach to mathematics during their everyday cultural practice may differ dramatically from the approach taken to school mathematics – the use of mathematics in a student's own cultural context is often more engaging. Related work with the children of sugarcane farmers found complementary tendencies to approach mathematical problem solving in different ways depending upon the value ascribed to the context or practice in play.

Conclusions

Concept learning is one of the most exciting and fundamental research areas within cognitive science because it concerns the very building blocks of thought. Early models which assumed that category learning consists of the accumulation of information about entities in the world have been superseded by approaches which stress that learning is in the service of goals, that it is guided by evolved, domain-specific constraints, and molded by cultural practices.

Cooperative Learning*

R E Slavin, Johns Hopkins University, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Cooperative learning refers to a set of instructional strategies in which students work together in small groups to help each other learn academic content. Cooperative learning methods vary widely in their details: group sizes may be from two to several; group members may have individual roles or tasks, or they may all have the same task; and groups may be evaluated or rewarded based on group performance or the average of individual performances, or they may simply be asked to work together.

In one form or another, cooperative learning has been used and studied in every major subject, with students from preschool to college, and in all types of schools. It is used at some level by hundreds of thousands of teachers. One national survey in the 1990s found that 79% of elementary teachers and 62% of middle school teachers reported regular use of cooperative learning (Puma *et al.*, 1993). Antil *et al.* (1998) found that 93% of a sample of teachers reported using cooperative learning, with 81% reporting daily use.

There have been hundreds of studies of cooperative learning focusing on a wide variety of outcomes, including academic achievement in many subjects, second-language learning, attendance, behavior, intergroup relations, social cohesion, acceptance of classmates with handicaps, attitudes toward subjects, and more (see Slavin, 1995; Johnson and Johnson, 1998; Rohrbeck *et al.*, 2003).

This article focuses on research on achievement outcomes of cooperative learning in elementary and secondary schools, and on the evidence supporting various theories to account for effects of cooperative learning on achievement.

Theoretical Perspectives on Cooperative Learning

While there is a fair consensus among researchers about the positive effects of cooperative learning on student achievement, there remains a controversy about why and how cooperative learning methods affect achievement, and, most importantly, under what conditions cooperative learning has these effects. Different groups of researchers investigating cooperative learning effects on achievement begin with different assumptions and conclude by explaining the achievement effects of cooperative learning in terms that are substantially unrelated or contradictory. In

earlier work, Slavin (1995) identified motivationalist, social cohesion, cognitive developmental, and cognitive elaboration as the four major theoretical perspectives on the achievement effects of cooperative learning.

The motivationalist perspective presumes that task motivation is the single most impactful part of the learning process, asserting that the other processes, such as planning and helping, are driven by individuals' motivated self interest. Motivationalist-oriented scholars focus more on the reward or goal structure under which students operate, even going so far as to suggest that under some circumstances, interaction may not be necessary for the benefits of cooperative goal structures to manifest (Slavin, 1995). By contrast, the social cohesion perspective (also called social interdependence theory) suggests that the effects of cooperative learning are largely dependent on the cohesiveness of the group. This perspective holds that students help each other learn because they care about the group and its members and come to derive self-identity benefits from group membership (Johnson and Johnson, 1998). The two cognitive perspectives focus on the interactions among groups of students, holding that in themselves, these interactions lead to better learning and thus better achievement. Within the general cognitive heading, developmentalists attribute these effects to processes outlined by scholars such as Piaget and Vygotsky. Work from the cognitive elaboration perspective asserts that learners must engage in some manner of cognitive restructuring (elaboration) of new materials in order to learn them. Cooperative learning is said to facilitate that process. One reason for the continued lack of consensus among cooperative learning scholars is that each perspective tends to approach the topic without reference to the body of similar work from other perspectives and without attending to the larger picture.

This article offers a theoretical model of cooperative learning processes which intends to acknowledge the contributions of work from each of the major theoretical perspectives. It places them in a model that depicts the likely role each plays in cooperative learning. This work further explores conditions under which each may operate, and suggests research and development needed to advance cooperative learning scholarship so that educational practice may truly benefit from the lessons of 30 years of research.

The alternative perspectives on cooperative learning may be seen as complementary, not contradictory. For example, motivational theorists would not argue that the cognitive theories are unnecessary; instead, they would

* Portions of this paper are adapted from Slavin, 1995.

assert that motivation drives cognitive process, which in turn produces learning. They would argue that it is unlikely that over the long haul, students would engage in the type of elaborated explanations found by Webb (2008) to be essential to profit from cooperative activity, without a goal structure designed to enhance motivation. Similarly, social cohesion theorists might hold that the utility of extrinsic incentives must lie in their contribution to group cohesiveness, caring, and pro-social norms among group members, which could in turn affect cognitive processes.

A simple path model of cooperative learning processes, adapted from Slavin (1995), is diagramed in **Figure 1**, below. It depicts the main components of a group learning interaction, and represents the functional relationships among the major theoretical approaches to cooperative learning.

This diagram of the interdependent relationships among each of the components begins with a focus on group goals or incentives based on the individual learning of all group members. That is, the model assumes that the motivation to learn and to encourage and help others to learn activates cooperative behaviors that will result in learning. This would include both task motivation and motivation to interact in the group. In this model, motivation to succeed leads to learning directly, and also drives the behaviors and attitudes that lead to group cohesion, which in turn facilitates the types of group interactions – peer modeling, equilibration, and cognitive elaboration, which yield enhanced learning and academic achievement. The relationships are conceived to be reciprocal, such that as task motivation leads to the development of group cohesion, that development may reinforce and enhance task motivation. By the same token, the cognitive processes may become intrinsically rewarding and lead to increased task motivation and group cohesion.

Each aspect of the diagrammed model is well represented in the theoretical and empirical cooperative learning literature. All have well-established rationales and some supporting evidence. What follows is a review of the basic

theoretical orientation of each perspective, a description of the cooperative learning mode each prescribes, and a discussion of the empirical evidence supporting each.

Four Major Theoretical Perspectives on Cooperative Learning and Achievement

Motivational Perspectives

Motivational perspectives on cooperative learning presume that task motivation is the most important part of the process, believing that the other processes are driven by motivation. Therefore, these scholars primarily focus on the reward or goal structures under which students operate (see Slavin, 1995). From a motivationalist perspective (e.g., Johnson and Johnson, 1998; Slavin, 1983, 1995), cooperative incentive structures create a situation in which the only way group members can attain their own personal goals is if the group is successful. Therefore, to meet their personal goals, group members must both help their groupmates to do whatever enables the group to succeed, and, perhaps even more importantly, to encourage their groupmates to exert maximum efforts. In other words, rewarding groups based on group performance (or the sum of individual performances) creates an interpersonal reward structure in which group members will give or withhold social reinforcers (e.g., praise and encouragement) in response to groupmates' task-related efforts (see Slavin, 1983).

The motivationalist critique of traditional classroom organization holds that the competitive grading and informal reward system of the classroom creates peer norms opposing academic efforts (see Coleman, 1961). Since one student's success decreases the chances that others will succeed, students are likely to express norms that high achievement is for nerds or teachers' pets. However, by having students work together toward a common goal, they may be motivated to express norms favoring academic achievement, to reinforce one another for academic efforts.

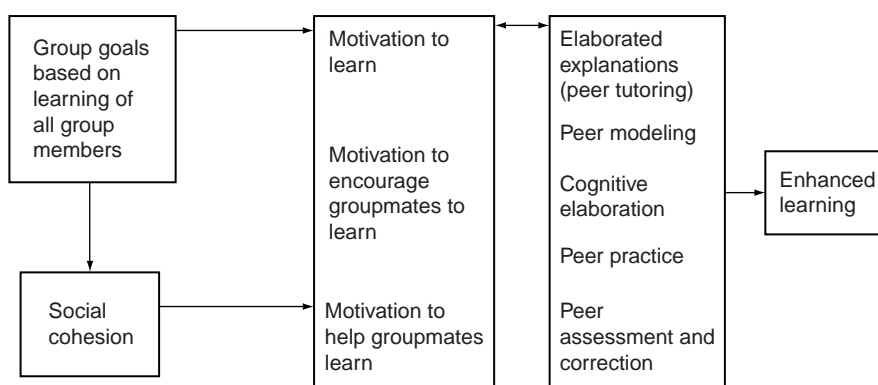

Figure 1 A model of achievement effects of cooperative learning. Adapted from Slavin, R. E. (1995). *Cooperative Learning: Theory, Research, and Practice*, 2nd edn. Boston, MA: Allyn and Bacon.

Not surprisingly, motivational theorists build group rewards into their cooperative learning methods. In methods developed at Johns Hopkins University (Slavin, 1994, 1995), students can earn certificates or other recognition if their average team scores on quizzes or other individual assignments exceed a preestablished criterion. Methods developed by Johnson *et al.* (1998) and his colleagues at the University of Minnesota often give students grades based on group performance, which is defined in several different ways. The theoretical rationale for these group rewards is that if students value the success of the group, they will encourage and help one another to achieve.

Empirical support for the motivational perspective

Considerable evidence from practical applications of cooperative learning in elementary and secondary schools supports the motivational position that group rewards are essential to the effectiveness of cooperative learning, with one critical qualification. Use of group goals or group rewards enhances the achievement outcomes of cooperative learning if and only if the group rewards are based on the individual learning of all group members (Slavin, 1995). Most often, this means that team scores are computed based on average scores on quizzes which all teammates take individually, without teammate help. For example, in Student Teams-Achievement Divisions, or STADs (Slavin, 1994), students work in mixed-ability teams to master material initially presented by the teacher. Following this, students take individual quizzes on the material, and the teams may earn certificates based on the degree to which team members have improved over their own past records. The only way the team can succeed is to ensure that all team members have learned, so the team members' activities focus on explaining concepts to one another, helping one another practice, and encouraging one another to achieve. In contrast, if group rewards are given based on a single group product (e.g., the team completes one worksheet or solves one problem), there is little incentive for group members to explain concepts to one another, and one or two group members may do all the work (see Slavin, 1995).

In assessing the empirical evidence supporting cooperative learning strategies, the greatest weight must be given to studies of longer duration. If well executed, these are bound to be more realistically generalizable to the day-to-day functioning of classroom practices. A review of 99 studies of cooperative learning in elementary and secondary schools that involved durations of at least 4 weeks compared achievement gains in cooperative learning and control groups. Of 64 studies of cooperative learning methods that provided group rewards based on the sum of group members' individual learning, 50 (78%) found significantly positive effects on

achievement, and none found negative effects (Slavin, 1995). The median effect size for the studies from which effect sizes could be computed was +0.32 (32% of a standard deviation separated cooperative learning and control treatments). In contrast, studies of methods that used group goals based on a single group product or provided no group rewards found few positive effects, with a median effect size of only +0.07. Comparisons of alternative treatments within the same studies found similar patterns; group goals based on the sum of individual learning performances were necessary to the instructional effectiveness of the cooperative learning models (e.g., Fantuzzo *et al.*, 1989, 1990).

Social Cohesion Perspective

A theoretical perspective somewhat related to the motivational viewpoint holds that the effects of cooperative learning on achievement are strongly mediated by the cohesiveness of the group. The quality of the group's interactions is thought to be largely determined by group cohesion. In essence, students will engage in the task and help one another learn because they identify with the group and want one another to succeed. This perspective is similar to the motivational perspective in that it emphasizes primarily motivational rather than cognitive explanations for the instructional effectiveness of cooperative learning. However, motivational theorists hold that students help their groupmates learn primarily because it is in their own interests to do so. Social cohesion theorists, in contrast, emphasize the idea that students help their groupmates learn because they care about the group. A hallmark of the social cohesion perspective is an emphasis on teambuilding activities in preparation for cooperative learning, and processing or group self-evaluation during and after group activities. Social cohesion theorists have historically tended to downplay or reject the group incentives and individual accountability held by motivationalist researchers to be essential. They emphasize, instead, that the effects of cooperative learning on students and student achievement depend substantially on the quality of the group's interaction (Battisch *et al.*, 1993). For example, Cohen (1994: 69, 70) stated "if the task is challenging and interesting, and if students are sufficiently prepared for skills in group process, students will experience the process of groupwork itself as highly rewarding . . . never grade or evaluate students on their individual contributions to the group product." Cohen's (1994) work, as well as that of Sharan and Sharan (1992) and Elliot Aronson (Aronson *et al.*, 1978) and his colleagues, may be described as social cohesiveness theories. Cohen, Aronson, and the Sharans all use forms of cooperative learning in which students take on individual roles within the group, which Slavin (1983) calls "task specialization" methods. In Aronson's Jigsaw method, students study material on one of four or five topics

distributed among the group members. They meet in expert groups to share information on their topics with members of other teams who had the same topic, and then take turns presenting their topics to the team. In the Sharans' Group Investigation method, groups take on topics within a unit studied by the class as a whole, and then further subdivide the topic into tasks within the group. The students investigate the topic together and ultimately present their findings to the class as a whole. Cohen's Finding Out/Descubrimiento program has students play different roles in discovery-oriented science activities.

One main purpose of the task specialization used in Jigsaw, Group Investigation, and Finding Out/Descubrimiento is to create interdependence among group members. In the Johnsons' methods, a somewhat similar form of interdependence is created by having students take on roles as checker, recorder, observer, and so on. The idea is that if students value their groupmates (as a result of teambuilding and other cohesiveness-building activities) and are dependent on one another, they are likely to encourage and help one another to succeed.

Empirical support for the social cohesion perspective

There is some evidence that the achievement effects of cooperative learning depend on social cohesion and the quality of group interactions (Battisch *et al.*, 1993). The achievement outcomes of cooperative learning methods that emphasize task specialization are less clear. Research on the original form of Jigsaw has not generally found positive effects of this method on student achievement (Slavin, 1995). One problem with this method is that students have limited exposure to material other than that which they studied themselves, so learning gains on their own topics may be offset by losses on their groupmates' topics. In contrast, there is evidence that when it is well implemented, Group Investigation can significantly increase student achievement (Sharan and Shachar, 1988). In studies of at least 4 weeks' duration, the Johnson *et al.* (1998) methods have not been found to increase achievement more than individualistic methods unless they incorporate group rewards (in this case, group grades) based on the average of group members' individual quiz scores (see Slavin, 1995). Studies of forms of Jigsaw that have added group rewards to the original model have found positive achievement outcomes (Mattingly and Van Sickle, 1991).

Research on practical classroom applications of methods based on social cohesion theories provides inconsistent support for the proposition that building cohesiveness among students through teambuilding alone (i.e., without group incentives) will enhance student achievement. In general, methods which emphasize teambuilding and group process, but do not provide specific group rewards based on the learning of all group members, are no more effective than

traditional instruction in increasing achievement (Slavin, 1995), although there is evidence that these methods can be effective if group rewards are added to them.

Cognitive Perspectives

The major alternative to the motivationalist and social cohesiveness perspectives on cooperative learning, both of which primarily focus on group norms and interpersonal influence, is the cognitive perspective. The cognitive perspective holds that interactions among students will in themselves increase student achievement for reasons which have to do with mental processing of information rather than with motivations. Cooperative methods developed by cognitive theorists involve neither the group goals that are the cornerstone of the motivationalist methods nor the emphasis on building group cohesiveness characteristic of the social cohesion methods. However, there are several quite different cognitive perspectives, as well as some which are similar in theoretical perspective, but have developed on largely parallel tracks. The two most notable of these are described in the following sections.

Developmental perspectives

One widely researched set of cognitive theories is the developmental perspective (e.g., Damon, 1984). The fundamental assumption of the developmental perspective on cooperative learning is that interaction among children around appropriate tasks increases their mastery of critical concepts. Vygotsky (1978: 86) defines the zone of proximal development as "... the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in *collaboration with more capable peers*" (emphasis added). In his view, collaborative activity among children promotes growth because children of similar ages are likely to be operating within one another's proximal zones of development, modeling in the collaborative group behaviors more advanced than those they could perform as individuals.

Similarly, Piaget (1926) held that social-arbitrary knowledge – language, values, rules, morality, and symbol systems – can only be learned in interactions with others. Peer interaction is also important in logical-mathematical thought in disequilibrating the child's egocentric conceptualizations and in providing feedback to the child about the validity of logical constructions.

There is a great deal of empirical support for the idea that peer interaction can help nonconservers become conservers. Many studies have shown that when conservers and nonconservers of about the same age work collaboratively on tasks requiring conservation, the nonconservers generally develop and maintain conservation concepts (see Bell *et al.*, 1985). From the developmental perspective, the effects of cooperative learning on student

achievement would be largely or entirely due to the use of cooperative tasks. In this view, opportunities for students to discuss, argue, and to present and hear one another's viewpoints constitute the critical elements of cooperative learning with respect to student achievement.

Empirical evidence for the developmental perspective

Despite considerable support from theoretical and laboratory research, there is little evidence, from classroom experiments conducted over meaningful time periods, that pure cooperative methods, which depend solely on interaction, do produce higher achievement. However, it is likely that the cognitive processes described by developmental theorists are important mediating variables, which can help explain the positive outcomes of effective cooperative learning methods (Slavin, 1995).

Cognitive elaboration perspectives

A cognitive perspective on cooperative learning quite different from the developmental viewpoint is one which might be called the cognitive elaboration perspective. Research in cognitive psychology has long held that if information is to be retained in memory and related to information already in memory, the learner must engage in some sort of cognitive restructuring, or elaboration of the material (Wittrock, 1986). One of the most effective means of elaboration is explaining the material to someone else. Research on peer tutoring has long found achievement benefits for the tutor as well as the tutee (Devin-Sheehan *et al.*, 1976). In this method, students take roles as recaller and listener. They read a section of text, and then the recaller summarizes the information while the listener corrects any errors, fills in any omitted material, and helps think of ways by which both students can remember the main ideas. The students switch roles on the next section.

Empirical evidence for the cognitive elaboration perspective

Donald Dansereau and his colleagues at Texas Christian University have found in a series of brief studies that college students working on structured cooperative scripts can learn technical material or procedures far better than can students working alone (O'Donnell, 1996). Dansereau and his colleagues found in a series of studies that while both the recaller and the listener learned more than did students working alone, the recaller learned more (O'Donnell and Dansereau, 1992). This mirrors both the peer-tutoring findings as well as those of Noreen Webb (2008), who discovered that the students who gained the most from cooperative activities were those who provided elaborated explanations to others. In this research as well as in Dansereau's, students who received elaborated explanations learned more than those who worked alone, but not as much as those who served as explainers. Studies

of reciprocal teaching, in which students learn to formulate questions for each other, have generally supported its positive effects on student achievement (Palincsar *et al.*, 1987; Rosenshine and Meister, 1994; O'Donnell, 2000).

Structuring Group Interactions

There is some evidence that carefully structuring the interactions among students in cooperative groups can be effective, even in the absence of group rewards. For example, Meloth and Deering (1992) compared students working in two cooperative conditions. In one group, students were taught specific reading comprehension strategies and given think sheets to remind them to use these strategies (e.g., prediction, summarization, and character mapping). In the other group, students earned team scores if their members improved each week on quizzes. A comparison of the two groups on a reading comprehension test found greater gains for the strategy group.

However, there is also evidence to suggest that a combination of group rewards and strategy training produces much better outcomes than either alone. Fantuzzo *et al.* (1992) directly made a comparison between rewards alone, strategy alone, and a combination, and found the combination to be by far the most effective. Further, the outcomes of dyadic learning methods, which use group rewards as well as strategy instruction, produced some of the largest positive effects of any cooperative methods, much larger than those found in studies that provided groups with structure but not rewards. As noted earlier, studies of scripted dyads also find that adding incentives adds to the effects of these strategies (O'Donnell, 1996). The consistent positive findings for Cooperative Integrated Reading and Composition (CIRC) (Stevens *et al.*, 1987), which uses both group rewards and strategy instruction, also argue for this combination.

Reconciling the Four Perspectives

The model shown above in **Figure 1** illustrates how group goals might operate in enhancing the learning outcomes of cooperative learning. Provision of group goals based on the individual learning of all group members might affect cognitive processes directly, by motivating students to engage in peer modeling, cognitive elaboration, and/or practice with one another. Group goals may also lead to group cohesiveness, increasing caring and concern among group members and making them feel responsible for one another's achievement, thereby motivating students to engage in cognitive processes which enhance learning. Finally, group goals may motivate students to take responsibility for one another independently of the teacher, thereby solving important classroom organization

problems and providing increased opportunities for cognitively appropriate learning activities. Scholars whose theoretical orientations deemphasize the utility of extrinsic rewards attempt to intervene directly on mechanisms identified as mediating variables in the model described earlier. For example, social cohesion theorists intervene directly on group cohesiveness by engaging in elaborate teambuilding and group processing training. Cognitive theorists would hold that the cognitive processes that are essential to any theory relating cooperative learning to achievement can be created directly, without the motivational or affective changes discussed by the motivationalist and social cohesion theorists.

From the perspective of the model diagrammed in **Figure 1**, starting with group goals and individual accountability permit students in cooperative learning groups to benefit from the full range of factors that are known to affect cooperative learning outcomes. While group goals and individual accountability may not always be absolutely necessary, to ignore them would be to ignore the tool with the most consistent evidence of positive effects on student achievement.

In summary, although cooperative learning has been studied in an extraordinary number of field experiments of high methodological quality, there is still much more to be done. Cooperative learning has the potential to become a primary format used by teachers to achieve both traditional and innovative goals. Research must continue to provide the practical, theoretical, and intellectual underpinnings to enable educators to achieve this potential. This article has advanced a cohesive model of the relationships among the important variables involved in the functioning of cooperative learning. It offers a framework for discussion and continued debate while calling for a move away from competitive attempts to explain this complex phenomenon toward a unified theoretical model which can guide future research efforts and inform education practice.

Glossary

Crystallized intelligence – One of two major subfactors of general intelligence, it represents the accumulation of knowledge over the life span of the individual and may be measured by tests in areas such as vocabulary, general information, and achievement (cf. fluid intelligence).

Deviation intelligence quotients (IQs) – A means of determining intelligence test scores, based on deviations from an average score, calculated such that the normative equivalent for the median score is 100, about 68% of the scores are computed to fall between 85 and 115, and about 95% of the scores fall between 70 and 130; strictly speaking, they are not IQs because no quotient is involved (cf. mental age and ratio IQ).

Emotional intelligence – The ability to perceive and express emotion, assimilate emotion in thought, understand and reason with emotion, and regulate emotion in the self and others.

Fluid intelligence – One of two major subfactors of general intelligence, it represents the acquisition of new information or the grasping of new relationships and abstractions about known information (may be measured, e.g., by timed tests involving analogies, series completions, or inductive reasoning; cf. crystallized intelligence).

Heritability coefficient – The degree to which heredity contributes to individual differences in intelligence, expressed in terms of a number on a scale from 0 to 1, such that a coefficient of 0 means that heredity has no influence on variation among people, whereas a coefficient of 1 means that heredity is the only influence on such variation.

Intelligence – The ability to implement goal-directed adaptive behavior.

Mental age – A means of indicating a person's level of intelligence (generally in reference to a child), based on the individual's performance on tests of intelligence, by indicating the chronological age of persons who typically perform at the same level of intelligence as the test-taker (used less frequently today than in the past; cf. deviation IQs, intelligence, and ratio IQ).

Mental retardation – Low level of intelligence, usually reflected by both poor performance on tests of intelligence and poor adaptive competence

(the degree to which a person functions effectively within a normal situational context).

Ratio IQ – A means of indicating performance on intelligence tests, based on a quotient of mental age divided by chronological age, times 100 (cf. deviation IQs).

Reaction range – The broad limits within which a particular attribute (e.g., intelligence) may be expressed in various possible ways, given the inherited potential for its expression in the particular individual.

Theory of multiple intelligences – A theory suggesting that intelligence comprises eight distinct constructs – bodily–kinesthetic intelligence, interpersonal intelligence, intrapersonal intelligence, linguistic intelligence, mathematical–logical intelligence, musical intelligence, naturalist intelligence, and spatial intelligence – that function somewhat independently, but may interact to produce intelligent behavior.

Triarchic theory of successful intelligence – A theory of intelligence that asserts that intelligence comprises three aspects, which deal with the relationship of intelligence to the internal world, to experience, and to the external world.

Theories of Intelligence

Implicit Theories

How do psychologists or educators know about what intelligence is? One way they find out is by asking people. For example, they might ask experts. What do experts say?

In a 1921 symposium on the definition of intelligence, an American psychologist, Lewis M. Terman, emphasized the ability to think abstractly. Another American psychologist, Edward L. Thorndike, emphasized learning and the ability to give good responses to questions. In a similar 1986 symposium, however, psychologists generally agreed on the importance of adaptation to the environment as the key to understanding both what intelligence is and what it does. They also emphasized learning skills and understanding one's own cognitive processes. Therefore, adaptation, learning, and metacognition (i.e., understanding oneself) won the day.

In a set of studies published in 1981, Robert J. Sternberg and his colleagues asked laypeople in the United States what they thought intelligence was. Three factors emerged from their responses: practical problem solving, verbal ability, and social competence. The conceptions that arise depend, however, on who is asked.

Robert J. Sternberg and his colleagues have studied implicit theories in various cultures. In comparable studies done in Taiwan, four factors prevailed: cognitive skills, getting along with other people, understanding oneself, and knowing when to and when not to show that one is smart. In other studies conducted in Kenya, cognitive skills also were emphasized less than in the West. In contrast, obedience, respect, and understanding people were emphasized more.

Most theories of intelligence are explicit rather than implicit. They are elicited not by asking people what they mean by intelligence, but rather, by having people perform tasks believed to require intelligence. There are several different kinds of explicit theories.

Psychometric Theories

Psychometric theories have generally sought to understand the structure of intelligence: What form does it take, and what are its parts, if any? Such theories have generally been based on and tested by the use of data obtained from tests of mental abilities. These tests include assessments of vocabulary, numerical reasoning, analogical reasoning, and visualization of what forms would look like if they were rotated in space.

The first major psychometric theories were proposed by the British psychologist Charles E. Spearman. In a 1904 article, Spearman argued that just two kinds of factors underlie virtually all individual differences in test scores. Spearman called the first and more important kind of factor the general factor or *g*. It was said to pervade performance on all tasks requiring intelligence. The second kind of factor, according to Spearman, was specific to each test. However, what exactly is *g*? In 1927, Spearman proposed it might be something he labeled mental energy.

An American psychologist, L. L. Thurstone, instead suggested that seven factors, or primary mental abilities, underlie individual differences in mental test performance: verbal comprehension (knowledge of vocabulary and in reading); verbal fluency (writing and producing words in response to a prompt, such as words beginning with the letter d); number (solving simple arithmetical computation and reasoning problems); spatial visualization (mentally visualizing and manipulating objects); inductive reasoning (completing a number or letter series); memory (remembering people's names or faces); and perceptual speed (rapidly proofreading to discover typographical errors in a typed text).

Raymond B. Cattell and John B. Carroll, among others, suggested that abilities are hierarchical. At the top of the hierarchy is *g* or general ability. Below *g* in the hierarchy are successive levels of gradually narrowing abilities, ending with Spearman's specific abilities.

Cattell suggested that general ability can be divided into two basic abilities, fluid and crystallized. Fluid abilities are the reasoning and problem-solving skills measured by tests such as the analogies, classifications, and series completions. Crystallized abilities derive from fluid abilities and are viewed as their products, which include vocabulary, general information, and knowledge about specific fields. John L. Horn suggested that crystallized ability more or less increases over the life span, whereas fluid ability increases in the earlier years and decreases in the later ones.

John B. Carroll proposed a three-stratum model of intelligence. It is considered by some to be the most definitive psychometric model of intelligence because it is based upon reanalyses of hundreds of data sets. According to this model, general ability is at the top of a hierarchy of abilities. At the next lower stratum are various broad abilities (including learning and memory processes and the effortless production of many ideas). At the bottom of the hierarchy are many narrow, specific abilities, such as spelling ability and reasoning speed.

J. P. Guilford, an American psychologist, proposed a structure-of-intellect theory, which, in its earlier versions, postulated 120 abilities. For example, in an influential 1967 work, Guilford argued that abilities can be divided into five kinds of operations, four kinds of contents, and six kinds of products. These various facets of intelligence combine multiplicatively for a total of $5 \times 4 \times 6$, or 120 separate abilities. An example of such an ability would be cognition (operation) of semantic (content) relations (product), which would be involved in recognizing the relation between lawyer and client in the analogy problem, lawyer:client::doctor:?. In 1984, Guilford increased the number of abilities proposed by his theory, raising the total to 150.

In an address to the American Psychological Association in 1957, Lee J. Cronbach proposed that psychologists unite the two disciplines of scientific psychology – experimental and differential (the study of individual differences). His proposal led to cognitive theories of intelligence, which are derived and tested by experimental means.

Underlying most cognitive approaches to intelligence is the assumption that intelligence comprises a set of mental representations (e.g., propositions and images) of information and a set of mental processes that can operate on the representations. A more intelligent person is assumed to mentally represent information better and also to operate more quickly on these representations than a less intelligent person does.

In 1975, Earl B. Hunt, Clifford E. Lunneborg, and J. Lewis showed that a critical ability underlying verbal intelligence is that of rapidly retrieving lexical information, such as letter names, from memory. A few years later, Robert J. Sternberg identified key mental processes alleged to underlie many cognitive tasks, especially ones involving inductive reasoning. The processes included, among others, encoding stimuli, inferring relations between stimuli, and applying what one has learned.

Ian Deary and his colleagues have sought to understand intelligence through the study of inspection time. They have found that more intelligent individuals can discriminate the lengths of the lines with lesser stimulus duration (inspection) times than less intelligent individuals can.

Two leaders in the field of cognitive psychology, Allen Newell and Herbert A. Simon, used computers to model intelligence. The underlying idea is that computers can, in some sense, show a kind of intelligence similar to that shown by humans. In 1972, Newell and Simon proposed a general theory of problem solving, much of which was implemented on the computer. It involves heuristics such as means–ends analysis, whereby one seeks, at each step of problem solving, to reduce as much as possible the distance between the solution and where one is in the problem.

Marcel Just and Patricia Carpenter showed that complex intelligence test items, such as figural matrix problems involving reasoning with geometric shapes, could be solved by a computer program at a level of accuracy comparable to that of human test-takers.

The models described above are serial-processing models, whereby the computer takes steps in sequence. David E. Rumelhart and Jay L. McClelland, proposed what they call parallel distributed processing models of the mind. These models postulate that many types of information processing occur at once, rather than just one at a time.

Perhaps the dominant cognitive approach today is one that stresses the role of working memory in intelligence. Patrick Kyllonen, Randall Engle, and others have suggested that the main source of differences in performance on intellectual tasks is in people's differential working-memory capacities, that is, their ability to remember and manipulate recently presented information in their minds.

Cognitive-Contextual Theories

Cognitive-contextual theories deal with the way cognitive processes operate in various environmental contexts. Two of the major theories of this type have been proposed by Howard Gardner and Robert Sternberg.

In 1983, Gardner proposed a theory of what he called multiple intelligences. In the 1999 version of the theory, the multiple intelligences include, at minimum, linguistic, logical–mathematical, spatial, musical, bodily–kinesthetic, naturalist, interpersonal, and intrapersonal intelligences. Gardner has also speculated about the existence of an existential intelligence.

An alternative theory, also taking into account both cognition and context, is Sternberg's triarchic theory of successful intelligence. According to Sternberg, intelligence has three aspects. These aspects relate intelligence to what goes on internally within a person, what goes on in the external world, and to experience, which mediates between the internal and external worlds.

The first aspect is the set of cognitive processes and representations that form the core of all thought. Sternberg has distinguished three kinds of processes: those involved in deciding what to do and, later, in deciding how well it was done; those involved in doing what one has decided to do; and those involved in learning how to do it in the first place. The second aspect is the application of these processes to the external world. According to Sternberg, mental processes serve three functions in the everyday world: adaptation to existing environments, the shaping of existing environments into new ones, and the selection of new environments when old ones prove unsatisfactory. According to the theory, more successful intelligent persons are not just those who can execute many cognitive processes quickly or well. Greater intelligence is additionally reflected in knowing what one's strengths and weaknesses are and capitalizing upon strengths while remedying or compensating for weaknesses. Successfully intelligent persons, then, find a niche in which they can operate effectively.

The third aspect of Sternberg's triarchic theory is the integration of the internal and external worlds through experience. One measure of intelligence is the ability to cope with relatively novel situations. The abilities to cope with relative novelty and to automatize cognitive processing are seen as interrelated: The more a person is able to automatize the tasks of daily life, the more mental resources there are left to cope with novelty.

Peter Salovey and John Mayer proposed the construct of emotional intelligence. It was popularized by Daniel Goleman in a 1995 book. It is the ability to perceive accurately, appraise, and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth. Several tests are now available to measure emotional intelligence. They generally show modest to moderate correlations with conventional tests of intelligence. They also predict various forms of real-world behavior.

Biological Theories

Biological theories are based in the neuropsychological functioning that produces, or at least is correlated with, intelligent behavior. Several biological approaches have been proposed.

One approach has been the investigation of the types of intellectual performance as related to the regions of the brain from which they originate. An American researcher in this area, Jerre Levy, found that the left hemisphere is superior in analytical functioning, of which a prime example is the use of language. The right hemisphere is superior in many forms of visual and spatial performance and tends to be more synthetic and holistic in its functioning than the left.

A second approach to research has involved the use of brain-wave recordings to study the relation between these waves and either performance on ability tests or in various kinds of cognitive tasks. Researchers, such as British researcher P. G. Caryl, have found a relationship between certain aspects of electroencephalogram (EEG) and event-related potential (ERP) waves and scores on standard psychometric tests of intelligence.

A third approach involves the measurement of blood flow in the brain, which is a fairly direct indicator of functional activity in brain tissue. In such studies, the amount and location of blood flow in the brain is monitored while subjects perform cognitive tasks. Using positron emission tomography (PET), Richard Haier discovered that people who perform better on conventional tests of intelligence often show less activation in relevant portions of the brain than those who do not perform as well. This pattern of results suggests that the better performers find the tasks easier and thus invoke less effort than the poorer performers do.

Development of Intelligence

There have been diverse approaches to studying the development of intelligence. Psychometric theorists, for instance, have sought to understand how intelligence develops in terms of changes in the factors of intelligence over time and changes in the amounts of the various abilities that children have. For example, the concept of mental age was popular during the first half of the twentieth century. A given mental age was believed to represent an average child's level of mental functioning for a given chronological age. Thus, an average 10-year-old would have a mental age of 10, but an above-average 8-year-old or a below-average 12-year-old might also have a mental age of 10 years. The concept of mental age has fallen into disfavor, however, and is used only rarely now. The concept does not work well over a chronological age of roughly 16. Moreover, its assumption of perfectly smooth continuous mental development is questionable.

The Theory of Jean Piaget

Jean Piaget, a Swiss psychologist, suggested that the child explores the world, observes regularities, and makes generalizations, much as a scientist does. Two fundamental cognitive processes are alleged to work in a somewhat reciprocal fashion. Assimilation involves incorporating new information into an already existing cognitive structure. Accommodation involves forming a new cognitive structure to incorporate new information. Cognitive development, according to Piaget, represents a dynamic equilibrium between these two processes of assimilation and accommodation.

Piaget also postulated that there are four major periods in intellectual development. The first, the sensorimotor period, extends from birth until roughly 2 years of age. During this period, a child learns how to modify reflexes to make them more adaptive, coordinate actions, retrieve hidden objects, and, eventually, to begin representing information mentally. During the second, preoperational period, from about 2 to 7 years of age, a child experiences the growth of language and mental imagery. He or she also learns to focus on single perceptual dimensions, such as color and shape. The third, concrete-operational period, is from about 7 to 12 years of age. It is the period during which a child develops an important set of skills that are referred to as conservation skills. The child will recognize that substances stay the same in amount, regardless of their form. Finally, children emerge into the fourth, formal-operational period, which begins at about age 12 and continues throughout life. The formal-operational child develops thinking skills in all logical combinations and learns to think with abstract concepts.

The Theory of Lev Vygotsky

Lev S. Vygotsky, a Soviet psychologist, suggested that intellectual development may be largely influenced by a child's interactions with others: a child sees others thinking and acting in certain ways and then internalizes and models what is seen. Vygotsky also proposed the notion of a zone of proximal development (ZPD), which is the range of ability between a person's observable level of ability and the person's latent capacity. This latent capacity is not directly observable, but may be detected by providing a context in which the latent capacity may be revealed and expressed. The ZPD is sometimes termed the zone of potential development.

Measuring Intelligence

Early Historical Background

The publication of Charles Darwin's *The Origin of Species* in 1859 had a profound effect on many lines

of scientific work. Darwin suggested that the capabilities of humans are, in some sense, continuous with those of lower animals. Hence, they can be understood through scientific investigation. One person who was strongly influenced by Darwin's thinking was his cousin, Sir Francis Galton. For 7 years – between 1884 and 1890 – Galton maintained a laboratory at the South Kensington Museum in London. For a small fee, visitors could have themselves measured on a variety of psychophysical tasks. These tasks included weight discrimination and sensitivity to musical pitch. Galton believed that these tests measured more than just psychophysical abilities. He believed that psychophysical abilities are the basis of intelligence and, hence, that his tasks were measures of intelligence. Galton's intelligence test, therefore, required a person to perform simple tasks, such as deciding which of two weights was heavier or showing how forcefully he could squeeze his hand. The Galtonian tradition was taken to the United States by the psychologist James McKeen Cattell.

The Intelligence Quotient Test

A more influential tradition of mental testing was developed in France by Alfred Binet and his collaborator, Theodore Simon. In 1904, the minister of public instruction in Paris named a commission to study or create tests that would insure that mentally retarded children received an adequate education. The minister was also concerned that certain children were being placed in classes for the retarded not because they were retarded, but because they had behavior problems, and teachers did not want them in their classrooms. Binet and Simon proposed that tests of intelligence should measure skills such as judgment, comprehension, and reasoning – the same kinds of skills measured on most intelligence tests today. Binet's early test was taken to the United States by a Stanford University psychologist, Lewis Terman, whose version came to be called the Stanford-Binet test. This test has been revised frequently and continues to be in use.

The Stanford-Binet test and others similar to it have traditionally yielded, at the very least, an overall score referred to as an intelligence quotient (IQ). In its most recent form, this test as well as the Wechsler Adult Intelligence Scale and the Wechsler Intelligence Scale for Children yield an overall IQ and other scores as well.

More recent tests of intelligence have expanded the range of abilities tested. For example, in 1997, J. P. Das and Jack Naglieri produced a test, the Cognitive Assessment System, based on a theory of intelligence first proposed by a Russian psychologist, Alexander Luria. The test measures planning abilities, attentional abilities, and simultaneous and successive processing abilities.

IQ was originally computed as the ratio of mental age to chronological (physical) age, multiplied by 100. It is

thus sometimes referred to as a ratio IQ. For example, if a child of age 8 had a mental age of 10 (i.e., performed on the test at the level of an average 10-year-old), the child was assigned an IQ of $(10/8) \times 100$, or 125. If the 8-year-old had a mental age of 6, the child's IQ would be $(6/8) \times 100$, or 75. A score of 100, whereby the mental age equals the chronological age, is average.

As discussed above, the concept of mental age has fallen into disrepute, and few tests continue to involve the computation of mental ages. Many tests still yield an IQ, but it is most often computed on the basis of statistical distributions. The scores are assigned on the basis of what percentage of people of a given group would be expected to have a certain IQ. Scores computed in this way are called deviation IQs.

The Distribution of IQ Scores

Intelligence test scores follow an approximately normal distribution, meaning that most people score near the middle of the distribution of scores. Scores drop off fairly rapidly in frequency in either direction from the center of the distribution. For example, on the IQ scale, about two-thirds of all scores fall between IQs of 85 and 115, and about 95% of scores fall between 70 and 130. Put another way, only one out of 20 scores differs from the average IQ (100) by more than 30 points.

It has been common to associate certain levels of IQ with labels. For example, at the upper end, the label gifted is sometimes assigned to people with IQs over a certain point, such as 130. In addition, at the lower end, mental retardation has been classified into different degrees depending upon IQ; therefore, for example, IQs of 70–84 have been classified as borderline retarded, 55–69 as mildly retarded, 40–54 as moderately retarded, 25–39 as severely retarded, and IQs below 25 as profoundly retarded.

Many psychologists now believe that IQ represents only a part of intelligence, and intelligence is only one factor in both mental retardation and giftedness. Most current definitions of mental retardation stress adaptive skills as well as IQ and also emphasize attributes such as creativity, motivation, and achievement in conceptions of giftedness.

The Heritability and Malleability of Intelligence

Historically, intelligence has been viewed as a more or less fixed trait. This view conceives intelligence as something people are born with. The function of development is thus to allow this genetic endowment to express itself. A number of investigators have suggested that intelligence is highly heritable, and that it is transmitted through

the genes. Heritability is here defined as the proportion of individual-differences variance that is genetically transmitted. Other investigators believe that intelligence is minimally heritable, if at all. Most authorities take an intermediate position. However, all agree that heritability operates within a reaction range, meaning that a given genotype for intelligence can result in a wide range of phenotypes, depending on how environmental factors interact with genetic ones.

Several methods are used to assess the heritability of intelligence. The most well known is perhaps the study of identical twins reared apart. For a variety of reasons, identical twins are occasionally separated at or near birth. If the twins are raised apart, and if it is assumed that when twins are separated, they are randomly distributed across environments (often a dubious assumption), then the twins would heritably have in common all of their genes, but none of their environment, except for chance environmental overlap. As a result, the correlation between their performances on tests of intelligence can provide an estimate of the proportion of variation in test scores due to heredity. Another method of computing the hereditary effect on intelligence involves comparing the relationship between intelligence test scores of identical twins and those of fraternal twins.

It appears that roughly half the variation in intelligence test scores is caused by hereditary influences. However, Robert Plomin and others have shown that the heritability of intelligence increases with age, suggesting that genetic factors become more important and environmental factors less important to individual differences in intelligence with increasing age. In adulthood, heritability may reach as high as 70% or more. The estimates are computed, for the most part, on the basis of intelligence test scores, so that the estimates are only for that part of intelligence measured by the tests. An interesting recent finding by Eric Turkheimer and his colleagues is that heritability appears to be substantially higher in higher social classes than in lower social classes.

Whatever the heritability factor of IQ, an entirely separate issue is whether intelligence can be increased. The work by a New Zealand researcher, James Flynn, has shown that, in the middle and later twentieth century, scores on intelligence tests rose rather steadily throughout the world. The precise reason for the increase is unknown, although speculations include better education, better nutrition, and advances in technology.

Despite the general increase in scores, average IQs continue to vary across both countries and different socioeconomic groups. For example, many researchers have found a positive correlation between socioeconomic status and IQ, although they disagree over the reason for the relationship. Most psychologists agree that differences in educational opportunities play an important role, and some investigators believe that there is a hereditary basis

for the difference as well. However, there is simply no broad consensus on the issue of why the differences exist. Again, the differences are based on IQ, not broadly defined intelligence.

No matter how heritable intelligence is, some aspects of it are still malleable. Heritability of a trait is a separate issue from its malleability. For example, height is not only highly heritable, but also highly modifiable by nutrition and other environmental factors. Thus, with intervention, even a highly heritable trait can be modified. There is a growing body of evidence suggesting that aspects of intelligence also can be modified. Intelligence, in the view of many psychologists, is not merely a fixed trait. A program of training in intellectual skills can increase some aspects of a person's level of intelligence. No training program – no environmental condition of any sort – is likely to make a genius of someone with low measured intelligence. However, some gains are possible, and a number of programs have been developed for increasing intellectual skills. A main trend for psychologists working in the intelligence field has been to combine testing and training functions in order to enable people to optimize their intelligence. Such work needs to take into account technological advances because the very existence of technology changes the nature of intelligence. Today, skills in computer literacy and database management, which were needed only rarely 50 years ago, have become important. Therefore, the nature of intelligence is, to some extent, a moving target, one that researchers in the field must constantly track.

Introduction

Recent research on reading and reading instruction has led to significant improvements in the understanding of word decoding and the teaching of primary-grade readers. This research is based on a single-text paradigm where students are invited to read texts as isolated pieces of information. Skills involved in single-text reading, such as decoding and inference making, are vital in all kinds of text-comprehension activities. However, when readers use multiple information sources, skilled reading involves even more complex processes. As readers in today's society are continually bombarded with information from innumerable, often conflicting, information sources, it is essential to understand how individuals handle challenging integrative reading tasks involving very complex cognitive processes.

In this article, multiple information sources refer to different text-based sources on the same topic. For instance, a student may read a newspaper article about immigration in Europe. Next day, the student reads another article about immigration and integration in a magazine, and later the same day a member of a right-wing party offers the student a flyer about the number of criminal immigrants in the country. The three different texts are focusing on different aspects of immigration, and some of the information may be closely related, even overlapping, whereas other parts of the texts may be partly conflicting, supplementary, or not related at all. The student may leave each text as is or, alternatively, take on the challenging task of trying to construct a coherent meaning from the three texts. Learning from multiple information sources is a common task in modern societies, not only in educational settings, but also at home and at most workplaces.

There is no unified theory regarding how students deal with manifold information sources. Several researchers prefer to use the term *intertextuality* when studying how people deal with different information sources. This term is traditionally associated with domains such as literary criticism, linguistics, and biblical research. In educational research, *intertextuality* has been linked to reading, writing, and literacy practices in classrooms (Shuart-Faris and Bloome, 2004). The focus is on the construction of meaning through texts, based on the assumption that texts are always related to other texts. Studies on *intertextuality* may include text materials such as transcripts of dialogs, student reports, textbooks, and several other forms of

written material. However, text may also be defined more broadly, as a product of textualizing, meaning that all sorts of phenomena can be made parts of a language system and thereby textualized (Bloome and Egan-Robertson, 1993). Generally speaking, this kind of research is interested in social and cultural processes in text-based meaning making.

Another line of research pays more attention to the interaction between readers and texts. This article primarily discusses work related to this last-mentioned approach, where multiple information sources mainly refer to different kinds of written nonfictional texts, both paper based and digital. Such texts may also include graphical representations, maps, and pictures, but this article does not discuss different kinds of multimedia sources. So far, much of the research on learning from multiple sources has been conducted within the domain of history, where the interpretation of different kinds of sources is an essential activity. Still, research on the reading of multiple information sources also spans other domains, for example, science, social science, language arts, and law. Most studies include adult participants, partly because the reading of multiple sources has been considered such a complex activity that younger students do not benefit from it, even though findings are not conclusive with respect to this issue.

Integrating Information from Multiple Sources

The reading of multiple information sources involves the same processes as single-text reading, but, in addition, the reader must integrate information from various sources and attend to specific features of each source. Part of the integration process seems to be more or less automatic, as when information in one source overlaps with information in another source (Kurby *et al.*, 2005). Other parts seem to require more strategic effort on the part of the reader. In an already classic study in this area, Wineburg (1991) found that expert historians demonstrated three strategies not shared by novices: *corroboration*, *sourcing*, and *contextualization*. *Corroboration* involves comparing details located in one source with those located in another to decide whether they are trustworthy or plausible. In this way, the reader may judge if the information is complete and in agreement with other sources. If not, the reader may question the credibility of the source. Wineburg (1991) found that experts used this strategy

frequently, whereas high school seniors tended to consider each source in isolation. Sourcing refers to how expert historians evaluate historical documents by first looking up a document's source information. In Wineburg's study, source information with respect to type of document, author, and date of publication, was included at the bottom of each document. Still, the experts focused on this information prior to reading the document, whereas the high school students generally paid little attention to source information. The third strategy, contextualization, refers to how experts use prior knowledge to reconstruct events described in historical documents in a broad context of time and space. Weinberg's seminal study demonstrated that experts benefit from having superior prior knowledge about text content. In addition, experts take advantage of more specialized knowledge about information sources and how to use them.

Later research has suggested that the use of strategies such as corroboration and sourcing is more a question of documentary expertise than of domain expertise. Rouet *et al.* (1997) found that graduate students familiar with different kinds of primary and secondary sources in their own content area (psychology) were able to benefit from this when working with documents in another content area (history). Thus, higher education may seem to promote skills in handling multiple sources, at least the kind of skills Wineburg (1991) identified. In contrast, students at lower levels do not spontaneously demonstrate such skills (Stahl *et al.*, 1996). However, there may be limitations to the kind of general documentary expertise noted by Rouet *et al.* (1997), as history and psychology differ less than for example history and physics. Readers' strategic processing of multiple sources probably adapts to disciplinary constraints, at least in part, but thus far, no comparative studies exist to confirm the impact of such constraints.

Still, results from several studies outside the domain of history indicate that at least adult college readers may actively integrate information from multiple sources and also benefit from intertextual reading. For example, Mannes (1994) studied undergraduate psychology students reading a text and one of two versions of an outline about the use of microbes in industry. One version of the outline represented the same perspective as the text, whereas the other version of the outline, although containing the same information, was written from a different perspective. Only the last version represented a distinctly different source in relation to the text. Results showed that students reading the text and the different-perspective outline integrated the two texts better than students reading the text and the same-perspective outline. The first group of students elaborated more on the content and produced more links between the two sources, thus generating a richer and more flexible representation of the content of the two documents.

Research within the domains of law (Strømsø *et al.*, 2003) and social science (Bråten and Strømsø, 2006b) confirms the importance of elaboration strategies when studying multiple information sources. That research also demonstrates the importance of monitoring strategies when students struggle to integrate the content of different sources and need to assess their understanding of a text in relation to other available sources. Moreover, use of such deep-level comprehension strategies may result in a better understanding of a topic when students read multiple sources than when they read a single text (e.g., a textbook chapter) with the same content.

In brief, the integration of multiple information sources may both require and generate active strategic reading. There is also evidence that such integration may result in a richer and more flexible mental representation of the text content than the reading of one single source.

Mental Representation of Multiple Information Sources

To construct an adequate mental representation of the content while reading a single text, a reader must select important information, generate coherence where necessary, and link information in the text to relevant prior knowledge. In one of the most influential theories of text comprehension, Kintsch (1988) argues that two central processes, construction and integration, produce a mental representation – or model – of the situation described in the text. When reading two or more related texts, a reader can produce two or more situation models which are completely separate from each other. Alternatively, a reader can construct a single highly integrated situation model based on the texts, or the result can fall somewhere in between the separate models and the integrated model. If there is much content overlap between texts, the likelihood of producing an integrated situation model increases, while contradictory texts, conversely, increase the likelihood of producing separate models. When one text explicitly refers to another text, this is also likely to promote the construction of an integrated situation model. In most situations where students read multiple sources about the same topic, the most adequate form of comprehension is neither a fully integrated representation of the texts, nor separate and isolated representations of each text. It is important, however, that students understand not only the content of each single source but also the relationships between the content of different sources and are able to judge the trustworthiness of the sources they study. This way of representing multiple sources has been called a documents' model (Perfetti *et al.*, 1999).

One component of a documents' model is the reader's representation of relationships between the content of multiple sources. In the introductory example with three

texts about immigration, the newspaper article presents descriptive data on immigration in different countries and describes trends during the last 20 years. The magazine contains a feature article about riots among young immigrants in Paris, and this article argues that lack of integration and unemployment are main explanations for public disturbance. In the right-wing flyer, it is argued that immigrants outnumber natives in statistics on crime in all European countries, and that this is due to genetic differences between Europeans and immigrants. Based on such information about the texts, it is possible to consider relationships between them. The newspaper article seems to be supplementary to the two other texts, provided it does not present any explanations for riots and crimes. The magazine article does not explicitly contradict the flyer, but the explanations it presents seem to be in conflict with the genetic explanation of the flyer. Thus, relationships between the three texts can be described as both supplementary and conflicting, and the reader needs to detect and remember the specific relationships between the texts to construct an adequate mental representation of the texts – a documents' model.

Different kinds of source information constitute a second component of a documents' model. In trying to understand the content of the texts and the relationships among them, the reader will benefit from being aware of properties of each text, such as who wrote it, possible motives for writing it, its cultural context, and genre. If, for example, the newspaper article was written by a journalist in a conservative newspaper usually arguing for severe restrictions on immigration, the reader might ask whether the descriptive data were selected to support a certain point of view. The reader's interpretation of the article might also be affected were the reader able to place it in a certain context, for example, in the context of a discussion about government expenses related to social security. Such a context would frame the article differently than the context of a discussion about the importance of immigration for economic growth. Finally, knowledge of genre could influence the reader's understanding of the content. In the example, it would be helpful to know the difference between a newspaper article and a research report. Likewise, knowledge about properties of a feature article and a flyer would probably affect the reader's construction of a mental representation of the texts, and also become part of such a representation. When reading multiple texts, source information forms an important part of the documents' model that good readers construct.

Thus, a good reader will probably construct a mental representation of the texts which includes the content of the texts, the relationships among the texts, and relevant source information tagged to the different information units. In this way, the reader not only constructs a representation of the central information in the texts, but also

keeps in mind where the different information units come from and how they are related.

Learning from Multiple Information Sources

Although textbooks still play an important role in most schools, as well as in higher education, students are continually exposed to multiple information sources about the same topic. Sometimes, a multitude of sources seem to benefit learning. From a pedagogical point of view, it is important to identify factors that may promote or constrain learning from multiple information sources. Such factors could be related to both individual-difference variables and to aspects of the task.

The Importance of Expertise

Given that the reading of multiple texts about a topic is a complex task, it is not surprising that expertise matters (Wineburg, 1991). First, good reading skills seem to be prerequisite for dealing effectively with multiple information sources (Britt *et al.*, 1999; VanSledright, 2002). Students who have difficulties with word decoding or reading comprehension need to concentrate their efforts on understanding each single text in isolation and they have less cognitive capacity to compare and integrate different sources. Still, there are indications that reading difficulties do not necessarily constrain students at higher levels, who may be able to compensate for such difficulties by employing deep-level strategies and activate relevant content knowledge (Strømsø *et al.*, 2003).

Second, experience with complex text materials and proficiency in the content area have an impact. Stahl *et al.* (1996) confronted high school students with multiple documents about an important incident taking place during the Vietnam War. It was found that students at this level did not benefit from reading more than two texts, most likely due to their limited knowledge about different kinds of historical documents. VanSledright and Kelly (1998) found that fifth graders reading multiple sources in history tended to accumulate as much information as possible without attempting to integrate information across sources or judge the trustworthiness of each source. Still, some students showed emerging awareness of the diverse views represented by different sources. These studies indicate that young students have the potential to develop competence in dealing with multiple sources but do not spontaneously come to grips with them. The dominance of the textbook as the single authoritative source in both primary and secondary education may explain why so many students struggle to comprehend and reason from manifold sources. Most students are

simply not trained to read and benefit from the reading of such complex text materials.

Personal Epistemology

Personal epistemology concerns the beliefs individuals hold about the nature of knowledge and the process of knowing. For example, some students may view scientific knowledge as a collection of proven facts transmitted from authorities, whereas others may believe scientific knowledge to be theoretical, problematic, and a result of ongoing inquiry. Lately, some studies have linked personal epistemology to the comprehension of multiple sources, with this body of research generally indicating that more naive epistemic beliefs (e.g., that knowledge is certain and simple) are related to poorer comprehension performance (for review, see Bråten, 2008).

For example, Jacobson and Spiro (1995) found that only students who preferred working with complex knowledge in multiple ways and valued active learner construction of knowledge were able to profit from the reading of multiple texts presented in a hypertext environment. Moreover, Rukavina and Daneman (1996) found that students who believed that knowledge is simple and consists of isolated facts had problems integrating information from two separate texts representing competing theories about scientific problems. Finally, Bråten and Strømsø (2006a) found that the reading of multiple texts facilitated deeper understanding only among students with more sophisticated epistemic beliefs.

Thus, research suggests that the understanding of multiple sources seems to require relatively sophisticated epistemic thinking, where knowledge is seen as constructed through both rational processes and the melding of information from different perspectives. Apparently, multiple sources constrain rather than promote comprehension for readers who hold the naive beliefs that knowledge consists of unchanging, isolated bits of information handed down by authority rather than tentative, interrelated concepts constructed by the reader.

The Reading Task

The nature of the reading task is also likely to affect how students understand multiple sources. A student looking for specific pieces of information does not read texts in the same way as a reader whose purpose is to construct a coherent and integrated understanding of the content of the texts. The knowledge of how reading tasks or purposes affect students' reading of multiple sources is still limited. However, some studies have demonstrated that students alter their text processing in accordance with differences in study-related reading tasks. For example, Strømsø *et al.* (2003) found that when law students reading self-selected study texts changed their understanding of the reading

task from reading to keep up with lectures to reviewing for the examination, they also adjusted their text processing to fit the new reading task. Results from other studies indicate that not only text processing but also level of understanding is affected by the task.

For example, Wiley and Voss (1999) had undergraduates read multiple documents about a historical event under the different task conditions of writing an argumentative essay, a narrative, a summary, or an explanation. They found that students who read in order to write arguments gained more integrated and deeper understandings of the topic than did students who read the same documents in the other three task contexts. The importance of the reading task for learning from multiple sources was also examined by Cerdan and Vidal-Abarca (2008), who showed that relatively broad questions may facilitate text integration and prevent readers from concentrating on isolated bits of information. Very narrow questions, on the other hand, may occasion that readers search for, find, memorize, and reproduce isolated bits of information, which may be sufficient for answering the narrow questions correctly but constrain rather than promote a deeper understanding of the texts' content.

Multiple Information Sources at the World Wide Web

The factors already described as important when learning from multiple information sources are also important when the sources are located at the Web. However, the myriad of informational Internet resources represents additional challenges to the reader. For instance, research on the readability of Web pages indicates that the texts located there are frequently quite difficult to read (Kim and Kamil, 2003). In addition, readers often have to read such texts framed by links to additional information, advertisements, or other potentially disturbing features. This article, however, focuses specifically on challenges regarding sourcing and integration.

First, students' sourcing skills are even more important as the majority of Web pages do not undergo the quality control most paper-based publications do. The judgment of texts' trustworthiness and quality is to a much greater extent left to the students. For instance, a primary school student looking for information about Martin Luther King at the Web may hit the apparently reliable website <http://www.martinlutherking.org/> containing plenty of information to include in an upcoming report. Only when comparing this information with other sources of information, the student may detect contradictions between sources and be able to evaluate the trustworthiness of each source. A competent reader includes source information in reflections on which source to trust. However, identifying the source may be difficult when reading

Web documents (Britt and Gabrys, 2000). In the above example, the attentive reader will notice that the document is hosted by Stormfront, and more research will reveal that this means Stormfront White Nationalist Community. Printed documents tend to carry very standard information about the author and the type of document, whereas Web documents in many cases do not.

Second, students face another challenge when they try to integrate information from different Web sources and construct a coherent understanding of a topic. This is related to the fact that Web texts are often linked to numerous other texts, and it is the student's own responsibility to choose what links to pursue. Links may be more or less relevant to the topic, and availability is often more important than relevance when links are embedded in a text. In such cases, links may interfere with students' efforts to construct a coherent representation of the content. On the other hand, links may also represent opportunities to gain a deeper understanding of a topic, provided the reader is able to compare and integrate information from the retrieved sources. In pursuing links across several texts, such integration may be quite demanding, however. Results from several studies indicate that students' prior knowledge about the topic is vital for their ability to cope with and benefit from using links in Web documents (DeStefano and LeFevre, 2007).

Educational Implications

The ability to integrate information from multiple information sources needs to be trained. Given the overflowing information in present-day knowledge societies, many students have received surprisingly little instruction in how to handle such sources. Consequentially, students ranging from primary to undergraduate level often strive with this task. However, results from several studies indicate that training may improve students' skills in handling various sources on the same topic.

For example, VanSledright (2002) attempted to teach fifth graders how to practice history by introducing both primary and secondary sources on a historical event and instructing the students to become historical detectives. They were explicitly taught that such detectives operated by identifying the nature of the sources and the different perspectives in the texts. They were also taught to check and corroborate evidence before drawing any conclusions. The results indicated that young students can benefit from being exposed to multiple texts, including primary sources, but that explicit training in dealing with such sources is necessary. Moreover, Goldman and Bloome (2004) studied academic discourse of literary analysis in seventh and eighth grade. At both levels, processes of construction and integration were stimulated and externalized in the classrooms. Students were instructed to

compare texts and look for both differences and similarities. When discussing the texts, students were instructed to back up explanations and arguments by always referring to the source. While these studies focus on efforts to expose young students to multiple sources and to externalize construction and integration processes in the classroom, other researchers have introduced computer-based training programs.

Britt and Aglinskas (2002) developed the Sourcer's Apprentice, a computer application teaching the skill of sourcing while reading multiple documents to research a historical controversy. In this approach, students are presented with a set of different documents about each controversy, varying in type from textbook excerpts to primary documents, which they read in a self-selected order. While reading each document, they fill in a note card with information about the author, document, and content. When the student thinks that he or she has studied the documents enough, the student answers a series of questions about the content and sources of the documents. Finally, the student writes an essay about the controversy, with only the note cards available during writing. Britt and Aglinskas (2002) showed that students who used the Sourcer's Apprentice in place of an integrated single-text presentation of the same content wrote essays on the controversy that were more integrated, cited more sources, and referenced more information from primary and secondary sources than did the comparison group. Later, Britt and colleagues supplied the Sourcer's Apprentice with a feedback mechanism that provides automatic and immediate feedback regarding skills in attending to and citing sources, as well as in integrating content from different sources, during the writing process (Britt *et al.*, 2004). The resulting Sourcer's Apprentice intelligent feedback mechanism has been found to help students write better essays after reading multiple documents.

Conclusion

The majority of research on text comprehension has thus far been restricted to a single-text perspective. However, being a proficient reader demands not only basic skills in decoding and the comprehension of single texts, but also skills in integrating and judging the trustworthiness of multiple sources. Results from several studies indicate that such skills partly depend on domain expertise, and it has been more or less assumed that students in primary school are not sufficiently mature and competent to handle such complex reading tasks. However, other studies indicate that students as early as fifth grade can be trained to cope with multiple information sources and also that they can benefit from reading them.

Further educational research on students' processing of multiple sources is important for two main reasons. First, students are confronted with multiple information

sources on a daily basis and therefore need skills to handle this situation. Second, the reading of multiple information sources can lead to richer and more flexible representations of text content, with such representations being less tied to any specific text and more accessible under a variety of circumstances. Research in this field has been dominated by studies on how students deal with different information sources in history, and there is a need for more studies on reading of multiple texts in other domains. As electronic learning environments become increasingly common, the study of learning from multiple texts should also be linked more closely to research on learning with multimedia technologies.

Glossary

Declarative memory – An essential property of declarative memory is that one is conscious of what one is remembering. Such memories are, by their very nature, verbal. For example, one can talk about one's experiences, and about new words that one has learned.

Episodic memory – Personal experiences and events are stored in episodic memory (see declarative memory).

False memory – A memory that appears real to the rememberer, but is not based on veridical experience is referred to as a false memory. They can be induced in the laboratory, but they are also prevalent in everyday situations, sometimes with drastic legal and interpersonal consequences.

Forgetting – It is the inability to recall an episode or a skill that was previously learned. In forgetting of declarative memory (*quod vide*), it is suspected that many failures to recall are in fact due to a failure to access a still-existent memory trace.

Memory systems – In contrast to previous schools of thought in psychology, where memory was considered to be unitary, in cognitive psychology one considers memory to be a multifaceted set of modules. There is a host of evidence to suggest that we possess many different types of memory.

Nondeclarative memory – We are not aware of everything that affects our behavior. These nonconscious effects of previous experience are evidence of nondeclarative memory. Also, our memory for motor skills, such as walking, typing, and skiing, is nondeclarative because motor skills are essentially nonverbal.

Perceptual representation system – Conceived of as the interface between perception and memory, it is a basic memory system storing perceptual information that enables us to perceive the world as meaningful.

Priming – Things that you have just seen, heard or thought about will facilitate thoughts about related concepts. This expression of memory is referred to as priming.

Semantic memory – Believed to be stored separately from personal experiences or episodes, semantic memory refers to a person's general knowledge of the world (see episodic memory).

Working memory – A coordinated set of short-term memory mechanisms that allow us to consciously manipulate what we are thinking about at any given moment.

Memory is a central part of the brain's attempt to make sense of experience, and to tell coherent stories about it. These tales are all we have of our past, so they are potent determinants of how we view ourselves and what we do. Yet our stories are built from many ingredients. Snippets of what actually happened, thoughts about what might have happened, and beliefs that guide us as we attempt to remember. Our memories are the powerful but fragile products of what we recall from the past, believe about the present, and imagine about the future (Schacter, 1996: 308).

A few years ago, a Norwegian newspaper (*Dagbladet, Magasinet*, 27 March, 2004) reported the story of Dodo, a young man of Asian origin who, in January 2003, woke up on the freezing ground in a small village in Switzerland with his well-equipped rucksack nearby, stuffed with expensive clothes and a money belt containing US\$5000, but no identity papers or tickets and with absolutely no personal memory. Dodo wandered around in Europe for some weeks, and, for reasons he could not explain, somehow managed to travel to Oslo, Norway. His memory loss of the time before he woke up in Switzerland is massive, he has no idea who he is, and he did not recognize his own face in the mirror. He had even lost his native language – he spoke heavily accented English but not any Asian language; the only thing he knew about himself was that he smoked Camel and liked pop music.

Dodo suffers from the condition of retrograde amnesia. That is, he has lost his memory in the sense people usually use the term memory, the recollection of private experiences and facts we have learned about the world. But Dodo remembered many things, he remembered what cigarettes were for, the workings of photographic equipment, he understood the value of money, was able to buy food, and mastered the skill of traveling by public transport. So he could make use many of the things he had learned. This type of selective memory impairment is a main argument cited by memory researchers in support of the idea that memory rather than being a single cognitive process or system, is a collective term for a family of neurocognitive systems that store information in different formats (Schacter *et al.*, 2000; Tulving, 2002).

Varieties of Human Memory

Modern taxonomies distinguish between several forms of memory, or memory systems. An important distinction is drawn between declarative memory, which refers to the conscious recollection of facts and personal experiences, and nondeclarative memory, which refers to behavior changes resulting from previous experiences that may or may not be accompanied by conscious recollection (see **Figure 1**).

The story of Dodo illustrates well the central role of declarative memory in human life. This young man had lost not only his personal past – his autobiographical memories – but also large parts of his general knowledge of the world and even his ability to speak his native language. Thus, the systems or forms of memory that we term episodic and semantic memory are heavily affected. Episodic memory is assigned a special role in human life: it is unique in the sense that memories are associated with a place and a time, and is, according to Tulving (2002), the only known example of a process where the arrow of time is turned back and the past can be re-experienced, a feat probably unique to humans. Without episodic memory, the mental representation that psychologists call the self – the organization of personal memories in a historical context – is lost. Obviously, this is what had happened to Dodo; however, his nondeclarative memory seemed largely intact.

In nondeclarative memory, the effects of previous experiences and exercises manifest themselves directly in behavior; the individual learning sessions may be vaguely remembered or be completely inaccessible to conscious recollection. Procedural memory is responsible for the maintenance of the cognitive and motor skills that we have acquired throughout life, from knowing how to eat with a knife and fork to the mastery of swimming, cycling, or driving a car, as well as the advanced skills of playing billiards or playing a saxophone. Conditioning is a basic memory system that in humans is particularly important in tying emotional reactions to external stimuli

or situations. For example, in phobic reactions, anxiety is triggered by the phobic stimuli but the person is typically not aware of the learning episodes in which the connection between the emotion and stimulus was established. Similarly, a piece of music, or a specific odor may evoke romantic feelings without an accompanying experienced-memory episode. Perceptual learning, or the perceptual representation system (PRS), enables us to perceive the world consisting of meaningful entities, because in order to produce a perceptual experience, online sensory signals must join stored representations, and this linking is part of the perceptual process itself. To see is to recognize, or to realize that you do not recognize. Tulving and Schacter (1990) also identified priming as an expression of non-declarative memory, coupled to the PRS. In priming, the person's performance on a specific task is facilitated (or inhibited) by the previous presentation of related information. For example, perceptual identification of a portrait as representing Hillary Clinton is speeded by the prior presentation of a picture of Bill Clinton, compared to the prior presentation of a picture of, say, the Pope.

An important feature of the memory systems concept is the idea that the various systems store information in different formats, and the information stored in one format is not directly translatable into other formats. This implies that the information stored in one system is not immediately accessible to other systems. However, assuming that the memory systems operate independently and in parallel, most experiences would be recorded and stored in parallel in different formats, and the memory performance assisted by several memory systems working in concert (Tulving, 2002).

Another basic distinction in memory theory is the division between a short-term memory mechanism that is the seat of consciousness and active processing, and is able to store limited quantities of information for a limited period of time, and a long-term memory mechanism that stores unlimited amounts of information for unlimited periods of time (Atkinson and Shiffrin, 1968). The short-term memory mechanism is currently associated with

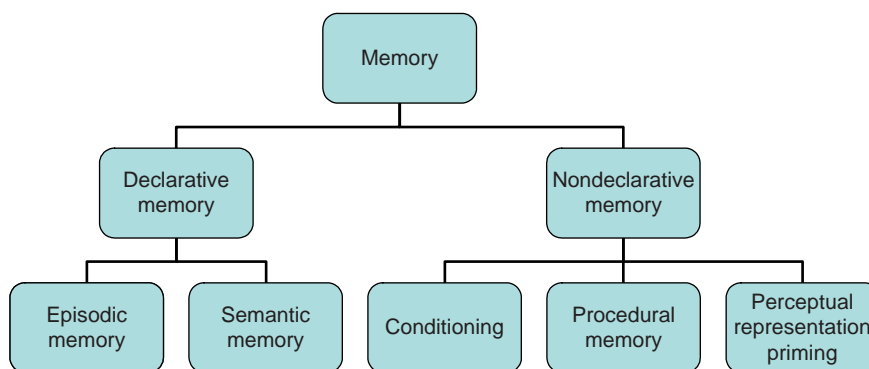

Figure 1 A common textbook taxonomy of human memory.

Baddeley's (1986, 2003) concept of working memory, a coordinated set of mechanisms that combine incoming information with information retrieved from long-term memory with the assistance of three support systems that actively manipulate verbal, visuo-spatial, and episodic information. The concept of working memory is closely associated with the concept of attention; only those pieces of information that are actively attended to, enter memory. Since the capacity of attention and working memory is limited, it follows that only part of the potentially available information confronting us at any time is registered, and much of the information that is registered is immediately forgotten. In a sense, most of the things we believe we have forgotten, never really entered a durable memory system.

In the context of education and everyday life, it is long-term memory that is the important aspect of memory.

Metaphors and Models of Memory – Strategies of Research

In the attempt to understand memory, scientists as well as laymen are forced to try to describe something that is not directly observable. We may be aware of some of the processes that take place during learning, and similarly of the processes that take place when we attempt to search for a piece of information in memory, but we have little access to the processes that mediate between encoding and retrieval. In order to make sense of the phenomena to which we have little access, both laymen and researchers tend to use metaphors and analogies, many of which are borrowed from the physical world (Magnussen *et al.*, 2007).

Koriat *et al.* (2000) pointed out that the study of memory following Ebbinghaus (1885) has been dominated by a storehouse metaphor, in which discrete items of information are stored and later retrieved, and which tends to evaluate memory in terms of the number of items that are retained (or lost). The storehouse metaphor invites an interest in the number of stored items. An effective store is one that contains many items, retains these items for long periods of time, and allows easy access to them. Memory then is evaluated in terms of its quantity – how much is retained, how much is lost.

Quantitative aspects of memory are frequently of great interest in everyday life, and research relevant to the classroom and academic achievement typically follows this strategy. However, an alternative approach to the study of memory, derived from the correspondence metaphor and that can be traced to the work of Bartlett (1932), evaluates memory performance in terms of the correspondence between the original event and the memory of it; the accuracy of the memory report. A high-quality memory is more faithful to the remembered event than an inferior memory, and contains fewer distortions and errors. Sometimes people remember events that

never happened. The assessment of memory correspondence should therefore start with the output – what the person reports – rather than with the input – what actually happened. An output-bound assessment reflects the accuracy of what is remembered – how much of what the person reports did in fact occur (Koriat *et al.*, 2000). In many real-life situations, such as in court, there is greater concern with the accuracy of the report than with the amount of information reported.

The Seven Sins of Memory

The modern study of the accuracy of episodic memory has convincingly disproved another popular metaphor, the idea of memory as a video recorder taping and replaying the original events. Episodic memory does not reproduce, it constructs, and the reconstruction of previous episodes is based on information from many sources with the assistance of many neural systems (Rubin, 2006). As some of the sources of information used in the construction of episodic memories are external to the original event, memory accuracy suffers. In a widely read book, Schacter (2001) identifies seven factors that he terms the “seven sins of memory,” which are at the origin of the tricks that episodic memory plays on us. The sins are: absent-mindedness; to be encoded into episodic memory, a piece of information or an event that must be attended to. When focal attention is diverted or attention is switched to auto-pilot, information may be missed, and the event is not properly remembered because the information was never registered in the first place. Transience refers to fact that memories fade. Some memories fade rapidly, others fade more slowly, depending on a number of factors, but no memory gets better over time. The general course of memory decay, first described by Ebbinghaus (1885), is the negatively accelerated function shown in **Figure 2(a)**, which represents the long-term forgetting of ordinary life events. However, as illustrated by **Figure 2(b)**, frequently studied or over-learned material shows very little decay, and some extraordinary life events, in particular dramatic and traumatic experiences, appear to be very resistant to fading and rather obey the sin of persistence. In fact, some memories we would like to forget, haunt us for the rest of our lives. And sometimes information that we know that is not forgotten – it is on the tip of the tongue – is unavailable to memory because of a failure of retrieval; this is the sin of blocking. Memories not only fade, they are subject to influences from several sources. The human mind is suggestible, our memories of events and facts are influenced by information from external sources, from what we read, and from what other people tell us. Memories may be biased in various ways. For example, our memories of the past depend on or are colored by the present, or as Schacter (2001) puts it, “the way we were depends upon the way we are.” The sin of misattribution refers to the confusions and

Figure 2 (a) Memory for personally experienced everyday events, (▲) and (■). (b) Very long-term memory for over-learned material, obtained by asking participants to match pictures of high-school classmates' faces to their names, (●), and testing participants' ability to translate unused Spanish vocabulary learned in school to English, (■). Despite the fact that we treasure our autobiographical memories and they play an integral role in our personal identity, we become incapable of bringing to mind the specifics of most of what we experience within a year or so of it happening. By contrast, multiple repeated exposures to something that is quite unimportant for one in later life and never practiced or recalled can allow access to memories decades later. This may be seen as paradoxical until one realizes that motivation to remember is not always as important as the amount of practice one has put in to learning something. (a) Adapted from Wagenaar, W. (1986). My memory: A study of autobiographical memory over six years. *Cognitive Psychology* **18**, 225–252 and White, R. (2002). Memory for events after twenty years. *Applied Cognitive Psychology* **16**, 603–612. (b) Adapted from Bahrick, H. P., Bahrick, P. O., and Wittlinger, R. P. (1975). mistakes we often make concerning the source of a particular piece of information, confusions of times, people, and places, and in the extreme case, the confusion of genuine memory and fantasy that gives rise to false memories.

Memory in Everyday Contexts

Ebbinghaus' (1885) pioneering studies investigated his own memory for nonsense syllables, and a century later, as cognitive psychology became the dominant school in psychology in the 1970s, the typical experiment on memory still clearly bore Ebbinghaus' imprint: university undergraduates sat in a darkened lab and learned long lists of words. A degree of discomfort with the potential lack of relevance of these experiments for understanding life outside the lab, led to a push for memory research to be more ecologically valid, and the study of applied memory has since grown into a very active research field. Drawing on the correspondence metaphor of memory, a key underlying question in this field has been, on how accurate is our memory, as it is used in everyday life. Another change has been in the types of material used: breaking out of the verbal learning tradition (learning lists of words), a concerted research effort over the past 20 years has, for instance, tried to shed light on our ability to remember more real-life stimuli, like people, and events we have experienced in our lives, a skill that Dodo apparently no longer possesses.

How do we remember people? A person represents an extremely complex and multifaceted biological stimulus:

while we most often recognize a person from their face, we can also judge who a person is from their name, their voice, their gait, besides many other potential routes. It turns out that the complexity of the stimulus is reflected in the diversity of memory representations we have for people. Not all types of person information are equally memorable either. In particular people's names pose a problem when it comes to recall. All readers will have experienced the tip-of-the-tongue phenomenon for a name, when one is unable to recall a name but feels that one might recall it at any time, and may be able to give partial information about the missing word. This phenomenon occurs particularly for people's names, and its frequency increases with age (Schwartz, 2002; Valentine *et al.*, 1996). On the other hand, our ability to distinguish between faces and to recognize that the one you are looking at now is one you have seen before is prodigious. This is perhaps not surprising from an evolutionary point of view: humans are social animals and there is a strong need to distinguish between family, friends, and enemies. On the other hand, more recent research in the applied memory tradition has cast doubt on our face-recognition skills in some practical situations. For instance, the use of credit cards with a picture of the holder's face is now widespread, but Kemp *et al.* (1997) have shown that, in fact, shop assistants are terrible at detecting that the face on the card does not match the person holding the card.

How much of our lives do we remember? Cognitive psychologists would agree with the sentiments of the novelist Milan Kundera who pointed out that in fact we

are only able to recall a vanishingly small proportion of the events in our lives. While we do of course remember many individual events from our lives, much of our memory appears to be based on generalized averages of similar events, so that while you may only be able to specifically recall a few of the times you have been to the Odeon cinema, you may know very well where you usually park, what sort of films you see, who you go with, and what snacks you buy. A systematic approach to answering the question was taken by Wagenaar (1986) who wrote down one incident from his life each day over a period of 4 years. When subsequently tested, he found that being cued by the who, what, or where of an event was more powerful a cue than when, and that single piece of information (who, what, or where) triggered recall of the incident only on about 50% of occasions for the first year and declined to 20% after 4 years. Multiple cues triggered over 60% of memories, even after 4 years, and even cases where he had apparently forgotten the incident completely could be recalled in cases when another person was central in the incident and could be asked to provide more cues. Thus, it is a case of the glass being half-full or half-empty: even events which were thought to be completely forgotten turned out to be retrievable, but on the other hand, normal cues failed to trigger a majority of memories. Results from Wagenaar's (1986) together with results from a similar study carried out across a 20-year interval by White (2002) are shown in **Figure 2(a)** and illustrate the dramatic decline of ordinary everyday memories. White (2002) tested his memory by having an assistant read event descriptions picked randomly, and he decided if he remembered the event vividly, vaguely, or not at all. At all testing times, most of the remembered events were vaguely remembered, and he encountered not a single case where an event forgotten at one time was remembered at a later time. Assuming the conditions of retrieval are the same at different testing points, memory does not improve over time.

False Autobiographical Memories

In the 1990s, the science of memory was the subject of a fierce debate in scientific journals, newspapers, and courts of law. A phenomenon that was first observed in the United States but that has since spread to other countries is that cases of alleged child-abuse were being brought to court by the victims, years and even decades later, because the victims had previously been unable to retrieve the memories. This was a powerful and deeply shocking claim that split psychology into those who thought of these memories as recovered, and those who thought of them as false, the so-called memory wars.

Since Bartlett's seminal research on how our memory for narrative introduces errors that fit in with the rest of our knowledge, memory research has known about the

malleability of our memories for events. Due to the memory wars, such memory illusions have been much studied over the past decade, showing that under certain circumstances, we can become convinced that, several years previously, one had been up in a hot air balloon, or had knocked over a punch bowl at a wedding when these events simply had not happened (Loftus, 2003). The key ingredients appear to be that one believes the authority telling one the information, and that one is given time to try to retrieve the information: over time, the false memories come to feel real to the rememberer. When it turns out that in many documented cases of recovered memories of child-abuse, the victim had been in therapy with a clinician who believed that symptoms of depression and anxiety in fact are the manifestation of early child-abuse, there is the very real possibility that the often grotesque and implausible accounts were genuinely believed by the rememberer but nonetheless entirely false, produced by the combination of an authority figure, the therapist, and several practice sessions in which to recover the memories. A number of documented cases show that false memories may be quite dramatic, as for example, remembering being witness to a murder that never happened (Goodman *et al.*, 2007). Modern research also fails to support the idea that early traumatic childhood experiences can be stored in a detailed fashion but repressed or blocked from consciousness, only later to be exhumed by therapeutic exercises. Rather, well-controlled studies show that such memories obey the sin of persistence (Goodman *et al.*, 2003).

Knowledge of the constructive nature of autobiographical memory is important for many professions, especially those dealing with psychiatric patients, children, and other groups with little power. The vulnerability of autobiographical or episodic memory is also the focus of another important area of applied memory research, the study of factors affecting the reliability of eyewitness testimony (Loftus, 2003; Wells *et al.*, 2006). In the interrogation room and in court, failures to remember are less damaging to the judicial process than are memory errors; absence of memory points nowhere, memory errors may point in the wrong direction.

Memory in the Classroom

One of the secrets to creating robust long-term memories, already shown by Ebbinghaus' experiments and known to centuries of teachers, is repetition or over-learning. Schoolchildren spend a lot of time in classrooms learning from teachers and books. The vast majority of children in the West spend upward of a decade of their lives in such a system. It is generally agreed that education is a good thing, but the exams that are used to test that the requisite knowledge has been acquired often take place within a few months of the teaching, which begs the question of the

fate of this knowledge in the long term. How much of the Spanish vocabulary that you learned in high school can you still recall? What about the fate of your university degree that you haven't used since your graduation exams? Seminal research by Harry Bahrick has shown that we are able to recall surprising amounts of knowledge even several decades after learning (see for example, Bahrick, 1984). Lots of material seems to become unavailable within the first year of learning. About 2 years after studying a topic, people are able to perform at around 50% of the level they were at when they stopped studying, but the surprising finding is that up to 50 years later, one performs at about the same level as one did 2 years after: very little forgetting appears to occur after an initial period. Similar results have been reported for mathematics, Spanish, and for cognitive psychology, so that this function appears to reflect general properties of the long-term semantic memory system, or permastore as Bahrick termed it (Figure 2(b)).

Another question is that of how best to study to ensure long-term learning. In the light of the prevailing orthodoxy in education, it might be surprising to some that a body of evidence has built up recently to suggest that the best way to study for a test is to test oneself. For instance, Roediger and Karpicke (2006) asked participants to read and learn a short essay. After all participants had read the passage through, one group was then given a test on what they had remembered, whereas the other group reread the passage. There was then a final memory test given, either 5 min, 2 days, or a week subsequent to the reading. After 5 min, those participants who had reread the passage performed better than the other group. However those tested after 2 days and those tested after a week had the opposite pattern: an extra opportunity to study the material led to worse memory compared to those who were tested also in the first phase (see Figure 3). The message from this study and many replications is clear: the very act of testing improves performance. It is to be hoped that educational systems will confront the challenge to incorporate the consequences of this finding into their classrooms: testing is not only a way of assessing students' performance, it also a way of facilitating their learning.

The Future for Memory Research

Memory research finds itself at the touching point between basic and applied research. On the one hand, it is becoming more integrated into neuroscience, with studies using cognitive tasks in conjunction with brain imaging methods, for instance. On the other hand, the emphasis on an understanding of memory in everyday contexts is strengthening. Up to now, the findings of memory research have been relatively slow to get out to practical situations. This is unfortunate because the focus

Figure 3 Having heard a story they were trying to learn, some participants were immediately tested on what they could recall, while others had a second chance to learn the story. Five minutes later, the second-chance group (the dark column) had better recall, but of potential importance to educationalists, the immediate-test group (the light column) did better on tests 2 and 7 days later. Adapted from Roediger, H. L. and Karpicke, J. D. (2006). Test-enhanced learning – taking memory tests improves long-term retention. *Psychological Science* 17, 249–255.

in recent decades on more applied sides of memory – how it is actually used in daily settings – has produced important results, which, at the risk of hyperbole, would appear important to be more widely known about. For all in the legal system, from the police to jury members, the studies showing that people can be induced to create false memories in themselves, should be required reading. Similarly, for the educational system, the generalized, positive gains obtained by the very act of testing someone's knowledge should become more widely known, and integrated into teaching systems.

Metacognition

L Baker, University of Maryland, Baltimore County, Baltimore, MD, USA

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Cognitive monitoring – It refers to any activity aimed at evaluating or regulating one's own cognitions, including planning, checking, self-testing, assessing one's progress, and correcting one's errors.

Comprehension monitoring – It refers to metacognitive control in reading or listening, which involves deciding whether or not one understands (evaluation) and taking appropriate steps to correct comprehension problems that are detected (regulation).

Executive function – It is the cognitive system that controls and manages other cognitive processes, is associated with frontal lobe functioning, and includes processes typically regarded as metacognitive in nature, such as planning, monitoring, and error correction and detection.

Metacognition – It refers to thinking about thinking; knowledge about cognition and regulation of cognition; knowledge about person, task, and strategy variables that affect performance in a given domain; and cognitive monitoring and control.

Metacomprehension – It refers to understanding one's understanding, that is, realizing that one has understood.

Metamemory – It is knowledge about memory and control of memory, that is, appraisal of one's memory on a given task.

Other-regulation – It refers to regulation of the behaviors and cognitive activities of one individual by another, usually more knowledgeable; it involves Vygotsky's proposed sequence of other-regulation to self-regulation.

Reciprocal teaching – It is an approach to foster cognitive and metacognitive strategies in reading that involves peer collaboration; students are taught to use strategies of predicting, clarifying, summarizing, and questioning.

Self-regulation – It is the ability to control one's own behavior and cognitive activities; self-regulated learning is self-directed, intrinsically motivated, and under the deliberate, strategic control of the learner; it involves effective use of processes included within the regulatory component of metacognition, such as planning, monitoring, and evaluating.

Self-system – It is the cluster of motivational and affective processes that influence why we do what we do; it includes self-perceptions, attributions for performance outcomes, goals for engaging in an activity, and achievement motivation.

Definitional Issues

A question of ongoing interest and importance is how and when students develop knowledge and control of their cognitive processes. This higher-level cognition was given the label metacognition by the American developmental psychologist John Flavell in the mid-1970s. Metacognition is concerned with our ability to reflect on our own thinking, and in an academic context it includes knowledge about ourselves as learners, about aspects of the task, and about strategy use. Metacognition also involves self-regulation of our own cognitive efforts, including planning our actions, checking the outcomes of our efforts, evaluating our progress, remediating difficulties that arise, and testing and revising our strategies for learning.

The construct of metacognition has had wide appeal and wide applicability, stimulating a great deal of research across a broad spectrum of disciplines. Research today spans the subdisciplines of educational, developmental, cognitive, clinical, social, comparative, and cognitive psychology, as well as related fields such as neuroscience, linguistics, and second language learning, special education, and speech and communication disorders. Once developmental psychologists began to study metacognition in the 1970s, the construct quickly attracted the attention of educational researchers seeking an explanation for why some students fared better in school than others. The consistent finding for more than 30 years has been that students who are more successful in a domain exhibit higher levels of metacognitive knowledge about the domain and are more skilled at regulating their cognitive processes. Instructional interventions to promote metacognition quickly became popular and remain so today. The focus in this article is on metacognition in educational contexts.

Metacognition has been defined in different ways, and that of course affects how it has been studied. The term literally means thinking about thinking. John Flavell and Ann Brown initially defined metacognition as knowledge about cognition and regulation of cognition.

This two-component conceptualization of metacognition has been widely but not exclusively used since then by educational researchers. Some have restricted the term to the knowledge component, whereas others have restricted it to the control component. For example, researchers within the cognitive-experimental tradition use a definition proposed by Thomas Nelson that includes two components, monitoring and control. Two closely related constructs are associated with the control aspect of metacognition: self-regulation and executive functioning. The term self-regulation is often used by educational psychologists to refer to the use of skills included within the regulatory component of metacognition, such as planning, monitoring, and evaluating. (Developmental psychologists have a broader definition of self-regulation that encompasses impulse control.) Executive function is a term with origins in cognitive psychology and neuroscience. It includes processes typically regarded as metacognitive in nature, such as planning, monitoring, and correcting and detecting errors, and it is typically linked to frontal lobe functioning in the brain.

Whereas metacognition once was studied solely in terms of how it is related to cognition, it is now recognized that one cannot understand how and why people perform as they do on cognitive tasks without an examination of motivational and affective as well as metacognitive factors. Accordingly, many contemporary researchers examine the role of the self-system, which includes motivation, perceived competence, and attributional beliefs, in conjunction with metacognition and cognition.

Origins of Metacognition

Much of the research on metacognition in educational contexts is descriptive in nature, documenting developmental and individual differences in knowledge and control. Less often do researchers address basic questions about the mechanisms of metacognitive growth. Nevertheless, it is now widely agreed that the origins of metacognition lie at least in part in social interactions. Russian psychologist Lev Vygotsky proposed that children first learn how to engage in cognitive tasks through social interaction with more knowledgeable others, usually parents or teachers. The expert initially takes the responsibility of regulating the novice's activity by setting goals, planning, evaluating, and focusing attention on what is relevant. Gradually, the expert gives over more and more responsibility to the novice as the novice becomes capable of assuming it, until finally the novice internalizes the regulatory mechanisms and can perform without expert assistance. Many successful interventions aimed at fostering metacognition draw on Vygotsky's proposed sequence from other-regulation to self-regulation.

Whereas Vygotsky emphasized expert-novice interactions, another influential social perspective is that of Swiss psychologist Jean Piaget, who emphasized the importance of peer interactions. Piaget argued that peers challenge one another's thoughts and thus advance cognitive development. Discussion and collaboration help students to monitor their own understanding and build new strategic capabilities. Instructional interventions often supplement an emphasis on individual cognition with an emphasis on peer support for monitoring, reflection, and revision. These interventions, too, have met with success, providing validation for the perspective that metacognition has its origins in social interaction.

It is important not to overlook maturation as a further contributor to metacognitive growth. Adolescence is a period of major development in the prefrontal cortex, the portion of the brain involved in executive function. As noted previously, executive function includes metacognitive processes such as planning and monitoring. The prefrontal lobes are the last portions of the brain to develop, with maturation not complete until late adolescence or early adulthood. This late maturation helps explain why limitations in metacognitive control are still apparent in high school and college students.

Methods for Assessing Metacognition

Considerable controversy exists as to the best ways to measure metacognition. Methods vary in part depending on the theoretical orientation of the researcher. Methods also must be selected with developmental considerations in mind. Therefore, a variety of approaches have been used to study metacognition. Each approach has limitations, so it is advisable to use multiple measures that converge on the construct.

Verbal Reports

The most frequently used approach to assess both metacognitive knowledge and metacognitive control is to ask students directly about what they know or what they do while engaging in cognitive activities. Such self-reports have been collected in a variety of ways. For assessing metacognitive control, participants may be asked to think aloud about what they are doing and thinking as they solve a problem or read a text or they may be asked to provide written comments periodically throughout the session. Participants may alternatively be asked to complete checklists of strategies they used in a given task after its completion, or they may complete questionnaires or study-strategy inventories.

Whereas verbal reports are but one way for assessing metacognitive control, they are the primary basis for collecting information about metacognitive knowledge, either

through interviews or questionnaires. John Flavell's early study of metamemory that fueled the interest in metacognition used a structured interview format. Questionnaires were subsequently developed, often based on interview findings or think-aloud protocols. The major limitation of such approaches is that there is not necessarily a correspondence between what people say they do and what they actually do. Comparisons of general questionnaire responses with performance measures on a given task often yield rather low correlations. In addition, students, particularly children, often respond according to what they think they should say, rather than what they actually believe or do. Nevertheless, despite their limitations, there is a general consensus that verbal reports can be valid and reliable sources of information about cognitive processes when elicited and interpreted according to established guidelines.

Most questionnaires designed to assess metacognition are domain specific (e.g., reading or mathematics), but a few are intended to be more domain general. A domain-specific inventory might tap a student's understanding of variables that affect reading outcomes and of strategies that are effective for comprehending text. A domain-general inventory might assess an individual's knowledge about cognition (including declarative, procedural, and conditional knowledge) and regulation of cognition (including planning, monitoring, debugging, and evaluating learning). Relatively few well-validated and reliable instruments are available for research or practical use.

Online Processing Measures

Metacognitive control is frequently studied by asking students to engage in a task and collecting process measures as the task is being completed. For example, to assess metacognitive control during reading, a passage may be presented to the reader on a computer screen. Patterns of movement through the text are collected automatically, revealing whether the reader paused at a particular point, whether he or she looked back at previous text, whether he or she jumped ahead. These measures are often supplemented by asking readers to reflect on what they were thinking, or by giving them comprehension questions and then relating outcomes to the processing measures. Computer technology has similarly been used to capture processing during writing tasks and during mathematical problem solving. An advantage of these approaches is that they reveal what students do instead of what they say they do. However, the naturalness of the cognitive task is often disrupted by the specialized technology demands.

Judgments of Learning and Predictions of Performance

In judgments of learning (JOL) tasks, students are presented with to-be-learned material, such as a list of words

or a passage, and then they are given a test over the material. They are then asked to judge how well they learned the material or how well they answered the comprehension questions (often referred to as an index of metacomprehension). Judgments of learning are then examined in relation to actual performance.

A related approach, often referred to as knowledge monitoring, involves presenting students with material and asking them how well they think they would perform on a test. For example, they might be presented with a list of vocabulary words and be asked how many they would be able to define, or a set of math problems and asked how many they can solve. They are then asked to complete the task, and their performance is compared to their predictions.

These types of tasks are more likely to be used in research conducted by cognitive psychologists interested in basic processes than by educational researchers concerned with more applied issues. Nevertheless, the approach has its origins in seminal research on memory monitoring, and research on studying (applied memory) often includes assessments of test readiness.

Metacognition in Specific Academic Domains

Most of the research on metacognition is focused on a particular academic domain, in recognition that metacognition is largely domain specific. In other words, a student may have a great deal of metacognitive knowledge about reading, but that knowledge does not necessarily generalize to mathematics. This section addresses research findings on metacognition as it has been studied in reading, writing, mathematics, and science.

Metacognition in Reading

Research on metacognition in reading began in the 1970s, shortly after the publication of Flavell's seminal studies on metamemory. Pioneers in this area of research were Ann Brown and Scott Paris. Reading is the academic domain most frequently studied, and so it is given more attention in this article than the other content areas.

Studies of metacognitive knowledge

Much of the research on metacognitive knowledge about reading uses structured interview procedures adapted from Flavell's metamemory work. In a typical study, children are interviewed about their knowledge of person, task, and strategy variables involved in reading. The pattern that has been found consistently is that younger readers have little awareness that they must attempt to make sense of text. They focus on reading as a decoding process, rather

than as a meaning-getting process. Ability-related differences in knowledge about reading, like developmental differences, have been documented in countless studies, across age groups ranging from early childhood through later adulthood. Students' metacognitive knowledge about reading, whether assessed through interviews, questionnaires, or verbal reports, remains an active and important area of inquiry.

Studies of comprehension monitoring

Effective text comprehension requires an important metacognitive control component known as comprehension monitoring. Comprehension monitoring involves deciding whether or not we understand (evaluation) and taking appropriate steps to correct whatever comprehension problems we detect (regulation). Research has shown that students of all ages often are ineffective at monitoring their understanding of text. These difficulties are perhaps most apparent when students are asked to read information text, such as science and history textbooks. Failures to evaluate and regulate understanding reduce the likelihood of meaningful learning.

The majority of studies of comprehension monitoring over the years have used the error-detection paradigm. In this approach, errors or problems are deliberately introduced into texts, and various indices are used to determine whether readers notice the problems and attempt to resolve them. For example, readers may be asked to underline or report detected errors, or online processing measures may reveal longer pauses when readers encounter problematic text. Caution is needed in interpreting these studies because of students' propensity to believe texts are true and well structured and because of their reluctance to acknowledge comprehension difficulties. Moreover, some types of errors are more likely to be reported than others; for example, younger and less-skilled readers are more likely to evaluate their understanding using a word-level criterion than an internal-consistency criterion.

Studies aimed at fostering metacognitive skills

Intervention studies began to be implemented in the 1980s, providing solid evidence that metacognitive knowledge and control could be enhanced through direct instruction. Comprehensive classroom reading interventions incorporated metacognitively oriented instruction, with the goal not of enhancing metacognition *per se*, but rather of promoting students' reading comprehension by increasing their metacognition. Interventions that use some variant of reciprocal teaching, in which peers collaborate to learn and apply strategies of predicting, clarifying, summarizing, and questioning, have yielded substantial effects on reading comprehension. The research

base for the effectiveness of metacognitive intervention is now so strong that professional organizations and national panels recommend that metacognition be included in reading comprehension curricula.

Metacognition in Writing

Metacognition plays a role in the production of text as well as in the comprehension of text. Research on metacognition in writing has followed a similar course to that on reading. In the 1980s, researchers began to compare the metacognitive knowledge and control of more-skilled and less-skilled writers. Across all age groups, clear differences are apparent in students' conceptions of writing, their knowledge of the writing process, and their abilities to implement effective control strategies. For example, better writers focus more on the function of writing, whereas poorer writers focus more on form. When asked about their conceptions of writing, better writers discuss the qualities of good writing, such as having a clear beginning, middle, and end, whereas poorer writers discuss spelling all of the words correctly. Skilled writers have higher-order awareness of the writing process, such as awareness of the need for clarity, organization, and audience sensitivity, whereas less-skilled writers tend to focus on lower-order processes dealing with spelling, grammar, and punctuation.

Interest in metacognitive control of writing coincided with the publication of a cognitive process model of writing by Linda Flower and John Hayes in the early 1980s. The model includes three recursive processes: planning, translating (sentence generation), and revising, all of which are controlled by a monitor or executive component. Research has demonstrated consistent differences in how expert and novice writers handle the planning and revision processes. For example, experts are more likely to have global goals for their writing that take into account the communicative purpose of the task, and they revise at a global level. In contrast, novices seldom have overall plans for their writing and their revisions are typically made at a sentence-by-sentence level.

Also, as with reading, classroom interventions have been devised and implemented to increase students' metacognitive awareness and control of writing processes. Many of these interventions aim to reduce the cognitive processing demands on less-skilled writers by providing prompts, cues, and scaffolds. Marlene Scardamalia and Carl Bereiter developed an approach known as procedural facilitation that has proven effective with elementary school students and has been adapted up through the college level. Prompts are provided to remind students of the steps in the planning process, for example, or things that need to be taken into account when revising a paper. Often the translation demands are reduced so that

students who are overly focused on spelling, punctuation, and handwriting do not get bogged down with the lower-level components (e.g., a word processing system is used).

Metacognition in Mathematics

Research on metacognition in mathematics also began to appear in the 1980s. As with reading and writing, attention focused on both knowledge and control and on students of all ages. A paper by Alan Schoenfeld in 1987 was particularly influential in bringing metacognition to the attention of mathematics educators (What's all the fuss about metacognition?). Schoenfeld presented evidence from the college-level math course he taught that showed that many students did not reflect on the problem-solving strategies they used and that they frequently failed to connect the solutions they obtained with the real world.

Mathematical strategy knowledge includes basic knowledge of algorithms and heuristics, as well as metacognitive awareness of strategies to help in comprehending problem statements, organizing information or data, planning solution attempts, executing plans, and checking results. Even first-grade children have some specific strategy knowledge about math, but students seldom monitor their approaches to problem solving until much later. At first, problem solving is often taken one step at a time, and students show little understanding of the general principles of the problems. This is similar to the sentence-level focus of young writers who approach the task without an overall plan.

Just as students must monitor their comprehension of what they read, so too must they monitor their cognitive processes while doing math. Consider the different levels at which one may monitor the adequacy of a solution to a word problem. One may evaluate the results of arithmetic procedures carried out to obtain an answer; such monitoring could occur simply by checking the arithmetic involved (e.g., subtracting an addition result). One may evaluate whether the procedure one has chosen is correct. This requires some semantic analysis of the text, whether rereading the entire text or simply finding a key word. One may also evaluate the sensibleness of the problem itself. This involves looking at the relations expressed in the text and making a decision about whether those relations make sense. Research has shown difficulties in monitoring at all three levels, with younger and poorer math students more likely to focus on the low-level calculation standard of evaluation. These results are comparable to the reading and writing research, which shows novices more likely to evaluate low-level aspects of the task (e.g., decoding or spelling).

Metacognitive research in mathematics also includes a line of work focused on students' judgments of whether they will be able to solve problems correctly and judgments of which problems they succeeded in answering

correctly. When judgments or predictions are compared with actual performance, the general pattern of results is that younger and less-skilled students are less accurate in monitoring their abilities than their older and higher-achieving peers.

As with literacy, professional organizations now advocate that reflection and metacognition be central components of mathematics teaching. Classroom interventions have been devised and successfully implemented to help students plan, monitor, and evaluate their own thinking during mathematical problem solving. The National Council of Teachers of Mathematics in the United States emphasized the importance of writing as a way of helping students reflect: "writing in mathematics can also help students consolidate their thinking because it requires them to reflect on their work and clarify their thoughts about the ideas" (NCTM, 2000: 61). Research has shown the value of peer collaboration and discussion in enhancing mathematics performance, as students make their cognitive processes, assumptions, and strategies explicit. Consistent with a Piagetian constructivist perspective, the cognitive conflicts that may arise as students justify their approaches are effective in stimulating cognitive and metacognitive growth.

Metacognition in Science

The body of research on metacognition in science focuses primarily on the reading of scientific texts; the research results are comparable to those already discussed in the domain of reading. Scientific problem solving is clearly another academic endeavor where metacognitive knowledge and control are critical, but it is much less researched. The term metacognition may be absent from the following statement in the National Science Education Standards (NSES) in the United States, but there can be no doubt as to the central concern: "Engaging students in inquiry helps students develop an appreciation of 'how we know' what we know in science" (p. xx). The standards call for teachers to guide students to understand the purposes for their own learning and to develop their abilities to assess and reflect on their own scientific accomplishments. They also call for providing students with opportunities to apply standards of scientific practice to their own and others' scientific efforts.

Summary and Conclusions

It might be tempting to conclude from this brief review of metacognition within specific academic domains that metacognition is domain general. This conclusion may be drawn because the developmental and individual differences that have been revealed across domains are conceptually similar. Nevertheless, correlations in performance across domains

are often rather low. It is therefore important not to assume that metacognitive skills can and should be fostered in settings devoid of academic content.

It also might be tempting to conclude that the relation between metacognition and cognition is uni-directional, given the evidence that metacognitive training can promote greater achievement in a given domain. However, reciprocal causation is most likely; that is, improvements in metacognition contribute to improvements in cognition (reading, writing, problem solving, etc.), which in turn contribute to further improvements in metacognition.

One of the reasons why young students exhibit limited metacognitive awareness and control is because the basic processes needed to carry out the activity are not yet routinized or fluent. For example, beginning readers who must allocate all of their processing capacity to decoding have little cognitive capacity left to devote to meaning construction, let alone evaluate the adequacy of the meaning that was constructed. With repeated experience, readers learn to decode and to monitor their comprehension sufficiently well that they do not have to allocate attention to the processes; it is only when an obstacle is noted that attention is directed to the problem area. Automaticity is also critical to mathematical performance – students need to be sufficiently fluent with basic number facts so that simple addition and subtraction do not take up the cognitive resources needed for higher-level conceptual processes. Similarly, monitoring and evaluation of ongoing processes need to become automatic, so that they can proceed without deliberate attention. The same logic follows for writing. In other words, students should be able to proceed with a cognitive activity fluently and automatically, with metacognitive control processes reaching conscious awareness only at times when they must be deployed.

When students have knowledge and control of their own cognitive processes, learning is enhanced. This holds regardless of the domain of learning, whether reading, writing, science, or any other activity that involves thinking. Educators across disciplines now have the common goal of fostering metacognitively sophisticated learners, and the means to accomplish this goal appear to be similar: (1) Scaffolded instruction should take place embedded within a meaningful context. (2) Metacognition should not be promoted as an end in itself but rather as a means of promoting learning and achievement. (3) Students should be taught to apply a critical stance toward the information they encounter, overcoming the common tendency to accept at face value the accuracy and plausibility of information conveyed to them by perceived authorities. (4) Students should be given opportunities to work collaboratively with their peers on common problems and tasks and to articulate their cognitive and metacognitive processes.

Although the construct of metacognition is now widely known in the educational research community, empirical findings still look a great deal like they did when metacognition first became an area of inquiry. For example, studies conducted in the current decade reveal that 8–10-year-olds rely almost exclusively on word-level criteria for evaluating their understanding, replicating the findings of more than 20 years earlier. Similarly, young students' conception of a good reader as one who reads quickly without making any mistakes is the same as that identified almost 30 years earlier. These patterns are troubling because they illustrate how slowly advances in research knowledge are translated into changes in classroom practice that in turn bring about changes in student outcomes.

Personal Epistemology in Education: Concepts, Issues, and Implications

What Is Personal Epistemology?

Epistemology, the study of knowledge and knowing, has absorbed philosophers from ancient times. As a branch of philosophy, epistemology concerns the nature, origins, and limitations of knowledge, as well as the justification of truth claims. Recently, educational researchers have become interested in the theories and conceptions of knowledge and knowing that students hold, with the term personal or folk epistemology used to distinguish the lay person's view about knowledge and knowing from the trained philosopher's view (Hofer and Pintrich, 2002; Kitchener, 2002). Thus, personal epistemology essentially refers to the theories or beliefs that students (and other individuals) hold about knowledge and the process of knowing (Hofer and Pintrich, 1997, 2002). Likewise, epistemic theories or beliefs refer to individuals' views about knowledge and knowing (i.e., the epistemic).

How Does Personal Epistemology Develop?

Most educational research on personal epistemology has been rooted in Perry's (1970) longitudinal interview studies at Harvard, resulting in a scheme describing the development of personal epistemology during the college years. Several researchers have continued Perry's (1970) effort to identify developmental stages or sequences in students' personal epistemology, mostly through the use of interviewing methodology (e.g., Baxter Magolda, 1992; King and Kitchener, 1994; Kuhn, 1991). This line of research has generally described a developmental trajectory beginning with a dualist view where knowledge is seen as either right or wrong and where it is possible to know what is right with certainty. This is followed by a period of multiplicity where multiple conflicting views are acknowledged and accepted as equally valid. Finally, a more evaluativistic perspective develops where individuals acknowledge that there is no absolutely certain knowledge but still believe that it is possible to evaluate competing knowledge claims and justify claims through the use of supporting evidence.

While educational researchers have been most concerned with development in personal epistemology during adolescence and early adulthood, some research has also

been conducted with children. Such research has linked the development of personal epistemology to children's theory of mind and also identified a predualistic stage of egocentric subjectivism where children believe that their own perspective is the only perspective (e.g., Burr and Hofer, 2002). Moreover, research conducted at younger ages has identified progression through the developmental stages observed in college students regardless of the age of the participants. Such repetition of previously passed stages, possibly several times from childhood to adulthood, suggests that the development of personal epistemology is recursive rather than linear, with recursion possibly occurring when students enter new educational contexts (e.g., traverse from elementary to secondary and from secondary to postsecondary education) (Muis *et al.*, 2006). However, other plausible explanations for the developmental-recursiveness puzzle also exist, for example, that development varies with the kind of facts considered (Hallett *et al.*, 2002).

What Are the Dimensions of Personal Epistemology?

Some researchers have been less interested in the development of personal epistemology than in its dimensionality. This approach was pioneered by Schommer (1990), who described personal epistemology as a system of more or less independent beliefs about certain knowledge (ranging from the belief that knowledge is absolute and unchanging to the belief that knowledge is tentative and evolving), simple knowledge (ranging from the belief that knowledge is best characterized as isolated bits and pieces to the belief that knowledge is best characterized as highly integrated concepts), omniscient authority (ranging from the belief that knowledge is handed down by authority to the belief that knowledge is derived from reason), quick learning (ranging from the belief that learning takes place quickly or not at all to the belief that learning is gradual), and fixed ability (ranging from the belief that ability to learn is given at birth to the view that ability to learn can be increased). Using a questionnaire to examine the described system, Schommer and associates identified factors corresponding to all the proposed dimensions except omniscient authority, even though this factor structure has not been consistently replicated by other

researchers (e.g., Bråten and Strømsø, 2005; Hofer, 2000; Qian and Alvermann, 1995).

Whereas the three first dimensions in Schommer's (1990) conceptualization fall under the cited definition of personal epistemology as theories or beliefs about the nature of knowledge (certain knowledge and simple knowledge) and knowing (omniscient authority), the two remaining dimensions are more controversial because they mainly concern beliefs about learning (quick learning) and intelligence (fixed ability). Hofer and Pintrich (1997) therefore placed quick learning and fixed ability outside the realm of personal epistemology and purified the construct by considering two dimensions concerning the nature of knowledge (what one believes knowledge is) and two dimensions concerning the nature or process of knowing (how one comes to know). In their conceptualization of personal epistemology, the dimensions certainty of knowledge and simplicity of knowledge, both concerning the nature of knowledge, correspond to the dimensions certain knowledge and simple knowledge as described by Schommer (1990). Within the area of nature of knowing, the dimension source of knowledge, in part paralleling omniscient authority in Schommer's belief system, ranges from the conception that knowledge originates outside the self and resides in external authority, from which it may be transmitted, to the conception that knowledge is actively constructed by the person in interaction with others. Finally, the dimension justification for knowing, also concerning the nature of knowing, refers to how individuals evaluate and justify knowledge claims. This dimension ranges from justification through observation and authority, or on the basis of what feels right, to the use of rules of inquiry and the evaluation and integration of multiple sources.

Even though the dimensionality proposed by Hofer and Pintrich (1997) is currently the most authoritative view on the dimensionality of personal epistemology, and as such widely recognized by researchers in the field, the conceptually derived dimensions have not been unequivocally empirically verified through factor analysis (Hofer, 2000). However, use of qualitative methodologies such as observations and interviews (Hofer, 2004a) or think-aloud protocols (Hofer, 2004b) indicates that all the four dimensions proposed by Hofer and Pintrich (1997) are represented in students' epistemic thinking.

Hofer and Pintrich (1997) conceptualized individuals' epistemic beliefs to be theory-like, that is, integrated and coherent rather than existing as more or less independent beliefs, as Schommer (1990) originally suggested. Regarding this issue, recent evidence suggests that the various dimensions of personal epistemology may exist and operate independently, meaning that a student may hold what could be characterized as a more sophisticated belief on one dimension (e.g., that knowledge is integrated) and, at the same time, hold what could be characterized as a more

naive belief on another dimension (e.g., that knowledge is unchanging) (Buehl and Alexander, 2005).

Is Personal Epistemology Domain General, Domain Specific, or Both?

Whereas initial educational research was based on the assumption that epistemic beliefs were independent of academic domains, implying, for example, that students would hold the same beliefs about knowledge and knowing in mathematics as they would in education, some studies conducted in the 1990s started to question this assumption. Those studies could be divided into between-subjects investigations, where students majoring in different domains were compared with respect to their epistemic beliefs, and within-subjects investigations, where the same students were asked about their epistemic beliefs in different domains. Buehl and Alexander (2001) found that most existing evidence supported the view that epistemic beliefs varied as a function of academic domains and, moreover, that such variation was related to domain structuredness (e.g., between mathematics as a well-structured domain and education as an ill-structured domain). However, Buehl and Alexander (2001) also argued that students' epistemic beliefs were not solely domain specific, that is, students could simultaneously hold both domain-specific and more domain-general or overarching epistemic beliefs.

A later review by Muis *et al.* (2006) confirmed that this is not an issue of either-or. Of the 19 studies that they reviewed, eight between-subjects investigations and 11 within-subjects investigations, 17 established evidence for domain specificity on one or more of the dimensions of personal epistemology, with six of those 17 studies also indicating some degree of domain generality. The review by Muis *et al.* (2006) also confirmed that epistemic belief similarities and differences across domains were related to whether the compared domains were similar or different with respect to structuredness, as well as whether they were similar or different on the hard-soft and the pure-applied dimensions. In general, students seem to view knowledge as more certain and integrated and more readily accept experts as sources of knowledge in well-structured or hard domains such as mathematics than in ill-structured or soft domains such as education.

The conclusion that personal epistemology includes levels of both domain generality and domain specificity was further supported by Buehl and Alexander (2005), who used cluster analysis to compare the student profiles that emerged from different dimensions of personal epistemology across the domains of mathematics and history. While the distinct epistemic belief profiles that emerged differed across the two domains, there was also some consistency in students' profile membership in mathematics and history, with this finding also consistent with a dual-level

conception of personal epistemology. Moreover, a useful distinction may concern domain and topic-specific epistemic beliefs. Just as domain knowledge and topic knowledge may form subcategories of formally acquired or schooled knowledge, with domain knowledge referring to the breadth of one's knowledge about a domain (e.g., psychology or history), and topic knowledge representing the depth of one's knowledge about particular contents or concepts within a domain (e.g., intelligence or World War II) (Alexander *et al.*, 1991), beliefs about knowledge and knowing in a domain may be distinguished from epistemic beliefs about topics within domains. As an example of such a topic-specific approach to personal epistemology, Trautwein and Lüdtke (2007) used questionnaire items to examine students' epistemic beliefs about specific scientific theories, for example, about biological theories concerning natural selection and extinction of the dinosaurs, respectively. It was found that epistemic beliefs differed considerably across theories. At the same time, a small but statistically significant association between topic-specific epistemic beliefs and more general epistemic beliefs about scientific knowledge was found. Likewise, Bråten (2008) described research on topic-specific epistemic beliefs concerning student views on knowledge about climate change and how one comes to know about climate.

There is a clear need to further examine how different levels of personal epistemology develop in interaction and how they operate together to promote or constrain various aspects of student motivation and learning. Possibly, personal epistemology at different levels of specificity has strongest impact on facets of academic learning at comparable levels of specificity (Schraw, 2001). Clearly, the consideration of various levels of personal epistemology also implies that measures of personal epistemology become tailored to particular levels.

The Role of Personal Epistemology in Student Motivation, Cognition, and Performance

Schommer's (1990) departure from the developmental paradigmatic approach to personal epistemology and her introduction of quantitative assessment in the form of a paper-and-pencil questionnaire initiated an important line of research on relations between personal epistemology and other academic constructs. In accordance with Schommer's (1990) initial findings, quite a few other studies have linked epistemic beliefs to students' text-based learning and comprehension (e.g., Buehl and Alexander, 2005), with this body of research generally indicating that beliefs that have traditionally been located at the naive ends of epistemic belief continuums (e.g., beliefs that knowledge is certain or simple) are related to poorer learning and comprehension. Other findings show that

more naive epistemic beliefs are negatively related to argumentative reasoning (e.g., Kuhn, 1991), conceptual change learning (e.g., Qian and Alvermann, 1995), and graded academic performance (e.g., Wood and Kardash, 2002). Such relations between epistemic beliefs and student learning, comprehension, and performance may well be mediated by the use of cognitive and metacognitive strategy use, as several researchers have documented that personal epistemology is related to students' strategic processing (for review, see Muis, 2007).

Bråten (2008) noted that research on personal epistemology and text-based learning and comprehension had almost exclusively focused on students' reading of one single text, and, moreover, that most research on personal epistemology and aspects of learning had been conducted in traditional print environments rather than in new technological environments. As personal epistemology may be particularly important when students work on complex learning tasks (Spiro *et al.*, 1996), these limitations are not trivial.

Regarding the reading of multiple texts, Rukavina and Daneman (1996) provided some early evidence that students holding more sophisticated epistemic beliefs about the complexity of knowledge were better equipped to integrate ideas across two texts presenting conflicting information on a topic. Later, Bråten and Strømsø (2006) provided new evidence that at least adult college readers are able to deal adequately with the challenge of integrating information from multiple, even conflicting, texts, provided that they hold relatively sophisticated beliefs about the nature of knowledge and knowing. Otherwise, even college readers may be better off when encountering the same content in an integrated textbook format.

Regarding the importance of personal epistemology when learning with hypermedia technology, Jacobson and Spiro (1995) provided preliminary evidence that students who believed in simple knowledge had problems handling the nonlinear and multidimensional nature of an ill-defined hypertext system. Bendixen and Hartley (2003) provided additional evidence to suggest that students' epistemic beliefs play an important role in hypermedia-learning environments. Moreover, Hofer (2004b) reported that when students thought aloud during online searching, those expressing naive epistemic beliefs were likely to pursue the searching task in a brief and perfunctory way, not seeing the need for additional sources or reflecting on the credibility and accuracy of the sources they located. Finally, Bråten and colleagues (e.g., Bråten *et al.*, 2005) found that students' epistemic beliefs predicted their Internet-based learning activities. In brief, the more naive beliefs students held about Internet-based knowledge and knowing, the more naive they seemed to be about the ease with which relevant Internet-based sources could be identified and used, also displaying an overreliance on the Internet as a communication tool and overestimating the value of

virtual exchanges at the expense of real-life encounters. Given the importance of being able to construct integrated meaning from multiple textual sources in today's knowledge society, with those sources more often than not located in complex computerized information systems, further research on the role played by personal epistemology in such endeavors is greatly needed.

Thus far, fewer studies have addressed relations between personal epistemology and academic motivation than between personal epistemology and academic cognition and performance. However, Bråten and Strømsø (2004, 2005) reported that naive epistemic beliefs were negatively related to adaptive motivational beliefs such as mastery goal orientation, self-efficacy, and interest. Conversely, Buehl and Alexander (2005) identified subgroups based on epistemic belief profiles and showed that clusters characterized by more sophisticated patterns of epistemic beliefs had higher levels on both expectancy and value components of academic motivation.

Although there is a fairly solid research base for asserting the importance of personal epistemology for student motivation, cognition, and performance, the complexity of the relationships among those constructs are not very well understood. As Schraw (2001) noted, structural models that specify the direct and indirect linkages among academic constructs, including epistemic beliefs, should be generated and then tested empirically through structural equation modeling to examine such complex relationships collectively.

How Can Personal Epistemology Be Assessed?

Perry (1970) and other later researchers primarily interested in the development of personal epistemology (e.g., Baxter Magolda, 1992; King and Kitchener, 1994) mainly conducted lengthy in-depth interviews to provide thick descriptions of how individuals' beliefs about knowledge and knowing change over time. For example, King and Kitchener (1994) have conducted structured interviews about ill-structured real-life problems or dilemmas, for example, about news or food additives, asking participants about their views on such problems and how they would justify their views. The interview tool used by these researchers is called the reflective judgment interview, with research providing evidence for the validity and reliability of this tool.

However, the possibility for doing larger-scale investigations of personal epistemology greatly increased with Schommer's (1990) introduction of a questionnaire allowing for group administration and statistical analyses of student scores. Schommer's epistemological beliefs questionnaire assesses personal epistemology at a domain-general level. Modifications of the questionnaire have

tried to improve its psychometric qualities. However, the dimensionality of personal epistemology has been somewhat different across the modifications, and the internal consistency reliabilities (Cronbach's Alphas) for the dimensions measured with those instruments have sometimes been smaller than required. Still, Schommer's questionnaire has been the most widely used quantitative assessment of personal epistemology.

Research on the domain-general versus domain-specificity issue eventually led to the construction of domain-specific personal epistemology questionnaires. First, a modified version of Schommer's domain-general questionnaire was developed where about every third item explicitly mentioned the domain (e.g., mathematics or science) that the student should keep in mind when completing the questionnaire (Schommer and Walker, 1995). However, Hofer (2000) constructed a measure more specifically devised to assess domain-specific epistemic beliefs, where each item on the questionnaire referred to a particular field or subject matter (psychology or science) as a frame of reference (e.g., in this field, knowledge is certain.). Likewise, Buehl *et al.* (2002) developed a self-report measure specifically devised to test for domain-specific epistemic beliefs, with the items focusing on either mathematics or history. In their more recent work, Buehl and Alexander (2005) have selected and combined items from the two above-mentioned domain-specific measures, the discipline-focused epistemological belief questionnaire (DFEBQ; Hofer, 2000) and the domain-specific beliefs questionnaire (DSBQ; Buehl *et al.*, 2002). Buehl and Alexander (2005) reported that the resulting domain-specific questionnaire captured the dimensions of certainty, simplicity, and source of knowledge in mathematics as well as in history.

As existing measures of personal epistemology primarily focused on conventional-print environments rather than new technological environments, Bråten *et al.* (2005) designed the Internet-specific epistemological questionnaire (ISEQ), a questionnaire specifically assessing beliefs about Internet-based knowledge (what one believes knowledge is like on the Internet) and Internet-based knowing (how one comes to know on the Internet), with this questionnaire especially suitable for studying relations between personal epistemology and learning with hypermedia or Internet technologies. As mentioned above, some researchers have also started to construct questionnaires that assess epistemic beliefs at a topic-specific level, for example, concerning specific theories within domains (Trautwein and Lüdtke, 2007) or specific scientific topics (Bråten *et al.*, in press; Stahl and Bromme, 2007).

Assessment of personal epistemology through survey methodology relies heavily on Likert-type rating scales where individuals express their degree of agreement with beliefs about knowledge and knowing. One issue with such scales is whether they can capture the complex and multifaceted nature of personal epistemology dimensions,

particularly the source of knowledge and justification of knowing dimensions (Hofer, 2004b). Another issue is whether they are suitable for measuring all the different epistemic positions identified within the developmental approach (i.e., dualistic, multiplistic, and evaluativistic positions) (Hofer, 2004b; see also, Muis *et al.*, 2006). Given such limitations, there has been a call for more qualitative, dynamic assessments of personal epistemology. One such approach, used by Hofer (2004b), involves having students think aloud during actual learning and knowledge construction and then analyzing the think-aloud protocols for instances of epistemic thinking (see also, Mason and Boldrin, 2008). Another possibility, also used by Hofer (2004a), is to use ongoing observations of classroom discourse combined with student interviews to examine how students' personal epistemology unfolds over time in the context of subject-matter instruction.

Finally, multi-method approaches combining quantitative and qualitative data sources may be especially valuable when assessing personal epistemology (e.g., Hofer, 2006; Schraw, 2001). For example, combining the use of questionnaires with in-depth interviewing may not only lead to a refinement of existing questionnaires (Hofer, 2006), but also allow for a triangulation of data that can give both researchers and educators a more complete picture of student epistemic beliefs.

Educational Implications

Schraw (2001) noted that one educational implication that might follow from the existing research on personal epistemology is that teachers should be helped to understand and change their own epistemic beliefs. According to Schraw (2001), teachers' beliefs affect their curricular and pedagogical decisions, and such decisions may, in turn, affect student epistemic beliefs (see also, Schraw and Olafson, 2003). This was partly confirmed in a qualitative study where Hofer (2004a) combined observations and interviews in two versions of introductory-level college chemistry. Hofer (2004a) observed dramatic differences in pedagogical approaches and implicit messages about knowledge and knowing in the two courses that she studied, also showing that students' existing epistemic beliefs were influenced by the instruction they experienced. Hammer and Elby (2002) suggested that innovative pedagogical approaches where class discussion is more typical than lectures, and where students are engaged in activities of design and construction to accomplish authentic tasks, are more likely than traditional pedagogical approaches to activate sets of epistemic resources that are productive for learning.

According to Muis *et al.* (2006), however, the dominant epistemologies of educational domains (e.g., of science or history education) often seem to reinforce the beliefs that

knowledge consists of right answers and unquestionable facts possessed by authorities and transmitted to students. In history, for example, students typically engage in the gathering of factual information about different topics, without much evaluation or questioning of the validity of that information. This concentration on accumulating historical facts may be reinforced by teacher beliefs in knowledge and knowing in history as the memorization and reproduction of factual information (cf., VanSledright, 2002). Instead, students need to be taught that there may be multiple opinions about historical events, with these opinions backed by varying evidence. Moreover, students need help to understand that interpretations of historical events can be justified by the amount of evidence that they account for, and that all available sources should be considered, not only a few select ones (Wolfe and Goldman, 2005).

Thus, given that teachers' epistemic beliefs in many instances seem to be less sophisticated than desirable, it is indeed an important task to try to promote belief change in teacher students as well as in more- and less-experienced teachers. Preliminary evidence suggests that this is not an impossible task. For example, Gill *et al.* (2004) showed that teachers may revise their existing epistemic beliefs through the reading of refutational text especially designed for this purpose.

Regarding the development of more sophisticated epistemic beliefs in students, Schraw (2001) suggested that schools should encourage an ongoing discussion and evaluation of such beliefs. In particular, Schraw argued that schools should try to promote critical-thinking skills and conceptual change among students, for example, by encouraging cooperative learning where students can discuss and evaluate their own epistemic beliefs. There is currently some research to underpin these suggestions, indicating that having students struggle to understand complex issues by reading texts presenting them with multiple perspectives on a topic, integrated with discussions of both text content and their current epistemic thinking, may bring about belief change. Thus, Valanides and Angeli (2005) observed that students who read a text presenting opposing views on a controversial topic and then discussed the text content, reflected on their thinking about the issue, and evaluated their thinking in light of principles for critical thinking, developed more sophisticated epistemic beliefs after the intervention. Accordingly, Kienhues *et al.* (2008) found that students who held naive epistemic beliefs concerning the scientific topic of genetics considered knowledge about this topic to be more complex and variable after reading a text focusing on the uncertainties of genetic fingerprinting. Bråten (2008) argued that the reading of multiple texts containing contrasting perspectives on a topic would be a good starting point for reflection on both content and epistemic beliefs in relation to that content, with such

reading and concomitant collective reflection presumably having the potential to foster the belief revision and conceptual change that many students seem to need.

Since personal epistemology seems to vary across domains, helping students become aware of their own epistemic beliefs, as well as develop more sophisticated beliefs, should probably take place within the frameworks of particular domains or even topics within domains. That is, an important part of instruction in a domain should concentrate on challenging students' existing beliefs about knowledge and knowing in the domain and, moreover, help them develop more sophisticated, expert-like beliefs about the nature of knowledge and the processes or methods of knowing within that domain. According to Hofer (2006), helping students develop from multiplicity to evaluativism is a particularly difficult instructional task in postmodern educational environments.

Glossary

Constructivism – Problems about knowledge and reality are twofold. One problem is in metaphysics (sometimes called ontology): what is reality like? The other problem is in epistemology: how is reality known? These problems have led to three main answers – realism, nominalism, and constructivism. To see what is at issue, take a particular case about the nature and knowledge of number. The ontological problem is: what are numbers, really? One answer is realism (also called Platonism after its first sponsor): really, numbers are abstract objects with properties independent of any knower. A second answer is nominalism: really, numbers are numerals for manipulation within some mathematical language. A third answer is constructivism: really, numbers are constructions guided by norms and causes in human actions and operations. The epistemological problem follows on: how are numbers known? Realists identify a human faculty, such as intuition, by whose use numbers as abstract objects can be grasped. Nominalists identify some aspect of language that enables language users to manipulate numerals. Constructivists identify human capabilities that forge meaningful connections in learning and knowing. Standard objections also follow on. Realism seems to lead to an ontological slum of infinitely many possible worlds actually unknowable by our lights. Nominalism seems to lead to a relativism without objectivity. Constructivism seems to lead to an inherent subjectivity that precludes objectivity – if all knowledge is relative to its level of construction, by reference to which level is any knowledge objective? On the positive side, all three answers have current sponsors.

Frege's rule – The rule is usually referred to as the fallacy of psychologism and has its basis in the work of Gottlob Frege, the founder of modern logic. There is an ambiguity in the notion 'laws of thought'. If these laws are laws of logic, they are true independently of being acknowledged. If these laws are psychological laws, they are true in one context or culture, but not in others. Frege's rule is that conflating this distinction amounts to psychologism, and that psychologism is a fallacy. Although psychologism is widely accepted to be a fallacy, it does not entail a division of labor with no joint work in the formal and empirical sciences.

Nonpsychologism is an alternative under which complementary work is possible without lapsing into psychologism.

Hume's rule – The rule, so-called after its author, David Hume in his *Treatise of Human Nature*, states that the is-ought relation is not entailment: the same facts are compatible with contrary 'norms' about what ought to be or what ought to be done (*q.v.* norms). By contrast, any deductively valid argument is such that contrary conclusions could not be entailed by the same premises.

Kant on the formation of knowledge – Immanuel Kant in his *Critique of Pure Reason* identified two questions about concept formation and other forms of human rationality. Questions about the origins are factual (*quid facti*), whereas questions about constitution are normative (*quid iuri*) – the right concepts are required to make true as opposed to false judgments. For Kant, an adequate account should deal with both since the many forms of pseudo-rationality have an origin and yet are fallacious in leading to error.

Norms – The term 'norm', and cognate terms such as 'normativity' have a variety of uses in biology (pattern of phenotypic expression), mathematics (function in a vector space), sociology (normality), and statistics (average). These uses are all valid. However, they differ from a norm-laden use central in making right/wrong judgments. Norms in this norm-laden sense include rules, imperatives, directives, customs, obligations, and ideals. While moral norms are norms, not all norms are moral. Norms operate in mathematics, " $3 + 4 = 7$, so $3 \times 4 = 12$. Yes, that's right," and in human action and thought generally due to their implications for what has to be done and what has to be.

Normative facts – Although a norm is not a fact, not all facts are causal facts. Normative facts are facts occurring in an individual's commitment to a norm operative in action or thought irrespective of its explicit recognition. Recognition of a norm involves some degree of conscious knowledge. The operation of a norm is extrinsic when a person conforms to others' norms due to the sociocultural causality of parents, peers, or teachers. Extrinsic conformity in this sense is normative pressure. The operation of a norm is intrinsic when a person makes a commitment

to a norm on his or her own account, whether to retain the same norm, revise it, or to recast it. Intrinsic commitment is normative autonomy, a potentially powerful source of novelty and creativity.

Peirce's semiotics – Charles Sanders Peirce elaborated a distinctive semiotic theory, that is, theory of meaningful signs, according to which all meaning is triadic. The triad consists of a sign-vehicle, object, and interpretant. It is thereby incompatible with any dyadic theory of meaning, for example, meaning is a relation between a word and object. In a triadic theory, things other than words have meanings, for example, a metal arrow on a pole can depict wind direction, its object. The metal is a physical object in the causal world, and it depicts only in terms of an interpretant that is itself capable of standing in triadic relations of its own. For Peirce, a person serves as an interpretant. In Piaget's account, frameworks (schemes, structures, systems) are interpretants.

The Story So Far

Jean Piaget (1896–1980) made the seminal contribution to the study of human development in the twentieth century – *Time* included him in the 100 most important persons ranking 4th in psychology and 77th in science, generally. Despite this, Piaget's work has led to contrary interpretations and evaluations.

Under the standard interpretation of Piaget's work, human development is a sequence of four stages by analogy with a ladder or staircase with four steps. These stages are universal: the same stages fit all human development in the same order irrespective of differences in cultures and contexts. Yet, there is massive evidence to show two things. One is that heterogeneity – not the predicted homogeneity – is characteristic of human development. The other is that alternative accounts can explain these differences that are not readily explained in Piaget's program. Further, the advance from one stage to the next is due to a special mechanism – equilibration – or the change from one level of equilibrium to a better level. However, this mechanism is reckoned to be obscure, resisting clarification, and so stage-like advance is a mystery, apparently downsizing, even eliminating, the contribution of nature and nurture. A twofold conclusion is usually drawn that Piaget's work was historically important in identifying fundamental questions, and that its answers have now been superseded by better accounts (Scholnick *et al.*, 1999).

Running contrary to this is the constructivist interpretation of Piaget's work under which human development

is a hierarchical series of levels of construction with neither a first nor last level (*construction sans fin, régression sans fin*) (Smith, 2009a). The implication is that developmental stages are merely some of these indefinitely many levels. A principal feature of this interpretation is that Piaget's work is necessarily interdisciplinary in that its epistemology, psychology, and pedagogy are interdependent parts for systematic, not piecemeal, analysis. The conclusion typically drawn is that Piaget's work has addressed questions of human knowledge that are both fundamental and unresolved. Actually, Piaget's answers are often argued to be superior to available alternatives (Müller *et al.*, 2009).

Piaget was referring to the standard interpretation when he made an ironic remark about the recognition that his work had received: "I'm pleased by it, of course, but it's pretty catastrophic when I see how I'm understood" (Bringuier, 1980: 54). This remark motivates the stance taken in this article which is in three parts:

- Recent work in education.
- Piaget's constructivist program.
- Ways forward.

Recent Work in Education

Most educational research on Piaget's work is based on the standard interpretation under which Piagetian stages seem to be biological constraints that preclude instructional interventions, thereby making Piagetian pedagogy a nonstarter. Two adverse consequences follow. One is that a Piagetian child is viewed as a solitary knower for whom teaching is nonrelevant. The other is a preoccupation with the American question: can progress through Piagetian stages be improved? However, viewed under the constructivist interpretation, both consequences are flawed, and Piagetian pedagogy is promisingly positive.

Piaget's Pedagogy

Piaget (1998; commentary on this French text is available in Smith, 2009b) frequently noted that educational research required evidence about instructional interventions, a precondition he accepted he had not met in his own work. However, two qualifications should also be noticed. One is that others have remedied this omission leading to strikingly successful results – more on this below. The other is that Piaget's program did include principles for formative assessment, that is, teaching-based assistance with a view to making learning possible, easier, or better. Four principles elaborate key aspects of this assistance in Piaget's pedagogy:

1. *Children have to be taught to think.* "Each individual is led to think and re-think the system of collective notions"

(Piaget, 1995: 76). Note the use of ‘led’: any individual requires social assistance in being led to think with a view to any re-think in the sequel. For Piaget (1998: 163) “children have to be taught to think. . . To think is to search for oneself, that is, to criticize freely, and to demonstrate autonomously.” Learning without teaching has a tendency to lapse into the twin pitfalls of anomie and anarchy, alienation and willfulness. Neither amounts to individual autonomy which is quite another matter.

2. *Teaching creates contexts for learning in which learners use their judgment.* The role of the teacher is to design contexts that facilitate the formation of better learning (Piaget, 1998: 190–91). The difference between creating learning and creating a context for learning is an important difference. The teacher’s role is not to make learners think – that can amount to surface learning – but rather to create conditions in which learners make their own judgments about what they think in the light of standards of coherence and objectivity. Making the right judgments in human experience, generally, is an outstanding issue for us all.
3. *Good learning is collaborative.* Indeed, it “necessarily presupposes collaboration in work” (Piaget, 1998: 46). This principle is explicitly stated and its basis lies squarely in Piaget’s epistemology: “human knowledge is essentially collective, and social life constitutes an essential factor in the creation and growth of knowledge, both pre-scientific and scientific” (Piaget, 1995: 30). It is patently incompatible with the standard interpretation that a Piagetian child is a solitary knower. Making the right judgments is no easy matter, and access to others’ judgments is indispensable.
4. *Good learning requires self-government.* “The method of self-government consists in attributing to pupils a share in the responsibility for scholarly discipline” (Piaget, 1998: 167). Self-government is polymorphic in assuming different forms, including national and international collaborations based on freedom of thought and speech, institutional control with individual and collective responsibilities, personal development notably with regard to rules and directives, and self-discipline in academic work.

These principles are incompatible with the standard interpretation; they are, however, a direct consequence of the constructivist interpretation of Piaget’s program.

Recent Research on Assessment and Intervention

National assessment based on adaptations of classic Piagetian tasks has proved to be highly reliable in two respects. First, the evidence from a major British study in the 1970s (Shayer and Adey, 2002) has stood up well in

recent international studies (Müller *et al.*, 2009). Second, the same Piagetian tasks from the 1970s were used three decades later with different cohorts and different curricula, revealing a substantial decrease in intelligence, that is, anti-Flynn effects or measured decreases in intelligence over generations (Shayer, 2008). This novel finding is significant: there are no other standardized measures applicable to different cohorts other than psychometric tests that have revealed a progressive increase in intelligence over generations, that is, Flynn effects.

Scientific assessment requires the use of an objective method. Piaget’s method – a critical method – has a distinctive rationale for entering the child’s mind by teachers and investigators (Ginsburg, 1997). This method with its intra-individual function is indispensable on two counts. One is to monitor spontaneity, such as individual differences in children’s judgments in their own right, not as mere noise due to causal variance. The other is to check on the robustness of a particular individual’s reasoning through a train of thought. This method continues to be indispensable on a diverse range of non-Piagetian tasks. It complements quantitative methods with an inter-individual function directed on the frequency of prespecified responses in a population. There is no inherent incompatibility in the joint use of complementary methods. One reason is the need for dialog between investigators in the human sciences in view of the dual requirements of measurement and meaning (Dawson *et al.*, 2006). Another is based on educational practitioners’ beliefs about reconciling the heterogeneity of educational problems and the objectivity of science (Niaz, 2008).

A series of interventions were designed to improve children’s understanding under classroom conditions (Shayer, 2008; Shayer and Adey, 2002). Piaget’s account of children’s reasoning through serial levels was used as a measure of the population baseline. Each intervention had several parts, including Piagetian tasks adapted for classroom use; pedagogical focus on understanding; teacher training in their use; designated classes 1 h weekly or fortnightly over 1–2 school years; subject-specific delivery with adolescents, but nonspecific with children; collaborative learning with individual reflection; and a quasi-experimental design with the control of school differences. The first intervention covered learners in science in grades 7–8 (aged 11–13 years) over 2 years with an outcome measured in externally organized, national examinations. The level of improvement of youngsters in the experimental classrooms over the control classrooms was almost double for good passes in three core subjects (Science, Mathematics, and English). The second intervention was a replication that resulted in a comparable level of improvement. An ongoing intervention dealt with mathematics in grades 1–2 (aged 5–7 years). The success rate of children in control classes on pre- and post-test tasks was substantially lower than that of children in the experimental classes.

This research evidence shows that Piaget's program works well under classroom conditions. It is incompatible with the standard interpretation in view of its constructivist rationale.

Piaget's Constructivist Program

Piaget (2006) called his program genetic epistemology (*épistémologie génétique*). Today, such a name is liable to be misleading. His program is not about genetics and DNA. Developmental epistemology is an alternative name for this program whose central aim is to explain the formation of knowledge in terms of its human development. Four main notions in this program are now analyzed and illustrated: formation of knowledge, norms, actions, framework, and reasons.

Formation of Knowledge

Kant distinguished two questions about the formation of knowledge (Smith, 2009a):

1. What is its origin (*quid facti*)?
2. What is its constitution (*quid iuris*)?

Objective knowledge has an origin in the human mind, but so too do the many forms of pseudo-rationality from astrology to zoism. Establishing the origin of something leaves open its qualities – are these the right ones? An appellation on a wine label identifies where the grapes were grown, but not whether the wine in the bottle is actually at the right standard. Kant's point was that human minds have the right intellectual tools for the acquisition of properly constituted knowledge. These tools have to be rich enough to capture the necessity of some types of knowledge. His famous example was that $7 + 5 = 12$ is necessarily true, and so could not be otherwise. Kant's conclusion was that the capacity to make necessary judgments is fundamental to the human mind whose proper functioning requires *a priori* knowledge based on norms that are neither innate nor learned, but are instead independent of experience.

The insight behind Kant's distinction is integral to the constructivist interpretation of Piaget's program; it is lost in

the standard interpretation due to its sole focus on (1) the origin of knowledge, without regard for (2) its constitution by the knower. However, Piaget modified Kant's conclusion in two ways, notably about the formation of necessary knowledge. First, necessary knowledge is not innately present in the human mind. But nor is it straightforwardly acquired through learning – seven drops of water added to five drops can make one pool. Young children are prone to conflate number with other objects: 2×3 objects added to one box are less than 3×2 added to another (Piaget, 2001: 57). For Piaget, *a priori* knowledge is not fully formed at the lower levels of human development, even if its formation is completed later. Second, Kant's implied division of labor – facts in (1) for psychology, norms in (2) for epistemology – is replaced by a linking science directed jointly on both. This linking science is Piaget's developmental epistemology whose focus is on the relations between norms and facts without committing the fallacy of psychologism, that is, without reducing norms to facts.

Norms

There are many varieties of norms including rules, commands, directives, customs, moral principles, and ideals (Smith, 2006). The function of norms is to lay down what is right, legitimate, appropriate, or proper, notably in making the right judgments not only in mathematics and morality but in human experience, generally. Norms have a binding force, the 'has to' of obligation in action and of necessity in thought – see the examples in **Figure 1**.

This binding force is manifest in human judgments based on norms. Norms are not causes even though normative commitments may have causal consequences. An instructive example is this (Brandom, 2000). An iron bar in wet conditions responds by rusting and turning red. Shown a rusty iron bar, a parrot may say "That is red." Yet neither the bar nor the parrot recognizes the incompatibility "So it can't be green," or the implication "But it must be colored." Inferential capabilities require norms for recognizing these necessitations. Norms are not directly observable, but become manifest as normative commitments made in their use, unwittingly or consciously. A commitment made through the causality of normative pressure can always be reaffirmed or revised in

Luther: "has to" in action	Spinoza: "has to" in thought
For they have contradicted each other. I cannot and I will not recant anything.	1, 2, and 3, therefore 6.
Here I stand, I cannot do otherwise.	The proportion in these numbers had to be so, and could not be otherwise.

Figure 1 Adults' norms. From Smith, L. (2003). Children's reasoning by mathematical induction: Causal facts and normative facts. *International Journal of Educational Research* 39, 719–742.

Figure 2 Children's norms. From Smith, L. (2002). *Reasoning by Mathematical Induction in Children's Arithmetic*. Oxford: Elsevier Pergamon Press.

an agent's autonomous commitments. For Piaget, a person is 'always norm laden' (*toujours 'normé'*) (Smith, 2006: 113). Normative capabilities are under development during childhood with an example in **Figure 2**. Two lines of blue or white buttons were presented in one-one correspondence with coincident endpoints, such that the children accepted that there is the same in each. After extending the white line, differences emerged. For some children, white outliers were disqualified from line-membership, and so were not counted – there were now “more Blues”. These children were using a personal norm – no doubt a pseudo-norm – to determine which buttons are still in the line, and so their judgments amount to normative misconception, not miscounting. For other children, necessary knowledge based on public norms was superbly on display about what has to be.

The use of a norm is a normative fact. Since facts are not norms, a normative fact is not the norm corresponding to it. And since norms are not causes, a normative fact is not a causal fact. However, any fact can be investigated empirically, including normative facts. Inferential reasons about entailments and implications, incompatibilities and contradictions, are paradigm examples of normative facts. That is why children's reasons for their judgments are always analyzed in Piaget's empirical studies. Piaget's constructivism deals both with norms in human development and with normative facts, that is, their actual use during childhood and the history of science.

Actions

An action is agent-initiated behavior and any living agent is always in action with objects in the world. Actions range from physical activities to acts of judgment, from sensorimotor activities to mental acts of thought and understanding, from knowing how to knowing that.

An action is an action in object selection (what is to be done with this object), not in object representation (which properties of the object are to be copied). For Piaget,

actions are not representations that copy or encode reality, and so his constructivism avoids the fatal objections that undermine the representational theories that are ubiquitous in psychology and education. Instead, a human action is always meaningful to its agent. An instructive parallel is with Peircean semiotics: a sign is meaningful because it stands in two relations, one to its object, the other to its interpretant. A metal arrow on a pole is a physical object in a causal world; it functions as a sign of wind direction only through some interpretative system. Lacking an interpretant, the arrow fails to comprehend the wind direction it is indicating. For Piaget, infants' actions have indicative, that is, indexical, meanings; symbolic and sign-based meanings emerge in later actions. This is because human agents are themselves interpretants and, for Piaget, an action framework is an interpretant.

Frameworks

The interpretant of agent's actions is a framework (*cadre*) or network of norms. Schemes and structure are types of framework. Every fact is registered through some framework. “Let us recall that, from the very beginning and even among our youngest subjects, a physical fact is recorded only within a logico-mathematical framework” (Piaget, 2001: 320). Since agents are always in action, frameworks are always in a state of Heraclitian flux during the agent's life, patterned through an agent's regulation. Changes due to regulation include: augmentation of new cases to existing norms; creating or annulling norms; recasting the relations between norms. Any change in a framework is recognized through the inferences made by their agent. These inferences are signifying, that is, meaningful implications, amounting to a logic that changes over time (Müller *et al.*, 2009).

Normative commitments are made both unwittingly and wittingly – see the examples in **Figure 2**. Either way, norms are continually being constructed and reconstructed in their use (*pratique*), that is, in the commitments made by a normative agent as advances to their conscious realization (*conscience*). These advances include conscious awareness and reflecting abstraction as aspects of equilibration (Müller *et al.*, 2009). A principal contribution to these advances is through inferential reasons.

Reasons

Piaget's early claim – “reason is a capacity born from action” – was recast in his final paper where the role of reasons is “to introduce new necessities into systems where they were merely implicit or remained unacknowledged” (2006: 8). Notice three things here. First, reasons may be trivial or profound and, either way, reasons may be learned or autonomous, that is, one's own reason due to human spontaneity. Following Kant, such is intellectual freedom (Piaget, 1998: 161). Second, reasons are never singletons

since the question “why?” is indefinitely iterative. Similarly, norms are never singletons, but always co-occur with other norms in networks. Third, reasons can embody inferences in being necessitating reasons, whether implicitly or explicitly. These inferential reasons are based on norms amenable to systematization in alternative logical models.

The plurality of norms and of reasons results in their complexity, and that is why the formation of knowledge takes time through serial levels of comprehension. Examples of children’s understanding of necessitating reasons are in **Table 1**.

An agent’s inferential reasons are norms in use (*pratique*) reflecting the norms in an operative framework. These reasons are gradually accessible both to their owner and to investigators (*conscience*). A science of the mind that ignores inferential reasons has no doubt given priority to measurement without due regard for meanings, notably the norm-laden meanings in the actions and acts of agents during their human development.

Piaget’s constructivism, then, looks like this. Human knowledge has its origin in action and its legitimation in action frameworks whose organization changes in their use through the life span. While factors in nature and nurture are always influential, there is a third factor operating interdependently with them. This third factor is equilibration, or the interplay between norms and their applications to specific cases by their self-regulating agents. Equilibration amounts to the formation of better levels of organization. Any level of organization currently in equilibrium always breaks down, that is, the balance between existing judgments is broken. No norm is a singleton with dilemmas arising when different norms point in contrary directions. No coherent network of norms can cover all possible cases, notably in rapidly changing modern worlds. Equilibration is the search – with success never written in – for a better level of equilibrium, whereby existing judgments are temporarily restored to balance when new judgments are coherently made. Inferential reasons are the accessible manifestations of epistemic advances, reasons that are accessible both to their agent and to investigators. Even the best scientific theories swim in a sea of anomalies; even sound systems of normative rules break down due to endless hard cases. Yet advances in the natural and human sciences does in fact take place. For Piaget, such advances are veritable human constructions. Central to Piaget’s developmental epistemology is the extent of the match between constructions in individuals and in science.

Ways Forward in the Future

In the twenty-first century, Piaget’s constructivist program embodies insights and evidence that merit and require attention, including reinterpretation and revision. Three ways forward are as follows:

Table 1 Varieties of necessitating reasons

^aNecessity denial

Switzerland has 26 cantons (counties) one of which is Vaud.

Florence was asked where she lived and her nationality.

JP What is your nationality?

FLO I’m from Vaud.

JP Are you also Swiss?

FLO You can’t be both at the same time, you have to choose.

^bPseudo necessity

The task was to make two collections of colored chips (towers) equal in number, taking chips 2 x 2 from one pile and 3 x 3 from another.

DOM (Initially denies that they ever could be equal) No, they’d have to be the same number (taken each time).

^cAd hoc necessity

Analogical reasoning requires two pairs of objects to be related in the same way, i.e., the relation between relations is identical.

Children were shown several drawings in a jumbled order. They were asked to place the drawings in pairs that go well together; then they were asked to bring together two pairs that go well together. Children who succeeded on the first comparison displaying a limited understanding of necessity did not always succeed on the second comparison.

CAN (Vacuum cleaner-socket) otherwise you can’t vacuum; (bird-feather) otherwise it can’t fly; and (dog-fur) otherwise he’ll be cold. (CAN does not succeed on any problem that requires relations among relations.)

^dNecessity

The task required the coordination of cardinal and ordinal numbers. Two boxes, one higher (H), the other lower (L), were connected by a tube and the child rolled a cardinal number of marbles down the tube. The question dealt with ordinal numbers. At the outset, H contained 5 marbles with 10 now in L.

JP Where is the 10th?

JOE In L.

JP How many are in H?

JOE Five.

JP How do you know?

JOE Because ten have been dropped and the sum is 15. (H = 5; L = 3)

JOE Three in L, five in H.

JP How did you do it?

JOE There are three of them in L, plus what is necessary to make eight. Therefore $8 - 3 = 5$

1. In recent evaluations, Piaget’s account is regarded as distinctive and superior to alternatives. These evaluations provide pointers and directives about how to refine, recast, and re-evaluate explanations of the formation of coherent and objective knowledge in human development.
2. The normativity of inferential reasons has priority over causality in the explanation of human development.

Piaget's work always respected this order of priorities; the converse order is evident in most alternative accounts. A major and outstanding task is the identification of good specimens of the many forms of normativity, notably norm-laden meanings, norms in use, pseudo-norms, and novel norms.

3. Education consists in norm-laden exchanges between teachers and learners. These exchanges amount to paradigm cases of the interplay between norms and normative facts. Yet the normative aspects of assessment and intervention contexts have been given scant recognition in most accounts. Human agents have normative capabilities by whose use human creativity gains its expression. It is a fundamental error to confuse the regularities in nonliving things with the regulations of living agents with the potential to change the world.

The Adult Development of Cognition and Learning

E A L Stine-Morrow and J M Parisi, University of Illinois at Urbana-Champaign, Champaign, IL, USA

© 2010 Elsevier Ltd. All rights reserved.

Introduction

Cognition in adult development arises out of the dynamic interplay of (1) gains in knowledge-based systems, expertise, and skill and (2) losses in speed of processing, working memory (WM) capacity, and inhibitory control processes. These changes have important effects on the nature of learning and entail that strategies in instruction be developmentally sensitive throughout the life span. At the same time, education early in the life span shapes these lifelong trajectories, while education and engagement in work and leisure through adulthood play an important role in engendering and maintaining competencies. Our goal in this article is to examine this interaction between the adult development of cognition and education. In the following sections, we examine the nature of cognition through adulthood and consider implications for learning. We also discuss recent research suggesting lifelong plasticity in neural networks, so that education is intimately tied with successful aging.

Theories of Life-Span Development

We review learning and cognition in adulthood and aging against the backdrop of a long history in psychology and education in which adulthood has been viewed merely as the culmination of what was achieved in childhood followed by a biologically driven decline. To the contrary, contemporary theories and empirical findings suggest that there are dynamic changes in cognition, motivation, and regulatory heuristics throughout the life span.

Multidirectionality in Cognition and Intellectual Function

While there are a number of competing theories for mechanisms that underlie age-related changes in cognition, there is broad agreement that age effects on cognition can be characterized at a coarse level as the result of two competing forces. On the one hand, the senescence process drives a decline in mental mechanics, the capacity to control attention and perform basic mental computations with accuracy and speed. On the other hand, there is accumulating evidence that the brain has immense potential for plasticity into late life; therefore, experience-based articulation of knowledge systems, skill, and expertise offers potential for growth. These divergent trajectories have also been characterized in terms of fluid versus crystallized

abilities, derived from the factor structure of typical tests of intellectual ability. Fluid ability is manifested in tasks that require the encoding and transformation of information and detecting underlying relationships (e.g., block design, digit symbol, inductive reasoning, and spatial orientation). Crystallized ability, or pragmatics, depends on the acquisition of culture (e.g., vocabulary, semantic memory, and world knowledge).

Beyond that first cut, there are various theories characterizing the specific nature of declines in mechanics with age. The slowing hypothesis suggests that aging brings a systematic decrease in the speed with which mental operations can be performed. The WM hypothesis posits that aging is associated with a decline in the capacity to perform basic processing operations and store their products (as might be required, e.g., as one listens to a lecture and tries to construct an understanding of what is currently being discussed and integrate it with what has come before). According to the inhibition deficit hypothesis, aging brings a decreased effectiveness in suppressing irrelevant or no-longer-relevant information, thus reducing the functional capacity of WM. Another recent variant on the WM hypothesis is the effortfulness hypothesis, which identifies sensory loss as a critical contributor to age-related deficits in mental mechanics, not simply because they diminish the quality of information coming into the cognitive system, but also because central resources are strained by effort allocated to interpret the muddled input.

At the same time, aging may bring growth in a variety of capacities. Unlike declines, which come for free as a consequence of the senescence process, growth appears to arise out of dedicated engagement with particular types of experience. Initial conceptualizations of life-span growth focused on the normative development of capacities that could be scaled within a cultural context, for example, vocabulary and areas of common knowledge (e.g., why does bread rise? Who wrote *Huckleberry Finn*?), termed crystallized ability. In fact, vocabulary and some aspects of verbal ability are often found to increase or show stability through adulthood, with some evidence suggesting that such growth depends on habitual engagement with literacy-based activities. More recent conceptualizations acknowledge that normative growth of knowledge within certain cultural contexts early in the life span arises out of age-graded curricula in which there can be considerable commonality in the types of experiences to which children are exposed. However, relative to childhood, experiences in adulthood are more diverse and, rather than arising out of

common school curricula, are tied to occupational and leisure activities. The particularized knowledge and skill systems that develop during adulthood are key achievements during this period and are intimately tied to selective allocation of resources to particular activities. Skill systems can be maintained well into late life, with recent evidence highlighting an important role for deliberate practice.

These two dimensions of intellectual function interact in interesting ways. First, because knowledge growth and skill development require attentional control, expansion of crystallized ability, particularized knowledge, and expertise ultimately depend on fluid abilities to some extent. Consequently, early in the life span, fluid and crystallized abilities grow apace with each other. In midlife to early old age, however, these trajectories diverge; knowledge and skill can continue their upward trajectories, but at a shallower slope as it takes a greater investment in attention to achieve the same gains, relative to earlier in the life span. On the other hand, to the extent that an individual has already invested in creating knowledge structures and skill systems (regardless of age), subsequent growth in those areas can be accomplished more easily. In part, this is because of a greater efficiency in processing information when existing knowledge can support learning. Another factor that contributes to knowledge-driven learning is that knowledge can support attentional control (i.e., effective allocation of effort).

Selectivity

A hallmark of adult development is increased selectivity, the focus of effort on a subset of available options. While the earlier part of the life span is a period in which effort is allocated to hone a diverse repertoire of skills and to expand social networks, movement through adulthood brings a motivational shift toward selectivity. There are two developmental forces that drive this.

First, the decline in mental mechanics limits the resources available to promote growth; therefore, selective focus of effort will increase the likelihood that selected domains will thrive. This strategy of selective optimization is distinctively an adult skill, with evidence suggesting that well-being in later life is enhanced by mindful selection of domains to which effort will be allocated toward growth, with the acknowledgment that this will entail loss in unselected domains. Expertise and knowledge systems may enhance selectivity by enabling more efficient focus on the most relevant features of a situation.

Selectivity is also thought to be driven by a changing perspective on the temporal horizon across the life span. Time is perceived to be open ended in youth, with unlimited – and unknowable – possibilities for experience. This expansive temporal horizon engenders concerns with information acquisition, skill development, and enrichment of social networks as a strategy for preparing for an uncertain future. With movement through the life span, the temporal horizon comes into view. Time is not limitless

and choices have consequences that may squander that limited resource. This salience of the temporal horizon may increase attention to emotional concerns and decrease motivation toward purely cognitive goals. This theory has been used to explain, for example, why social networks typically decrease in size but become more emotionally satisfying. One implication of this socioemotional selectivity theory for learning is that cognition itself may be used most reliably in service of emotional goals; therefore, learning is expected to be relatively enhanced in later life if it is well integrated with the socioemotional system.

Self-Regulation

Another theme that emerges in adult developmental theory is the extent to which aging brings a change in the ability to engage processing resources for learning. While adult education textbooks often proclaim that adult learning is self-directed, the ability to self-initiate and self-direct learning may well depend on the level of existing knowledge and skill in the domain. In fact, one theory of cognitive aging holds that it becomes more difficult to self-initiate processing and that age-related difficulties in learning can be ameliorated to a large extent by the availability of environmental supports to guide processing.

Beliefs about one's capacity to accomplish cognitive and intellectual tasks appear to play a critical role in learning throughout the life span, but these may be particularly important in later adulthood and old age. Two related constructs that have received a lot of attention in the literature are self-efficacy and perceived control, each of which appears to be domain specific (e.g., one can conceive of being able to master health-related behaviors, but be undone by a cognitive task like filing a tax form). Self-efficacy is the confidence that one can execute the behavior or process necessary to achieve the desired outcome; perceived control is a multidimensional construct defining beliefs about the locus of control for achieving desired outcomes, with internal control reflecting beliefs of personal efficacy in achieving outcomes, and external control (chance or power others) reflecting beliefs that control of achievement rests with other sources. Relative to younger adults, older adults are sometimes found to have reduced levels of self-efficacy and may be more likely to believe that there are other people who will be able to control cognitive outcomes. To some extent, certain effects of aging are beyond our control; therefore, such beliefs may arise, in part, from an overgeneralization of a veridical perception. Another factor that may contribute to these beliefs is negative aging stereotypes, which can be internalized, and thus reduce effort to cognitive performance. In any case, such beliefs can become self-fulfilling prophecies. In fact, individual differences in self-efficacy and control beliefs can often account, in part, for age differences in cognitive performance, effects that are themselves sometimes mediated by strategy utilization.

Learning through Adulthood

Memory and Aging

Memory is among the first cognitive domains to be studied through adulthood and it remains a complex and vibrant literature. Memory is often conceptualized as involving three stages: encoding of information into a relatively durable trace, retention, and retrieval of the information into consciousness. Memory failure is among the most prevalent of aging stereotypes, and with aging, many adults complain about a difficulty with memory. In fact, age differences in memory performance can depend, to a large degree, on the task conditions, the materials, and the educational levels of the samples compared. Semantic memory (e.g., the meanings of words) and retrieval of well-learned information can show great resilience throughout the life span. By contrast, episodic memory, the ability to associate information with a particular learning context, may show pronounced age differences under some circumstances.

Deficits have been attributed, in part, to the demands that effective encoding places on mental mechanics and attentional control. Normatively, in an episodic memory task, older adults may be less likely to encode information in a way that is organized, elaborate, and distinctive. Critically, older learners have a more difficult time forming new arbitrary associations. Fairly modest interventions (e.g., instruction in organizational strategies) can improve memory performance. Interestingly, even though memory training can improve performance into very late life, training gains are typically greater among the young, suggesting that it is ultimately age-graded declines in mental mechanics that limit how well these strategies can be implemented.

Age changes in the effectiveness of episodic memory can also be attributed to retrieval. For example, age deficits in memory performance are often exaggerated in free recall relative to recognition or cued recall, a difference that presumably resides in the reduced demands to generate the information. In recognition, older adults are more likely to rely on familiarity rather than direct recollection.

Difficulty with name retrieval is one of the more common memory complaints. Aging does bring more tip-of-the-tongue experiences, in which an individual knows the word he/she wants to say but is unable to retrieve any of the phonological information. This is most likely to happen for relatively rare words or for infrequently encountered names. Happily, these are most typically resolved, even among older adults.

Learning from Text

Learning from text is often conceptualized as involving distinct processing systems that operate in concert to construct different facets of the language representation. At the surface level, individual lexical items (words) are encoded from the orthographic or acoustic signal and their meanings are activated. The semantic representation can be described

in terms of integrated ideas (or propositions) that establish relationships among concepts described by the text, a representation called the textbase. Knowledge plays a role in facilitating integration, enabling elaborative inference, and evoking a simulation of the situation suggested by the text. Consistent with the divergent age trajectories of mechanics and knowledge-based processes, age deficits are more likely for the resource-consuming aspects of language processing.

Understanding words

Vocabulary often shows an increase with age, particularly among those who are regularly exposed to text; therefore, word recognition and word-level comprehension appear to be highly resilient in reading. Visual-processing declines can impact reading rate, especially if the font is small or hard to decode. In speech processing, declines in auditory processing can make spoken word recognition more demanding; therefore, more acoustic information is needed to understand individual words. Such effects may not merely disrupt encoding of the surface form, but also tax WM resources that would otherwise be used to construct a representation of the text's meaning. For example, elders with normal and impaired hearing listening to a word list interrupted periodically to report the last word presented may show negligible differences; however, if asked to report the last three words, the hearing-impaired elders will show deficits. The explanation for such a provocative finding is that the hearing-impaired elders overcome a sensory loss at some attentional cost so as to exert a toll on semantic and elaborative processes that enhance memory. Presumably, the same mechanisms operate in ordinary language processing. At the same time, there is evidence that older adults can take differential advantage of context in the recognition of both spoken and written words, especially in noisy environments. One area of difficulty that older adults may have in word processing is in deriving the meaning of novel words from context, with research showing that older adults are likely to infer more generalized and imprecise meanings relative to the young, a difference that can be largely accounted for in terms of declines in mental mechanics.

Textbase processing

Older adults typically show poorer memory for the content expressed directly by the text. Processes used to construct the textbase (e.g., to instantiate and integrate concepts in the text, essentially an associative memory task) are among the most resource-consuming of those required in learning from text and are, hence, the most vulnerable to aging. When reading is self-paced, older adults require more time for effective propositional encoding (e.g., as indexed by effective reading time, the time allocated per idea unit recalled). In listening, when the pace is controlled by the speaker, older adults may have particular difficulty in understanding and retaining the information, especially as

informational density is increased or in noisy environments. Older adults appear to have no difficulty drawing anaphoric inference (i.e., correctly identifying the referent when the pronoun is used to refer to a noun that was introduced earlier) over short distances, but may find it difficult when the pronoun and referent are separated by intervening text. Thus, the general impression from this literature is that the semantic (textbase) representation is more fragmented and less distinctive as a function of aging.

There is an important exception to age declines in text memory that appears to derive from socioemotional selectivity. That is, memory for text may be very good if it is consonant with emotional goals or if the task is embedded in a social context. For example, it has been reported that emotional content in narratives (e.g., characters' emotional reactions) is well retained among older readers relative to emotion-neutral information. It has also been reported that age differences in narrative memory may be minimized if there is a social goal (e.g., tell a story to a child) as opposed to an information-acquisition goal (e.g., recall the text to an experimenter).

Situation model

Aside from deriving ideas directly from the text, learning from the text also involves elaboration on these ideas based on existing knowledge. Some theories focus on the perceptual quality of this level of representation, which gives rise to a perceptual simulation of the events described by the text. Therefore, for example, in narrative understanding, readers track goals and emotional reactions of characters as well as their movement through space and time. Behavioral methods to study this level of representation include probe recognition for objects in the narrative, as well as reading time, both of which show subtle effects of situation model processing. Readers are slower to verify the existence (in the narrative world) of objects that are spatially distant from the protagonist relative to those that are nearby. Readers also slow down when new characters are introduced, or when there is a spatial discontinuity (e.g., the locus of narrative events shifts from the village to the castle) or a temporal discontinuity (e.g., *The next day...*). When the text describes a goal to be achieved (e.g., Susan intends to buy her mother a purse for her birthday), the goal is activated in memory until it is achieved; therefore, concepts related to the goal are more quickly verified as long as the goal is open (e.g., purse will be more quickly verified if Susan can find the purse when she goes to the store relative to a condition in which she could not find one). To the extent that these paradigms have been used to explore adult age differences in situation model processing, there has been very little evidence of developmental differences in situation construction and updating; if anything, attentional allocation to situation construction may increase with aging. This is important because it suggests that the experiential aspects of reading and language understanding

(i.e., the phenomenal experience of entering the world described by the discourse) are resilient or even enhanced through adulthood. In addition, to the extent that perceptual simulation is required to understand expository or procedural text (e.g., how the heart works or how to put together a grill), the preservation of situation model processing may enable authentic learning from text – even if measures of explicit recall might suggest otherwise.

Older adults may particularly rely on the situation model to support textbase processing. For example, in ambiguous text (e.g., “The strength and flexibility of this equipment is remarkable. Not everyone is capable of using it even though most try at one point or another. . .”), older readers take differential advantage of titles (e.g., driving a car) that disambiguate the meaning to facilitate processing. Since the title renders the situation instantly transparent, both younger and older adults are more efficient in reading when it is available; however, older adults show this effect to a larger degree.

To the extent that the hallmark of situation model processing is an integration of textbase content with knowledge, one might expect that older adults would be particularly adept at inferential processing; however, this is not always the case. While older adults are more likely to draw elaborative inferences (e.g., in recall, to annotate their recollections with personal experiences or related information learned in another context), if inference is constrained so that it requires retrieval of textbase content, age deficits are the norm.

Discourse structures and context

Beyond sentence processing, different genres of text have characteristic forms. For example, narratives typically begin by introducing a setting and characters and proceed to describe a series of episodes in which goals or problems are introduced to be resolved, and so on. Expository texts have certain characteristic forms of argumentation (e.g., problem–solution and thesis–evidence). Older readers generally appear to track these larger discourse structures in the same way as the young. Adult readers have also been shown to benefit from explicit instruction in discourse forms to enhance memory and understanding.

Cognitive Reserve: Lifelong Effects of Education

Differential Developmental Trajectories as a Function of Education

A growing body of evidence suggests that there is a relationship between early educational experiences and cognitive development in adulthood. Numerous studies linking education and cognition have found that greater educational attainment is associated with higher levels of cognitive performance and lower risk for the development

of Alzheimer's disease. Although the mechanisms for education–cognition relationships remain unclear, four plausible explanations have been suggested, which may be operative individually or interactively. First, educational level may be a marker for innate levels of vitality or for capacities that are developed very early in the life span, such that those who are initially more able are also more likely to succeed in the educational system. Second, educational experiences early in the life span may expand neural networks, so as to create a lifelong cognitive reserve that enables relatively high levels of cognitive functioning even as the senescence process winnows neural connections later in life. Third, early educational experiences may be related to cognition through their association with socioeconomic status; therefore, it is socioeconomic advantage that enables lifelong conditions (e.g., nutrition, leisure that affords regular exercise, and medical care) that promote health and, thereby, successful cognitive aging. Finally, educational attainment may afford self-regulatory skill that promotes lifelong mental stimulation. Since educational experiences often lead to occupational, professional, and leisure experiences that provide intellectual challenge in domains in which one is invested, it may be that lifelong patterns of mental stimulation promote neural health, thereby engendering cognitive vitality. It is this latter possibility that is particularly exciting, and an important thrust of recent research in psychology, cognitive neuroscience, and education.

Cognitive and Neural Plasticity

In fact, there is growing evidence from animal models and human research that exposure to stimulating environments promotes neural growth and cognitive vitality. Studies that have administered cognitive training or practice sessions have revealed that the cognitive abilities of older adults show considerable plasticity. For example, the Advanced Cognitive Training for Independent and Vital Elderly (ACTIVE) trial is a randomized clinical trial to examine the effectiveness and durability of cognitive interventions on basic cognitive processes (memory, reasoning, and speed of processing). Results to date indicate that, in spite of the fact that each intervention has targeted a domain tapping into mental mechanics, training effects are ability specific (e.g., increased speed of processing does not transfer to better reasoning or memory). Interestingly, these effects have been shown to be durable up to 5 years. Such data not only provide evidence for the modifiability of cognitive abilities into late life, but also demonstrate that training effects may be highly selective.

On the other hand, certain conditions appear to enhance executive control (e.g., the ability to switch between two tasks) that may ultimately have the potential to affect a relatively wide array of activities. For example, aerobic exercise can increase executive function throughout

adulthood. Recent evidence suggests that language processing may impact this control function as well, with several recent demonstrations of enhanced executive function among fluent bilinguals who habitually manage two language systems.

There may be limits to plasticity very late in the life span, with some training studies showing reduced effects with increasing age. Such findings highlight the dynamic nature of change during adulthood, and also imply that cognitive vitality past the age of 85 or 90 years may depend on the cognitive reserve established up to that point.

Neuroimaging studies offer further insight into how the brain is shaped by learning and experience, in particular, showing effects that are specific to experience. For example, adults with long-term experience in navigation show enhanced neural development in brain regions thought to be responsible for spatial processing (posterior hippocampus). Experimental studies in which individuals are randomly assigned to receive training in a particular skill (e.g., juggling and videogames) show distinctive patterns of change in neural structure and function (e.g., among jugglers, bilateral expansion of mediotemporal and left posterior parietal areas, thought to be responsible for visual storage and processing).

At the same time, older adults may show compensatory patterns of resource allocation and neural recruitment. In a number of different task domains, neuroimaging data have provided evidence that older adults show reduced hemispheric asymmetry in activation patterns, demonstrating expanded recruitment of brain regions from both hemispheres. Older adults, especially those with relatively better performance, are likely to show greater activation of the prefrontal cortex, suggesting that successful cognitive performance may increasingly require executive attentional control with age. Interestingly, recent research also suggests that increased frontal recruitment with aging may be exaggerated among those with relatively high levels of education, providing some support for the self-regulatory account of education–cognition relationships.

Conclusion

This article has discussed the dynamic interplay between cognitive development and educational experiences throughout the life span, so that trajectories of adult cognitive development must shape educational practices and educational practices can promote cognitive vitality. Within this framework, education throughout the life span becomes a public health issue.

Sociologists have distinguished between age-segregated and age-integrated social structures. In age-segregated structures, permissible social roles are tightly tied to chronological age (e.g., education during youth and work during midlife). Within developed countries, advances in

medicine and health practices have stimulated a worldwide shift in demographics toward older populations, such that age segregation is no longer a tenable model. Life is simply too long now: effective work cannot rest on temporally removed education, and intellectual engagement is critical to vitality at every stage of the life span.

Vygotsky and Recent Developments

J V Wertsch, Washington University in St. Louis, St. Louis, MO, USA

© 2010 Elsevier Ltd. All rights reserved.

The study of learning and cognition has been heavily influenced by the ideas of Lev Semënovich Vygotsky. Vygotsky was born in Byelorussia in 1896 and spent the most important period of his professional life working in research and educational institutes in Moscow, where he died of tuberculosis in 1934. During his short life, Vygotsky addressed a remarkable range of topics in philosophy, psychology, semiotics, pedagogy, and literary analysis.

Vygotsky's works fill more than ten volumes, most written during the final decade of his life. His ideas have spawned a new round of research in the post-Soviet years, including intellectual biographies and analyses of how his ideas are tied to those of other major figures of his time such as Gustav Gustavovich Shpet.

Vygotsky's contributions to contemporary psychology can be spelled out in terms of three general themes that run throughout his writings. To one degree or another, these themes also characterize much of the writing of contemporary researchers influenced by Vygotsky, researchers who have developed ideas about cultural–historical and sociocultural approaches to psychology, and they characterize much of the writing on activity theory as well. These themes can be stated as follows:

- Cognition must be understood developmentally (i.e., genetically) in terms of its origins and subsequent development at individual and cultural levels of analysis.
- Cognition is mediated by semiotic mechanisms, especially natural language.
- Higher (i.e., uniquely human) mental processes such as problem solving, voluntary memory, and voluntary attention have their origins in social activity.

All of these themes reflect the general idea that mental functioning in the individual is fundamentally shaped by the social and historical context. Instead of focusing on how individual mental processes are made manifest in social expression, Vygotsky focused on how social expressions become manifest in individual mental processes.

Although such an approach emphasizes the social world, social interaction, and what Vygotsky termed intermental functioning, it does not amount to some form of social reductionism. Individual agency is still a central part of the picture. Like Mead, Vygotsky postulated that the key to understanding higher mental processes is how individuals participate in, and appropriate, social processes. In a nutshell, the approach asserts that developmental or genetic analysis must be employed to study how

processes that originate in social action shaped by semiotic mediation are transferred to the individual plane and shape higher mental processes.

Genetic Analysis

Vygotsky approached the early years of ontogenesis in terms of the interaction of two lines of development: the natural and the cultural, and he viewed the qualitative transformation of mental functioning that results from this interaction as key. He viewed any attempt to reduce all mental functions to amalgamations of lower order, biologically driven stimulus–response patterns as fundamentally misguided. The development of will or volition, for instance, is not to be seen as growing out of an iterative process of stimulus–response mechanisms, but as a qualitatively different type of phenomenon grounded in social processes. This was part of his effort to avoid the traps of the associationist and other reductionist approaches.

Like other major developmental theorists of his day, Vygotsky did not view developmental analysis as applying only to ontogenesis, and although much of his empirical study focused on children, he by no means assumed that developmental analysis could be equated with child psychology. Instead, it applies to several, qualitatively distinct genetic domains (Wertsch, 1985), namely phylogenesis, sociocultural history, ontogenesis, and microgenesis. As such, his notion of developmental psychology was much broader than what is often assumed in contemporary writings.

Vygotsky's approach to genetic analysis tends to interpret cultural differences in terms of developmental hierarchy, something that is no longer readily accepted by many cultural anthropologists. In their comparative studies of abstract reasoning in the 1930s, for example, Vygotsky and Luria interpreted differences between Uzbek and Russian performance as reflecting different stages in a grand developmental hierarchy. For them, this was what might be termed a cross-historical, rather than a cross-cultural study since they interpreted differences in the groups' performance as reflecting different stages in the evolution of a single general form of human civilization. The findings from these studies and the methods Luria used to generate them continue to provide inspiration for empirical research today. For example, a great deal of fruitful work over the last three decades on

cross-cultural comparisons of the psychological effects of literacy and schooling stems from the ideas of Vygotsky and Luria.

Contemporary modes of interpreting empirical findings, however, are quite different from what Vygotsky and Luria used. While accepting genetic analysis as a valuable technique in domains such as sociocultural history and ontogenesis, investigators today are likely to reject Vygotsky's assumption that cross-cultural differences can somehow be reduced to cross-historical differences. At least since the work of Franz Boas (1966) and Edward Sapir (1921), this assumption has been highly suspect in disciplines such as cultural anthropology in the US and Europe. Specifically, any tendency to view cultural differences in terms of historical evolution is likely to lead to charges of Eurocentricism since it is virtually always the case that the perspective used to do the comparing turns out to be at the top of the developmental hierarchy. Even with this caveat, however, Vygotsky's ideas have had a powerful impact on cross-cultural comparisons of cognition and other forms of mental functioning (Cole, 1996).

Mediated Nature of Human Mental Functioning

For Vygotsky and sociocultural approaches to cognition in general, the key to development is that social interactions are mediated by semiotic systems, most importantly language. His emphasis was on how forms of language use that shape human communication are appropriated by children in the development of cognitive processes on the individual plane. Vygotsky made increasingly strong claims toward the end of his career to the effect that an understanding of language and other cultural tools provides the foundation for the rest of his approach. Under the general heading of psychological tools, he included "language; various systems for counting; mnemonic techniques; algebraic symbol systems; works of art; writing; schemes, diagrams, maps, and mechanical drawings; [and] all sorts of conventional signs" (Vygotsky, 1981a: 137). Researchers such as John-Steiner (1991) have explored the role of symbol systems including drawing, gesture, music, or diagrams in the development of cognition.

An essential aspect of Vygotsky's treatment of mediational means is that its incorporation into human action (including mental functioning) does not simply make this action easier or more efficient in some quantitative sense. Instead, its incorporation typically results in a qualitative transformation. In his view "by being included in the process of behavior, the psychological tool [sign] alters the entire flow and structure of mental functions. It does this by determining the structure of a new instrumental act, just as a technical tool alters the process of a natural adaptation by determining the form of labor operations" (Vygotsky, 1981a: 137).

Vygotsky's emphasis on language as a cultural tool is evident in the writings of his followers as well. For example, Luria (1982) argued that just as mastery of a physical tool transforms human physical activity, mastery of the symbolic tool transforms human mental activity:

Language, in the course of social history, became the decisive instrument which helped humans transcend the boundaries of sensory experience, to assign symbols, and to formulate certain generalizations or categories. Thus, if humans had not possessed the capacity for labor and had not had language, they would not have developed abstract, "categorical" thinking. (p. 27)

Such studies by Vygotsky and his colleagues reveal that they tended to view language and other cultural tools as always working in favor of more advanced human functioning, as inevitably leading to more sophisticated performance. Other analysts have challenged Vygotsky's relatively uncritical stance toward mediation and have explored ways in which cultural tools constrain as well as facilitate action. These critiques suggest that language and other cultural tools may restrict, as well as enable activity often because they emerge or are privileged for reasons other than to facilitate the action in which they are eventually embedded.

The study of forces that give rise to cultural tools has not usually been the main focus of analyses of mediated action, but there are a few general points to make nonetheless. Perhaps the most interesting of these is that many of the cultural tools employed in mediated action were not designed for the role they have come to play. An illustration of this can be found in the keyboards used to type in English. Almost all users of such keyboards use the so-called QWERTY version, named after the fact that these letters are located at the upper left-hand portion of the array. Unless otherwise informed, most users of this keyboard assume that it was designed to facilitate their typing. In actuality, however, just the opposite is the case from today's perspective. The QWERTY keyboard was designed in an era of mechanical typewriters when the biggest impediment to efficient typing was having two or more keys jam together. As a result, the designers of the QWERTY keyboard specifically devised it to slow typists down.

With the appearance of electric typewriters and word processors, there is obviously no such need to slow typists down. Nevertheless, the vast majority of individuals who type in English continue to use the QWERTY keyboard, something that is made all the more striking by the fact that there is a readily available alternative keyboard design that is superior for most typists in terms of speed and accuracy. For example, the Dvorak keyboard is relatively easy to master, and most computer keyboards can easily be converted to its configuration.

The fact that the vast majority of individuals typing in English continue to use the QWERTY keyboard speaks

of the power of historical, economic, and other forces in shaping the cultural tools we employ. It also speaks of the tendency to use whatever psychological tools are handed to us in an uncritical way. This suggests that many of these tools may not be designed, or may not have evolved to facilitate the forms of mediated action in which they are currently employed. The particular case of the QWERTY keyboard is sometimes viewed as an isolated example of how technological and economic forces can go wrong. However, as authors such as Norman (1993) have argued, institutional, cultural, and historical forces often result in technology that is far from ideally designed from the perspective of the user, and this raises the question of whether similar issues might not be involved for all sorts of cultural tools.

The history of natural language presents an intriguing set of problems from this perspective. For the most part, language is not consciously planned or designed, a point that makes it somewhat different from the QWERTY keyboard example. However, many of the lessons of this illustration apply to language as well. For example, literacy and its impact on social and individual action raise several interesting questions. Literacy skills acquired in formal educational settings are associated with a specific set of cognitive skills, and the kind of language use required in formal literacy training is related to a willingness and ability to engage in tasks such as syllogistic reasoning.

However, it is generally accepted that literacy did not emerge in human history as part of an effort to facilitate skills such as those required in abstract reasoning tasks. Instead, literacy emerged in response to needs such as keeping records and conducting communication about commercial transactions. Furthermore, specific writing systems have often emerged when speakers of one language have borrowed the script used for another. Such facts serve to reinforce the claim that many cultural tools arise in response to forces that have little to do with the range of functions they are eventually required to serve.

In summary, cultural tools are often not simply neutral cognitive instruments. Instead, they may introduce historical and political dimensions into mental functioning and its socialization. Indeed, the distribution of psychological tools is often part of larger sociocultural debates and social differentiation. An example of this can be found in debates in the US surrounding the efficacy of Spanish or African-American vernacular as classroom instructional languages. These debates provide stark reminders that all mediational means are not equally valued in a society. Nor are they made equally available. This of course also applies to the distribution and use of tools such as computers in modern societies. The digital divide in the US means that computers may be widespread in many well-funded public and private schools, and all but absent in low-income urban or rural schools.

This suggests that cultural tools are implicated in the reproduction of social hierarchies. Many analysts of learning and cognition may consider these issues to be outside the boundaries of their area of inquiry, but to the extent that sociocultural psychology is concerned with the intersection of human mental functioning and the institutional, historical, and cultural contexts in which it occurs, it must take account of the social and political aspects of cultural tools. As scholars such as Duncan (1996) suggest, those working within a Vygotskian tradition must critically appraise the function of cultural tools and pattern of access to social spheres that they afford.

Social Origins of Individual Mental Functioning

In his approach to human mental functioning, Vygotsky outlined an account that began with action, namely mediated action (Zinchenko, 1985). Furthermore, he argued that the origins of this action are social, and in this connection he sought the developmental precursors of individual mental functioning in social processes. Perhaps the most general statement of this theme in Vygotsky's writings can be found in his general genetic law of cultural development:

Any function in children's development appears twice, or on two planes. First it appears on the social plane and then on the psychological plane. First it appears between people as an interpsychological category and then within the individual child as an intrapsychological category. . . .but it goes without saying that internalization transforms the process itself and changes its structure and function. Social relations or relations among people genetically [i.e., developmentally] underlie all higher functions and their relationships. (Vygotsky, 1981b: 163)

In this view, human mental functioning originates in inter-individual activities and only gradually develops into intramental processes. The very definition of mind is expanded such that its origins can be traced to activities between people, and the structural and functional organization of mind on the intermental plane provides the foundation for intramental functioning.

An essential part of Vygotsky's formulation of the intermental and intramental planes is that he viewed them as being inherently related. Indeed, the boundaries between social and individual functioning are quite permeable in his account, and his concern was with ongoing transformations between intermental and intramental processes rather than with any sharp distinctions that can be drawn. From this perspective, an element of sociality characterizes even the most private and internal forms of mental functioning:

[Higher mental functions'] composition, genetic structure, and means of action – in a word, their whole nature – is social. Even when we turn to [internal] mental processes, their nature remains quasi-social. In their own private sphere, human beings retain the functions of social interaction. (Vygotsky, 1981b: 164)

This statement does not assume that higher mental functioning in the individual is a direct and simple copy of socially organized processes; the point Vygotsky made in his formulation of the general genetic law of cultural development about transformations in internalization warns against any such view. Furthermore, it does not assume that nothing of interest goes on in the mind or brain of the individual when participating in intermental functioning. Instead, it simply posits a close connection, grounded in genetic transformations, between the specific strategies and processes of intermental and intramental functioning.

Vygotsky's general genetic law of cultural development underlies several aspects of his account of human mental functioning. For example, his research on what Piaget had called egocentric speech convinced him that the origins of children's problem solving and concept development lay not in interaction with the physical environment, but in their participation in social processes. By participating in social interaction, children appropriate certain linguistically mediated problem solving, thinking, and regulatory techniques first for external, social activity, then for individual cognitive activity as well. In Kozulin's (1990) words, "Development is therefore not an unfolding or maturation of pre-existing 'ideas'; on the contrary, it is the formation of such ideas – out of what originally was not an idea – in the course of socially meaningful activity" (p. 114).

The general genetic law of cultural development has received the most attention in the West in its incarnation as the zone of proximal development. The implications of this construct have been examined from perspectives such as general development and learning and psychoeducational assessment. In many cases, Vygotsky's comments about this zone are extracted from the more general context of his argument, and as a result it may be difficult to appreciate that it is just one way that he played out the implications of the general theme about the social origins of individual mental functioning. In fact, he developed the notion of the zone or proximal development fairly briefly on only a couple of occasions in his writings.

Vygotsky defined the zone of proximal development as distance between the performance level of an apprentice operating independently on the intramental plane and the level of intermental functioning involving an apprentice and an expert. It has provided the foundation for analyzing adult-child interaction and instruction; interaction and learning of children with disabilities; assessment; and other purposes.

Vygotsky's discussion of intermental processes has also played a role in the formulation of ideas about socially shared cognition, distributed cognition, and other topics. In several of these cases, the discussion does not posit a transition from the social to the individual plane that Vygotsky mentioned in the general genetic law of cultural development. Instead of speaking of social origins, with the assumption that the primary role of intermental functioning is to give rise to intramental functioning, investigators of socially shared cognition are often concerned with human cognitive activity that remains on the intermental plane. This is now widely recognized in studies of workplace activities, and it has taken on new importance in educational settings as well with the rise of interest in issues such as reciprocal teaching (Palincsar and Brown, 1984) and communities of learners (Lave and Wenger, 1991).

In analyzing these processes, investigators have raised questions about how to understand and assess intermental functioning in its own right, that is, independent of how it may give rise to intramental functioning. This brings with it some interesting new assumptions about how the expression cognitive development is to be used. In contrast to the usual assumptions grounded in methodological individualism (Lukes, 1977), the point is that intermental functioning itself may be examined from the perspective of development. From this perspective, it is appropriate to examine the development of cognition of a group and not just of the individuals in it.

Some dyads and larger groups such as institutions and even entire societies seem to function differently and perhaps at more advanced levels than others. Differences in how institutions think (Douglas, 1986) or societies remember (Connerton, 1989) have long been recognized by anthropologists, sociologists, and other scholars, but such expressions, let alone the conceptual framework behind them are quite alien to most studies of cognitive development.

This raises questions requiring conceptual frameworks that will be quite different from those we currently employ. What does it mean for a group – as a group – to develop cognitively? How can we formulate the processes involved such that they can be studied in some kind of a principled way? How would we go about assessing the relative levels of development of groups? Such issues need to be addressed without falling into the traps of strong versions of collective memory or cognition (Wertsch, 2002).

Returning to the issue of social origins of individual mental functioning as outlined by Vygotsky in his general genetic law of cultural development, it becomes crucial to consider how the transition from intermental to intramental functioning is envisioned. As suggested by Vygotsky, development should not to be understood as simply the internalizing for private uses of what were originally

social forms of behavior. In fact, Cazden (1988) warns against a “mechanical conception of the process of internalization whereby overt social interaction (speaking and listening) becomes transformed into covert mental processes (thinking)” (p. 108).

Instead, during learning activity, a transfer of competence – or the transfer of strategic responsibility – from expert to novice occurs. In the process, both the learner and the activity are transformed. In order for this transfer and transformation to take place, both the learner (novice) and the teacher (expert) must be active partners in the dialog surrounding a task.

This focus on active participation on the part of the tutor as well as the apprentice has been a major theme in the writings of Rogoff (1990) on guided participation. From this perspective, it is as essential to recognize and understand the contributions made by the learner, or apprentice, as it is to recognize those made by the teacher. This amounts to a corrective to what some view as sort of cultural transmission model inherent in Vygotsky’s view, a model in which the learner is taken to have little active role. Instead of being passive recipients of an input or a hypothesis-generating algorithm, children (or adult novices for that matter) are taken to be active participants in the co-construction of conversation and activity. Strategic responsibility for the task is gradually transferred to them, and through activity, they transfer strategies for organizing and monitoring problem solving from the intermental to the intramental plane. On the way, the practice itself undergoes qualitative changes.

Conclusion

This overview of Vygotsky’s model of cognitive development has focused on three basic themes that run throughout his writings. The first of these is the supposition that genetic or developmental analysis provides the foundation for understanding human mental functioning. For Vygotsky, genetic analysis was not simply one among many modes of inquiry – it was the most important and fundamental one. Furthermore, this vision of developmental analysis did not apply only to ontogenesis, but to other genetic domains as well.

A second theme that runs throughout Vygotsky’s writings concerns the mediated nature of human mental functioning. Instead of viewing cognition as a process that occurs within the skin, his approach posits that human mental functioning is typically distributed between active agents and cultural tools. His insights about cultural tools and the mediated action to which they give rise bring with them a range of conceptual implications that are still to be fully explored. Among other things, it leads us to introduce cultural and political questions into the study of cognition by asking where the cultural tools that shape

cognition come from and whether they are accessed in equal or unequal ways in the contemporary world.

The third theme in Vygotsky’s writings concerns the social origins of individual mental functioning. This constitutes a second sense, along with mediated action, in which Vygotsky viewed mind as extending beyond the skin and as being distributed. His claims about how higher mental processes appear first on the intermental, and then on the intramental planes of functioning underlie many other aspects of his thinking, including his claims about the zone of proximal development.

Although Vygotsky died in 1934, many of his ideas have come to have a powerful impact on discussions of cognitive development only over the past few decades in the West. This impact has grown drastically as contemporary researchers continue to employ his theoretical claims to formulate new empirical studies. There is every reason to expect this trend to continue as we focus on how cognitive development occurs in complex sociocultural settings.

Introduction

What is the causal impact of emotion on cognition, and of cognition on emotion? Although this question is as classical as the one about, for example, the relation between nature and nurture, or consciousness and unconsciousness, it is not possible at this time to find a mapping of its possible answers within the fields of educational and psychological sciences. The investigation of the causal relation between cognition and emotion within these fields can be characterized as a disparate archipelago of research islands each somewhat isolated from the others and often covered or surrounded by an almost impenetrable fog. This article presents a representative map of this territory.

Why is it important to address the nature of the causal relation between cognition and emotion? The reasons are multiple. First, this question is interesting as a fundamental concern of human psychology that has attracted relatively little empirical attention. Of more than 200 000 psychological and educational publications (articles, book chapters, and books) including in their title the terms cognition or emotion (or equivalent terms such as intelligence, intellect, reasoning, mood, feeling, or affect), less than 4% include both terms (source PsycINFO and ERIC, May 2009). Moreover, of this 4%, almost all investigate cognition and emotion as the cause or the effect of a third phenomenon (e.g., the impact of gender on cognition and emotion or the impact of cognition and emotion on music). Few studies address the causal relation between cognition and emotion

and, when they do, it is typically in one direction. Second, a better understanding of the causal relation between cognition and emotion could improve our understanding of both phenomena via the analyses of a sometimes underestimated dimension of their nature; that is, the emotional nature of cognition and the cognitive nature of emotion. Third, within pragmatic or applied contexts, such as educational settings, these two phenomena are currently assessed independently; for instance, educational attainment and behavioral/emotional problems are known to be linked but are treated as separate domains. Improved understanding of the relation between children's cognitive and emotional development should contribute to the elaboration of integrated methods for assessment and treatment or intervention; not just for atypical children, for all those within an educational setting. Last but not least, most cognition and emotion researchers and professionals within psychology and education recognize that cognition and emotion are in some sort of relation. Yet, most of the time, such individuals are quite ignorant of each other's expertise or hold false beliefs about one another even when they work in the same institution. For these four reasons, among others, the simultaneous consideration of cognition and emotion, and the nature of their relation, has much to offer.

Why does the nature of the relation between cognition and emotion still remain so open today? There are at least two reasons: the oldness of the schism between these two domains of psychological and educational enquiry, and the relative youth of affective sciences (i.e., the scientific

study of emotions, moods, and feelings, and their constitutive elements). Indeed, the failure to provide integrated accounts of cognition and emotion as psychological phenomena has its roots in the history of philosophy, within which there is a classical distinction between reason and the passions, reason having been given pride of place in philosophical enquiry. Solomon explains the persistent failure to integrate these two domains as a function of the inferior role accorded to emotion, beginning with Plato, and the fact that emotion and cognition have been treated as though they are different kinds, thereby excluding the necessity of simultaneous consideration (Solomon (2000) in Lewis and Haviland-Jones (2000)). Pascal (1670/1998) eloquently captured this latter distinction when he said, “The heart has its reasons that the reason does not know.”

Contemporary cognitive science continues to be dominated by a preoccupation with cognition as a cold phenomenon. Predominantly, emotion is not considered or it is viewed as a confounding variable. When emotional and cognitive phenomena are considered together, emotion is often treated as a heating process, not directly integrated with cognition but causing spikes in temperature that interfere with cognitive processes.

The cognition–emotion dualism is to a great extent perpetuated methodologically within contemporary psychological and educational sciences. Indeed, in experimental sciences, you cannot study everything at the same time; it is very difficult to be simultaneously deep and broad. The fine-grained questions of experimental sciences need focused methods and are, in many cases, deeply connected to certain procedures such as reaction time or failure–success paradigms. By contrast, the study of emotion has relied to a great extent on subjective self-report at one end of a spectrum, and expressive behaviors (e.g., facial expressions) or physiological measures (e.g., blood volume pulse) at the other end of the spectrum. Such methodological disparities are lessening as a function of the rapid growth in neuroscientific methods (e.g., functional magnetic resonance imaging (fMRI), positron emission tomography (PET), second-generation electroencephalography (EEG)) but it remains unclear when we will be able to identify and assess both cognitive and emotional functions unfolding in real time: this is a goal for the future. In the meantime, cognitive scientists and emotion researchers very often talk a different talk and walk a different walk.

As indicated earlier, the affective sciences are still relatively young. It is also notable that they have to some extent define themselves against a backdrop of cognitivism – just as the cognitive scientists once defined themselves against behaviorism. Whereas the demise of behaviorism opened the way to studying cognitive processes within the black box, the affective revolution no longer considers persons merely as cognitive processors, more or less similar to Turing machines, and has allowed scientists to ask what

was happening in the heart of people: emotion has become an object of scientific enquiry to be described, explained, predicted, and even transformed. At one end of the methodological spectrum, private, conscious experiences such as feelings and moods and their self-report via introspection are again considered as legitimate scientific objects and methods. At the other end of the spectrum, neuroscientific methods raise the possibility that scientists will find some of the physical correlates of peoples’ subjective experiences, thus reinforcing their status as a legitimate object of scientific enquiry. Such methods may also undermine the dominant dualistic attitude in psychological and educational sciences regarding the mind–body relationship: they open a space where the study of emotion can take place (as the missing link) between the mind and the body.

The rest of the article is divided into four sections. We start with a short discussion about the meaning of emotion and cognition. Then we discuss the straightforward conceptions of the causal relationship between cognition and emotion: cognition as a cause of emotion, and emotion as a cause of cognition. In the conclusion, we speculate about the circular causal relationship between cognition and emotion and about some promising future research and intervention programs.

The Problem of Definition

Problems surrounding the meaning of cognition and emotion are at least as old as psychological and educational sciences. The question of how to define these terms is sometimes construed as a false problem with no existence, a real problem with no solution, or a problem with as many solutions as people trying to resolve it! It is not the function of the article to offer a definitive definition for each term but, rather, to consider how the two constructs have been related to one another. Nevertheless, it is important to set out the scope of these terms as they are used in the psychological and educational sciences. Indeed, many misunderstandings and conflicts centered on the relation between cognition and emotion are related to the absence of a common understanding of the phenomena in question and to the overgeneralization of some quite specific definitions.

Here, cognition refers to the different forms of knowledge (e.g., belief, thought, etc.) that we have and, critically, to the mental functions (e.g., systems, schemas, processes, etc.) making the acquisition, storage, retrieval, transformation, and use of this knowledge possible, for example, memory, attention, intelligence, language, mental imagery, and so on. This knowledge can be empirically or logically true or false, real or unreal, and more or less certain. It can be more or less simple or complex, sensory or symbolic, temporary or permanent, general or specific, conscious or unconscious, controllable or uncontrollable, and universal or idiosyncratic.

Importantly, it is traditionally held that knowledge is (usually implicitly) rule bound or structured and that the mental functions operate in accordance with such rules; for example, knowledge of language implies some form of syntax (that is consciously inaccessible to language users without formal education). Finally, such knowledge and mental functions are considered as interrelated states and processes of the mind (e.g., subjective experience of the color red), the body (e.g., neuronal correlates associate with the perception of the color red), and the culture (e.g., words to represent the color red: red, *rod*, *rojo*, rouge, etc.).

Emotion, on the other hand, is a class of feelings directed to objects, where objects include persons, things, and situations, both real and imagined. Emotions can be pleasant or unpleasant and more or less intense or moderate, but they can be differentiated from sensations and states of bodily arousal because of their inherent aboutness (i.e., intentionality) and their close connection with actions (Kenny, 1963). Emotions can be more or less basic (e.g., happiness, anger, fear, sadness, disgust, or surprise) or complex (e.g., guilt, shame, pride, jealousy, and mixed emotions), sensory or symbolic/abstract, temporary (e.g., sadness about a specific event) or enduring (e.g., an ongoing depressive mood), conscious or unconscious, controlled or uncontrolled, general or specific, and universal (e.g., fear of death) or idiosyncratic (Spanish Duende, Portuguese Saodade, etc.). Not all these aspects of emotion are uncontested, of course, but they fall under the common sense notion of emotion and the emotional lives of persons. Emotions are generally thought to be organized in that they are discrete (particularly in childhood) and they have their own natural history: certain situations and thoughts, as well as expressions and states of the body, are universally constitutive of specific emotions presumably because of our evolutionary origins (Darwin, 1872/1899; Ekman, 1999 in Dalglish and Power, 1999; Lazarus, 1991). Finally, emotions are interrelated states and processes of the mind (e.g., subjective experience of happiness about or of something), of the body (heart rate changes, respiration rate, muscle tension, pupil dilatation, etc.), and of the culture (e.g., the social and cultural norms related to the feeling of anger).

In the foregoing discussion, we have provided a sketch of emotion that is clearly cognitive in some sense: That is, the inherent aboutness of emotion entails that an emotion has cognitive content. For example, we are scared of the ferocious dog or happy about recent political events. The object of an emotion (e.g., the ferocious dog) and the beliefs on which an emotion is founded (e.g., that ferocious dogs may do us an injury) have a conceptual rather than a causal relation to the emotion (see Solomon, 2000 in Lewis and Haviland-Jones (2000) for a discussion). In the following sections, however, we take as a starting point the historical assumption that emotion and cognition may be treated as separable phenomena that

may stand in a cause or effect relations to one another – an assumption that may ultimately unravel.

Before we embark on this discussion, however, consider some research that suggests that emotional responses can occur before there is time for any cognitive processing (even unconscious). For example, LeDoux (1996) demonstrated that some emotional answers, taking place within a few milliseconds (e.g., fear of already known stimuli) result from an immediate mid- and lower-brain (i.e., the amygdala and the thalamus) response to a stimulus and can be produced without the involvement of the cortex, where cognitive processes are assumed to take place. It should be noted, however, that LeDoux also showed that learning a new emotional reaction to a stimulus involves the (sensory) cortex and therefore, it is reasoned, some cognitive processing, until this emotional reaction is completely automatic. Interestingly, to the best of our knowledge, no experimental study has tried to demonstrate that cognitive answers can be produced without being linked to emotion (e.g., without the emotional areas of the brain being involved), though this seems entirely plausible.

Cognition as a Cause of Emotion

Until 30 years ago, explanations of emotional phenomena had been preoccupied mainly with the body. Two hypotheses were then in competition: the James-Lange and the Cannon. In a nutshell, the former postulated that emotions resulted from subjective perceptions of bodily states (e.g., we are sad because we cry) and the latter postulated almost the opposite (e.g., we cry because we are sad). The debate about the relation between the subjective experiences of emotions and their body correlates is still very much alive (e.g., Cacioppo *et al.*, (2000) in Lewis and Haviland-Jones, 2000; Damasio, 1994; Ekman and Rosenberg, 2005).

With the affective revolution, however, attention shifted to the role of cognition – specifically, the role of cognitive appraisal or evaluation. Schachter and Singer (1962) were among the first to give an empirical demonstration of the existence of this kind of appraisal. They injected people with adrenaline. One group was told that the injection would have an impact on their heart beat (which was true) while a second that it would have no impact (which was untrue). Although, the two groups had the same bodily experience (increase of heart beat), only the second group of people reported feeling emotions. Moreover, when the second group was exposed to a happy person, they reported happiness, and anger when exposed to an angry person (these emotions were feigned by actors present in the room with the subject).

The cognitive-appraisal hypothesis has been the object of active debate (see Lazarus, 1982, 1984 in Lazarus, 1991; Zajonc, 1980 in Zajonc, 1984) and criticism (see Reisenzein (1983) for a review): is cognition (whether conscious or not)

a necessary (albeit nonsufficient) condition of emotion? Nevertheless, the basic premise that cognitive appraisal often has an influence (both as an antecedent and as a modulator) on emotional experience (whether that be the valence of the emotion experienced or the level of emotional arousal) found numerous empirical supports (e.g., Frijda, 1986; Roseman, 1984; Scherer, 1984; Smith, 1989), and underpins those cognitive-psychotherapy theories that aim to alter the cognitive-appraisal process in emotional disorders (e.g., Beck, 1976). Several dimensions of the cognitive appraisal of stimuli have been identified: novelty/familiarity, valence, goal/need significance, coping potential, and compatibility with personal and cultural norms (e.g., Kappas (2006) and Scherer *et al.*, (2001) for reviews). For example, a stimulus that is appraised as pleasant (valence) and acceptable (according to personal and cultural norms) could result in feeling happiness.

While there are many variants of cognitive appraisal, they are unified in stressing a very tight and, in most cases, subjectively instantaneous connection between an experienced emotion and the beliefs or thoughts that accompany it. There is, however, another sense in which our emotional experience is affected by our understanding of circumstances: in addition to knowing things about the situations in which we feel emotions, we also have knowledge of emotions (of their nature, causes, consequences, and possibilities of regulation) which has a tremendous potential to impact on our emotional experience by changing the nature of the relation we have to the emotion eliciting circumstances or the emotion itself (e.g., see for reviews, de Rosnay *et al.*, 2008; Haga *et al.*, 2008; Harris, 2006; Pons *et al.*, 2005). For example, between 4 and 5 years of age, children begin to understand the effect of memories on emotions. They realize that the intensity of anger decreases over time; looking at a picture of a lost loved one can reignite sadness; or thinking about a positive past event can cause joy. Development brings further emotion insights. From about 8 years of age, even sooner under certain conditions, children begin to understand how feelings can be regulated via the use of cognitive strategies such as the cognitive re-evaluation of the situation (e.g., “that’s not the end of the world”) and the re-orientation of attention (e.g., “let’s think about something positive”); thus children demonstrate conscious knowledge of the influence of thought process (cognition) on emotions. Consider as an example the well-documented association between depression and the understanding of the strategies to regulate feelings: children and adolescents who think that the use of strategies such as rumination and passivity are better to deal with negative emotions than strategies such as reevaluation of the situation or re-focusing show more depressive symptoms.

Furthermore, there is accumulating evidence that children’s knowledge about emotions has an impact on their emotional experiences and well-being in a social context.

This impact has been identified in both preschool and school children (see Pons *et al.*, 2005 for a review). For example, young children who better understand situation–emotion regularities (e.g., feeling happy when receiving a gift or sad when breaking a toy) are also the most popular with their day-care friends. At 5 years of age, children who are better able to recognize basic emotions are also the most popular with their classmates 1 or 2 years later. The relationship between emotion understanding and social functioning is also seen in middle childhood: 9-year-old children (particularly girls) with a good understanding of negative emotion-regulation strategies are considered, by their classmates and teachers, to be the most socially competent.

Surprisingly, there is relatively little research on the impact of school achievement on emotion. Some studies reveal a complex pattern of relations between positive and negative emotions, and school performance and self-evaluation of academic competencies. The link seems to be stronger between emotions and self-evaluation of academic competencies than between emotions and actual school performances (Gumora and Arsenio, 2002).

Emotion as a Cause of Cognition

It is widely held, in some form or another, that our emotions put us in some kind of meaningful relation to the world: A big ferocious dog is not just a fast-moving, big-toothed, furry creature; it is something to be feared because it is a potential threat to our well-being. How, then, does this meaningful relation between the person experiencing the emotion and the world influence our cognition? The answer to this question, within psychological and educational sciences, is twofold: emotional arousal is considered to be motivational, and emotional valence is considered to be a compass that guides our cognition.

At a general level, emotional arousal has an impact on cognition because it mobilizes the mind, as well as the body and the culture, to act and react (e.g., fear prepares the mind, the body, and the culture for fight or flight). This motivational function is the only one recognized by Piaget (1954/1981). He acknowledged that the intellect needs emotional arousal, which can speed up or slow down the functioning of the intellect and therefore its development. In 1908, Yerkes and Dodson postulated that an appropriate level of emotional arousal is needed to achieve an optimal level of cognitive performance. Too much anxiety (high arousal) or not enough interest (low arousal) might have a negative impact on the cognitive functions. They also postulated a functional relation between emotional arousal and task demands: the more difficult the task, the lower the level of emotional arousal required to reach the optimum level of cognitive performance.

Emotion not only makes cognition move but also orients its movement. Emotional arousal provides energy, whereas emotional valence gives the direction for cognition to move and therefore to develop. This is well illustrated by the behaviorist research tradition. Most classical and operant conditioning would not be possible without emotional valence: Emotional reactions (more or less positive or negative) to a stimulus (more or less conditioned or unconditioned) very often determine the behavioral response to it such as the appearance, disappearance, prioritization, and transformation of the (cognitive) behavior. This compass function of emotional valence for cognition is also recognized by Freud (1905/2002). The expressed or repressed drive coming from the Id not only gives its energy to the cognitive self but also orients (e.g., activation and inhibition) its functioning and development (in collaboration with the cognitive super-ego).

Numerous experimental studies have demonstrated the impact of emotional arousal and valence on cognition (e.g., memory, attention, and creativity). For example, when shown a list of positive and negative words, most people recall more positive words. If these people are clinically depressed, however, then they will tend to recall more negative words especially when these words have a clear negative valence (death, cancer, war, etc.). In a similar vein, typical people recall more elements of a story when the emotional valence of the story matches their own current mood, especially when the story is sad and they are in a sad mood while reading the story. It should be noted that when typical people are in a neutral mood, they remember more positive than negative elements of the story (e.g., Matt *et al.* (1992) for a review). It is as if, by default, when we are feeling nothing or at least at peace, our memory has an emotionally positive orientation, which may be adaptive. Other studies have also shown that the recall of information is facilitated when the mood of the person is the same at encoding and recall, irrespective of the emotional valence of this information. This effect is stronger when the information is autobiographical. For example, the recall of a list of neutral words is facilitated if the person is in a sad mood both when trying to learn (encoding) and to recall this list (see Eich and Forgas, (2003) for a review). Such findings may help to explain why the recall of a traumatic autobiographical event is facilitated when people are already in a negative mood – a vicious cycle recognized by many schools of psychotherapy (Beck, 1976).

Emotional arousal and valence also have a direct impact on attentional processes (Eysenck *et al.* (2007); MacLeod (2005) for reviews). People with mood disorders pay more attention to information (words, pictures, faces, etc.) with an emotional valence matching their mood. For example, depressed people have the tendency to pay more attention to their personal characteristics (internal locus of control) when explaining their failures (e.g., because who I am,

what I did, or what I said) and they pay more attention to their environment (external locus of control) to explain their success (e.g., because of luck, fate, or external events). In stark contrast to typical people, those who are clinically anxious (phobia, posttraumatic stress disorder (PTSD), etc.) direct their attention more toward threatening words (cancer, evil, death, etc.) than neutral words (house, picture, chair, etc.). When confronted with homonym words (e.g., batter-pancake vs. batter-assault), non-anxious people have the tendency to activate the neutral meaning of the word, whereas anxious people have the tendency to activate the negative meaning.

A person's level of emotional arousal and the valence of their emotional experience may also play an important role when constructing new information. Projective tests such as the Thematic Apperception Test (TAT) and the Rorschach are partially built on this assumption. It is argued, for example, that people's emotions determine, via a process of projective identification, their interpretation of reality, especially when this reality is ambiguous (ambiguous inkblots could be interpreted as a loving mother, a threatening father, a lost child, an unfaithful partner, etc.). Attachment theory (Bowlby, 1969/1997) presents us with an interesting illustration of this phenomenon. It is widely held that distinctive patterns of emotion co-regulation in infancy, so-called attachment styles (i.e., secure, ambivalent, avoidant, and disorganized), continue to inform the child's understanding of relationships much later on via enduring cognitive representations of such relationships (i.e., internal working models). Thus, if presented with a quasi-ambiguous picture of a mother and father leaving a child as they go on holiday for 2 weeks, children's understanding and construal of the events depicted are to a great extent determined by their emotional attachment style in infancy.

Of course, emotions may have an impact on other aspects of memory, attention, and creativity (e.g., research on flashbulb memories and autobiographical memory) and more generally on cognition (e.g., intelligence, language, perception, and moral reasoning). It should also be noted that most studies of the impact of emotion on cognition were conducted with adults (e.g., Brennen *et al.*, 2007; Overskeid, 2000). However, findings with children seem to confirm those obtained with adults.

Indeed, a substantial number of studies have shown that emotions such as anxiety (but also joy, pride, shame, and fear) have an impact on several aspects of learning at school: achievement, motivation, interest, goals, metacognition, etc. These studies showed that this impact may differ from one academic domain to another (i.e., mother tongue, mathematics, arts, etc.) and from one pupil to another (i.e., individual differences due to gender) (see Lafortune and Pons 2005 in Pons *et al.* (2005); and Schutz and Pekrun, (2007) for reviews). For example, induced positive mood in children (e.g., a compliment about

clothes) improves their performance in a block-design task, which is a classical measure of intelligence. Anxiety can prevent pupils from exercising all of their capacities and can, in some cases, prevent them from doing any mathematical reasoning altogether. Anxiety also influences the functioning of metacognition. Certain students feel that when mathematical explanations are given, a veil, even a wall, suddenly appears in front of them, stopping them from reaching the concentration level necessary for understanding what they are being shown. They are thus prevented from engaging in the metacognitive processes necessary to solve the problems. More generally, these studies showed that pupils' emotional competences (i.e., their capacity to experience, recognize, express, control the expression of, regulate the experience of, and understand emotions) have an impact on their school achievement.

Until quite recently, most of the studies on the impact of emotions at school had been almost exclusively focusing on pupils. Lately, a new line of research has emerged which suggests some interesting relations. Positive emotions experienced by teachers are related to the level of support from parents and colleagues, and to pupils' cooperative behaviors and learning achievement. Teachers' negative emotions (e.g., anger, frustration, or sadness) stem from the absence of support from colleagues and parents, and are related to pupils' disruptive behaviors. Teachers' emotions also vary according to their professional experience and the academic level of their teaching: Novice teachers report more anxiety than experienced teachers and primary school teachers report more sadness and helplessness than secondary school teachers (often related to their pupils' life difficulties). In sum, the emotional constellation of the teacher may significantly influence the educational environment of the classroom.

Conclusion

The aforementioned studies demonstrate how cognition and emotion can work together. Cognition and emotion may be thought of as two different languages, to represent and communicate about the world (ourselves, others, the physical world, etc.) that coexist within all typical individuals: Every person is emotionally and cognitively bilingual.

While illustrating impressive relations between cognition and emotion, many of the aforementioned studies actually make it difficult to know which is causally antecedent. The allocation of cause, in many cases, may depend on the moment you are taking the snapshot in the flow of the person's subjective experience (e.g., "I am anxious, which makes me focus my attention on anxious information, which in return reinforces my anxiety, which in return makes me focus on anxious information, etc.").

We may also speculate on the fact that, as a function of the situation (context, circumstances, etc.) and the individual (personality, level of development, etc.), either cognition or emotion may be dominating the individual's mental functioning and, further, that the absence of this circularity would be dysfunctional for the individual.

Until quite recently, pedagogy had focused its attention almost exclusively on the cognitive dimension of the mind, for pupils and teachers. There are at least two challenges for researchers and professionals in education and psychology. The first is the development of reliable and valid, but also realistic and interdisciplinary, methodologies to improve emotional competences within school settings. This applies to children and adolescents in relation to their school achievement, and also to teachers in relation to their teaching skills. Today, few if any of these methodologies have been properly developed, let alone evaluated for their reliability and validity. There is a need for interventions that make a discernable impact on pupils' and teachers' emotional competences and bring about stable long-term positive changes in pupils' school achievement and teachers' pedagogical competences. The second challenge is to introduce emotional competences (i.e., the abilities to experience, recognize, express, control the expression of, regulate the experience of, and understand emotions) in the standard curriculum of preschool and compulsory school, and in the training programs of the teachers. This implies strong political decision. Indeed, the introduction of emotion pedagogy at school is still often seen as irrelevant when there are no existing problems – the object and goal of the school institution being still often considered as cognitive and instructive rather than emotional and educative. This change in thinking about the importance of emotions at school also implies a reorganization of pupils' and teachers' curriculum, teachers already having much to teach and learn. Such reorganization can be quite problematic not only because it is a source of change (and that can cause some resistance) but also because it implies that some topics which are currently taught have to be reduced within the curriculum and may be even eliminated.

Summary

Three main results can be abstracted from the educational and psychological studies discussed in this article:

1. Some (old) emotional reactions can be elicited without the intervention of cognition (via a direct biological appraisal of the stimulus and without the involvement of the cortex). Surprisingly, the opposite (i.e., cognition without emotion) has not yet been so well documented; this absence perhaps being due to the fact this documentation is too trivial (or impossible).

Some researchers have been tempted by an overgeneralization of these no-causal findings. However, the fact that cognition and emotion are sometimes not causing one another (or that they are not the only cause of one another) does not imply that they are never causing one another.

2. Indeed, numerous studies have demonstrated that many emotional reactions and modulations are caused by the individual's cognitive appraisal of the stimuli coming from his/her body, mind, and environment. They have also demonstrated a robust relationship between children's cognitive understanding of emotions (including the possibility to regulate emotions) and their social and emotional well-being.
3. Numerous studies have equally demonstrated that emotional arousal and/or valence have an impact on memory (encoding, storage, and retrieval of existing information), attention (activation and inhibition of existing information), and creativity (elaboration of new information). They have also shown that the impact of emotional arousal on cognition is not linear and that the impact of positive and negative emotional valences is not symmetrical. Emotional arousal has to be neither too low nor too high to have an optimum impact on cognition (i.e., not an additional burden for cognitive executive functions) and the impact of negative emotions on cognition seems clearer than the impact of positive emotions.

While illustrating impressive relations between cognition and emotion, many of the studies discussed in this article actually make it difficult to know which is causally antecedent. The allocation of cause, in many cases, may depend on the moment you are taking the snapshot in the flow of the person's subjective experience (e.g., "I am depressed, which makes me focus my attention on depressive information, which in return reinforces my depression, which in return makes me focus on depression information"). We may also speculate on the fact that, as a function of the situation (context, circumstances, etc.) and the individual (personality, level of development, etc.), either cognition or emotion may be dominating the individual's mental functioning and, further, that the absence of this circularity would be dysfunctional for the individual.

Finally, although most of the studies reported here have been conducted in laboratories, an increasing number of studies seems to confirm, with some nuances, the mutual impact of cognition and emotion on pupils and teachers. In the future, it would be interesting to further investigate this mutual impact of cognition and emotion at school. Such investigations could have a positive influence on pupils' school achievement and on the quality of teachers' teaching. It would also test the validity of our understanding of the relation between cognition and emotion. Indeed, one thing is to demonstrate the logical coherence and the

empirical correspondence of our understanding; another is to demonstrate that our understanding can change pragmatically the world of practice for the best.

Cognition: Overview and Recent Trends

J Wiley, University of Illinois at Chicago, Chicago, IL, USA

All processes of thought, conscious and unconscious, fall into the realm of cognition. These processes operate by manipulating information-laden mental representations, which are either retrieved from memory or constructed from sensory information. In this way, the mind can be understood as an information processor, continuously adding to its repertoire of mental representations as well as producing overt physical behaviors. The study of human cognition thus becomes the study of the information-processing characteristics of the mind: What is the nature of the representations? How are they manipulated? How much information can be active at once? Cognitive researchers are concerned with discovering such facts about cognition, with the overarching goal of explaining human behavior in its various forms.

The study of human cognition is relevant to many fields, and researchers from several disciplines have contributed to our understanding of the mind. These disciplines include psychology, philosophy, linguistics, artificial intelligence, anthropology, education, and neuroscience. In fact, many cognitive researchers are multidisciplinary, simultaneously working in a variety of fields, and interdisciplinary, integrating aspects of the different disciplines.

The growing field of cognitive science was born out of the perspective that cognitive research must span multiple disciplines. However, less than 50 years ago, the study of cognition was largely considered unscientific, at least among many psychologists in North America. To understand the current approach to the study of cognition, it is important to consider its origins, as well as its obstacles. It is not the goal of this article to provide a detailed historical review of inquiries into human cognition (for such a review, see Gardner, 1985). Rather, we focus on the relatively recent emergence of the information processing framework that permeates contemporary cognitive science, and consider various major areas of cognitive research.

The Cognitive Revolution

The modern approach to the study of human cognition was forged by a series of events in the mid-twentieth century, known as the cognitive revolution. While scholars continue to debate whether the cognitive revolution truly qualifies as a scientific revolution, the era certainly marks an important shift in psychological theory and methodology, especially for psychology in North America. In the

first half of the twentieth century, experimental psychology in North America was dominated by behaviorism, which generally disavows the use of mentalistic explanations of behavior. Mentalistic terms, such as belief and desire, were branded as superfluous and unscientific, and removed from accepted terminology. Behaviorism came in a variety of forms, including theoretical behaviorism and methodological behaviorism. The methodological behaviorist did not necessarily dismiss the existence of mental constructs, but would argue that psychological science should not include such unobservable entities. Theoretical behaviorism went further, holding that mentalistic constructs could be reduced to overt behaviors. Under this view, remembering a certain stimulus, like a sugar cube or a foul-tasting liquid, amounts to producing a specific learned behavior in response to it. Rather than building explanatory theories, behaviorism had the goal of describing relationships between reinforcements and observable behavior. Such descriptions were, according to behaviorism's founding father, Watson, as far as experimental psychology could and should progress.

The apparent scientific rigor of behaviorism played a large role in its rise to prominence in psychology. However, to many American psychologists of the mid-twentieth century, it became increasingly apparent that limiting psychology to a science of behavior would be inadequate for explaining learning and higher-order processes of problem solving, reasoning, and decision making. Evidence for this inadequacy came from various sources, including a central research area in behaviorism, animal learning. For example, studies finding that rats could quickly learn an association between ingesting salty water and illness or an association between a certain noise and a shock, but had difficulty learning other pairings of the same elements (salt with shock or noise with illness), seemed to defeat the notion that learning is purely a result of experiential factors. The behaviorist approach could also not explain instances of creative cognition where novel responses are generated.

It would be incorrect to assert that the decline of behaviorism in American psychology was immediate, or due to any single set of events (Miller, 2003). Indeed, behaviorism was widely debated and defended throughout the 1960s and into the 1970s in various areas of psychology. In addition, the shift from behaviorism to cognitivism that marks the cognitive revolution in American psychology was influenced by developments outside of

America. For example, the Swiss psychologist Jean Piaget argued that the organization of the human mind is shaped by biological factors, while Russian psychologist Lev Vygotsky stressed sociocultural influences. Besides advancing new theories of psychological development, these researchers provided examples that psychology could maintain its scientific rigor without the constraints of strict behaviorism.

The cognitive revolution was also fueled by developments outside of psychology, notably in the fields of linguistics and artificial intelligence (AI). The linguist Noam Chomsky's famous critique of B. F. Skinner's *Verbal Behavior* stands out to many as a critical event. Skinner, the leading behaviorist researcher of his era, attempted to provide an explanation of language strictly in terms of environmental input. Chomsky argued that behaviorist principles are inadequate to explain human verbal behavior, because language acquisition does not seem to develop as a function of the environmental conditions that are presented to the learner. Chomsky cited evidence of children's rapid language learning, and of people's ability to create and comprehend entirely novel expressions. Chomsky argued that the external conditions are too impoverished to support such learning, and posited universal, innate language abilities. While Chomsky's arguments did not settle the issue on language learning, they did, in the eyes of many, serve to defeat the purely behaviorist account.

Fueled by post-World War II interests in advancing science and technology, the field of AI flourished in the 1950s and 1960s, and played a crucial role in the rise of cognitivism. The birth of AI can be traced back to 1956, when an influential conference on AI was held at Dartmouth College (Miller, 2003). Attendees included John McCarthy, Marvin Minsky, Herbert Simon, and Allen Newell, each of whom became leading figures in AI and cognitive-science research for decades to come. AI labs around the United States began producing computer programs that were capable of carrying out tasks that were previously believed to require the highest human intellect, such as solving complex logic and math problems. The new synergy between computer science and psychology was apparent not only in the tasks that computers were programmed to perform, but also in how they carried these tasks out. For example, McCarthy's List Processing (LISP) possessed a unique memory organization for its time, which stored not only the contents of independent entries, but also their connectedness. These memory trees allowed the computer to store complex relational structures, a powerful new tool.

With advancing computer technology bringing promise of creating AI, the abstract notion of the computer served as a powerful metaphor for the human mind. Broadbent is widely credited with developing this computer metaphor into the information-processing model of the mind, which has become the dominant model for cognitive science.

The new idea was that the mind could be described in terms of input, internal representation, processing, and output. In this way, the mind was not only like a computer, it was a computer. Psychological theories could be legitimately instantiated in computer models, a view that more closely bound psychology to the field of AI.

The Birth of Cognitive Psychology

The emergence of new scientific fields outside psychology and the open consideration of alternative theoretical positions within psychology supported the birth of a new psychological field, one committed to the study of human cognition under the information-processing framework. The publication of Neisser's *Cognitive Psychology* in 1967 marked the emergence of this new field. Neisser defined cognition as all of the processes that transform, reduce, elaborate, store, recover, and use sensory input. For Neisser, the realm of cognitive psychology included how actions and experiences are affected by perceptions, memories, and beliefs. Like behaviorists, cognitive psychologists apply a strict scientific method to study the mind, but unlike behaviorists, they accept the existence of internal mental states within their science.

Armed with the information-processing framework, cognitive psychologists set out to explore many new questions about the mind. A primary concern was the mind's basic architecture: Is the mind comprised of distinct cognitive systems, and if so, how do these systems operate? Research on human memory was central in addressing these questions. Memory is not simply a storage system, but is thought to be actively engaged in all aspects of cognition. The memory system has three interrelated functions: encoding, storing, and retrieving information. Evidence from numerous studies suggested the existence of distinct, but interacting systems of memory, distinguished primarily by the duration that information is retained. First, there is sensory memory, which holds a large amount of incoming sensory information for only a few hundred milliseconds. There is thought to be a unique sensory store for each of the five senses, although visual sensory memory has received the most research attention. The next memory system is short-term memory, which receives input from sensory memory, and holds, by recent estimate (Cowan, 2001), about four chunks (i.e., meaningful units) of information for a few seconds. A more contemporary view, Baddeley's model of working memory (e.g., Baddeley, 2007), emphasizes not only short-term storage, but also how information is manipulated in immediate memory. The most recent incarnation of the working-memory model consists of three distinct short-term memory subsystems, commanded by a central executive. One subsystem processes and stores visuospatial information, a second deals with phonological information

(including speech), and a third integrates different modalities of information and integrates temporal information into an episodic representation. A final major memory system is long-term memory, characterized by its near-unlimited capacity and duration. Information from working memory may be stored in long-term memory for later retrieval; however, the storage of information depends on many factors, including how it is processed during encoding. Long-term memory can also input information into working memory, affecting the interpretation and elaboration of its contents, and making information accessible for use in higher-order processes such as comprehension, problem solving, and reasoning.

The field of cognitive psychology, realizing the potential of information-processing theory and building on basic assumptions about the architecture of memory, flourished in the latter quarter of the twentieth century. New areas of research emerged, exploring a range of cognitive phenomena, from the most basic processes, such as perception and pattern recognition, to more complex, higher-order processes, like comprehension and problem solving. Traditionally, cognitive researchers aim to determine specific processes that underlie human performance using experiments that isolate the particular demands of any given task. Participants are usually presented with fine-grained variations of stimuli or tasks, and performance is typically measured in terms of response accuracy or reaction time. This approach is essentially reductionist in nature, but it allows for causal determinations to be made through adherence to the scientific principles of quantification and strict experimental control. Beyond the basic controlled experiment, cognitive scientists have a number of other approaches in their methodological arsenal. Cognitive modeling, the simulation of cognition through computer programs, is a popular tool for instantiating theories and pitting them against one another. Technology in neuroscience, particularly functional magnetic resonance imaging (fMRI), has made it possible to examine the online brain activity of normal adults. Similar recordings can be obtained in terms of event-related potentials (ERPs), eye movements, skin conductance, and pupil dilation. Verbal and video protocols also provide a rich source of data, including gestures and think-aloud reports, which may give insights into the behaviors that people engage in during cognitive tasks.

Overview of Research in Cognition

Given that one of the main goals of education is to train and inform students through instruction, research in cognition has direct application, especially with respect to issues of learning. There are several areas of cognitive research, including perception and attention, language acquisition and reading, memory, comprehension, problem solving

and reasoning, and metacognition, which can all inform educational practice.

Perception and Attention

One of the most basic areas of research within cognitive science concerns perceptual and attentional processes, which serve as gatekeepers for stimuli and determine what is available for further cognitive processing. The extent to which information must be explicitly processed, how attention is drawn to or away from stimuli, and how often information needs to be attended to during learning, are important and well-studied topics (Pashler, 1998). Repeated exposure or practice is a central mechanism in skill and knowledge acquisition, and can result in automaticity and proceduralization of cognitive processes over time. These principles can inform our understanding of successful acquisition of spoken language, reading skills, and various problem-solving skills. A related literature explores individual differences in the ability to control one's attention, or the ability to focus on a goal in the face of interference. Research has found that these abilities affect the amount of information that people can consider in immediate memory, which in turn impacts their performance on many cognitive tasks. As such, the ability to control one's attention has also been referred to as working-memory capacity (Conway *et al.*, 2005).

Language Acquisition and Reading

First-language acquisition is perhaps the most impressive of all cognitive skills. Language develops universally in some form in all humans, and development typically proceeds in a remarkably rapid fashion. Present approaches emphasize both the biological predisposition to acquire language as well as the role of exposure to patterns in the environment (Gleitman and Newport, 1995). The differences between first-language acquisition occurring in infancy, and second-language acquisition that occurs afterward, are important issues, as are the questions of how bilinguals represent and process information in their second language (Kroll and Tokowicz, 2005). Additionally, recent research has highlighted several cognitive advantages among young bilingual students and aging bilingual adults, including superior executive functioning and facilitated acquisition of reading skills (Stock, 2001). A great deal of cognitive research has also explored reading behavior more generally. This research supports two important conclusions: that mastering the alphabetic principle (that written symbols correspond to sounds, or phonics) is essential to becoming proficient, and that methods that teach the alphabetic-decoding principles that underlie our written language are more effective than methods that do not, especially for children who are having difficulty learning to read (Rayner *et al.*, 2001).

Memory

The relevance of cognitive research on memory is perhaps obvious if a main goal of education is the acquisition of knowledge. Memory research concerns the mechanisms that enable the encoding, storage, and retrieval of new information. A long tradition of research has demonstrated more durable learning and memory result from spaced practice (Cepeda *et al.*, 2006), and when information is presented in a context that allows for imagery, elaboration, or integration with prior knowledge (Baddeley, 2007). Other highly relevant lines of investigation examine how memory tests affect subsequent memory for information, in some cases by introducing false memory traces through distractors in multiple-choice tests (Roediger and Karpicke, 2006). Testing may also cause patterns of facilitation for the tested information, and interference for nonretrieved information.

Comprehension and Conceptual Understanding

Perhaps the most common medium for subject-matter transmission is through expository text, with lectures and discussion also being common forms of instruction. In these cases, learning depends on text and discourse processing which is another major area of cognitive research. As information is processed, multiple levels of representation are constructed, and as Kintsch (1998) has suggested, it is especially the deepest level of representation, called the situation model, that represents understanding or comprehension of phenomena. This area of research has explored the contexts and individual differences that support construction of better-situation models during learning, including encouraging the activation or use of prior knowledge and encouraging active processing through tasks such as question-asking or self-explanation (Graesser *et al.*, 1997; McNamara, 2007). A special case of learning occurs when new information or evidence in some way conflicts with prior understandings. In these cases, conceptual change or belief change may be required, especially for learning in science (Chi, 2000; Chinn and Malhotra, 2002).

Problem Solving and Reasoning

A great deal of research on problem solving has been informed by using a contrastive approach – comparing better or more expert problem solvers to less-effective, or less-expert, problem solvers. This work has shown that experts use their experience to see the deep (more explanatory) structure of a problem, while novices often process problems at a superficial level. This line of research has in fact spurred the research on self-explanation cited above (Chi, 2000). In a similar vein, instruction that emphasizes procedural elements of math problem solving can promote shallow understanding, while conceptual or

mixed approaches can lead to better understanding as well as improvement in procedural skill (Siegler, 2003). A third important area of problem-solving research has explored the effectiveness of scaffolded practice, worked examples, and feedback (Atkinson *et al.*, 2000).

Ill-structured problems represent a special class, where solutions, goals, and assumptions are less constrained. But even here, expertise in a domain gives the solver ways to constrain the problem space (Voss *et al.*, 1983) and turn the problem into a well-structured one. Solving this type of problem, where no single agreed-upon answer exists, requires argumentation or informal reasoning skills. In such cases, the reasoner must consider the evidence and arguments and whether they provide support for conclusions. Such skills underlie disciplinary thinking in both the humanities and the sciences, as well as reasoning in most everyday contexts. Thus, the development of scientific reasoning and argumentation skills in students has been an area of much recent interest.

As opposed to these skills of informal reasoning, formal reasoning relies on the application of the rules of logic or mathematics, with the goal of determining the validity of syllogistic or propositional arguments. Formal-reasoning performance often improves with more familiar or meaningful contexts, as well as when arguments are phrased in more intuitive language. Several forms of reasoning have been found to improve with training in statistics, but generally, people tend to be poor at all types of reasoning without training. Substantial individual differences in reasoning abilities have been attributed to thinking dispositions (Stanovich *et al.*, 2003) which have been found to correlate with the ability to learn and engage in many higher-order cognitive tasks. This in turn suggests a critical role for instruction in reasoning that is largely absent from our current curricula.

Metacognition

Metacognition is the act of monitoring cognitive performance, which serves as input to self-regulation of cognitive behaviors such as studying. Much research on this topic has used prediction paradigms for memory and comprehension tasks. Metamemory paradigms typically consist of the task of learning word pairs, such as a word in a foreign language and its English translation. When students are asked to predict their ability to recall a translation, metamemory accuracy has been found to be quite good, especially when judgments are made at a delay (Dunlosky *et al.*, 2007). Predictive accuracy for comprehension tests following the reading of expository texts is typically much lower, although recently some contexts that promote accurate metacomprehension have been found. When readers are asked to self-explain while reading, or to generate summaries or keywords at a delay before making their judgments, metacomprehension accuracy

can be substantially improved (Thiede *et al.*, 2009). The ultimate value of supporting better predictive accuracy among students is that it then can help them to make effective decisions of what material to re-study as they attempt to learn material on their own.

Recent Trends

Transfer

The goal of instruction is ultimately to promote learning that transfers to new problems and situations, especially ones that are quite dissimilar from the initial learning context. When students are able to activate prior knowledge or learned-solution strategies and apply them by analogy in novel contexts, it is referred to as far transfer. However, a recurring theme in the cognitive literature is that students often fail to activate relevant prior knowledge as they process new information. Thus, little experimental evidence has supported the existence of far transfer (Barnett and Ceci, 2002). More often than not, people are unlikely to recall critical information in situations that are superficially dissimilar to the context of acquisition. Despite the elusiveness of findings of far transfer in cognitive laboratories, there is evidence from observational studies that people can and do apply analogies to solve novel problems in the real world. Scientists, for example, spontaneously construct analogies to help solve problems that they encounter in their research. One reason for the apparent void between laboratory and observational findings could be that experimental participants are not able to represent the analog at a level of abstraction that is sufficient to support transfer. The issue of whether initial instruction should be concrete and contextualized, versus abstract and symbolic, is currently receiving a great deal of attention, with some advantages being found for each mode of acquisition. When students are taught a principle through concrete examples that gradually become more abstract, they are better able to transfer the principle in some contexts (Goldstone *et al.*, 2008). However, in other contexts, starting with abstract or symbolic representations leads to better learning and transfer, as concrete representations may distract learners from recognizing the basic principles.

Spatial Thinking and Gesture

Spatial skills are thought to be important to many aspects of cognition, including thinking and problem solving in math and science domains. Individual differences in spatial ability have been well documented, and recent work is attempting to differentiate among distinct subtypes of spatial abilities (Hegarty and Waller, 2005). One important aspect of spatial thought is the ability to parse, mentally manipulate, and use symbolic representations, such as maps and diagrams. To the extent that spatial skills

affect learning and understanding, it is particularly encouraging that such skills do seem to improve with practice or input from the environment (Newcombe and Huttenlocher, 2000). Another important aspect of spatial cognition is the bodily gestures that people produce (Alibali, 2005). Gestures can be used to support spatial thinking and communication, but also may be used to express knowledge that is difficult to verbalize. Gestures may reveal a student's preparedness for learning a concept even when their verbal expressions suggest poor understanding. Interestingly, gestures seem to be used as much for the self as for others. Such findings suggest that cognitive processes may be tied to the body's interactions with the world, and an extreme version of this perspective, referred to as embodied cognition, is receiving a great deal of attention in the recent literature.

Culture and Cognition

Research in early science education and developmental psychology has demonstrated that most children need to overcome some of their intuitive ideas of the world around them in order to comprehend scientifically accurate explanation of phenomena. However, the vast majority of this work has involved children in mainstream, North American, urban, technologically dependent populations. Recent work by Medin and his colleagues has shown how intuitive concepts are shaped by society, and how children in specific cultures (such as Native American communities) differ in their understandings of biological concepts (Bang *et al.*, 2007). These differences are attributed to exposure to cultural values and beliefs transmitted through the discourse within the community. Interestingly, children in Native American communities were found to have more advanced understandings of living things and ecologies. Yet, disturbingly, they did less well than mainstream students in academic classroom performance. These results suggest conflicts between traditional science instruction and the ways of thinking instilled by different communities. Such findings highlight the need to recognize the differences in intuitive understandings that children from many different kinds of communities bring to the classroom, and represent one example of the recent research trend to better understand the interaction of culture and cognition.

Collaboration

A final trend in recent research explores the impact of social interaction on learning. The communication between the teacher and a class is essentially a social interaction, but because of the number of students, it is essentially one-sided. The teacher necessarily becomes the transmitter of information, and there is little role for either individualized discourse or interactive activity on the part of most students.

Thus, it is not surprising that researchers have attempted to increase interactive communication for all students through the creation of small group exercises, peer-collaboration activities, or intelligent tutoring environments. Interacting with others can be particularly motivating, but there are also a number of pitfalls that can make collaborative learning less successful than individual work. Intelligent tutors can provide students with timely feedback and expert knowledge, but if systems provide too much scaffolding or help, then the students may never actually engage with the content (Anderson *et al.*, 1995). Alternatively, working with peers can be quite motivating and effective as a supplement to classroom instruction, but guidance for students on how to collaborate is critical, otherwise they may engage in superficial discussions that do not reach a high level of discourse (O'Donnell and King, 1999). The goal of current investigations is determining which contexts are most effective and in what ways, for different subject matters, and different kinds of students (VanLehn *et al.*, 2007), as well as the discovery of the mechanisms that are responsible for successful collaborative learning and transfer.

Glossary

Creative performance – The actual use of creative talent.

Creative potential – The range of possible talent determined largely by genetic makeup.

Domain of performance – The different areas (e.g., art and mathematics) which seem to require different skills and seem to be associated with different backgrounds.

Family structure – The number of persons in the home, birth order, and age gap among siblings.

Fourth-grade slump – A drop in creative thinking experienced by approximately 50% of children at age 9.

Humane creativity – A domain wherein talents are used in a moral and socially beneficial manner.

Old-age style – The tendency of some artists to make changes to their work simply for the sake of change and personal originality.

Problem finding – This is required before problem solving and often determines the quality of a solution. A creative solution may depend on the identification and definition of a creative problem.

Remote model – An individual in books or the media whom children may imitate.

Creativity is an extremely valuable resource, both for individuals and for society as a whole. It is most accurate to distinguish creative potential from creative performance, especially in studies of development. This is because an individual who is putting his or her creative talents to work is actually performing or applying those talents. The individual may not be performing publically – many creative endeavors involve problem solving, adaptation, coping, or other everyday, mundane, or personal actions. Yet many other individuals, including most children, have notable creative potential yet are not using all of their talents. Studies of development are useful in part because they suggest how such potentials can actually be fulfilled and how individuals can make the transition to actual creative performance and achievement.

This is not to say that creative potentials are entirely fulfilled through systematic experiences. Indeed, creative talents exemplify the same interplay between nature and nurture that is apparent in most aspects of human development. In addition, there is a kind of bidirectionality in

that creative talent both results from maturation and experience and contributes to learning and adaptation. It is, put simply, both a cause and an effect of development.

Creativity behavior requires both originality and effectiveness. Each of these follows its own developmental trajectory. To chart these trajectories, it is useful to define originality and effectiveness more specifically. The former can be defined in terms of novelty, uniqueness, or unusualness, and the latter in terms of fit, appropriateness, and value. When creative behavior is directed toward a problem, and is thus a kind of problem solving, effectiveness can be defined in terms of the quality of the solution(s). Yet, not all creative behavior is problem solving. Some precedes solving problems and is involved in what has been called problem finding or problem discovery. The creative behavior of children is often entirely independent of problems and is simply original self-expression. Adults also sometimes express themselves creatively; and in fact there are strong connections between self-actualization, spontaneity, authenticity, and creativity. Yet another manifestation of creative talent, which is independent of problem solving, is being proactive. Problem solving is usually reactive in that the individual is responding to an obstacle or problem. Proactive creativity may entirely circumvent the problem. This, of course, is a very important form of creativity and may be especially useful, given some of the contemporary threats facing our society. Indeed, it would make a great deal of sense to focus developmental and educational efforts specifically on proactive creativity, and on humane creativity or creativity in the moral domain.

The concept of domains is vital for understanding the development of creativity. The background of an artist may differ dramatically from that of an engineer, scientist, leader, manager, or educator. Even within the arts there are differences among subdomains, with dancers differing from writers, for example, and poets differing from novelists.

The developmental trajectory of originality begins at what is for many individuals the peak or maximal level. Young children are often uninhibited and unconventional. In fact, they are unaware of what conventions are, and, of course, do not take them into account when emitting behavior. They are instead enormously spontaneous. This lack of inhibition, unconventionality, and spontaneity supports their originality. Adult originality and spontaneity are often stifled by inhibition and by a recognition of conventions (e.g., cultural norms, traditions, and expectations of others). Children also do not make the same assumptions as adults but instead tend to be much more

mindful of immediate experience – they have few, if any, routines. Adults, on the other hand, often rely on assumption and routine. This helps the adult to conserve resources and is often beneficial, but it is difficult, if not impossible, to be original if the person is merely following routine or making assumptions rather than mindfully attending to the situation at hand.

Note, however, that all these provide children with easy access to originality, but not necessarily to creative action. Again, creative behavior requires effectiveness as well as originality, and children are often ineffective, at least in the sense that they are egocentric and ignore conventions. Their originality is unchecked rather than discretionary, and for that reason it is often just originality and not creativity. As a matter of fact, many of the advantages just listed, giving children easy access to originality, make it very difficult to strike an optimal balance with effectiveness. Very often, then, the developmental trajectory of originality peaks early and drops with age and increased conventionality, while the trajectory for effectiveness has the nadir early but gradually increases as the individual learns to fit in and exercise discretion and appropriate conventional action. The balance of originality and effectiveness has been called postconventional, the idea being that the individual is aware of conventions but mindfully decided whether or not to conform to them.

This is not to say that the development of creativity is entirely smooth and continuous. Various stages have been proposed. The problem-finding talents related to creative performance above, for instance, have been assigned to a postformal stage of development, which implies that it would be apparent only late in adolescence or in early adulthood – if at all. There are also various developmental slumps. One common slump occurs at approximately age 9 and was labeled the fourth-grade slump by E. Paul Torrance in 1968. This has also been found in several other countries around the world and has been reported much more recently as well. It is, however, only apparent in approximately 50% of the children of that age. Another slump occurs late in life. This involves cognitive flexibility, which is very frequently associated with creative performance. It is apparent when an individual is able to consider various perspectives, generate different kinds of ideas and solutions, and avoid rigidity and functional fixedness. Apparently, many older adults have difficulty doing just that and rely more and more on routines. They become more rigid and less flexible, and their creative thinking is likely to suffer.

However, just as the fourth-grade slump is only experienced by approximately 50% of the children of that age, so also is rigidity common and flexibility lacking only in a segment of the population. Consider in this regard the creative breakthroughs that are sometimes discovered by individuals late in life. Piaget and Picasso, for instance, were productive and creative well into their 80s. Apparently some

individuals actively invest in their creative potentials throughout their lives. Among artists, this has been labeled the old-age style. Simplifying it a little, this is seen when the older artist intentionally changes his or her style or medium, even if this means leaving previous successes behind.

Nature and Nurture in Development

Individual differences, such as those implied by the fourth-grade slump and the old-age style, can be understood in terms of the interplay of nature and nurture. Some individuals, for example, probably inherit the genes which increase the likelihood of a slump. Great strides have recently been made toward a deeper understanding of the genetic basis of creativity and its development. There is, for example, one gene known as *DRD2* which is involved in the reception of the neurotransmitter dopamine and which is found in perhaps 20% of the population. It is correlated with certain tests of creative potential. Other indications of a heritability of creativity and the role of nature include the genealogies of some famous creative persons. This evidence is not entirely convincing, however, because while there are a number of examples of creative talent within multiple generations of one family (many of which were identified by Galton in his 1869 classic titled *Hereditary Genius*), there are also clear counter examples (e.g., William Shakespeare did not seem to have any outstandingly talented relatives).

Whatever genetic contribution does exist, it does not work in isolation. Behavioral scientists do contrast nature with nurture any longer; most now acknowledge that biology and experience work together. Thus, it is most appropriate to say that the development of creativity is a function of both nature and nurture. This can be further explained with the concept range of reaction whereby the genetic potential for creativity sets a range of possibilities, and nurture and experience determine where within that range and individuals perform. This idea of an interplay between nature and nurture is important because although not just anyone can be an Einstein or Mozart, everyone does have potentials which can be fulfilled. Hence, much of what we learn about the development of creativity applies very widely, if not universally.

Models, Motivation, and Values as Influences on Creative Development

The experiences which contribute to the development of creativity and the fulfillment of creative potential are quite diverse. Nurture may include, for example, formal and informal education. Much of the latter occurs within the context of the family. Indeed, a great deal of research

has suggested that early family experiences are critical for the development of creativity. Creative potentials are most likely to be fulfilled if a child has numerous opportunities to experience and practice creative behaviors, as well as models, including the parents, who demonstrate how to be creative and convey the idea that creativity is a valuable thing, and who provide appropriate feedback and reinforcement for creative behavior. The last of these is probably the most complicated because certain kinds of reinforcement may in fact undermine creativity. Creative behavior is frequently, though not always, tied to intrinsic motivation. This is the motivation that comes from within the individual. Frequently extrinsic factors, including rewards and incentives, inhibit intrinsic interests. This is known as overjustification. Hence, a child must be allowed to explore his or her own interests, and it is unwise to excessively reward creative behavior.

The motivational influences are also complicated because creative behavior is tied to originality. This means that it is often unexpected, and children may do something which is creative but very different from what the parents – or teachers – expect or even desire. Yet if it is original, it might be tied to creativity, and at times must be appreciated. This can be quite difficult. Creative children may require a certain amount of tolerance. They may do surprising, unexpected, and original things, and they may be unconventional and highly autonomous. Parents may target mature behaviors and socialize a child to what is conventional within that culture, but some of the time the child needs to experience the latitude for self-expression. The idea of postconventional behavior is very relevant here: parents and teachers may both attempt to support that balance of originality and socially appropriate behavior. Also relevant is that adults sometimes value creativity in the abstract but have difficulty in supporting the specific behaviors and traits which contribute to creative behavior (e.g., unconventionality, autonomy, nonconformity, and intrinsic motivation). The problems may be especially acute in a classroom, where the educator has not one or two children but several dozens, which makes it particularly difficult to support independence and originality.

Both parents and teachers may be creative models for children. Remote models may be found in books and entertainment media. These models are individuals who a child never actually meets but with whom the child does have some sort of experience. All models probably exert two different kinds of influence: children may learn specific creative behaviors by interacting with creative adults, but they may also internalize the values which are implied by the fact that the adult behaves in that fashion. The impact of values may be most clear in cross-cultural studies, for certain cultures emphasize harmony and collectivism, while others more clearly support creativity because their values emphasize individuality and originality.

Family Structure

Some of the clearest developmental influences on creative behavior are those which are determined by family structure. Family size, for instance, may be related to creative behavior, with large families possibly having an advantage. There are very clear data indicating that small families often have children who do well academically and in conventional areas of performance. Yet, academic performance and conventional or convergent thinking are distinct from the divergent and original thinking which is more typically associated with creative behavior, and divergent and original behavior seem to be better nurtured in large families.

The research on birth order is even more clear-cut. More often than not, firstborn children tend to develop a need for achievement in conventional areas, and, as a result, tend to do very well academically and in similar conventional areas. Second-born and many middle children, on the other hand, apparently attempt to obtain their individuality and develop strategies which ensure that they too can earn attention and obtain resources within the context of the family, even though they are younger than their older brother or sister. This situation has been compared to the evolutionary ecology which influences species diversification. If two species share an environment, they are the least likely to compete for resources if they are different from one another. Perhaps one is nocturnal and the other diurnal. If both are nocturnal, however, competition is likely. Something similar holds true in families. If two siblings are similar, they probably will compete, and often the older of the two will have an advantage because of his or her age and maturity. However, if a second child puts his or her effort into a unique area, that child will be seen as an individual and is much more likely to receive attention and other resources from the parents. One key point in this theory is that eldest children tend to learn the most directly from their parents and are, more often than not, the most conventional of the children within a family. This may in part reflect the fact that the eldest children were at one point only children, and, without any effort, received all of their parents' discretionary attention. When the second child was born, however, the child very likely had to put some effort into obtaining even a small portion of that same discretionary attention. There is a cute and helpless sibling demanding much of it! How can the eldest child regain parental attention? By achieving in conventional areas – hence the need for achievement. What direction does this leave the second or middle child? The unconventional area, which means that the child will probably put most effort into nontraditional and perhaps original areas. If the firstborn is academically astute, for instance, the second born may not put much effort into school but instead may perceive sports or some creative domain.

With this in mind, it is not surprising that Frank Sulloway found very clear-cut tendencies for revolutionaries to be middle children. He referred to the second child with a family as born to rebel. Such rebellion may take the form of creative behavior.

Final Comments

The best way to view the development of creativity is as a fulfillment of potentials. If potentials are fulfilled, actual manifest creative action and performance are likely. The individual and society will both benefit. Creativity has, for example, been tied to psychological and physical health, adaptability, problem solving, invention, entrepreneurship, and innovation.

There is reason to believe that we can be optimistic about creativity because in some ways the fulfillment of potential seems to depend on intentions and decisions. Think back on the idea of postconventionality, for example, and the discretion exercised when the individual recognizes conventions but ignores them in order to

express an original idea. Consider also the old-age style and artists' decisions to make changes, which are not necessary except in the sense that it keeps them out of ruts and routine. Many other examples of the importance of choice and decision making are available, but the point is that, although genetics set limits, each of us has a range of potentials and can fulfill those potentials and be as creative as possible by making the right choices as we grow older.

Knowledge Domains and Domain Learning

L Maggioni and P A Alexander, University of Maryland, College Park, MD, USA

Glossary

Conditional knowledge – A state of knowledge that pertains to when and where knowledge (declarative or procedural) could or should be applied. For this reason, it has been described as “knowing when and where”.

Declarative knowledge – Involves factual information and is the state of knowledge referred to as “knowing what”.

Disciplinary knowledge – Represents the specialized knowledge associated with a foundational discipline (e.g., history or mathematics) and includes a specific taxonomy, vocabulary, concepts, theories, research methods, and standards of justification aligned with that discipline. It is knowledge of an academic discipline that is taught; a specialized field, or study, or particular branch of learning.

Discourse knowledge – A type of conceptual knowledge that is more particularly about language and its use.

Heuristics – Refer to general guidelines and practices that facilitate a systematic approach to a task and thus favor arriving at a solution (e.g., identifying the data of a problem, looking for related problems, and checking the results).

Knowledge domain – Refers to the part of the world investigated by a specific discipline. Such knowledge is characterized as the object (e.g., plants, numbers, or the past) of a specific body of knowledge (e.g., botany, mathematics, or history).

Metacognition – Typically defined as knowledge of knowledge; knowledge about one's cognition and the regulation of that cognition.

Misconception – An erroneous, sometimes naïve, idea or theory that can seriously hinder understanding.

Procedural knowledge – Described as “knowing how.” Procedural knowledge is, in effect, that state of knowledge encompassing certain processes, strategies, or routines.

Schemata – (pl. of schema) Knowledge structures that are interconnected with and embedded in, one another. The term schemata has been associated with the organization of conceptual knowledge or used to represent all one knows about the physical, social, or mental world.

Second-order knowledge – Refers to concepts regarding how historical knowledge is generated (i.e., the doing of history), such as evidence, accounts, change, and cause.

Skill – A procedure that has been routinized or habitualized, a mental habit that prompts specific actions in front of simple and highly familiar situation, usually operating at an unconscious level.

Strategy – A mental operation or technique, employed to solve problems or to enhance performance. Some strategies are called general, because they can be successfully applied across various domains, while others are called specific, because they target a specific domain or task within a domain.

Substantive knowledge or first-order knowledge – Refers to concepts that identify clusters of kinds of things in the world and, as such, they refer to what a discipline is about (e.g., market, migration, revolution). Such knowledge implies understanding of the rule that guides the formation of those clusters and being able to identify instances of that rule across time and space.

Although educational psychologists' interest in how knowledge develops within specific domains has fluctuated across time, formal education throughout the world is organized around particular fields of studies, and students soon come to characterize their experience of school in terms of subject matters. Thus, in education, domains seem to make a difference. The term knowledge domain refers to the part of the world investigated by a specific discipline. In other words, the domain can be characterized as the object (e.g., plants, numbers, or the past) of a specific body of knowledge (e.g., botany, mathematics, or history).

Herein, we offer a survey of the development of increasingly specialized disciplines and of the corresponding identification of ever-narrower knowledge domains. In particular, we consider the cultural trends that accompanied these changes and the major influences on the structure of formal education. Subsequently, we turn to consider the characteristics of learning and generating knowledge within specific domains. Specifically, we consider the findings of educational research in understanding the processes

of learning and teaching in history, mathematics, and science. We also include contributions regarding the processes of reading and writing, given their relevance in the school curriculum and the tendency in educational research to conceptualize these activities as domains of learning in their own right.

The Development of Disciplines

Besides being characterized by its systematic knowledge of a particular domain, each discipline is also distinguished by a specific way of thinking about associated phenomena. Thus, disciplinary knowledge includes a specific taxonomy, vocabulary, concepts, theories, research methods, and standards of justification. Histories of science, such as those offered by Fehl (1966), Hall and Hall (1988), and Libby (1917) illustrate that disciplines developed over the centuries as privileged pathways toward an understanding of almost any topic. The reciprocal influences between the prevalent cultural climate, disciplinary developments, and formal education are well exemplified by cultural histories of Western education, such as the one composed by Butts (1955).

These studies concur in affirming that organized bodies of knowledge arose in conjunction with the human needs of gaining understanding of the world, establishing some control on the physical environment, and organizing social life. In ancient Egypt, for example, efforts toward controlling and predicting the floods of the Nile fostered remarkable advances in geometry and astronomy. However, it was in the Greek cities of Asia Minor and, later, Athens that the investigation of philosophers into the nature and origin of the universe introduced the method of rational inquiry that so deeply influenced the development of knowledge in Western civilization.

In fact, Western thought owes much of its systematization of knowledge to the Greeks and to their reliance on critical reason in speculating about the origin and nature of the universe. The Greeks came to regard rationality as the human faculty allowing the acquisition of knowledge and truth; hence, the intellectual formation afforded by mathematics and philosophy was considered a privileged road to knowledge and learning and acquired centrality in education.

Over time, increased complexity in the knowledge and skills characterizing competence in specific areas fostered the development of formal instruction and the establishment of schools as separate institutions. The process of organization of knowledge was greatly favored by reliance on the written form, a practice adopted relatively soon by the liberal arts, but not by the practical arts. In the practical arts, informal apprenticeship remained the prevalent way of passing technical skills from one generation to the next. On the other hand, formal education tended to focus

on those bodies of knowledge that were systematically organized in written form.

The importance of accurate definitions in furthering thoughts and the power accorded in Athenian life to those who could speak effectively prompted the development of grammar and rhetoric. The need to think clearly encouraged the development of logic or dialectics. In addition, Greek philosophy began to organize into bodies of knowledge studies regarding the ultimate reality of things (metaphysics), the theory of knowledge (epistemology), human nature and human conduct (ethics, political science, economics, sociology, and psychology), the physical world (astronomy, geography, physics, mechanics, hydraulics, mineralogy, and botany), and the living world (zoology, physiology, and anatomy). The search for intellectual discipline and the problems investigated by the developing sciences favored the progress in the field of mathematics and the refinement and systematization of theories and concepts in arithmetic, geometry, and trigonometry. In addition, Greek inquiry extended to the human past, investigating the causes of historical events and thus laying the foundation of history. Finally, although the fine arts were not organized into systematic bodies of knowledge, the Greeks cultivated several forms of literary criticism, thus giving systematic organization to the theory of art and esthetics.

Roman culture widely drew from Greek thought, furthering the systematization of knowledge and its organization in forms suitable for teaching. By the end of the fourth century, the liberal arts had been circumscribed to the study of compendia (written in Latin) of those Greek works deemed suitable to the spiritual and intellectual development of the pupils. Specifically, the trivium, that is, the elementary liberal art curriculum, included grammar, rhetoric, and logic. The higher liberal arts, or quadrivium, mainly incorporated mathematical studies and comprehended arithmetic, geometry, astronomy, and music. The boundaries of these disciplines did not necessarily include the same content that they comprise in modern times. For example, grammar also involved the study of poetry and literature. In addition, the content reflected changes in the Roman intellectual climate. For instance, the purpose of rhetoric changed from preparation to active participation in the debates over public policies to the study of elegant language to be employed in public celebrations. At the same time, the Romans did not tend to value the sciences for their own sake, but applied the theoretical knowledge gained from the Greeks in geometry, astronomy, and natural philosophy to the solution of practical problems.

The disciplines included in the trivium and the quadrivium continued to constitute the backbone of knowledge during the Middle Ages. However, many changes were made in each of the seven disciplines in response to the varying needs and interests of the time. Latin increasingly

became the language of educated people; hence, grammar gained preponderance among the elementary liberal arts during the Early Middle Ages when the non-Latin people began to take part in the intellectual life of Europe. Nonetheless, Medieval Latin became increasingly different from classical Latin, reflecting the influence of the various languages spoken by the European peoples. Rhetoric lost most of its celebratory purpose and focused on the use of the written language for drawing up legal and feudal documents. Logic was increasingly identified with the rules of deductive thinking and, essentially, became distinguished from philosophy.

Arithmetic, geometry, and astronomy saw important developments during the Middle Ages. The cultural exchanges with the Arab world and the translation of the most important Greek, Arab, and Hindu works into Latin laid the foundations for the scientific and mathematical investigations of later centuries. Within the quadrivium, music retained its theoretical nature, even if its performance gained importance in medieval life. Although knowledge of the Greek tradition was praised by Christian philosophers for the contribution it gave to truth, and thus as an aid to the understanding of God and the soul, the intellectualism of pursuing knowledge for knowledge's sake was rejected. In the Benedictine tradition, where the monastery became the home of practical agriculturalists, as well as of religious, artists, and scholars, the alliance between learning and concrete reality foreshadowed the importance of factual knowledge and the relation between science and technology that came to characterize modern science.

Beginning in the twelfth century, teachers and students began to organize themselves into guilds for protections against the king, the bishop, or anyone else who tried to control them. Over time, the term *universitas* began to refer specifically to guilds of teachers (faculties) and students. Reflecting the articulation of knowledge of the time, the typical guilds of teachers were the faculties of liberal arts, law, medicine, and theology. Specific universities became famous for one specific faculty, thus deeply influencing the development of a particular discipline. In addition, the university system fostered an expansion of the liberal arts curriculum, adding the works of Aristotle on the physical sciences, ethics, politics, and metaphysics. The system also promoted the institutionalization of the educational curriculum (with its degrees, licenses to teach, exams, and titles) and, thus, the grouping of studies into separate faculties.

The Renaissance celebrated the return to the classics (Latin, Greeks, and Hebrew) and highly regarded rhetoric as a way to cultivate polite letters and expression. Logic fell in disrepute due to the humanist opposition to scholasticism. However, these changes had a deeper effect on the content of the trivium and quadrivium than on the disciplines taught in the universities, where medieval

philosophy conserved its predominance. In the sciences, humanists turned away from the deductive methods of argumentation and advocated the use of the inductive method (observations of facts and generalization).

The belief that the method of induction is the proper method to gain scientific knowledge is at the root of the classification of human knowledge provided by Francis Bacon in the seventeenth century. Here, the disciplines came to be mainly characterized as histories of nature, collections of descriptions regarding a vast array of natural phenomena. At the same time, a method common to all sciences began to take shape. The scientist should observe nature, collect facts, identify their common qualities, and express these similarities in general formulas. Empiricism highlighted the patient work of scientists in acquiring facts. However, it dismissed the guiding role of theory in deciding observations and experiments. Although the almost exclusive reliance on induction disappeared in later work on method by Descartes, the uniqueness of the scientific method to gain knowledge was not challenged. In fact, the certitude granted by mathematics was upheld as the goal of scientific knowledge, and the scientific method was considered applicable and appropriate to all fields of human thought.

Whereas in the physical sciences this new method of gaining knowledge proved compatible with the emergence of a unitary principle of explanation, that is, the mechanism, a close relation between abstract thought and scientific investigation failed to surface in the biological sciences. The complexities involved in studying living things and the philosophical impossibility of reconciling the existence of human soul with a completely mechanistic physiology supported the specificity of different bodies of knowledge.

The search for natural laws was extended to the study of society and political economy during the era of Enlightenment. The rules for scientific data gathering also began to be applied in the field of the social sciences, and historians began to identify progress as the fundamental law of history. This process was furthered by the role played by Darwinism in the biological science, where the process of change assumed a central explanatory role. From biology, the idea that change is an inherent part of natural and human development influenced the social sciences and their methodological approach, which increasingly tried to emulate the scientific approach of the natural sciences. In the nineteenth century, the rise of positivism in philosophy further promoted the assumption that reality obeys general and universal laws. The purpose of the disciplines became to discover by observation and experimentation relationships able to explain nature, the universe, human nature, and social institutions. Psychology, anthropology, and scientific medicine were all deeply influenced by this way of thinking.

In the nineteenth century, the effect on education of the increasingly important role attributed to the sciences in the overall knowledge landscape was delayed by the lingering humanist belief that a truly liberal education has to be strongly based on a deep acquaintance with the classics. Secondary instruction was particularly successful in protecting this view; in contrast, in the universities, and especially in Germany, where professors and students were recognized for their remarkable degree of independence and freedom, mathematics and science became the dominant studies during the second half of the nineteenth century.

In the American colleges and universities, the attempt to extend to all fields of knowledge the application of the scientific method and the rise of professional organizations of scholars and specialists in various fields encouraged the subdivision of traditional bodies of knowledge into specialized subjects. What, at the beginning of the century, was studied under the label of natural history was, by the end of the century, subdivided into the various biological and natural sciences, thus including botany, zoology, physiology, psychology, paleontology, ornithology, entomology, and anthropology. Natural philosophy was articulated into specialized physical sciences (astronomy, physics, chemistry, mineralogy, geology, meteorology, and physical geography); similarly, history, economics, political sciences, sociology, and anthropology acquired their own specificity within the field of moral philosophy.

The scientific discoveries of the twentieth century in astronomy and physics challenged the positivistic assumptions of a rigid and indestructible matter, obedient to rigid laws. More generally, these new insights questioned the close correspondence between what the universe is really like and the picture rendered by science at a certain point in time, and brought the debate about the epistemic status of scientific knowledge to the forefront. At the same time, and almost paradoxically, the process of disciplinary subdivision went even further as scholars tended to specialize in ever-narrower aspects of one discipline. However, as noted by Easton and Schelling (1991), real-world problems are rarely confined to a specific knowledge domain and the parceled understandings afforded by the increasing specialization do not easily reassemble into a unitary view of the issue at hand. Proposed solutions include interdisciplinary training and teamwork within specific research topics, although the point of departure for these attempts at integration tends to remain the specialized knowledge granted by the various disciplines.

On one hand, the overview of the development of disciplinary knowledge showed that a certain partition of the world in different domains reflects broad cultural and institutional trends. On the other hand, the nature of the object investigated makes specific methodological choices more effective and fruitful than others, thus characterizing

each discipline as a specific way of knowing. In the next section, we turn to consider the influence that these differences in thinking have on learning and teaching.

Domain Learning

Do teaching and learning differ across domains? As documented by Shulman and Quinlan (1996), educational psychologists' answer to this question has changed considerably across time. During the first two decades of the twentieth century, the answer has been mainly in the affirmative. In particular, Dewey (1902/1916) advocated the need to psychologize the subject matter of the studies by making explicit the research work that generated knowledge in a specific domain and by referring it to the present experience of the child. His experimental research was thus located within the naturalistic setting of the laboratory school.

In the next decades, following the lead of researchers such as Thorndike, educational psychologists' interest shifted toward the search for general theories of learning. Even when their research was nested within a particular subject matter, the general theoretical framework constrained the analysis of the disciplinary tasks. In addition, the controlled experiment in laboratory setting became the preferred methodological approach, further detaching psychological research from the educational setting.

Beginning in the 1980s, subject matters regained centrality. For instance, studies on classroom teaching increased understanding of the importance of pedagogical content knowledge. Further, comparisons between novices and experts uncovered the role played by heuristics typical of a certain discipline in the performance on domain-specific tasks. Moreover, the classroom, with its complexities, came to be considered a viable and preferred setting for studying these issues. Overall, researchers found that performance of domain-specific tasks calls for particular psychological processes. These findings spurred investigations of what pedagogical practices can best favor the development of these processes and thus improve students' learning.

In the ensuing sections, we consider some of the outcome of this research for the domains of reading, writing, history, mathematics, and science. Traditionally, these domains occupy a large portion of the educational curriculum, especially in the early years. Thus, it is not by chance that a large body of research about domain learning focused on these areas. We also mention a few controversial issues regarding the translation of research results into pedagogical practice. A general review of the work of educational psychologists in regard to learning within these specific domains may be found in the relevant chapters of the first and second editions of the *Handbook of Educational Psychology* (Alexander and Winne, 2006; Berliner and Calfee, 1996). Alexander (2006) offers an introductory overview of these topics.

Reading

Theories of learning have played a critical role in identifying what is meant by reading and writing, and, more generally, by literacy. Thus, definitions of reading span from the ability to decode (i.e., breaking the linguistic code) and encode (i.e., convert written signs fluently into meaning) to being well learned in a variety of topics as well as in a set of cultural practices (with more or less emphasis on the power structure engrained in them). The method chosen to study the process of reading and writing contributed to influence the definition of literacy also. For example, the exclusive focus on observable behavior characterizing research in the behaviorist tradition precluded the possibility to study understanding. Thus, these researchers mainly focused on handwriting, grammar, word recognition, and perception of print. Further, assuming that meaning is inherent in the text and the individual's role consists in uncovering it, understanding was mainly studied by observing vocabulary and recall. The pedagogical implications of this approach, still present in current curricula, include the suggestion to break the reading process into steps and to teach reading as a series of skills and subskills.

As well exemplified by Bruner (1990), the cognitive revolution focused on explaining mental processes; thus, understanding how meaning was generated became crucial. However, within the cognitive tradition, researchers conceived meaning in different terms. Specifically, the researchers working within the framework of information-processing theory assumed that meaning is transported from the author to the readers, while constructivists posited that meaning is constructed by the readers on the basis of information provided by the author.

This difference notwithstanding, cognitive psychologists fostered understanding of how individuals make sense of information conveyed by texts. By investigating the nature of readers' schemata and how information was organized in memory, researchers studied the role of background knowledge (Anderson and Pearson, 1984). Other studies focused on how different texts work, paying attention to their various structures (e.g., narrative or expository; Alexander and Kulikowich, 1994). Finally, research on the control that individuals maintain during meaning making has explored individuals' knowledge of their own cognitive processes (i.e., metacognition). In particular, researchers investigated individuals' knowledge of the tasks and goals required by reading or writing (i.e., declarative knowledge), of the strategies that allow one to pursue these goals (i.e., procedural knowledge), and individuals' awareness of how, when, and where to use a specific strategy (i.e., conditional knowledge; Garner, 1987). This work provided the background for research in strategy instruction and, limits notwithstanding, shifted the attention of educational psychologists from product to process.

Finally, cognitive psychologists fostered understanding of two basic processes of reading: phonemic awareness and automaticity. Phonemic awareness is the ability to think and manipulate sounds and plays a central role in the study of reading development. Automaticity regards the ability to process perceptual information necessary to the decoding of print with a minimum cognitive load, thus freeing attention for meaning-making purposes; within this process, accuracy and speed emerged as good predictors of comprehension (Stanovich, 1990). These findings suggest the soundness of a balanced reading program, in which mastering basic processes and meaningful engagement with text reinforce each other.

The social constructivist perspective highlighted the social dimension of learning. Thus, the definition of text was extended beyond the printed words to include conversation, media, and, more generally, social discourse. This perspective also implied a crucial epistemological shift since it defined knowledge as the consensus reached by the community of knowledgeable peers for the time being. Thus, according to this view, the external world may exist, but knowledge is not defined by a correspondence to it anymore (Bruffee, 1986). Such a view also suggested that thinking is an internalized version of conversation; thus, learning happens first on the social plane and, subsequently, is internalized by the individual (Vygotsky, 1934/1986). Pedagogically, this perspective advocated practices such as reciprocal teaching and whole language approach. This framework also drew attention on the influence of the context on the meaning-making process.

Writing

The importance of writing for communication, learning, and knowledge transmission can hardly be overstated. However, the scientific study of the process of writing is relatively recent (Graham, 2006). In the previous section, we considered the influence of different theoretical approaches on the study of literacy in general and described their pedagogical suggestions in terms of reading. In this section, we focus on the body of research that specifically addressed the writing process and on its pedagogical implications.

Mainly relying on analyses of think-aloud protocols collected from individuals of different ages and levels of expertise while composing texts, researchers in this domain emphasized that writing is a self-directed process. Often proceeding in a nonlinear fashion, this process requires individuals to simultaneously attend to several cognitive demands and, thus, entails a high level of effort. Although most of the research focused on cognitive processes, motivational and contextual factors were also found to influence writing (e.g., competence beliefs and environmental support).

Most theorists view writing as the interplay of three main components (Hayes and Flower, 1980). The first comprises factors external to the writer, such as topic, audience, and text produced so far. The second component regards the cognitive processes involved in writing and includes planning (e.g., setting goals, generating ideas, and organizing ideas into a plan), text production (e.g., translating plans into a written text), and reviewing (critically reading the text, determining how to address emerged problems, and editing). The final component is the writer's long-term memory, which includes knowledge of the topic, of the intended audience, and of rhetorical devices, as well as general plans to perform the writing task.

This body of research suggests that teaching writing should address all its components (Hillocks, 1986). In particular, direct teaching of strategies for planning and revising has proven particularly effective (Graham, 2005). At the same time, mastering of basic skills such as handwriting and spelling is also crucial to allow individuals to attend to the multiplicity of writing demands.

The learning environment can sustain students' development of writing strategies by offering appropriate scaffolding and peer interactions. Finally, increased awareness of the processes of reading and writing, of their differences as well as of their similarities, can foster the development of programs that facilitate development in both domains (Shanahan, 2005).

History

Although there is general agreement in identifying the domain of history with the past, psychological research has associated strikingly different processes to learning in history. In the first decades of the twentieth century, for example, learning history was viewed as the acquisition of temporal perspective and moral ideals (Hall, 1911), the maturation of chronological and causal thinking (Judd, 1915), and the development of historic sense (Bell, 1917).

Educational researchers, overall, agreed that learning history could not be reduced to answering factual questions; however, they also realized that this component of learning was the easiest to test. Behaviorism further restricted the study of domain-specific topics; in the case of history, research was limited to study how to apportion facts in order to facilitate memorization. It was only with the cognitive revolution that the attention of researchers focused on the psychological processes involved in learning history (Wineburg, 1996).

Aided by the use of qualitative methodologies, educational psychologists explored learners' background knowledge in an attempt to uncover beliefs and conceptions that may have fostered or hindered thinking in history (e.g., ideas about time and chronology, sparse information about historical people and events, and

beliefs about the nature of history). They also studied how historians and novices generated historical understanding while reading primary and secondary sources about specific events (Wineburg, 2001).

This body of research suggested that learning history entails developing familiarity with concepts and ideas that allow a description of the past (i.e., substantive knowledge) and also becoming acquainted with the strategies employed by historical inquirers to research and interpret the past (i.e., procedural knowledge). In particular, the development of historical knowledge includes not only being able to answer who, what, when, where, and how questions about the past (i.e., first-order knowledge), but also developing an understanding of concepts such as causation, change, historical significance, empathy, evidence, and account that allow historical investigators to interpret the past (i.e., second-order knowledge; Lee, 2005).

By comparison, procedural knowledge regards being able to use strategies such as assessing the status of sources, corroborating sources, contextualizing events, constructing evidence-based arguments, and writing accounts (VanSledright and Limón, 2006). The difference of these processes with the experience of memorization of information commonly associated to learning history is striking.

Although research in the past 20 years has increased understanding of the process of learning history and highlighted its specificity, the intense debate about the role of history in the school curriculum makes it difficult to translate these findings into pedagogical practice. In schools, the goal of developing historical thinking is often countered by the will to use history to build a collective, national identity. While the first purpose is well served by pedagogical approaches that foster a view of history as a critical inquiry into the past, the second is better pursued by the transmission of a specific narrative viewed as coinciding with the past. In addition, more research is needed to understand how to prepare teachers to be able to foster historical thinking in their students.

Mathematics

Historically, the characterization of mathematics evolved from a science of numbers and space to a science of patterns. More recently, the view of mathematics as a human activity defined within historical, cultural, and social contexts also emerged. In psychological research, specific aspects of mathematics learning were often used for studying general theories and pedagogical approaches. However, the specificity of thinking within this domain was usually ignored (De Corte *et al.*, 1996).

As surfaced in other domains considered herein, different psychological theories of cognitive development espoused distinctive views of mathematics, used a various array of research methodologies, focused on particular aspects of mathematics learning, and thus reached

different pedagogical conclusions. Behaviorism and connectionism, for example, favored drill and practice of well-defined information, skills, and associations.

The view of mathematics learning changed remarkably with the cognitive revolution, shifting the focus on the processes involved in thinking mathematically. In characterizing the domain, researchers highlighted the dual nature of mathematics. Rooted in the perception and description of the order of objects and events, once mathematics succeeds in modeling these structures through a process of symbolical representation, these representations become amenable to study in an abstract fashion, independent from their real-world roots. The pedagogical consequence of acknowledging this feature of the domain is a shift of focus from computation to modeling (i.e., the thinking of the mathematician; Davis, 1992).

A second characteristic of the domain regards the fact that, historically, mathematical concepts evolved hierarchically through a series of restructuring of previously developed concepts, definitions, and functions. The parallel with the Piagetian characterization of cognitive growth through a series of restructuring engendered by a situation of disequilibrium perhaps explains why mathematics was so often used by cognitive psychologists to study general cognitive development. Pedagogically, this feature of the domain supports practices that help the child relive the developmental process of the discipline (Freudenthal, 1991). This indication does not suggest that children need to reinvent the product of this development (e.g., the definition of rational numbers), rather that they have to tread the same cognitive path of people facing mathematical problems (e.g., abstracting and formalizing).

Finally, development in mathematics requires that individuals are comfortable with multiple modes of representation (e.g., verbal/syntactic, visual/spatial, and formal/symbolic) and fluent in translating from one system to the other. In particular, researchers theorized that mathematical thinking implies the interplay of external representations (e.g., language, symbols on a page, and objects), and internal mental processes, which include internal representations, affective processes, and executive functions (e.g., planning, and monitoring; Goldin, 1992). Pedagogically, this theory suggests that learning mathematics means fostering the development of internal representations well connected and consistent with conventional external representations; fluid movement across different systems of representation also needs to be promoted.

In schools, mathematics is often associated to doing mathematics rather than thinking mathematically. Thus, problem solving takes a central place in the curriculum and a large body of research in mathematics focused on investigating this process. From these studies, it emerged that problem solving involves the interplay of four factors:

domain-specific knowledge, heuristic methods, metacognitive knowledge, and affection (beliefs and emotion).

Domain-specific knowledge refers to definitions, formulas, symbols, algorithms, and concepts typical of the domain. Although this knowledge in experts is well organized and thus flexibly accessible, misconceptions and defective skills often hinder problem solving in novices. In addition, experts tend to categorize problems according to their mathematical structure, whereas novices focus on problem surface characteristics (Chi *et al.*, 1988; Confrey, 1990).

Heuristics are general guidelines that facilitate a systematic approach to the task and thus favor arriving at a solution (e.g., identifying the data of the problem, looking for related problems, and checking the results). However, knowledge of isolated heuristics is usually not very helpful. Research suggests that a more successful approach requires teaching heuristics concurrently with metacognitive skills and while exposing students to a variety of situations, so that learners may understand when and how to use a certain heuristic (Schoenfeld, 1992).

Metacognitive knowledge regards knowledge of one's own cognitive functioning and self-monitoring of these cognitive activities. Skilled problem solvers demonstrate high control of their actions, including planning and monitoring, and, if necessary, make the required corrections to a previously implemented strategy. Finally, affective components of problem solving include beliefs about the self and about mathematics, and emotions such as interest in the task (McLeod, 1990). Research on problem solving has shown that it is possible to teach students to plan and monitor more effectively (Schoenfeld, 1985). In addition, when the learning environment is structured in such a way as to favor reflective practice and talk among students about their thinking, mathematical learning is usually improved (Lampert, 1990).

Science

Reflecting a trend evidenced in other domains, the definition of what it means to learn science and of what psychological processes are central to its development has been influenced by theories of cognitive development. The meaning of learning science has increasingly broadened to include an understanding of substantive concepts and of the nature of science, logical reasoning, procedures used to develop scientific explanations, and metacognitive awareness (Linn *et al.*, 1996).

Comparisons between expert and novice thinking demonstrated that novices' knowledge is organized around concrete factors (e.g., formulas), while experts' knowledge tends to be hierarchically organized around abstract elements (Chi *et al.*, 1981). Beginning in the late 1970s, researchers increasingly distinguished between the

development of logical skills and that of scientific concepts (Pfundt and Duit, 1991). In addition, research extended beyond the acquisition of science information to investigate learners' ideas about the nature of science (Hestenes, 1992). The acknowledgment of the role of metacognition in learning paralleled this shift in focus, suggesting that monitoring one's own cognition is an important component in learning science, once one abandons the idea that science consists of universal truth contained in textbooks (White, 1988).

The interpretation of students' misconceptions also changed; previously conceptualized as instances signaling faulty reasoning on the students' part, these ideas began to be interpreted as alternative intuitions or framework to model the world. Researchers noted that students' misconceptions may originate from inaccurate implications drawn from accurate observations, with a focus on inessential characteristics of phenomena, or on the adoption of standards of evidence and views of science markedly different from those espoused by the scientific community (Kuhn *et al.*, 1988).

From these insights, two lines of research developed; the first focused on conceptual change and the second, on the restructuring of knowledge. Consistent to the Piagetian theory, conceptual change tended to be promoted by using cognitive conflict as a mechanism to foster scientific understanding. More recently, researchers studied what can motivate students to change their current understandings and found that, in addition to facing disconcerting evidence about their current concepts, students also need to confront clear alternatives (Strike and Posner, 1985). This new approach prompted teachers to focus on fostering and guiding the reasoning process of students while they investigate phenomena, rather than contradicting the conclusions they reach.

The investigation of experts' organization of scientific knowledge showed that scientists often use qualitative models (e.g., free-body diagrams) as an aid in problem solving. They also tend to chunk knowledge in patterns that can be used in a variety of situations, developing production rules that link a condition (e.g., the object in contact has different temperature) to a consequent action (e.g., the objects will tend toward equilibrium). In addition, experts tend to entertain several models of scientific phenomena and to choose which one to rely on according to the specific problem they face (Reif and Larkin, 1991).

Studies of novices found that students often entertain conflicting interpretations of scientific phenomena. Some researchers hypothesized that students' scientific knowledge tends to be fragile and fragmented (diSessa, 2002); other studies showed that students tend to contextualize their views, applying one set of ideas to interpret phenomena within the classroom context and another set to deal with the same instance out of class (Gilbert and

Boulter, 2000). In addition, novices' ability to generalize a model across a range of experiences is usually limited.

These findings supported a change in the goals set for science education, with the focus shifting from acquiring science information and concepts to developing the ability to scientifically reason about phenomena (Linn and Eylon, 2006). Pedagogically, this view suggests that students are exposed to a variety of explanatory models and provided with criteria for selecting among them according to the problem considered. Far from engaging students in inquiry or discovery activities for their own sake, this approach highlights the development of background knowledge, modeling and discussion of key processes and strategies, instructional guidance, feedback, use of evidence to test one's own ideas, and monitoring of one's progress (Alexander, 2006).

Concluding Thoughts

The roots of current disciplines and domains of study reach well back in history. These areas of knowledge and practice have not only reflected societies and cultures of their time, but have also influenced them, especially through formal educational systems. The differences in domains continue to shape the landscape of academic practice due to their inherent and socially constructed nature. Here, we have explored several of those features that define contemporary domains and their instantiation in educational practice.

Glossary

Absolute methods – A research methodology that consists of an in-depth examination of high-level experts, usually in a task specific to their domain of expertise (e.g., playing a game of chess for chess experts).

Chunk – A unit of knowledge that is composed of several smaller units of information.

Declarative knowledge – This consists of descriptions about the world including facts, strategies, and principles, and is commonly referred to as knowing that.

Knowledge compilation – A cognitive mechanism hypothesized to interpret declarative knowledge into a set of specific procedural rules given a particular goal.

Procedural knowledge – This consists of information for how to perform particular actions to accomplish task goals, and is commonly referred to as knowing how.

Relative methods – A research methodology that consists of comparing more- to less-experienced participants, often in a neutral task not typically practiced in their domain of expertise (e.g., recalling chess positions for chess experts).

Schema – A hierarchical knowledge structure that includes prototypical information about the type of problem, including declarative knowledge of objects, facts, strategies, and constraints and may also include procedural operators for solving the problem.

Problem solving is a critical cognitive activity that permeates many aspects of our day-to-day lives. We solve problems at home, school, and work ranging from the simple – such as figuring out the tip on a bill – to the complex – such as planning the logistics of a family trip. Problems sometimes have clear goals and steps you can take (as in algebra problems), but sometimes have vague goals or ambiguity about what solution methods are possible. The latter are called ill-structured problems and are considered much more difficult than well-structured problems. Developing expertise in problem solving is critical to the success of a wide range of human activities, including pursuits in science, art, business, and politics. As our society becomes ever-more technologically diverse and

sophisticated, experts are sought in more and more specialized fields. Having a scientific explanation of expert performance is needed to understand its development and to facilitate its acquisition. Knowing what to teach influences the methods of teaching. Expertise research is an area that provides a basis for determining what needs to be taught. Our purpose in writing this article is to provide an integrative review of the psychological research on expert problem solving by taking a close look at what it is, how it is acquired, and the implications for education and instruction.

We structure the article around two interrelated themes. First, that expertise can be understood from an information-processing perspective by focusing on the role of knowledge, its content, and the cognitive processes that bring that knowledge to bear during problem solving. Second, that expert performance is acquired through deliberate practice (Ericsson *et al.*, 1993). This view that expertise can be decomposed into a set of knowledge structures that are learned has implications for how to structure learning environments in order to facilitate its acquisition. In the rest of this article, we explore these themes beginning with a brief review of the methods used to examine expertise, followed by a detailed analysis of how expertise impacts each stage of problem solving. We then review the research on its acquisition with a focus on the underlying cognitive processes. In the final section, we discuss current directions and implications for instruction.

Methods

Researchers have typically used one of two approaches to study expertise, what Chi (2006) has called absolute and relative methods. Absolute methods consist of an in-depth examination of high-level experts, usually in a task specific to their domain of expertise, such as playing a game of chess for chess experts. Defining the level of expertise occurs through established criteria for a particular domain. For some domains, there are written criteria (a rating or scoring system) to determine rank, such as in chess. In other domains, expertise is determined by a certain level of professional achievement, such as becoming a professional ballet dancer, physicist, or a commercial airline pilot. The absolute approach is aimed at providing an in-depth description of the knowledge and cognitive processes underlying

expert performance. This approach includes both observational studies as well as historical analyses of famous cases (e.g., James Clerk Maxwell; Nersessian, 1992). Relative methods involve comparing more- to less-experienced participants, often in a neutral task outside of their domain expertise, such as recalling chess positions for chess experts. The advantage of this approach is that it can uncover the structures and processes of performing the task, and not merely the ways that experts can excel. Both approaches have made extensive use of verbal protocols to obtain detailed data as to the thinking processes that accompany expert (and novice) performance (Ericsson, 2006).

These approaches have produced a wealth of findings on the nature of expertise (for general reviews see the section titled 'Further reading'). In the next section, we draw upon this literature to examine the impact of expertise on problem solving. We begin by describing a general theory of problem solving and then at each stage of the process describe the differences between expert versus novice performance and the explanations to account for those differences.

Expert Problem Solving: Major Findings

Most theories of human problem solving consist of some formulation of the following seven stages:

1. problem categorization,
2. construction of a mental representation of the problem,
3. search for the appropriate problem-solving operators (e.g., strategies or procedures),
4. retrieval and application of those operators to the problem,
5. evaluation of problem-solving progress and solution,
6. iterating stages 1–4 if not satisfied with progress/solution, and finally
7. storage of the solution (e.g., Newell and Simon, 1972).

These stages may not be strictly sequential, but may be iterative. In the following subsections, we describe the expertise findings relevant to each stage and discuss the theories proposed to account for them (see **Figure 1** for an illustration of the problem-solving stages and the impact of expertise on each one).

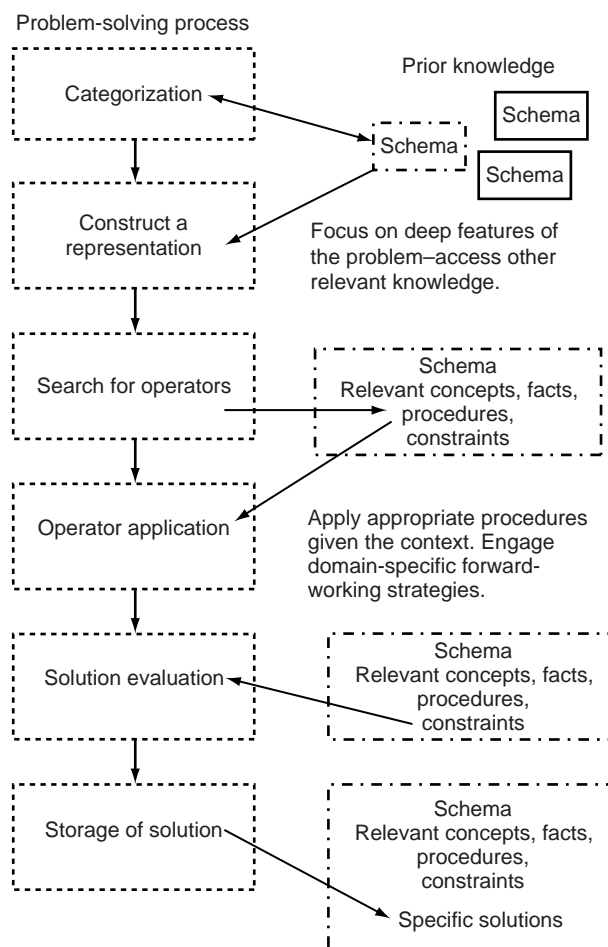

Figure 1 The impact of expertise on each stage of the problem-solving process.

Problem Categorization

The first stage involves the categorization of the problem. This stage is critical as it impacts all subsequent problem-solving processes, such as determining what knowledge to use and what strategies are relevant. For example, after a statistician categorizes a statistics problem as a permutations problem, she or he can proceed by retrieving and applying the appropriate formula to solve it. Much research has shown that experts' domain knowledge actually influences problem perception. When experts are presented a problem or task relevant to their domain of expertise, they see the problem in terms of prior meaningful patterns of information. For example, Chase and Simon (1973a, 1973b) found that expert chess players recalled more than novices on a memory task in which they were briefly presented a game scenario that they had to reconstruct. The experts recalled approximately four times as many pieces as the novices but only for scenarios that were from real games; when the scenario consisted of randomly placed pieces, experts performed at the same level as the novices. It was hypothesized that the experts' prior knowledge facilitated the recognition and recall of domain-relevant patterns, or chunks, of information from the scenarios (see **Figure 2** for an example of chunks in chess). These chunks provide experts useful ways to perceive and reason about large amounts of domain-relevant information.

Similar effects have been shown in research on medical expertise. For example, Lesgold *et al.* (1988) compared expert to novice physicians as they diagnosed X-ray films of the lungs. The physicians were asked to draw on the X-rays to identify the important features of their diagnosis. Both groups noticed abnormalities associated with a collapsed lung. However, experts were much more likely to identify the correct shape and size of the abnormality, whereas novices identified abnormalities that were approximately half the size of those identified by the experts. This work shows that experts and novices can perceive a problem very differently even when looking at the exact same stimulus. This finding that expert knowledge impacts problem perception has been found in a variety of tasks and domains including: architecture (Akin, 1980), mathematics (Silver, 1979), and naturalistic decision-making (NDM) tasks such as a fireman determining the safety of a room in a burning building (Klein, 1998).

A related effect is the finding that experts are more likely than novices to categorize problems at a deep level of abstraction (or function), whereas novices are more likely to categorize problems based on the surface features. For example, in the seminal work by Chi *et al.* (1981) experts and novices were asked to sort physics word problems based on their similarity. Experts sorted them according to their underlying physics principles, such as Newton's second

Figure 2 An example of a chess master's chunk-by-chunk recall of position 67 from Reinfeld (1945) with each new chunk circled. From Chase, W. G. and Simon, H. A. (1973). *The minds eye in chess*. In Chase, W. G. (ed.) *Visual Information Processing*, pp 215–281. New York: Academic Press. With permission from Elsevier.

law, whereas novices sorted them based on their surface features such as inclined planes or pulleys. Similar results have been shown in mathematics, where novices categorized algebra problems on the basis of the problem content (e.g., river problems), whereas more experienced students categorized them based on the underlying equation or principle (Silver, 1979). This effect has been found in a number of domains, including computer programming (Adelson, 1981), medicine (Groen and Patel, 1988), and engineering design (Moss, *et al.*, 2006) among others.

These results have typically been explained by the hypothesis that experts' problem schemas are organized differently than novices. Schemas are hierarchical knowledge structures that include prototypical information about the type of problem, including declarative knowledge of objects, facts, strategies, and constraints, and may also include the procedural operators for solving the problem (Marshall, 1995). Expert schemas are hypothesized to include many principle or structural features of the problem type, whereas novice schemas include few structural features and shallower, surface features. Schemas play a critical role in categorizing a problem. See **Figure 1** for the interactive role schemas play in both problem perception and construction of the problem representation. Next, we discuss how experts and novices construct a mental representation of the whole problem.

Construction of a Representation

After a problem has been categorized, the problem solver can begin to elaborate their mental representation that goes beyond the given information of the task environment. For some simple or well-practiced tasks (e.g., puzzle-type tasks, NDM tasks, and procedural skills), this step happens as rapidly as categorization but for other complex, multistep problems, such as those in physics or ill-structured tasks such as design tasks, constructing a mental representation is an iterative process that takes time to develop. Constructing a representation involves specifying the important features of the task such as the relevant objects, operators, and constraints. When experts are solving complex or ill-structured problems, they approach them qualitatively, first examining and elaborating the givens of the problem and then refining that representation. For example, Voss and Post (1988) examined how experts and novices in political science solved an open-ended problem on how to increase crop productivity in the Soviet Union. They showed that experts spent more time than novices in developing their representation of the problem by elaborating the history and causal factors underlying the problem.

These results are consistent with the schema account of expertise in which experts' schematic knowledge provides access to additional knowledge and strategies to

help elaborate and develop the initial problem representation. This process has been hypothesized to be highly interactive (Chi *et al.*, 1981). Based on the initial categorization, the activated schema can provide additional information, strategies, constraints, and expectations to further characterize and elaborate the problem representation that may in turn activate other relevant schemas. For very complex problems, this process may take several iterations. Consistent with the categorization results described earlier, McDermott and Larkin (1978) (see also Reimann and Chi, 1989) have proposed that physicists construct problem representations at different levels of abstraction including: literal, naive, scientific (qualitative), and algebraic (see **Table 1** for a description of each level). Differences in levels of representation have also been shown in medicine where experts represent text descriptions of patient cases with an abstract situation model, whereas novices represent them more at the text-based (or surface) level (Groen and Patel, 1988).

Not only does expert knowledge facilitate the development and elaboration of the problem representation, but research also shows these representations are very durable. Experts have been shown to quickly encode problems and are able to easily access that representation even after disruption, whereas novices often take much longer to encode and re-represent a problem (Ericsson and Kintsch, 1995). The durability of expert memory and encoding has been shown in a variety of domains, including bridge (Charness, 1979), medicine (Norman *et al.*, 1989), and computer programming (McKeithen *et al.*, 1981). To account for these findings, Ericsson and Kintsch postulate that experts have developed effective long-term working memories that use very specific cues in the task environment to reliably retrieve prior knowledge structures (chunks and schemas).

Table 1 Four different levels of abstraction in representing physics problems

Representation level	Description
Literal	Representations containing keywords from the text.
Naive	Representations containing literal objects and their spatial relationships, often accompanied by a sketch of the situation.
Scientific	Representations containing idealized objects (points, bodies) and physical concepts (forces, momenta).
Algebraic	Equations containing physical concepts and their relationships.

From Reimann, P. and Chi, M. T. H. (1989). Human expertise. In Gilhooly, K. J. (ed.) *Human and Machine Problem Solving*, pp 161–191. New York: Plenum, with permission from Springer.

Application of Problem-Solving Procedures

After a problem representation has been constructed, the problem solver can then access and apply the appropriate problem-solving strategies and procedures to solve it. Experts have been shown to have more reliable access than novices to domain-specific solution procedures for well-practiced problem types. For simple problems, they make decisions faster and more accurately than novices. Research has also shown that experts and novices use different types of strategies when solving simple problems. Experts are more likely to use forward-working strategies for well-practiced problems, whereas novices use backward-working strategies. Forward-working strategies consist of working toward the solution from the domain principles. For example, physics experts first identify the principles for the task and then apply the domain-specific strategies and procedures, working step-by-step toward the solution (Simon and Simon, 1978). In contrast, novices have been shown to use general problem-solving heuristics, such as means-ends analysis to work backward from the problem goal (e.g., a sought value in physics or math). However, strategy use for both experts and novices critically depends on the relationship between prior knowledge and the task. Experts may also use general problem-solving methods and backward-working strategies when solving very novel tasks in the domain (e.g., physicists in their own research).

Solution Evaluation and Storage

Solution evaluation is the process of assessing a problem solution. Research has shown that experts spend more time than novices evaluating their solutions to make sure they satisfy task constraints (Groen and Patel, 1988; Voss and Post, 1988). Experts are also more likely than novices to identify and correct errors. For example, historians given a problem outside their subdomain are more likely than novices to seek additional resources and information to revise their initial framing of the problem, whereas novices are more likely to proceed with their initial incorrect assumptions (Wineburg, 1998). This research suggests that experts have developed better meta-cognitive skills (i.e., reflective monitoring) than novices for domain-relevant tasks. These skills may be particularly useful when adapting their knowledge to novel tasks in the domain.

After a solution has been generated it can be stored for later use. Much research shows that prior knowledge has a large impact on what is learned. For example, it is easier for experts to acquire new knowledge in the domain than for novices. Baseball experts have better recall than novices after listening to the broadcast of a novel baseball game (Spilich *et al.*, 1979) and expert pilots recall more than novices after listening to new air traffic control messages (Morrow *et al.*, 2001). Experts' rich, well-organized knowledge structures

enable them to easily incorporate (assimilate) new information into their prior knowledge.

Summary

Theoretical accounts of expert-novice differences are primarily articulated in the representation and organization of expert knowledge. Not only do experts have more conceptual and procedural knowledge than novices, but their knowledge is also organized in ways that facilitate effective problem solving. They are able to quickly recognize large chunks of domain-relevant information, see the deep features of the problem, and effectively elaborate their initial problem representations. They can apply domain-specific strategies, efficiently monitor their problem-solving progress by refining and correcting solutions, and can learn new domain-relevant information easier than novices. In the next section, we briefly review the theoretical accounts of how this knowledge is acquired.

Acquisition of Expertise

Much research shows that a minimum of 10 years of daily deliberate practice is necessary to develop expertise in most domains (Ericsson *et al.*, 1993). Ericsson and colleagues refer to deliberate practice as

repeated experience in which the individual can attend to the critical aspects of the situation and incrementally improve her or his performance in response to knowledge of results, feedback, or both from a teacher (Ericsson *et al.*, 1993: 368).

This perspective emphasizes how the type and structure of practice is critical to the acquisition of expert performance. In contrast to this perspective is the view that expertise is due to some talent or innate ability. The talent perspective, originally proposed by Galton (1869), is the notion that psychological traits, like physical traits, are inherited and family lineage (i.e., genes) strongly influences the person who achieves expert performance. Most modern formulations of this perspective hypothesize that expertise is the result of a complex interaction between genetic dispositions and experience (e.g., Simonton, 1999). Given that the talent perspective has received limited empirical support (see Howe *et al.*, 1998 for a discussion and commentary) and much research shows that expert advantages are due to their domain knowledge (and not general reasoning or memory abilities), we focus on the cognitive learning processes that give rise to this knowledge.

Expert knowledge is composed of both declarative and procedural components. Declarative knowledge consists of descriptions about the world, including facts, strategies, and principles, and is commonly referred to as knowing that. Procedural knowledge consists of information for how to

perform particular actions to accomplish task goals, and is commonly referred to as knowing how. Different learning processes have been hypothesized to account for the acquisition of these two types of knowledge. Learning declarative knowledge has been hypothesized to occur through observation, comprehension processes for oral and written discourse, induction, analogy, inference, and self-explanation (see Chi and Ohlsson, 2005 for a recent review of the learning mechanisms that lead to the acquisition of complex declarative knowledge). The key point is that declarative knowledge can be acquired through a number of reflective cognitive processes. Learning environments (e.g., classroom instruction) can be structured to facilitate its acquisition by including and improving these processes.

The acquisition of procedural knowledge or skill is hypothesized to occur through the repeated practice of a particular task or problem (Anderson, 1982, 1987). Fitts (1964) has characterized skill acquisition into three stages of performance, including the cognitive, associative, and automatic stages. During the cognitive stage, a person applies declarative knowledge to solve a problem and performance is characterized as being slow, effortful, and error prone. In domains such as mathematics and physics, novices rely heavily on declarative knowledge from prior examples to solve new problems (e.g., VanLehn, 1998). Students often apply this knowledge by making an analogy between the current problem they are solving and a previous problem that was solved similarly or had similar content. In the associative stage, the skill is practiced and performance becomes faster, more accurate, and less susceptible to interference. In this stage, students rely less on examples and more on applying learned rules to solve the problem. In the automatic stage, the skill has become proceduralized and is characterized by the fast application of the knowledge (or rules) with little or no errors and requires minimal cognitive resources.

Research on skill acquisition has revealed a power-law relationship between the amount of practice and performance. Generally, it shows that performance improves most when first learning a task, followed by decreasing learning gains as practice continues until performance asymptotes. However, the pattern of learning is more specific than the fast-then-slow pattern: when plotted on a logarithmic scale, the power-law relationship is revealed as an exact straight line. This exact relationship has been shown to be a very general phenomenon and has been observed in a variety of activities from learning to roll cigars to learning to solve math problems (see Proctor and Dutta, 1995 for a review). See Figure 3 for a real-world example of the power-law relationship.

One mechanism hypothesized to account for procedural learning is knowledge compilation (Anderson, 1987). Knowledge compilation acts as a translation device that interprets, or compiles, declarative knowledge into a set of specific procedural rules given a particular goal. As those

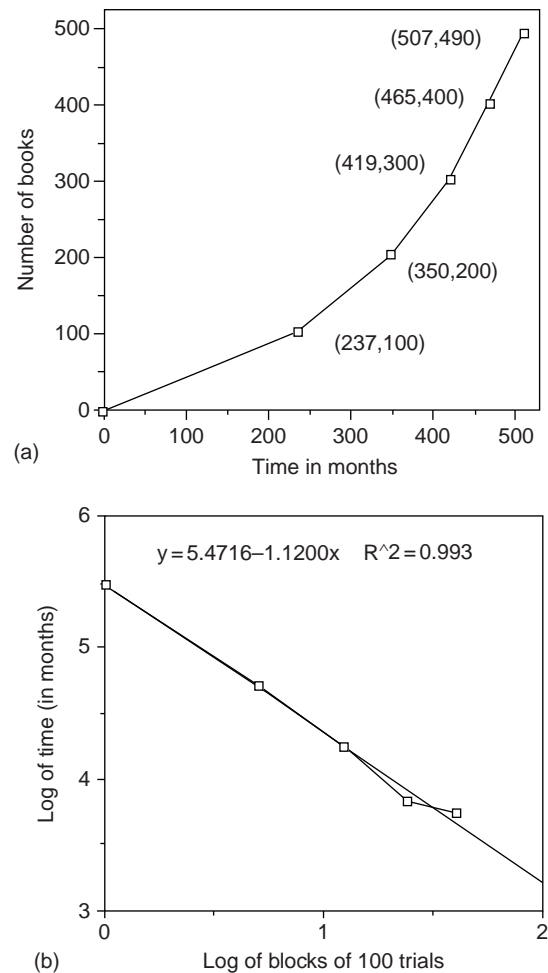

Figure 3 An illustration of the power-law relationship for the development of Professor Asimov's professional writing skills. (a) The number of books Professor Isaac Asimov wrote as a function of time in months. (b) The time to complete 100 books as a function of practice, plotted with logarithmic coordinates on both axes. procedures (rules) get repeatedly applied they become concatenated or chunked together into more compact rules. This mechanism shows how cognitive processing changes from relying on the interpretation and retrieval of declarative knowledge to embedding that knowledge into a set of procedural rules that become more compact with use. The result is a context-specific representation of the skill that can be quickly and efficiently executed.

In sum, research has shown that the acquisition of expert performance requires extended deliberate practice in the domain. Expert knowledge is composed of both declarative and procedural knowledge and research on learning has shown that declarative knowledge can be acquired through multiple cognitive pathways, whereas procedural knowledge comes from the repeated practice of a task. This view suggests that the type and structure of

the learning environment are critical to the acquisition of expert performance. In the final section, we discuss two extensions to the traditional paradigm for research on expertise.

Current Directions

Current research extends the traditional paradigm in a number of ways. In this section, we focus on two: collaborative expertise and using expert–novice differences to determine targets of learning. In recent work, Schunn and colleagues (Tollinger *et al.*, 2006) had the unique opportunity to examine how over 50 NASA scientists worked together to plan the day-to-day operations of the two Mars rovers (Mars Explorer Rover Mission). The scientists' daily task was to analyze the data from the previous day and then come up with a plan for what experiments the rovers would conduct on the next day. They found that the amount of planning decreased across days and followed a learning curve similar to those typically observed for the acquisition of individual expertise, suggesting that expertise can also be acquired at the group level. Initial analyses suggest that the speedup in planning was due to both cognitive factors, such as individual knowledge chunking, plan reuse, and reducing task uncertainty, as well as social factors, such as coordinating information with others and the effect of leadership on the group.

In other recent work, Nokes *et al.* (2006) conducted a laboratory experiment on the effect of expertise on collaborative problem solving. They examined both expert and novice pilots' problem-solving performance when either working alone or with another participant of the same level of expertise. They found that experts working in pairs showed much larger collaborative benefits than novices working together, particularly for complex problem-solving tasks. Analysis of verbal protocols revealed that expert collaborative performance was supported by both domain knowledge (e.g., elaborating each other's contributions) and collaborative skill (e.g., acknowledging and restating the partner's contributions). The pilot and NASA scientist work extends the traditional paradigm and asks how expertise impacts cognitive and social processes at both the individual and the group level.

A second direction focuses on using expertise research to help identify targets of learning for novices. For example, Mestre and colleagues have used some of the classic findings in physics expertise (e.g., Chi *et al.*, 1981) to develop an instructional intervention to help students adopt similar strategies to that of the experts (Dufresne *et al.*, 1992; Mestre *et al.*, 1993). In one study, students were instructed to perform conceptual analyses vis-à-vis a computer interface that was based on the way experts strategize and solve problems, by first identifying the appropriate principles, justifying the use of those principles, and then

articulating the solution procedures. They found that this type of strategizing improved student's conceptual understanding and subsequent problem solving compared to control conditions where students used more traditional approaches to solve problems (e.g., textbook instruction). This research provides one example for how findings from the expertise literature can be used to help improve instructional techniques.

Conclusions

In this article, we reviewed the psychological research on expertise in human problem solving. We saw that expert knowledge impacts each stage of the problem-solving process from problem perception to solution storage. Expert knowledge is composed of both declarative and procedural knowledge and is organized into knowledge structures (e.g., chunks and schemas) that facilitate the categorization and construction of a mental representation of the problem, support the selection of appropriate strategies and procedures, provide constraints to evaluate problem-solving progress, and provide a framework to effectively store new information about the domain. These knowledge structures are acquired through deliberate practice, and learning environments can be designed to facilitate their acquisition. Future work should build upon this rich knowledge base to further advance theories of learning and instruction.

Problem Solving and Reasoning

R E Mayer, University of California, Santa Barbara, CA, USA

Problem solving and reasoning are frequently in the spotlight of educational reform. In addition to remembering information, students must be able to use what they have learned to solve new problems. A major goal of education is to help students become effective problem solvers, that is, people who can generate useful and original solutions when they are confronted with problems they have never seen before.

Definitions

A problem consists of a given state (i.e., a description of the current situation), a goal state (i.e., a description of the desired situation), and a set of operators (i.e., rules for moving from one state to another). A problem occurs when a situation is in one state, the problem solver wants it to be in another state, and there are obstacles preventing a smooth transition from one state to another. Duncker (1945: 1) defined a problem in the following way: “A problem arises when a living creature has a goal but does not know how this goal is to be reached.” Although Duncker’s definition is still valid, it must be updated to include the possibility of problem solving by machines, and so the term problem solver can refer to both living creatures and machines.

Problem solving occurs when a problem solver engages in cognitive activity aimed at overcoming a problem. Duncker (1945: 1) noted that “when one cannot go from the given situation to the desired situation simply by action, then there has to recourse to thinking” and “such thinking has the task of devising some action which may mediate between the existing and desired situations.” Similarly, Polya (1981: ix) defined problem solving as “finding a way out of a difficulty, a way around an obstacle.” In developing computer simulations of problem solving, Newell and Simon (1972) defined problem solving as a search for a path between the given and goal states of a problem. Mayer (1992) summarized three major elements in a definition of problem solving: (1) problem solving is cognitive because it occurs internally within the problem solver’s cognitive system, (2) problem solving is a process, because it involves manipulating or performing operations on the problem solver’s cognitive representations, and (3) problem solving is directed, because the problem solver is attempting to achieve some goal. In short, problem solving is directed, cognitive processing aimed at finding a way to achieve a goal.

What is the relation between problem solving and other high-level cognitive processes such as thinking and reasoning? Thinking can be broken down into two types – directed and nondirected thinking. Problem solving is a common and pervasive type of thinking, namely, directed thinking in which the thinker engages in cognitive processing aimed at achieving some goal. On the contrary, in nondirected thinking, the thinker engages in cognitive processing that is not aimed at achieving some goal, such as daydreaming or the abnormal thinking of autistic or schizophrenic people. In general, the terms problem solving and thinking can be used interchangeably, with the recognition that nondirected thinking is excluded.

Reasoning can be viewed as a type of problem solving, and is required in deductive reasoning tasks and inductive reasoning tasks. In deductive reasoning, the problem solver is given premises and must apply the rules of logic to derive a conclusion. For example, if you know all four-sided polygons are quadrilaterals and all squares are four-sided polygons, you may logically conclude, all squares are quadrilaterals. In inductive reasoning, the problem solver is given a series of instances or events or examples and must infer a rule. For example, after learning the Spanish words *la casa*, *el libro*, *la escuela*, *el perro*, *la muchacha*, and *el muchacho*, you may conclude that the article *la* goes with words ending in *a* and the *el* goes with words ending in *o*, a grammatical rule that is not without exceptions in Spanish.

Finally, creative thinking occurs when a problem solver generates ideas and critical thinking occurs when a problem solver evaluates them. Two important criteria in creative and critical thinking are that the ideas must be original and useful.

Types of Problems

An important distinction – based on the clarity of the problem statement – can be made between well-defined problems and ill-defined problems. A well-defined problem has a clear given state, a clear goal state, and a clear set of allowable operators. For example, finding the value of x in an algebraic equation such as $2x + 5 = 8$ is a well-defined problem because the given state is the equation, the goal state is a value for $x = \underline{\hspace{1cm}}$, and the operators are defined by the rules of algebra and arithmetic. In contrast, an ill-defined problem has a poorly specified given state, goal state, and/or operators. For example, choosing an

appropriate education for a career path is an ill-defined problem because the goal and allowable operators are not clearly specified. Most problems encountered in school are well-defined problems, whereas most crucial problems in everyday life are ill-defined.

Another important distinction – based on the knowledge of the problem solver – can be made between routine and nonroutine problems. Routine problems are identical or very similar to problems that the problem solver already knows how to solve, and therefore require what Wertheimer (1959) called reproductive thinking – reproducing responses that have been produced previously. For example, a routine problem for most high school students is “ $5 + 5 = \underline{\quad}$ ” or “The headquarters of the United Nations is located in the city of .” In the strictest sense, routine problems do not conform to the definition of problem, since they do not include an obstacle between the given and goal states. In contrast, nonroutine problems are different from any problems that the problem solver already knows how to solve and therefore require what Wertheimer (1959) called productive thinking – creating a novel solution. Examples for most high school students include writing a computer program to compute the mean and standard deviation of a sample, or working out why Spanish explorers waited several centuries before colonizing California. In school, students often work on routine problems called exercises; however, most important problems in everyday life are nonroutine.

A third distinction can be made between problems requiring convergent and divergent thinking. Convergent thinking problems have a single correct answer that can be determined by applying a procedure or retrieving a fact from memory. Examples include arithmetic computation problems and answering factual questions. Divergent thinking problems have many possible answers, and so the problem solver’s job is to create as many solutions as possible (Guilford, 1967). Classic examples include uses problems, such as “List all the possible uses of a brick,” and consequences problems, such as “List all the consequences of humans having six rather than five fingers.” Creativity can be measured in terms of the originality and usefulness of the answers, and divergent thinking skills, which underlie creativity, are taught in courses on creative thinking (Sternberg, 1999). Although divergent thinking is the hallmark of creativity, most school-based problems require convergent thinking.

Cognitive Processes and Types of Knowledge in Problem Solving

Problem solving can be divided into two major phases: problem representation and problem solution. Problem representation involves building a mental representation of the problem, and includes the cognitive process of

representing (i.e., building a situation model, that is, a mental representation of the situation described in the problem). Problem solution involves devising and carrying out a plan for solving the problem, and includes the cognitive processes of planning (i.e., devising a plan), executing (i.e., carrying out the plan), and monitoring (i.e., tracking the effectiveness of the plan).

The cognitive processes involved in problem representation and problem solution may interact, rather than occur in linear order. For example, a student may be given the following word problem: “Sarah has three marbles. David has two more marbles than Sarah. How many marbles does David have?” In representing the problem, the student must translate each sentence into an internal mental representation, such as “Sarah’s marbles = 3” and “David’s marbles = Sarah’s marbles + 2,” and mentally integrate them into a situation model, such as a spatial representation consisting of a bar for Sarah’s marbles (3 units high), a bar on top of it for the difference between Sarah’s and David’s marbles (2 units high), and a bar next to these for David’s marbles (indicating that Sarah’s marbles and the difference set of marbles are subsets of David’s marbles). Planning involves determining the operations to be performed, such as determining that 3 and 2 must be added together. Executing involves carrying out the operation(s), such as computing that 5 is the sum of 3 and 2. Monitoring involves detecting when a plan is not working, a step was not executed correctly, or an answer is questionable. Although school instruction tends to emphasize execution of basic skills, students’ major difficulties are in learning how to represent problems, devise plans, and monitor problem-solving processes.

Several types of knowledge are required for successful problem solving: facts, concepts, procedures, strategies, and beliefs (Anderson *et al.*, 2001; Mayer, 2008). Facts are elements of a factual knowledge about the world, such as, “There are 1000 milliliters in a liter.” Concepts are principles or models (which are elements of conceptual knowledge) such as, “In the number 567, 6 refers to the number of tens,” or categories or schemas (which are elements of schematic knowledge), such as knowing that “What is probability of flipping a fair coin three times and getting heads all three times?” is a joint probability problem. Procedures are step-by-step processes, such as knowledge of the procedure for long division used for 252 divided by 12. Strategies are general methods for problem solving, such as knowing how to break a problem into smaller parts. Beliefs are thoughts about one’s cognitive processing, such as believing, “I am good at solving statistics problems.” Facts and concepts are useful in the process of representing; procedures are useful for the process of executing; and strategies and beliefs are useful for planning and monitoring. Although instruction may tend to emphasize facts and procedures, all five kinds of knowledge are needed to support problem solving.

Rigidity in Thinking

A major obstacle to effective problem solving is rigidity in thinking. For example, in some problem-solving situations, the problem solver must use an object in a new way, such as using a brick as a doorstop or using a pencil as a bookmark. When a problem solver can only conceive of using an object in its most common function, then the problem cannot be solved. Duncker (1945) used the term *functional fixedness* to refer to a situation in which a problem solver cannot think of using an object in a new function that is required to solve the problem. Another example of rigidity occurs when a problem solver uses a well-learned procedure on a problem for which the procedure is inappropriate. For example, if a student solved a long series of arithmetic story problems that all contain the word 'more' and require adding the numbers together, the student may incorrectly carry out this same addition procedure for a new problem that actually requires subtracting the numbers from one another. Luchins (1942) used the term *einstellung* (or problem-solving set) to refer to this phenomenon. A goal of instruction in problem solving is to help students avoid rigid thinking.

Problem-Solving Transfer

Transfer is the effect of prior learning on new learning. When the new learning task is a problem to solve, we can use the term *problem-solving transfer* to refer to the effect of prior learning on solving a new problem (Mayer and Wittrock, 2006). Positive transfer occurs when previous learning helps you on a new task, whereas negative transfer occurs when previous learning hurts you on a new task. For example, if you have learned arithmetic, it should be easier for you to solve an arithmetic word problem – which would indicate positive transfer. If you learned to drive on the right side of the road in the United States, you may experience negative transfer in trying to learn to drive on the left side of the road in Australia. How does transfer work? This has been a central research question in psychology and education since Thorndike's (1931) (Thorndike and Woodworth, 1901) pioneering work in the early 1900s, and has generated three alternative explanations: general transfer, specific transfer, and mixed transfer. General transfer is the idea that learning task *A* can help you on task *B*, even if *A* and *B* have nothing specifically in common. For example, the doctrine of formal discipline (which is a classic theory of general transfer) posited that learning certain school subjects, such as Latin and geometry, would improve students' minds in general and thereby help them on unrelated tasks in the future. The doctrine of formal discipline was used to justify the establishment of Latin schools, in which the curriculum consisted of learning Latin, Greek,

geometry, and similar subjects. In one of the first experiments in the field of educational psychology, Thorndike (1931) (Thorndike and Woodworth, 1901) was able to show that students who learned Latin did not perform any better in learning bookkeeping than did students who had not learned Latin. Subsequent research (Singley and Anderson, 1989) also found little support for the idea of general transfer. In contrast, specific transfer is the idea that learning task *A* will help you in task *B* only to the degree that *A* and *B* have identical elements in common. Thus, learning Latin may help you learn Spanish because some of the verb conjugations are similar and many of the words are similar. The theory of specific transfer is problematic for educators because it suggests that students need to learn every specific piece of knowledge they will ever need.

Mixed transfer is a compromise between general and specific transfer that involves specific transfer of a general principle, that is, mixed transfer occurs when a learner abstracts a general principle from learning *A* and is able to apply it to solving a new problem *B*. The transfer is specific because both *A* and *B* can be solved by the same general principle but what is being transferred is a general principle rather than specific behaviors. For example, if students learn to make sense out of text passages by producing summaries, this general method can be transferred to the task of making sense out of a new text passage. Research on teaching of cognitive strategies shows that students can benefit from learning general strategies such as summarizing in reading comprehension (Pressley and Woloshyn, 1995).

Promoting positive transfer is a fundamental goal of education, that is, educators seek to help students learn in ways so that they will be able to use what they have learned to solve new problems. Mayer and Wittrock (2006) have described seven ways to promote problem-solving transfer: load-reducing methods, such as helping students build automaticity in basic skills; structure-based methods, such as using concrete models; schema-based methods, such as using advance organizers or pretraining; generative methods, such as encouraging learners to engage in elaboration or self-explanation; guided discovery methods, such as providing hints as someone solves a problem; modeling methods, such as providing worked examples; and teaching thinking skills, such as training people to use effective methods and strategies.

The Distinction between Productive and Reproductive Thinking

Why is it that some people invent clever solutions when confronted with a problem, whereas others do not? The Gestalt psychologist, Wertheimer (1959) attempted to answer this question by distinguishing between two kinds of thinking mentioned above, namely productive thinking and reproductive thinking. Productive thinking

involves producing a novel solution when confronted with a problem, whereas reproductive thinking occurs when problem solvers use solution procedures that they already know as a result of solving previous problems.

For example, Wertheimer (1959) described two ways of learning how to find the area of a parallelogram – learning by rote and learning by understanding. In learning by rote (or rote learning), the student is taught to measure the height, measure the base, and then multiply height times base. According to Wertheimer, students who learn by rote perform well on retention tests, such as finding the area of similar parallelograms, and poorly on transfer problems, such as finding the area of an unusually shaped parallelogram. In contrast, students who learn by understanding (or by meaningful learning) are encouraged to discover that the parallelogram can be converted into a rectangle by cutting the triangle off one end and moving it to the other end. Students who learn by understanding are expected to perform well on both retention and transfer tests. Thus, rote learning leads to reproductive thinking (as measured by retention tests) whereas meaningful learning leads to productive thinking (as measured by transfer tests).

The Nature of Insight

Insight is the cognitive process by which a problem solver suddenly moves from a state of not knowing how to solve a problem to a state of knowing how to solve a problem (Mayer, 1995). Insight plays a crucial role in creative thinking (Sternberg, 1999), in which a problem solver invents novel solutions to a problem. How does insight work? Gestalt psychologists and others have offered five somewhat interrelated explanations (Mayer, 1995): insight as completing a schema, insight as sudden visual reorganization, insight as reformulation of a problem, insight as removing mental blocks, and insight as finding a problem analog. Selz, working in the early 1900s in the Netherlands, produced psychology's first explanation of insight as completing a schema (Frijda and De Groot, 1982). For example, when given a problem such as "What is a co-ordinate of baseball?" a problem solver may say, "Let's see. Baseball is a sport. Another sport is football, so football is the answer." In this case, the problem solver is not following a chain of associations, but rather is trying to build a cognitive structure that has a superset (sport) linked to two subsets that are co-ordinates (baseball and one more), so coming up with an answer amounts to completing a schema. The idea that meaningful learning requires active construction by the learner is the fundamental theme of many current theories of learning (Bransford *et al.*, 1999).

Kohler, also working in the early 1900s, provided evidence that insight is a process of sudden visual reorganization in which the problem solver literally sees how all the parts of the problem fit together (Kohler, 1925).

For example, when an ape was put in an area that had stackable crates on the floor and bananas hanging overhead out of reach, the ape looked around and then in an apparent flash of insight, suddenly stacked the crates to form a sort of ladder leading to the bananas. This approach is consistent with current interest in using computer-assisted visualizations and concrete representations to help people understand how various systems work.

Duncker (1945) described insight as a reformulation of the problem, particularly a restatement of the givens or the goal in a new way. For example, in the tumor problem, you are asked to free a person of an inoperable stomach tumor by using "rays which destroy organic tissue at sufficient intensity" (p. 1). In order to solve the problem, the problem solver must restate the goal as, "lower the intensity of the rays as they pass through the healthy tissue," which leads to the solution of having many weak rays all converge on the tumor. This approach is consistent with the current idea that the most difficult aspect of problem solving is mentally representing the problem in a productive way.

Duncker (1945) also described insight as a process of removing mental blocks, that is, of being able to use an object in way that is different from its conventional use. For example, in the candle problem, the problem solver is given a box containing candles, a box containing tacks, and a box containing matches, and is asked to mount a lighted candle on a wall. The solution – involving using a box as the base, which is tacked into the wall – is much more difficult if the objects are in the boxes rather than next to them. According to Duncker, presenting the objects in the boxes creates functional fixedness – the tendency to be able to conceive of only one use of an object even though a problem solution requires using an object in a new way. Removing mental blocks is a key focus of current programs aimed at teaching thinking skills.

Finally, Wertheimer (1959) offered a fifth explanation of insight – finding a problem analog – in which the problem solver abstracts a general principle from one problem and applies it to a new one. Thinking by analogy is still an important theme in cognitive science, and is the basis for more current views of problem-solving transfer (Holyoak, 2005).

A sixth explanation – insight as nothing new – holds that solving insight problems is no different from solving other problems (Weisberg and Suls, 1973), although Metcalfe and Wiebe (1987) have shown that problem solvers use qualitatively different thinking processes for insight problems and routine problems.

Problem Space and Search Processes

Information-processing theories of problem solving focus on constructing a problem space and finding a path through the problem space (Newell and Simon, 1972;

Novick and Bassok, 2005). A problem space consists of a representation of the initial state, goal state, and all intervening states. For example, the problem space for solving the equation, $2X - 5 = X$, has this equation as the initial state, and $X = \underline{\hspace{1cm}}$ as the goal state. Two of the intervening states, directly after the initial state are $2X = X + 5$ and $2X - X - 5 = 0$, which were created by applying legal operators such as add 5 to both sides or subtract X from both sides. Similarly, other states are created by applying operators to these states, and so on.

Once a problem is represented as a problem space, the problem solver's task is to search for a path from the initial state to the goal state. Means-ends analysis is a search strategy in which the problem solver works on one goal at time; if that goal cannot be achieved directly, the problem solver sets a new goal of removing barriers, and so on. This search strategy is commonly used in computer simulations of problem solving and is consistent with the way that beginners solve problems.

Problem Solving in Realistic Situations

Although classic research focused mainly on solving artificial puzzles or formal syllogisms, cognitive science research on problem solving and reasoning has been shifting toward realistic situations including everyday problem solving, expert problem solving, and problem solving in subject areas (Ericsson *et al.*, 2006; Holyoak and Morrison, 2005).

Research on everyday thinking shows that people rarely use school-taught methods to solve problems encountered outside of school (Lave, 1988; Nunes *et al.*, 1993). For example, to determine the best buy in a supermarket – such as 90 cents for a 10-ounce can of peanuts or 45 cents for a 4-ounce can – the school-taught procedure is compute the unit cost of each item (i.e., 9 cents vs. 11.25 cents, respectively). However, Lave (1988) found that people almost never used the school-taught procedure; instead, they invented arithmetic procedures suited to the situation, such as the ratio strategy in which the problem solver notes that the larger one is a better buy because it costs twice as much and gives you more than twice as many ounces.

Research on expert problem solving compares differences in how novices and experts solve problems in domains such as physics, medical diagnosis, computer programming, and the game of chess. For example, when Larkin (1983) asked experts and novices to think aloud as they solved physics problems, she found that experts were more likely to focus on underlying physics concepts (such as forces and weights) whereas novices focused on surface characteristics (such as pulleys and ropes). Similarly, when Chi *et al.* (1981) asked experts and novices to sort physics problems into groups, experts sorted problems based on their underlying physics principle (such as conservation of energy), whereas novices sorted the problems based on

their surface characteristics (such as inclined planes and springs). Results of expert–novice studies suggest that experts represent and solve problems differently from novices, and so instruction can focus on helping novices think more like experts.

Another example of problem solving in realistic situations involves psychologies of subject matter, that is, research on problem solving in subject areas, such as reading, writing, mathematics, science, and history (Mayer, 2008). Instead of asking, how do people think in general, researchers ask, how do people think about testing a scientific theory, solving a mathematics word problem, or explaining why a historical event happened, or how do people think as they create an essay or make sense out of a printed passage. This approach suggests that instruction in subject matter areas should focus on helping students learn the cognitive processes and strategies required for successful problem solving.

Glossary

Behaviorism – The psychological theory stating that all internal cognitive function can be captured by observing individual behavior. According to this theory, no additional information about an individual's psyche can be gleaned from attempting to understand internal processes.

Heteronomy – Piagetian stage of moral development during which an individual is said to be adherent to the demands of an authority source without question or detraction.

Moral justifications – Reasoning that appeals to justice, others' welfare, and rights to the end of supporting a moral judgment.

Psychological justifications – Reasoning that appeals to autonomy, individuality, and personal choice to the end of supporting a psychological judgment.

Social cognitive domain theory – The proposition that social cognition and the perception of action can be parsed into three mutually exclusive but interactive domains of social knowledge: moral, conventional, and psychological.

Social-conventional justifications – Reasoning that appeals to values existing to promote the orderly function of groups such as customs, conventions, and etiquette.

Stage model – A theory that posits that an individual's development occurs in a linear and nonrecursive direction.

Transgression – An infraction. A potentially subjective belief that an action runs contrary to agreed upon way of operating in the world.

Introduction

Moral and social reasoning, which refer to how individuals evaluate social issues and events that occur throughout the life time, emerge in early childhood and evolve through adolescence. Moral reasons refer to those pertaining to justice, others' welfare, and rights. Social reasoning includes social-conventional reasoning about customs, conventions, and etiquette, as well as psychological reasoning about autonomy, individuality, and personal choice. The historical

background about the study of moral and social reasoning will be described followed by current findings on how these types of reasons develop, are acquired, and emerge in different cultures.

Historical Background

Jean Piaget (1932), a Swiss child developmental psychologist, first theorized about the origins of moral reasoning in the early part of the latter century. Piaget drew on deontological moral philosophy to define morality, which he posited referred to judgments that were universal, autonomous of authority, and distinct from cultural norms. Piaget did not examine children's performance on exams or tests, but rather developed an interview method to examine the forms of reasons that children used in their everyday interactions, such as the underlying principles associated with the rules and conventions of the game of marbles. This developmentally appropriate methodology represented a challenge to the prevailing measurement of behavior as an index of morality in the 1950s, with Piaget's focusing instead on intentions, motivations, and principles. Adapting the stage-model reasoning used to explain cognitive development (1932), Piaget postulated that there were three distinct stages of moral development, premoral, heteronomy (authority orientation), and autonomy (principles of justice). One of the unique aspects of Piaget's theory was the focus on the role of peer interaction in the development of moral judgment. Piaget demonstrated how children's peer interactions enable them to develop concepts of equality and fairness.

Lawrence Kohlberg (1969, 1971), a professor at Harvard University, extended the work of Piaget (1932) and critiqued the behaviorist conception of morality as learning rather than knowing (Kohlberg, 1971). Kohlberg characterized morality as a set of stages with universal moral principles as the highest level (1969). It was postulated that an individual's morality developed in a series of six stages moving from the personal, to the conventional, then finally to the moral. At this final stage of moral development, it was theorized that an individual would only act in accordance with universal morality, never heeding to competing commands from would-be sources of authority. Kohlberg hypothesized that moral reasoning developed much later than Piaget had first documented. Kohlberg developed a dilemma used throughout the

social sciences to measure reasoning, which involved a man's decision to steal a drug to save his wife's life (the Heinz dilemma task).

More recently, Elliot Turiel (1983, 1998), who worked with Kohlberg, expanded the study of moral reasoning by outlining three domains of knowledge: the moral, social-conventional, and psychological. Turiel provided evidence to show that children as young as 4–5 years of age were not premoral in the way that Piaget and Kohlberg suggested, and instead understood basic ideas about fairness, equality, and justice. At the same time that children recognize that certain transgressions such as hitting and not sharing with others are wrong due to the intrinsic negative consequences to others, they also begin to develop an understanding about conventions that serve to make groups function. Turiel's approach to social and moral reasoning was applied to children and adolescents in many cultures around the globe by many of his students and colleagues (see Smetana, 2006).

In the next sections, moral and social reasoning in childhood and adolescence are described, followed by how these forms of reasoning emerge in different cultures, as we note implications for education, and educational programs.

Preschool and Early Childhood

One of the first studies to assess moral transgressions in comparison to social conventional violations was undertaken by Nucci and Turiel (1978). Nucci and Turiel (1978) identified these differentiated domains within a preschool-aged sample. The researchers found that children and adults were quick to respond to moral transgressions, but only the adults reacted to the social conventional violations. Specifically, Nucci and Turiel (1978) discovered that moral transgressions were often addressed by peers when violated (as compared to social-conventional violations) and done so in the language that a child knows best: the language of another child. This study confirmed the basic distinction between domains of social knowledge, specifically assessing that conventional transgressions are bound up with authority dictates (i.e., a teacher's comments about the transgressions), while moral transgressions are generalizable and lack authority contingency (i.e., both teachers and peers responded to physical transgressions).

Further extending the empirical and theoretical framework of domain theory, Judith Smetana conducted a study using a preschool-aged sample to assess their understanding of the nature of morality. Smetana (1981) assessed seriousness, rule contingency, rule relativism, and amount of deserved punishment for ten different age-appropriate moral (hitting and not sharing toys) and social-conventional (child sitting in the wrong seat and putting a toy in the wrong place) violations. Across age and sex, all children considered moral violations to be more serious and more deserving

of punishment than social-conventional transgressions. Furthermore, children considered moral transgressions to be wrong regardless of the presence of a rule forbidding such an act, judging the inherent wrongness of a moral transgression to be what made the action wrong. Neither the presence of a rule, context, nor consensus determined the morality of a transgression. In comparison, social conventions were more likely to be contingent upon rules and relative contexts (place, time, etc.). This seminal work by Judith Smetana provided both confirmation and extension of social cognitive domain theory and an elaboration of Nucci and Turiel's earlier findings (Smetana, 2006).

A study by Killen and Smetana (1999) assessed children's evaluations of moral, social-conventional, personal, and mixed-domain events. Observing children's and teachers' reactions to a variety of rule violations, the researchers coded different behaviors and subsequent responses. When observing student/teacher interaction, the researchers found that teachers used the most didactic language when addressing moral and social-conventional violations. Conversely, teachers were not nearly as direct when addressing personal-domain and mixed-domain violations. Perhaps most significantly, children often vocalized personal-domain assertions ("I want juice, not milk"), thereby demanding autonomy when they believed their personal free choice was violated. However, not just children are aware of this domain of thought. When interviewed, teachers identified a personal domain for their students as well as understood the children's need for autonomy (the child can choose the type of toy with which they want to play).

Middle Childhood

As we might expect, children's social and moral reasoning do not simply plateau in early childhood. Rather, the developmental story of social and moral reasoning continues through the years. Conducting interviews with over 100 children, Tisak (1986) assessed children's conceptions of parental authority. Specifically, Tisak examined the boundaries of parental authority and found that children view authority as heteronymous and context dependant. Children were asked to consider the legitimacy of a parent's moral rule (do not steal toys), social-conventional rule (do not leave dishes on the table), and personal choice (you cannot play with a certain child). In addition, children were asked to evaluate the obligation to follow an established rule once it has been put in place. Rather than viewing rules and authority as homogeneous, children considered the domain-specific demands of each rule, differentiating moral rules (stealing) to be most legitimate, followed by social-conventional rules (family chores), and finally personal (friend choice) to be the least legitimate within the range of reasonable parental jurisdiction. It seems that children's

expectations of autonomy and evaluations of authority change dramatically as the child develops.

Considering the issue of authority, rules, and regulations, Laupa *et al.* (1995) examine children's concepts of authority (Laupa *et al.*, 1995) as a means of assessing the different components of authority evaluation, reasoning, and the subsequent act of obedience or dissent. Children understand what underlies authority jurisdiction, and, contrary to popular conceptions, they do not view authority as right because of punishment or strict obedience. Children judge the nature of the authority comments, whether the request is legitimate, and the basis for why the authority figure is making a command (Tisak, 1986).

Laupa's study addresses the source of the command and the attributes of the authority. The authority is assessed by age (or adult/child status), knowledge specific to the command, and social position (e.g., the authority's place in the hierarchy within an organization or system: a school teacher compared to a principal, etc.). Laupa *et al.* (1995) also study the relationship between dominant and subordinate individuals. This relationship between authority figures and subordinates is contingent on the specific context and content of each situation, as those sources of authority deemed legitimate in one situation may not be considered viable in another.

Accordingly, individuals critically consider the source of an individual's legitimacy when assessing the imperative to obey an order (Laupa, 1991). If the social context is the source of a body's authority, then the risk of punishment may influence rates of obedience (Laupa, 1991). Compliance to authority is not punishment-avoidant (Kohlberg, 1969) or heteronomous, as Piaget hypothesized (1932/1965), but based on the specific exigency of the specific command and its components.

Children do not just consider the immediate or tangible when reasoning about social and moral rights, but rather actively assess larger issues of freedom and civil rights. Charles Helwig (1995) found that individual rights to freedom of religion and speech were considered moral: natural, unalterable, and generalizable with children across a variety of ages, all rejecting the impediment of these rights by the government. In addition, Helwig found that despite the moral imperative to maintain freedom of religion and speech, children were aware of the complexities and intricacies of these rights. Specifically, children understood that these rights presented choices that younger individuals may not yet be fit to make and are accordingly denied such rights till they have reached a more experienced age. This understanding of the complexity of civil rights emerges with age. Children as young as 6 were aware of these civil rights and reason that such rights should be upheld without waiver. However, by age 8 children begin to evaluate these rights in light of greater contextual needs and issues as they attempt to coordinate the mutual demands of multidomain issues (e.g., "Is a racial slur protected as free speech?").

Adolescents

In another study by Nucci (2001), it was found that as children develop, a greater number of issues (such as those pertaining to the body and privacy) become considered matters of personal choice, existing outside of both moral and social-conventional domains (1991). Some issues of personal autonomy and privacy, which had never been contentious in the past, become all the more important as a child develops. Expectations of increased privacy and autonomy both mark the development of an individual from late childhood into adolescence. Specifically, the issue of drug use was studied by Nucci *et al.* (1991) insofar as how 9th and 12th graders reason about the use of controlled substances. This study revealed that across age groups and frequency of drug use, adolescents view the choice to use drugs as one of personal choice rather than a moral or social-conventional matter. However, those participants who were considered high users were more likely than their low-user counterparts to consider drug use an entirely personal choice. Conversely, participants who were considered low users also used prudential reasoning (concerns for harm to the body and physical dangers associated with drugs) in addition to asserting autonomy and identifying the choice to use drugs as a personal one (Nucci *et al.*, 1991).

Expected autonomy over conventional, prudential, and personal issues (as well as issues which require the coordination of these distinct domains) predictably increases through adolescence. However, Smetana and colleagues found that adolescents and parents reason differently about these three types of issues.

When interviewed, mothers thought prudential and social-conventional decisions were within the realm of reasonable and expected parental authority. Conversely, adolescents viewed prudential and social-conventional issues as a matter of joint authority, and not the sole decision of a parent. Multifaceted personal issues requiring the coordination of several domains were considered by adolescents to be best explored with the aid of a parent. Although adolescents are not content to merely act on a parent's opinion, it was shown that they do still seek out parental input as a valuable source of information when making a complex or significant choice. This choice to seek out additional information from parents seems to be a highly beneficial one for adolescents, as outcomes were found to be dramatically better for those participants who sought this additional parental perspective. Yet, a balance is required. As teenagers enter late adolescence, a lack of autonomy is also often marked by increased depression and a reduction in the adolescent's sense of self-worth. The work of Smetana would seem to argue for a careful balancing act in which parents and parenting matters a great deal to adolescents, yet, these emerging adults also require some degree of autonomy with respect to the increased number of responsibilities expected of an older teenager (Smetana *et al.*, 2004).

Culture

Up to this point, the studies described for social and moral reasoning have been empirically investigated in the United States. However, an entire body of cross-cultural research on consistencies and variations in moral reasoning has also been conducted.

Wainryb (1995) explored the moral reasoning of both Israeli Jewish and Israeli Druze populations. Concerned with both personal and justice-based decisions within authority-sanctioned or interpersonal contexts (whether or not it was alright to keep someone else's lost money if sanctioned by a parental authority), Wainryb assessed reasoning in both groups of participants. It was found that culture was not a good predictor for how individuals framed and reasoned about different moral and personal issues. Rather, the content and context-specific attributes of the vignette was the better predictor of participant outcome across the two distinct and very different cultures.

Considering the traditional social psychology dichotomization of Eastern and Western cultures, the findings of Kristin Neff and Charles Helwig are of particular import. Neff and Helwig (2002) examined conceptions of rights and individualism in China, India, the United States, and Canada. Importantly, prior research had almost exclusively associated individualistic cultures (the United States, Canada) with concerns for rights and justice and collectivist cultures (China, India) with tradition and authority. However, all four cultural groups expressed concerns for justice and rights as well as for tradition and authority simultaneously. Furthermore, commonly held conceptions and traditions were not blindly accepted by participants, but rather participants questioned the cultural traditional practices with a critical eye.

Ardila-Ray and Killen (2001) studied evaluations of loci of control, compliance, teacher legitimacy, and teacher methods of conflict resolution in moral, social-conventional, and personal domains in Colombia, which is considered a particularly collectivistic culture for the Western hemisphere. Developmentally, the expectation of personal autonomy for choice of activity, playmate, and adherence to social-convention increased with age. Older children expected more freedom for making such choices. In addition, students preferred more elaborated explanations from their teachers with age, as students were increasingly less satisfied with explanation-void punishment. These findings, in what has been traditionally considered a collectivistic culture, indicate that children critically evaluate their rights and the role of authority.

Similar to Colombian children's homogenous and critical evaluations of rights and authority, school-aged Chinese children critically evaluated social situations. Yau and Smetana (1996) examined the developmental demands of children for autonomy in Hong Kong. Consistent with a global model of emerging demands in the personal

domain, children, as they move from early adolescence (9th grade) into late adolescence (12th grade), require more autonomy. Accordingly, Chinese children's reports of warmth and closeness with family members were negatively correlated with rating of conflicts and controlling behaviors. This finding supports a developmental model of social reasoning with respect to autonomy that is not an exclusively Western phenomenon but rather an emerging need and concern throughout the world.

Nucci *et al.* (1996) reported that middle and lower socioeconomic status (SES) school-aged children in Brazil found that concerns for physical well-being were subject to parental authority and judgment. In addition, the personal domain was examined and an effect was found to have an interaction with SES where children in middle-class families expected more autonomy and attributed a greater number of choices to the personal domain than their lower SES peers. However, and, perhaps most interestingly, this SES-based difference for distinguishing the contents of the personal domain disappeared with age. Lower and middle SES children both expected comparable levels of personal freedom and autonomy by the time they reached age 16.

This cross-cultural research indicates a break from the traditional dichotomy of Eastern and Western cultures. Rather, researchers find that both Eastern (traditionally conceptualized as collectivistic) and Western cultures (traditionally conceptualized as individualistic) value traditions and values. Furthermore, as the literature of subversion will support, there is heterogeneity within these larger groups.

Complex issues that are not prototypically moral, social-conventional, or personal often demand the simultaneous coordination of multiple domains at once. Killen and colleagues have investigated exclusion in intergroup relation settings, where moral, social-conventional, and psychological issues bear on decisions about who to include and who to exclude. In a study with preschool-aged children, participants gave priority to fairness in the context of gender stereotypic reasons for exclusion (e.g., girls exclude a boy from doll playing) when the exclusion was straightforward, but relied on stereotypes when the exclusion involved multiple considerations (Killen *et al.*, 2001). Further, in a study with first, fourth, and seventh graders, children were asked about exclusion in straightforward and equal and unequal qualification situations (Killen and Stangor, 2001). Results showed that in the equal qualifications context, participants were more likely to choose the nonstereotypical child to join the group (e.g., choose the boy for ballet and the girl for baseball cards), but were less likely to include the nonstereotypical child if that child was not as qualified as another child (Killen and Stangor, 2001). Developmentally, seventh graders were most sensitive to context, justifying exclusion in the unequal condition more strongly than either the first or the fourth graders. Older children have more experience with groups and know that effective

functioning is important. Thus, their reasons for picking a more qualified child often pertain to considerations of group dynamics and group functioning.

Stereotypes and Social Reasoning

There is a paucity of research specifically addressing the interplay between stereotypes and social reasoning; however, it is important to address the role of stereotypes in social contexts involving exclusion, because stereotypes inform an individual's judgments on who to include, as well as their justifications for doing so. A stereotype that negatively informs a judgment could result in someone denying resources to the stereotyped individual. Conversely, a stereotype that positively informs judgments may result in inclusion of the stereotype-inconsistent person because of the knowledge that that person may not get many chances to do something stereotype inconsistent (i.e., Killen and Stangor, 2001).

In a related study, Horn (2003) analyzed high school participants' judgments regarding exclusion based on group membership (e.g., cheerleaders, jocks, preppies, etc.) when given ambiguous and nonambiguous information about the situation and the target's qualifications. Similar to the findings by Killen and Stangor (2001), Horn and colleagues found that participants judged exclusion in the ambiguous condition as more wrong than exclusion in the nonambiguous condition (Horn, 2003). Extending previous findings, they also found that participants used more group-related stereotypes when judging ambiguity. Specifically, ninth graders used more stereotypes than did 11th graders in the ambiguous condition (Horn, 2003). This research, along with the Killen and Stangor (2001) study, has been important in showing that in exclusion situations, different factors are taken into account, and also that group functioning is important in the eyes of adolescents. However, it is important to understand that stereotype-laden social reasoning is a product of an individual's belief and understanding of facts, rather than being a matter of simple bigotry.

Educational Implications

The place of morality in the classroom – and whether or not it is in fact a school's responsibility to offer moral education – has been debated for decades. Larry Nucci has examined the trend and controversy of moral education as it had emerged and shifted over the course of the 20th century. Nucci (2001) suggests that moral education is not so much about judgment as it is about reasoning. We now know that children begin to learn about the features that underlie and distinguish different domains of social knowledge from a much younger-than-expected age. Findings suggest that children are engaged in this task

by age 5, the same time that the child begins formal schooling. The according import of teaching students to critically assess and evaluate, rather than didactically instruct on what is or is not right is undeniable (Wainryb *et al.*, 2004). The most significant work before teachers charged with educating students is therefore the skill and art of critical thinking.

Conclusions

In summary, social and moral reasoning begin in childhood and reflect a central part of what it means to live in a culture and be a member of a society and community. The process of basing everyday decisions on such concepts as fairness, justice, equality, and respect for autonomy is universal. It is not unique to one culture or to one category of persons. Giving priority to moral and nonmoral social considerations varies by the context, and thus, in many situations, children are learning how to do this for the first time. Parents and educators can facilitate this process by helping children to determine the various salient issues in any specific decision-making context, particularly those involving social and moral reasoning.

Glossary

Conversation analysis (CA) – The detailed analysis of how talk makes things happen in social life, business life, healthcare, education, leisure, politics, etc.

Discursive psychology – The study of the relations between psychological topics and everyday talk through the examination of the ways in which we use common-sense ideas about thoughts, emotions, attitudes, etc., as resources for accounting for everyday life.

Metacognitive formulation of remembering and forgetting – It refers to how we use what it is to remember and forget in warranting our claims to experience and accounts of events and our position on and within them.

Schema – A conceptualization of a principle for the organization of the content of experience.

Introduction

Memory is of critical importance in any consideration of learning. To become knowledgeable through any process of learning appears deeply bound up with what it is to remember and forget. Without memory we have no purchase on what we knew, know, and might come to know. So then, we might expect that all that is required is an understanding of how we consign to, contain within, and conscript the contents of memory.

Charles Dickens graphically illustrates rote learning and the centrality of memory as the container of knowledge in his cryptic parody of English Victorian education in *Hard Times*. Indeed, Gradgrind's teaching is emblematic for all that was lacking in schooling where verbatim rehearsal of multiplication tables, scientific formulae, grammar, poetry, and historical dates was the order of the day:

'Bitzer,' said Thomas Gradgrind, 'Your definition of a horse.' 'Quadruped. Graminivorous. Forty teeth, namely twenty-four grinders, four eye-teeth and twelve incisive. Sheds coat in the spring; in marshy countries sheds hoofs too. Hoofs hard, but requiring to be shod with iron. Age known by marks in mouth.' Thus (and much more) Bitzer.

'Now girl number twenty,' said Gradgrind. 'You know what a horse is' (p. 6).

For Bitzer to thrive in Gradgrind's world, he must enter a particular world defined by what Gradgrind marks as institutionally relevant. Bitzer's mnemonic performance is isomorphic with what it is to know. Equally, girl number 20 is presented with a model performance in Gradgrind's terms of what sort of practice frames and circumscribes what she should take to be relevant about a horse. We may pride ourselves that such iconoclastic domination of the tutorial process is no longer a property of contemporary educational practices. However, the key point here is, that notwithstanding the limitations of such a rote-approach learning, this fictional representation is accomplished in terms of the practice of memory; and its performance is part of what it is to display competent membership of the classroom setting within which Gradgrind, Bitzer, and all those other serried ranks of numbered pupils belonged.

It is fair to argue that until comparatively recently, psychologists have overwhelming thought of memory in terms of the storage of past experience. This container metaphor has dominated psychological research in the same way that talk of wax tablets and theatres was common for more ancient discussions on the topic. The problems that arise from treating mind as a vast warehouse wherein individual memories are cataloged and retrieved have been much rehearsed, not least by psychologists themselves. Such a view leads us to expect a kind of clarity and order to exist in human remembering that is simply absent from empirical evidence. Container metaphors may then ultimately be the wrong kind of metaphors in which to approach memory.

Work in psychology focusing on social practices of remembering and forgetting aims to displace the container view of memory in favor of an understanding of memory as a form of communicative action. Work in this area argues that psychological phenomena such as memory are better understood as accomplishments that occur in the course of communicative action, whether talk or text. Memory, on this account, is something that speakers/writers perform rather than simply possess in the course of routine interaction. These performances are informed by cultural understandings of what is to be counted as adequate and felicitous recall. The discursive study of memory entails a shift from viewing memory as some entity, whether in the mind or in the world. Instead the focus is on remembering and forgetting as social acts, as ways of accomplishing some activity in the present through invoking the past in an appropriate and resourceful manner.

This discursive approach also draws inspiration from Maurice Halbwachs' (1925/1992, 1950/1980) prioritization of language as the principle means in the collective organization of remembering and forgetting. If we treat remembering as a situated and contingent communicative act, three key issues emerge. First, since speakers must necessarily act toward and respond to one another in real time in order to sustain an interaction, we are led to attend to the ways in which remembering is sequentially organized. Second, given this sequential organization, we may analyze how inferences about the past are used by speakers when they co-opt one another into projects of remembering and forgetting. Third, that co-option into such projects involves the realization of memberships that are made relevant in the social occasioning and organization of remembering and forgetting.

These discursive issues – sequential organization, co-option, and membership – open up promising lines of empirical research into the social practices of memory. They also have relevance for understanding the memory practices in educational settings (see e.g., Edwards, 1987).

Interactive and Sequential Organization of Memory

Early exploration of discursive remembering focused upon the conversational devices we use in producing joint version of events and how we build a taken as given (default) continuity, as part of the sequential organization of talk concerning narrative sequence of events (Edwards and Middleton, 1986). In doing this, we share the burden of recall, comparing recollections, inserting out-of-sequence reminiscences, and commenting when we run into difficulty on what it is to remember and forget.

Such enquiry demonstrates the usefulness of conversational data in making visible the way we provide explicit formulations of inferential links and rationalizations concerning the past in our accounts of experience. In the course of such public thinking we often explicate such links and causal inferences. In addition, we justify and warrant versions against alternatives and the possibility of refutation. That is, our acts of remembering are always cast in an anticipated argumentative context. We are aware that we may be called upon, almost immediately, to justify, warrant, or produce supporting evidence for the claims we make about the past, and therefore build in to our claims rhetorical features that are designed to address possible objections (such as reporting mundane detail; using reported speech of others; and, for example, the manipulation of whether we are make a claim about the past from a first of third-person position – I vs. they).

These early findings, derived from conversational action within groups deliberately set up for the purposes

of studying joint recall, have been demonstrated in a wide variety of everyday contexts, including family, work, and leisure contexts where participants talk to each other in the social creation and justification of memories. However, the joint recall of events is a familiar and well-practiced activity that may occur across a wide range of settings, including classrooms (see e.g., Mercer, 2000). A range of linguistic resources are identifiable for remembering jointly in settings such as: overt requests for assistance that signal or invite ratification of claims concerning what may or may not have happened in the past; overt agreements (“yes that’s right”); ratification through the repetition of the previous speaker’s contribution; metacognitive formulations of the process of remembering itself and the specific problematic of remembering (“I’ve been trying to remember for quite a while”).

Metacognitive formulations are more than public expression of our personal understanding regarding the nature of our own mental processes (Flavell and Wellman, 1977). In fact, to understand these expressions solely in this way is to commit the same error as treating a schema as purely a mental representation. Metacognitive formulations arise in an occasioned manner, in particular discursive contexts, typically at points of difficulty – for instance, when speakers claim not to be able to remember something, or are suddenly reminded, or attempt to remember and try to fit a putative version of events with what another speaker is saying. On all these occasions, a public reflection on one’s own mental processes may strengthen or warrant a subsequent claim.

Instead of treating conversational action as a window upon mental processes, we can see that conversations act as significant environments in which thoughts are formulated, justified, and socialized according to how other speakers talk about mental processes. We do not need to know whether the claims people make about their mental processes – their memory – are actually correct or not in order to study how remembering and forgetting are socially accomplished (Middleton and Edwards, 1990). For example, consider the following two instances of talk analyzed by Charles Goodwin:

‘what was that guy’s name.=Blake?’

‘and what was the solution do you remember we discussing it here?’

Goodwin (1987) points out that displays of uncertainty in conversation are typically glossed in talk as remembering or forgetting. Orientations to uncertainty and forgetfulness can provide speakers with “resources for shaping their emerging interaction” (p. 116). In other words, saying something like “I don’t remember” is a good way for speakers to leave options open in the conversation. This is an instance of metacognitive construction – acquiring a conventional vocabulary and discourse for mental life designed to serve the social pragmatics of

conversation (Edwards, 1997). All of these linguistic devices contribute to the sequential unfolding of recollection, as each speaker's utterance dovetails with the last. A continuity by default is constructed, where each contribution builds upon and adds to the last.

Inference and Co-Option in Socially Organized Settings

Discursive analyses can also demonstrate that remembering is a fundamental aspect of the social ordering of the settings within which it occurs. Indeed, its occurrence appears to be functional to the continuing integrity not only of the psychological functioning of people in those settings but of the settings themselves. For example, we can examine conversations between parents and young children talking about family photographs. Such conversations frequently turn on establishing just what it is that people are looking at. However, the issue rarely stops there. In working out what is depicted in such snapshots, in jointly remembering, children are drawn into conversations that provide the basis for elaborating issues of identity, relationships, and emotional reactions to previous experiences.

In such conversations, past experiences are offered as a meaningful part of a continuing biography and development of personal identity. This is more than accessing the contents of memory. It is part of the ways in which what it is to remember and forget are used in communicative action. For example, parents may demonstrate something important both about remembering and about taking meaning from pictures – the role of inference: “it must have been a sunny day in that photograph(.) mustn't it?”. Photographs can be read for clues about the scene depicted. Sunny days are associated with pictures with sharp contrast and deep shadows, with sea and sand, blue skies, summer activities and clothing, and so on. None of those clues are explicit in what a parent says, but the implication is clear, that photographs in some way permit or afford inferences about the weather.

Parents can therefore demonstrate how remembering can be done by displaying how to read the photographs for clues to the contextual circumstances depicted. By so doing, children are taught to treat past events as memorable in terms of how they are affected and how they reacted to them as a family group. Inference serves as a basis for reconstruction. Children are therefore inducted into two sets of procedures. First, the use of artifacts such as photographs as inferential puzzles which may resource acts of remembering, and second, the resolution of such puzzles as a way of displaying a continuity between past and present. For instance, by establishing a continuity of personal experience over time, past experiences, and preferences, as they are inferred from the photographs, are

constructed as relevant to a discussion of the sort of persons children are at the time of speaking. This sort of discursive analysis also makes visible how we recruit or co-opt one another into social activities. Remembering can be achieved through talking to people. Children can learn how this is accomplished through the ways in which parents actively involve them in conversational projects concerning the past.

The collective accomplishment of remembering appears to be functional to the continuing and indeed developing lives of children and parents as members of family groups. As Bakhurst (1990) argues, in settings where remembering is mediated by cultural objects such as photographs, “we remember by constructing narratives which require the recall of past events for their intelligible completion” (p. 211). In other words, our narratives set up puzzles that are seemingly completed by the act of remembering, which as a consequence does a work of establishing continuities in identity. Such narrative puzzles then make up and sustain the very setting that entails what it is to be an accountable member of a grouping such as a family where the past is a direct topic of conversational concern.

Membership

This concern with continuity is illustrated in a final detailed example of discursive analysis taken from the conversations between a 4-year-old boy (Paul) and his mother as they looked through a family photograph album. Paul is constantly positioned as the next speaker, and as a consequence of the sequential organization of talk thereby co-opted into the project of remembering. How is the potential significance of Paul's experience achieved in terms of making his actions and supposed feelings (at the time of taking the photograph) relevant to family relationships, implied identities, and emotional significances? This involves the use of a series of contrasts between the interdependent experiences of a series of family members (including his father and sister).

From Middleton, 1997:

- Mother: oh look (.) there's when we went to the riding
[stables wasn't it?
Paul: [yeh (.) er er
Mother: you was trying to reach up and stroke that horse
Paul: where? (laughs)
Mother: would you like to do that again?
Paul: yeh
Mother: you don't look very happy though
Paul: because I thought I was going to fall off
Mother: you thought you was going to fall off did you?
(.) right misery (.) Daddy was holding on to you
so that you didn't (1) did it FEEL very bumpy?
Paul: yeh

- Mother: did it make your legs ache? [Paul laughs]
 Rebecca enjoyed it
- Paul: yeh
- Mother: she's a bit older wasn't she? (.) you were a little boy there

The mother's talk constantly appoints Paul as the next speaker in the project of remembering. In doing this, the mother provides candidate experiences in terms of Paul's actions and feelings, both physical and emotional, that would count as plausible interpretations of the events depicted and his position within them ("you was trying to reach up and stroke that horse"; "would you like to do that again?"; "you don't look very happy though"). The interactive appointment of Paul as accountable elicits an explanatory reminiscence from him ("because I thought I was going to fall off"). That is, Paul is required to produce a recollection in order to resolve the narrative puzzle that his mother has set up for him. In doing this, Paul provides an account occasioned in their talk for the display of unhappiness his mother has assigned to his actions in the photograph. What is more, the particular kind of account which Paul produces is of necessity one couched in terms of mental states, since only this kind of account will adequately address the narrative demands which have been interactionally established.

The mother responds by putting another question ("you thought you were going to fall off") and retakes the initiative of monitoring and displaying the form and content of the interaction in terms of candidate accounts of the actions, motives, and feelings of those depicted in the photo: of Paul as a ("right misery"); of his father's actions in the account offered of the events ("daddy was holding on to you"); for Paul's continued discomfort ("did it feel very bumpy"); and for his sisters engagement in the same event ("Rebecca enjoyed it"). In other words, the interactionally occasioned claims concerning his supposed experience of the events depicted in the snapshot are presented as relevant in terms of family relationships; relative and changing identities ("she's a bit older wasn't she"; "you were a little boy there"); and comparative affective reactions of family members ("Rebecca enjoyed it"). In summary, the experiences claimed on Paul's behalf are contrasted with those of other family members and with himself in the past. The negotiation of Paul's experience is then simultaneously a restating of what it means to be an accountable member of this particular family.

The sequential organization of such conversational remembering privileges the claims made in terms of their relevance beyond a pure statement of what is depicted in the photo – children, horses, adults, beaches, etc. We can see how the Mother's pursuit of contextual reminiscences co-opted Paul into justifying the claims being made on his behalf about the nature and consequence of his experience. For example, Paul is in some sense forced to accommodate

to the evaluation that he is a right misery because to do otherwise would involve challenging the mother's purported statement of fact that "daddy was holding on to you so that you didn't [fall]". When we use reminiscences in this way we interactively commit others to the relevance of our experience claims, or as in this case, the claims made by the mother on Paul's behalf. In this way, experience claims are not just an individual concern, they are presented as a concern of others and a concern in terms of the collectivities with which people are associated within conversational remembering, be they families, teams, classrooms, or any other educational setting. Accomplishing accountable memberships of a setting is no easy matter. The work of the conversation analyst Harvey Sacks (1992) is instructive on this issue. Sacks argues that it is not enough just to claim entitlements to the consequences of particular experiences. We must show them to be warranted in their conversational action. The point being that when we tell a story about events and describe their consequences for us, what we can say we felt is closely regulated in terms of the interactions of the moment. He makes the point that the experience and its consequences that we claim to have had in virtue of our participation in events must be the ones we are entitled to have. Sacks goes on to suggest and show that such entitlements are accomplished through the way we place ourselves as speakers in the events we narrate. This is of pertinence to the socially organized engagement of pupils and teachers in, and reproduction of, educational settings.

Summary

We can see how a discursive approach to psychology studies and how everyday versions of events (including persons, things, and states of affairs) are constructed and occasioned in talk and text. As descriptions of events can be indefinitely varied, discursive analysis examines how specific versions are produced and fitted to the occasions of their production (see Heritage, 1984). Overall, discursive analysis aims to reveal how versions are produced (how events are described, and so on), and what interactional business we accomplish by constructing our descriptions in one way rather than another (Potter and Wetherell, 1987). Any account of events reported is one of an indefinite number of possible reports. Often accounts are contrasted rhetorically, with alternative versions (Billig, 1996). Even the idea of versions being wrong can be treated through considering the way we orient to and address issues of accuracy, rather than deciding such matters in advance (as is typically done in experimental studies of memory). The factual and cognitive status of a report, as being offered from memory, or on the basis of direct experience, or as lies, error, or hearsay, are also studied as matters to be established by participants, rather

than as categories applied by analyst after the event. Psychological concerns are redefined within discursive psychology as those that may arise for participants (Edwards and Potter, 1992).

These issues go beyond the relevance of memory for educational settings as one of consigning, containing, and conscripting content in the service of understanding. It is possible to examine how our efforts as speakers at recollection are dependent on the contributions of others, or as premised upon a collectively held experience. Remembering therefore unfolds on a social and collective basis. Moreover, it is possible to identify various facets of the interactional organization of remembering, such as sequential organization, inference and co-option, and membership. These facets are all integral to the way speakers in educational setting communicate past experience as part of current pedagogical projects and activities.

Introduction

Computer-supported collaborative learning (CSCL) is the field concerned with how information and communication technology (ICT) might support learning in groups (co-located and distributed). It is also about understanding the actions and activities mediated by ICT. Its educational applications range from generic collaboration environments (e.g., forums) to tools for developing domain-specific knowledge. The research questions addressed by CSCL include how individuals learn with specific tools, how small groups interact and develop shared meanings over time, how institutions change and create new conditions for teaching and learning, and even how the opportunities for learning change as society adopts new models for education. Societies increasingly require new types of knowledge, new means of knowledge advancement and, consequently, new models of education.

To account for the multiple perspectives associated with CSCL without risking oversimplification, we adopt a sociocultural approach and present the main concepts and results. In particular, we make use of two overarching concepts – scaffolding and mediating artifact. Scaffolding is an instructional technique with which the teacher models the learning task, then gradually fades away and shifts responsibility to the students (Wood et al., 1976). In collaborative learning, students might also take on this role. By a technological scaffold, we mean features built into educational software that perform similar functions (e.g., guidance in virtual collaboration).

Related to scaffolding is the concept of mediation, proposed by Vygotsky (1986). This implies that technology for teaching and learning is first of all a mediating and

enhancing artifact. In the article we explore a special type of mediation, which is the relation between design-based research (DBR) and innovative CSCL tools (Collins *et al.*, 2004), on the one hand, and how this creates new opportunities for education on the other (Andriessen *et al.*, 2003).

CSCL emerged in response to skills that are important in a knowledge-based society. These are skills that were previously associated with deep learning of specialized knowledge, metacommunication, metacognition, and task reconceptualization (Järvelä and Salovaara, 2004). These skills are not easily taught through memorizing and fact finding using textbooks, which are the prevailing methods for learning basic skills. In fact finding, for example, the goal of the activity is most often invisible to students and the focus tends to be on tasks (Hewitt, 2001).

The shift in perspective concerning learning and cognition that CSCL provides is, in part, a result of the raised expectations in a knowledge-based society. The labor market of today demands: (1) specialized (domain-specific) skills and (2) an ability to work in teams (the capacity to integrate different types of knowledge and skills through collaboration). Specialized knowledge is important because the labor market is fragmented and interwoven in complex ways. The demands for skills in collaboration and knowledge integration (e.g., critically evaluate information resources found on the World Wide Web (WWW)) have come to the foreground over the past 10 years, making the teaching of communication, information seeking, and collaboration more important than ever.

CSCL is about teaching and learning the knowledge and skills required for participation in the knowledge-based society in concert with the basic skills they rely upon. The view we present here is consistent with those of

scholars who argue that the needs for specialized knowledge and collaboration skills must be met with a comprehensive approach (Järvelä and Salovaara, 2004; de Jong, 2006; Scardamalia and Bereiter, 2006).

CSCL is also a result of the widespread use of Web-based information systems and their acceptance by a broad group of actors at all levels in the education sector and by many workplaces (e.g., learning management systems and discussion forums). Two specific directions in educational research that have taken advantage of CSCL are ICT as mediators of accumulated knowledge (Paavola and Hakkarainen, 2005) and ICT as cultural tools (Wertsch, 1991; Ludvigsen and Mørch, 2003).

This article covers the major issues, research approaches, and questions concerning CSCL. We start by providing an overview of the field, including a presentation of key events and directions. Then we provide an overview of some important results grouped into two research approaches. Next, an overview of DBR and its implications for CSCL is provided. In closing, we identify the remaining open issues and point out some directions for further research.

Background

CSCL is a new and emerging field in the educational sciences (Stahl *et al.*, 2006). The term was first publicly used at an international workshop in 1989 in Maratea, Italy. The first international conference was organized in 1995 (Koschmann, 1996), and since then a biannual series of CSCL conferences has been arranged across Europe, North America, and Asia. In 2006, the *International Journal of Computer-Supported Collaborative Learning* (IJCSCL) brought-out its inaugural issue.

Broadly speaking, there are two main traditions within the learning sciences: cognitive psychology and the situated/sociocultural perspective. The former is based on the information-processing perspective (e.g., Anderson, 1993) and the latter on American pragmatism (e.g., Dewey, Mead, Garfinkel, and Schön,) and Soviet psychology (e.g., Vygotsky, Leontiev, Luria, and Wertsch). In CSCL studies, methods and techniques from both traditions are used and sometimes blended (e.g., interaction analysis). However, within each tradition there are unique interpretations of key concepts, methods, and empirical design.

Technical advances in computer science have contributed to CSCL in various ways. For example, researchers in computer-supported cooperative work (CSCW) have developed groupware systems that have been adopted for educational purposes (e.g., Stahl, 2006). Groupware provide shared spaces (Bannon and Bødker, 1997) on the WWW for storing and sharing information (messages, documents, pictures, and videos) and engaging the learners in social interaction (Girgensohn and Lee, 2002). When adopted in schools, they allow teachers and learners to interact online using a variety of communication and collaboration tools.

Examples of shared spaces are Basic Support for Collaborative Learning (BSCL) (Stahl, 2006), Future Learning Environment (FLE) (Muukkonen *et al.*, 1999), and Knowledge Forum (Scardamalia and Bereiter, 2006).

The relationship between computer support (CS) and collaborative learning (CL) in CSCL is complex as a result of the broad scope of the research questions, the multiplicity of approaches, and the plethora of educational technologies. This complexity needs to be unraveled in order to provide a more comprehensive account of the field. Although technology has had an enormous influence on CSCL, educational technologies should not be thought of as recipes for organizing teaching and learning. Similarly, the term CL does not imply that learning in small groups is better than individual learning. They are both needed and depend on each other. Findings indicate that detailed analyses of talk are necessary to understand how collaboration is carried out (Arnseth and Ludvigsen, 2006). It is not a question of an either/or situation, but rather how to identify specific situations that require mastery of new skills and design scaffolds for those situations. The common denominator is Vygotskian epistemology, which states that social interaction precedes learning and cognition at the level of the individual. To design for this requires CSCL tools and pedagogical models that foster social interaction and ease the transition from social interaction to learning and development. In this way, CSCL both represents a subfield in educational research and broadens the scope of educational research since it interacts with computer science and information systems.

Research Approaches in CSCL

We have grouped mainstream CSCL research into systemic and dialogical approaches (Arnseth and Ludvigsen, 2006). This distinction gives us the possibility to provide a more aggregated picture of what we know about research in CSCL.

Systemic Approach

The systemic approach concerns the generation of models of how specific features of technological tools afford or constrain collaboration, reasoning, knowledge representation, and inquiry (Dillenbourg, 1999) and to what extent these features will enhance students' capacities to solve problems in different domains (Arnseth and Ludvigsen, 2006). From a systemic approach, the analytic purpose is to identify interdependencies between quantifiable variables. The unit of analysis is the individually acting and thinking agent, and the two important cognitive processes are internalization (acquiring new or improving existing knowledge) and transfer (what is learned in one situation is applied to another similar situation). Models (often computer generated) of

how individuals construct, store, retrieve, and modify information serve as explanations of these phenomena (Anderson, 1993; Greeno, 2006).

Using a systemic approach in a traditional classroom setting in mathematics and reading, Lamon *et al.* (1996) demonstrated that students with CSCL tools performed better than students without such tools. The Jasper project (The Cognition and Technology Group at Vanderbilt, 1990) also reported similar results. The researchers in this large project studied the impact of educational technology on mathematics education in North America. They found that cooperative problem solving and discussion helped to engage the students in learning. In Europe, Fischer and colleagues studied how different types of scripts and tasks impact students' CL activities (Fischer and Mandl, 2005). Computational scripts were used to scaffold actions, and social scripts, such as role distribution, were used to organize turn taking. The authors found that scripts were useful for scaffolding learning and knowledge construction. However, these findings did not hold for all conditions (these conditions are further discussed in the last section of the article).

One of the most influential approaches within the systemic approach is knowledge building developed by Scardamalia and Bereiter (2006). Knowledge building is a model for distributed CL that is based on how professional scientists work to solve problems. The authors developed CSCL tools to support knowledge building (Computer-Supported Intentional Learning Environment (CSILE), Knowledge Forum). The latest version includes a Web-based shared space (WebCSILE). A further development of the Knowledge Forum is FLE (Muukkonen *et al.*, 1999).

The activities students engage in when involved in knowledge building can be formulated as a scientific-inquiry process, and many studies have been conducted using this approach (e.g., Hewitt, 2001). The phases of scientific inquiry include problem identification, proposing personal theories or hypotheses, experimentation, critical evaluation, data interpretation, scientific explanation, and summarizing. The studies in this area demonstrate that students who are engaged in knowledge building develop a deeper understanding of the domain under study. However, not all students benefit from it (Ludvigsen and Mørch, 2003). This may be related to the approach used, since a shortcoming in many of the studies is the timeframe adopted, which may range from a few hours to a few days. A consequence of this brevity is that conversational data is analyzed without taking into account the historical context of the interaction, which unfolds over time. The implication of such an approach is that the students' learning trajectories become less visible in the analysis (Crook, 1998; Rasmussen, 2005).

de Jong (2006) summarized recent research in scientific inquiry learning. He found that a number of students learn more effectively and develop deepening knowledge when supported with CSCL tools. The recommendation

de Jong proposes is that it is possible to design scaffolding mechanisms into CSCL environments that enhance students' learning. On the other hand, the results also show that most students have problems using predefined structures and processes adopted from professional science. An explanation for this difficulty is that the students do not have sufficient background knowledge to grasp the significance of the scientific inquiry process, and prefer instead to use everyday interpretations of scientific phenomena. Using a professional model of science to scaffold a learning environment provides a certain kind of insight, but it also generates new problems that are not easily resolved with a systemic approach.

In summary, the systemic approach gives useful guidelines for how we can build scaffolds for cognitive processes like hypothesis generation, data interpretation, and scientific explanation. However, this model-based approach to learning and cognition needs to be supplemented by a situational approach from a social and cultural perspective to provide a full account of CSCL.

Dialogic Approach

The dialogic approach is based on the idea that learning is a socially organized activity. The unit of analysis is a group of individuals interacting to accomplish a shared goal. Key concepts are mediation, artifacts and tools, and social practice, and mediation by tools to support learning is essential. It is through talk and interaction with significant others that we can understand how participants use tools and resources in learning and cognition. Externalization is seen as the main cognitive activity. The dialogic approach is influenced by research in situated learning and sociocultural perspectives (Greeno, 2006; Vygotsky 1986; Rommetveit, 1992; Valsiner and van der Veer, 2000; Wertsch, 1991). A basic premise is that both physical and abstract tools mediate human activities, and the main abstract tool is language (Vygotsky, 1986). The use of tools for learning is not only goal driven, but can also be seen in connection with how tools connect us with the past (predecessor artifacts) and with the future (unexplored potentials). The tools span both spatial and temporal dimensions.

In a study performed by Mercer and Wegerif (1999), students were exposed to a set of ground rules for communication. These rules included the use of arguments, disputes, clarifications, and explanations. The students and teachers were trained to talk together in specific ways in order to develop shared knowledge about a specific phenomenon of interest. In a series of interventions, the ground rules became a focus of the inquiry and previously implicit structures, like norms for participation, became explicit and transparent. This increased the probability for the kind of talk Mercer and Wegerif (1999) refer to as exploratory talk. Exploratory talk is characterized by the mutual

development of problems and ideas over time as a result of reflection and elaboration. They designed learning environments and new types of tasks to support these activities to promote more productive interactions in classrooms. It is further suggested that productive interaction needs to be understood not only as sequences of interaction, but as part of a broader context of institutional activities and sociocultural developments (Crook, 1998; Arnseth and Ludvigsen, 2006).

An example of a micro-study using the dialogic approach is the study of the effects of copy and paste on learning productivity. The cognitive effort involved in using copy and paste for text production and school presentations is low. As a result, many students use this technique uncritically. Some scholars have argued that it does not promote learning and should be discouraged (Hewitt, 2001; Kumpulainen and Wray, 2002). Using the dialogic approach, we can study this phenomenon in conjunction with how participants use the tools they have at their disposal to identify how the talk among the participants unfold as a result of tool mediation and emergent intermediate processes. Rasmussen (2005) found that students used copied texts as resources to deepen and broaden their understanding of the subject they studied.

Another finding concerning the use of the dialogic approach is that tasks are often open ended and cannot be taken for granted (Rasmussen, 2005). When studying how talk emerges in interaction as an analytic approach, the task needs to be constructed among the participants (Linell, 1998). The effect of this is that understanding the task becomes a learning activity in its own right, and this will stimulate the development of a higher-order skill (task conceptualization). When we assume that students working together share goals, task reconceptualization should be seen as an outcome of the activities rather than part of the premises for working together.

Suthers (2005) has identified intersubjective meaning making (Rommetveit, 1992) as one of the unique areas that CSCL is well equipped to support, and he suggests CSCL researchers undertake studies that attempt to understand how intersubjective meaning making impacts learning and how it can be mediated by technology affordances (Norman, 1999) embedded in CSCL tools. Suthers (2005) defines intersubjective meaning making as a joint composition of interpretations of a dynamically changing context. With this proposal, he provides a bold attempt to go beyond an information-sharing conception of CL. Technological affordances for exploratory learning and cooperative problem solving are proposed to support this process.

In summary, a dialogic approach to CSCL provides new analytic concepts to analyze how students and teachers interact in collaborative learning. The dialogic approach gives broader insights and explanations concerning the development of traditional skills, and pays particular attention

to skills such as those for communication, coordination, information seeking, information sharing, collaboration, negotiation, critiquing, and decision making, and how to design CSCL tools to support these activities.

Design-Based Research

Pedagogical Design

DBR has influenced research methodology in CSCL. DBR provides a solution for one of the dilemmas that confront researchers in the field – on the one hand, understanding how people learn, particularly within school settings, and on the other designing ways to ensure that learning will happen in a better manner in these settings (Brown, 1992; Collins *et al.*, 2004). The development of DBR has been on theoretical and methodological levels. On the methodology level, DBR suggests partnerships among researchers and educators with the goals of conducting rigorous and reflective inquiry, testing, and refining innovative learning environments, and defining new design principles based on previous research (Sandoval and Bell, 2004). On the theoretical level, design principles are the practical application of what we know about learning. As such, DBR does not provide direction for which research approach would be appropriate. Both the systemic and the dialogic approaches could be used.

Technology Design

The link between DBR and technology design is harder to establish. This is a result of the focus on theoretical and methodological issues (not well integrated with technological issues) and the difficulty involved in creating design principles that are practically useful for technology developers. There is an implied link between design principles and technology affordances in that the latter operationalize the former. However, this is a normative assumption upheld by some CSCL researchers, arguably strongest in the systemic tradition. Although many educational researchers agree that the basic principles of the sociocultural approach are important for the design of learning environments, the adoption of these principles have been hampered by a complex chain of elaborations before the principles can be used for developing specific tools. This is an important area for further work in CSCL (e.g., Suthers, 2005).

The basic idea of design principles in DBR is that we make use of what we know about previous research on learning when we design new learning environments. Although there is not an exact correspondence between the design principles proposed based on previous empirical studies and the design of an innovation for a new setting, the idea that the designers try to support the learning processes and anticipate its outcomes in specific directions

is likely to succeed over time. For example, the principle of deep learning can be found in many CSCL environments, in various forms (e.g., Linn *et al.*, 2004, Scardamalia and Bereiter, 2006). de Jong (2006) provides a recent overview.

The operationalization of design principles into technology affordances works best for principles that lend themselves to tool support, such as scaffolding (Wood *et al.*, 1976). This principle has been successfully incorporated into many CSCL tools, often in the form of automated feedback and/or guidance. Technology scaffolds takes advantage of regularities of:

- subject domains (Fischer *et al.*, 1991);
- knowledge types and scientific inquiry (Muukkonen *et al.*, 1999; de Jong, 2006);
- presence of others, group awareness, and social networks (Kreijns and Kirschner, 2004); and
- feedback and advice for online collaboration (Soller *et al.*, 2005; Mørch *et al.*, 2005).

One debate among technology developers concerns the degree to which computerized feedback should simulate or provide higher-level representations of user-interaction data before output (feedback or guidance) is generated. Soller *et al.* (2005) suggest three levels of feedback: mirroring (awareness), metacognitive tools, and guidance. This gradually increases the system's interpretation of the user data and consequently requires the users to be equally critically aware of the feedback generated.

Another debate explores to what extent automated feedback should be proactive, reactive, or requested (Mørch *et al.*, 2005). A system that provides sentence openers and step-by-step guidance is proactive. If it allows wrong actions to be taken before it gives hints and critique, it is reactive. If the system does not take any suggestive action on its own at all, but allows the learner to request guidance upon demand, it is requested (Mørch *et al.*, 2005). All three intervention strategies are important in CSCL environments, but not at the same time. The equation for balancing the three strategies depends on the complexity of the knowledge domain to be supported (e.g., the severity of making a wrong move vs. stimulating explorative learning) and the choice of research approach (systemic vs. dialogic).

Open issues and Directions for Further Work

In the 1990s, many people discussed how technology and the Internet would revolutionize schools and educational institutions. Now, after a 10-year period, these assumptions seem rather opaque and romantic. The CSCL research has, to a large degree, provided insight concerning the condition under which we can expect students to develop deep

knowledge using innovative technology support. A reasonable interpretation for the CSCL field across the different traditions we have surveyed in this article emphasizes that such capacity needs to be cultivated over a number of years, and it is dependent on the design of the learning environment, the social norms of the actors involved, and the institutional settings (Krange and Ludvigsen, 2008).

Two of the more general tendencies in complex CSCL environments are the following: first, that teachers and students need to engage deeply in specific problem-solving activities in order to learn concepts that are part of their actual knowledge development; second, that such a deep engagement often involves disagreement, identifying problems and conflicting ideas that need to be resolved (problematizing), and providing explanations, negotiations, etc. However, disagreement is not always a necessary condition. In exploratory talk, for example, reciprocal elaboration also serves as a means for engaging in deep learning. We need to conceptualize tensions, breakdowns, alignments, and elaborations as basic activities for learning to become productive for students over a long period of time.

Improving educational settings, with the scaffolding techniques for collaborative learning, is one of the aims of CSCL. This improvement includes pedagogical models and technological tools for problematizing tasks, hypothesis generation, elaboration, judgment about resources from the Internet, interpretation of data, evaluation of performance (metacognition), deliberate perspective shifts, etc. This is likely to be accomplished by scaffolding at the level of action and activities in classrooms, and supported by CSCL tools. The approaches developed by the CSCL community deal with micro-level phenomena and educational practices as seen from the teachers' and learners' points of view. In this way, CSCL has contributed to how schools can become better places for teaching and learning, and it is through the adoption and use of technology as a mediating artifact that it has achieved this status (Rasmussen, 2005; de Jong, 2006; Scardamalia and Bereiter, 2006). The historical tensions between old and new social practices create grounds for further development. It is the cognitive, social, historical, and institutional aspects, in combination, that must be taken into account for us to understand how we can improve the learning condition for students.

The systemic and the dialogical approaches to CSCL provide directions for how educational practices can and should be changed. However, an ongoing issue concerns how to constructively combine them without over simplification. Carefully designed (e.g., model-based) CSCL environments are important for improving our understanding of learning with ICT tools, but the analysis should be done from multiple perspectives, drawing on a broader set of student skills. Only by taking multiple perspectives as a starting point can we identify commonalities across

approaches that enrich our understanding of social interaction and its relationship with learning and cognition, as well as how to design new learning environments that enhance both productive learning and cognitive performance.

Learning as Inquiry

Inquiry as a purposeful approach to teaching and learning – sometimes called inquiry-based learning, or discovery learning, or inquiry-based teaching – is at least as old as Socrates. In the *Republic*, Socrates uses questioning techniques to prove to his students that anything worthy of the name knowledge had to be constructed by the learner through processes of questioning and answering. Teaching-as-telling could produce imitation, but not real knowledge. Even in arithmetic, he says, “No one uses it rightly; no one treats it as something that can truly lead to [knowledge of] reality.” (Plato in *Sterling and Scott*, 1985: 216, 523-a).

What is now called Socratic method was, in Plato’s telling, actually various approaches to using inquiry to help students learn. Chief among these were guided inquiry, in which the teacher already knew the answer but was posing questions so that the student might discover, construct, or even recover knowledge (as in the *Meno*), and shared inquiry, in which the teacher knew what questions to pose but was joining students in pursuit of an answer that even the teacher did not yet know. In either case, the teacher’s expertise lay in the method of finding answers, and his role was to help students learn that method, as well as the answers to which that inquiry method might lead. As Socrates said of the act of teaching, “[S]ome things are likely to provoke thought and some not” (*Republic*, 218, 524-d).

In short, inquiry learning foregrounds the question rather than the answer and places the locus of learning in the learner, not in the material that can be transmitted by the teacher. Although there are many approaches to inquiry learning, addressing all the core subjects taught in schools, these approaches share a defining feature: the learner’s engagement with the processes of answering one or more questions. The learner, the teacher, or the learning material can frame the question and the answer is developed from that point. This is a common design feature of inquiry-based curriculum materials for pre-K-12 schools. Ultimately, answers to questions do matter. However, in inquiry learning, the processes of inquiry are valued for their particular impact on the learner’s knowledge, skills, and dispositions toward learning itself. Educators and researchers find that these learning outcomes differ from those that arise when the learner focuses primarily on an answer to be memorized, a skill to be used algorithmically, or something otherwise learned apart from the process of arriving at that answer for him or herself.

The early history of public schools in the United States included little use of inquiry methods, Socratic or otherwise. Rather, rote memorization, recitation, and repetition were the primary approaches to teaching in rural and urban schools. In the twentieth century, progressive educators such as John Dewey began to explore how forms of inquiry learning could be implemented in public and private schools. “The rise of what is called new education and progressive schools,” Dewey wrote in *Experience and Education* “is of itself a product of discontent with traditional education. In effect it is a criticism of the latter” (Dewey, 1959: 4). In books such as *How We Think* (first published in 1910); *Democracy and Education* (first published in 1916); *Logic: The Theory of Inquiry* (first in 1938); and *Experience and Education* (also in 1938), Dewey so shaped contemporary thinking about the role of inquiry in teaching and learning that in 1992 Donald Schön titled an analysis of Dewey’s influence “The theory of inquiry: Dewey’s legacy to education’.

Like Plato, Dewey began with a notion of what it means to know something, rather than what it means to teach it or learn it. In contrast to Plato, for whom wisdom and virtue were the highest forms of knowing, Dewey focused on scientific knowing as the model for knowledge. For Dewey, science was an instructive model because it produced consensus about scientific answers only through shared agreement about the methods of inquiry needed to reach those answers. Dewey saw that the methods of science were essential for arriving at warranted knowledge, just as Plato saw that the methods of philosophical inquiry were indispensable for arriving at truth. In this way, Dewey wrote in *Experience and Education* of “scientific method as the pattern and ideal of intelligent exploration and exploitation of the potentialities inherent in experience” (1959: 108).

Dewey therefore saw the domain of science as particularly useful in thinking about teaching and learning in schools. To teach science as static subject matter, as opposed to teaching it through processes of inquiry, was not to teach science at all. To teach science meant that students needed to engage in the methods of inquiry essential to science, at whatever level their development would permit. Without using the term inquiry learning, in *Experience and Education*, Dewey described some of its particulars and challenges.

Adaptation of the method to individuals of various degrees of maturity is a problem for the educator, and the constant factors in the problem are the formation of

ideas, acting upon ideas, observation of the conditions which result, and organization of facts and ideas for future use. The ideas, the activities, the observations, or the organization are not the same for a 6-year-old person as they are for a 12- or 18-year-old, to say nothing of the adult scientist (Dewey, 1959: 112).

Dewey claimed that the experience of such learning differed markedly from the experience of more traditional learning approaches, and that the nature and quality of experience influenced the nature and quality of learning. Traditional learning approaches fostered rote learning and recitation of information as evidence of learning. Such shallow understanding would be less likely with inquiry-learning approaches. Students would not simply learn new subject-matter knowledge; they would also learn habits of mind – the disposition to form and pursue questions, the tendency to think critically and analytically, a reflective stance toward experience, and an interest in learning itself. Most importantly, he argued, these habits of mind are critical to future learning.

Collateral learning in the way of formation of enduring attitudes, of likes and dislikes, may be and often is more important than the spelling lesson or lesson in geography or history that is learned. These attitudes are fundamentally what count in the future. The most important attitude that can be formed is that of the desire to go on learning. (Dewey, 1959: 49)

Dewey and other progressive educators believed that such habits of mind were important to adult participation in a democratic society, which places a premium on individual as well as collective problem solving and decision making. In *Democracy and Education*, Dewey popularized the notion of the classroom as a community and as a laboratory for democracy, where groups of students could engage in shared problem solving and making decisions together under a teacher's guidance. *Democracy and Education* applied this thinking explicitly to a range of school subjects beyond science, demonstrating that different domains of knowledge afford different opportunities for students to engage in different kinds of learning – and that inquiry could be motivated and guided by student interests based on the prior experiences they brought to the classroom.

Despite the inquiry-learning influence of progressive-era educators, at no time in the twentieth century could it be said that inquiry teaching and learning were dominant in American public schools. Throughout the late twentieth century, studies of American classrooms typically documented modes of instruction that centered on teacher dissemination of information through presentation and books, rather than on students' engagement in inquiry methods, either guided or shared. However, research on learning over the past 40 years generated a renewed interest in inquiry learning in that it demonstrates that the learner is an active participant in the learning process. The active view of the learner contrasts

with the behaviorist tradition and its view of the learner as a passive recipient of knowledge, the view that pervades traditional classroom instruction.

Contemporary Classrooms and Inquiry Learning

Inquiry-focused education was simply not compatible with behaviorist traditions and instructional approaches based on the passive learner. Transmission from the teacher to the student was the dominant instructional philosophy, with metaphors of students as sponges or empty containers dominating education. However, findings from cognitive and social research conducted over the past 40 years painted a different picture of the learner and the role of disciplinary communities of practice. This research showed that learners were active participants in the acquisition and construction of knowledge and that learning was a social, interpersonal activity, not just an individual act. These characteristics were manifest in the functioning of communities of practice in the discipline. Furthermore, twenty-first-century society is a knowledge society with an increasing basis in technology. In a knowledge society, inquiry learning is an essential skill for successful and productive functioning. People need to be able to formulate appropriate questions and seek out their answers. Therefore, at the beginning of the twenty-first century, inquiry-based learning is increasingly evident in classroom instructional programs, albeit in many diverse forms.

Examples abound of both guided inquiry and shared inquiry, from unique teacher-invented learning exercises to commercial, mass-produced curricula that support teachers' use of inquiry learning in many different subject areas. The diversity of these reflect different strategies to include purposeful questioning by learners about a system, whether it is for learning about a discipline or learning to use knowledge obtained from a discipline. In addition, classrooms vary in the nature of the teachers, the students, the resources available, and the degree to which the school environment supports the independence that teachers need for inquiry teaching. This means that particular inquiry curricula are implemented in different ways in different classrooms and different student outcomes result. Implementation that is not completely faithful does not necessarily compromise the benefits of inquiry, although that is often the case.

Relationships between Professional Inquiry and Inquiry Learning in Schools

Many educators and scholars, usually following or responding to Dewey, have examined the nature of the relationship between professional communities of inquiry and their K-12 classroom counterparts. There are clearly

essential differences between these two communities: professional inquiry is conducted by an exclusionary community of people who have undergone extensive training and apprenticeship, while classroom communities are by definition inclusive, lacking in specialized training, and unfamiliar with many aspects of the domain. Professional inquiry involves well-established procedures for vetting claims, such as peer review, while classroom inquiry results in fragmentary claims that may lack complete information and lead to unwarranted arguments.

Beyond these differences in the participants and their backgrounds, disciplinary and classroom practices also differ in their epistemological assumptions. Scientists, historians, and other researchers investigate questions with the goal of creating new knowledge, challenging or clarifying existing assumptions. This contrasts sharply with the most common classroom goal of inquiry, that is, to help students acquire knowledge that is assumed to be already well established among more knowledgeable others outside the classroom community of inquirers. In this sense, the products of professional inquiry – understandings that are seen as tentative and subject to challenge within professional inquiry communities – are treated as something quite different by classroom communities, namely as established and unimpeachable facts.

Another difference lies in the source of authority in each community. Of necessity, a single authority (the teacher) exists in classrooms to serve as arbiter and facilitator of all inquiry activity. In contrast, complex hierarchies of authority exist within professional communities, with any member of the community vested with the authority to challenge any proposition made by any other. In this sense, classroom communities of inquiry may be seen as both more egalitarian, in that all students have nominally equal status, yet also more authoritarian, in that the teacher holds a position of ultimate authority which can only be challenged with his or her own consent.

In light of these differences, the appropriate relationship of inquiry activity in the classroom to professional inquiry is not self-evident. Some educators seek ways to simulate aspects of professional inquiry practices in classrooms and scaffold the knowledge and skills required to engage in them. Others attempt to simplify overly complex aspects of investigations, an effort that can have the unfortunate consequence of changing which cognitive processes are engaged by the inquiry process, sometimes turning inquiry into rote procedural execution. Still others seek to create ways for students to engage as peripheral participants in the actual work of scientific communities. In contrast, other approaches focus on the act of problematizing the conceptual content of the domain itself, rather than in the trappings of real-world investigations, seeing this activity as the most important relationship between professional communities of inquiry and the work done by students in classrooms. Finally,

there are those that question the relevance of the professional practices of scientists for the design of science instruction, instead focusing on the nature of inquiry as a knowledge-building practice that can be enacted in classrooms based on the experiences, lives, and cultures of the members of the classroom community itself.

Implementing Inquiry in Classrooms

The range of conceptions of inquiry that exist mean that, unsurprisingly, inquiry-based instruction takes on many forms in classrooms. It varies from single-classroom innovations designed by the teacher to large-scale curricula distributed by publishing houses or educational research-and-development institutions. Many of the established inquiry curricula share certain characteristic approaches to designing materials and learning experiences to scaffold classroom inquiry. At the same time, the particular characteristics of inquiry vary depending on the domain and, sometimes, the subdomains of inquiry (e.g., science, history, mathematics; biology, ecology, and physics) to reflect the epistemological orientation of the content area.

Inquiry Cycles

Notable among characteristic approaches to inquiry is the use of inquiry cycles that emphasize (to different degrees) the iterative relationship among research questions, investigation procedures, findings, and new or modified research questions. Such inquiry cycles typically move through a problematizing phase (engagement, posing of the challenging task), an investigation phase (e.g., guided inquiry within small groups), a feedback phase (e.g., analysis and reflection), and a revision phase based on the feedback. For example, the Inquiry Island curriculum and instructional approach includes six elements: ‘question, hypothesize, investigate, analyze, model, evaluate’, and returning to question. A similar circular model underlies the design of the inquiry-support software *Symphony*. It represents an investigation process as being constituted of five steps: develop problem, collect data, visualize data, model data, and review progress. A similar five-phase cycle for younger children consists of engage, prepare to investigate, investigate, prepare to report, and report. Important to the inquiry cycle is a driving question to necessitate collaborative investigation, communication of findings, and generation of work products that learners can talk about and use as a basis for feedback and revision.

Participation in these types of inquiry cycles in science supports students’ long-term engagement with their own learning. Each phase presents “different learning opportunities and teaching challenges” . . . and “different types of thinking and activity on the part of the students and the teacher; hence, each phase has a unique role to play in

supporting the development of scientific knowledge and ways of knowing” (Magnusson and Palincsar, 2005: 428). Within each phase, instruction emphasizes the metacognitive knowledge relevant to the work students will be doing, including the what, when, and why (i.e., the procedural and conditional knowledge) necessary for students’ developing expertise and ownership of strategies and concepts taught and applied appropriately to the content learning. Instruction itself takes the form of a gradual release of responsibility, in which teachers and students are co-participants in the learning process. As students gain more knowledge and control over strategies taught, they assume greater responsibility for the full learning cycle. The development of the metacognitive or reflective skills and habits needed to manage the complexity of these inquiry projects is often an explicit instructional goal.

Many inquiry-oriented interventions include the use of software or other highly structured materials to constrain and enable particular kinds of thinking and activity. This is in part because inquiry teaching often involves long-term projects with multiple phases and types of activity, requiring students to reason across many experiences to make sense of their investigation.

Some educators emphasize the value of more open-ended or student-driven inquiry processes as an alternative to sequential or otherwise highly structured investigations. In the domain of mathematics, applications of concepts to the real world are not the only way for students to engage in inquiry. Instead, students can engage in constructing solutions to problems about the conceptual issues of mathematics themselves and discover new relationships in mathematics. Given the opportunity to engage with such problems when learning mathematics, children’s inquiry replicates elements of argumentation and reasoning used by mathematicians, suggesting modes in which inquiry learning aligns to inquiry in a field. Conversely, it may be most important that students engage in discourse that draws out the unseen knowledge, assumptions, and experiences they bring into the classroom from their home cultures and lives into the classroom. The investigation of any science phenomenon through science talk that both values students’ understandings and challenges them to establish evidence for claims has the potential to become a focus of authentic scientific inquiry.

Although science and mathematics instruction are the most common home of inquiry curricula, other subject areas are increasingly providing examples of inquiry. For example, inquiry projects in history engage middle-school students in generating explanations for historical events, using historical documents to gather evidence to support or refute particular explanations, and critiquing one another’s interpretations. In one such investigation, students tried to establish the precise seat which Rosa Parks refused to surrender on a Montgomery bus, the incident that triggered the anti-segregation bus boycott of 1955.

Design projects in the domain of engineering emphasize inquiry and prioritize the work of creating an actual designed artifact as a key component of the inquiry process. These inquiry projects include not only design and artifact production but also phases of experimentation, testing, communication of results, and communal negotiation of the nature of the problem being addressed and the relative qualities of competing designs. This form of inquiry emphasizes knowledge as a building tool and brings out the usefulness of knowledge to solve problems.

Inquiry learning also can be found in the study of literature. Cultural modeling scaffolds high school students’ investigations of great American novels. This approach helps students develop inferences about layered meanings in the novel, supporting them with evidence drawn from the text. Knowledge building is an approach that provides computer tools for developing inferences about texts, giving and receiving feedback, and building connected knowledge across a community of inquirers. Finally, collaborative reasoning and book clubs engage youngsters of elementary school age in conducting inquiries into moral and social dilemmas often faced by the characters in literary works written for the young reader.

Challenges for Inquiry Learning in Classrooms

Research and development efforts over the past 15 years have brought to light several challenges that arise in conducting inquiry learning in the classroom, as well as approaches to dealing with the challenges. The four challenges discussed below echo the issue Dewey raised regarding the adaptation of the inquiry method so that it is implemented in classrooms in developmentally appropriate ways.

1. Providing sets of resources that enable students to understand the problem, including sources that provide information essential to solving the problem. Many informational text sources are too complex from a conceptual, vocabulary, and often grammatical perspective for students to be able to use them successfully. Some approaches provide students with strategies designed to assist them in understanding the key concepts and relations among the concepts. Examples of these are ‘Questioning the Author, Leslie’s Notebook’, text annotation, and concept webs or mapping. Other approaches find or adapt more complex sources so that the concepts are accessible to the target student group. Still others move away from traditional written texts as sources of information and use alternative media, such as video and dialog, to present the information. Embedded data and embedded teaching are examples. The issue of accessibility of text resources may be more problematic in some

disciplines than in others due to the importance placed on working with primary source documents.

2. Ensuring accessibility of the processes of thinking about the information and using it to address the problem to be solved. Students need to develop both the language for structuring acceptable arguments in a discipline and the processes for generating the content from sources. A number of scaffolding tools assist students in this. Some help students organize, sort, and categorize information, while others prompt for explanation, thinking, and reflection and some enable both.

3. Understanding and being able to use a discipline's representational formalisms. These include maps, various forms of data arrays (e.g., graphs and tables), equations and formulas, and dynamic and static physical models, for example, of chemical elements and their behavior. Efforts to introduce these formalisms to students include various technology-based modeling environments of dynamic graphs and chemistry phenomena. In addition, several groups of researchers make the issue of data representation a major focus of their work with school-age children.

4. Creating or providing relevant and meaningful problems that students care about. Such problems increase the likelihood that students will engage in intentional, conscious processes of learning complex ideas. A number of major development projects have produced inquiry materials rooted in significant societal, local, or personal needs and research indicates that these are engaging to students.

There are three challenges that relate to the classroom instructional context and the importance of the teacher in providing guidance to the inquiry process.

1. Teachers preparedness to guide inquiry-learning projects. Effective guidance of inquiry-learning activities requires that teachers understand the process and content of the inquiry. They must also understand how students are likely to engage with the inquiry and the problems and strategies that arise in moving students' thinking forward. Accordingly, many inquiry development projects include both development of curricula for students and teacher professional development. Some development efforts involve teachers as collaborators and, in so doing, create both professional development opportunities and curriculum materials.

2. Changing the norms of classroom discourse from the traditional pattern of teacher initiation, student response, and teacher evaluation (called I-R-E) to those of reasoned arguments in which claims are made and supported with evidence in ways appropriate to the discipline. A related change in classroom discourse patterns concerns the kinds of questions that teachers ask. Known-answer questions predominate in traditional classrooms: Teachers ask questions that they already know the answers to and students know that the teacher knows the answer. When teachers ask questions to which there are not known

answers, students have something genuine to contribute to the classroom discourse and become more engaged and energized. Such questions engage students in inquiry rather than test their knowledge. Making these changes in the patterns of classroom discourse is often challenging for teachers who typically have had little opportunity to experience this form of interaction themselves. Professional development institutes often model and provide opportunities for teachers to engage in more inquiry-oriented discourse.

3. Related to changing instructional interactions is the challenge of moving from the informal language of everyday life to more precise technical language of the discipline. As students engage in inquiry processes, their descriptive language needs to move toward the language used in the disciplines. For example, words such as conjecture, hypothesis, evidence, data, and conclusion take on specific meanings in the context of discipline-based inquiry. Yet, many of these words have less formalized meanings in the everyday world. Developing inquiry learning involves acquiring a good command of the ways in which members of the disciplinary community use these terms and expressions. Guiding the inquiry-learning process involves introducing and modeling the use of the language as much as the understanding of the content.

Although the challenges of doing inquiry in classrooms are substantial, there is an increasing body of evidence that instruction and materials can be designed to engage students with inquiry-learning problems over extended periods of time. This engagement produces evidence of student learning on assessments closely aligned with the inquiry-learning situations as well as on more generic achievement tests.

Learning Through Narrative Socialization

A Fasulo, University of Portsmouth, UK

© 2010 Elsevier Ltd. All rights reserved.

Glossary

Homesign – The sign language that spontaneously develop between deaf children and their hearing or nonsigning parents and caretakers.

Tellability – The property of a narrative that justify its emergence in the interactional context, and makes it relevant for its audience.

Narrative Socialization in the Life-Course

The capacity of the narrative to be an instrument of learning extends well beyond the stage of childhood socialization. Adolescents build their way into adulthood and gendered identities through gradual acquisition of narrative sophistication (Bamberg, 2004; Moissinac, 2007). Groups and institutions produce narratives as part of their daily functioning and these become fundamental socializing resources for newcomers and for the circulation of knowledge in general (Orr, 1990); societies reveal their major concerns and incipient changes in narrative fictions (Moretti, 1987). Anthropologists discuss narratives, especially those aimed to public representation, as reflexive devices through which community members reflect upon their social world and their role in it (Turner, 1974). Important changes in life – immigration (De Fina, 2003), conversion (Ayometzi, 2007), physical (Mattingly, 1998), or psychological treatments (Cain, 1991) – typically involve the emplotment (Mattingly, 1998) of ordinary actions and of one's life trajectory in a new but socially provided narrative form. Emotions have also been described as narrative plots that actors verbally and bodily enact when the situation calls for it (Sarbin, 2001).

The narrative is so central to human life that an evolutionary hypothesis wants it derived from mammals' chase play, as both are seen as interactional spaces in which to learn, in a neurophysiological condition aroused by entertainment adaptive behavioral models, and their variations (Steen and Owens, 2001; Hernadi, 2002). An independent motivation to narrate has been spontaneously produce narratives in homesign even when entirely deprived of language input, verbal or signed (Van Deusen-Phillips *et al.*, 2001). On the contrary, following Bruner and Feldman (1993), such an innate propensity to narrate is what is crucially missing in autism, so that autistic

children and adults are deprived of the basic communicative resources to share personal experience and access socio cultural knowledge. Narratives, in fact, not only contain ordered facts but also repertoires of interpretive procedures and lay theories about social and psychological functioning; narrative practice enables individual selves to develop along a path legible to comembers.

Narrative Discourse in Children

Early Narrative Stages

Antecedents to narratives have been identified in the formats, routine sequence of vocalizations and gestures which, in the story of parents and infants, evolve through variations and complications (Bruner, 1983). Such variations following Molinari (2002) are comparable to the complicating events that are the defining features of stories (Labov and Waletzky, 1967). Narrative activity has also been considered similar to symbolic play (Fasulo, 1997; Nicolopolou, 2002, Sawyer, 2002), for both reliance on scripted action and necessity of improvisation. Scarcity of research and theoretical efforts in this direction are also noted (Nicolopoulou, 2002): this might be due both to the more frequent focus of research on parent – child over peer interaction, the latter a setting in which fantasy narratives, play, and in fact the meshing of the two (Sawyer, 2002) are more likely to be encountered, and to a preference for personal or familial past events over other genres.

Genres

According to a growing number of studies on children's narratives, narrative discourse does not coincide with story telling solely, but includes a wider set of discourse types and genres. Heath and Branscombe (1986) and Ochs *et al.* (1992) enlarged the range of inquiry comprehending unproblematic reconstructions of events (respectively called recounts and reports), and ongoing description of action (event-casts and broadcasts). Meshing of narrative and nonnarrative genres have also been reported together with oscillations between different spatio-temporal locations (Ochs, 1994; Ochs and Capps, 2001). As a unifying feature and coding index for young children's narrative and protonarratives, Sperry and Sperry (1996) adopt the category of displacement, and are able to confront the longitudinal emergence and perseverance of a variety of past, future, and fictional genres (among the most striking

results, a higher percentage of fiction before 3–5 years, suggesting, in accordance with the play-narrative similarity, a common base in the work of imagination).

Such a broad perspective does not constitute an adjustment to immature language, but reflects an understanding of narrative as a natively hybrid genre, or metagenre, well established in literary theory (Bachtin, 1981). Genres, conceived of as linguistic means to accomplish culturally defined tasks (Eggins and Martin, 1997), are part of the interrelated set of practices children have to learn in order to act competently in the different provinces of their world (Wolf *et al.*, 1994).

Conarration

Narratives emerging naturally in interaction can show high degrees of conarration whatever the age of the participants (Goodwin, 1986; Lerner, 1992). As vehicles of evaluative perspectives (Labov and Waletzky, 1967), narratives can also easily become arenas where different views or interpretations are confronted.

Children's narratives at home exist basically in conarrated form: Parents and siblings can be responsible for eliciting narratives from children or introducing them, contributing substantial information, such as internal states and responses, and challenging the point, or argumentative line the narrative is trying to pull (Edwards and Middleton, 1988; Ochs *et al.*, 1992). Multiparty interactions more than dyadic ones represent complex environments in which, on the one hand, the floor is harder to gain and the audience more difficult to keep; on the other hand, family members' incursion into children narratives and the sheer listening in offer children precious occasions for narrative learning. In the talk of family reunited at the dinner table, children have accordingly been shown to narrate quantitatively less, compared with talk in dyadic settings, but to be involved in more complex participatory roles and to be more frequently faced with teasing and irony by family members (Aukrust, 2002). Also, the same data, reveal an overall higher proportion of narrative talk of all members in multiparty than dyadic interaction, thus exposing the child to more narrative discourse. As concerns the role played by children, children up to 6 years of age have been found to be more often the protagonists of stories told by others compared to their older siblings who figure more frequently as narrators; children in general appear to introduce far more less narratives than parents, although they may frequently become tellers of stories that parents ask them to narrate (Ochs and Taylor, 1992).

Participation formats also appear to reflect culturally valued aspects to narrative: Georgakopoulou's (2002) observations of middle-class families in Greece reveal a pattern of conarration inflected by the importance accorded in Greece to skilled narrative performance and

by the local practice of reiterating communal stories in support of group solidarity: Children would often prompt parents to tell stories from the family lore and also stories about the children themselves, while parents would intervene in the course of children's narration, assisting in the shaping of the stories' high point and seeing about the achievement of the best dramatic effects.

Such parental activity is bound to have long-term effects: coconstruction, via exposition to parental narrative styles, has been amply documented as affecting both quantity and nature of children's production, at least in the area of events' recall and autobiographical memory (Fivush, 2008; Fivush and Nelson, 2004; Reese, 2002).

Finally, participation may cross the borders of the present scene of the interlocutors to implicate absent actors: Goodwin (1982) illustrates a narrative genre through which preadolescent children instigate peers future confrontation by reporting words of an absent mate. These narratives sometimes developed into rehearsals of the future confrontational scene through imaginary dialogs. Practicing politics in the peer group, as well as sitting in at adult's meetings (Haviland 1986), foster learning on the subtleties of narrating about third persons.

As these studies demonstrate, narratives can be conceived of as chain-rings of interpersonal events, born to be repeated, spread across groups, and used like weapons or tokens of alliance. Inner politics of groups and communities, with their enmities and partisanship, have narrative as a resource for reaching remote audiences, gathering consensus, and keep relevant episodes within the active memory of the group.

Narrative Socialization to Cognition

Narrative Thinking

One of the most powerful effects of narrative relies in its fostering thinking through analogy, or *exempla*. From different arenas ranging from philosophy to psychology to history of science, analogical or narrative thinking has been acknowledged as a vital component in a variety of intellectual activities (Cazden and Hymes, 1980; Holton, 1992; Polkinghorne, 1988; Melandri, 2004). Even scientific paradigms (Kuhn, 1962) are sometimes described as normative models of a discipline built upon a core research enterprise that became the master narratives of the field. Concepts in the social and moral domains are often but a collection of stories about exemplar behaviors, positive or negative, and their expectable consequences (Feyerabend, 1999; Gergen, 1988).

Ontogenetically, as illustrated by the analyses of the child Emily's monologs (Nelson, 1989), narrative logic is mastered before piagetian logic and when the second appears in language is at the service of narrative rhetorics (Bruner, 1990) and narrative problem-solving

(Feldman, 1989). The joining and conflict between narrative versions, together with the pursuit of consensus, that characterize narrating within the family, has been likened to the process of scientific theory-building activity, where an initial storyline may lead to argumentation in the specialists' community and undergo several redrafting before achieving at least temporarily general acceptance (Ochs *et al.*, 1992).

Practicing narrative fosters abstract thinking also by exercising in decontextualized use of language, high-order coherence among interrelated actions of characters (Nicolopolou, 2002: 122), and the logic of part-whole relationships (Heath, 1983).

Narrative and Theories of the Mind

In the traditions of linguistic anthropology (Whorf, 1956; Cardona, 1985) sociology of knowledge (Berger and Luckmann, 1966) and discursive psychology (Edwards and Potter, 1992), language contributes in structuring the categories of experience and forming ideas about the functioning of the human mind. For example, the Western primacy of individual intentionality in the assessment of the meaning and moral weight of an action is not shared in many non-Western or Westernized countries (Duranti, 1993): such different perspectives on the relation between internal states and observable actions are enforced by a range of language practices and played out in narrative plots. Theories of minds are different across cultures although they may all rely on the assumption that others too have minds and socialization plays a key role in their formation. Children acquire lay psychological theories through immersion in the language of their community, but it is narratives that articulate more thoroughly observable events and behaviors with the inner world of thoughts and feelings (Bruner, 1986). The idea of others' minds and of their basic similarity to one's own is to a great extent owed to encounters with the represented minds of minds of narrative characters as well as to being a character in others' stories.

Narrative discourse embeds theories of cognition in conventional formulas and specific genres (e.g., the "do you remember when" or "I'll never forget..." initiations of, respectively, narratives of shared experience or extraordinary facts; Norrick, 2005). As, Reese (2002) points out, a theory upon others' mind is likely to be as much a product than a precursor of autobiographical memory, which is in turn deeply dependent on social factors.

Narrative Socialization and Sociocultural Groups

Although the studies reported above concerns children from very provenances, the discussion up to this point has

not taken into account the differences in narrative socialization on children of different gender, social class, or ethnic group. The following section presents an overview of research results focused on sociocultural differences and the production of culturally inflected identities.

Narrative Socialization and Gender

A large psycholinguistic study on 1300 elicited personal narratives of white children of working-class families has not revealed significant differences in the narratives of boys and girls, apart from girls resulting slightly more loquacious than their male counterparts (Peterson and McCabe, 1983). Differences have been found in subsequent studies in relation to narrative contents: analyzing narratives produced by preschools middle-class children in California and Massachusetts, Nicolopolou (1977a, b) finds that girls' characters and scenes were mainly drawn from family life or fairy tales themes, and their stories tended to depict harmonious relationships: boys, on the contrary, were more keen to represent "powerful and frightening characters" and include "conflict, movement, and disruption" (Nicolopolou, 2002: 127). In a different study on African-American children aged from 2 to 3.5, girls produced a lower number of narrative overall, and less fictional narrative than boys proportionally (Sperry, 1996). These studies, all set in the US, converge in showing a preference for boys to engage in imaginary worlds dominated by action and for girls to revolve on more tranquil and reality-based situations across different social origins and age of children. Mothers, in turn, have been found to be more elaborative, evaluative, and emotional when engaged in personal narratives with their daughters than with their sons (Fivush and Buckner, 2003), an observation matched by the presence in adult women of earlier and more complex memories (Pillemer, 1998).

Gender differences such as the one illustrated above do not ensure exclusively from caretakers' socialization, though: in her inspection of Grimm's fairy tales, Ortnor (1996) finds that the agency of female characters is either weaker than that of males – as when there are victims of misfortunes – or deflated in the course of the tale, when their initiatives end badly and it is left to male characters to resolve the complications and be rewarded for that. A very vast array of available narratives contribute, in synergy with other factors, to inform children's imaginative life along the preferential route that society designs for their gender.

Narrative Socialization and Social Class

In Bernstein's (1971) influential work on the relationship between social class, linguistic code, and school career, abilities to narrative appeared to vary with the children

familiar milieu. Middle-class children in UK, in an experiment he discusses, could more easily produce formally correct, decontextualized stories closer to the written code than working-class children; on the other hand, the stories of the latter were more rich and animated, and these narrators were more at ease with requests of invention and free elaboration. In school, though, only the former kind of stories were met by reward, coherently with the decontextualized approach to knowledge favored by educational institutions (Snow and Blum-Kulka, 2002). Bernstein discusses these results invoking socialization into societal roles and linguistic style of parental instructive practices. While groundbreaking at the time, Bernstein's work posits a dividing line between social classes which is problematic in light of the very different circumstances that could be subsumed under the middle- and working-class labels.

The issue of the internal differentiation of social classes is taken up by Miller and colleagues in a series of fieldwork studies on middle- and working-class children of different areas. Miller *et al.* (2005) discuss the results of a long-term project about young (2–3 years old) children's narrative in two working class communities in South Baltimore and Chicago, as well as middle-class community of another Chicago neighbourhood. The first community consisted of poorer, single-mother households which received public assistance or had low-income jobs. In the second one, children lived with both parents and the parents were regularly employed as blue-collar workers at jobs in which they had generally achieved higher positions with respect to parents from the first community. Researchers analyzed both adults' and children's narratives. Comparison between the two Chicago communities revealed that working-class mothers produced a higher rate of spontaneous narratives than middle-class mothers, and more frequently centered on negative events; their narratives, supported by a rich and dramatic performance, presented the image of a combative self struggling in the face of difficulties. Middle-class parents' narrative privileged instead a focus on inner experience and the use of emotion state terms. The same pattern held for the children of these mothers: both the South Baltimore and Chicago working-class children were more prolific narrators and recounted more negative events, although both the quantity and the dramatic intensity of negatively framed stories were higher in the poorer South Baltimore group. The preference of this group was also for colourful and action-based descriptions, in contrast with their middle-class counterparts' greater recourse to psychological language. In the working-class households, furthermore, children were often engaged in conarration, encouraged to recruit a public for the sharing of personal experience, and frequently contradicted, corrected, or otherwise pushed toward what was considered an adequate rendition of events, whereas middle-class mothers mitigated or withheld

correction even in spite of patent inaccuracies. This result is interpreted by the authors as indicating a more serious attitude toward narrative activity in working-class environments than in middle-class ones. However, as the authors remark, these data can also be read with a focus on the similarities among the groups, which largely overlap in engaging in conarration with the children, reminiscing both adults' and childrens' past and family events, and in short revealing that narrative is intended and used as a significant socializing tool.

Narrative Socialization and Cultural Communities

It has already been observed that the way narratives are told in the family reflects (and reinforces) local views on both what good stories look like and how they can serve societal values (Blum-Kulka, 1993; Georgakopoulou, 2002). Research on Italian families shows that children's narrative activity often takes place within disputes, and that family members' contributions supports the enhancement of children's rhetorical skills, encouraging them to present stories as persuasive evidence (Pontecorvo and Fasulo, 1997). These results are in line with Corsaro and Rizzo's (1988) observations regarding Italian preschool children routine engagement in dispute-like interactions.

Preferences for certain narrative topics over other may also vary across different communities. In a comparative study on Norwegian (Oslo) and US (Cambridge) families, Aukrust (2002) finds that in the former, which are richer in narrative altogether, there are also more frequent reports of children's school events, and a larger gallery of characters related to the children; more recurrent are also retellings of known events, although they are not simply replayed but enriched with new details. Differently, in the Cambridge corpus, the school genre enjoys a lower degree of tellability, often for the resistance of children to disclose details of their school life; when school narratives to appear, they tend to be about events still unknown to members. Overall, explanatory discourse genres are generally favored over narrative ones.

Focusing on the theme of transgression, Miller *et al.* (1997) compare Chicago and Taipei middle-class adults' and children's narratives, and find that Chinese parents typically recall children's transgression within a didactic narrative genre, whereas Chicagoan parents avoid to perpetrate the memory of such events or treat them in a humorous mode so to preserve a positive image of the child. The reverse holds for narrative about themselves or adults in general: in Taipei, parents never tell the children about transgression or faults committed in their young years, concentrating instead on instructive stories about their sacrifices and rewarded efforts on the contrary, Chicagoan parents may often disclose to their children transgressive episodes from their past (Miller *et al.*, 2001).

Interestingly, mothers from the two groups offered rather similar motives for such different practices, namely reducing distance between generations and conveying instructions for life. But whereas Taipei mothers thought that stories illustrating exemplar conducts would lead their children on the right path, Chicago mothers thought that acquaintance with parental misdeeds, beside being funny, would give children trust in the possibility of happy endings even in the face of initial mistakes.

Chinese mothers were therefore more didactic and serious in tone and emphasized children's immaturity and need to learn, whereas the American ones were more protective of the child image and less protective of their own. These results hint at different ideas of the construction of the "good life" (Freeman, Brockmeier, 2001), the first being steady and coherent and the second admitting false steps and diversions.

Following the results of the first comparative study by Miller *et al.* (1997) Van Deusen-Phillips *et al.* (2001) scanned their corpus of narratives from US (Philadelphia and Chicago) and Chinese (Taipei) deaf children for differences in the same direction. In line with the divergent ethics portrayed above, the authors found that Chinese children's narrative and protonarratives contained a much higher degree of evaluative comments than their American counterparts (100 vs. 5), and that these comments tended to be serious in the Chinese corpus and playful in the US one. As already reported, these children had not been exposed to language, narrative or otherwise: these findings suggest that essential cultural components of narrative can be socialized through embodied and other environmental resources.

Doing Research on Narrative Socialization

The present article has highlighted at several junctures how narrative is sensitive to multiple aspects of the situation of the telling. Hence, a crucial dimension for the study of children's narrative socialization is the methodology chosen for harvesting stories.

A multiparty setting has proven effective for the study of the range of participatory roles children can engage in, and of the types and quantity of other speakers' interventions in their stories (Ochs *et al.*, 1992), but the total number of narratives involving children in whatsoever role can be lower than in dyadic settings (Aukrust 2002). Anyhow, some ethnographers consider the multiparty situation a central site for children's socialization, in that it encourages observational learning and posits the need to sort out complex interpersonal demands. Researcher-elicited narratives can on the contrary provide robust narrative corpora, as proved by the seminal study by Peterson and McCabe (1983), but at the risk of scarce correspondence with *in vivo* story-telling characteristics:

Beals and Snow (2002) compared dinner-table to elicited narratives and found no correlation in the competence evidenced by the same children in the two settings.

School appears a setting wherein it is possible to construct a variety of narrative-relevant situations, circumventing uncontrolled contextual interpretations and also possibly creating, as Nicolopolou's research shows, highly motivating and socially meaningful tasks of narrative performance.

Interaction around written narratives has also proved an interesting site for the study of children understanding and production of narrative discourse (McArthur *et al.*, 2005). Perhaps counterintuitively, the written support does not impoverish narrative discourse but creates a steady common framework between child and adult for narrative elaboration and other types of reasoning. The paradigmatic and the narrative, as pointed out by Bruner (1990) can collaborate to enrich and expand the story realm. Also, joint reading is for children a gratifying experience and one they spontaneously engage in, whereas solitary consumption of texts seems to be more a normative prescription of adults that a spontaneous way of treating books (Sterponi, 2007).

A final comment concerns intercultural and intergroup comparisons. The study of children's narratives addressed across different communities is an invaluable window into the fundamentals of social and cultural groups, beside revealing the pedagogic ethnotheories of adult caretakers. A point by point comparison, though, as in all cross-cultural research, must be undertaken with some caution. Isolating children's stories from their growing soil and focusing on differences in skills, length, or other variables of production could, lead to interpretations of the resulting differences in terms of stereotypical or at best generic cultural traits, often accompanied by a negative portrayal of one of the groups (e.g., in terms of poor input, lack of pedagogical efforts etc.). The pioneering studies of Heath (1983), and the more recent research by Miller and her colleagues, are good illustrations of methodological choices that resist easy, dual minded comparisons in favour of dense and articulated accounts of the nature of differences and the wider circumstances of their emergence.

Glossary

Domain – A culturally constructed area of knowledge, such as language, math, music, or social interaction.

Neural network – A set of neurons that are structurally and functionally interconnected so that they activate in coherent patterns associated with mental functions.

Neuroimaging – A variety of research techniques, some invasive and some not, concerned with measuring and mapping the physiology and structure of the brain.

Neuromyth – A misguided, oversimplified, or incorrect tenet in education that concerns the brain or neuroscience.

Skill – An ability to behave or think in an organized way in a particular context.

Beyond Neuromyths: Mind, Brain, and Education Is a Cross-Disciplinary Field

All human behavior and learning, including feeling, thinking, creating, remembering, and deciding, originate in the brain. Rather than a hardwired biological system, the brain develops through an active, dynamic process in which a child's social, emotional, and cognitive experiences organize his or her brain over time, in accordance with biological constraints and principles. In the other direction, a child's particular neuropsychological strengths and weaknesses shape the way he or she perceives and interacts with the world. Like the weaving of an intricate and delicate web (Fischer and Bidell, 2006), physiological and cultural processes interact to produce learning and behavior in highly nuanced and complex patterns of human development.

People in the field of education often begin with a preconception that biology refers to traits that children are born with, that are fixed and unfold independent of experience, while children's social and cultural experiences, including schooling, are at the mercy of these biological predispositions, somehow riding on top of, but not influencing, biology. However, current research in neuroscience reinforces the notion that children's experiences shape their biology as much as biology shapes

children's development. The fields of neuroscience and more broadly biology are leading education toward analyzing the dynamic relationship between nurture and nature in development and schooling. A more nuanced understanding of how biology and experience interact is critically relevant to education. As neuroscientists learn about which aspects of experience are most likely to influence biology and vice versa, educators can develop increasingly tailored educational experiences, interventions, and assessments.

Due to this bi-directional relationship between a child's biological predispositions and social and cognitive experiences, the fields of neuroscience and education are coming increasingly into a research partnership. This relationship can be studied at many levels of analysis, from the workings of genes inside cells to the workings of communities inside cultures. However, in order for new information about the brain and learning to influence the design of learning environments, teachers and others involved in educational policy and design need to know about the newest principles about the brain and learning. Likewise, neuroscientists need to investigate phenomena that are relevant to real-world learning and development. To these ends, a new field has gradually taken shape over the last few years: mind, brain, and education (MBE). As a field, MBE encompasses educational neuroscience (a branch of neuroscience that deals with educationally relevant capacities in the brain), philosophy, linguistics, pedagogy, developmental psychology, and others.

In this interdisciplinary and applied climate, educators are in a particularly good position to help generate new questions and topics for research on learning and the brain, as they deal on a daily basis with the developmental issues and situations that affect real children and adults in their learning. For this reason, educators including teachers should have some familiarity with neuroscience and brain functioning, in order to become more informed consumers of educationally relevant findings as well as, ideally, contributors who help identify and shape new questions for neuroscience to pursue. For example, teachers can use information on the development of networks for numeric processing to design more effective curricula to teach math concepts, and educational assessments of students' math learning can help to shape new scientific questions about the development of math networks.

However, this does not mean that neuroscience is capable of contributing insights into all educational problems.

One of the challenges for the new field of MBE is for educators to learn about the applicability, implications, and limits of neuroscience research methods to various sorts of educational questions, and for neuroscientists at the same time to learn about the problems, issues, and processes of education, so that the two fields can collaborate as profitably as possible. For this to happen, educators and educational researchers need to know something about the tools, techniques, assumptions, and approaches that guide neuroscience research on learning, and need to develop a critical ability to consume and digest neuroscience findings and evaluate them for their potential applicability in the classroom. Toward this goal, teacher-training programs are beginning to incorporate information about the science of learning into their course offerings, and several new graduate programs in MBE have been launched at major universities in several countries in the last few years.

Before proceeding further, we felt the need to insert a strong cautionary note. As is typical during periods of rapid discovery, technological innovation, and theoretical advance, the field of MBE, as well as other related fields seeking to apply brain science to mainstream societal issues, are experiencing a lag between new technologies and findings on the one hand and the ability to interpret these findings on the other. In recent years, multiple examples of brain research misapplied have gone forward, including, for example, the overt labeling of elementary students as different categories of learners, from kinesthetic to auditory and beyond. Indeed, the scientific community agrees that much of what has been called brain-based education rests on very shaky ground. There is a proliferation of books written by nonscientists about the applications of neuroscience to learning, and while some of these books might present useful interpretations of neuroscience for educators, many of them suffer from a lack of basic understanding about the meaning and limitations of neuroscience research on learning and related processes. These books should be read with skepticism, as they often present models that are so oversimplified as to be misleading or even harmful or dangerous to children.

Overall, major changes in neuroscience research methods and theory are allowing better applicability of brain findings to educational issues and questions, and new insights into the processes that happen in schools. In this article, we focus on the prominent contribution of neuroimaging to the current view of learning as the construction of distributed neural networks that support skills, and how the development and recruitment of these neural networks is modulated and facilitated by domain-general processes in the brain, including emotion, attention, and mechanisms of social learning. We conclude with a call for further research that evaluates neuroscientific principles as they play out in classroom contexts.

New Neuroscience Methods Bring New Information and New Challenges for Interpretation

Educators' views of brain research have shifted in the past few years. While many educators continue to cling to so-called neuromyths, neuroscientists in the MBE field have been working to dispel these myths. In particular, the last decade has seen huge advances in *in vivo* neuroimaging technologies. Scientists are now able to study the workings of the human mind in healthy participants as they solve problems and perform other sorts of cognitive and emotional tasks in real time. Availability of these new-research technologies is pushing the field forward at an unprecedented pace; hardly a week goes by, it seems, without a picture of the brain appearing on the cover of a major magazine or in a major newspaper article.

To make sense of the new findings, it is critical that educators understand the logic and constraints in the neuroscience research underlying these articles. While neuroimaging techniques differ in their specifics, there are three main approaches. The first approach involves measuring and localizing changes in the flow of blood in the brain as subjects think in different ways, under the assumption that changes in regional blood flow are indicative of changes in neural activity. The second approach involves measuring the electrical activity of the brain, generated by the firing of networks of neurons (brain cells). The third approach involves measuring changes in the anatomy and structure of the brain. In conjunction or separately, these techniques can be used to study the neurological correlates of a wide variety of tasks, such as reading, math, or social processing, as well as developmental changes (for reviews, see Katzir and Pare-Blagoev, 2006; Thatcher *et al.*, in press).

While these recent advances in neuroimaging have had a profound effect on the field of neuroscience and its potential relevance to education, it is important to remember that new technological capabilities inevitably come with limitations. For example, in functional magnetic resonance imaging (fMRI), the changes in regional blood flow in the brain associated with a particular task of interest are not absolute, but either implicitly or explicitly calculated from comparisons between a target and a control task. The design of the two tasks and the differences between them are critical to the findings and interpretation. When one brain area is reported to light up (i.e., to become more active) for a particular task, this does not mean that the lighted brain area is the only area actively processing. Instead, this means that this particular area was relatively more active for this task than for the control task. Many other areas are certainly actively involved, but are equivalently active in the two conditions. In reality, a network of neural areas always supports the skill being tested. As educators are concerned with supporting the

development of coherent functional skills rather than isolated brain areas, it is essential that neuroimaging findings be correctly interpreted before any attempt can be made to apply them in the classroom.

Educational Skills are Supported by Specialized Neural Networks

Nonetheless, the advent of neuroimaging has precipitated major advances in neuroscientists' understanding of how the brain works. In the past, the neuroscientific localization tradition prevailed; that is, cognitive functions were mapped onto specific locations in the brain, as much as possible in one-to-one correspondence. However, neuroscientists now understand that learning involves the development of connections between networks of brain areas, spread across many regions of the brain. This means that while specific brain areas do carry out characteristic kinds of processing, skills for real-world and academic tasks are embodied in the networks they recruit, rather than in any one area of the brain. For example, there is no music, reading, or math area of the brain that is not also involved in processing many other skills and domains (culturally constructed areas of knowledge).

Instead of one brain area, learning involves actively constructing neural networks that functionally connect many brain areas. Due to the constructive nature of this process, different learners' networks may differ, in accordance with the person's neuropsychological strengths and predispositions, and with the cultural, physical, and social context in which the skills are built (Immordino-Yang, 2008). There are various routes to effective skill development, for example, in reading (Fischer *et al.*, 2007) or math (Singer, 2007). The job of education is to provide support for children with different neuropsychological profiles to develop effective, yet flexible skills. Children use whatever capacities they have to learn the most important skills in their lives, and although there is often a modal way of learning a specific skill, people can adapt their capacities to learn skills in diverse ways. For example, Knight and Fischer (1992) found that young children followed one of three pathways in learning to read words. In a related vein, in studying two high-functioning adolescent boys who had recovered from the surgical removal of half of their brain, Immordino-Yang (2007) found that each boy had compensated for weaknesses by transforming important neuropsychological skills into new ones that suited the boys' remaining strengths.

Neural Networks for Mathematics

One area that has seen much advance in the past few years is the study of neurological networks underlying processing

for mathematics and number representation. Overall, the findings suggest that networks for processing in math are built from networks for the representation of quantity that start in infancy – one for the approximate representation of numerosity (numeric quantity), and one for exact calculation using numbers (Dehaene *et al.*, 2004). These networks are further organized and differentiated with development and training in math concepts (Singer, 2007). For example, preschoolers go beyond innate number systems to build a mental number line, gradually adding one digit at a time (Le Corre *et al.*, 2006).

Interestingly, this math network shares many processing areas and features with language processing, including reading. Current research is exploring how math processing relates to other domains, such as spatial representation, as well as the development of math networks in atypically developing populations, such as children with learning disabilities.

Neural Networks for Reading

Another area of concentrated research interest is the study of reading development, both in typically developing and dyslexic children. Acquiring literacy skills impacts the functional organization of the brain, differentially recruiting networks for language, visual, and sound representation in both hemispheres, as well as increasing the amount of white-matter tissue connecting brain areas. Work on individual differences in the cognitive paths to reading has enriched the interpretation of the neurological research (e.g., Knight and Fischer, 1992), and helped to bridge the gap between the neuroscience findings and classroom practice (Katzir and Pare-Blagoev, 2006; Wolf and O'Brien, 2006). In dyslexic readers, progress is being made toward better understanding of the contributions of rapid phonological processing (Gaab *et al.*, 2007), orthographic processing (Bitan *et al.*, 2007), and visual processing to reading behaviors, as well as to thinking in other domains (Boets *et al.*, 2008). For example, the visual field of dyslexics may show more sensitivity in the periphery and less in the fovea compared to nondyslexics, leading to special talents in some dyslexics for diffuse-pattern recognition (Schneps *et al.*, 2007). Most recently, research looking at developmental differences in neurological networks for reading across cultures has begun to appear (e.g., Cao *et al.*, 2009), which ultimately may contribute to knowledge about how different kinds of reading experiences shape the brain.

The neural networks for learning reading and math have important implications for education, as the most effective lessons implicitly scaffold the development of brain systems responsible for the various component skills. For example, successful math curricula help students to connect skills for calculation with those for the representation of quantity, through scaffolding the

development of mental structures like the number line (Carey and Sarnecka, 2006; Griffin, 2004; Le Corre *et al.*, 2006). While different students will show different propensities for the component skills, all students will ultimately need to functionally connect the brain systems for quantity and calculation to be successful in math.

Domain-General and Emotion-Related Processes Enable Learning

The brain is a dynamic, plastic, experience-dependent, social, and affective organ. Due to this, the centuries-long debate over nature versus nurture is an unproductive and overly dichotomous approach to understanding the complexities of the dynamic interdependencies between biology and culture in development. New evidence highlights how humans are fundamentally social and symbolic beings (Herrmann *et al.*, 2007), and just as certain aspects of our biology, including our genetics and our brains, shape our social, emotional, and cognitive propensities, many aspects of our biology, including processes as fundamental as body growth, depend on adequate social, emotional, and cognitive nurturance. Learning is social, emotional, and shaped by culture!

For a stark example of this interdependence between biology, social interaction, and cognitive stimulation, in their work with Romanian orphans, Nelson *et al.* (2007) found that cognitive, social, and physical growth were delayed in institutionalized children, relative to their peers raised in foster or biological families. Although the institutionalized children's basic physical needs were met, the lack of high-quality social interaction and cognitive stimulation lead these children not to thrive.

Overall, while educators often focus on neural networks for domain-specific skills like reading and math, domain-general and emotion-related networks function as modulators and facilitators of memory and domain-specific learning. These networks include emotion, social processing, and attention.

Emotion and Social Processing

One cutting-edge area of research in neuroscience is the study of affective and social processing. All good teachers know that the way students feel, including their emotional states (e.g., stressed vs. relaxed, depressed vs. enthusiastic) and the state of their bodies (e.g., whether they are sick or well, whether they have slept enough, or whether they have eaten), are critical factors affecting learning. In addition, it is now becoming increasingly evident that emotion plays a fundamental role not only in background processes like motivation for learning, but in moment-to-moment problem solving and decision making as well (Adolphs and Damasio, 2000; Haidt, 2001). That is, emotion forms the

rudder that steers learners' thinking, in effect helping them to call up information and memories that are relevant to the topic or problem at hand. For example, as a student solves a math problem, she is emotionally evaluating whether each cognitive step is likely to bring her closer to a useful solution, or whether it seems to be leading her astray.

From a neurobiological perspective, emotional processing in the brain depends on somatosensory systems – the systems in the brain responsible for sensing the state of the viscera and body. These systems can reflect actual changes to the state of the body during emotions (i.e., increased heart rate during fearful states, or a feeling of having been kicked in the stomach when hearing bad news), or they can reflect simulated body states, conjuring how the viscera and body would feel, without actually imposing those physiological changes onto the body (see Figure 1 from Immordino-Yang and Damasio, 2007). Through regulating and inciting attention, motivation, and evaluation of simulated or actual outcomes, emotion serves to modulate the recruitment of neural networks for domain-specific skills, for example, for math or reading. In this way, cognition and emotion in the brain are two sides of the same coin, and most of the thought processes that educators care about, including memory, learning, and creativity among others, critically involve both cognitive and emotional aspects (Figure 1).

In addition, social processing in the brain is strongly interrelated with the processing of emotion. People's behavior is organized and influenced by cultural factors and the social context, which in turn reflect experience and learning. For example, many of the reasons the student above solves her math problem relate to the emotional aspects of her social relationships and cultural goals – the way her parents will feel about her behavior, or her desire to go to college. In turn, she feels the influences of these cultural constructs as emotional reactions that play out in her body and mind, and predispose her to think in particular ways.

But how does this student internalize or predict the emotional reactions of her parents? Interestingly, research over the past decade has revealed glimmers of the workings of a basic biological system for internalizing the actions, emotions, and goals of others, in order to learn from, empathize with, and influence others in social contexts (Immordino-Yang, 2008; Oberman *et al.*, 2007). Specifically, it appears that watching other people's actions and inferring their emotions and implicit goals recruits some of the same neural systems involved in planning and carrying out those actions in one's own self. This discovery was dubbed as mirroring by its discoverers (Gallese *et al.*, 1996; Umiltà *et al.*, 2001), and while neural systems for mirroring do not tell the whole story of the neurological system for social learning, current research suggests that they afford an important low-level mechanism on which social and cultural learning can build.

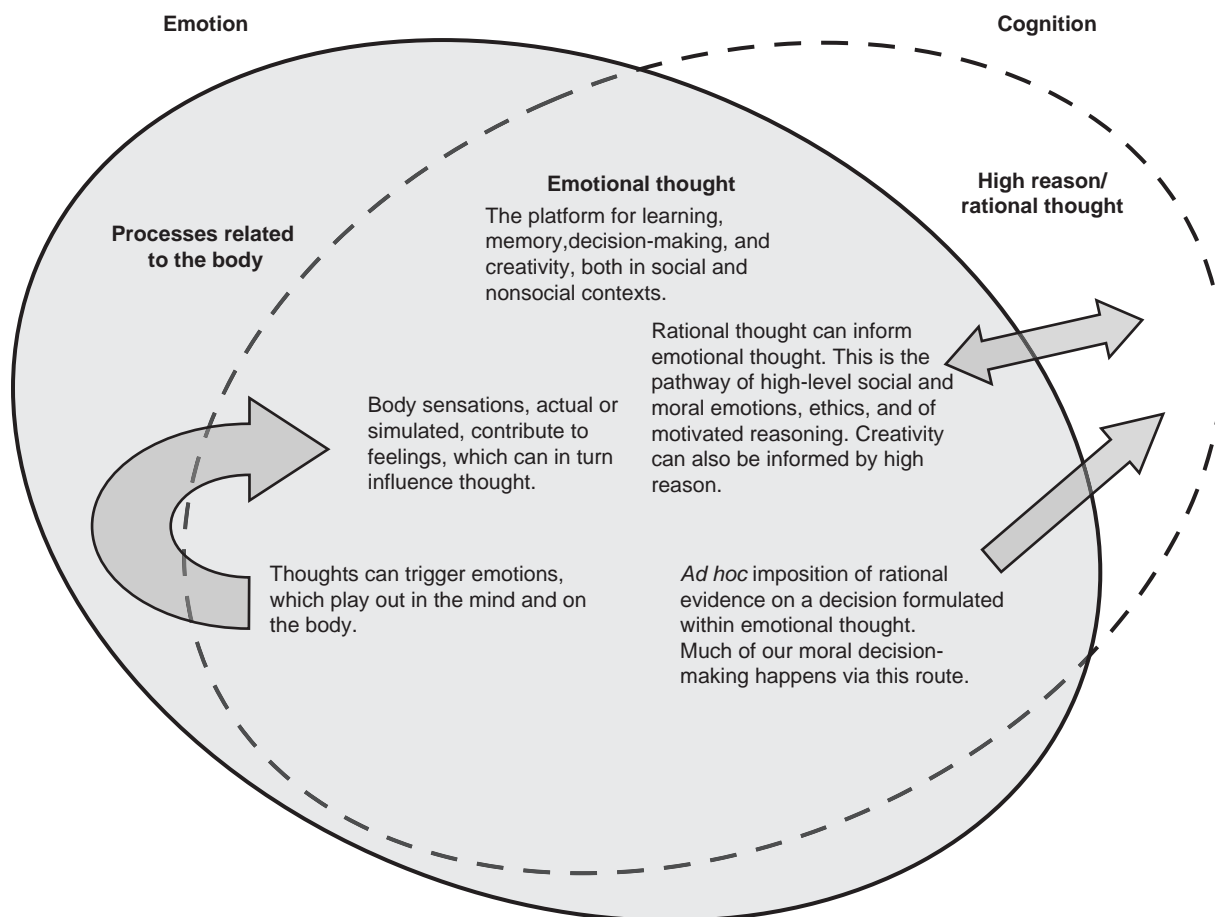

Figure 1 Emotion and cognition come together to produce the thought processes that educators care about, among them learning and memory. In the figure, the solid ellipse represents emotion and the dashed ellipse represents cognition. The extensive overlap between the two ellipses represents the domain of emotional thought. Note that emotional thought reflects a dynamic relationship between the brain and body. Reprinted from Immordino-Yang, M. H. and Damasio, A. R. (2007). We feel, therefore we learn: The relevance of affective and social neuroscience to education. *Mind, Brain and Education* 1(1), 3–10, with permission from Blackwell publishing.

Memory and Attention

To understand the current state of research on memory and attention, it is helpful to first discuss current views on how reality is constructed in the mind and brain, and the relationship of this process to perception. Work in various areas of neuroscience, for example, in vision or somato-sensory perception and location of the body in space, has shown that unlike the often predominant intuitive view, we humans do not construct reality directly from our perception of the environment, as if we were equipped with some sort of internal video camera. Instead, our prior learning, our neuropsychological predispositions, and the current context heavily influence the reality that we construct and experience. That is, reality is never perceived directly from the environment. Instead, we construct reality based on our own best guesses, interpretations, and expectations. For a trite but illustrative example, imagine why visual illusions work: our visual system

uses context and prior experience with the world to construct images that incorporate our best guesses about the color, form, movement, and identity of what is actually in front of our eyes.

Related to this, our memories do not reflect the objective replaying of an actual occurrence, but our iterative mental reconstruction of an event, fact, or procedure, for example, the skills to solve a math problem, or a student's conversation with her teacher about her test grade. This means that the iterative reconstruction or mental conjuring of a remembered event will be very similar to the neural processes for imagining an event that never happened, or for simulating possible outcomes of future events. Notably, each of these processes is organized by our emotions, and reflects the subjective meaningfulness and relevance of the remembered, imagined, or simulated thought, as well as the social, physical, biological, and developmental contexts in which the person is operating.

Given all these factors, it is no wonder that different teachers and learners perceive, experience, and remember lessons and educational contexts in different ways!

Another process that is related to the study of memory and emotion, and that is an important prerequisite for the recruitment of neural networks, is attention. The last decade marks theoretical and methodological advances in the study of attention and its relationship to the development of academic skills (Corbetta and Shulman, 2002). In particular, Posner and colleagues have distinguished three different attentional networks important for learning, including networks for alerting, orienting, and executive attention (for a review, see Posner and Rothbart, 2007). They have also shown that individual differences in attention networks can be related to genetic and environmental factors, and that training in these aspects of outwardly directed attention, that is, the ability to regulate one's focus on different aspects of the environmental context, can improve preschooler's academic abilities in various areas such as reading skills and social interaction at school (Berger *et al.*, 2007). Future work should investigate how attention monitoring can be taught in schools, as a way to increase the efficiency with which neural networks are built and recruited.

Back to the Big Picture: Mind, Brain, and Education are Becoming Usefully Connected

Over a decade ago, John Bruer cautioned educators that given the current state of knowledge, directly connecting brain science and education was premature – a bridge too far (Bruer, 1997). But, much has happened since then to narrow the chasm between these two sources of knowledge about development and learning. A new field has been established whose aim is to further knowledge about children's learning by bringing together methods and evidence from various fields, among them neuroscience, psychology, cognitive science, and education.

In this stimulating climate, it is important that new neuroscience advances be carefully examined in light of psychological, developmental, and pedagogical theory and research, to ensure that the field proceeds with caution as well as optimism toward educational innovation. In the past, techniques and ideas from so-called brain-based education have led to the formation of neuromyths – oversimplified, misunderstood, or misapplied notions whose integration into educational contexts is unjustified and, in some cases, detrimental or even dangerous. Instead, findings from neuroscience must be carefully implemented and evaluated, starting in educational microcosms such as research schools, where students and faculty partner with cognitive neuroscientists in the design and assessment of research.

In conclusion, it is an exciting time for the field of MBE, and for studying the neuroscientific bases of learning. In the end, learning happens primarily in the brain; studying the neuroscientific bases of learning can therefore provide educationally relevant insights that, with careful implementation and evaluation, may improve schools and other learning environments for the generations to come.

Glossary

EEG – Electroencephalography, a time sensitive imaging method based on direct measurement of electrical brain activity.

fMRI – Functional magnetic resonance imaging, a spatial imaging method based on blood flow.

MEG – Magnetoencephalography, a time sensitive imaging method based on the magnetic fields generated by electrical brain activity.

Introduction

The neural demands made by learning to read appear to be very similar in different languages. Current neuroimaging research suggests that the core neural systems involved are the same across languages, and that the atypical neural processing characteristic of children with developmental dyslexia is also highly similar across languages. Current neuroimaging technologies are able to provide information about the time processes in reading (electroencephalography (EEG) technology), information about the parts of the brain that are involved in reading (functional magnetic resonance imaging (fMRI) technology), and information about the temporal sequential activation of different neural regions (magnetic source imaging (MSI)). Connectivity analyses also provide important information on the white matter tracts (information highways in the brain) that develop to support successful word recognition.

The most prevalent neuroimaging technologies used with children work in different ways and provide different kinds of information. In EEG, sensitive electrodes are placed on the child's scalp and brain electrical activation is recorded directly. The sensitive electrodes can measure the low-voltage changes in networks of neurons caused by cells communicating with each other (an electrochemical process). EEG is very time sensitive, and is able to record changes in brain activity at the millisecond level. For example, EEG can pinpoint the exact time at which a child recognizes a word. However, EEG signals are difficult to localize, hence the neural regions responsible for word recognition are not revealed by this technique. A second prevalent measure – currently the most dominant measure in use with children – is fMRI. fMRI

measures changes in blood flow in the brain, through detecting the magnetic resonance signal generated by the protons of water molecules in neural cells. This generates a blood oxygenation level-dependent (BOLD) response. The BOLD response peaks over time, and relative activation in different neural regions will be recorded. Images are typically acquired over 0.5–several seconds, and so fMRI lacks the millisecond temporal resolution of EEG. However, fMRI offers very good spatial resolution, indicating where exactly in the brain reading-related neural activity takes place. Finally, MSI depends on a combination of magnetoencephalography (MEG) and MRI. MEG measures the magnetic fields generated by the electrical activity in the brain rather than the electrical activity itself (the latter is measured by EEG). These magnetic fields are tiny; they are 1 billion times smaller than the magnetic field generated by the electricity in a light bulb. By combining this information with MRI scans – which detect changes in blood flow – both the time course and the spatial localization of brain activity is possible. There are currently very few MSI studies of children's reading.

The Development of Reading

The history of behavioral research on reading acquisition in English reveals considerable debate about the extent to which visual processes versus phonological processes are critical for learning to read. For example, in the 1970s there was debate concerning the relative contribution of Phonician (code-breaking) versus Chinese (visual memorization) reading-acquisition strategies. Developmental dyslexia was assumed to be a primarily visual disorder, conceptualized as a congenital word blindness. More recently, behavioral researchers have proposed stage or phase models of reading acquisition in English, in which early logographic or visual memorization strategies are replaced by code-breaking or phonological recoding strategies, with a final phase of automatic orthographic word recognition. Dual-route models of reading acquisition were also popular. These models assumed that, developmentally, children could choose to learn to read by either whole-word-based strategies (a visual or direct route to meaning) or by using grapheme–phoneme assembly (a phonological or indirect route to meaning). It was also assumed that developmental dyslexia could either reflect visual-orthographic difficulties in developing a sight vocabulary (surface developmental dyslexia), or difficulties

in learning to recode words using letter-sound rules (phonological surface dyslexia). Most of these ideas are looking increasingly dated with the advent of brain imaging.

Brain imaging studies available at the time of writing suggest that reading begins primarily as a phonological process. In the earliest phases of reading acquisition, it is the neural structures for spoken language that are particularly active. As reading expertise develops, an area in the visual cortex originally named the visual word-form area (VWFA) becomes increasingly active (Cohen and Dehaene, 2004). Although described as processing visual forms, this area is not a logographic system that accesses meaning directly from a holistic pattern. Although close to the visual areas that are active during picture naming, the VWFA is also active during nonsense word reading (reading aloud nonlexical forms, such as *tegwump*). Nonsense words do not have visual word forms in the mental lexicon, hence the VWFA is thought to store orthography–phonology connections at different grain sizes. Orthographic sequences and their connections to sound appear to be stored at both the whole-word and sub-word level.

Many behavioral studies in developmental psychology have demonstrated the critical role of phonological awareness in learning to read (see Ziegler and Goswami, 2005, for a recent review). Phonological awareness is thought to develop from natural language-acquisition processes. Word learning is exponential between the ages of 1 and 6 years, and in order for the brain to represent each learned word as a distinct and unique sequence of sounds, the mental lexicon must incorporate knowledge of the sound elements that comprise a particular word, and the order in which these elements occur. Behavioral studies across languages have shown that a child's awareness of these sound elements at different linguistic levels (syllable, onset–rime, and phoneme) predicts the acquisition of reading (see Ziegler and Goswami, 2005, for a review). Further, training phonological awareness has positive effects on reading acquisition across languages, particularly when it is combined with training about how letters or letter sequences correspond to sounds in that language (e.g., Schneider *et al.*, 2000). Children with developmental dyslexia across languages appear to have specific problems in detecting and manipulating component sounds in words, called a phonological deficit (e.g., Snowling, 2000).

Neuroimaging Studies of Learning to Read

There are still relatively few neuroscience studies of children who are learning to read. Most neuroimaging studies of reading have been carried out with adults (see Price and McCrory, 2005, for a recent synthesis). Adult fMRI studies show a very consistent picture concerning the neural networks that underpin skilled reading. Skilled word recognition appears to depend on a left-lateralized

network of frontal, temporoparietal, and occipitotemporal regions – whatever language is being read. However, there is some additional recruitment of visuospatial areas for languages with nonalphabetic orthographies (e.g., left middle frontal gyrus for Chinese, see meta-analysis by Tan *et al.* (2005)). The frontal, temporoparietal, and occipitotemporal regions essentially comprise the language, cross-modal, and visual areas of the brain. At a very simple level, semantic and memory processing is thought to occur in temporal and frontal areas, auditory processing in temporal areas, visual processing in occipital areas, and cross-modal processing in parietal areas. Data on neural timing from EEG studies suggest that the brain has decided whether it is reading a real word or a nonsense word within 160–180 ms of presentation. This has been demonstrated both for children and adults across languages (e.g., Csepe and Szucs, 2003; Suaseng *et al.* 2004).

Studies of children using fMRI have tended to use a restricted range of tasks. These include asking participants to read single words and then comparing brain activation to a resting condition with the eyes closed; asking participants to pick out target visual features while reading print or false font (false font is made up of meaningless symbols matched to letters for visual features like the ascenders in the letters b, d, and k); making phonological judgments while reading words or nonsense words (e.g., “do these items rhyme?”: *leat* and *jete*), and making lexical decisions (e.g., pressing a button when a word is presented, and a different button when a nonsense word is presented). Nevertheless, the developmental studies that have been completed demonstrate a high degree of consistency between the neural networks recruited by novice and expert readers. For example, work by Turkeltaub and colleagues used fMRI and the false-font task to compare neural activation in English-speaking children and college students aged from 7 to 22 years (Turkeltaub *et al.*, 2003). This task was selected because 7-year-olds can perform it as well as adults, meaning that changes in reading-related neural activity are likely to reflect developmental differences rather than differences in task expertise. Turkeltaub and colleagues reported that adults activated the usual left hemisphere sites, including left posterior temporal and left inferior frontal cortex. They then restricted the analyses to children younger than 9 years of age. In this instance, the main area engaged was the left posterior superior temporal cortex. This region is traditionally considered the focus of phonological activity, and is thus thought to be active during grapheme–phoneme translation. As reading developed, activity in left temporal and frontal areas increased, while activity previously observed in right posterior areas declined. This pattern was interpreted as showing that reading-related activity in the brain becomes more left-lateralized with development.

In further analyses focusing only on the younger children, the researchers investigated the relationships

between three core phonological skills and word processing. The three core phonological skills are usually taken to be phonological awareness, phonological memory, and rapid automatized naming (RAN). Turkeltaub and colleagues calculated partial correlations between activated brain regions and each of these three measures while controlling for the effects of the other two measures. They reported that the three different measures correlated with three distinct patterns of brain activity. Brain activity during phonological awareness tasks appeared to depend on a network of areas in the left posterior superior temporal cortex and the inferior frontal gyrus. The level of the children's phonological skills modulated the amount of activity in this network. Activity in the inferior frontal gyrus increased with reading ability. This area is also a key phonological area (Broca's area) – important for the motor production of speech. Phonological short-term memory (digit span) appeared to depend on a different neural network, including left intraparietal sulcus – the dominant site of working memory in adults – the middle frontal gyri (bilaterally), and right superior temporal sulcus. RAN appeared to depend on a different, bilateral network including right posterior superior temporal, right middle temporal, and left ventral inferior frontal gyri. Other studies report increasing engagement of the VWFA as reading ability increases. This suggests that the VWFA is a kind of skill zone – with greater activation reflecting increasing expertise with orthography–phonology connections (see Pugh, 2006, for an overview).

A similar developmental picture emerges from an fMRI study of 119 typically developing readers in the age range 7–17 years by Shaywitz and colleagues (Shaywitz *et al.*, 2007). This study used a rhyme-decision task (e.g., “do these items rhyme?": leat and kete), and a visual line orientation task (e.g., “Do [V] and [V] match?"). Shaywitz and his colleagues reported that networks in both left and right superior and middle frontal regions were more active in younger readers. Activity in these networks declined as reading developed. In contrast, activity in the left anterior lateral occipitotemporal region increased as reading developed. This region includes the putative VWFA. Hence both Turkeltaub *et al.* (2003) and Shaywitz *et al.* (2007) report decreased right hemisphere involvement as reading develops. The difference in the behavioral tasks used (e.g., false font vs. rhyme judgment) may explain why somewhat different neural networks became less active.

Overall, therefore, current neuroimaging data appear to support a single route model of reading development. Neuroimaging data suggest that phonological recoding to sound rather than logographic recognition is the key early reading strategy, accompanied by an incremental process of developing orthographic–phonological connections at different grain sizes in the VWFA. This reflects the development of an orthographic lexicon containing both whole words and fragments of familiar words

such as orthographic rimes (Pugh, 2006). The VWFA is not a logographic or visual lexicon, able to support Chinese processing or a direct route from printed word to meaning postulated by dual-route theory.

Neuroimaging Studies of Developmental Dyslexia

The Networks Recruited for Reading

Neuroimaging studies of adult readers with developmental dyslexia suggest biological unity with regard to the affected neural networks. These studies report atypical activation in the three important neural sites for reading – namely, the left posterior temporal regions, the left inferior frontal regions, and the left occipitotemporal regions (such as the VWFA) (e.g., Paulesu *et al.* (2001), for a comparison of Italian, French, and English-speaking adult dyslexics). Further, neuroimaging studies carried out with children with developmental dyslexia report a similar pattern to adult studies (e.g., Shaywitz *et al.*, 2002, 2007; Simos *et al.*, 2000). However, when interpreting neural differences in developmental studies, it is important to ensure that behavioral performance in the tasks being used is equivalent. If children with dyslexia are worse in such tasks than control children, then any differences in neural activity could reflect differing levels of expertise rather than the neural differences that are core to being dyslexic.

In one of the first developmental studies, Shaywitz *et al.* (2002) studied 70 children with dyslexia, mean age of 13 years, and compared them to 74 11-year-old typically developing controls (although the controls were not matched for reading level). The children lay in the fMRI scanner while performing a variety of reading-related tasks – namely, letter identification (e.g., Are t and V the same letter?), single-letter rhyme (e.g., Do V and C rhyme?), nonword rhyming (e.g., Do 'leat' and 'jete' rhyme?), and reading for meaning (e.g., Are 'corn' and 'rice' in the same semantic category?). Brain activity in each condition was contrasted with activity in a baseline condition; the line-orientation task (e.g., do [V] and [V] match?). Shaywitz *et al.* (2002) reported that the children with developmental dyslexia showed underactivation in the core left temporoparietal networks, with older dyslexics showing overactivation in right inferior frontal gyrus. The children with developmental dyslexia also showed increased activation in right temporoparietal networks. However, some of the differences found in brain activation could have reflected differing levels of expertise with the tasks. For example, for the nonword-rhyming measure, the controls (79% correct) were significantly better at the task than the children with dyslexia (59% correct). In a subsequent study of an expanded sample, Shaywitz *et al.* (2007) used in-magnet nonword-reading

ability as a covariate to control for this problem. Shaywitz and colleagues compared 113 dyslexic children in the age range of 7–18 years to the 119 typically developing readers discussed above in the nonword rhyme and visual line-orientation tasks. Compared to the typically developing children, the dyslexic children showed no age-related increase in the activity of the VWFA. Instead, activity both in the left inferior frontal gyrus (speech articulation) and the left posterior medial occipitotemporal system increased, and reading did not become left-lateralized, with continued right hemisphere involvement.

Developmental Differences in the Time Course of Neural Activation

If basic word-recognition processes are delayed in developmental dyslexia, this will delay access to semantics and, therefore, affect reading comprehension. Similarly, cognitive processes such as grapheme–phoneme conversion might take longer in developmental dyslexia. EEG and MSI technologies can help us to study these questions.

One of very few longitudinal neuroimaging studies of children learning to read used MSI to gain information about developmental differences in the time course of neural activation. Simos and his colleagues studied 33 English-speaking children – 16 of whom were thought to be at high risk of developing dyslexia. The researchers compared brain activation in a letter-sound task (the child saw a letter and had to provide its sound) and a simple nonword-reading task (recoding nonwords like ‘lan’ to sound). Both tasks were administered at the end of kindergarten and again at the end of the first grade (see Simos *et al.*, 2005). In kindergarten, the high-risk group were significantly slower to show neural activity in response to both letters and nonwords in the occipitotemporal region (requiring, on average, 320 ms compared to 210 ms for those not at risk). The high-risk group also showed atypical activation in the left inferior frontal gyrus when performing the letter-sound task. For this task, the onset of activity actually increased developmentally – from 603 ms in kindergarten to 786 ms in the first grade. The typically developing readers did not show a processing-time increase.

When Simos and his colleagues compared the onset of activity of the three core neural networks for reading, they found that low-risk children showed early activity in the left occipitotemporal regions. This was followed by activity in the temporoparietal regions, predominantly in the left hemisphere, and then by bilateral activity in the inferior frontal regions. In contrast, high-risk children showed little differentiation in terms of the time course of activation between the occipitotemporal and temporoparietal regions. High-risk children who were also nonresponsive to a phonological remediation package being administered during the study ($N = 3$) were distinct in showing earlier onset of

activity in the inferior frontal gyrus compared to the temporoparietal regions. Simos and colleagues commented that the increased inferior frontal activation probably reflected the role of compensatory articulatory processes. This may indicate that children with phonological difficulties rely more heavily on networks for articulation when phonological processing is required.

The Neural Effects of Remediation

Neuroimaging studies of different types of remediation for reading difficulties are consistent in showing that when targeted phonology-based interventions are used with affected children, neural activity is normalized. This indicates that levels of activation in the left-lateralized network of reading areas typically improve following such interventions (e.g., Shaywitz and Shaywitz, 2005; Simos *et al.*, 2002; Temple *et al.*, 2003). Most such studies rely on fMRI, and hence it is difficult to be sure how extensive such normalization really is, given that the BOLD signal reaches a peak over several seconds. Simos and his research group, therefore, used MSI to explore neural activation in eight children with developmental dyslexia who had received 80 h of intensive training with a phonological remediation package (Simos *et al.*, 2002). MSI scans were taken during a nonword rhyme-matching task (e.g., ‘yoat’ ‘wote’), both before the intervention and following remediation. Prior to the intervention, the dyslexic children showed the usual hypoactivation of left temporoparietal regions. Following the intervention, all eight children showed a dramatic increase in the activation of left temporoparietal regions, predominantly in the left posterior superior temporal gyrus. As will be recalled, these networks support grapheme–phoneme recoding in typically developing readers (see Turkeltaub *et al.*, 2003). However, Simos and colleagues found that neural activity was delayed in the children with dyslexia relative to the controls even after this remediation. For example, the peak in left superior temporal gyrus activity occurred at 837 ms, on average, for the dyslexic children, and at 600 ms for the controls. Therefore, even with intensive remediation, children with dyslexia are slow to achieve the reading fluency shown by nondyslexic children.

Shaywitz and Shaywitz (2005) used retrospective examination of the large sample of children with developmental dyslexia reported in Shaywitz *et al.* (2002) to compare whether children at risk for reading difficulties showed different neurodevelopmental trajectories. They distinguished three groups within the sample – a group of persistently poor readers (PPR), who had met criteria for poor reading both in the second/third and in the ninth/tenth grades; a group of accuracy-improved poor readers (AIR), who had met criteria for poor reading in the second/third grades but who did not meet criteria in the ninth/tenth grades; and a control group of nonimpaired readers

(C), who had never met criteria for poor reading (the participants had been studied since age 5). Shaywitz and Shaywitz reported that both the PPR and the AIR groups showed hypoactivation in neural networks in left superior temporal and occipitotemporal regions. However, the groups were distinguished by their neural activity when reading real words. The AIR group still demonstrated underactivation in the usual left posterior areas for real-word reading, whereas the PPR group activated the left posterior regions to the same extent as controls.

Shaywitz and Shaywitz then carried out further analyses based on connectivity. Connectivity analyses examine the neural areas that are functionally connected to each other during reading. The connectivity analyses suggested that reading achievement depended on memory for the PPR group, and not on the normalized functioning of the left posterior regions. The unimpaired controls demonstrated functional connectivity between left hemisphere posterior and anterior reading systems, but the PPR group demonstrated functional connectivity between left hemisphere posterior regions and right prefrontal areas associated with working memory and memory retrieval. Prospective longitudinal studies comparing patterns of neural activation and connectivity in dyslexic children as high-frequency words become over-learned would clearly be very valuable.

Conclusions

Neuroscience studies using fMRI have provided a clear picture of the neural networks that underpin reading both in typically developing and dyslexic readers. It has been shown that the functional organization of the networks for reading is similar in typical development and in dyslexia. Rather than relying on different neural networks, dyslexics show hypoactivation of crucial parts of the network of areas involved in word recognition, and an atypical pattern of continuing right hemisphere involvement. These fMRI studies are essentially correlational studies. They do not answer research questions about what goes wrong in the dyslexic brain. Neuroimaging methods that provide data on the time course of neural processing, such as MEG (MSI) and EEG, are beginning to answer such causal questions. For example, studies using MSI demonstrated that neural activation is delayed in core components of the left-lateralized reading network, and suggested that core components of the reading network may be activated in a different order in developmental dyslexia. We need more longitudinal studies to find out whether there are different neurodevelopmental routes to word recognition for dyslexic children compared to typically developing children. Only longitudinal studies can illustrate the response of a dyslexic brain to being trained to learn to read.

It is believed that the most informative studies with respect to causation in reading will be longitudinal

prospective studies that use neuroscience techniques to study basic sensory processing in at-risk children. Such studies may give insight into the causes of the phonological deficit. In this regard, the most promising studies to date are those investigating basic auditory processing, using EEG and MEG methodologies. For example, a large-scale Finnish study (the Jyväskylä Longitudinal Study of Dyslexia or JLD; see Lyytinen *et al.*, 2004) has followed babies at familial risk for dyslexia since birth. EEG measures of auditory sensory processing (evoked-response potentials to speech and nonspeech cues) have been found to distinguish the at-risk babies from controls even during infancy. Hence EEG technologies may soon be able to offer robust neural markers of risk for reading difficulties, enabling much earlier intervention.

Glossary

Comprehension monitoring – This occurs when learners check their understanding of something they are trying to learn using some form of self-assessment.

Domain-dependent learning strategies – The learning strategies that are specific to a particular content area or type of academic task.

Domain-independent learning strategies – The learning strategies that are widely applicable across content areas and academic tasks.

Elaboration strategies – The deep-level strategies used to build bridges or meaningful connections between what the learner is trying to learn and their prior knowledge, experience, attitudes, and/or beliefs.

Learning strategies – Any behavioral, cognitive, metacognitive, motivational, or affective process or action that facilitates understanding, learning, and meaningful encoding into memory.

Organization strategies – The deep-level strategies used to meaningfully translate or transform information into a configuration or form that creates some sort of coherent scheme that makes the information more understandable and easier to encode and remember.

Rehearsal strategies – The surface-level repetition strategies used to memorize discrete information or hold information in working memory so that it can be processed further.

Self-regulation learning strategies – The strategies used by learners to control, manage, and

oversee cognitive, motivational, emotional, and environmental factors that influence learning.

Our desire to understand our world and learn what we need to know and do to survive and thrive has existed since the origin of mankind on the earth. However, it is only since the 1970s that the psychological study of the strategies we use to learn about our world began in earnest. In the broadest sense, a learning strategy is any behavioral, cognitive, metacognitive, motivational, or affective process or action that facilitates understanding, learning, and meaningful encoding into memory. The problem with such a broad definition is that it includes almost any psychological variable. Everything affects learning to at least some extent. For this reason, educational psychologists study variables that have been found to have the greatest direct or indirect impact on learning and encoding into memory, and that can be modified by some type of training or educational intervention. This second criterion excludes some variables such as personality traits because, although they may affect learning, they are not amenable to change by an educational intervention (however, we can teach students learning strategies that reduce the negative impact of some individual variables such as impulsivity or attention deficit disorders).

The major categories of learning strategies include: cognitive information acquisition and processing strategies, motivational strategies, self-regulation and monitoring strategies, affect regulation strategies, and behavioral strategies. Several of these strategies are discussed further after the presentation of a brief historical overview of this area. This is followed by a discussion of the ways in which models of

strategic and self-regulated learning incorporate learning strategies, how learning strategies are assessed, and types of instruction used to teach learning strategies.

Historical Overview

From the time humans first appeared on the earth, they were concerned about learning and memory. Some anthropologists have hypothesized that cave drawings were at least in part an attempt to learn and remember animal migrations and the seasons for different foods. They may also have been a way to help the young learn the knowledge, culture, and norms of life as it then existed. The Greeks are famous for the development of mnemonic devices, or mental memory aids, some of which are still used today (e.g., using the ABC song in the United States to learn the alphabet, associating a new item we are trying to remember with an existing image, or the first letter mnemonic HOMES (Huron, Ontario, Michigan, Erie, and Superior) to remember the five Great Lakes in America). In the 1800s and early 1900s many parlor entertainers at parties or gatherings would use mnemonics to perform prodigious feats of learning and memory. Today, advertising experts use mnemonic tunes and phrases to help people remember to buy their brand when they see it in a store.

For the first half of the twentieth century the study of mnemonics or any other cognitive learning strategy lay dormant as the overwhelming charge of behaviorism swept through psychology. Behaviorists, in their attempt to make psychology a science, rejected not only philosophical or introspective methods of research but also any theoretical or empirical work involving mental processing. The world of environmental manipulations, reinforcement, and extinction had little interest in the black box (mind).

It was not until the late 1960s and 1970s that the study of mental processes made its way back into psychological theories and research. Once again, mnemonics played a key role. Some of the earliest studies during this period focused on mnemonics but this time, once it was established that they were not just parlor tricks, the focus shifted to why and how mnemonics worked and what we could learn about human information processing from them. What cognitive processes were involved in the creation and use of mnemonics? What fundamental information did this give us about human information processing? In the 1970s, this work was greatly enriched by other early researchers in the area of what we now call cognitive educational psychology. For example, a major influence was the work of John Flavell and his colleagues who developed the concept of metacognition, or thinking about our thinking. Basically, metacognition is thinking that focuses on knowledge, self-reflection, and analyses of

how we think and learn. As a direct result of this early work examining cognition, variables that might influence cognition and the degree to which cognition might or might not be influenced through some form of educational intervention, the area of learning strategies developed as a field of study.

Types of Learning Strategies

There is general agreement about the basic types of learning strategies as originally codified by Weinstein and Mayer (1986) and expanded upon by continuing theoretical and research work in this area. The development of interactive models of strategic and self-regulated learning at all educational levels has, however, changed the ways we explore, study and teach students how to use learning strategies. This is discussed further later in this article.

Rehearsal Strategies

These are the most basic of all learning strategies and can be used most effectively in the first stages of building a knowledge base in a content domain. Rehearsal strategies are most useful for basic memorization, processing new information at a surface level, but are not generally useful for creating a deep and sophisticated understanding of the material. Researchers differentiate between passive rehearsal, which is not very effective for most learning tasks, and active rehearsal, which can be more beneficial. Passive rehearsal is based on early mental muscle models of learning which assumed that the mind is like a muscle – the more you practice, the more you will build up the strength of your memory. It involves learners repeating something over and over until they remember it (similar to the use of flash cards) or using other memory aids, such as mnemonics. While these methods may be useful for learning discrete bits of information (e.g., isolated facts and lists of information), they are not very effective as learning strategies for more complex content or learning tasks involving reasoning. In addition, these methods do not contribute efficiently to the integration of new information one is trying to learn with existing knowledge and expertise, a major goal for many learning tasks.

Active rehearsal, while using some of the same methods as passive rehearsal, differs in terms of the goals for using this strategy. In passive rehearsal, repetition is the end point of the process, while in active rehearsal, repetition is used as an enabling tool to hold onto information so that it can be further processed and encoded into more stable areas of memory. Highlighting important information in class notes or a textbook and then reviewing the highlighted material at a future time would be examples of using repetition to help learn the content by creating

additional opportunities to further process it. Even something like flash cards could be used for active repetition, if the goal was to continue thinking about and encoding the information on the cards.

Elaboration Strategies

Elaboration strategies are the largest and most diverse category of learning strategies. Fundamentally, elaboration involves building bridges or connections between what the learner is trying to learn and their prior knowledge, experience, attitudes, and beliefs. Building these bridges forces the learner to actively process the new information and it is this engagement that is believed to be the core cognitive mechanism involved in reaching learning goals. It is not just the elaborations that result from using these strategies but the process of creating those elaborations that facilitates meaningful encoding into memory. In addition, elaboration has been found to increase related variables such as task focus and concentration, task interest and enjoyment, motivation, and positive attitudes and emotions toward the learning content and task itself.

Elaboration learning strategies take many forms depending on the nature of the content, the learning task, and the learner's individual differences and learning goals. The most basic forms of elaboration involve paraphrasing and summarizing. Even though these are fundamentally a form of repetition, unlike rehearsal strategies, they are not simple verbatim recall which does not involve higher-level cognitive processes. To paraphrase or summarize what a student is trying to learn requires some degree of encoding and transformation of the targeted information so active cognitive engagement is required. More advanced and complex forms of elaboration include: using everyday experience to try to understand a new concept, applying what the student is learning to new and diverse tasks, trying to teach the material to someone else, perspective taking, visualization, using a problem-solving strategy in a new context, creating analogies, using compare-and-contrast methods to highlight the differences and similarities between two related concepts, and creating and responding to questions about the material being studied.

Research has shown that the active processing involved in using elaboration strategies is what is key to learning and that the specific elaboration strategy used for a learning task is not as important. However, it has been shown that it is important for students to learn a repertoire of diverse strategies so that they can both develop their preferences and have alternative strategies to fall back on if their preferences do not work for a particular learning task. This issue also relates to what strategies students should learn and in what context they should learn them. The instructional issues this raises are discussed further in later sections.

Organization Strategies

Organization strategies involve translating or transforming information into another configuration and creating some sort of scheme to provide structure to this new way of characterizing or representing the information. These strategies are used to organize information into meaningful categories, hierarchies, and sequential structures so that it can be visualized, analyzed, understood, and encoded meaningfully into memory. Similar to elaboration strategies, organization strategies facilitate deep processing of the information and meaningful encoding into memory. By organizing the new information the learner is actively engaged with the material and it is believed that this active engagement underlies much of the benefit of using organization strategies. In addition, the product that results can be used in the future to review and deepen understanding. Moreover, similar to elaboration, organization strategies have been found to increase related variables such as task focus and concentration, task interest and enjoyment, motivation, and positive attitudes and emotions toward the learning content and task itself.

Creating outlines, concept maps, and concept matrices are types of organizational strategies. Creating an outline involves organizing material into a hierarchical structure with a logical flow using an outline format (e.g., I. Thesis statement; A. Major point; 1. Supporting detail). Creating concept maps is another organizational strategy that is used to graphically represent relationships among and between concepts. For example, connecting concepts with arrowed lines and identifying those relationships with phrases such as: results in, contributes to, decreases, is a defining attribute of, or is a subcategory of is a common type of organization strategy. Creating concept matrices refers to graphically organizing information about related concepts into a matrix of rows and columns in order to learn and analyze those concepts (e.g., organizing the names of concepts in the first column, concept definitions in the second column, and examples of the concepts in the third column). Organizational strategies have been found to help students analyze, learn, and remember their course material at a deep level. Research suggests that the effectiveness of organization strategies derives not only from the active processing that is required to create the organizational structure but also from the product itself since it can be later used for review, as a study aid, or incorporated into a larger and more encompassing scheme in that knowledge domain.

Self-Regulation Learning Strategies

Self-regulation learning strategies are used by students to control, manage, and oversee cognitive, motivational,

emotional, and environmental factors that influence learning (both positively and negatively). Goal-setting/planning, implementing/monitoring, and evaluating both process and outcomes are types of self-regulation strategies. Goal-setting/planning refers to setting learning goals and planning for how one will reach those goals (e.g., choosing one rehearsal strategy, two elaboration strategies, and one organizational strategy that will be used to reach the learning objectives for an upcoming exam). Implementing/monitoring involves implementing these learning plans and monitoring the pursuit of the learning goals (e.g., implementing and monitoring a plan to summarize each section of a textbook). Evaluating the success of one's strategic approaches to achieve a learning goal is another type of self-regulation strategy (e.g., evaluating whether or not the cost in time of creating a concept map was worth the payoff in learning). Self-regulation learning strategies can help students fine-tune their strategic approaches to reaching their learning goals and develop more effective and efficient study routines. These strategies can also be used to oversee and manage the regulation of motivational, emotional, and environmental variables that influence learning.

Metacognitive Strategies – Comprehension Monitoring

An important component of self-regulation involves using metacognitive strategies for learning. Within this broad area, the most relevant type of metacognitive strategy for the purposes of this article is comprehension-monitoring strategies. Basically, comprehension monitoring involves checking our understanding of something we are trying to learn using some form of reviewing or self-testing. Comprehension strategies both support and contribute to meaningful learning. Without them, learning could be incomplete or errors might persist undetected. Reviewing and self-testing also contribute to knowledge consolidation and integration across topics. Using mental reviews, going over notes and course materials, thinking of potential questions to guide reading or help prepare for an exam, trying to use new information in novel ways, and trying to apply a principle or method are all important methods for checking understanding, consolidating new knowledge, and integrating related information (both from what is being learned and from what is already known). Although comprehension-monitoring strategies include many of the strategies discussed under elaboration, the purpose is different. When learning new content material, using a strategy like applying a principle is designed to enhance understanding and encoding into memory. When applying a principle such as a comprehension-monitoring strategy, the goal is to see if that understanding and accessible memory encoding has been established.

Need for a Learning Strategies Repertoire

Rehearsal, elaboration, and organization strategies can be used to help students actively process and learn new information. However, students differ over which learning strategies work best for them both within and across different types of learning tasks and contexts. For this reason, it is important that students learn and develop a repertoire of learning strategies both within and across all three of these categories so that they can mindfully develop their preferences and have a range of strategies to fall back on if their preferences do not work.

Domain-Independent Strategies Versus Domain-Dependent Strategies

In current theory, research, and practice, the applicability, or generalizability, of particular learning strategies to different learning content areas or tasks is still being debated. The general issue is whether it is best for students to learn domain (content or task)-specific strategies (e.g., strategies for solving a particular type of physics problem or learning a new vocabulary term in a foreign language) or more generalizable, or domain (content or task)-independent strategies that can be applied to many content areas (e.g., how to approach an unfamiliar textbook or using self-testing to check your understanding of what you are learning). In fact, if you think about it in terms of a generalization gradient, they are really just different points on the line. If the strategy has a narrower domain of applicability (i.e., it can only be used for a relatively small number of learning or performance activities), then it is domain dependent. If, on the other hand, it can be used in a wide variety of situations or content areas, then it has a wide domain of applicability and is domain independent. Like many controversies, it appears that it takes a bit of both to help students become self-regulating, strategic learners. Some strategies may be more effective and efficient for the content and tasks in one particular academic area, while others may be helpful for a wider variety of academic areas and tasks.

Learning Strategies in Models of Strategic and Self-Regulated Learning and College Readiness

The study of learning strategies has evolved from an isolated area of study into a critical component of most models of strategic and self-regulated learning. This integration of learning strategies into more complex and interactive models of academic learning is exemplified

by the work of Pintrich (2004), Weinstein *et al.* (2004), and Zimmerman and Schunk (2001). As an example of these theoretical models that guide much of the current research and instructional development designed to help students become more strategic and self-regulated learners, the most recent version of the Model of Strategic Learning (MSL) developed by Weinstein *et al.* (2006) is briefly discussed (see **Figure 1**).

Model of Strategic Learning

Similar to other recent models, the MSL is a multidimensional, interactive model where the focus is on the interactions among the components rather than the simple effects of one or two elements. Even many of the recent advances in statistical analyses are based on the need for analyzing interactive models. The core of the model (within the triangle) is the learner and all of the individual differences, self-system variables, and long-term goals learners bring to any learning event. In addition, most meaningful learning is goal-driven and the model will be

used in different ways by students with different learning tasks and goals.

The variables outside the rectangle (e.g., requirements of the task and instructor expectations) are important variables for completing a learning activity but they are not usually under the student's direct control. The three main components of the model are listed at the three points of the triangle: skill, will, and self-regulation. Skill focuses on declarative (knowing what to do), procedural (knowing how to do it), and conditional (knowing when to use the strategies) knowledge that students need to develop in order to become more strategic learners (e.g., not only knowing about different learning strategies but also knowing how to use them effectively and when it is most appropriate to use a particular strategy). Will focuses on attitudes, beliefs, and goals that help students thrive and persist when faced with roadblocks to learning (e.g., setting specific and challenging, yet realistic, learning goals and avoiding or coping with self-sabotaging beliefs and attitudes). The self-regulation component focuses on managing the learning process and one's own cognition, motivation, and emotion related to the task (e.g., time

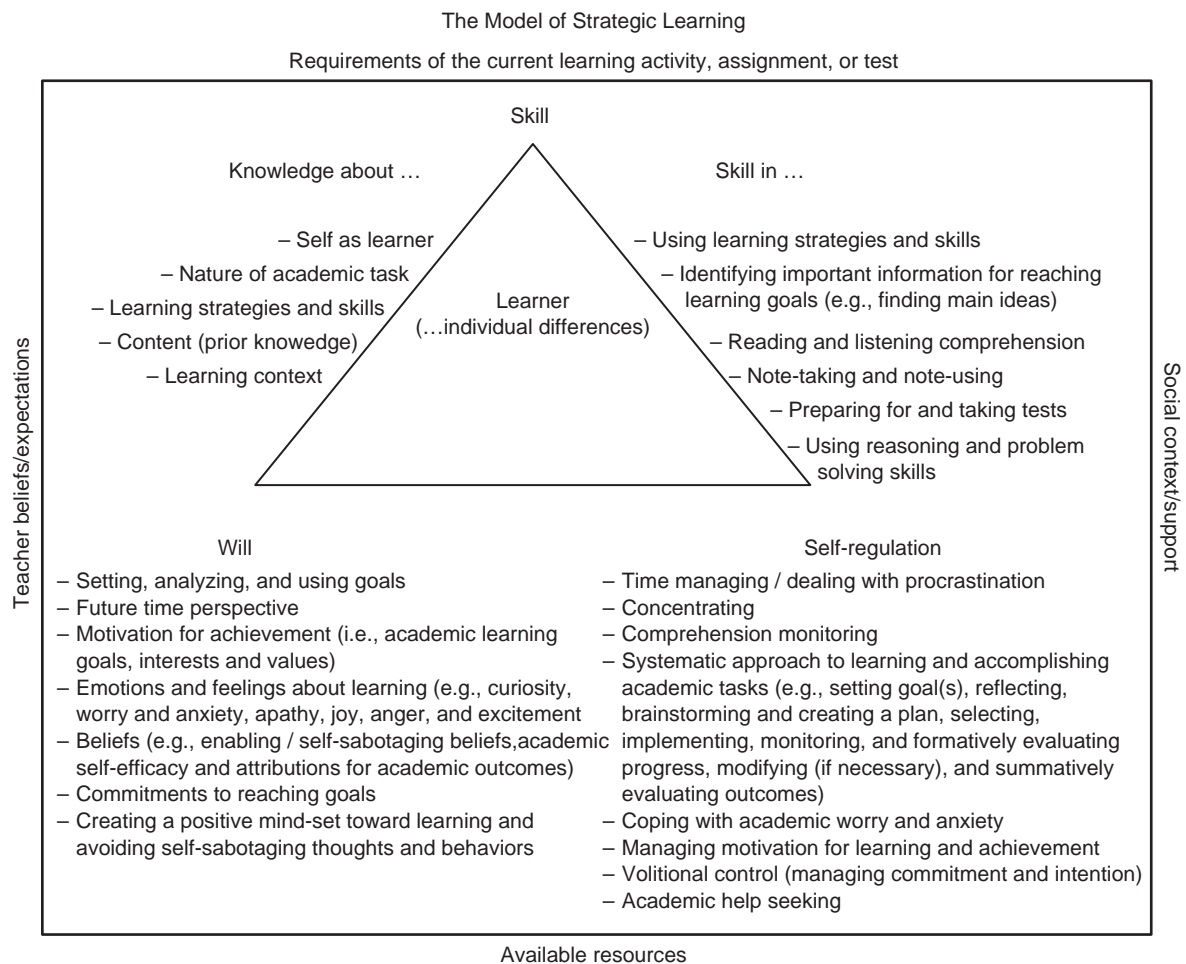

Figure 1 The Model of Strategic Learning.

management, comprehension monitoring, and coping with anxiety). For any given learning task, the student must take into account variables from each of the three components. Like the systems of the body, variables related to skill, will, and self-regulation need to function together in order to facilitate strategic learning. Which elements of each component will be most important to think about or use for completing a task will be largely determined by the learner's goals, prior knowledge, past experiences, and the nature of the task.

Assessment of Student Learning Strategies

Purposes for Assessment

The primary purpose of most learning strategy instruments is to identify students' knowledge and use of learning strategies in order to:

1. investigate correlational and causative relations with other variables, such as motivational goal types, class participation, or academic performance;
2. identify students' strengths and weaknesses in different areas of learning strategies to identify students who might need additional instruction in the areas where they scored low;
3. use as a pre-post and/or delayed outcome measure for interventions designed to teach learning strategies;
4. provide information to educators about individual needs of their students so they can target part of their instruction to helping their students learn or enhance their use of learning strategies; and
5. help developmental educators, student affairs counselors, and advisors who work with at-risk students to identify students who may be at risk of failure or dropping out from higher education settings because of their lack of knowledge and use of learning strategies so that they can be placed in learning strategies courses or other types of interventions.

Approaches and Instruments Used to Assess Students' Learning Strategies Knowledge and Use

There are a number of experimental and published instruments that assess students' knowledge and use of learning strategies. These instruments use some type of self-report method, usually involving some type of instrument or questionnaire. Some studies do have students describe or explain their strategies as they are using them, or just after completing a learning task, but these assessment methods still rely on self-report. While the limitations of self-report methods have been repeatedly

documented, it remains the best method for providing a window on the mind.

Some of the more commonly used measures include: The Learning and Study Strategies Inventory (2nd edition) by Weinstein *et al.* (2002), the Learning and Study Strategies Inventory – High School Version (2nd edition) by Weinstein and Palmer (1990), the Motivated Strategies for Learning Questionnaire by Pintrich *et al.* (1991), the Approaches and Study Skills Inventory for Students by Entwistle (1997), the Learning Process Questionnaire by Biggs (1987), the Survey of Study Habits and Attitudes, Form C by Brown and Holtzman (1984), and the Study Behavior Inventory by Bliss *et al.* (2000).

Teaching of Learning Strategies

Another controversy in the current literature focuses on the best way to teach students about learning strategies and how to use various learning strategies. This controversy also relates to the debate over the domain of applicability issue and whether we should teach content-dependent or content-independent strategies. Proponents on one side of the controversy believe that learning strategies should be taught in content courses, such as math, history, or biology, and not as a separate course. Proponents on the other side of the controversy believe that learning strategies should be taught as part of a course or training program in strategic or self-regulated learning. Recent research literature indicates that both groups are right – for students who are highly deficient in their knowledge and use of learning strategies, an adjunct course is best. For students who already have some level of skill, refining their knowledge and skills in content-dependent settings appears to be more helpful.

However, the most powerful instructional model appears to be a combination of the two. Using an adjunct course to help teach students general knowledge and skills in using strategies with a broad domain of applicability combined with what Weinstein has called the metacurriculum in content courses. Basically, a metacurriculum involves purposefully teaching learning strategies while also teaching course content. It can be as simple as paraphrasing a lesson and then teaching the class to do the same thing on their own to check their understanding, or as complex as teaching students how to develop, implement, monitor, and modify a test-preparation plan for an upcoming exam. For example, implementing a metacurriculum would involve not only teaching students what to learn in a history course but also how to learn and think like an historian.

Concluding Statement

It has often been said that the present belongs to those who have learned but the future belongs to those who are

learning. Increasing longevity and our increasingly complex and technologically sophisticated world requires that students be prepared to be lifelong learners throughout the different stages of their life span. Having an extensive repertoire of learning strategies is one step toward helping individuals become more effective and efficient learners.

Learning Through Play

K Aronsson, Stockholm University, Stockholm, Sweden

© 2010 Elsevier Ltd. All rights reserved.

Play Dichotomies

Historically, play has often been described as a type of mode that constitutes a natural way of being close to children, innocence, and nature. Play has been set up as a contrast to school, where pupils have been seen as unduly tamed citizens, colonized by methods that are alien to the child itself. Critical thinkers like Rousseau and Huizinga, and acclaimed authors like Goethe and Tolstoy have all foregrounded and celebrated the creative nature of play. Consequently, they have advocated pedagogies that offer leeway for the child's own free roaming, and playful explorations. For instance, on his estate in tsarist Russia, Tolstoy educated the children of poor peasants through Socratic dialogues, play, and creative writing.

Within the social sciences, play has often been studied in terms of instrumental goals. Following Sigmund Freud, Erik H. Erikson, and other psychodynamic thinkers, play has been advocated as the therapeutic method par excellence in work with clinical and psychiatric problems of children. For instance, play-world methods, which are widely used within child psychiatry, and in other clinical contexts, draw on the basic idea that children display and learn to handle envy, jealousy, and other difficult feelings through the use of play. Thereby, play becomes both a diagnostic and therapeutic method. Similarly, play has been advocated as an important method for learning. In both cases, diagnostic/therapeutic or instructional goals are set as the privileged or superordinate goals of play activities. Play is thus situated within a set of implicit value dichotomies that form a hierarchy, where play and exploration is generally cast as what is less valuable and that has to be upgraded through connections to what is serious:

Play	Work/school
Play	Game
Role play	Play with rules
Simplicity	Complexity
Nature	Culture
Exploration	Instruction

Play is thus not studied per se but subsumed under ulterior societal goals, such as diagnosis, therapy, or instruction. Moreover, such theorizing on play situates play in terms of a number of set more-or-less fixed dichotomies.

In contrast, exploratory models of play celebrate the inherent qualities of play. Play in itself is worthy of an

important role in child development as it is the child's natural or authentic mode of being. In fact, the human being should be seen as a playing creature, someone who has an inborn capacity and predisposition for play, what Huizinga has called *homo ludens*. Within Vygotskian theorizing and activity theory (e.g., Vygotsky, 1976, 1995), play has been theorized as a key mode of thinking in childhood. On a theoretical note, two of the most influential developmental theorists of the twentieth century, Jean Piaget and Lev Vygotsky, in fact discussed the role of exploration in learning, arguing that play forms an important aspect of learning.

Play, Semiotic Competence, and Mediation

Piaget (1945) claimed that cognition and learning always require adaptation. More specifically, adaptation necessarily involves both imitation (accommodation) and play and subjective thinking (assimilation). From the infant's first attempts at world making, learning and cognition draw both on imitation and other attempts to mimic others, and on assimilation, that is, play and subjective meaning. For instance, an infant may imitate words of its caregivers but endow them with idiosyncratic meaning. In their very first appropriations of words in their mother tongue, Swedish infants may, for instance, employ *pappa* (daddy) for *lampa* (lamp) as the two Swedish words are phonologically fairly similar, and both phenomena tend to be objects of interest within the young child's world making.

In much of his early work in the 1920s–1940s, Jean Piaget had a phenomenological focus, manifested in a series of ethnographic studies of children as philosophers. This phenomenological period involved extensive theorizing on play, on the basis of observations of his own children's (infants/toddlers) actions in nursery-room contexts (Piaget, 1945). He claimed that cognition involves a constant balancing (equilibration) between the known and the unknown. The child therefore repeats, experiments with, and recombines what is not yet quite mastered. The learning of a first language is a clear example of the ways in which children learn, not through explicit instruction, but through observations, exploration, and experimenting, which can, for instance, be seen in children's hyper-corrections and other self-corrections (for a review of contemporary work, see Rogoff *et al.*, 2003). Within

Piagetian theorizing, such exploratory work will characterize all the semiotic modes of young children: language, art, imitation (including pantomime), and role play as well as construction games (Piaget, 1945). A basic notion is that play is a form of intelligence that is parallel to and equivalent to language, imitation, and art in the child's early development. However, fantasy play or role play is primarily an aspect of the young child's early learning.

In contrast, Vygotsky (1976, 1995) locates both play and game activities at the heart of his theorizing on children's activities and development. In fact, he sees play (including games) as something that defines much of the child's imagination and combinatorial thinking. In contrast to Piaget, who did not discuss the role of fantasy play in later learning or modernists like Herbert Read (who discussed children's art work as something that is arrested through schools and schooling), Vygotsky (1995) claimed that the child's imagination continues to develop all though the school years. This is partly an effect of the fact that mediation is always an important aspect of learning. A given mode of mediation, for example, creative writing, may involve difficulties that the child does not encounter in verbal story telling (Vygotsky, 1995). The medium as such (e.g., speaking/writing/in contemporary society also new media) involves specific difficulties and challenges. In Vygotskian theorizing, one of the important roles of teachers and other masters is to build on children's play activities by introducing topics that appeal to their imagination, and by choosing types of mediation (drama, play, writing, art work, and new media activities) that appeal to children in relation to their stage of thinking and in relation to a specific area of learning. Today, it can be seen that children spontaneously engage in quite complex cognitive activities when engaging in, for instance, digital activities on the Internet. Play as such is one type of mediation, what Vygotsky would call an intellectual tool in children's development. This also means that play can be an intellectual resource all through life.

Piaget, Vygotsky, and Peer Learning

Drawing on his work on children's thinking around games of rule, Piaget (1932) presented a model of informal learning and social order, claiming that school-age children develop much of their moral thinking from social exchange with peers, and in particular from intellectual disputes with peers about games with rules (e.g., marbles). Peer relations are more symmetrical than adult-child dialogs, and children may therefore engage more wholeheartedly in critical disputes with peers, challenging the others' thinking. In contrast to their conflicts with adults, children who argue with peers thus tend to engage in more extended and more elaborate arguments. Thereby, they develop their perspective talking skills in ways that

they do not do with adult authorities. However, even though Piaget emphasized the role of peers for critical thinking, he did not document sibling or peer-play dialogs, whereas he did document adult-child-play interactions (Piaget, 1945), and adult-child dialogs on games with rules (Piaget, 1932).

In contrast, Vygotsky (1976) meant that all human behavior, including social life, includes rules. Therefore, it is not meaningful to see role play as an activity that has to be less complex than game activities and construction play. In Russian, there is but one word, *igra*, for both play and games. However, Vygotsky (1976) explicitly challenged a major divide between role play and play with rules, as well as any major divide between exploration and instruction. Instruction does not arrest imagination and free exploration. In fact, imagination increases as children appropriate more knowledge of the world (Vygotsky, 1995).

He theorized on the role of apprenticeship in children's learning, and on informal master-apprentice relations that form zones of proximal development, where children may surpass themselves, moving into a higher stage of mental processes, if assisted by a master. He claimed that, when playing, children would rise above themselves. "In play, a child is always above his average age, above his daily behaviour; in play it as though he were a head taller than himself" (Vygotsky, 1976: 552). Play thus constitutes a potential zone of proximal development, where children may assist each other in exploring the world. Moreover, play is about recollections or memory in action which means that children collaboratively advance their imaginative faculties, as they gradually appropriate more knowledge. This, of course, also means that collaborative play may profit from the accumulated prior experiences of all co-present peers.

Whereas Piaget foregrounded the developmental role of games with rules and peer disputes, Vygotsky emphasized the role of all kinds of play. Thereby, he also indirectly laid the ground for a focus on peers in children's development. Along with Piaget's analyses of peer disputes, his foregrounding of mediation, including both play and games, has prepared the ground for a novel focus on peer dialogs in children's learning. In contemporary language, socialization studies, and sociocultural theorizing, play and play communities have become central foci, and there is today a growing awareness of the role of peers for children's learning (Goodwin, 2006; Whalen, 1995).

Play and Intent Participation

Recently, Rogof *et al.* (2003) have reviewed various ways in which children acquire new knowledge without formal instruction but through keen observations and listening-in, what they have called intent participation. Such

informal apprenticeship would often take place in various horizontal types of collaboration, for example, between siblings or peers or with adults when children are allowed to watch and listen-in. In contrast to the lesson-style conversational practices that often characterize middle-class adults and their ways of socializing children, for example, at dinner time or in school contexts, such informal practices may thus involve keen observations, mimicking, and exploration, rather than instruction. These practices may involve various aspects of children's appropriations of cultural know-how: acquiring a first language, learning other tasks, and the appropriation of local norms for what is an accepted community member.

Play as Participation and Play Communities

Recently, a substantial body of work has been devoted to participation and its role in informal apprenticeships, and more specifically, to the ways in which people become fully competent members of communities of practice (Lave and Wenger, 1991). It is argued that apprenticeship is often linked to membership in communities of practice, where members advance from onlookers and peripheral participants to fully accepted members (Lave and Wenger, 1991). Lave and Wenger primarily discussed adult communities, such as alcoholics anonymous, where participants gradually move from peripheral to full participation. In the field of play, such emergent participation may, for instance, involve informal play communities, related to hip-hop culture, pogo-game activities (Sparrman and Aronsson, 2003), computer gaming, graffiti, skateboarding, or hopscotch (Goodwin, 2006), that is, various play and game activities, where children and youth in informal groups learn from each other within informal communities of practice.

Vygotsky (1995) described children's play products as crystallized imagination. In line with Vygotskian theorizing, recent research shows that such imagination is not located in a social vacuum. Imagination emerges within a given social order, and it is socially ordered. The value that is placed on, for instance, play materials tends to be strictly regulated within local communities of practice, where peers play together and in various ways assess each others' play performances and play materials. Children who, for instance, play with pogs (Sparrman and Aronsson, 2003) constantly assess each others' pogs and their trade values in ways that establish local hierarchies of what Bourdieu would call symbolic capital.

At a first glance, children's play worlds may seem totally free and accessible. Yet, one of the first matters to be learnt by young children is when and how to get access to play – to playmates, to peers' sustained attention, and to play materials. In his documentations of young toddlers'

play practices, Corsaro (1979) documented ways in which children acquired various access rituals for gaining the attention of desirable playmates. Such access rituals were apparently learnt through prior successful and unsuccessful attempts at achieving joint attention in play. What could be seen was that even very young preschoolers engaged in quite complex perspective taking when trying to secure access to ongoing play activities. In her work on mixed-age peers, Whalen (1995) has similarly documented that quite young preschoolers engage in complex tactics, calibrating their play directives in relation to peers' prior utterances, and that they delicately avoid alliances that might upset co-participants (and eventually lead to the arrest of play). It could be argued that children recurrently form what could be called play communities, where it is important for participants to be able to take part in local teasing, joking, and other play practices. Obviously, such communities are closely tied to participation, and to local rules for inclusion or exclusion in play activities.

On the basis of a broad review of prior work on play in different cultures and in contemporary society as well as in historical settings, Schwartzman (1978) has demonstrated that play negotiations take up a great proportion of children's playtime throughout much of children's play lives, and she therefore advocated an increasing attention to issues concerning access to play. The negotiations may concern who gets access to material resources as well as who gets to play what role or in what ways or with whom. Play negotiations – or what we could call play politics – thus concern both physical and virtual play resources. Play politics of course also concerns who gets to play, and even more importantly, who does not get to play (Garvey, 1993). In his work on preschoolers' play improvisations, Sawyer (1997) observed that young children spent more time than older ones on planning, negotiations, and other types of meta-communication about play. Moreover, he found that friendship had an effect that was similar to age and experience in that friends would go more seamlessly into play; needing less time for planning and coordination.

Threat-Tell, Teasing, Format Tyings, and Play Politics

As shown, jokes and other playful performances are often important discursive resources for securing participation in local play communities. Teasing, threats, and play politics have been documented in great detail by Marjorie Goodwin, who has conducted video ethnographies of children's play practices in school yards and neighborhood areas (e.g., Goodwin, 2006). She has analyzed the ways in which children spend much time, negotiating with each other about inclusion and exclusion and play rules,

as well as about material resources. Moreover, she has moved beyond gender stereotypes, showing that both boys and girls engage in insults, gossip, teasing, and other play practices that, at times, border on what is aggressive or violent. In fact, verbal insults, at times, take the form of what she has called highly complex format tying practices, that is, whole or partial repeats of prior utterances, where the participants build upon each others' contributions. Through creative repetitions of the prior speaker's insults, a child may thus build on peers' repertoires of invectives and insults, building new and more elaborate versions.

Such conversational work can already be seen in the play of preschoolers. Traditionally, Piagetian and other theories on play have generally positioned games and rule play as more complex forms of play than role play or so-called imaginative play. However, contemporary research, involving videorecordings of children's play worlds, has revealed a different picture. One of the pioneers within psychology is Garvey (1993). Like Goodwin, she has shown that recyclings, or what she called alternatives, were highly productive tactics in conflict talk among preschoolers' play practices. She also reported on ways in which role play may be quite complex, requiring substantial account work, that is, social explanations or reason giving, and other types of mitigations on the part of the participants. On the basis of analyses of the conversational work of preschool and school children's play dyads, Aronsson and Thorell (1999) have reported similar findings, showing in detail ways in which preschool children engage in quite elaborate perspective taking in order to solve play-conflict scenarios (about who is to use the only available play equipment, in this case a bike).

In their work on children's joking events and second-language learning in a Swedish first-grade-immersion-classroom setting, Čekaite and Aronsson (2004) have documented how refugee and immigrant children recurrently engaged in meta-pragmatic play, that is, play that comments on ways of saying things in that the participants joked about or enacted stylized performances of the ways in which something would be said by other role players, for instance, teachers. During informal work in the classroom, peers thus made funny role enactments or teasing each other for community members' mutual enjoyment.

Recently, work on teasing practices have also shown ways in which older school-age children create complex tactics, where they build upon prior insults in subtle ways, turning the weapons of their attackers against them as it were (Tholander and Aronsson, 2002).

Learning What?

What do children learn in their play dialogs? Apparently, much of a first language (or a second language in

immersion contexts) is learnt through playful repetitions, and increasingly more complex variations. Such informal learning involves all types of semiotic mediation, and both, what is said and how, that is, matters of style and so-called pragmatic awareness. Children are neither formally instructed in their first language, nor in how it should be used in terms of everyday diplomacy or politics, for instance, when and how to deploy mitigations and other politeness strategies. Yet, they obviously acquire quite broad repertoires of styles that can be deployed to upgrade or downgrade the intensity (and offensiveness) of potentially sensitive messages. Play dialogs are important sites for displaying and learning such strategies. If we do not assume that there is substantial learning through intent participation, it is difficult to explain the skills with which even preschool-age children eventually engage in intricate play dialogs, adopting the perspective of others, and predicting the ways in which conversational strategies may upgrade or downgrade potential challenges to the hearer. Role play is thus often as complex as play with rules in that children have to take into account both their co-participants' past moves, and their projected uptake. Simultaneously, all this has to be calibrated to local rules of comportment, local diplomatic protocols for what may be said in what way. Yet, this largely takes place without any explicit instruction. It means that play theories should by now move away from any rigid dichotomies between role play, on the one hand, and play with rules, on the other. Vygotsky (1976) similarly claimed that there is no major divide between work and play. In children's lives, play is serious business. Contemporary studies show that play dialogs involve important relational work in that children display and acquire conversational tactics for handling conflicts. This can also be seen both in children's extended play-access rituals, and in their sustained engagement in play activities.

Glossary

Cognitive apprenticeship – A method of teaching school subjects that embodies many of the practices of apprenticeship training, such as modeling, coaching, and careful observation of the learner's practice.

Community of practice – A group of people participating together to carry out different activities, such as garage bands, ham-radio operators, recovering alcoholics, and research scientists.

Goal-based scenario – Educational settings where learners are given real-world tasks and the support they need to carry out such tasks; they can be set either in computer-based environments or naturalistic environments.

Legitimate peripheral participation – Describes the relationship of apprenticeship learners who have access to the practices that they are expected to learn and to genuine participation in the activities and concerns of the group.

Situative – A perspective on cognition, learning, and education that analyzes processes of interaction, in which individuals participate, along with other material and informational systems.

Many practices of conventional schooling consider knowledge and skill as discrete structures of cognition that can be adequately transferred from teachers to students in classrooms and studied in laboratories. Knowing and thinking, in this view, are assumed to go on in individual minds isolated from the complexity of the world outside, from which abstract knowledge can be successfully distilled. However, a growing body of research that considers cognition and learning in activities outside of specialized learning environments is undermining the plausibility of these presuppositions (e.g., Brown *et al.*, 1989; Engeström, 2001; Greeno *et al.*, 1996; Hutchins, 1995a; Lave and Wenger, 1991; Nersessian *et al.*, 2003; Rogoff, 1990; Rogoff and Lave, 1984). This research supports the view that knowing and learning by individuals are inextricably situated in the physical and social contexts of their acquisition and use. It is a mistake to think that classrooms or laboratory experiments produce knowledge or follow principles of learning

that are somehow context free. Cognition and learning by individuals always occur in a context; the issue has to be what the context is, not whether there is one.

For most of the last half-century, active research programs have been studying structures and processes of social interaction, as well as cognitive processes of representing and transforming information. However, these research programs have been largely separate from each other. Situative research and theorizing attempts to unify the two perspectives of individual cognitive theory and the analysis of interactional structures and processes. The primary level of a situative analysis is an activity system, in which one or more individuals participate along with material and informational resources in the environment. Cognitive processes are understood as aspects of the practices of a community or group. Studies include analyses of perceiving (Goodwin, 1996), remembering (Hutchins, 1995b), reasoning and understanding (Greeno and van de Sande, 2007; Ochs *et al.*, 1996), and learning (Bowers *et al.*, 1999; Engeström, 2001; Engle, 2006; Stenning *et al.*, 2002). In these analyses, successful cognitive performances are considered as part of an interactive system, and analyses focus on how the multiple participants coordinate their contributions. Information structures, which the individual cognitive perspective attributes to individual minds, are attributed in the situative perspective to the interacting group as achievements of communication that enter the group's common ground (cf. Clark, 1996). Such analyses do not preclude also having analyses of the same events that focus on one or more individual participants, identifying their respective contributions to the interactions, and explaining these in terms of their individual capabilities, and with other participants and systems considered as the context (cf. Bowers *et al.*, 1999; Hatano and Inagaki, 2003).

If knowing is understood as successful situated participation, then many conventional assumptions must be questioned. In particular, a situative theory of knowing challenges the widely held belief that abstraction of knowledge from situations is the key to transferability. An examination of the role of situations in structuring knowledge suggests that abstraction and explication provide an inherently impoverished and often misleading view of knowing. Knowing by an individual is fundamentally a capability of the person to interact in the world. In this view, hypotheses or assessments of an individual's or

group's knowing are about their capabilities for interacting in situations. Hypotheses that represent knowledge only as abstract propositions do not capture the densely interwoven nature of knowing.

The situative perspective views knowing as distributed among people and their environments, including the objects, artifacts, tools, books, and the communities of which they are a part. Analyses of activity focus on processes of interaction of individuals with other people and with physical and technological systems. Several research traditions have contributed to the situative perspective. The best established of these is ethnography, including the study of cultural practices and patterns of social interactions, as well as discourse analysis and conversation analysis in activity theory, sociolinguistics, anthropology, and sociology. Another research tradition is ecological psychology, which studies behavior as physical interaction in which animals, including people, participate in physical and technological systems. A third research tradition is situation theory in logic and philosophy, which analyzes meaning and action as relational systems and is developing a reformulation of logic to support these relational analyses. Knowing in this perspective is both an attribute of groups that carry out cooperative activities and an attribute of individuals who participate in the groups. Learning by a group or individual involves becoming attuned to constraints and affordances of the material and social systems with which they interact. Discussions of motivation in this perspective often emphasize engagement of individuals with the functions and goals of the community, including interpersonal commitments and ways in which individuals' identities are enhanced or diminished by their participation.

Apprenticeship and Identity

When knowing is viewed as practices of communities and of the abilities of individuals to participate in those practices, then learning is the strengthening of those practices and participatory abilities. Systems in which individuals learn to participate in social practices are very common, and include apprenticeship and other forms of being initiated into the practices of a group. Lave and Wenger (1991) reviewed several studies of learning by newcomers to communities of practice and concluded that a crucial factor in the success of such a system is that learners must be afforded legitimate peripheral participation, which involves access to the practices that they are expected to learn and genuine participation in the activities and concerns of the group. Lave and Wenger characterized learning of practices as processes of participation in which beginners are relatively peripheral in the activities of a community, and as they become more experienced and

adept, they progress toward fuller participation. A crucial issue in the nature of learning is whether, and in what ways, the peripheral participation of beginners is legitimate. They described four cases of learning by newcomers and emphasized how learners' identities derive from being part of the community as they become more fully participating members in the community. They also noted that an apprenticeship relationship can be unproductive for learning, as in a case of meat cutters they cited, where the apprentices worked in a separate room and were isolated from the working community. For an environment of apprenticeship to be a productive environment of learning, learners need to have opportunities to observe and practice activities in order to progress toward fuller participation.

The degree to which people participate fully and are respected by other members of a community determines their sense of identity (Lave and Wenger, 1991; Wenger, 1998). The fully participative roles are those that most directly contribute to the collective activities and knowledge of the community. The motivation to participate more fully in a community of practice can provide a powerful incentive for learning. Smith (1988) argued that children learn to read and write if the people they admire read and write. That is, they will want to join the literacy club and will work hard to become members. Learning to read is part of becoming the kind of person they want to become. Identity is central to deep learning.

An important aspect of learners' identities is the way in which they are positioned in the participant structures (Phillips, 1972) of learning activities. An important distinction by Pickering (1995) involves different kinds of agency, called conceptual and disciplinary. Students who are positioned with a disciplinary agency only participate as receivers and reproducers of the established meanings and procedures of the discipline, and their learning is evaluated only by whether they can perform procedures and explanations correctly. Students who are positioned with conceptual agency are expected to question and adapt concepts and methods of the discipline. For example, they might construct understandings that utilize disciplinary concepts in novel ways or consider alternatives to standard definitions of concepts. As an example, research by Boaler (2002) compared learning of mathematics in two English secondary schools and found that students who learned primarily through investigations understood mathematics as a general resource for understanding and problem solving, whereas students whose learning was primarily mastery of set procedures understood mathematics as a set of rules to be followed.

Wenger (1998) argued that people participate in a variety of communities – at home, at work, at school, and in hobbies. In his view a community of practice is a group of people participating together to carry out different

activities, such as garage bands, ham-radio operators, recovering alcoholics, and research scientists.

For individuals, it means that learning is an issue of engaging in and contributing to the practices of their communities. For communities, it means that learning is an issue of refining their practice and ensuring new generations of members. For organizations, it means that learning is an issue of sustaining the interconnected communities of practice through which an organization knows what it knows and thus becomes effective and valuable as an organization (Wenger, 1998: 7, 8).

The view that learning occurs through participation is at the root of the practices of apprenticeship, where apprentices are guided and supervised by masters. In successful apprenticeship learning, masters teach by showing apprentices how to do a task (modeling), and then helping them as they try to do it on their own (coaching and fading). Lave and Wenger (1991) emphasized how an apprentice's identity derives from becoming part of the community of practitioners. The motive for becoming a fuller participant in a community of practice can provide a powerful motivation for learning. Of course, what is learned in apprenticeship may not generalize easily to other contexts. Collins *et al.* (1989) attempted to characterize how the modeling, coaching, and fading paradigm of apprenticeship might be applied to learning the cognitive subjects of school in an approach they called cognitive apprenticeship.

Educational Applications of the Situated View

A major goal of educational reform is to have students participate more actively and legitimately in learning communities, including participation in formulating and evaluating questions and problems, and constructing and evaluating hypotheses, evidence, arguments, and conclusions (Brown and Campione, 1996). Abilities for participating in these activities have to be learned, and the research literature on that kind of learning is sparse. Several projects have been focused on creating classroom practices of discussion and inquiry, and the investigators in those projects have discussed some aspects of the process of establishing norms and expectations by the students that support productive collaborative learning (Cohen, 1986; Lampert, 1990; Slavin, 1983).

In the view of learning as coming to participate more fully in a community of practice, transfer is often thought to be a problematic issue (e.g., Anderson *et al.*, 1996). Viewed in the situated perspective, transfer can occur when learning leads to better performance or learning of new practices within a community (e.g., for school communities this might mean working on new problems

or accomplishing new kinds of tasks) or outside the community (e.g., for school these might be work environments such as those studied by Beach (1995) and Saxe (1990)). Many of the resources and supports that occur within a community of practice do not carry over to a different community, and so the problem of transfer becomes one of marshalling the resources needed to be successful in a new environment. This requires sophisticated social and information-processing skills, which are the kinds of skills that businesses think they will need in the future.

In a view of transfer in the situative perspective proposed by Greeno *et al.* (1993), transfer depends on constraints and/or affordances that are invariant under the transformations that change the learning situation into the transfer situation. For transfer to occur, learners must become attuned to those invariants in their initial learning. One of the ways to be attuned is to have an abstract representation that can be applied in the new situation, but this is only one possible way for attunement to occur, and may not be the typical way to generalize many learned activities (Greeno, 1997).

Although the situative view insists that all cognition and learning are situated, learning designers who take a situative perspective generally attend to the activity settings in which learning is to occur. For example, in goal-based scenarios (Schank *et al.*, 1994, Nowakowski *et al.*, 1994) learners are given real-world tasks and the scaffolding they need to carry out such tasks. They can be set either in computer-based environments or naturalistic environments. In one computerized goal-based scenario, learners are asked to advise married couples as to whether their children are likely to have sickle-cell anemia, a genetically linked disease. In order to advise the couples, learners must use the facilities in the system to find out how different genetic combinations lead to the disease and run tests to determine the parents' genetic makeup. There are scaffolds in the system to support the learners, such as various recorded experts who offer advice. Other goal-based scenarios support learners in a wide variety of challenging tasks, such as putting together a news broadcast, solving an environmental problem, or developing a computer-reservation system. Goal-based scenarios make it possible to embed cognitive skills and knowledge in the kinds of contexts where they are to be used. Therefore, people learn not only the basic competencies they will need, but also when and how to apply these competencies.

Video and computer technology has enhanced the ability to create simulation environments where students are learning skills in context. A novel use of video technology is the Jasper series developed by the Cognition and Technology Group (1997) at Vanderbilt University to teach middle-school mathematics. In a series of 15–20-min videos, students are put into various problem-solving contexts: for example, deciding on a business plan for a school fair or a rescue plan for a wounded eagle. The problems are

quite difficult to solve and reflect the complex problem solving and planning that occurs in real life. Middle-school students work in groups for several days to solve each problem. Solving the problems develops a much richer understanding of the underlying mathematical concepts than the traditional school-mathematics problems.

Another novel use of technology is the curriculum developed by the middle-school mathematics through applications project (MMAP) at the Institute for Research on Learning (Goldman and Moschkowich, 1995; Greeno *et al.*, 1999). The leading activities in the MMAP curriculum are design problems, supported by software that provide computer-aided design environments in which students design floor plans of buildings, models of population growth and decline, lexicographic codes, or geographical analyses of environmental quality. Mathematical reasoning and problem solving involving topics such as proportional reasoning, linear and exponential functions, and geometrical properties of geographical space are required for successful progress in the design activities. Printed curriculum materials are provided to support teachers in organizing activities for students to encounter, recognize, and learn important mathematical concepts and methods.

These kinds of learning tasks are different from most school tasks, because the contexts of most school tasks lack characteristics of practices that occur outside of school. Imagine learning tennis by being told the rules and practicing the forehand, backhand, and serve without ever playing or seeing a tennis match. If tennis were taught that way, it would be hard to see the point of what you were learning. But in school, students are taught algebra and Shakespeare without being given any idea of how they might be useful in their lives. That is not how a coach would teach you to play tennis. A coach might first show you how to grip and swing the racket, but very soon you would be hitting the ball and playing games. A good coach would have you go back and forth between playing games and working on particular skills – combining global learning with focused local knowledge. The essential idea in the situative view of learning is to consider learning and cognition as participation in an activity system. This view supports designers' and educators' efforts to tightly couple a focus on accomplishing authentic tasks with a focus on the underlying competencies needed to carry out the tasks.

Glossary

Cognition – A collection of largely integrated mental operations that include thinking, perceiving, remembering, and learning.

Cognitive neuroscience – The interdisciplinary field of study that aims to describe and explain cognitive behavior in terms of neural mechanisms and structures.

Development – The outcomes of the interplay between the accumulation of experiences and time-related biological processes that affect behavior and physiology throughout the life span of individuals.

Dopamine – A substance that is manufactured in the cells of the substantia nigra and that travels in pathways connected to the frontal cortex. Reductions in dopamine level have detrimental consequences for cognitive and psychomotor functions.

Epigenesis – The premise that development throughout life is shaped by an in-common genetic plan that gradually unfolds with age. This genetically programmed unfolding of development occurs in a particular cultural or environmental context and that context can modify the outcome of the genetic program.

Executive control processes – The cognitive processes that are controlled by the individual and that serve to coordinate and regulate multiple tasks and actions.

Functional magnetic resonance imaging (fMRI) – A noninvasive technique for assessing brain function. fMRI uses the magnetic qualities of water molecules to evaluate the changing distribution of oxygenated to deoxygenated blood, an indirect measure of neuronal activity.

Neural plasticity – The extent to which change and effective adaptation is possible within the individual.

Neurogenesis – The production of new neurons originating from stem cells and progenitor cells.

Introduction

As the average age of the population in developed nations continues to increase, in large part due to increased

longevity, there is growing interest in trying to understand the cognitive and neurobiological changes that accompany aging. As individuals are living longer, it is important to explicate the potentials as well as the limits of cognitive functioning in older individuals. One general observation is that there are large interindividual differences in the amount and kinds of cognitive deficits that can be observed. That is, some individuals show only minor deficits in particular forms of remembering as they grow older, and continue to function effectively in everyday life. But some individuals show substantial declines in cognitive functioning, not associated with dementia or disease. Inevitable age-related changes in neurobiological processes contribute directly to the effectiveness of cognitive functions. Certainly some portion of interindividual differences in cognitive effectiveness corresponds directly to within-person changes in particular brain structures and neurobiological processes. Scientific knowledge about the specific relations between brain aging and cognitive aging has increased tremendously in recent years, in part due to advances in noninvasive techniques for assessing cognition–brain relations, such as structural and functional magnetic resonance imaging (fMRI) and positron emission tomography (PET). Recent advances in neuroimaging allow identification of the brain regions associated with age-related changes in selected cognitive functions. Improved technologies of neuroimaging, such as diffusion tensor imaging (DTI), reveal relatively detailed descriptions of the relations between neural activity and cognitive function. For example, DTI studies show that the greatest amount of age-related alterations in white matter occur in the prefrontal cortex and the anterior corpus callosum. The kinds of cognitive tasks that show the largest age-related deficits depend on exactly these brain regions.

It is important to point out that the aging of brain–cognition relations is a consequence of the interplay between multiple etiologies and moderators that involve not only neural mechanisms and structural changes in the brain, but also the influences of genetic factors, environmental factors, and health and lifestyle experiences of the individual. We begin this article with a brief summary of brain aging. Then we briefly discuss current knowledge about age-related changes in cognition in healthy adults. Next, we discuss the relations between cognitive aging and brain aging and recent advances in the understanding of age-related changes in brain–cognition relations.

Brain Aging

Brain aging reflects the interplay of a variety of mechanisms. Time-related processes, individually and interactively, alter neuroanatomical structures and the biochemistry of neural functions. Structurally, MRI data using voxel-based morphometry show age-related shrinkage in the volume of the ventricles of the brain, and show that the degree of shrinkage varies somewhat for different brain regions. The ventricles are interconnected cavities within the brain that contain cerebrospinal fluid. As the ventricular cavities are interconnected, changes in the ventricular system can be considered to be a fair index of the general health of the brain. As the brain shrinks in size with aging, the ventricles expand to take up more space.

Epigenesis refers to the premise that development throughout life is shaped by a genetic plan. Age-related changes in brain structures unfold to a large extent according to an epigenetic plan at the level of cell physiology. However, the rate of genetically-programmed aging depends on a host of within-brain factors and external factors. Neural integrity and neural functions are impaired by the accumulation of beta amyloid and by inflammations within the environment of neurons. Within-brain environmental factors affect the vitality of neurons and their physiology. For example, either acute or chronic exposure to toxins can accelerate inflammation in the central nervous system and the pace of epigenesis (Campbell, 2004).

Neurogenesis refers to the production of new neurons originating from stem cells and progenitor cells. Stem cells are unprogrammed cells that divide and can change into cells with specialized functions. A host of factors (including individually controlled actions such as exercising and maintaining a healthy diet) can stimulate or deter neurogenesis. The hippocampus, a brain region that is centrally involved in associative learning and memory, is known to produce new neurons throughout life (e.g., Abrous *et al.*, 2005; Kemperman, 2006). A steady production of new neurons supports effective hippocampal function, whereas deterred neurogenesis eventually results in serious memory loss. There is some evidence to suggest that cognitive status is associated with increased neurogenesis and the strengthening of particular pathways in the hippocampus in line with functional demands (Hertzog *et al.*, 2009).

Intraindividual changes in cognition depend on the interplay between neural mechanisms and brain structures, genetic influences, and environmental influences. For example, recent findings show that the catechol-O-methyltransferase (COMT) genotype affects age-related variability in decision time in younger and older adults (Li *et al.*, 2008). The COMT gene affects the degradation of dopamine in the prefrontal cortex. Dopamine is manufactured in the cells of the substantia nigra and travels in the pathways connected to the frontal cortex.

Dopaminergic systems normally decline with aging across various brain regions. Age-related reductions in dopamine are known to have detrimental consequences for cognitive and psychomotor functions including the planning and execution of actions (Bäckman *et al.*, 2006). Compared to older individuals with a genetic predisposition for efficient dopamine signaling in the prefrontal cortex, older individuals with a genetic predisposition for less-efficient dopamine signaling in the prefrontal cortex show greater variability in performance and an overall lower rate of information processing when carrying out a simple two-choice perceptual-decision task (Li *et al.*, 2008).

A relation between the cholesterol ester transfer protein (CEPT) genotype and cognitive function has also been demonstrated (Barzilai *et al.*, 2006). A variant of the CEPT genotype is associated with preserved cognitive function in very old adults. This variant is associated with lower CEPT levels and a favorable lipoprotein profile. These and other findings of associations between particular genetic variants and polymorphisms and differences in relative efficiency of neuromodulation and cognitive function point to the necessity of a multicausal view in building a comprehensive understanding of developmental changes in brain–cognition relations.

Cognitive Declines in Healthy Aging

One way to examine the degree to which aging affects memory and other cognitive functions is to ask individuals to report the frequency of their memory failures in everyday situations. Older adults' self-reports about memory losses are fairly accurate, but it is also true that older adults tend to exaggerate and worry about their memory failures more so than younger individuals. Discrepancies between self-reports and actual memory performance may have to do with mistaken ideas about the functions and organization of human memory. Human memory is more than a filing cabinet for storing precise recollections of events and experiences and their circumstances. In this article, we approach the topic of memory and learning from the perspective that there are multiple forms of memory. This view is useful for the purposes of understanding cognitive declines with aging, since not all forms of memory show decline to the same extent as individuals grow older, and there are interindividual differences in the extent to which different forms of memory decline. Further, recent findings in cognitive science suggest that different forms of memory recruit and depend on somewhat different neural mechanisms.

Short-Term Memory and Long-Term Memory

More than 100 years ago, in 1890, the psychologist and philosopher William James suggested a distinction

between the conscious awareness of immediate events (primary memory) and the retrieval of events that had left consciousness (secondary memory). Modern findings substantiate James's early speculations about the differences between primary or short-term memory and secondary or long-term memory. Developmental studies show that span of short-term memory is only slightly affected by aging, whereas there are large age-related deficits in the amount and accuracy of retrieval of details about events and experiences that have been out of consciousness (even for just a few minutes).

Cognitive neuroscience research has shown that the extent to which there are age-related declines in long-term memory depends on the brain regions that are recruited for retrieval and the kind of information that is being retrieved. That is, age-related deficits in long-term memory are larger in tasks that require individuals to literally declare and consciously retrieve past events. Only minor age deficits are usually observed when memory for past experience is assessed indirectly or by non-declarative measures.

One way to study nondeclarative memory is to assess performance on priming tasks. In a priming task, individuals are instructed to identify or make judgments about stimuli that were (or were not) presented previously. Priming is demonstrated if previous exposure to items improves performance. Consider the following example of a two-phase priming experiment. In phase 1, participants study a list of words such as motel. In phase 2, the participants are presented with three-letter stems for the words that were on the study list (e.g., mot–) and for properly matched words that did not appear at study, and participants are instructed to complete the word stems with the letters that first occur that spell a word. Priming or nondeclarative memory is demonstrated if more stems are completed correctly for items presented in phase than for nonstudied items, and usually there are only minor age-related differences in such tasks.

The extent to which there are age-related differences in long-term memory tasks also depends on whether or not conscious recollection is required for retrieval (i.e., explicit memory). In an explicit memory task, an individual is instructed to deliberately recollect particular events. Typical measures of memory, such as recognition, recall, and cued recall, assess explicit memory. For example, in a cued-recall task, in contrast to a priming task, participants might be shown a list of words in phase 1, and then in phase 2 asked to complete three-letter word stems with the words from the study list. Usually, there are large age-related differences in explicit memory, and small differences in tasks that do not require explicit recall of information (i.e., implicit memory). Recent findings also suggest that the age-performance differences on implicit and explicit memory tasks are due to the recruitment of different brain regions.

Episodic and Semantic Memory

The extent to which there are age-related differences in long-term memory tasks also depends on whether the task taps episodic memory or semantic memory. Tasks that require episodic memory require conscious recollection of specific details of previous events. In contrast, semantic memory refers to retrieval of general information or acquired knowledge without the specific details about when and where the information was acquired. Semantic memories are not accompanied by the kinds of source details that mark episodic memories. Aging negatively affects episodic, but not semantic, memory.

Recollection and Familiarity

The extent to which there are age-related differences in long-term memory tasks also depends on whether the task at hand taps recollection or familiarity. Recollection refers to the retrieval of specific details about particular events or experiences and their contexts. In contrast, memories based on familiarity depend on nonspecific feelings of recognition or oldness about the event. When older adults do not recollect the specific details of an experience, they can instead rely on their familiarity with similar experiences. Age-related deficits are greater on tasks that require recollection than on tasks that allow familiarity.

Executive Functions and Working Memory

Substantial age-related declines are found on cognitive tasks that require individuals to manage or coordinate multiple tasks (i.e., executive function) and on tasks that require individuals to simultaneously process and store information in immediate memory (i.e., working memory). Executive functions refer to higher-order cognitive actions that are controlled by the individual and that serve the planning and regulation of complex tasks.

General Effects of Aging on Cognition

Behavioral and neurophysiological findings suggesting differential aging of specific types of memory must be tempered by data analyses that show that a large portion of the observed age changes in various types of cognition can be accounted for by general or core deficits. Across-the-board slowing in the speed of carrying out any mental operation seems to account for much of the decline in a wide variety of cognitive tasks. Moreover, age-related sensory deficits and age-related deficits in the ability to inhibit or suppress irrelevant information form core ingredients in many kinds of cognitive tasks, and contribute substantially to observed age differences. In addition, the effect sizes for the age difference on tests of episodic memory are consistently about one standard deviation

across a wide range of measures of episodic memory. Overall effect sizes are consistently somewhat smaller for episodic recognition.

Aging of Cognition–Brain Relations

The findings reported above derive from comparisons of different age groups (i.e., cross-sectional studies) or descriptions taken from groups of individuals followed across the adult years. Data from cross-sectional and longitudinal studies are consistent in showing age-related declines in long-term memory (declarative memory and associative memory), in the encoding and retrieval of events and experiences (i.e., episodic memory and recollection), in executive functions and the ability to simultaneously maintain and manipulate information in memory (i.e., working memory), and in the speed at which information can be processed and retrieved (see Hoyer and Verhaeghen, 2006). In recent meta-analyses, it is reported that the mean weighted-effect sizes are between -0.6 and -1.0 standard deviations in cross-sectional studies of episodic memory (using measures of recall), working memory, and processing speed (Old and Naveh-Benjamin, 2008; Verhaeghen and Salthouse, 1997). In contrast, the mean weighted-effect sizes for age-related differences in memory for emotional content, short-term memory span, nondeclarative memory (e.g., perceptual priming and implicit memory), and retrieval of semantic knowledge are much smaller or negligible.

The observed differences in the patterns of the effects of aging on measures of memory reflect the distinctive effects of aging on the status of the particular neural systems that serve particular behavioral and cognitive functions. The well-known findings of age-related deficits in episodic memory in contrast to smaller age-related decrements in nondeclarative forms of memory (e.g., repetition priming) are associated with age-related changes in the medial temporal area, encompassing the hippocampus and surrounding cortical regions (perirhinal, entorhinal, and para-hippocampal cortices). The extent to which the hippocampus supports the formation, organization, and retrieval of richly detailed memories and their distinctive contexts diminishes with aging.

In terms of age-related deficits in recollection, fMRI studies show different patterns of activation for recollection and familiarity across several brain regions. In the hippocampus, it was found that recollection was directly related to activation whereas familiarity was inversely related to activation. In the prefrontal cortex, it was found that recollection was related to an anterior medial region, and that familiarity was related to the anterior and dorsolateral prefrontal cortex. In the lateral parietal cortex, it was found that recollection was related to the temporal region, and that familiarity was related to a more superior region.

In the medial parietal region, it was found that recollection was related to the posterior cingulate, and that familiarity was related to the precuneus.

In terms of executive functions, neuroimaging data show reliable patterns of activation in three regions of the lateral frontal cortex in relation to cognitive activities that involve the executive functions of task coordination and the updating and maintenance of information in memory. Recent findings suggest that individual differences in executive cognitive function are largely determined by genetic factors (Friedman *et al.*, 2008). Of course, the person's prior experience with related tasks, and the person's abilities to initiate and deliberately deploy strategies that bring about effective learning and memory serve to reduce the magnitude of observed age-related deficits in executive tasks.

Neurocognitive Plasticity

Cognitive aging is dynamic and reflects adaptation and compensation in response to cognitive losses. Perhaps the most striking headlines in the cognitive neuroscience of aging are about discoveries of continued neural plasticity, continued functional reorganization and compensation, and continued neurogenesis throughout life in healthy adults. Neural plasticity is essential to effective adaptation to changes in internal and external conditions. The evidence suggestive of continued cortical reorganization and neurocognitive plasticity in healthy older adults does not contradict the evidence documenting the deleterious consequences of aging on neurobehavioral functions. Evidence suggestive of continued neural plasticity informs the extent to which there is potential for older adults to function effectively in society. An appreciation of the multicausality and multidimensionality of aging mechanisms is central to the understanding of boundaries of late-life cognitive adaptation.

Conclusions

The magnitude of the overall age-related deficit observed for episodic memory and related forms of learning, memory, and cognition is about one standard deviation. Individual differences in the extent to which deficits are observed in samples of older adults are due to a mix of factors, including ability status, genetically based differences in predisposition to neural inefficiencies and disease, and individual actions (exercise, diet, cognitive enrichments, and interventions) that can help to sustain effective cognitive functioning. In a long-term prospective study of cognitive change in a group of healthy octogenarians, for example, individuals who showed cognitive decline over a 13-year period had worse memory at

entry into the study and carried a particular genetic variant, the APOE4 allele (Howieson *et al.*, 2003).

Developmental changes and individual changes in neural plasticity represent a limit as well as potential. Neural plasticity undoubtedly decreases with advancing age in adulthood, but the extent to which there is continued neural plasticity indicates the potential of individuals to adapt to insidious losses associated with normal aging and to relatively abrupt insults associated with disease. The extent to which there is neural plasticity depends on actions of the individual that stimulate compensation or restoration of function and on cognitive interventions and educational programs that can promote plasticity.

Glossary

Genre or register – It refers to the constellation of lexical and grammatical features that characterize particular uses of language.

Lexicon or vocabulary – It is the body of words used in a particular language or in a particular sphere of activity.

Morphology – It is the way in which words are formed and related to each other. Morphology is therefore the subsystem of the smallest units of meaning in a language – words and parts of words.

Narrative – It is a sequence of language or words that describe a sequence of events.

Phonology – It refers to the sound system of a language which involves the rules for combining sounds.

Pragmatics – It refers to the rules of language use, and the way members of a community use language to accomplish their intentions and achieve their goals. It includes systems of commonly held conventions and constraints in interpersonal and institutional relations and purposes (e.g., indirect forms of expression in which the meaning is inferred rather than stated explicitly in polite conversation).

Semantics – It refers to the ways in which language conveys meaning.

Syntax – It is the system of phrases and clauses that are used to create sentences.

Word recognition – It refers to how phonological and visual–orthographic information is combined for the identification of individual words in a text.

Language plays an essential part in education. It is a prerequisite for most of the learning that takes place in schools. Language is also a set of complex cognitive and linguistic skills that schools foster. The role of language in learning has attracted educational researchers from various disciplines, such as linguistics, psychology, sociology, and anthropology. Moreover, across the disciplines, perspectives on the role of language in learning have been underpinned by a number of different theoretical contributions. In examining the role of language in education, this article asks the following questions:

1. How is language learned? In responding to this question, emphasis is placed on two major perspectives on language learning: the cognitive and the sociocultural perspectives.

2. What is the role of language in literacy acquisition? Most researchers agree that language and literacy are integrated systems, and that language is the primary system. But, more precisely, how does research based on the cognitive and the sociocultural perspectives relate language to literacy?
3. What is the role of language in subject-matter learning? Although most researchers agree on the importance of language for literacy learning, the role of language in subject-matter learning that is not reading is less obvious and much less examined. This article examines the impact of academic language on subject-matter learning.

Most children around the world learn more than one language. Several languages may be spoken at home and the child will learn to use them and switch between them, or the child will learn to use one language at home and perhaps another language (the majority language) in the community and school. Many children will also learn one or several foreign languages in school. The multilingual learning situation of most children is not addressed here. A large body of research has addressed the early phases of language learning, emphasizing continuities and discontinuities in the transition from being a child communicating through natural (rather than conventional) vocalizations that are interpreted by the child's caretakers, to the child that acquires and uses conventional vocabulary and syntactical structures, and follows pragmatic rules. This article addresses first-language learning from an age when language has been acquired in at least a rudimentary form.

How Is Language Learned?

Approaches to the study of language rest within a broader set of approaches related to human learning. Recent reviews of learning theories often distinguish between three broad views on learning: the behaviorist/empiricist view, the cognitive/rationalist view, and the situative/pragmatist–sociohistoric view (Greeno *et al.*, 1996). These are distinct traditions in educational theories and practices and are presented here as behavioral, cognitive, and sociocultural perspectives. The behaviorist perspective has played an important role in language research in the past; the cognitive and sociocultural perspectives are contemporary comprehensive accounts of language learning and they will be the focus of this article. There are significant variations within each of these last two broad perspectives in terms of their theoretical positions and the questions they have asked, as well as points of contact and overlapping issues between them.

Language learning theories vary and can be distinguished in the following ways:

1. Theories that concentrate on how the task of language learning is conceptualized, and by how they define what it means to know a language. Does it primarily have to do with developing the conceptual basis for language use, or being able to participate fluently in everyday linguistic practices?
2. Theories that relate to the nature/nurture dimension. How children acquire language has long been contended: on one side, Chomskian linguistic generative structuralists articulate a nativist position in which basic presuppositions are claims about the poverty of the stimulus. This means that however rich the input is, children can never extract the underlying structural rules of grammar from it. On the other side are psychologists who have a functional approach focused on social inputs and child strategies. Most theories of language development acknowledge both an inborn and a learning component, but differ in the emphasis they give to these elements.
3. Theories that pay attention to the individual versus the community or culture in which the child grows up.
4. Theories that look at different aspects of language. Language is a complex system with subsystems such as phonology, morphology, semantics, lexicons, and pragmatics. Are phonological skills that support children's word processing basic in language learning, or should the language researcher turn to how children learn to express their intentions in language, acquire meaning, and learn the pragmatics of language use in their speech communities?
5. Theories that examine how the relationship between language and literacy is conceptualized.

The Behaviorist Perspective on Language Learning

There are many different hypotheses concerning language acquisition that fall under the general heading of behaviorism. All these approaches share a common focus on the observable aspects of language behavior. Learning is seen as the formation, strengthening, and adjustment of associations between stimuli and responses. Behaviorist perspectives on language learning following from Skinner explain language through two major types of conditioning – classical and operant – and through imitation and shaping (Bohannon and Warren-Leubecker, 2001). Language learning takes place when stimuli in the environment become associated with internal responses, which then become associated with overt behavior through the application of classical and operant conditioning, imitation, and shaping. Operant conditioning is the learning principle that explains productive speech. Simply put, behavior that is rewarded tends to be repeated by the learner. Behaviorists assume that caregivers reward children when their speech, or parts of it, most closely approximate adult speech. Children's word combinations

are assumed to be acquired in much the same way as single words, through shaping, imitation training, and rewards. The hypothesis is that smaller units must be mastered as a prerequisite for more complex units. Therefore analysis of complex tasks into learning hierarchies has been used in designing instruction sequences.

The behaviorist perspective is on the very end of the nature/nurture continuum, emphasizing the role of experience in language learning. Behaviorists focus on how the small units of language are acquired, and how more complex learning outcomes build on these. The behaviorists' view has been criticized for relying too much on simple principles to explain language development. The idea that smaller behavioral units must be mastered as a prerequisite for more complex units has also been questioned. Moreover, caretakers have not been found to consistently provide rewards for grammatically correct utterances or punishment for incorrect ones. Rather, they respond to the content of the utterance. In spite of its significance in the history of language-learning research, behavioral views play a minor role in contemporary educational research, compared to cognitive and sociocultural perspectives which we now turn to.

The Cognitive Perspective on Language Learning

The process of language acquisition by children remains one of the critical issues for contemporary cognitive theory. Within the cognitive perspective, learning is considered as change in conceptual and cognitive structures. Various theoretical contributions – connectionism, constructivism, and the sociocognitive approach – have contributed to the cognitive perspective on language. In this article, the sociocognitive contribution is included in the group of cognitive studies because of its commitment to study individuals, even though sociocognitive research has incorporated sociocultural ideas of the mediated mind, and its conceptual contributions such as intention reading, perspective taking, and communicative collaboration have impacted sociocultural views on language learning. The three theoretical examples of the cognitive perspective in this article share assumptions regarding the importance of the individual as the processor of input from the environment. They differ in their views on the relative role of innate conditions versus environmental input in language learning, and in the relative emphasis on individual versus social and cultural dimensions in explaining learning.

Connectionism

Connectionism emphasizes constraints on the processing of information and the experience-driven reorganization of lower-level behavior into more complex patterns.

Connectionists argue against the need to postulate abstract rule systems to explain emerging regularities in language use (cf. Chomsky and the generative structuralists) and emphasize the role of experience or input. The question is how a system like the brain, given streams of input from the structured world, comes to discover that structure. For example, when children start to produce the past tense of verbs they initially get them correct (e.g., she went), and then they begin to make errors (e.g., she goed). This has been cited as evidence for the theory that linguistic development proceeds in stages that reflect the children's acquisition of rules (first learn the word, e.g., went, then acquire the rule about the past tense, and finally discover that rules have exceptions – the two-route way to verb learning). A connectionist simulation of children acquiring knowledge of the use of the past tense showed that they used a mixture of correct and erroneous past tenses in a way that was not stage-like (the one-route way to verb learning).

Constructivist approaches

The constructivist model emphasizes the child's ability to actively organize and construct knowledge. Piaget's influence on conceptual learning as the basis for language learning has been considerable. Piaget focused on the conceptual structures that children develop and which their language presupposes and builds on. Generally, the constructivist approach following from Piaget stresses that language is only one of many complex cognitive skills that children acquire.

Sociocognitive approaches

Although the cognitive perspective on learning has traditionally focused its attention on the individual's learning processes, such as the development of cognitive structures, and has regarded social interaction as only one factor influencing learning, more attention has been paid recently to the social context in which learning occurs. Tomasello (1999) and Nelson (1996) have contributed to these recent developments within the cognitive perspective.

Tomasello emphasizes on children's sociocognitive skills that enable them to participate with others in joint attention, and learn from others, to understand the communicative intentions of others, to take the perspective of others in interpreting and using language, and to collaborate communicatively. Children apply sociocognitive skills to acquire and use language – skills of joint attention, intention reading, perspective taking, and communicative collaboration. Tomasello presents a two-way relationship between children's social cognition and their language. Their sociocognitive skills support their language acquisition, but engaging in linguistic communication leads them to create new sociocognitive skills such as taking the perspective of the other. Cultures shape the development of children,

especially through the intentional instruction of others. According to Tomasello, grammar, regardless of its language, is a perspective-taking device, learned in part by the human capacity to see experience from someone else's perspective.

Similarly, Nelson's sociocognitive theory emphasizes the relationships between cognitive development and language. Language is not separable from cognitive development, and cognitive development cannot be detached from language. Nelson takes as a starting point that the primary cognitive task of the child is to make sense of his or her situated place in the world in order to participate in its activities. She argues that, for the child, knowledge of the object world is embedded within knowledge of the sociocultural world, with the basic task for the child being to predict activities. She introduced the idea of participatory interactions, referring to children taking part in activities without fully understanding them. Through participation they learn their parts and acquire knowledge about them. The meaning of words and language forms such as narrative is acquired through participation in social discourse and it requires extensive practice. When internal language representations come into play, thinking in language emerges.

The Sociocultural Perspective on Language Learning

Sociocultural views of language learning emphasize the social nature of learning (also known as situative, pragmatist, sociohistoric views, and as social constructivism and cultural psychology). This article foregrounds three contributions that are related: the Vygotskian tradition, sociolinguistic research with an emphasis on language socialization, and ethnographic studies of discursive practices in homes and schools. These three sociocultural branches represent a family of related frameworks. They share the approach that the unit for studying language is the socially situated individual. In this group of approaches, language learning is based on children's repeated participation in everyday activities with other more-competent participants. Through extended engagement in activities with others who are more knowledgeable or expert, children transform the specific means for realizing these activities into individual skills.

The Vygotskian tradition

According to Wertsch (1985), there are three major lines of thought in Vygotskian sociocultural theory. First, to understand a psychological phenomenon, such as language or literacy learning, it is necessary to understand the origin of the phenomenon and the processes by which it is acquired. Vygotsky referred to it as genetic or developmental analysis. Central to this analysis is the conception that any competence appears on the scene twice, first

as an intermental capacity between the language-learning child and more competent others, and subsequently through a process of internalization as an intramental capacity in the child. Second, for Vygotsky, mind is social in nature and constituted through language-based social interactions with others. Third, human action is mediated by signs and tools – primarily psychological tools such as language. Researchers working with the Vygotskian idea of internalization have recently included the Bakhtinian notion of appropriation to emphasize the active making-of-one's own that is part of the process of learning language (Aukrust, 2001).

The child's developing capacities are seen as internalization or appropriation of the society's practices via the support of adults or more knowledgeable peers. Through guided participation, children appropriate cultural tools such as language, literacy practices, and social rituals. Children's participation and subsequent development are mediated by the symbolic tools and resources that constitute their learning environments. The metaphorical term scaffolding has become common for this guided assistance that supports the child's growing linguistic participation in everyday routines and formats. Scaffolded assistance in the zone of proximal development supports children's development into the practices deemed important in their culture. Studies of play (Bruner, 1983) and book reading (Snow and Goldfield, 1983) have shown that children's early language acquisition takes place within structured and repeated scaffolded interactions in familiar routines.

Sociolinguistic approaches emphasizing language socialization

Language socialization studies emphasize the complex social norms that govern the use of specific language constructions. These studies clearly define the implicit and explicit socialization practices involved in the child's developing language.

The term language socialization refers to the interactional processes through which a child develops the competence required for participation in the social life of a particular community, including routine cultural practices, such as language and literacy activities. Language socialization research builds on the view that acquiring a language is part of a much larger process of becoming a member of society. The language socialization paradigm is concerned with two phenomena: how children are socialized to use language, and how they are socialized through the use of language.

Ochs and Schieffelin (1995) argue that language socialization accounts for children's grammatical development in terms of the indexical meanings of grammatical forms. Children are viewed as tuned into certain lexical meanings of grammatical forms, which link those forms to, for

example, the social identities of interlocutors. They may use a form they do not hear often because it is indexically appropriate to use it. A language socialization approach relates children's use and understanding of linguistic forms to how information is linguistically presented within and across socially recognized situations.

Ethnographic studies

Ethnographic studies emphasize that language always takes place in a specific social and cultural setting. Acquisition of language and literacy is conceptualized as a gradual process of adopting local cultural practices. This group of studies, closely related to the language socialization approach, was developed originally as part of linguistic anthropology. This research demonstrated the cultural specificity of language and literacy socialization practices and their developmental consequences in the transition from home-based to school-based activities (cf. Heath's study below).

During the last two decades, ethnographic studies have examined the characteristics of language learning in the multiparty interaction of classrooms (for review, see Cazden, 2001; Wolf *et al.*, 2006). Many classroom activities are created through classroom discourse, and therefore its role is important in the creation of learning environments and thus of individual learning. This group of studies has been concerned with children's pragmatic learning – their learning of discourse participation. The most common participant structure in classrooms is described as initiative–response–feedback (IRF), initiative–response–evaluation (IRE), triadic dialog, and recitative conversation. In its characteristic form, this participant structure comprises three moves: initiative (I), usually in the form of a teacher's question which often relates to known information; response (R) where the student answers the question; and feedback (F) or evaluation (E), where the teacher follows up or comments on the student's response. A number of international studies have documented that classroom conversations displaying the IRF structure serve to control the students and make them passive within an asymmetrical balance of power: it is the teacher who controls the theme, gives the questions to the students, and the opportunities for them to answer, and it is the teacher who evaluates the answers. However, several recent studies have also emphasized the learning potential in the IRF sequence and have concluded that the relationship between the students' responses and the teachers' feedback is a decisive factor in establishing shared background knowledge. Educators have also explored more complex classroom discourse under terms such as reciprocal teaching (Brown *et al.*, 1996) and dialogic enquiry (Wells, 1999), which refer to discursive activity in classrooms that permits the co-construction of meaning between teachers and students.

Comparing the Cognitive and Sociocultural Perspectives

Cognitive and sociocultural perspectives differ in the ways they conceptualize language learning, in their relative emphasis on innate versus learned aspects of language learning, in the role of the individual versus the collective in language learning, and in which aspects of language they are focused.

How is the task of language learning conceptualized?

In the cognitive perspective, language is a system that must be acquired in terms of a processing system. For the majority of theorists working within the cognitive perspective, learning is a process of acquiring new representations that gradually take on a more decontextualized quality. This is the task the individual child faces when acquiring language, but there is considerable variation among researchers working within the cognitive perspective when it comes to how this task is conceptualized – from the constructivist tradition following Piaget, who addresses individual construction, to the culturally embedded approaches of Tomasello and Nelson.

For the sociocultural researcher, language is a system of cultural practices into which the child is gradually socialized. Language learning is not so much a process of incorporating information or individual construction, but a process of socialization in which the novice gradually participates more and engages in cultural practices. These two main perspectives therefore differ in their view of what it is to know a language (concepts, schemas, networks, versus participation in social activity). The sociocultural perspective tends to disregard acquisition of decontextualized knowledge and emphasizes increasingly competent and fluent participation in cultural routines.

What is the relative emphasis of innate versus acquired aspects of language learning?

Although the innate versus acquired dimension of language development has historically received much attention in language development research, neither the cognitive nor the sociocultural perspectives have a one-sided stance in this question. In the extent to which these issues are discussed in the cognitive and sociocultural research literature, the argument seems to be that young children are biologically predisposed to interact with their environments, but that the effects of language input, and the language structure and culture on children's developing language systems, suggest an enormous susceptibility on the part of the language learners to the effects of input.

Studies applying a cognitive perspective tend to expect that relatively little higher-level knowledge is innate. They tend to emphasize how lower-level learning mechanisms

lead to higher-level concepts and rule-governed behavior. The connectionists propose a combined nativist and input-sensitive language-learning system; similarly, the sociocognitivists emphasize that children are biologically prepared for culture (Tomasello), but that their participation in culture supports acquisition of new cognitive and linguistic skills. They start with the premise that language serves cognitive and social functions of human life, and claim that the structures of language emerge from its functions. Generally, socioculturalists do not speak about input as such, but focus on the culturally or institutionally embedded interactions in which children participate. The analytic focus is not on the child receiving input to process, but on ways of participating fluently and competently in significant cultural routines surrounding the child.

What is the role of the individual versus the social or collective in language learning?

The primary analytic level of the cognitive perspective is the individual processing information. The sociocultural perspective often distinguishes between three analytic levels: individual development, social interaction, and the cultural activities in which both take place. Sociocultural studies commonly view individual development as changed ways of participation in social interaction embedded in cultural activities. The individual level is therefore not the primary focus when socioculturalists explain individual change or learning. Although the sociocognitive approach is concerned with how culture enters the young mind and with how thinking becomes culturally mediated when it emerges in language, its focus is on the child constructing this knowledge.

As there is variation along the individual–collective continuum between the cognitive and the sociocultural perspectives, there is also variation within each of these perspectives regarding the conceptualization of the individual as active versus fairly passive and about the focus of the social interaction.

The cognitive perspective on learning language consists of a number of approaches that differ in the importance they attribute to the individual versus the social context. At one end of the continuum is Piagetian constructivism, which emphasizes the individual's mental processes in the construction of meaning. At the other end of the continuum is the sociocognitive approach, which pays more attention to the social context in which the individual is constructing knowledge. Piaget highlighted the child as an active constructor of knowledge and conceptual structures, whereas connectionism tends to view the child as a receiver of information. Also the sociocognitive approach emphasizes the actively constructing child, but unlike the Piagetian tradition, the research focus is on the child making use of culturally embedded meanings.

While the cognitive perspective pays attention to the individual and distinguishes between individual children and the cultures into which they are born, the sociocultural perspective turns primary attention to social/institutional/cultural opportunities and constraints for learning, and emphasizes the role of social experience and cultural tools in a child's developing language skills. Learning is a matter of how people transform through participation in the activities of their communities. Within the sociocultural perspective, studies differ when it comes to their specific focus on social/cultural analysis, whether transformed participation is studied within dyadic interaction (often characteristic of many Vygotskian-based language learning studies), within cultural activities (Heath, 1983; Ochs and Schieffelin, 1995), or power relationships (many ethnographic studies of classroom interaction).

Which aspects of language learning are focused on most?

The cognitive and sociocultural perspectives differ in their orientation to the aspects of language that are studied. The former perspective has a long tradition of interest in grammar, whereas the latter has primarily addressed social meanings, genres, and the mediating role of language. For example, cognitive research on word learning tends to focus on the number of semantic features the child knows, whereas socioculturalists emphasize the child's usage of a word across various contexts and performance rather than generalized knowledge. It is worth noting that sociocognitive theory has offered significant work on language-mediated narrative thinking and on children's acquisition of socially and culturally embedded word meanings, while research within the sociocultural perspective has examined children's functional learning of grammar, from the starting point that grammatical forms are linked to social meaning and social identities.

What is the Role of Language in Literacy Acquisition?

Literacy is not acquired in the same way as language and needs to be taught. There is consensus in the field of literacy research that language plays a major role in reading and writing, and that these activities are fundamentally linguistic activities. But what is the role of language in literacy? We now turn to how this relationship is conceptualized within the cognitive and sociocultural perspective. Various bidirectional relationships exist between oral language and literacy, but the impact of reading on language is not addressed here.

Language in Literacy: The Cognitive Perspective

Researchers who study literacy from cognitive and psycholinguistic orientations generally agree that literacy

draws upon multiple interrelated skills, including oral language, phonological awareness, knowledge of the graphic features of print, and an understanding of how sounds map into print. Cognitive research, particularly within psycholinguistics, has identified components of skills that need to be mastered in order to become a qualified reader. Within the cognitive perspective, literacy has been analyzed as a combination of skills to encode information from text into mental representations of letters and words, to recognize the words and activate representations of their meanings, to combine representations of words into phrases and sentences, and to form representations of the propositions they cover.

Early predictors of reading comprehension are word recognition and oral language skills. Two processes are involved in word recognition: a visual process and a phonological decoding process, which concerns the correspondences between printed letters and the sounds of the language, especially phonemes (the small sound units within spoken words). Research in alphabetic reading has developed the consensus that phonological decoding is a routine part of skilled word recognition. How the phonological and visual-orthographic information combines for the identification of individual words has been the focus of much research within the cognitive tradition, reflecting theoretical debates about how to conceptualize the cognitive mechanisms of word recognition. In addition to supporting word recognition, phonological processing supports cognitive processes such as comprehension and memory of the text. It is well documented that word recognition is an important source of individual variation in reading. In word recognition, accuracy and fluency are crucial for processing meaning. Fluency enables readers to access and apply relevant higher thinking skills for comprehension.

Moreover, reading comprehension is predicted by oral language which again is comprised of multiple skills. As noted, phonological skills are precursors to literacy. The importance of phonological awareness (the ability to reflect upon and manipulate the sound structure of spoken language) is well documented. Moreover, vocabulary has long been known to be predictive of later-reading comprehension. One of the most robust findings in the field of literacy research is actually the high correlation between vocabulary and reading comprehension. Also, variability in syntax skills has been found to be related to reading. Finally, knowledge of discourse types (expository text, narrative) predicts comprehension. Good comprehenders tend to have a more advanced understanding of various discourse types, which helps them interact with texts strategically and construct meaning successfully. Two types of extended discourse – explanations and narratives – have received much attention in literacy research, and children's exposure to such discourse has been linked to literacy-related outcomes. Over all and in sum, it is widely agreed that specific and multiple oral-language skills prepare children for comprehension.

Phonological processing and oral-language skills influence different aspects of reading acquisition at different times. The association between oral language – particularly vocabulary – and reading has been found to be greater for the later years, from fourth grade on. This does not mean that oral-language skills have no importance for early reading. Oral-language skills seem to have an indirect relationship with phonological processing as early as kindergarten and across the early years of schooling.

Language in Literacy: The Sociocultural Perspective

Within the sociocultural perspective, literacy practices are considered part of social practices, the most fundamental unit of analysis of human action within the field. Sociocultural researchers often adopt a broad view of literacy and have also proposed multiple literacies, such as digital literacy and science literacy.

Language is considered the most significant resource for creating and reproducing meaning and is an essential feature of social practices. Human knowledge is stored in discourse, systematically organized systems of language in which meaning is produced according to certain semiotic principles. Socioculturalists' emphasis on language and literacy recognizes the role of mediational means in understanding human collective and individual action.

Two important contributions to the role of language in literacy within the sociocultural perspective are considered: Heath's anthropological study of continuities and discontinuities in ways with words in home and school, and the new literacy studies (Gee, 1996).

Heath (1983) described how children in different communities in the USA learned their community's way of using language in everyday social practices. She suggested that each community had specific ways of socializing members. For example, Heath found that children from Trackton, a mostly African-American community, and Roadville, a mostly white community, exhibited very different story-telling behaviors. Heath documented how children learned to use language and how their use of language established their identity, roles, and relationships among family and friends. Following these children into their schools, she documented how their distinct ways of learning language affected their integration into academic life. Most critical to academic success were certain ritualized uses of language, such as the assignment of labels to objects and responses to questions about events already known to the questioner. She also described how children from some communities were encouraged to look at letters and books at home. The children developed a familiarity with texts that supported their learning in school. The study reports on continuities and discontinuities in literacy practices at home and school, and underlines the many relationships between language,

literacy, and academic learning, beneficial for children who experienced continuity in ways with words between home and school and detrimental for those who did not. The study finds support in more recent ethnographic studies, which have concluded that the failure of many children from low-income homes in reading results from a mismatch between home and community patterns of language and literacy use, and the uses of language and literacy typically expected in schools.

The new literacy studies took as a starting point that reading and writing only makes sense when studied in the context of social and cultural practices. This group of studies is closely related to work on situated cognition that has argued that knowledge does not reside solely in individuals' heads, but rather is distributed across the social practices (including language practices) and the various tools, technologies, and semiotic systems that a given community of practice uses in order to carry out its activities. Learning to read and write is to become a participant in literate social practices, and further learning is a matter of changing patterns of participation in literacy practices. The new literacy studies pays attention to different styles of oral language use and the various types of literacy that are tied to specific domains, such as science in classrooms, or to specific sociocultural groups. Cognition is studied in terms of how thinking is mediated by the physical and social environment, various semiotic systems, and different sorts of tools.

The Role of Language in Literacy – The Two Perspectives Compared

In the cognitive perspective, language plays an important role in reading comprehension. Various oral skills have been examined, and many of them, such as vocabulary, phonological processing, syntactic skills, and discourse knowledge, showed a relationship to reading outcomes. Though there is much developmental continuity between language and literacy, and though language is a strong predictor of later literacy, there are also discontinuities and differences, the most important being that literacy needs to be taught to be acquired.

Research based on the sociocultural perspective does not apply a skills approach to literacy. Literacy is not considered an individual accomplishment, but a social practice to which communities and schools socialize children. Texts and other cultural tools mediate the ways people communicate and think in a culture. The formation of literate identities and the acquisition of academic social languages are important achievements in literacy education. Moreover, the sociocultural perspective does not differentiate sharply between language, artifacts such as the alphabetic system and texts, and social practices. Artifacts are conceived as forms of human knowledge and as mediating resources that structure social practices as well as human thinking.

This article has culled out some differences in how researchers within the cognitive and sociocultural fields respond to questions of the role of language in literacy. When it comes to reading programs, there are many examples of researchers who draw from both the individual skills and the social practices perspective. An example is reciprocal teaching which is partly Piaget based and partly Vygotsky based, and is a cognitive apprenticeship model for teaching reading comprehension within communities of learners (Brown *et al.*, 1996). Teachers and students take turns leading a discussion that includes four types of strategic activities: predicting, questioning (making up a question on the main idea in the text), summarizing, and clarifying.

The Role of Language in Learning Subject Matter: Academic Language

While much research has examined relationships between language and literacy, less is known about the impact of language on learning subject matter in general, outside the mediating role of reading for learning. This final section turns to the role of academic language in children's discipline learning. Both the cognitive and the sociocultural perspectives have paid attention to academic language, the former with a focus on the particular language skills required to cope with textbooks and classroom discourse, the latter related to genres or registers as mediating tools for learning. While the term academic language represents a fairly recent attempt at identifying those qualities of language that support acquisition of content-area knowledge, a variety of terms have been used to capture the same language qualities, and these are reviewed briefly first:

1. *Decontextualized language.* Decontextualized language is talk that goes beyond the here and now, and relies on language to convey information about other times and places. The term was frequently used in child language research from a cognitive and psycholinguistic perspective in the 1980s and 1990s. Offering oral definitions is, for example, a discourse task in which children need to rely on their decontextualized language skills. The term has also been used to point out similarities in spoken and written language. Oral stories, in which the speaker does not presuppose shared knowledge with the interlocutors, take on some of the characteristics of written language: they have a relatively complete message, adequate explicit references, and an assumed audience that does not share much background information with the writer. These characteristics are all examples of decontextualized language skills. Advocates of the sociocultural perspective have argued that all language use is contextualized in social practices. They have also suggested applying the term recontextualized to messages that do not presuppose shared background knowledge.

2. *Extended discourse.* Extended discourse is the term suggested in child language research to cover much of the same meaning as decontextualized language. The term extended has two meanings. First, it emphasizes sustained use of language, such as in conversations, as opposed to simple directives – that is, talk that extends over several utterances or turns. Second, it refers to talk that extends the here and now. Narratives and explanations are examples of extended discourse that children participate in and that have been found to support their development of oral language and reading. Making convincing arguments and providing formal definitions are also examples of extended discourse.
3. *Cognitive Academic Language Proficiency (CALP).* The distinction between cognitive academic language proficiency (CALP) and basic interpersonal communicative skills (BICS) was proposed by Cummins (1979) to draw attention to the time required by immigrant children to acquire second-language conversational fluency (BICS) compared with grade-appropriate academic proficiency which was needed for school learning. Conversational fluency was often acquired within about 2 years of exposure to the second language, whereas academic aspects of the second language required a much lengthier process to be learned.
4. *Accountability talk.* The term accountability talk is used to point out various features of types of talk that support reading comprehension. These three features are:
 - *Accountability to accurate knowledge.* Participants make use of specific and accurate knowledge, recognize the kind of knowledge required to address a topic and appropriate evidence for claims and arguments, and show commitment to getting it right.
 - *Accountability to rigorous thinking.* Participants use strategies to present arguments and to challenge each other's reasoning, synthesize several sources of information, construct explanations, formulate hypotheses, and apply generally accepted standards of reasoning.
 - *Accountability to the learning community.* Participants make efforts to ensure that all participants understand the ideas and positions shared, elaborate and build on each other's ideas and work to clarify or expand propositions, and ask each other questions aimed at clarifying propositions (Cazden, 2001; Wolf *et al.*, 2006).

Academic Language in Cognitive versus Sociocultural Perspectives

Academic language in the cognitive/psycholinguistic perspective

Academic language has various typical features: the interpersonal stance is detached or authoritative, the information

load is dense, the organization of information involves explicit marking of text structures (metadiscourse), and at the lexical level academic language is diverse and precise, including terms that are discipline-specific as well as terms used academically across disciplines. Moreover, these linguistic features must be combined with additional cognitive achievements: genre mastery, mastery of argumentative strategies, and content-area knowledge (Snow and Uccelli, 2009). Academic language, like all linguistic communication, involves challenges at the level of self-representation, of representing a message, and of constructing discourse.

Academic language in the sociocultural perspective

Within this perspective, academic language is integrated with social identities and social practices and is at the core of school-based literacy (Gee, 2004). Academic language is part of social languages which again are defined as ways of using language so as to enact a particular socially situated identity and carry out a particular socially situated activity. School success is based on the ability to cope with academic language, which is different from everyday language in face-to-face conversation. Science has, for example, been conceptualized as a special-purpose language. To acquire an academic social language, students must be willing to see the acquisition of the academic social language as a gain (gaining traits, categorizations, etc.) and also accept certain losses (attitudes, interests, values left out by the speaker/writer).

What is academic language: Summary

Even in the early grades, children are expected to learn new information from content-area texts, so failure to understand the academic language of those texts can hinder their access to new information. Academic language is often defined as the language used in textbooks and in schools, that is, academic language is defined by the context in which it appears. In addition, academic language has special linguistic features, puts specific demands on self-representation (the cognitive/psycholinguistic perspective), and is integrated with the enactment of social identities (the sociocultural perspective).

Concluding Comments

The behaviorist perspective was historically a main line of development in the psychology of learning and played a significant role in the study of language learning in the 1950s and 1960s. The cognitive perspective became influential in research on learning and cognition in the 1970s, while recent developments like connectionism and socio-cognitive research continue to vitalize the study of language learning. The sociocultural perspective is the youngest of the three, but defines an area of educational

research with vital activity during the last decades. In their broad review of the field of learning and cognition, Greeno *et al.* (1996) discuss potential future developments and relationships between these theoretical perspectives. One possibility is that the different views will live side by side, complementing each other and analyzing processes of learning at different levels of aggregation. Another possibility is a somewhat more competitive relation among the perspectives, in which one perspective can provide a kind of synthesis of the others. One salient theoretical question for the study of how language is learned and how it impacts literacy and academic school learning will be the continuing clarification of relations among research perspectives.

Bilingualism and Learning

Bilingualism is defined as a speaker's ability to use two languages for communication. Due to the complexity of its nature, the study of bilingualism relies on several fields within linguistics, including anthropology, psychology, neuroscience, and education. The study of bilingualism describes language behaviors of bilingual speakers, social and pragmatic patterns of using two languages, language development, and acquisition and loss, among many other issues. Researchers attempt to explain the effect that bilingualism has on human cognition, societal relationships, and education of bilingual children. This article discusses bilingualism and learning from three perspectives: types of bilingualism, bilingual processing, and bilingualism and academic learning.

Types of Bilingualism

One of the issues that has a direct effect on education is the distinction between individual bilingualism and societal bilingualism. The term societal bilingualism describes various situations when two or more languages are spoken in a society. Societal use of two languages may take different shapes. For example, during the colonization period, societies were formed where two monolingual groups spoke different languages to each other. An example of a different pattern of societal bilingualism are societies where two or more languages are used on a daily basis, as in many African countries and in parts of Asia. Yet another pattern of societal bilingualism is represented in the US, where minority groups must learn the main language of the community, while the socially dominant group remains monolingual (Hoffman, 1991). Finally, there are societies where two languages that may be closely related have different degrees of prestige. The high-prestige language is used in formal contexts, whereas the language of low prestige is spoken at home. Such a situation is referred to as diglossia (Ferguson, 1959) and is widespread in German Switzerland, Morocco, and Paraguay, to name just a few countries. Many factors account for societal bilingualism. Historically, reasons for societal bilingualism may include occupations, conquests, political marriages, colonization, neocolonization, migration, immigration, and internationalization.

As a result of these factors, the majority of the world's societies are bilingual. What is especially noteworthy is that about 70% of the world population is bilingual to some extent. Therefore, globally, bilingualism is much more of a norm than monolingualism.

Individual bilingualism is a term that describes an individual speaker who has command of two languages. Some of the reasons for individual bilingualism include immigration, migration, close contact with other linguistic groups, schooling, and growing up in a bilingual family. Depending on the reason for acquisition of a second language (SL), the level of the speaker's competence in two languages will vary. Only one of these languages is commonly used in the society where the speaker lives. An individual bilingual uses each language for different purposes and usually with different people. For example, in the United States, a Russian-English bilingual speaks Russian to his/her family members about household issues, but uses English at a car dealership or in the bank. Individual bilingualism may be viewed as a positive or negative attribute, depending on the society and its tradition. When the attitude toward bilingualism is positive, bilinguals take their ability to use the two languages as a fact of life. When the societal attitude toward individual bilingualism is negative, monolingual speakers may find it threatening and undesirable, which results in societal unacceptance of bilingual individuals. This attitude forces many young bilinguals to stop using their two languages in favor of the dominant societal language. Abrupt interruption in language maintenance leads to language loss and may result in semilingualism, a situation where speakers are unable to express themselves clearly in any language (Baker, 2006).

Researchers who study individual bilingualism attempt to explain how the two languages within one speaker are able to interact, to be activated and deactivated depending on the communicative needs of the individual, how these languages are represented in the brain, and what kinds of practices, attitudes, and behaviors such a speaker may experience that are different from a monolingual speaker.

Another important issue in the study of bilingualism is the age of acquisition of the SL. When a child grows up in a bilingual family and acquires two languages from birth, the acquisition is simultaneous and such bilinguals are referred to as early and simultaneous bilinguals. The term simultaneous bilingualism emphasizes that the SL is acquired through the same acquisitional mechanisms as the first language. This type of acquisition is qualitatively different from sequential acquisition where the SL is acquired after the first language is in place.

Under immigration, first-generation immigrants continue using their native language while acquiring the majority language of the country where they have settled.

Their children usually acquire the first language from their parents and the new language from people outside the home. In other words, first-generation immigrants are monolingual speakers who add another language to their repertoire and are expected to adapt to the norms of the new country. These bilinguals are referred to as sequential bilinguals; that is, they acquire their two languages in sequence, rather than simultaneously. Sequential bilinguals may be early bilinguals, if they acquire the SL during childhood, or late bilinguals, if they acquire the SL during the adult years.

One of the issues that arises for sequential early bilinguals is the maintenance of their native language. It is typical for young bilinguals to switch entirely to the majority language of their society. If such a switch occurs, it is likely that the first language will be lost and these speakers will become monolingual users of the SL.

Families that use more than one language sometimes make a decision to raise their children bilingually. In this case, they often use the one-parent-one-language strategy, where each parent consistently speaks only one language to the child.

The level of development and use of the two languages is another aspect of the study of bilingualism. Sometimes, bilinguals are equally proficient in both of their languages and are able to use them for similar purposes. This situation, described as balanced bilingualism, is difficult to achieve, especially when one of the languages is a minority language and is not used in the society at large.

A more common situation is unbalanced bilingualism – when the two languages are developed unequally in an individual because languages are used in different domains of life, for different purposes, and with different people. As unbalanced bilingualism constitutes a prevailing scenario, it is important to understand that the bilingual speaker is not a sum of two complete monolinguals in one (Grosjean, 1989). Rather, the language that the speaker is more fluent in is recognized as the dominant language. Importantly, the dominant language is not necessarily the first acquired language of the speaker. The balance between languages can change if the speaker's circumstances change. One of the languages may undergo attrition, fossilization, and forgetting by an individual or by the society (language death); on the other hand, one of the languages may be revitalized, maintained, or standardized.

It is noteworthy that the two languages may be present in the speech of an individual at the same time. If the conversation takes place between bilingual speakers who share the same languages, it is common that two languages will be used alternately within one sentence, across sentences, or even within one word. This type of alternation of languages is referred to as code switching. Code switching is often stigmatized as an ungrammatical, uneducated way of speaking. Despite the seemingly haphazard patterning of the two languages in code switching, one of the

languages controls the grammatical system of the utterance, while the other provides lexical information, that is, fills in the words. Therefore, code-switched production is a complex, rule-governed activity that involves activation and use of two languages simultaneously.

During code switching, both languages overtly appear in the production. However, when a bilingual's production in one language is underlyingly affected by the other language, only one language appears on the surface. The other language is used covertly.

Such covert incorporation of the dominant language is often referred to as convergence to the dominant language (Myers-Scotton, 2002). When converging, the speaker uses all the lexical and grammatical markers from one language, but parts of the structure come from another language in the speaker's repertoire. Such covert use of the SL is indicative of gradual language loss and may alert educators to the necessity to help the speaker maintain both languages.

One of the other aspects of bilingualism that may be of particular concern to educators is whether bilingualism of their students is additive or subtractive. In additive bilingualism, the new language adds to learners' skills and experiences without undermining their native language and existing knowledge. In subtractive bilingualism, learning of the new language takes place at the expense of the native language and the existing skills and knowledge. Researchers emphasize that successful learning of a new language takes place in additive situations due to high levels of motivation and feeling of self-worth that additive circumstances project (Cook, 2001). In monolingual societies, conditions are often created for subtractive bilingualism for those students whose primary language is other than English as it undermines the value of their native tongue. Subtractive bilingualism often results in anomie, which in a bilingual context refers to a bilingual's feelings of discontent and regret for losing ties with one group mixed with fearful anticipation of entering a relatively new group. Anomie can be avoided if educators and parents help young bilinguals to define their identities, which are different from those of monolinguals (Lambert, 1972).

Bilingual Processing

Researchers have established that bilinguals process language differently than monolinguals do as their two languages are in contact and they constantly make decisions as to what language to use. Linguists believe that both languages are continuously activated, but the degree of activation may differ for each language depending on the initial choice and intention of the speaker. Recent studies indicate that speakers have an option to switch to the SL

at any time during their utterance. This means that the degree of activation of both languages is quite high.

Depending on whether the speaker is an early or late bilingual and on the circumstances under which the SL was acquired, the speaker may rely on different types of knowledge when using the two languages. Explicit knowledge of the language refers to the speaker's familiarity with the facts about the language. For example, the speaker may be able to recite a grammar rule. Implicit knowledge refers to the computational operations that the speaker is never consciously aware of and that allow us to actually build and produce intended utterances. Importantly, explicit knowledge can never become implicit, as these are qualitatively different entities. However, it is important for educators to know that explicit knowledge may contribute to the faster development of implicit knowledge (Paradis, 2004). Moreover, studies in bilingual aphasia as well as magnetic resonance imaging (MRI) studies of the bilingual brain have shown that two languages of late bilinguals are localized in different parts of the brain, while early bilinguals seem to have one language center (Paradis, 2004).

Regardless of language location in the brain, activation is currently viewed as the key to language availability and maintenance. The activation threshold hypothesis proposes that in order for an item (vocabulary or grammar) to be activated, a certain amount of neural impulses need to reach neural substrate. The amount of neural impulses sufficient for activation is called the activation threshold. Each time an item is activated, the threshold becomes lower. If an item is not activated for a longer period of time, the threshold rises (Paradis, 2004). While the activation threshold operates on both monolingual and bilingual speakers, the activation is more complicated for bilinguals. In order for an item from one language to be activated, the competing item from another language must be inhibited. In other words, the activation threshold of a similar item in the unwanted language must be raised. Importantly, production of an item is more difficult than comprehension of the same item because the activation threshold needs to be lower for production than comprehension. That is why when bilinguals do not use one of their languages, their activation threshold may rise to the extent that they are no longer able to produce utterances in that language, but are still able to comprehend them (Köpke, 2002).

Some items require lower level of activation threshold than others. For example, lexical items require a higher level of activation threshold than do morphological features that are a more permanent part of the language. However, at the initial stages of acquisition of a new language, we observe that new lexical items of high frequency in the speaker's environment rather quickly achieve lower level of activation threshold, whereas grammatical markers are at high level of activation threshold. This often results in structural interference, that is, a negative effect of one language on the other.

Bilingualism and Academic Learning: The Education of Bilingual Children

Bilingual children and, in particular, school children who are in the process of becoming bilingual, pose particular challenges to school systems. Schools throughout the world deal with bilingualism in various ways. In some cases, schools' intentional goals are to produce bilingual children. In other cases, schools may approach the education of their language minority students (those students who do not speak fluently the language used in the school) as a problem that needs to be solved, because the language minority children may not have sufficient language proficiency to understand the language of the school instruction. In yet other cases, schools may intentionally or unintentionally ignore the linguistic plight of their language minority students and expect the students to either sink or swim in the mainstream academic setting.

Theoretical Constructs of Bilingual Education

Before examining the various types of school models of bilingual education, it is important to identify two theoretical constructs that help shape school choice in this area: the distinction between conversational language and academic language, and the interdependence between the first-language and SL literacy.

Language use varies depending upon setting. In simplistic terms, language use can be divided into two types: conversational language and academic language (Cummins, 1984). Conversational language use allows people to engage in basic, interpersonal conversation, such as visiting over coffee or on the school playground, ordering food in a restaurant, inviting someone over to the house, or narrating a story of what happened earlier in the day. Generally, conversational language assumes that: (1) both speakers (and hearers) have some sense of shared history or are speaking about a topic in the here and now; (2) both speakers can make use of gestures and visuals, and intonation; and (3) both speakers have the opportunity to negotiate meaning, that is, to signal if they do not understand and to seek clarification. As two speakers move away from any of these three features, the talk becomes less and less contextualized by the here and now, by visuals and gesture, and by the ability to negotiate meaning. When this happens, more of the burden of the talk is invested in the language, rather than the above-mentioned contextualizing devices. As the speakers move away from all three features (imagine this movement on a continuum), the language activity becomes less conversational and more academic.

Academic language (or literate language) is the second of the two language-usage types. Academic language is the language of school textbooks, expository writing,

classroom lectures, and some classroom discussions. This language type is distinctly different in its linguistic composition from conversational language, containing specialized lexical choices, more logical connectors, more clause-combining strategies, and more sophisticated use of tenses and aspect (Schleppegrell, 2004).

The distinction between conversational language and academic language is important for this reason. The time required to develop each language type varies significantly; conversational language skills take 1–2 years to develop, while academic language proficiency requires 5–9 years. (Hakuta *et al.*, 2000; Thomas and Collier, 2002). Consequently, language-learning students with strong conversational language skills may sound like they are fluent in their new target language, but may still be developing their academic language skills in this new language. As a result, teachers may mistakenly place students into mainstream instructional settings without the additional support required to help the students acquire the more refined academic/literacy related aspects of the new target language.

The second theoretical construct important to the education of bilingual children is the interdependent relationship between the literacy skills of the student's first language and the literacy skills of the SL. It has been determined that many of the literacy skills acquired in a student's first language are readily transferable to the student's SL. Therefore, time spent learning how to read in a child's first language is not time lost and, in fact, may be important time invested in that student's literacy development process (August and Shanahan, 2006; Cummins, 1991).

The educational implications of these two theoretical constructs are as follows:

1. Bilingual children, learning an additional language, will need sufficient time and academic support to develop the academic language skills of that target language.
2. Literacy in the first language, if at all possible, can be a most important step in that student's literacy development. It will not detract from the child's development of literacy in the SL, and it may provide a most important foundation.

Types of Bilingual Education

Schools throughout the globe offer a wide variety of education program types for bilingual students. These programs have a wide variety of names attached to them. In an attempt to solidify and simplify, we discuss six types:

1. bilingual immersion;
2. two-way/dual bilingual;
3. maintenance bilingual;

4. transitional bilingual;
5. sheltered content instruction; and
6. SL, such as English as a Second Language (ESL)

Bilingual immersion programs place students, all of whom share a similar language background, into a classroom setting in which students are immersed into a language other than their own. Successful examples of such programs include the Canadian Immersion Model, in which English-speaking children are immersed in French schooling for the first 2 years of school, or alternatively during the students' middle school years. Another example can be found in Hawaii, where native English-speaking children attend school in Hawaiian during the first 5 years of schooling. In each case, a small portion of schooling is conducted in the students' native language each day. It should be noted that immersion models are radically different from submersion models, in which students must simply sink or swim. In structured immersion models, the students speak a home language that has societal value and learn a target school language that holds a societal value or an historical value. Importantly, the value of their home/native language is not questioned, nor is there a danger of students losing their home language. In the submersion model, the language minority students receive no instruction or support in their home language. They are submersed into an instructional environment that is designed for the majority native-language speaking students. Therefore, the successful history of structured immersion programs cannot serve as justification for the use of submersion models.

Dual bilingual programs serve classrooms comprised of two groups of children, each of which speaks a different first language. The two languages represented by the students become the shared medium of instruction. Part of the school day or school week is conducted in one language; the other part of the day or week is in the other language. At any time, half of the students are working in their first language, while the other half of the students are working in a new, target language. The goal of these programs is to develop students who are bilingual in two languages, with conversational and academic language proficiency in both.

Maintenance bilingual programs serve classrooms comprised of all SL learners, students who speak a single, common minority language at home, and who need to acquire the societal majority language at school. In such programs, both languages are used. How the classroom teacher divides the class time between the two languages varies, but this is not done randomly. The program specifies if the use of the two languages is 50/50, or 60/40, or even 90/10 at the beginning of the student's time in school. Oftentimes, literacy is developed first in the home language, and later in the target language of the school. The goal of the program is to not only develop the target,

societal language, but also to maintain and develop the students' home language, and to develop the students' academic fluency in both languages.

Transitional bilingual programs serve a school population similar to that served by the maintenance bilingual program. However, the goal of the program is to develop the students' proficiency in the dominant, societal language. Therefore, the transitional program uses the students' first language only as a tool to bridge the students' academic development until they are able to fully perform academically in the target language of the school. In transitional programs, students often do not develop a strong literacy base in their first language, but rather, are taught literacy skills primarily through the target school language.

Sheltered content instruction is a relatively new method of teaching bilingual children in school systems. This method teaches course content in the language of the school, but in language environments that are highly structured. Sheltered instruction requires that teachers trained in specific content disciplines learn how to deliver instruction in these content areas in ways that make the content comprehensible to students who do not share the language of the course content. They do this by contextualizing the academic content through the use of visuals, shared history, and frequent negotiation of meaning (as described earlier in this article), and through the highly controlled use of the target, school language. The goal of sheltered instruction is to develop content and academic language proficiency in the new language.

SL programs (such as ESL) attempt to teach the target school language to bilingual students who speak a home language other than the school language. Students in one SL classroom may represent a large number of different home languages; therefore, the SL teacher must rely almost completely, if not entirely, on the school language. Bilingual students who need such help may be pulled out of their mainstream classes to attend SL classes; or, teachers trained in SL instruction may be pushed into the mainstream class, where that teacher works as a partner with the content teacher. SL classes can focus on conversational language or on the specific academic language of the content courses.

Efficacy of Bilingual Education

The decision of what type of bilingual educational program a school system will employ generates much public discussion, even political heat. In some cases, laws have been passed which strictly dictate how a school system will handle bilingual education. One recent study provides us an insight as to the efficacy of program types. Thomas and Collier (2002) compared dual, maintenance, transitional, and various ESL programs in major cities in the United States of America and found that only those

bilingual programs that develop both languages (dual and maintenance programs) ultimately resulted in bilingual students' ability to perform at minimally the 50th percentile or better as compared to native English-speaking students in these same school systems. While the Thomas and Collier study indicates that programs using only the target school language have not been successful for bilingual students, it should be noted that this study was conducted at a time when there was still too little ownership in mainstream education for the education of bilingual children. It was thought that the bilingual or ESL programs should bear the responsibility for the education of bilingual children until they were mainstreamed. Now that research has made it clear that it takes anywhere from 5 to 9 years to develop academic language, school systems are understanding that all teachers must bear the responsibility of the education of bilingual children. Hence, teachers are learning to employ sheltered strategies in their classrooms and to offer sheltered content courses to large groups of bilingual children. Educators remain hopeful that with increased training in sheltered and differentiated instruction for content teachers, future studies will reveal more positive findings for the academic performance of bilingual students.

Despite the findings of Thomas and Collier, the discussion of whether or not to use language minority children's first languages in their education remains a much heated, politically divisive debate in many countries. However, in general, the research is clear on this topic. A preponderance of evidence from various studies in various countries (Norway, England, Netherlands, Sweden, Australia, Mexico, and China) suggests that the use of students' first language in their educational experience does not hurt the child, and in many, if not most, cases students benefited, either in increased academic abilities, enhanced literacy skills, and/or even improved student behaviors (Krashen, 1999).

Glossary

Academic register – The language style most commonly used in academic contexts, typically incorporating features of written language.

Authentic questions – The questions that reflect genuine openness about the sought-after response.

Code-shifting – The alternation between two or more languages or language varieties within the same discourse.

I–R–E sequence – A three-part interactional sequence beginning with a teacher initiation followed by a student response and teacher evaluation.

Decontextualized language – The language that does not rely for its interpretation on the speaker and hearer's shared context; it is often characteristic of academic and written language.

Display question – A question that requires the respondent to verbally display information that is already known to the questioner.

Elicitation sequence – A chain of teacher questions and student responses in which the teacher attempts to elicit a sought-after response.

Nonstandard dialect – A community language variety such as African-American English vernacular that displays systematic differences with the standard form of the language.

Open-ended question – A question that does not elicit only a yes–no or phrasal response.

Speech event – A routinized communication situation involving particular participants, settings, move sequences, and communicative goals.

Definition/Scope

Classroom discourse research arose in the 1970s as a special focus within the new discipline of conversation analysis and early on identified some of the distinctive formal characteristics and social purposes of talk in schools. Research has generated descriptions of the forms of talk that are specific to academic contexts, characterizations of the rules that govern teacher–student talk, and accounts of the ways in which the development of language skills can be fostered or hindered in classrooms. As analytic tools have been applied to different kinds of

school settings, the field has contributed to better understanding of varied issues such as the socialization of academic language, gender roles in classrooms, and processes of second-language learning in school.

Differences with Everyday Conversation

As early research convincingly documented, teacher–student talk proceeds according to different rules and conventions than everyday conversation. These arise from the social purposes of much classroom talk, which center on the teacher's presentation of academic content and assessment of students' uptake of information. Largely absent from teacher–student communication are the phatic exchanges that are common in other forms of everyday talk: "How's it going?" Instead, teachers lecture, ask questions to check on student understanding, and provide brief evaluations of the adequacy of students' responses ("Good!" or "Anyone else?").

At the level of individual utterances, classroom talk often displays features of decontextualized language such as nominalizations (multiplication, thinking), and embedded clauses (such as that-clauses). Classroom discourse incorporates these features because teachers and students often talk about abstract concepts or entities that are physically absent from the context of conversation: carbon bonds, the Treaty of Paris, animal habitats, and the thoughts and feelings of fictional characters. In contrast to the topics of much everyday conversation outside of classrooms, the referents for classroom topics are often not visible or mutually accessible through other nonverbal channels, for example, through shared activity ("Could you hand me that?" "We can tackle it later."). The potentially supportive role of shared physical and social context is often diminished and therefore, in classroom discourse, interactants are typically obliged to use more explicit and verbally elaborated strategies for describing their conversational topics. Topical referents need to be first introduced through talk and then disambiguated and elaborated upon through verbal commentary. Repeated reference to the same topic is usually accomplished through definite reference in classroom talk (the theme of the story, the lesson, or the point) rather than through the deictic strategies more commonly used in thematic progression in everyday informal conversation (it, this, or that).

Classroom discourse is often motivated by the need to build up shared and elaborated understandings of

particular topics over time, for example, across the course of a unit or academic year; thus teachers and students use a variety of strategies to mark what is jointly understood and remembered about a topic.

Asymmetric Roles

A notable characteristic of teacher–pupil talk is an asymmetry of speaking roles: teachers lecture and ask questions and students answer the questions that are posed to them. Teachers dominate and monopolize the conversational floor in classrooms at every stage of the educational system, taking longer and more frequent turns than student participants. In contrast to other types of conversation in which children and young people can take more varied roles, in classroom discourse, teachers typically reserve the right to introduce new conversational topics and to engage in most forms of questioning. Teachers control access to the conversational floor through nominating respondents to their questions (“Hands, please!”) and often through limiting opportunities for side conversations or talk on student-initiated topics. In addition, different from other conversational contexts, many of the questions that teachers pose are close-ended, questions that require only minimal or fragmentary responses from students. The forms of teacher questions largely determine that syntax and degree of elaboration of student responses:

Teacher: Where do most cats live?

→ Student: Houses?

Teacher: They live in houses, right.

Many teacher questions take the form of what have been called display or known-answer questions. Unlike what have been termed authentic questions, display questions require students to present information that is already known to the teacher.

→ Teacher: So what’s the title of the story that we read?

Student: The Sea Serpent.

Student responses to known-answer questions are often quite brief; the point is to demonstrate recognition of the right answer rather than to present a unique or personal perspective on the topic. Responses to known-answer questions are often only interpretable within the context of the preceding teacher talk:

Teacher: Let me see your folder first. The book report cover. Okay, what do you have here? What’s that? (points)

→ Student: Title.

Teachers’ open-ended questions, on the other hand, require students to construct relatively autonomous turns that often present new information about the topic:

Teacher: Do you have a prediction about that?

Student: I think if we keep rolling the dice, we’ll keep getting numbers under 30. Because the dice numbers aren’t that big and if you multiply them, it will be like 20 and 16 and 10 and 8 like we have been getting.

Responses to open-ended question often elicit students’ most sophisticated language skills, requiring vocabulary that is specialized for particular subject areas and grammatical forms that include conditionals, subjunctives, and embedded clauses.

Three-Part Sequence

Much classroom interaction follows a three-part scheme, where the teacher first initiates a question–answer sequence, followed by a response from a student who either volunteers or is selected by the teacher to respond. A third element in what has been called an I–R–E structure is an optional teacher evaluation move, offering feedback to the student about the adequacy of his or her response. These three-part question–answer exchanges create the framework for most student contributions to talk within classrooms, typically alternating with longer stretches of teacher monolog or lecture.

Teacher: Do you know what that means, when they say water’s getting rough?

Student: That the water’s like getting wavier?

Teacher: Right.

Teachers use I–R–E exchanges for several social and pedagogical purposes: to assess student background knowledge before introducing a new topic or reintroducing a subject; to assess student uptake of new information, to break up monologic presentations of information; to mark transitions between topics; and to re-engage students whose attention may be flagging. Many teacher questions do not immediately elicit the desired response; thus classroom discourse often includes extended elicitation sequences in which the teacher repeats or reshapes the original question, seeking a closer approximation of a correct answer through hints, simplifications, and restatements:

Teacher: Look at the cover and tell me what you think the story will be about.

Student: It’s about animals.

→ Teacher: What kind?

Student: Cats. Mice.

The teacher evaluation moves that follow partial or incorrect answers (“What kind?”) provide cues to students that their expressed understanding of the topic is not yet fully adequate. A positive evaluation move by the teacher often serves to not only confirm the adequacy of an answer but can also mark the end of a particular topical

focus (we're clear about this aspect of the topic now) and can set up a shift in lesson focus:

Teacher: What's a landing? If you're in a boat, what's a landing?

Student: Oh you like go to the um to the um sand?

Teacher: You go to the where?

Student: To the sand, uh the boat.

Teacher: To the sand?

Student: Where the people are, where you play.

Teacher: You mean what, you go back to...?

Student: Where you were.

Teacher: Where you were. What's that called? What's that called, where you were?

Student: You go back to the shore?

→ Teacher: To the shore, very good. Good word. So it's a rough landing because, why? Why was it a rough landing? What was pushing them in? They thought it was the wind, but what was it?

Student: A sea serpent?

Teacher: The sea serpent was pushing them in and it made for a rough landing.

Effects on Opportunities for Student Participation

The combined effects of several characteristics of classroom discourse: teachers' monopoly over the introduction of conversation topics and access to the floor, teacher preferences for closed questions, and the use of I-R-E sequences, all may serve to limit opportunities for extended student participation. Student turns are short in many classroom contexts because student contributions function most often to ratify, rather than expand upon topics introduced by the teacher. Although the topics of classroom talk often call for decontextualized word choices and sentence patterns, very often student turns are grammatically incomplete because they respond to closed teacher questions that require only a yes/no or phrasal response (e.g., sodium, 1815, in Philadelphia, and sad). The goal of developing student thinking and mastery of content through talk is often subordinated to the more local goal of getting the right answer on the floor.

Socialization into Academic Registers

Classrooms present opportunities not only for learning academic content but also for learning how to talk about academic topics. Children begin school with discourse histories that reflect the norms and interactional practices of their families and communities. For some children, these include an expectation of close adult attention to child-initiated topics, considerable experience with holding the conversational floor, and experience of frequent encouragement from

adults to say more, to verbally elaborate on intentions, feelings, and beliefs. Not all cultures, however, view children as entitled to set the topics and take long turns in adult-child interaction. As a result, many children begin school with greater reticence in adult-dominated conversation and with less willingness to go beyond what is minimally required in adult-child exchanges. Children also start school with varying degrees of facility with the vocabulary and syntax of academic talk, including knowledge of verbs for talking about cognition (e.g., wonder, suppose, predict, and imagine), and understanding of academic vocabulary, for example, terms commonly used in primary schooling such as add, uppercase, government, and story character. These contrasts in children's preparation for engagement in academic talk often reflect differences in family social status, parental education levels, and cultural beliefs. Parents who have experienced success through the educational system seek, often unconsciously, to reproduce that success for their children through home-socialization strategies aimed at producing verbal responsivity and fluency within some of the adult-child questioning and responding routines that are characteristic of classrooms. Children from educated families enter school with experiences from family contexts like shared book reading and mealtime talk that position them to be highly responsive and confident in classroom discourse. Other children look for cues in classroom interaction on how to participate competently, often waiting for adult guidance and prompting.

Among the tasks that children face in learning how to engage in classroom talk in the early years (and that older students face at junctures in their education as well) include acquiring the vocabulary for particular academic subjects and learning to recognize the varied forms of participation that are required in response to different types of teacher questions: "Who can tell us something about penguins?" "How did you feel when the parents couldn't find Sylvester?" "Why do we need to regroup when we're adding 15 and 6?" To be successful participants, children need to know what content is relevant to particular academic contexts and the discourse shape this content should be presented in, for example, a request for a personal response to an event in a work of literature requires the expression of emotion state words (sad, worried) followed up by specific references to details in the literary work (his mom and dad walked right next to him and couldn't tell that he was there). Some teacher questions require fragmentary answers while others signal in subtle or more marked ways that more extended student responses are required.

Classroom Speech Events

Similar to talk outside of classrooms, classroom discourse is organized into speech events or subroutines that are set off from the flow of talk by movement into particular

settings: the book corner, the lab table, the rug, or by formal announcements, “It’s time for morning meeting.” Classroom speech events incorporate specific participants (the reading group members, lab partners, or the whole class) and specialized participant roles that children learn through participation: everyone will get a chance to speak, only one child speaks at a time, and a newsworthy contribution will merit an extended turn at speaking. Teachers use overt cues, “Let’s turn on our listening ears now,” and more implicit signals, for example, shifts in posture or eye gaze, to mark the initiation of specialized talk sequences. Classroom speech events typically follow a predictable sequence of moves, such as reciting names for attendance, doing a weather and calendar chart, and presenting personal news, the moves of a morning meeting speech event within many early childhood classrooms in the US. Moves within speech events also have differentiated rules governing access to speaking rights (going around the room one by one for attendance; raising hands to be selected to tell personal news) and moves have their own internal discourse structure, for example, the narrative forms required for telling personal news. The complexities of classroom speech events pose challenges to students at all stages of schooling; however, teacher talk provides support in acquiring the desired forms.

Modeling

One of the ways that teachers help children learn how to participate in classroom talk is through direct modeling of the desired response or response type. Teachers frequently answer their own questions in order to get some approximation of the sought-after response on the floor and to provide models for students of the kind of responses they are seeking. Teachers often effectively fill both slots, questioner and respondent, in the interactional sequence:

Teacher: What kind of a soup is it – how would you describe pea soup?

Student: Mmm. . . (shrugs)

Teacher: Hard to describe, huh? What does it look like?

Student: It’s like it’s a bunch of peas inside a pan with water.

→ Teacher: And the water’s called broth and broth is real, real thick. Have you ever had it? It’s a real thick – you know how some soups are almost watery?

Students: Yeah.

→ Teacher: Well this is real, real thick. And I want you to remember that cause that has something to do with why this story is called, “Pea Soup”.

Modeling is especially commonplace in classrooms for students who are second-language learners or speakers of nonstandard dialects. Teacher support through modeling

is also particularly common in classrooms where students are being introduced to new topics or initiated into new classroom speech events.

Scaffolding

Teachers use a wide range of scaffolding strategies to help students articulate the desired answers to the questions they pose. These include calling on another student (“Maybe Stephen can help.”), evaluating an answer as only partially correct (“Not quite.”), and providing concrete strategies for arriving at a better response (“Read to the end of the sentence.” “Look at the board.”). Scaffolding works towards the goal of having the student arrive at the correct answer and often forestalls a negative teacher evaluation.

Teacher: Okay. Right there, what does it mean, “. . .the helicopter descended?”

Student: Slowed down.

→ Teacher: Not quite.

Student: Stopped.

→ Teacher: Read to the end of the sentence.

Student: Oh, “came down”.

Recasts

Teachers also offer recasts or expansions of student responses that fall short of the desired answer. Frequently, these teacher moves repeat the student’s response, substituting more elaborate syntax, more precise vocabulary, or language specific to the academic subject:

Teacher: How would you get the answer?

Student: I would times it.

→ Teacher: So you times the two numbers, or multiply them to get the answer.

These moves juxtapose the learner’s response with a response that expresses the same content more formally, recasts are particularly effective in promoting acquisition of the vocabulary and syntax of academic language.

Learning Specialized Academic Registers

Teacher coaching and support are often needed as students begin to participate in talk within particular academic registers. The discourse of mathematics, for example, differs in many dimensions from the ways teachers and students talk about literature, even in the early years of schooling. Mathematics talk includes generalizations about the rules governing number relations and often presents hypothetical operations upon numbers. Talk about literature, on the other hand, incorporates elements of narration (e.g., descriptions of character actions and reactions) and values direct citation from the

literary text. Children learn that they are often called upon to relate a personal response or read a supporting passage during literature discussions, but virtually never are asked for these kinds of contributions during mathematics lessons.

In learning to talk in different ways during particular subject lessons, students begin to understand some of the ways of thinking that are characteristic of particular academic disciplines, for example, literary analysis' close attention to the text and mathematics' concern with the hypothetical and with logical proof and demonstration. These ways of thinking are embodied in language practices that are pervasive in classroom talk, even in the primary grades. The most successful teachers explicitly prompt students to produce discipline-specific talk and provide rich models and explanations of the language rules that operate within the disciplines.

Teacher Talk and Particular Populations

Classroom discourse research has been particularly helpful in elucidating language practices that both support and hinder the progress of particular groups of learners in schools. Second-language learners, speakers of nonstandard dialects, and girls, all face particular challenges in participating successfully in classroom talk.

Second-Language Learners

Schooling in a language of instruction that is not students' home language is common across the developing world and in communities with immigrant students in developed countries. In addition, in many countries, students from language minority communities are schooled in a national language such as English, Spanish, or Malay. Thus, many students must simultaneously acquire a new language in school and learn new academic vocabulary and discourse practices. Teachers whose students are still acquiring the language of instruction often simplify their talk and augment verbal exposition with gesture, demonstration, and illustration. Clarification sequences, where teachers use multiple interactional moves to clarify their meaning or their students' intended meaning, are commonplace in bilingual classrooms. Code-shifting and code-mixing, in which teachers and pupils alternate or mix languages within or across turns, are also common in second-language classrooms. Teachers and peers use code alternation both as a strategy for bridging or repairing communication gaps and as a social practice. Teachers who are themselves bilingual may present academic content in the national language but shift into a community language for greater clarity, for disciplinary exchanges ("¡Dámelo!"—Give it to me!), or to mark a boundary between whole class and private, off-the-record communication. Students

may read aloud in the official language but shift into the home language when offering commentary on the text. Such practices in second-language classrooms are natural extensions of the complexities of language use in multilingual communities and may in fact promote more rapid acquisition of the target language.

Speakers of Nonstandard Dialects

For students who are speakers of nonstandard dialects such as African-American vernacular English, classroom talk can be a productive context for acquiring a second, standard dialect or alternatively, a context for depreciation of community language norms. Although some teachers expect standard forms in all contexts of classroom communication, many teachers, particularly those working in language minority communities, hold differentiated expectations for the appropriateness of community dialects within different classroom speech contexts. These teacher expectations often mirror community beliefs about the appropriateness of dialect or standard language forms in particular contexts. For example, children may be corrected or prompted for use of the standard dialect when reading text aloud or in recitation contexts but may be allowed to use nonstandard forms in problem-solving groups and in private teacher–student exchanges. Classroom regulation of the use of nonstandard forms begins as early as preschool, through prompts like, "No street talk, Frankie," and accelerates as school-aged children acquire skills in two dialects and develop sensitivities to the social contexts that are intertwined with dialect variation.

Children's dialect patterns often extend beyond nonstandard word choices and syntactic constructions although these sentence-level differences with the standard dialect are especially likely to be targets of teacher corrections and recasts. Particularly complex and potentially problematic in classrooms are dialect patterns that affect discourse organization and participation roles, such as preferences for overlapping turns at talking, extended silences after teacher questions, or topical chaining in narrative discourse. When teachers and students do not share discourse styles, the task of acquiring skill within academic registers is particularly difficult. Teachers may interpret students' discourse patterns as signs of defiance, academic inadequacy, or failure to understand classroom-speaking rules. If there is little teacher awareness of differences in the discourse rules between the school's language and the language of many students, classroom discourse may be experienced as a context for failure, misunderstanding, or shaming.

Gender and Participation

The participation of girls and women in classrooms has been the focus of special investigation. In gender-mixed

classrooms, particularly at the secondary level, boys often volunteer to speak more readily than their female classmates and hold the floor longer when they are called on to contribute. Girls engage in more hedging in their contributions, diminishing their degree of commitment to the points they are presenting through verbal downgraders, such as “kinda,” “maybe,” “I think,” and through question intonation when they make statements. Male students have been observed engaging in more floor competition, overlapping a classmate’s turn before he or she is done speaking, and calling out answers even when the teacher is using a nomination strategy to select the next speaker turn. Although girls’ language development is often in advance of male classmates’, the rules of classroom engagement do not necessarily favor girls’ development. In fact, boys often occupy a middle position in the classroom social hierarchy, taking on some of the roles that are reserved for teachers when they produce longer floor-holding turns, carry on side conversations, and challenge classmates for control of the conversational floor.

Conclusion/Evaluation

Classroom talk serves as a critical context for the acquisition of more sophisticated language skills and for children’s socialization of academic identities. As early as preschool, children learn through contexts like classroom sharing time and morning meeting to participate in talk about physically and temporally absent topics: our family’s weekend events, yesterday’s weather, my pet. Different from many home contexts for extended discourse, the audience for such talk – peers and teachers – may lack first-hand knowledge of the entities that the child is talking about. Thus, classroom communication creates an essential motivation for learning to be clearer and more explicit than is typically required of children as they participate in everyday family talk.

The topics of classroom communication often draw upon children’s most advanced vocabulary and cognitive skills and require that children use newly acquired metacognitive verbs and complex syntax: conditional, subjunctive, and embedded clauses. Teachers (and sometimes peers) are often demanding as communicative partners, pushing for greater clarity and elaboration, and providing models for the use of academic vocabulary and sophisticated sentence structures. For children who speak other languages or dialects at home, classroom talk provides especially rich opportunities for language learning, although these opportunities may be blunted by failure to respect and include a role for the home language or dialect in school.

Although the field of classroom discourse began with critiques of the inauthentic character of much classroom talk and was accompanied by skepticism about classrooms

as environments for language learning, research of the past 15 years has demonstrated that many aspects of classroom talk support language learning and cognitive development. Teacher roles in modeling academic language and scaffolding effective contributions appear in the light of contemporary research to be much more positive than was suggested by earlier commentary. Teachers often use knowledge of the learner’s current stage of development to offer prompts that press for expression of the learner’s best understandings. Although the strategies teachers employ are inauthentic when compared to many adult roles in everyday conversational exchanges, teacher talk is often well adapted to the cognitive and interpersonal purposes of the classroom. Student-participation slots are often constrained and limited in classroom talk, but the simplification and orchestration of student contributions support an ability to focus on content and on precision of expression.

Early Writing

B E Hagtvet, University of Oslo, Oslo, Norway

Writing as a Multimodal Phenomenon

An increasing awareness, during the 1970s, with regard to preschool children's literacy learning led to a growing body of research on early writing during the last part of the twentieth century. These studies complemented the work of pioneers Montessori (1971), Luria (1978), and Vygotsky (1978). They also marked a new era in literacy research – by highlighting how literacy emerges during preschool and early schooling, and by emphasizing children's early writing as an interdisciplinary field with great educational implications.

Writing is a social practice – an act of communication that uses script to compose messages. Similar to reading, writing basically consists of two skills: the ability to use a notational system (i.e., the alphabetic code) and the ability to handle word messages. Over the past decades, research on early writing has been prolific – covering the development of graphic script as well as the skills needed to write down verbal messages. There has also been a focus on linguistic and cognitive knowledge in the interface between oral and written modalities. For example, studies of the emerging notational system, of how early scribbling is transformed into letters via drawings and various graphic symbols, have shed light on the development of children's understanding of language as a system, and on the relationships between phonemes and graphemes. The research has also examined differences between drawing and writing and between signs and letters, as well as how older preschoolers and young school children tackle orthographic spelling and spelling rules. Furthermore, researchers have focused on the process of constructing verbal messages, on how children act, speak, and interact while transforming speech into written script. There have been studies of how children make use of pencils, computers, and toys in writing, and of how written language learning is culturally embedded with the script mediated by significant adults and peers in the child's environment.

Research on early writing has drawn attention to not only the understanding of emerging literacy, but also to the importance of the preschool years in literacy learning. In defining early literacy, there is no need to make a strong distinction about the point in time that children start formal writing instruction at school. Children – around the world – start school at different ages, and different school systems emphasize formal introduction to literacy differently. Thus, the term early writing is defined here more pragmatically as the period prior to a child mastering the conventional writing system with a certain consistency.

Disciplinary and Theoretical Roots

Prior to the 1970s, the idea of early writing was mainly associated with writing as a motor activity or with early spelling using alphabetic script. In some cases, it was also associated with the skills of young fluent readers, that is, children who taught themselves to read and write prior to formal schooling (Clark, 1976). Only in rare cases was early writing seen as an integral part of developmental theory – first and foremost by Luria and Vygotsky. The research was typically anecdotal and conducted in natural settings at home and in school.

In the 1970s, there was a major shift toward a broader concept of writing. The concept of emergent literacy was coined – reflecting an interest in the study of how literacy emerges during the preschool years. Writing was now more often studied ethnographically by focusing writing practices in different contexts: in nursery school, in collaborative play, or in informal situations in children's homes (Clay, 1975; Teale and Sulzby, 1986). In addition, children's creative spellings, that is, how children come to terms with the alphabetic and orthographic rules of the notational system by child-driven explorations, was focused upon (Read, 1986; Treiman, 1993).

Generally, the development of writing skills has been studied from four main perspectives (Tolchinsky, 2004):

1. The sociocultural approach originated in the early work of Vygotsky (1978) and Luria (1978). Focusing on written language as tools of linguistic and cognitive change in the development of the individual, their work contributed to moving the study of early writing to the scientific arena of higher-order psychological functions. In a literate society, a child is surrounded by print that is brought to the child by adults and more competent peers mediating the written language. These ideas of Vygotsky's about mediated learning have inspired much modern pedagogy, for example, that writing skills are learned while children collaborate and interact verbally with adults or more competent peers, and that tools (artifacts) such as words, pencils, lap tops, and symbolic toys are crucial mediating elements. Moreover, they have vitalized research on how children construct ideas about written language via writing practices, through collaborative writing, children's think alouds, and verbal dialogs during writing.
2. The psychogenetic approach dates back to the theoretical and methodological work of J. Piaget and was recreated in the field of early writing by the groundbreaking work of

E. Ferreiro and her collaborators (e.g., Ferreiro and Teberosky, 1983). With a constructivist point of departure, this strand of research focuses on how children achieve mastery of the script by exploring and experimenting with the script as an object. Children reconstruct the conventions of written language through processes of assimilation and accommodation (see this). They build hypotheses about connections between oral and written language that are not idiosyncratic but developmentally ordered. By making use of controlled tasks in combination with clinical interviews, researchers within this line of research have shed light on how children's growing knowledge of literacy may be described in terms of developmental stages and how each stage reflects a dominant or favored strategy of writing.

3. The emergent literacy approach typically involves ethnographic researchers studying how literacy emerges during the writing process in classrooms and families in various cultures and social contexts. A primary concern is how children's emergent graphic signs are influenced by their interaction with parents or peers, or by their talking to themselves during the writing process, and how drawing, talking, and writing interact during the writing process (e.g., Bissex, 1980; Clay, 1975; Dyson, 1989; Teale and Sulzby, 1986). Often influenced by sociocultural theory of learning, researchers within this line of research have highlighted phenomena such as children's self-regulatory speech during writing, scaffolding interactions, writing conferences, etc. (e.g., Graves, 1983). However, ethnographic researchers have expanded this paradigm by focusing more broadly on literacy events, that is, on learning to write as an event with specific purposes that are culturally defined by certain ways of relating to other participants and by expected text topics and structures, such as how children (and adults) collaborate in composing a letter or a story (Heath, 1983). Shedding light on cultural variations and on the importance to literacy of both family literacy and classroom practices, this strand of research has had great implications for educational practice, for example, in the ramifications of terminology such as classroom events.
4. Approaches focusing on invented spelling typically concentrate on the product and process of writing in a more restrictive sense than the above-mentioned approaches. Spelling is seen as one component of writing (Treiman and Cassar, 1996) and concerns the ability to write words in accordance with orthographic rules. In line with this narrow definition, the term invented spelling regards child-driven activities, referring to the children's own experimentation with meaningful links and with connections between spoken and written language (Read, 1986). Many will side with Richgels' (1995: 99) definition of invented spelling as children's ability to "sound units in words and associate letters with those units in a systematic though

non-conventional way before being taught to spell or read." However, the term is also used with broader meanings (Saada-Robert, 2004), blurring its distinction from terms such as invented or emergent writing. Invented spelling typically regards a later developmental period, when the child experiments with the conventional notational system, that is, the alphabetic system, while invented writing typically refers to a larger developmental period including also pre-alphabetic periods. Important issues relating to research on invented spelling in the last 20–30 years include: the role of phonology and morphology in early spelling, the development of spelling, including the roles of logos, children's names, and letter naming in children's creative attempts to break the alphabetic code. More recently, there have been comparative studies of how orthographic systems influence early spellings (Nunes and Hatamo, 2004).

Within each of these approaches, there are large variations, and the distinguishing criteria are more pragmatic than logical. The four approaches have inspired researchers theoretically and methodologically. In practice, research projects transcend theories and methodologies. For example, while the process of writing within a sociocultural paradigm is commonly studied by ethnographic methodology (observation, interviews, etc.), semi-structured, test-oriented methods associated with the microgenetic approach of the Piagetian constructivist paradigm are also used. While invented spelling is quite often studied by test-oriented procedures, for example, dictation of single words over time, it may also be studied ethnographically via spontaneous writing of informal notes.

Stages of Early-Writing Development

Despite differences associated with specific characteristics of scripts and languages across orthographies and cultures, certain universal periods or stages of writing skills may be revealed, for example, in Hebrew (Levin and Landsmann, 1987), Italian (Pontecorvo and Zuccheromaglio, 1989), Spanish (Ferreiro and Teberosky, 1983), English (Clay, 1975), German (Brügelmann, 1999; Valtin, 1997), French (Jaffré and David, 1998), Norwegian (Elsness, 2001; Hagtvet, 2003), and Swedish (Liberg, 1993). These developmental periods share similarities with Piagetian stages to the effect that the strategies used by children at each stage determine the characteristics of that particular stage. However, this does not imply that the individual child makes consistent use of one strategy at the time. Rather, a child typically makes use of multiple strategies cutting across different stages, so the borders between stages are variable. Nevertheless, at a specific point in time, there appears to be a domination in a child's preference for one specific strategy, even though it may be used inconsistently.

So, a developmental stage is a period when there is a domination of a specific strategy.

Stages of early writing have been described using various terminologies depending on the focus of study and classification criteria for a stage. The basis for the developmental description below is a combined set of criteria reflecting qualities associated with the process and the product of writing (Hagtvet, 1989, 2003).

Prephonetic writing

In prephonetic writing, the graphic signs do not refer to phonetic entities in the child's speech. They reflect a weak awareness about the linguistic segments that constitute sentences (words, syllables, and phonemes). Serving a multitude of functions, prephonetic writing has been operationalized differently, depending on the perspective taken by the researcher and on the focus of study, for example, pretend writing, preliterate spelling (Henderson and Templeton, 1986), visual writing (Valtin, 1997), and precommunicative writing (Ellis, 1997). It is often produced as an imitation of adult writing or in symbolic play (pretend writing). Written from memory, the graphic signs are visual renderings of reality (visual writing) – often with an unfocused intention of communicating (precommunicative). However, even young children typically intend to communicate when writing. Therefore, the term precommunicative does not necessarily capture the essence of this early stage.

Children's early drawings and scripts symbolize referents, and drawing is seen as a precursor of scripts. According to Vygotsky: "... A child's memory does not yield a simple depiction of representational images at this age. ... A major feature of this mode is a certain degree of abstraction, which any verbal representation necessarily entails. ... drawing is graphic speech that arises on the basis of verbal speech. This gives us reasons for regarding children's drawing as a preliminary stage in the development of written language" (Vygotsky, 1978: 112–113). A big leap in development takes place when children come to understand that graphic signs can represent objects or events, for example, big circles, much text, or large letters refer to big, many, or long objects (Ferreiro and Teberosky, 1983).

Three different types of scripts are typically seen during this prephonetic stage reflecting different sub-stages or subperiods:

Scribbling and symbols with no similarity with letters

This form has also been labeled figurative writing (Valtin, 1997) alluding to the symbolic and imaginative nature of early script. Its relation to the referent is initially imprecise reflecting a weak understanding of the relationships between segments of speech and graphic scripts. At an early age (typically before age 3), scribbling is not differentiated from drawing. It is performed

rather arbitrarily – similar to an imitation of the writing movement observed in adults and for a purpose that appears to be an accompaniment to speech. Somewhat later, the scribbling becomes loaded with meaning – as observed when children follow their text with eyes and fingertips while reading their newly written text (Sulzby, 1986). Slowly, the graphic signs take on a more advanced, symbolic content – representing a more conscious and verbalized interpretation of things and events in the real world (around age 4). This is illustrated in **Figure 1** Leonard, age 3.4, has been asked to draw a picture, to write what he has drawn, and to write his name. Leonard's reading of his texts indicates that he differentiates between his drawing ("many big snakes"), his writing of the word snake, and his name (Leo). Four months previously, he did not know the difference between drawing and writing, and when asked to write his name, he said he did not know how to.

Letters in rows that represent words

When letters are written more or less randomly on the page, children typically remember and experiment with the form of the letters, but without phonetic awareness.

Figure 1 Leonard, age 3.4 draws and writes. From Hagtvet, B. E. (2003). *Språkstimulering. Tale og skrift i førskolealderen.* (Language stimulation. Speech and literacy before school age.) Oslo: Cappelen Akademisk.

Copying letters as pictures (sometimes from memory), this strategy has also been termed visual or logographic. **Figure 2** illustrates how letters may be used as pictures in a row when writing a Christmas card.

Global writing

When words are written as word pictures, the graphic scripts may be labeled global writing. Based on visual memory, this form of writing is still logographic. Own names and names of friends and family members are common among early words written by young children, but logos read on signs and posters (e.g., MILK, SHELL, and COKE) are also typical. This early writing of names commonly sets the stage for alphabetic exploration. Because these early names and word pictures are familiar and well-known in content – and, in most cases, emotionally important – they commonly act as catalysts for active and self-driven identification of phonemes in words. Slowly, children who regularly explore letter-sound relations in word pictures discover the alphabetic principle while writing.

Semiphonemic writing

Semiphonemic writing makes use of a phonetic strategy, but in a phonemically imprecise way: the child signals an awareness of the relationship between the phonological system and the script by means of graphic signs, pretend letters, or letters. An early phase of this developmental pattern is illustrated in **Figure 3** where Helene has written the sentence, *Helene liker is* (Helene likes ice cream). When reading the sentence, she underlines the syllabic pattern and rhythm of the sentence by means of voice punctuations and by tapping her finger tip on the relevant parts of the text revealing an awareness of the correspondence between word length and length of text: "He-le-ne li-ker is".

The discovery that different marks or signs in the text represent different aspects of speech (usually around

ages 3–4) is seen by Vygotsky as a shift in the development of written language from drawing things to drawing speech. From then on, spoken language disappears as the intermediate link between the world and the text, and written language slowly becomes as directly perceived as spoken language.

When letters are used in the semiphonemic stage, they are not copies of letters as pictures like they are in the prephonetic stage. Letters now represent sound patterns (sentences, words, onset, rhymes, and syllables) or language sounds (phonemes), and they now have a functional meaning to the child: they are used as building blocks in making word messages.

The writing of language sounds (phonemes) is a late phase in the semiphonemic stage. From then on, the writing becomes more and more phonemically oriented. First, the most prominent phoneme in the word is written down; each phoneme typically representing a larger unit of phonemes, for example, HS for house. The omission of vowels is a typical characteristic, as is the incorrect sequencing of phonemes or mirror imaging of words, for example SKRM for Markus.

Many children depend on letter naming during this early phonemic writing, for example, MSE (mess) or HLP (help) (Treiman and Cassar, 1997). However, this strategy may also be a barrier to proper phonemic writing by making the vowels less visible, which may explain why vowels are commonly omitted during this stage, for example, KM (come).

Phonemic writing

During the phonemic stage, children can identify phonemes in words, combine them with relevant graphemes, and write the graphemes in correct sequence. In early phonemic writing, children typically write as they say, tending to use this strategy systematically without

Figure 2 Experimenting with letters when writing a Christmas card, Christoffer, age 5.8. From Hagtvet, B. E. (2003). *Språkstimulering. Tale og skrift i førskolealderen*. (Language stimulation. Speech and literacy before school age.) Oslo: Cappelen Akademisk.

Figure 3 Syllabic writing, Helene, age 4.0.

orthographic information or spelling rules. This can yield charming examples such as RUDF? (Are you deaf?) (Bissex, 1980). They understand the alphabetic principle, but apply it orthodoxically phonemically . . .

Analyses of how early phonemic writing deviates from the adult norm have revealed that children's errors are quite logical. Children appear to actively construct a system of spelling patterns in accordance with the logic provided by their current level of skills. For this reason, it has been argued that spelling errors are windows into the child's written-language awareness, that is, to the systemic understanding of how the phonological structure of language matches the graphic structure of the script (Read, 1986).

Writing with conventional orthography

Increased experience with phonemic writing typically triggers children's interest in text and an acceleration of reading activities. This, in turn, generates an increased familiarity and awareness of the orthographic system and facilitates the inclusion of orthographic patterns in their writing (Treiman, 1994). The phonemic writing is then transformed into an orthographically driven process where orthographic representations are coordinated with phonological strategy. Jaffré and David (1998) see this developmental span from phonemic to orthographic spelling as two sub-phases, the first being a second logographic phase (in contrast to the logographic or visual phase described above). This is a phase where phonographic and morphological knowledge becomes integrated. Morphological knowledge is inherent in the orthographic system; it is based on rules and semantic insights. The second phase is the final orthographic phase.

The increasing awareness that the same sound can be spelled in one way when it represents one morpheme or has one grammatical meaning and in another way when it represents other ones, is demonstrated by children's unconventional or invented spellings (Read, 1986; Treiman, 1993). Children's spellings of regular past tense in English are good illustrations of this: the morphological rule being that past verbs end in -ed. In a longitudinal study of English children (Nunes *et al.*, 1997), children around age 6 ignored this ending and wrote past tense phonetically, for example, KIST for kissed. This was followed by an intermediate period when the children tended to avoid the -ed ending. Then, they used it too often, including non-verbs and irregular past verbs – in addition to some, but far from all, regular verbs. This phase is illustrated by the spellings of a boy aged 7.5 years: DRESD (dressed), FILLD (filled), SLEPED (slept), SOLED (sold), NECSED (next), and SOFED (soft). Following this period of overgeneralization, the children used the past tense with past verbs only, finally restricting its use to regular past tense verbs (Bryant and Nunes, 2004).

Individual Variations

Universality of stages

The extent to which these stages (prephonetic, semiphonemic, phonemic, and orthographic) are universal is debatable. Differences in language, culture, and school systems, no doubt, affect development. Literacy varies in importance and emphasis in different cultures (Heath, 1983). However, evidence suggests that despite cultural diversity, children in literate societies go through the same stages, but at a different pace (see above). Generally, there appear to be surprisingly many commonalities across cultures, languages, and orthographies.

In addition, there are similarities in the onset of literacy development. It has been observed that the integration of scripts in children's drawings is suggestive of an increased interest in the written language on the part of the child. The universality of this observation, at least within the Western hemisphere, is illustrated in **Figure 4** where drawings by two girls age 5.4 are presented. Nicola grew up in New Zealand in the early 1970s while Benedicte grew up in Norway in the early part of this millennium. Nicola started school at age 5, while Benedicte started at age 7. Despite these differences of time and culture, their approach to early writing is surprisingly similar – in particular, in the style of their drawings and in their writing as an integral part of their drawing.

Variations within cultures

Despite general similarities, there are also noticeable differences – such as in the differences between boys and girls. Boys are often reported by their nursery school teachers to be less interested in paper-and-pencil activities than girls are. However, this may be an effect of the task more than biological differences. When encouraged to write on topics that appeal to them and allowed to make use of their own script, boys quite often produce more imaginative and detailed writing and drawings than girls do (Hagtvet, 2003). This is illustrated in **Figure 5** where Carl, age 5.3 has drawn a picture of the lives of sea animals and made up an explanatory text.

Girls appear generally less oriented toward details and events in the real world in their early writing. They are more inclined to tell stories about people, often inspired by fairy tales, such as tales about the prince and the princess, or a girl below a blue sky with a yellow sun as in **Figure 6**.

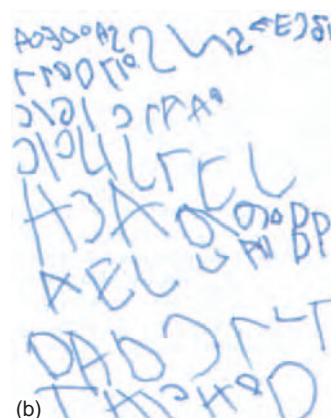

Carl and Melanie (Clare) approach the writing task differently, yet it is hard to rate one above the other. There are intragender differences as well. However, the gender differences in early writing are so striking that they invite more research attention – in particular, because boys tend to fall increasingly behind girls in literacy skills, according to recent international comparative studies (Programme for International Student Assessment (PISA)). Careful studies

Nicola, aged 5.4

Figure 4 Integrating scripts in drawings, Nicola, age 5.4 (New Zealand) and Benedicte (Norway), age 5.5. (a) Adapted from Clay, M. M. (1975). *What Did I Write? Beginning writing behaviour*. Heinemann: Auckland. (b) Adapted from Hagtvet, B. E. (2003). *Språkstimulering. Tale og skrift i førskolealderen*. (Language stimulation. Speech and literacy before school age.) Oslo: Cappelen Akademisk.

Carl, 5.3 år leser:
Der står haiene og der delfinene
og der står de derre bena
og så de derre bollene
også de der reunde ballene
også den gule ballen
også de små lekene
og regn og stener og pinner
og en til
kongler og pinner

(b)

Carl, 5.3 years reads while pointing:

It says the sharks and it says the dolphins
and it says those odd feet
and then those balls
and the yellow ball
and the small toys
and rain and stones and sticks
and one more
cones and pins

(c)

Figure 6 Melanie, age 5.0: A girl's drawing and text. Text showing the child's reading of written text: "She was about to marry. She went out to pick flowers." From Hagtvét, B. E. (2003). *Språkstimulering. Tale og skrift i førskolealderen*. (Language stimulation. Speech and literacy before school age.) Oslo: Cappelen Akademisk.

of the importance of early writing for continued motivation for reading and writing appears to be a promising line of research.

Variations across languages

During the last 10 years, studies of literacy across languages have been a major focus of research (e.g., Joshi and Aaron, 2006; Perfetti *et al.*, 1997). In learning to spell orthographically, children are challenged differently by different orthographies. The closer the orthographic system depicts the pattern of pronunciation, the smoother is the road to mastery of conventional orthographic spelling (Wimmer and Landerl, 1997). For example, children learning to spell in languages with many written markers that have no corresponding pronunciation tend to be slow in conquering these silent orthographic patterns. This was demonstrated in French speaking children who typically learn to spell the silent endings in nouns, verbs, and adjectives rather slowly (Fayol *et al.*, 1999). On the other hand, even dyslexic Norwegian-speaking children making

use of a semi-structured orthography achieved mastery of regularly spelt words quite easily while irregularly spelled words were more difficult (Hagtvét and Lyster, 2003).

Summary

In conclusion, the pace and ways at which children come to terms with alphabetic and later orthographic writing reflects biological maturation as well as differences in languages, culture, and educational practice. When encouraged to write, children typically start writing once they know how to hold a pencil or use a computer, and literacy development is further supported by intervention means. Recent studies have shown that the quality of maternal mediation of children's writing in kindergarten affects children's literacy scores 2 years later (Aram and Levin, 2004). In addition, teaching of morphological rules to deaf children with spatially based sign language as mother tongue improved their orthographical spelling of

English (Burman and Pretzlik, 2004). These are examples underscoring the importance of active mediation to early writing. Mastery of orthographic spelling and skills in constructing word messages in different genres is typically achieved following several years of schooling, but for some children – for example, for dyslexic or deaf children – this is a continuous struggle.

Glossary

Affix – It is an element appended to a root word form, which may convey grammatical information (e.g., plural, past tense) or lexical information (e.g., un-, re-).

Dative sentence – It is a sentence form in which the normal sequence of direct object and indirect object has been inverted (e.g., I gave the present to the girl → I gave the girl the present).

Figurative language – It refers to the nonliteral use of language (e.g., a cold woman).

Finiteness – It is an attribute of verb forms that convey person, tense, number, and mood (e.g., he runs).

Formants – They are concentrations of acoustic energy caused by the resonant properties of the vocal tract that are particularly critical for distinguishing among vowels in a language.

Indirect language – They are linguistic forms that do not directly convey intended meaning, such as use of “it’s hot in here” to request that someone open a window.

Inflection – It refers to a grammatical affix.

Metalinguistic ability – It is the ability to use language to talk about the characteristics and use of language.

Morpheme/morphology – A morpheme is the smallest meaningful unit in a language, for example, words and affixes; morphology is the study of word structure.

Over-extension – It is the use of a word to refer to a larger category of referents than is appropriate, for example, calling all four-legged creatures doggie.

Passive sentence – It is a sentence form in which the order of subject and object are inverted, as in John(s) loves Mary(o) → Mary is loved by John.

Phonemic awareness – It refers to the ability to appreciate the fact that spoken words are composed of individual sounds (phonemes).

Phoneme/Phonology – A phoneme is a minimally contrastive sound in a language; phonology is the study of the sound system of a language.

Phonotactics – It refers to the permissible ordering of phonemes within a language.

Pragmatics – It is the study of language use in socially appropriate ways, which may vary with context, addressee, and other factors.

Pronominal reference – It refers to the use of pronouns to refer back to previously mentioned nouns or concepts (also called anaphora or anaphoric reference).

Segmental/supra-segmental – It is the distinction between information conveyed by sounds and words (segments) and prosodic characteristics such as intonation, volume, and stress that may extend over more than one segment.

Semantics – It is the study of meaning.

Specific language impairment – It is a developmental disorder in which comprehension and use of language is below age-expectations, in the absence of observable deficits in intellectual, hearing, or motor function.

Syntax – It is the study of sentence structure and grammatical morphology.

Vocabulary burst – It refers to a stage early in children’s vocabulary development during which words are learned at a very rapid pace.

The Nature of Human Language

Human languages are distinct from animal communication systems in a wide variety of ways. Among them are infinite creativity (the ability for speakers and hearers to produce and understand an infinite variety of utterances), their symbolic nature (the arbitrary relationships among words, utterances, and the concepts to which they refer), and hierarchical organization, which allows a number of levels of rules governing appropriate structure and use (see Fromkin *et al.*, 2007).

Within any language, there is a set of rules that governs appropriate use of sounds, words, grammar, and meaning. Moreover, competent language users must also master socially appropriate means of conveying and interpreting linguistic messages. Briefly, these subsystems of language knowledge consist of phonology, morphology, syntax, semantics, and pragmatics.

Phonological features of any given language specify its sound inventory (phonemes) as well as ways in which sounds may be legally combined to create well-formed words (phonotactics). The smallest units of language that convey meaning or grammatical distinctions are morphemes; for example, in English, a word such as *cats*

consists of one lexical morpheme, *cat*, which can stand alone, and one grammatical morpheme to signal the plural. Languages have large numbers of lexical (or open class) morphemes, and a much smaller and delimited number of grammatical morphemes (closed class), which may stand alone (such as *the* or *can*), or must be attached to lexical morphemes (such as the plural, past tense, possessive, etc.).

Mastery of syntax requires appropriate use of morphology as well as any rules governing the ordering of elements in sentences and their smaller constituents, such as noun and verb phrases. Some languages, such as Finnish, permit fairly free word order, while others are highly constrained. In addition, languages may differ in basic word order; for example, English tends to employ subject–verb–object as its canonical ordering, while the Philippine language Tagalog is primarily verb–subject–object.

Meaning in language can be conveyed by the meanings of individual words (as in knowing what the word *chair* refers to), as well as the order in which words are combined to reflect themes such as subject and object (most readers will readily appreciate that “John loves Mary” does not necessarily mean that “Mary loves John”). Finally, the meanings of sentences often go beyond the strict interpretation of their words and syntax. Pragmatic intent is obtained by evaluation of the sentence within a context to ascertain its function within conversation – whether one’s objective is to inform, warn, request action, etc., as might variously be the case in hearing someone say, “It’s late.” All of these rule systems must be adequately mastered in order for the child to function as a capable speaker–hearer of a language.

Techniques in Understanding Language Development

Facts about the typical milestones in language acquisition are obtained from a variety of sources. Historically, diary data and small, longitudinal studies offered the first insights into stages and strategies in child language development. This tradition has been continued with the broad use of open access data archives such as the Child Language Data Exchange System (CHILDES, <http://childes.psy.cmu.edu>) by developmental psycholinguists to investigate new questions about children’s behaviors using existing data from a broad variety of languages and populations.

Observational data are augmented by experimental or quasi-experimental studies in which production or comprehension of various language targets is elicited. More recently, the use of electrophysiological measures, such as event-related potentials (ERPs), eye tracking, and functional magnetic resonance imaging (fMRI), have

enabled researchers to explore the underlying substrates of infant and child linguistic performance (Karmiloff and Karmiloff-Smith, 2001).

Milestones in Speech and Language Development

Despite some degree of individual variation in timing and sequencing of the development of specific linguistic abilities, there is considerable uniformity in children’s language development. This predictability in sequencing permits educators and other professionals working with infants and children to apply developmental expectations to assessment and, if necessary, intervene with children not meeting typical pacing or sequencing of skill development (Oller *et al.*, 2006). Knowledge of typical developmental milestones also permits educators to construct appropriate curricular goals and strategies for all activities involving language and reading which build upon earlier linguistic skill development.

Pre-Linguistic Achievements

Language learning begins right from the womb. There is evidence that a fetus can be conditioned to recognize the rhythm and cadence of stories repeatedly read aloud in the last trimester of pregnancy; shortly after birth, use of non-nutritive sucking paradigms show that babies demonstrate a marked preference for the voices of their own mothers, and samples of conversational speech in their own language, rather than a foreign language or dialect.

In early infancy, babies show a capacity to distinguish linguistic contrasts used by all the world’s languages, rather than merely their own. For example, they can distinguish contrasts in voicing, place, and manner of consonants, as well as between vowels very similar in formant characteristics. However, by approximately 10 months of age, such discrimination ability wanes, as the infant begins to narrow contrasts to those used by his or her native language. Concurrently, their expressive babble begins to reflect segmental (sound) and supra-segmental (prosodic) characteristics of the ambient language or languages to which they are exposed.

Use of a number of laboratory paradigms has shown that the very young infant is able to begin to discriminate individual words within the conversational speech stream, as well as features within utterances that signal possible word boundaries, an important skill that will enable the child to begin to map early vocabulary and grammar. This ability to segment the speech signal is critical because even infant-directed speech typically takes the form of multiword sentences, with few words produced in isolation. Some milestones in segmentation skills occur relatively early. For example, typically developing infants

usually can discriminate their own names from similar-sounding foils, even in noise, by 4 months of age, while children later diagnosed with developmental language disorders may not show such ability. By 7–8 months of age, if an infant is familiarized with a novel word in isolation, she will listen longer to short spoken passages containing that word, and the inverse is also true. This discrimination is quite precise, and infants will not falsely respond to words that are similar, but differ by only one speech sound. Segmentation is not an all-or-none skill, and appears to rely on development of sensitivity to certain language-specific cues, such as the typical stress patterns within words and among words in sentences, as well as more general statistical regularities (such as co-occurrences of sounds or syllables). Word discovery progressively enables further and finer segmentation of elements in input, creating a circular relationship between segmentation and lexical development, with segmentation skill leading to enhanced word-learning, which in turn improves segmentation skill and future word learning.

Speech segmentation abilities may be quite delayed in children with identifiable syndromes known to be accompanied by significant cognitive and linguistic deficits, supporting the idea that segmentation may be a necessary precursor to normal language development. Infants who appear to be developing normally but fail to show typical segmentation abilities have significantly poorer language outcomes than infants who succeed in these tasks.

Production and Understanding Prior to First Words

Infant babble and conversational turn taking during vocal interactions with caretakers increasingly reflect the typically developing child's knowledge of both the shape of the ambient language as well as pragmatically appropriate eye gaze and gestures; these patterns appear to be mutually reinforcing, with more vocal children typically receiving a greater degree of conversational input from their caretakers. Failure for infants to develop appropriate eye-contact, reciprocal vocalization patterns, and gesture may be an early indicator of developmental delay, particularly autism spectrum disorder.

Typical early babble uses prosodic features of the language to convey pragmatic intent, such as requesting, notice, or displeasure, well before actual identifiable words are used for such functions; this pattern of vocalization is sometimes called jargon. By about 10 months of age, many infants will have developed proto-words, phonetically consistent forms that are regularly used to convey a particular message.

At about this same age, an important change occurs in infants' social cognition. They begin to intuit other people's thoughts, desires, and goals (sometimes called a theory of mind). They follow the direction of a point

(unlike animals, who will simply fixate on the hand doing the pointing), and will begin to follow others' gaze to an object or action of interest. Both behaviors signal the infant's ability to engage in joint attention. The pattern of responsiveness by both infants and adults is important to the rate of language development; inability of the infant to engage in joint attention is a marker of developmental delay, while the adult's ability to discern the infant's interest in objects or activities and comment on them contingently and responsively has been linked to more rapid achievement of early linguistic milestones.

The Nature of Early Word Production and Comprehension

Well before the production of first recognizable words of the language, usually at 12–15 months of age, infants use their segmentation skills to construct a fairly broad receptive vocabulary that can be assessed using parental report inventories. First words are usually not pronounced in an adult-like fashion, but are used consistently to convey intent. Across most languages that have been observed, first words are highly likely to be names of objects or people (a preference for nouns) that they actively interact with (rather than being merely the most frequently used word in a language), but individual children may show a preference for more conversational vocalizations, such as greetings, or terms used in play with adults. Semantic representation of first words is likely to be under-specified, leading to over-extension, in which words are applied to an overly broad category of referents (e.g., *doggie* for many additional types of four-legged, furry animals). However, word learning is governed by a number of principles that seem quite uniquely human, such as a tendency to associate labels with the entirety of a reference, rather than one of its component features, and the presumption that new words refer to novel, rather than known, referents.

Infants and toddlers comprehend more words than they tend to produce, and show good evidence of understanding general rules of syntax (such as preferred word order of the language, signaling the difference between "Big Bird pushes Ernie" and "Ernie pushes Big Bird") in laboratory tasks well before they produce multi-word utterances themselves. By 2 years of age, the typically developing child will have achieved at least a 50-word expressive vocabulary (the average is approximately 200) and begin to combine words into two-word utterances. Children who have failed to reach this stage by 24 months are significantly at risk for a variety of communicative disorders, although a substantial proportion of late talkers do appear to recover and later function within the normal range.

Early two- and three-word utterances are likely to lack appropriate grammatical affixes in a language such as

English, in which they are relatively sparse. Acquisition of the relatively closed set of grammatical morphemes in English has been tracked extensively, beginning with Roger Brown and his colleagues at Harvard in the early 1960s, and it follows a relatively consistent order and trajectory (see **Table 1**).

Classic studies, such as that conducted by Jean Berko in the late 1950s demonstrate that the learning of these morphemes represents abstraction and generalization of rules which can be extended to novel exemplars (see **Figure 1**) and even mis-applied to exceptional forms

Table 1 Typical order of acquisition for 14 common English morphemes

Morpheme	Example
Present progressive	Baby crying
Prepositions in/on	Cookie on table; Mommy in car
Regular plural	Cats, dogs, dishes
Past irregular (learned as lexical items)	Early examples: came, fell, broke, sat, went
Possessive	Daddy's car
Uncontractible copula	Eve is girl
Articles (a, the)	See the kitty, Give a cookie
Past regular	Hugged, kissed, patted, cried
Third person regular	Boy runs, doggie barks
Third person irregular	He does/has it
Uncontractible auxiliary	I am going.
Contractible copula	What's that
Contractible auxiliary	Puppy's eating

Mastery may span from 1 year and 6 months to 4 years in typically developing children.
Adapted from Brown (1973).

Figure 1 The Wug test.

(e.g., when a child says *foots* or *wented*), rather than rote memorization of items the child has overheard. Among the most difficult morphemes are those conveying tense and finiteness, and these continue to be problematic for children later diagnosed with specific language impairment. Children learning highly inflected languages will show earlier productive use of grammatical elements, even during the single-word stage.

While it may take many months for the child to compile the initial 50-word vocabulary, this achievement is usually followed by what some have termed a vocabulary burst, in which hundreds of words are acquired within a very short space of time. Most children entering kindergarten have vocabularies upward of 14 000 words, which may represent both unique roots as well as morphologically complex forms such as *un+comfort+abl+y*.

Combining Words into Utterances

In English, mastery of basic sentence forms tends to proceed from those types of utterances requiring few verbal auxiliaries, such as the imperative, to those that require manipulation of, or changes and additions to the typical components in declarative sentences, as in negative utterances (*He is/isn't going, I like/don't like spinach*), and finally, those that additionally require re-ordering or permutation of elements, as in questions (*Is he going? Doesn't he like ice cream?*). Mastery of *wh*-questions (e.g., *Where is he going?*) requires additional skills, including further understanding of the specific meanings conveyed by question terms such as *what*, *when*, *where*, and *why*, with the latter requiring perhaps the greatest level of sophistication.

Progressively longer and more complex utterances are formed by conjoining, using conjunctions, and embedding. Conjoining is typically first observed in object clauses, then subject clauses ("He likes cookies and milk vs. Daddy and Mommy are coming home"). The conceptually simpler conjunctions such as *and* are mastered before those requiring higher levels of understanding of causality (*because*), time (*before/after*), or conditionality (*if*). Prior to full understanding of such terms, the child is likely to respond to clauses linked using later-learned conjunctions using an order-of-mention strategy, in which the first clause is presumed to occur before the second.

In a language such as English, which shows a strong preference for subject–verb–object ordering, sentences deviating from this order are likely to lead to misinterpretation, or reliance on conceptual plausibility. Thus, inaccurate comprehension of the subjects of verbs in passives ("Big Bird (object) is pushed by Ernie (subject)"), direct objects (DO) and indirect objects (IO) in datives ("Mary showed the baby(IO) the kitty(DO)" vs. the more canonically ordered "Mary showed the kitty (DO) to the baby (IO)"), center-embedded relative clauses ("The man who lives next to my

sister is a doctor”), and other exceptional constructions (e.g., “The boy is easy to see”), is quite likely, at ages up to 8 years or so, depending upon situational context and other cues provided by the specific words in the sentence.

Later Acquisitions

As the child nears kindergarten entry and progresses through the early school years, refinements occur in phonological, lexical, and grammatical skills. Residual problems in adult-like pronunciation of late-acquired sounds (in English, e.g., sounds such as /r/ and /l/, consonant clusters containing these sounds, and /s/) subside before age 8 years. In lexical development, the ability to comprehend relative terms (those with no fixed meaning, that require perspective, such as *big* or *daughter*), and those which convey abstract concepts (such as *honest*) emerges, as does the awareness that words may be ambiguous (having more than one meaning). This last skill enables elementary school-aged children’s growing appreciation of jokes and riddles. The ability to decompose and assemble multi-morphemic forms (e.g., *anti+dis+establish+ment+arianism* or *mono+the+ism*) will continue across the school years and is critical to continued development of linguistic skills required of skilled readers. Skilled readers will also need to expand vocabulary mappings to include figurative and metaphorical uses of language common to advanced literary forms.

Other skills required in the academic setting include the ability to make sound–symbol associations (phonemic awareness) in the child’s language and orthography necessary for the decoding of the written word. Fluency in word decoding will need to be achieved in order for the child to retrieve the meanings of utterances before information fades from the short-term memory store.

Written language skills will require mastery of more complex language forms than those typically used in conversation, and the student’s writing will increasingly demonstrate frequent use of compound and complex sentences. In addition, success in writing for academic purposes will depend upon the child’s ability to comprehend complex text, including passages with long-distance pronominal references (also known as anaphoric reference, as in “The European colonization of the Americas in the fifteenth and sixteenth centuries resulted in progressive decimation of native populations, as *it* introduced diseases to which they had no natural resistance. . .”). Students are also expected to demonstrate metalinguistic knowledge of terminology for the forms they already understand and produce (e.g., notions such as subject–verb agreement). Finally, both oral and written assignments will require them to demonstrate facility with different genres of language use, such as narratives and formal expository text. Most classroom writing assignments will also require the child to comprehend text more linguistically sophisticated

than that he or she conventionally produces, and to then paraphrase that information into a unique, but accurate recast of the original wording found in source materials.

While even the youngest child has control over a variety of pragmatic functions, including the ability to request, argue, explain, engage in appropriate turn taking, etc., socially appropriate use of language continues to develop over the school years. Acceptable ways to convey politeness or deference will grow from relatively simple strategies (such as the use of *please*) to the use and comprehension of indirect forms (as in knowing that the phrase, “Yum, that looks good” is an appropriate way to convey a desire to receive a bite of the coveted food item).

Cross-Linguistic Variation in Profiles of First-Language Acquisition

It is both theoretically and practically relevant to understand that patterns of acquisition in one language do not necessarily map directly to others. The order in which aspects of grammar, in particular, are learned in a specific language may be impacted by a number of factors. These may include the pervasiveness of a linguistic concept (e.g., whether or not verbs are invariably marked for person and number as in Spanish, contrasted with relatively sparse marking in English). Other considerations may include conceptual simplicity of a grammatical form (whether a language distinguishes between singular and plural only, or requires some marking of physical number), and whether or not a grammatical rule is relatively uniform or is characterized by numerous exceptions. The study of different trajectories seen in languages which differ typologically can do much to identify which aspects of acquisition appear dependent upon language-specific features, generalized cognitive development and ability, or input characteristics, and which appear relatively uniform regardless of the language being learned. When relatively invariant patterns or strategies emerge across language differing widely in their rule systems, they provide evidence of innate predispositions that govern the process of language acquisition (see section titled “Theories of language acquisition”).

Practically speaking, knowledge of the specific stages and strategies in acquisition of individual languages enables the important process of assessing the adequacy of children’s progress in language learning, and the identification and remediation of delayed or disordered language development. It is already abundantly clear that even within a single language, dialectal variation may compromise the sensitivity or appropriateness of language-assessment instruments. Additionally, because concepts and rules are acquired at different points and in differing orders across languages, a simple translation of a test written in

English, for example, regardless of its solid psychometric properties when used with English-speaking children, will be inappropriate in assessing the development of a child learning Spanish or Urdu.

Individual Variation

While the many generalizable patterns of language learning within a specific language community enable us to have appropriate expectations of children of a given age, individual variation does exist in how children approach the task of language acquisition. Some children appear to be more attracted to learning the names of things early in lexical development, while some appear more attuned to the social and conversational uses of language. Some children appear to map the prosodic characteristics of adult language when producing early utterances, while others appear to pay more attention to the segmental properties of target words. Some children appear to make relatively rapid progress in acquiring an initial vocabulary, while some appear to accumulate first words more slowly. However, precocious language learners do not appear to keep their verbal advantage over the life span. In contrast, a significant number of slower language learners do continue to experience long-term delay (see section titled ‘Developmental language disorders’).

Theories of Language Acquisition

Given the rapidity with which a child learns his or her first language, it is not surprising that multiple theories of language acquisition have been advanced and debated. The traditional contrast has been between those researchers and theorists who attribute the major impetus in language development to innate or nativist predispositions and those who reserve a relatively larger role for social-interactionist factors, such as the nature, quality, and quantity of verbal interaction the child receives. The first approach is most classically associated with Noam Chomsky and Steven Pinker, while the second is often attributed to Jerome Bruner and Catherine Snow. In most respects, the contrast between the positions is artificial. There clearly appear to be features of language learning, particularly in the domains of syntax and the course of phonological development, that are constrained by innate strategies and are not very easily accounted for by aspects of the nature of input addressed to the child, nor generalized cognitive strategies. In contrast, aspects of a language such as its vocabulary and pragmatic conventions can only be learned through exposure, although some aspects of lexical learning appear constrained by apparently innate strategies.

Additional theories of language learning often appeal to more generalized cognitive strategies for the discovery and abstraction of linguistic rules and regularities. Among them are connectionist models of language acquisition, which liken the process to that seen in learning by computing networks. Researchers most highly identified with what might be termed an information-processing approach include Brian MacWhinney and the late Elizabeth Bates.

Developmental Language Disorders

Estimates vary, but between 6% and 10% of preschool and school-aged children demonstrate problems in language acquisition. Some delayed or deviant skills may be attributable to primary problems in intellectual development, hearing impairment, or autism spectrum disorder, but others appear relatively unique to language, thus leading to a diagnosis of specific language impairment (SLI). SLI has significant ramifications for later educational achievement, as it shows high co-morbidity with dyslexia, but also impacts later-reading/writing skills development and use that are reliant upon linguistic knowledge. Chief among these are the abilities to make phoneme–grapheme correspondences, decode complex multi-morphemic words, as well as to comprehend and use complex syntax. Weaknesses in decoding ambiguity, following pronominal reference and resolving metaphorical and figurative usages of language are common.

Early identification of language-learning disorders and appropriate intervention are crucial during the preschool and early elementary school years because of impacts on later school achievement. SLI is highly heritable and children at familial risk should be carefully monitored.

Foreign Language Learning

Current Challenges in Research on Foreign-Language Learning

In the latter decades of the twentieth century, the dominant paradigm for both foreign- and second-language acquisition (SLA) research, derived from psycholinguistics, has been the input–interaction–output (IIO) perspective focusing on development of second-language grammars via mechanisms considered analogous to those of computer-information processing. Within this paradigm, language acquisition is viewed as a learner-internal cognitive process by which language input in the environment is entered into a transitional system (or interlanguage) governed by universal processing constraints. Input may be tailored for the individual acquirer, particularly in the context of conversational interaction, but the process itself is impervious to influence from the social environment, including the classroom and the efforts of teachers. Evidence for acquisition is provided by the extent to which the system's output approximates native speaking norms. Computational models of SLA emphasize the autonomy of the human individual while also validating communicative interaction as a source of learning. Research in this paradigm has yielded valuable insights on the sources of systematicity and the difficulty in the development of grammatical competence. However, due to their exclusive focus on psycholinguistic processes, computational models deliberately set aside explanation of relationships between the learner and the social context.

Many researchers continue to find inspiration and to perform productive research within the IIO perspective. However, in response to calls for more socially grounded theories, research on foreign-language learning has undergone considerable expansion in the variety and scope of its theoretical perspectives over the course of the past decade. Researchers eager to redress a perceived imbalance favoring the cognitive over the social aspects of language learning have introduced a range of descriptive or explanatory approaches from sociology (conversation analysis), anthropology (language socialization), literary study (narrative analysis), corpus linguistics, and sociocultural/historical psychology. Rather than a uniform monoculture, the field now resembles the flower garden predicted in Lantolf's (1996) metaphor, where diverse and quite distinct approaches grow – and compete for space – alongside one another. It is hardly surprising, in such an environment, that the more influential writers in the field argue in favor of an ecological approach where language learning is conceptualized as a relational human activity, “co-constructed

between humans and their environment, contingent upon the position in space and history, and a site of struggle for the control of social power and cultural memory” (Kramsch, 2002: 5).

Regardless of the precise form it takes, the need for conceptual expansion is highlighted by changes in the practice of foreign-language education within its broader societal context. Rapidly accelerating globalization, including the spread of communication technologies, the dominance of English as a *lingua mundi*, and the relative ease of travel, has exerted considerable influence on the field of foreign-language learning. As learners now typically enjoy ready and immediate access to foreign-language-mediated texts and interaction via the Internet, the focus of classroom pedagogy has shifted from enhancement or importation of authenticity to furthering students' skill in intercultural dialog. In order to meet this challenge, models of language competence beyond the grammatical must be taken seriously.

Meanwhile, the sociopolitical aspects of foreign language learning have come into clearer focus. Demand for English-language instruction is such that, in many countries, foreign-language learning has become synonymous with the study of English for international communication. Because English as a foreign language is plagued by questions about the cultural allegiance and colonial heritage of its speakers, the norms imposed by native-speaker models are also subject to critical scrutiny. In other words, the desired developmental end point implied within mainstream psycholinguistic approaches is no longer universally accepted. In parallel with the rise of English-language instruction, the promotion of foreign languages other than English, particularly among the educated populace of predominantly Anglophone countries, has become a matter of urgent concern. Teachers of foreign languages struggle to prove the relevance of their subject matter without allowing it to be cast in a strictly utilitarian light, and thus find support for their endeavors in broadly conceived models of language ability.

Defining Foreign-Language Ability

In the past several decades, researchers and language educators have devoted considerable attention to the definition of foreign-language ability. New perspectives from second and foreign-language acquisition research, language teaching, and corpus linguistics have challenged

prevailing views. Since the early 1980s, the dominant model of foreign-language ability has been based on the notion of communicative competence. This construct originated in a debate between the linguist Noam Chomsky and the anthropologist Dell Hymes during the mid-1960s. Chomsky defined linguistic competence in terms of an underlying, innate and universal grammar, or set of principles capable of generating the structural properties of any human language. For Hymes, this view of language was too restrictive in that it did not take into consideration knowledge of the social aspects of language use as shared within a given speech community. When such knowledge is absent, according to Hymes, utterances may be grammatically correct but socially inappropriate. In coining the term communicative competence, Hymes (1972) conveyed the notion that knowledge of language, and of variation within languages, is closely tied to the social conditions of use in particular contexts, including features of the setting, characteristics of the participants, and norms for interpretation.

In the early 1980s, under pressure to generate more realistic and practical approaches to language teaching, theorists began to elaborate models of communicative competence intended for use by the language-education profession. The first comprehensive model was presented to the profession by Canale and Swain (1980) and revised by Canale (1983). This model included four interrelated components that have remained at the core of the construct through subsequent revisions (see **Table 1**).

A similar model, under development by van Ek (1986) and the Council of Europe, added to these four components a provision for sociocultural competence, or knowledge of the social components of situations where communication is likely to occur, and for social competence, a category encompassing the learner's motivation, attitude, and stance toward second-language communications. In subsequent years, the model was revised, most notably by Celce-Murcia *et al.* (1995) to place discourse competence squarely at the core, with the other components seen as support for the practice of socially situated language use.

Models of communicative competence have traditionally attempted to portray the abilities of expert language

users within their own speech communities, that is, native speakers of their own first language. As noted above, the idealized native speaker has come under critical scrutiny due to the sociopolitical climate of foreign-language teaching in the late twentieth and early twenty-first centuries. In the 1990s, a number of foreign and SLA researchers also began to question the rational basis for proposing that first-language users should be held up as models for the emulation of second-language speakers. Such views imply a deficit model of the second-language user who can rarely achieve more than a native-like competence in circumscribed contexts. Moreover, multilinguals, it is argued, possess capabilities different from, and in some ways greater than those of monolinguals. For example, they exhibit greater metalinguistic awareness, and more divergent thinking, but may require more time than monolinguals do when performing language-related cognitive tasks. These and other observations led Cook (1999) to conclude that users of more than one language possess multicompetence wherein the development of second-language abilities interacts with first-language abilities to produce unique and complex communicative repertoires. The model for the language learner should therefore not be a native speaker of that language but instead a person possessing relevant multilingualism.

In the field of foreign-language teaching, researchers have also critiqued the notion that language learners should be interpreted as aspiring native speakers. Rather, they should be construed as developing intercultural communicative competence, or the knowledge and abilities required for communication in situations where the language in question is either the dominant medium of interaction or is the code shared among speakers of divergent primary languages. In Byram's (1989) model, intercultural communicative competence consists of: (1) a cognitive dimension, including knowledge of conventions for communicative activity in one's own and the other group; (2) an affective dimension including empathy and understanding of others' perspectives; and (3) a behavioral dimension including abilities such as the tolerance for diverse communicative styles and the ability to initiate interactions and form interpersonal relationships.

A further challenge to the idealized native-speaker model and the view of language competence as consisting of an underlying sentence-level grammar has come not from second- or foreign-language theorists but rather from the robustly empirical investigation of language in use via corpus linguistics. Based on computerized collections of spoken and written texts, this research aims to reveal regularities and patterns in the documented language use of real speakers and writers, thus demonstrating, for example, that expert users are in command not only of individual words but also of the ways in which these words conventionally form collocations in discourse. Corpus-based analysis also reveals that the grammar of spoken

Table 1 Components of communicative competence

<i>Grammatical competence</i> : knowledge of and ability to use the forms of the language (lexical items and rules of syntax, morphology, and phonology)
<i>Sociolinguistic competence</i> : ability to use the language appropriately in a variety of social settings
<i>Discourse competence</i> : ability to interpret and create spoken, written, or multimedia second-language texts that are cohesive (internally well structured) and coherent (interpretable and appropriate within their contexts)
<i>Strategic competence</i> : ability to compensate for lacunae in any of the other areas

language use should be described in terms of probabilistic statements based on empirical observation of discourse rather than as resulting from the application of deterministic rules (McCarthy, 1998).

Taken together, efforts to revise and refine the field's core definitional construct correspond to a perceived need for realistic, rationally defined, and empirically based goals for language learners to inform both research and instruction. Over time, a shift has occurred, moving the field away from a view in which the abstract, sentence-level grammatical competence of native speakers is taken as the desired developmental end point of foreign-language learning. In its place is a perspective suggesting that the field's centerstage should be occupied by the discourse of intercultural communication and the competence of multilinguals as revealed by empirical observation in the settings where foreign languages are used.

Investigating Foreign-Language Learning

In this climate of conceptual change, recent investigation of foreign-language learning has been characterized by a social turn (Block, 2003) favoring attempts to align the priorities outlined above with the foci of research. One consequence of this development is a new level of attention to aspects of communicative ability beyond the grammatical, particularly the characteristics of foreign-language pragmatics, or the study of how learners develop the ability to understand and perform action in a second language (Kasper and Rose, 2002: 5). Another effect of the social turn has been the importation of research methodologies from adjacent fields emphasizing language in use or grounded in usage-based linguistics. Increasingly, for example, in-depth description of learner-foreign-language use is informed by the rigorous empiricism of conversation analysis, and the growth of language ability is traced longitudinally through the collection and analysis of developmental-learner corpora. More broadly, the field has become increasingly responsive to the sociopolitical, cultural, and historical aspects of foreign-language learning, including the agency and identity of learners. Ethnographies and case studies attempt to illuminate relationships between language learning, the cultures of learners and host communities, personal history, and the qualities of learning environments. Inquiry based on learner and teacher narratives has pointed out the significance of sociopolitical and historical contexts in the shaping of motives and opportunities to learn.

Theories of mind or of language development incorporating a significant social dimension have begun to exert a considerable impact on the nature of foreign language research. From anthropology, researchers borrow the concept of language socialization (Ochs, 2002), focusing on the longitudinal interactive processes by

which novices acquire the competence needed for participation in the social life of a community or classroom, including routine cultural practices such as language and literacy activities, and local preferences for action, thought, and emotion. Others have emphasized the potential of Vygotskian sociocultural theory (Lantolf and Thorne, 2006), a theory of mind, in which language and other semiotic systems play a major role, whose core notion is that there exists an inherent, dynamic, and dialectical connection between human action and the cultural, historical, and institutional contexts in which it occurs. In arguing for a sociocognitive approach, Atkinson (2002: 534) adopts a radically integrative stance, suggesting that neither language acquisition nor language use – nor even cognized linguistic knowledge – can be properly understood without taking into account their fundamental integration into a socially mediated world.

For Kramsch (2002), the new relevance assigned to the social in second- and foreign-language studies suggests a need to address the relationship between approaches grounded in theories of language acquisition and those whose core metaphor represents language socialization. It has often been noted that the disciplinary roots and epistemological stance associated with these two approaches to research are seen as fundamentally incompatible, with each field conceptualizing the social context in its own way. For Kramsch, this conflict is best expressed in terms of underlying conceptual metaphors, with SLA researchers preferring the learner as computer, as noted above, and language socialization researchers, the learner as apprentice. Thus, these two fields of endeavor conceptualize the role of participation in learning in very different ways.

When researchers view the social context as an environment for acquisition of language, the relationship between participation and language learning is relatively simple: more is better. It is assumed, not unreasonably, that the more the social context exposes learners to relevant input, and the more the interactive setting highlights that input is effective in ways, the more we may expect the learner to acquire. When language acquisition does not result, or is not equally distributed among participants, it is further assumed that input processing has been hindered or blocked. Perhaps the process is slowed by factors related to the psychology of individuals who, for example, display motivational deficit, or employ a learning style inappropriate for the setting, or, alternatively, there has been insufficient provision of input via constraints on the learner's presence in communicative settings.

Approaches based on the concept of language socialization, emerging as they do from the field of linguistic anthropology, have at their core the notion that language learning is part of the much larger process of becoming a person in society. Here, the learner becomes an apprentice within communities of practice rather than an input-processor. "As novices learn more from expert members

how to use the language accurately and appropriately, they enact social relationships and other sociocultural phenomena that will make them into expert members” (Kramsch, 2002: 2). From the perspective of language socialization, language study is an opportunity for apprenticeship into and through language (Ochs, 2002: 106) within the socially organized practices of the classroom or host community. Language socialization research therefore strives to understand the dialectical relationship between individual development and broader sociocultural contexts, seeking a maximally holistic perspective while simultaneously attending to the micro-level details of language use. Normally, researchers adopt a longitudinal approach emphasizing developmental processes and choose research sites believed to be places of transformation, where change in the skills and capacities of novice participants is assumed to be observable over time. In foreign-language research, these sites are typically classrooms or other instructional settings such as language-immersion programs, but they may also include the homes, schools, and workplaces frequented by learners during their sojourns abroad.

In recent years, many researchers in this tradition have been influenced by “. . . the poststructuralist realization that learning is a non-linear, relational human activity, co-constructed between humans and their environment, contingent upon their position in space and history, and a site of struggle for the control of power and cultural memory” (Kramsch, 2002: 5). Language-socialization researchers increasingly emphasize the role of language as symbolic capital and the subtle mechanisms by which power is circulated, and relations of power reproduced, in the discourse of socialization processes. Agendas of social critique have effectively changed the view that language socialization is inevitable, desirable, and equally accessible to all. Rather, many researchers are sensitive to the dynamic and negotiated nature of this process, observing that ready access to language socialization may not be available to all comers, but may be constrained by interpretations of identity and societal norms on the part of all participants. Participants in discourse are positioned by their interlocutors in ways related to local ideologies and resources for the performance of identity, such as gender, nationality, and foreignness. Furthermore, language learners are endowed with agency, and may accept, accommodate, resist, or reject the practices they encounter. A great deal depends upon the ways in which students position themselves in interaction: how they envision their success as users of their foreign language and the extent which they can imagine their fuller participation in the communities whose languages they study in positive light.

Within the field of applied linguistics more broadly drawn, the relationship between acquisition and socialization research has been uneasy, and there has traditionally been little dialog between them. This lack of cross-disciplinary communication is due in large part to

differences in focus and in criteria for success in each case. Language acquisition researchers seek to illuminate the linguistic processes underway as individuals achieve mastery of grammatical and communicative competence. Language-socialization researchers traditionally examine the nature of sociocultural phenomena in play as individuals become assimilated members of communities. Ultimately, however, the distinction between language acquisition and language socialization is not clear cut. When the goal of SLA processes is expressed in terms of communicative competence (including pragmatic, sociolinguistic, or discourse competence), socialization clearly has a part to play. To the extent that development of expert membership requires precise linguistic expression, it is difficult to separate language acquisition from socialization.

Conclusion

Due to the recent history of debate over the province of foreign-language-acquisition research, and in equal part, due to widely perceived need for inclusive models of foreign-language ability, a key issue in foreign-language learning research has become the integration of the cognitive and the social. There is widespread appreciation of the need to overcome dichotomous views of mind and society, implied by the Cartesian heritage of Western research in the social sciences, in order to further the investigation of developing communicative competence, multicompetence, or intercultural communicative ability. Block (2003: 138), for example, suggests that the future of language acquisition research lies in approaches combining attention to acquisition and socialization as researchers “attempt to reconstruct detailed life stories of learners hand-in-hand with an interest in linguistic development over time.” Kramsch and Lam (2003: 144) argue for an ecology of language learning, focused on the meaning-making environment and attempting to capture the interconnectedness of psychological, social, and environmental processes. It is not yet clear as to how, or indeed if, this goal will be reached, or which among a broad range of candidate approaches will prevail in gathering the allegiance of researchers. In the meantime, while many continue to work within the IIO framework, examining foreign-language acquisition as a learner-internal process of cognitive restructuring based on received input, other investigators continue to explore alternative, often integrative or socially oriented approaches.

Considerable promise for the future of the field may be observed in several recent developments. First, a new level of tolerance for methodological ecumenicalism has emerged as researchers committed to language education agree to set aside debates over competing epistemologies in favor of returning to their core mission – to inform and assist the foreign-language teaching profession. The field

has thereby become more inclusive of efforts to elaborate and test the applicability of many socially grounded approaches to language learning, including language socialization, sociocultural theory, and sociocognitive theory. Along with this expansion at the level of theory has come a growth in the field's accepted repertoire of analytic techniques as well as the inclusion of new data sources both quantitative (e.g., developmental corpora) and qualitative (e.g., learner narratives and case histories). Second, there appears to be a new level of dedication to the grounding of conclusions in observation of authentic learner-language use. The empirical rigor of foreign-language learning research has been greatly enhanced by the application of usage-based approaches to linguistics and of conversation analytic methodologies, in combination with the development of new technologies such as first language and learner corpora or multimedia recording and transcription techniques. Finally, the social turn in language-acquisition research has been accompanied by an increase in the scope of inquiry as witnessed by renewed emphasis on the ethics of foreign-language teaching and learning. Attention to the sociopolitical contexts in which foreign-language learning takes place has added a dimension of social activism and critical reflection to the discourse of the field. Taken together, these observations suggest that the field of foreign-language-learning research is a dynamic enterprise entering the twenty-first century with a multifaceted and complex yet compelling agenda.

Glossary

Acquisition – Perspectives which portray learning as the acquisition of knowledge by individuals through various mechanisms.

Cognitive – Approaches to theorizing learning focusing on thinking by individuals.

Conceptual change – Perspectives which address how individuals' conceptual understanding changes during learning, or on descriptions of individuals' conceptual understanding before, and after, learning.

Development – Perspectives which focus on the maturation of individuals' intellectual abilities.

Participation – Perspectives which portray learning in terms of learners' growing ability to participate in various social practices.

Science concepts – The substantive ideas of science (force, evolution, etc.), as opposed to methodological and procedural ideas. For the purpose of this piece we do not differentiate these substantive ideas into facts, models, generalizations, theories, etc. Our primary focus is the physical and life sciences.

Social constructivist – Perspectives which focus upon how individuals make personal sense of meaning-making through social interactions.

Sociocultural – Perspectives which focus upon meaning-making through social interactions.

Introduction

In this article we present major perspectives that have influenced thinking on science learning. A range of perspectives on science learning can be found in the literature. We have therefore found it helpful to identify two key features which we use as organizing dimensions in developing and presenting the article. The first dimension is taken from the influential paper by Anna Sfard (1998) in which she proposed two key metaphors for learning: the acquisition metaphor and the participation metaphor.

According to Sfard (1998), human learning has been conceived of as an acquisition of something “since the dawn of civilization” and, in recent decades, “the idea of learning as gaining possession over some commodity has persisted in a wide spectrum of frameworks, from moderate

to radical constructivism and then to interactionism and sociocultural theories” (p. 6). Gaining possession implies that something is stored or held somewhere. Sfard makes clear that it is concepts which are learned and then stored in the learner's head: “Since the time of Piaget and Vygotsky, the growth of knowledge in the process of learning has been analyzed in terms of concept development. Concepts are to be understood as basic units of knowledge that can be accumulated, gradually refined, and combined to form ever richer cognitive structures” (Sfard, 1998: 5).

By way of contrast, Sfard sees the participation metaphor as offering a fundamentally different perspective on learning, in which “the learner should be viewed as a person interested in participation in certain kinds of activities rather than in accumulating private possessions” (Sfard, 1998: 6). According to this perspective, “learning a subject is now conceived of as a process of becoming a member of a certain community” (Sfard, 1998: 6).

From the outset it is important to recognize that the acquisition–participation dimension is not a continuum. The two metaphors offer fundamentally different perspectives on learning, or as Sfard (1998: 7) stated, “the acquisition/participation division is ontological in nature and draws on two radically different approaches to the fundamental question, ‘What is this thing called learning?’” Majority of approaches to conceptualizing science learning which we review here relate to the acquisition perspective.

The second dimension that we take into account is the distinction between individual and social perspectives on learning. This takes us from a starting point where the main focus is on the individual learner, moving toward approaches where increased account is taken of various social aspects of the learning process and of knowledge itself.

We begin this article with approaches to conceptualizing science concept learning which belong to the acquisition perspective and then move on to those which relate to participation.

Science Concept Learning as Acquisition: Cognitive Approaches

Following the ideas set out earlier, we first consider those approaches which see science learning as involving a process of acquisition and which focus on the individual in providing an account of that learning.

Perspectives on student concepts and conceptual learning in science have been heavily influenced by the seminal

work of the Swiss genetic epistemologist Jean Piaget. This influence was particularly dominant during the 1960s and 1970s, as can be confirmed by looking through the citations of Piaget in papers published in the main science education journals of that period. Piaget described an interactive learning process whereby an individual makes sense of the world through cognitive schemes, which are themselves modified as a result of the individual's actions on objects in the world. This model is summarized in the phrase '*L'intelligence organise le monde en s'organisant elle-même*' (intelligence organizes the world by organizing itself) (Piaget, 1937). Piaget emphasized the significance of the child's social environment on knowledge development, claiming that:

Society is the supreme unit, and the individual can only achieve his inventions and intellectual constructions insofar as he is the seat of collective interactions that are naturally dependent, in level and value, on society as a whole
(Piaget, 1971: 368).

Nonetheless, in most of Piaget's writing – and writing addressing the significance of Piagetian theorizing for science education – knowledge is portrayed as schemata in the individual's head, with little prominence being placed upon wider social aspects. The proposed mechanism for changes in intellectual organization as a result of interactions with the world (termed adaptation) involves the processes of assimilation and accommodation. Assimilation is the process by which an individual interprets particular sensory information and in so doing includes that information in their existing cognitive structure. Accommodation is the process by which cognitive structure adapts in order to make sense of specific information. Assimilation and accommodation cannot be dissociated: whenever an individual interacts with sensory information, both assimilation and accommodation take place.

Although primarily interested in development as a result of maturation rather than learning as a result of instruction, Piaget's empirical work addressed the development of children's knowledge about various aspects of the natural world including life, time, and mass, weight, and volume. Drawing upon this body of empirical work, an account of conceptual change based upon the development of content-independent logical structures was proposed (Piaget and Inhelder, 1956). Characteristic stages in the development of logical thinking were set out, based upon students' abilities to perform tasks involving skills such as conservation and seriation (the serial ordering of items). The concrete operational stage, for example, runs between approximately 2 and 12 years and is characterized by the development and coordination of conceptual schemes including conservation, classification, and seriation. Children at the concrete operational stage are not, however, capable of performing operations at a purely symbolic level; that competence is characteristic of the formal operational stage.

Piaget's work has influenced perspectives on student conceptions and conceptual learning in several ways. His account of how individuals come to know can be seen in much writing about students' conceptions, conceptual change, and personal constructivism through references to assimilation and accommodation. Piaget's methods for probing an individual's understanding, which involve an interviewer asking children questions without attempting to lead their responses, have also been drawn upon in research on students' alternative conceptions. Furthermore, Piagetian stage theory has been drawn upon to inform science curriculum design and sequencing (Science Curriculum Improvement Study, USA; Cognitive Acceleration through Science Education, UK).

Various criticisms of the use of Piagetian theory in science education have been advanced. Driver (1978), Donaldson (1978), and Carey (1985) have questioned the empirical basis on which claims for characteristic stages in logicomathematical thinking are founded. Specific criticisms include the following:

- Tasks requiring identical logicomathematical reasoning are made easier or more difficult by the degree of familiarity with the task's context (Donaldson, 1978).
- Tasks characteristic of a given stage can be performed by much younger children (Driver, 1978).
- The analysis used in Piagetian research is designed to validate existing theory rather than account for children's reasoning (Driver, 1978; Carey, 1985).

Perhaps the most significant break from the Piagetian account of conceptual learning in science can be traced back to the developmental psychology of David Ausubel (1968). Ausubel argued that the most significant influence on the learners' conceptual development is their existing conceptual knowledge in the target domain. During the early 1970s a small number of empirical studies were conducted which accounted for students' science learning in terms of domain-specific factors, rather than explaining learning in terms of global logicomathematical reasoning skills (e.g., Viennot, 1979).

An empirical research program subsequently developed (Novak, 1978), focusing upon the content of students' domain-specific reasoning (or students' alternative conceptions: Driver and Easley, 1978) about natural phenomena and involving researchers from around the world. Two particularly influential books in the development of research on students' alternative conceptions were *The Pupil as Scientist* by Rosalind Driver (1983) and *Learning in Science: The Implications of Children's Science* edited by Osborne and Freyberg (1985). The number of publications in this field of science education research moved into thousands. Helga Pfundt and Reinders Duit of the Leibniz Institute for Science Education (IPN) in Kiel, Germany, developed a comprehensive bibliography, *Student' Alternative Frameworks and Science Education* (Pfundt and Duit, 2007). All the

evidence suggests that there are strong commonalities in the alternative conceptions of students from different cultures and, furthermore, these ideas about the natural world have a profound influence on what is learnt as a result of science teaching, and some ideas are extremely resistant to change (Driver, 1989).

Learning as Conceptual Change

Recognition that prior knowledge influences learning (Ausubel, 1968), together with Piagetian ideas of accommodation and assimilation, and work from the philosophy of science all underpinned the seminal paper by Posner *et al.* (1982) on conceptual change in science learning. In their paper, the conditions needed for a major change in thinking within a scientific field (such as the shift from Earth-at-center to Sun-at-center models of the solar system) were considered to be analogous to the conditions that are needed to bring about accommodation or conceptual change in individual learners. Posner *et al.* (1982) identified four conditions which must be fulfilled before such an accommodation can occur. These conditions are that a learner must first be dissatisfied with existing ideas and then that the new ideas must be seen as intelligible, plausible, and fruitful. Empirical evidence from students' learning about the special theory of relativity was used to illustrate and exemplify this model of conceptual change learning. Though taking the view that learning is a rational activity, Posner *et al.* recognized that such accommodations might take considerable time, involving "much fumbling about, many false starts and mistakes, and frequent reversals of direction" (p. 223). The conditions of intelligibility, plausibility, and fruitfulness contribute to the status of an idea. During conceptual change the status of different ideas within a person's conceptual ecology (the range of ideas they hold) changes (Hewson and Lemberger, 2000). In addition, Scott *et al.* (1992) outlined two broad types of approach to conceptual change teaching. The first of these is based upon promoting cognitive conflict and follows from the model proposed by Posner *et al.* (1982), while in the second the learner's existing ideas are built upon and extended.

A significant point of confusion in this whole area of work concerns the different meanings which are attached to the term conceptual change. Sometimes conceptual change refers to the process of learning, while at other times to the products. Furthermore, conceptual change sometimes refers to situations where one concept (seen as a unit of knowledge) is exchanged for another; or where a concept is modified in some way, for example, by differentiation into two; sometimes where the relationship between concepts changes; or at other times where new concepts are added without loss of the original ideas. The interest in student misconceptions, or alternative

conceptions, in the 1980s led to a focus on conceptual change as revolutionary, with new ideas replacing the original ones (through a process of exchange) rather than evolutionary and gradual, with the possibility of several views existing simultaneously (through a process of addition) and used in different contexts (see, e.g., Sinatra, 2002).

What Changes During Conceptual Change?

The model of conceptual change by Posner *et al.* focused on the conditions under which radical accommodations occur. Alongside this, the focus of much work in developmental and cognitive psychology has been on what changes, exploring the performance of learners at different ages and attempting to explain this in terms of the ways in which concepts are mentally represented and related and the cognitive processes by which they are acquired and change.

One of the early proponents of domain-specific approaches, Susan Carey, proposed two forms of knowledge restructuring in learning – one similar to that demonstrated in the shift from novice to expert and one analogous to that of theory change in science. In the first, weak restructuring, the relations between concepts are changed. In the second, strong restructuring, the concepts themselves change (Carey, 1985) and this is regarded as being difficult to achieve. Considerable attention has been given to these latter situations where radical restructuring is needed, particularly in the context of learning physics concepts. The idea that learning occurs as discrete concepts are formed and then linked into more complex conceptual structures has largely given way to a view that concepts are part of larger relational structures from the start (Vosniadou, 1994). Following the seminal work of Keil (1979), ontological categorization is also seen as being of fundamental importance in learning science concepts (Chi, 1992). diSessa and Sherin (1998) pointed out some difficulties with the standard model of conceptual change. They argued that the notion of concept needs to be replaced by more carefully defined theoretical constructs within a knowledge system, which allow us to understand how that system functions. Focusing on the cognitive processes by which we gain information from the world, they proposed entities such as coordination classes and phenomenological primitives, or p-prims. Coordination classes include cognitive strategies such as selecting and integrating information and are "systematically connected ways of getting information from the world" (p. 1171).

Although Posner *et al.* (1982) noted that motivational and affective variables were not unimportant in the learning process, the model of conceptual change they

proposed was based on a view of learning as a rational activity. Pintrich *et al.* (1993) in their critique of cold conceptual change models proposed that the conditions of dissatisfaction with existing conceptions and the intelligibility, plausibility, and fruitfulness of the new, whilst necessary, are not sufficient to support conceptual change. Cognitive, motivational, and classroom contextual factors must also be taken into account as the individual student in the classroom is subject to influences from the broader social setting.

Cognitive Approaches: Summary and Implications

The following fundamental insights about science concept learning are common to the majority of cognitive perspectives:

- Individuals' beliefs about the natural world are constructed, rather than received.
- There are strong commonalities in how individuals appear to think about the natural world.
- A person's existing ideas about a given subject greatly influence the subsequent learning about that subject.

In addition, some have argued that there are more general aspects of reasoning, such as Piaget's logicomathematical reasoning skills.

Science Concept Learning as Acquisition: Sociocultural and Social Constructivist Perspectives

At this point in the article, we take a significant step in moving from approaches to characterizing science concept learning which focuses on the individual, while recognizing the influence of the social context, to those which take the social context as being an integral part of the learning process.

A fundamental theoretical reference point for sociocultural and social constructivist perspectives on learning is provided by Lev Semenovich Vygotsky (Vygotsky, 1987). Central to Vygotsky's views is the idea that learning involves a passage from social contexts to individual understanding (Vygotsky, 1978). Thus, we first meet new ideas (new to us, at least) in social situations where those ideas are rehearsed between people, drawing on a range of modes of communication, such as talk, gesture, writing, visual images, and action. Vygotsky referred to these interactions as existing on the social plane. The social plane may be constituted by a teacher working with a class of students in school; it may involve a parent explaining something to a child. As ideas are explored during the social event, each participant is able to reflect on, and

make individual sense of, what is being communicated. The words, gestures, and images used in the social exchanges provide the very tools needed for individual thinking. Thus, there is a transition from social to individual planes, whereby the social tools for communication become internalized and provide the means for individual thinking. It is no coincidence that Vygotsky's seminal book is titled *Thought and Language* (Vygotsky, 1962).

The social origins of learning are thus a fundamental and integral part of Vygotsky's account and it is the job of the teacher to make scientific knowledge available on the social plane of the classroom, supporting students as they try to make sense of it. Vygotsky brought the activities of teaching and learning together through his concept of the zone of proximal development or ZPD (Vygotsky, 1978). The ZPD provides a measure of the difference between what the student can achieve working alone and with assistance. The key point here is that the student's learning is conceived of as being directly connected to, and dependent upon, the supporting activity of the teacher on the social plane.

In addition to drawing attention to the social origins of learning, Vygotsky also emphasized the role of the individual in the learning process. The process of internalization, as envisaged by Vygotsky, does not involve the simple transfer of ways of talking and thinking from social to personal planes. There must always be a step of personal sense-making. Leontiev, one of Vygotsky's contemporaries, made the point in stating that, "the process of internalisation is not the transferral of an external activity to a pre-existing 'internal plane of consciousness': it is the process in which this plane is formed" (Leontiev, 1981: 57). That is, individual learners must make sense of the talk which surrounds them on the social plane, relating that talk in a dialogic way to their existing ideas and ways of thinking.

In this respect Vygotskian theory shares common ground with the constructivist perspectives outlined earlier, which emphasize that learners cannot be passive recipients of knowledge. It is perhaps with this point in mind that those contemporary approaches to conceptualizing science learning, which draw on Vygotskian sociocultural theory, are often referred to as social constructivist perspectives.

Social Constructivist Views of Learning Science

Vygotskian theory has been directly drawn upon by a number of researchers in developing an account of science learning (see, e.g., Driver *et al.*, 1994; Hodson and Hodson, 1998; Scott, 1998; Leach and Scott, 2002; Leach and Scott, 2003; Mortimer and Scott, 2003; Wells, 1999).

Hodson and Hodson, for example, outlined a social constructivist perspective on teaching and learning science, which was "based on the Vygotskian notion of enculturation" (1998: 33). They argued that this perspective

provides an alternative to personal constructivist accounts of learning, which they claimed often imply “that students who construct their own understanding of the world are building *scientific* understanding” (1998: 34, emphasis as in original).

Central to social constructivist views is the fundamental epistemological tenet that areas of knowledge such as science are developed within specific social communities. Thus, Driver *et al.* (1994) stated that, “. . . if knowledge construction is seen solely as an individual process, then this is similar to what has traditionally been identified as discovery learning. If, however, learners are to be given access to the knowledge systems of science, the process of knowledge construction must go beyond personal empirical enquiry. Learners need to be given access not only to physical experiences but also to the concepts and models of conventional science” (1994: 7). The implications of this point are fundamental. The understanding of an individual, acquired, on the one hand, through the individual’s interactions with the material world and, on the other, through introduction to the concepts and models of conventional science, are ontologically different. The concepts and models of conventional science embody practices, conventions, and modes of expression that are socially and institutionally agreed. Because scientific knowledge is the product of the scientific community, it cannot be learnt through interactions with the material world alone. Such differences between empiricist interpretations of personal constructivism and social constructivist accounts of learning are discussed by Leach and Scott (2003).

Following the ideas set out in the preceding sections, social constructivist accounts of learning can be deemed to be social in nature on two counts. First, in the sense of specifying the social origins of learning through the interactions of the social plane and, secondly, in recognizing the social context of the scientific community for the development of scientific knowledge.

The sociocultural view of learning offers an interesting perspective on the origins and status of alternative conceptions or misconceptions. From the sociocultural point of view an alternative conception such as the idea of a plant drawing its food from the soil, is representative of an everyday way of talking and thinking about plants. This is the way in which ordinary folks talk about such things and in this respect there is a very real sense in which the scientific point of view (based on the concept of photosynthesis) offers the alternative perspective. Viewed in this way, it is hardly surprising that the alternative conceptions or misconceptions identified by the science education community are robust and difficult to change. These are not the ephemeral outcomes of the solitary musings of a child trying to make sense of the natural world around them, but the tools of an everyday language which continuously acts to define, and reinforce, our ways of talking and thinking.

Social Constructivist Perspectives: Summary and Implications

The following insights about science concept learning are common to social constructivist perspectives:

- Learning scientific knowledge involves a passage from social to personal planes.
- The process of learning is consequent upon individual sense-making by the learner.
- Learning is mediated by various semiotic resources, with language being the most important.
- Learning science involves learning the social language of the scientific community which must be introduced to the learner by a teacher or some other knowledgeable figure.

Where do these distinctive aspects of the social constructivist perspective take us which are different from the interests and outcomes of the cognitive viewpoint? The most obvious development has been the increased attention, during the late 1980s and 1990s, to the role of the teacher and the ways in which teachers guide the discourse of the classroom to support the introduction of scientific knowledge and scientific ways of explaining (Edwards and Mercer, 1987; Ogborn *et al.*, 1996; Van Zee and Minstrell, 1997; Mortimer and Scott, 2003). Through this kind of work, we have a much better grasp of the ways in which teachers make scientific knowledge available on the social plane of the classroom.

Science Concept Learning as Participation

In this final section we take the step from approaches to conceptualizing science learning which are based on acquisition to those which entail some form of participation.

Situated Cognition

The metaphor of learning as participation has largely arisen through a perspective on learning known as situated cognition (see, e.g., Brown *et al.*, 1989; Lave and Wenger, 1991).

The pioneering work in this field focused on the use of mathematics in the workplace and in day-to-day life. For example, Scribner (1984) analyzed the arithmetical practices of people as they worked in a dairy factory, while Lave (1988) focused on the use of arithmetic in everyday shopping. These studies, and others, have identified forms of mathematics which are radically different from those taught in school. The skilled users of these everyday forms of arithmetic vary their problem-solving approaches depending on the specific situation and problems, which

appear to be structurally identical but are solved using different strategies. In this sense, the strategies are seen to be directly linked to context and thereby situated in nature.

According to the situated cognition perspective, learning is seen as a process of enculturation, or participation in socially organized practices, through which specialized skills are developed by the learner as they engage in an apprenticeship in thinking (Rogoff, 1990), or in legitimate peripheral participation (Lave and Wenger, 1991). According to Collins *et al.* (1989), the key components of the apprenticeship process include modeling, coaching, scaffolding, fading, and encouraging learners to reflect on their own problem-solving strategies. This apprenticeship leads to the learner becoming involved in the authentic practices of a 'community of practice' (Lave and Wenger, 1991). Seely-Brown *et al.* (1989) argued that, "Unfortunately, students are too often asked to use the tools of a discipline without being able to adopt its culture. To learn to use tools as practitioners use them, a student, like an apprentice, must enter that community and its culture." Roth (1995a: 29) suggested that authentic practices involve activities, "which have a large degree of resemblance with the activities in which core members of a community actually engage."

In the context of education, situated cognition perspectives have received a lot of attention, particularly in North America and particularly in relation to mathematics education. According to Cobb and Bowers (1999), "A situated perspective on the mathematics classroom sees individual students as participating in and contributing to the development of the mathematical practices established by the classroom community."

Situated perspectives on learning have also been drawn upon as part of a theoretical justification for inquiry-based approaches to science teaching and learning (see, e.g., Roth, 1995b). Roth (1995a: 29) suggested that "situated learning emphasizes learning through the engagement in authentic activities." He explained his use of the term authentic by suggesting that in classrooms focusing on scientific activities, the students would "(1) learn in contexts constituted in part by ill-defined problems; (2) experience uncertainties, ambiguities, and the social nature of scientific work and knowledge; (3) engage in learning (curriculum) which is predicated on, and driven by, their current knowledge state; (4) experience themselves as part of communities of inquiry in which knowledge, practices, resources, and discourse are shared; and (5) participate in classroom communities, in which they can draw on the expertise of more knowledgeable others" (Roth, 1995a: 29; see also: Wells, 1999).
